Release 2024 R1
January 2024

ANSYS, Inc. and ANSYS Europe, Ltd. are UL registered ISO 9001: 2015 companies.

Copyright and Trademark Information

© 2024 ANSYS, Inc. Unauthorized use, distribution or duplication is prohibited.

ANSYS, Ansys Workbench, AUTODYN, CFX, FLUENT and any and all ANSYS, Inc. brand, product, service and feature names, logos and slogans are registered trademarks or trademarks of ANSYS, Inc. or its subsidiaries located in the United States or other countries. ICEM CFD is a trademark used by ANSYS, Inc. under license. CFX is a trademark of Sony Corporation in Japan. All other brand, product, service and feature names or trademarks are the property of their respective owners. FLEXlm and FLEXnet are trademarks of Flexera Software LLC.

Disclaimer Notice

THIS ANSYS SOFTWARE PRODUCT AND PROGRAM DOCUMENTATION INCLUDE TRADE SECRETS AND ARE CONFIDENTIAL AND PROPRIETARY PRODUCTS OF ANSYS, INC., ITS SUBSIDIARIES, OR LICENSORS. The software products and documentation are furnished by ANSYS, Inc., its subsidiaries, or affiliates under a software license agreement that contains provisions concerning non-disclosure, copying, length and nature of use, compliance with exporting laws, warranties, disclaimers, limitations of liability, and remedies, and other provisions. The software products and documentation may be used, disclosed, transferred, or copied only in accordance with the terms and conditions of that software license agreement.

ANSYS, Inc. and ANSYS Europe, Ltd. are UL registered ISO 9001: 2015 companies.

U.S. Government Rights

For U.S. Government users, except as specifically granted by the ANSYS, Inc. software license agreement, the use, duplication, or disclosure by the United States Government is subject to restrictions stated in the ANSYS, Inc. software license agreement and FAR 12.212 (for non-DOD licenses).

Third-Party Software

See the legal information in the product help files for the complete Legal Notice for ANSYS proprietary software and third-party software. If you are unable to access the Legal Notice, contact ANSYS, Inc.

A Linearized Stress Result Cannot Be Solved. 2359
A Load Transfer Error Has Occurred. 2360
A Master Node is Missing from the Condensed Part 2360
Although the Exported File Was Saved to Disk 2360
Although the Solution Failed to Solve Completely at all Time Points. 2360
An Error Occurred Inside the SOLVER Module: Invalid Material Properties 2361
An Error Occurred While Solving Due To Insufficient Disk Space 2362
An Error Occurred While Starting the Solver Module 2362
An Internal Solution Magnitude Limit Was Exceeded. 2363
An Iterative Solver Was Used for this Analysis 2363
At Least One Body Has Been Found to Have Only 1 Element 2364
At Least One Spring Exists with Incorrectly Defined Nonlinear Stiffness 2365
Animation Does not Export Correctly 2365
Application Not Closing as Expected 2365

Overview

Ansys Mechanical is a Workbench application that can perform a variety of engineering simulations, including stress, thermal, vibration, thermo-electric, and magnetostatic simulations.

A typical simulation consists of setting up the model and the loads applied to it, solving for the model's response to the loads, then examining the details of the response with a variety of tools.

Mechanical has "objects" arranged in a tree structure that guide you through the different steps of a simulation. By expanding the objects, you expose the details associated with the object, and you can use the corresponding tools and specification tables to perform that part of the simulation. Objects are used, for example, to define environmental conditions such as contact surfaces and loadings, and to define the types of results you want to have available for review.

The following Help topics describe in detail how to use Mechanical to set up and run a simulation:

- Application Interface (p. 35)
- Steps for Using the Application (p. 323)
- Analysis Types (p. 359)
- Specifying Geometry (p. 847)
- Setting Up Coordinate Systems (p. 1191)
- Setting Connections (p. 1207)
- Configuring Analysis Settings (p. 1417)
- Setting Up Boundary Conditions (p. 1497)
- Using Results (p. 1927)
- Understanding Solving (p. 1791)
- Commands Objects (p. 2303)
- Setting Parameters (p. 2337)

After you become comfortable using Mechanical, you might want to write scripts that automate your routine tasks. Eventually, you might even want to create extensions that customize and automate Mechanical itself. You can accomplish all of this using Ansys ACT and its powerful API (Application Programming Interface).

- For an introduction to writing scripts and information on using the ACT API to access and manipulate objects in the Mechanical tree, see the *Scripting in Mechanical Guide*.
- For descriptions of all ACT API objects, methods, and properties, see the *ACT API Reference Guide*.
- For information on how to use ACT to create apps (extensions) that customize and automate Ansys products, see the *ACT Developer's Guide*.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- For ACT usage, customization, and automation information specific to Mechanical, see the *ACT Customization Guide for Mechanical*.

The Ansys Product Improvement Program

This product is covered by the Ansys Product Improvement Program, which enables Ansys, Inc., to collect and analyze *anonymous* usage data reported by our software without affecting your work or product performance. Analyzing product usage data helps us to understand customer usage trends and patterns, interests, and quality or performance issues. The data enable us to develop or enhance product features that better address your needs.

How to Participate

The program is voluntary. To participate, select **Yes** when the Product Improvement Program dialog appears. Only then will collection of data for this product begin.

How the Program Works

After you agree to participate, the product collects anonymous usage data during each session. When you end the session, the collected data is sent to a secure server accessible only to authorized Ansys employees. After Ansys receives the data, various statistical measures such as distributions, counts, means, medians, modes, etc., are used to understand and analyze the data.

Data We Collect

The data we collect under the Ansys Product Improvement Program are limited. The types and amounts of collected data vary from product to product. Typically, the data fall into the categories listed here:

Hardware: Information about the hardware on which the product is running, such as the:

- brand and type of CPU
- number of processors available
- amount of memory available
- brand and type of graphics card

System: Configuration information about the system the product is running on, such as the:

- operating system and version
- country code
- time zone
- language used
- values of environment variables used by the product

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Session: Characteristics of the session, such as the:

- interactive or batch setting
- time duration
- total CPU time used
- product license and license settings being used
- product version and build identifiers
- command line options used
- number of processors used
- amount of memory used
- errors and warnings issued

Session Actions: Counts of certain user actions during a session, such as the number of:

- project saves
- restarts
- meshing, solving, postprocessing, etc., actions
- times the Help system is used
- times wizards are used
- toolbar selections

Model: Statistics of the model used in the simulation, such as the:

- number and types of entities used, such as nodes, elements, cells, surfaces, primitives, etc.
- number of material types, loading types, boundary conditions, species, etc.
- number and types of coordinate systems used
- system of units used
- dimensionality (1-D, 2-D, 3-D)

Analysis: Characteristics of the analysis, such as the:

- physics types used
- linear and nonlinear behaviors
- time and frequency domains (static, steady-state, transient, modal, harmonic, etc.)
- analysis options used

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution: Characteristics of the solution performed, including:

- the choice of solvers and solver options
- the solution controls used, such as convergence criteria, precision settings, and tuning options
- solver statistics such as the number of equations, number of load steps, number of design points, etc.

Specialty: Special options or features used, such as:

- user-provided plug-ins and routines
- coupling of analyses with other Ansys products

Data We Do Not Collect

The Product Improvement Program does *not* collect any information that can identify you personally, your company, or your intellectual property. This includes, but is not limited to:

- names, addresses, or usernames
- file names, part names, or other user-supplied labels
- geometry- or design-specific inputs, such as coordinate values or locations, thicknesses, or other dimensional values
- actual values of material properties, loadings, or any other real-valued user-supplied data

In addition to collecting only anonymous data, we make no record of where we collect data from. We therefore cannot associate collected data with any specific customer, company, or location.

Opting Out of the Program

You may *stop* your participation in the program any time you wish. To do so, select **Ansys Product Improvement Program** from the Help menu. A dialog appears and asks if you want to continue participating in the program. Select **No** and then click **OK**. Data will no longer be collected or sent.

The Ansys, Inc., Privacy Policy

All Ansys products are covered by the Ansys, Inc., Privacy Policy.

Frequently Asked Questions

1. *Am I required to participate in this program?*

   No, your participation is voluntary. We encourage you to participate, however, as it helps us create products that will better meet your future needs.

2. *Am I automatically enrolled in this program?*

   No. You are not enrolled unless you explicitly agree to participate.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. *Does participating in this program put my intellectual property at risk of being collected or discovered by Ansys?*

   No. We do not collect any project-specific, company-specific, or model-specific information.

4. *Can I stop participating even after I agree to participate?*

   Yes, you can stop participating at any time. To do so, select **Ansys Product Improvement Program** from the Help menu. A dialog appears and asks if you want to continue participating in the program. Select **No** and then click **OK**. Data will no longer be collected or sent.

5. *Will participation in the program slow the performance of the product?*

   No, the data collection does not affect the product performance in any significant way. The amount of data collected is very small.

6. *How frequently is data collected and sent to Ansys servers?*

   The data is collected during each use session of the product. The collected data is sent to a secure server once per session, when you exit the product.

7. *Is this program available in all Ansys products?*

   Not at this time, although we are adding it to more of our products at each release. The program is available in a product only if this *Ansys Product Improvement Program* description appears in the product documentation, as it does here for this product.

8. *If I enroll in the program for this product, am I automatically enrolled in the program for the other Ansys products I use on the same machine?*

   Yes. Your enrollment choice applies to all Ansys products you use on the same machine. Similarly, if you end your enrollment in the program for one product, you end your enrollment for all Ansys products on that machine.

9. *How is enrollment in the Product Improvement Program determined if I use Ansys products in a cluster?*

   In a cluster configuration, the Product Improvement Program enrollment is determined by the host machine setting.

10. *Can I easily opt out of the Product Improvement Program for all clients in my network installation?*

    Yes. Perform the following steps on the file server:

    a. Navigate to the installation directory: `[Drive:]\v241\commonfiles\globalsettings`

    b. Open the file **ANSYSProductImprovementProgram.txt**.

    c. Change the value from "on" to "off" and save the file.

Mechanical Application Interface

This section describes the elements of the Mechanical interface, their purpose and conditions, as well as the methods for their use.

The following topics are covered in this section:

Interface Overview
Ribbon
Graphics Toolbar
Outline
Details Pane
Geometry Window
Status Bar
Quick Launch
Help Menu
Color Theme
Ribbon Customization Options
Scoping Recovery following Geometry Update
Creating User-Defined Buttons
Engineering Data Material Window
Windows Management
Preference Migration
Resource Prediction
Print Preview
Report Preview
Full Screen Mode
Contextual Windows
Group Tree Objects
Interface Behavior Based on License Levels
Environment Filtering
Application Preferences and Default Behaviors
Using Macros
Data Export
Keyframe Animation
Graphical Selection and Display
Hotkeys and Keyboard Shortcuts

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

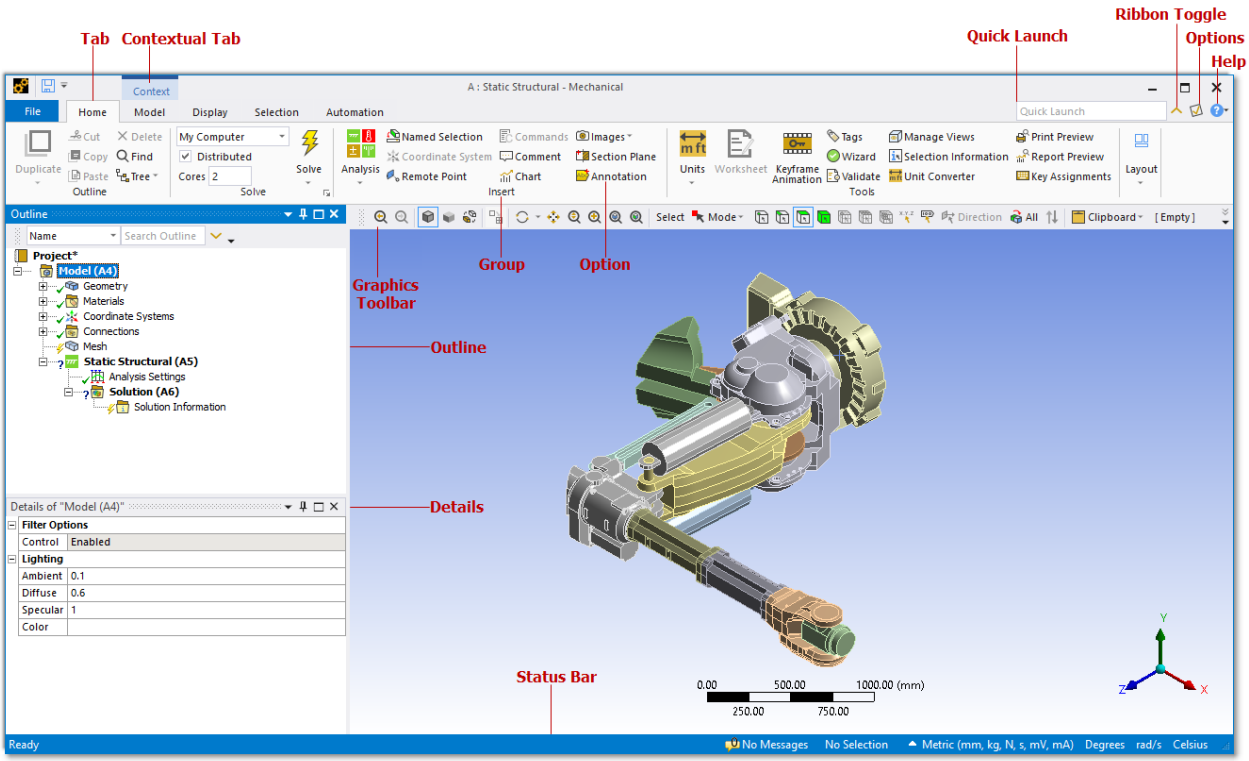
Interface Overview

The Ansys Mechanical application user interface is illustrated below.



The primary interface elements include:

- Ribbon (p. 37)
- Graphics Toolbar (p. 97)
- Outline (p. 105)
- Details View (p. 119)
- Geometry Window (p. 129)
- Status Bar (p. 135)
- Quick Launch (p. 139)
- Help (p. 141)

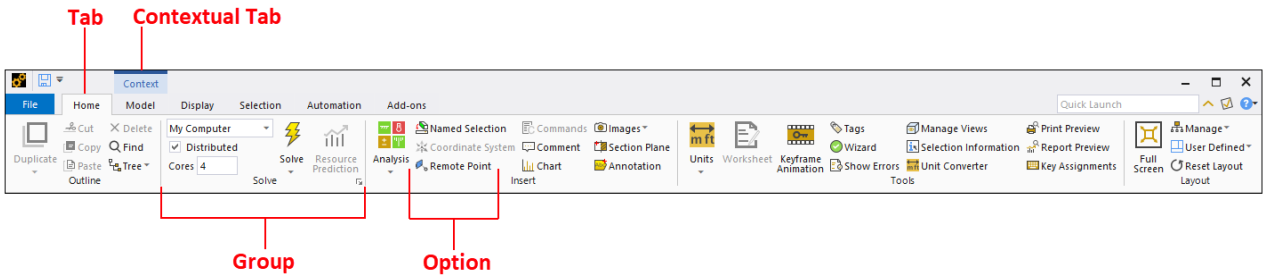
Published: 2023-10-23

Ribbon

The ribbon provides easy-to-use option toolbars organized by Tabs. By grouping similar commands together, you will work faster and more efficiently.



Ribbon Structure

The ribbon is organized by Tabs (**Home**, **Display**, **Selection**, **Automation**, etc.). Within each Tab, Options (command buttons) are organized into Groups (**Outline**, **Solve**, etc.) by functionality. This reduces your search time when looking for specific commands. Additionally, a **Context** tab appears based on your currently selected object with options specific to the selected object.

Review the following sections for additional information about each tab:

- File Tab (p. 37)
- Home Tab (p. 40)
- Context Tabs (p. 47)
- Display Tab (p. 78)
- Selection Tab (p. 88)
- Automation Tab (p. 94)
- Add-ons Tab
- Learning and Support Tab (p. 95)

File Tab

The File tab contains a variety of options for managing your project, defining author and project information, saving your project, and launching features that enable you to make changes to default application settings, integrating associated applications, and/or setting up how you want your simulation to operate.

Option	Description
Info	Includes entry fields for project description and ownership (**Project**), a summary of the details of the project (**Model Summary**), as well as a history of when the project was saved (**Save History**). Also see the Project object

Option	Description
	reference section. This information can also be defined in the Details view of the **Project** object. **Note:** When you import a mesh file, the option **Import Summary** becomes available in the **Model Summary** content. When you select this option, the application goes to the **Import Summary** object in the Outline. That object presents upstream source file data.
What's New	Displays an illustrated review of the release's new features and capabilities. This display is also available from the Help (p. 141) drop-down menu option on the title bar.
Home[a]	Go to the Home page. This page displays recently opened projects as well as an option to open a new project.
New[a]	Begin a new session of Mechanical.
Open[a]	Open an existing project.
Save[a]**/Save Project**	Saves your project.
Save Project As[a]**/Save Project As**	Saves the current project under a different name and/or location. You are prompted to specify the name and location for the file.
Archive[a]**/Archive Project**	Generates a single archive file that contains project files. During the archive process, the application prompts you with the following dialog to make optional selections.  
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
	These options enable you to control whether the archive includes certain data. This can be helpful if you have file size concerns. Supported file types include Mechanical (`.mechpz`), Workbench Project Archive (`.wbpz`) or Zip (`.zip`/`.tar.gz`). You can also perform this action in Workbench. See the Archiving Projects section for more information.
Save Database	Enables you to save the current Mechanical session without having to save the entire project. However, you must save the project when you exit the application to properly save your changes.
Refresh All Data	Updates the geometry, materials, and any imported loads that are in the tree.
Clear Generated Data	Clears all results and meshing data from the database depending on the object selected in the tree. This option is available via the right-click context menu on many objects.
Import	Available when you open Mechanical without a geometry or mesh. Selecting **Import** displays two additional options: **Geometry** and **Mesh (External Model)** (p. 908). These options enable you to import a geometry or a mesh file. Select **Geometry** or **Mesh (External Model)** and then select from the **Recent** list or select **Browse** to open a file. Using the **Mesh (External Model)** option automatically inserts and links a corresponding system to the appropriate cells (**Engineering Data** and **Model**) of the existing system. **Note:** Linux platform does not support the: • **Import** option. • Link between the **External Model** system and the **Engineering Data** cell.
Export	Exports your project. You can export a `.mechdat` file (when running the Mechanical application) that later can be imported into a new Workbench project. Note that only the data native to the Mechanical application is saved to the `.mechdat` file. External files (such as solver files) will not be exported. You can also export the mesh for input to any of the following: Fluent (`.msh`), Polyflow (`.poly`), CGNS (`.cgns`), and ICEM CFD (`.prj`).
Addins	Launches the **Addins** dialog that enables you to load/unload third-party add-ins that are specifically designed for integration within the Workbench environment.
Options	Opens the **Options** (p. 217) dialog. This dialog enables you to customize the application and to control the behavior of Mechanical application functions. This option is also available on the title bar of the application, beside the **Quick Launch** feature.
Solve Process Settings	Displays the Solve Process Settings (p. 1804) dialog to configure your solution process.

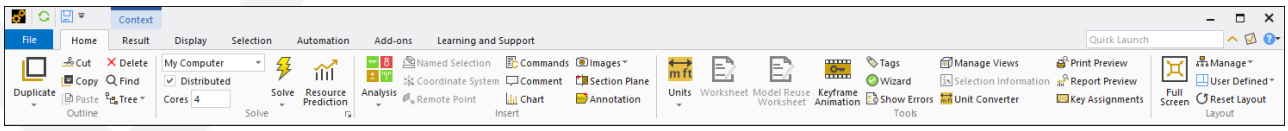
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Variable Manager	Opens the **Variable Manager** (p. 247) dialog. This dialog enables you to enter an application variables that can override default settings.
Licensing	Displays the **License Options** pane. This pane displays a list of all the licenses available to you as a user. Mechanical uses the first relevant license in the list. You can change the order using the **Up**/**Down** and **Save** options. You can also use the **Disable** option to exclude a potential license from your current and future Mechanical sessions. The application checks out a license for a session based on these preferences. For any subsequent license requests, the application refers to the preferences to fulfill the request. If any other license is available, individual or shared, the application uses that license. As indicated by a displayed message, it is necessary to close and reopen Mechanical for licensing changes to take effect. **Shared Licenses** Workbench controls shared licenses. Using shared licensing, the active application holds the license, preventing other applications that are sharing that license from using it during that time. The application or operation requiring use of the license is called a concurrency event. For example, meshing and solving would each be a concurrency event. Single license sharing applies only to licenses of the same type (for example, Mechanical Enterprise). If a license is not available/checked out when you open Mechanical, the application automatically opens in **Read-Only Configuration** mode (as displayed on the Status (p. 135) bar). Under the **License Options**, the **Activate License** button displays. This option is only available when no license is checked out and the application is in **Read-Only Configuration** mode. From the **License Options** pane select a license and click the activate button. This removes the application from read-only mode. Review the material in the Ansys Workbench Licensing Methods section of the Workbench User's Guide for additional information.
Close Mechanical	Exits your current Mechanical session.

[a] Mechanical opened independently.

Home Tab

The **Home** tab displays by default when you open the application.



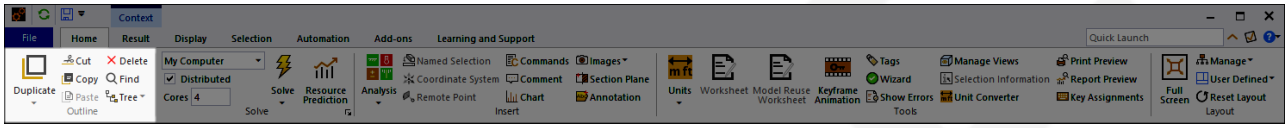
This tab contains the following **Groups**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Outline** (p. 41)
- **Solve** (p. 41)
- **Insert** (p. 42)
- **Tools** (p. 45)
- **Layout** (p. 47)

Outline

The **Outline** group provides options that enable you to make basic changes to Outline pane objects.



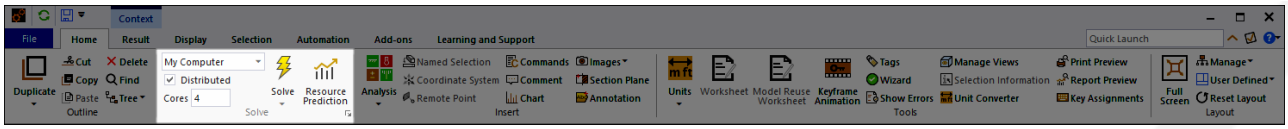
Options for this group include:

Option	Description
Duplicate and **Duplicate Without Results**	Duplicates a selected **Outline** object. This option is only available if an object supports being duplicated. A drop-down menu is also available from this option. Once you have solved your analysis, the additional option **Duplicate Without Results** becomes available in the drop-down. This option is only available when you select a result object. It duplicates your selected result object, including all subordinate objects. This is a faster option than duplicating a result that includes result data.
Cut/**Copy**/**Paste**	Cuts, copies, or pastes **Outline** objects.
Delete	Deletes a selected **Outline** object.
Find	Displays the **Find in Tree** (p. 119) dialog that enables you to search Outline objects, such as the name of an object or objects or a string of characters that are included in the name of objects.
Tree	Displays a drop-down menu of the following options: • **Expand All**: Expands all **Outline** objects • **Collapse All**: Collapses all **Outline** objects • **Collapse Environments**: Collapses only the Environment objects.

Solve

The **Solve** group provides options that enable you to specify some basic solution configurations and to solve your analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Options for this group include:

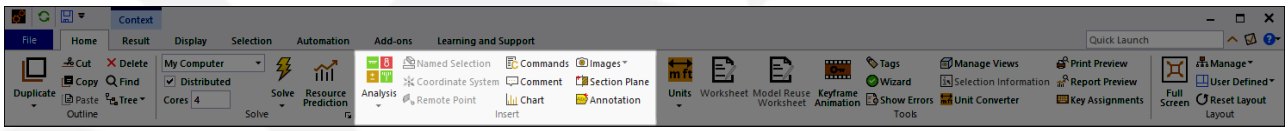
Option	Description
Solve	Displays a drop-down menu for **My Computer** and **My Computer, Background** solution selections. Initiates the solution when selected.
My Computer / **My Computer, Background**	Provides a drop-down menu to specify your desired selection only.
Resource Prediction (p. 170)	Opens a window that enables you to select an available analysis and then generate an estimate of the computing resources needed to perform a solution for the environment.
Solve Process Settings (p. 1804)	 Launches the **Solve Process Settings** (p. 1804) dialog. This dialog enables you to configure solution settings.

Note:

The **Solve** drop-down menu and dialog options are also available on a number of Context tabs (Environment, Solution, etc.).

Insert

The **Insert** group provides a variety of regularly used options.



Options for this group include:

Option	Description
Analysis	Displays a drop-down menu of standalone analysis selections to add to your existing model. A corresponding analysis system, with the appropriate connections, is also included in the **Project Schematic**. The new analysis shares the **Engineering Data**, **Geometry**, and **Model** cells with the other analysis systems under the model.
Named Selection	For a supported parent object, inserts a Named Selection, and parent folder as needed, into the Outline.
Coordinate System	This option is available when the **Coordinate Systems** object is selected. It inserts a new **Coordinate System** object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Remote Point	This option is available when the **Model** object is selected. It inserts a new Remote Point object and parent folder as needed.
Commands	For a supported parent object, inserts and specifies a new Commands object.
Comment	For a supported parent object, inserts and specifies a new Comment object.
Chart	Inserts and specifies a new Chart object.
Images	Displays a drop-down menu of the following options: • **Figure**: Captures the current **Geometry** window content and places it under the currently selected object. You can manipulate **Figure** objects in the **Geometry** window as well as use other options on the object, such as adding an Annotation. • **Image**: Captures a two-dimensional screen shot of the **Geometry** window content and places it under the currently selected object. • **Image from File**: Imports an existing image and places it under the currently selected object. • **Image Plane from File**: Imports an image into Mechanical and places it on or around your model based on the XY-plane of the selected coordinate system. This option is used primarily with the Construction Line (p. 895) feature to overlay and accurately sketch one or more line segments. However, it has many applications. For example, you can place logos on your model, specify a background, set up physical rulers to help measure deformations, incorporate image planes into custom ACT extensions, etc. • **Image to File**: Saves an image of the active viewport of the **Geometry** window. When you select this option a dialog displays, as illustrated below. By default, the option **Current Graphics Display** is active. With this option selected, the application captures the content of the **Geometry** window using the application default settings. In order to make any changes on the dialog, you must first deselect the **Current Graphics Display** option. The expanded dialog, illustrated below, provides graphical resolution and image capture options that you can modify. If you change the settings, the application saves your selections for future use of the feature. In addition, the dialog includes the **Append Graph** option that enables you to add a graph of the **Graph** window data in the lower left-hand corner of the image.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

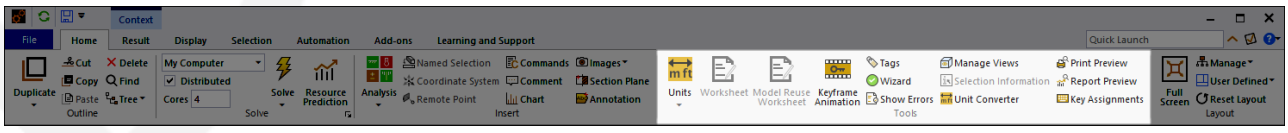
Option	Description
	  Deselecting the **Show Preference Dialog** instructs the application to not show the above dialog and immediately display the **Save As** window. Supported file formats for this feature include: PNG (.png), JPEG (.jpg), and BMP (.bmp). **Note:** You can change the default settings for these options using the properties of the Image Export (p. 232) group of the **Graphics** category of the **Options** (p. 217) dialog. • **Composite Image to File**: This option is available when you have specified more than one viewport (p. 284). This option acts the same as the **Image to File** option. It includes the same options as the above dialog, with additional options that are specific to saving viewport images, including the options **Interior Borders** and **Exterior Borders** under the **Multiviewport Screenshot Settings** title, as illustrated below. These options enable you to add borders around and in-between the viewports you capture.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
	  • **Image to Clipboard**: Copies **Geometry** window content to the clipboard. The image may then be pasted into different applications. This feature is for the Windows platform only.
Section Plane	Displays the **Section Planes** window to specify a section cut-through on your model in order to view a cross section of your geometry, mesh, or of a result. See the Creating Section Planes (p. 294) section for additional information about this feature.
Annotation	Adds a text comment to a particular spot of your model. See the Graphics Annotations Window (p. 202) section for additional information about this feature.

Tools

The **Tools** group provides a variety of display-based options.



Options for this group include:

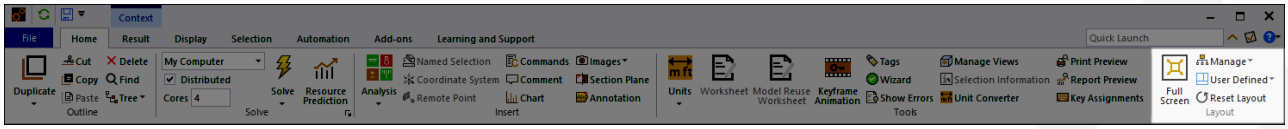
Option	Description
Units	Displays the Unit Systems drop-down menu. Modify unit system as desired. **Note:** The **Celsius** and **Kelvin** settings are not available if you select either of the U.S. Customary settings.
	For a supported objects, displays (or hides) the **Worksheet** (p. 192) window.
Model Reuse Worksheet	Displays (or hides) the **Model Reuse Worksheet** pane. This pane enables you to specify the use of boundary conditions across multiple analysis environments (p. 1787).
Keyframe Animation	Displays the **Keyframe Animation** (p. 255) window.
Tags	Displays the **Tags** window to apply meaningful labels to objects that can then be filtered. See the Tagging Objects (p. 2349) section for additional information about this feature.
Wizard	Activates the Mechanical Wizard (p. 321). This feature helps you construct your simulation.
Show Errors	Displays error messages, in the **Messages** window, for invalid **Outline** pane objects. Once you correct an invalid object, selecting this option removes the error message from the window. **Note:** Even though the application does not check for solution and mesh related errors with this feature, selecting the option may also clear those errors from the **Messages** window.
Manage Views	Displays the **Manage Views** (p. 292) window. This feature enables you to save a graphical view of your model.
Selection Information	Displays the **Selection Information** (p. 180) window.
Unit Converter	Displays a Unit Conversion tool. It is a built-in conversion calculator that enables you to perform conversions between consistent unit systems (p. 1874). The Units menu sets the active unit system. The status bar shows the current unit system. The units listed in the tool and in the Details pane are in the proper form (include no parenthesis).
Print Preview	Displays a printable image of the currently selected object. See the **Print Preview** (p. 173) section for more information about this feature.
Report Preview	Displays your analysis in the Report Preview view. See the **Report Preview** (p. 174) section for more information about this feature.
Key Assignments	Displays a dialog that lists all available hotkey and hotkey combinations that enable you to quickly perform certain actions. See the Key Assignments (p. 314) section for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Layout

The **Layout** group provides options to manage the display of the interface.



Options for this group include:

Option	Description
Full Screen	Activates a full screen display (p. 178). This display can also be turned on and off using the **F11** key.
Manage	Provides a drop-down menu of interface display selections.
User Defined	Displays a drop-down menu of the following options: • **Store Layout**: Saves an interface layout that you have created. For example, you may like to size the interface windows in a specific way or you like to display certain interface windows, such as Section Planes, or you may wish to hide certain interface windows. Once you have designed/configured an interface layout, you select the **Store Layout** option and then enter a name for the layout. This name then displays in the drop-down menu enabling you to select it and any time. • **Remove Layout**: Becomes available once you have saved a layout. Selecting this option displays a small dialog that you use to delete existing layouts.
Reset Layout	Restores the interface layout to the default setting.

Context Tabs

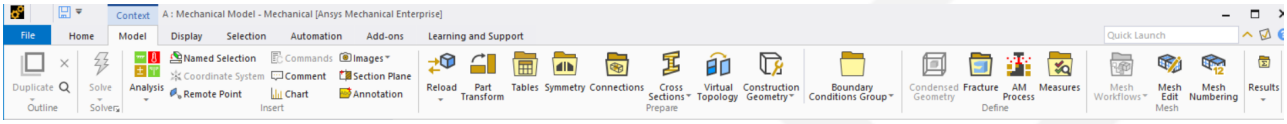
The ribbon contains a **Context** tab for most objects. The Context tabs provides relevant options based on the selected object. Primary Context tabs include:

- Model Context Tab (p. 48)
- Geometry Imports (p. 55)
- Geometry Context Tab (p. 56)
- Materials Context Tab (p. 57)
- Tables Context Tab (p. 57)
- Cross Section Context Tab (p. 58)
- Coordinate Systems Context Tab (p. 58)
- Connections Context Tab (p. 50)
- Mesh Context Tab (p. 58)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Environment Context Tab (p. 61)
- Environment Context Tab Display Group for Variable Data (p. 61)
- Solution Context Tab (p. 62)
- Solution Information Tab (p. 62)
- Result Context Tab (p. 62)

Model Context Tab



The **Model** Context tab becomes active when the **Model** object is selected in the **Outline**. The **Model** Context tab contains options for creating objects related to the model, as described below.

Option	Description
Import Geometry/Reload	The import option for geometry is labeled **Import Geometry** if no primary geometry has been imported and **Reload** if a geometry has been imported. Therefore, the **Reload** option imports secondary geometries into your analysis. See the Geometry Imports (p. 55) description below.
Tables	Inserts a Tables object that houses all of the Table objects that you create.
Part Transform	Inserts a Geometry Transforms folder object that houses all of the part transformations (p. 1014) (via Part Transform objects) that you create.
Symmetry	Inserts a **Symmetry** object. For symmetric (p. 1127) bodies, you can remove the redundant portions based on the inherent symmetry, and replace them with symmetry planes. Boundary conditions are automatically included based on the type of analyses. Also see the Symmetry Context Tab (p. 50) topic below.
Connections	Becomes available only if a Connections object is **not** already included in the Outline (such as a model that is not an assembly), and you wish to create a connections object. See the Connections Context Tab (p. 50) topic below. Connection objects include contact regions, joints, and springs. You can transfer structural loads and heat flows across the contact boundaries and "connect" the various parts. See the Contact (p. 1207) section for details. A joint typically serves as a junction where bodies are joined together. Joint types are characterized by their rotational and translational degrees of freedom as being fixed or free. See the Joints (p. 1292) section for details. You can define a spring (longitudinal or torsional) to connect two bodies together or to connect a body to ground. See the Springs (p. 1395) section for details.
Cross Sections	Inserts a desired cross section type.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

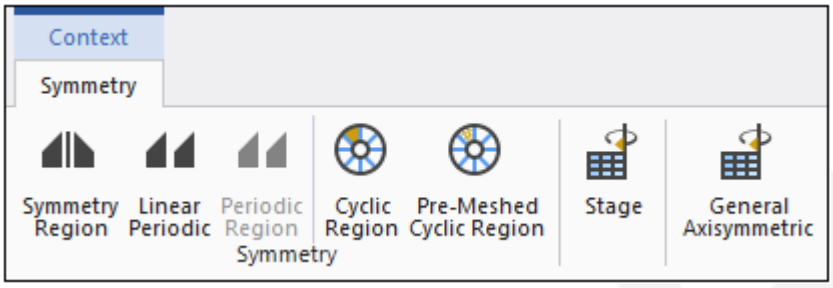
Published: 2023-10-23

Option	Description
Virtual Topology	You can use the **Virtual Topology** option to reduce the number of elements in a model by merging faces and lines. This is particularly helpful when small faces and lines are involved. The merging will affect meshing and selection for loads and supports. See Virtual Topology Context Tab (p. 51) below as well as the Virtual Topology Overview (p. 349) section for additional details.
Construction Geometry	See the Specifying Construction Geometry (p. 883) section for additional details.
Boundary Conditions Group	Define boundary conditions to be used across multiple analysis systems included in your simulation. See the Specifying Model-Level Boundary Conditions (p. 1787) section for more information.
Condensed Geometry	Inserts a **Condensed Geometry** object. See the Condensed Geometry Context Tab (p. 52) topic below as well as the Substructure Analysis (p. 781) section for additional information.
Fracture	Inserts a **Fracture** object. See the **Fracture Context Tab** (p. 52) topic below as well as the Performing a Fracture Analysis (p. 406) section for additional information.
AM Process	Inserts an AM Process object. By default, it is inserted along with the child object Build Settings. You use this object when you are performing an additive manufacturing simulation. Also see the AM Process Context Tab (p. 53) topic below.
Measures	Inserts a Measures object. See the Measures Context Tab (p. 53) topic below.
Mesh Workflows	Inserts a **Mesh Workflows** object. Also, see the Mesh Workflows Context (p. 53) topic below.
Mesh Edit	Inserts a **Mesh Edit** object. Also see the Mesh Edit Context (p. 54) topic below.
Mesh Numbering	Enables you to renumber the node and element numbers of a generated meshed model consisting of flexible parts. See the Specifying Mesh Numbering (p. 1035) section for details.
Solution Combination	Combines multiple environments and solutions to form a new solution. A solution combination folder can be used to linearly combine the results from an arbitrary number of load cases (environments). Note that the analysis environments must be static structural with no solution convergence. Results such as stress, elastic strain, displacement, contact, and fatigue may be requested. To add a load case to the solution combination folder, right-click the worksheet view of the solution combination folder, choose add, and then select the scale factor and the environment name. An environment may be added more than once and its effects will be cumulative. You may suppress the effect of a load case by using the check box in the worksheet view or by deleting it through a right-click. For more information, see Solution Combination (p. 2288).
Fatigue Combination	Inserts a Fatigue Combination object. When you are running an analysis that includes multiple systems that each include a Fatigue Tool object, the **Fatigue Combination** feature enables you to sum (generate a sum total of) the Damage results for all of the linked systems. This option only supports all analysis types that support the use of the **Fatigue Tool**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

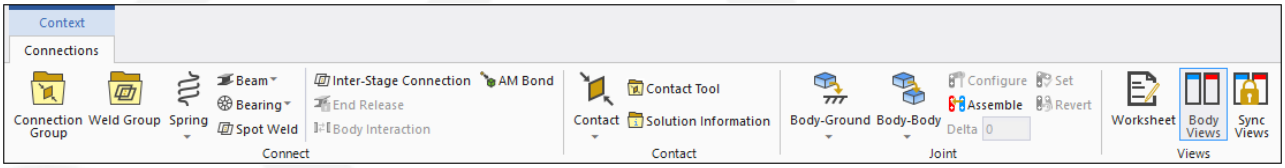
Option	Description
Ply	When you select a ply object, the **Ply** group displays and contains the **Direction** drop-down menu. The options of the menu enable you to graphically display ply and element directions for imported ply structures. • **Fiber**: Ply Fiber Direction. • **Transverse**: Ply Transverse Direction. • **Normal**: Ply Normal Direction. • **Element Reference**: Element Reference Direction. • **Element Normal**: Element Normal Direction.

Symmetry Context Tab



Based on your analysis type, the **Symmetry** (p. 1127) Context tab includes options to insert **Symmetry Region** (including **Linear Periodic**), **Periodic Region**, **Cyclic Region**, **Pre-Meshed Cyclic Region**, **Stage**, and **General Axisymmetric** objects.

Connections Context Tab



The **Connections** Context tab includes the following options and functions:

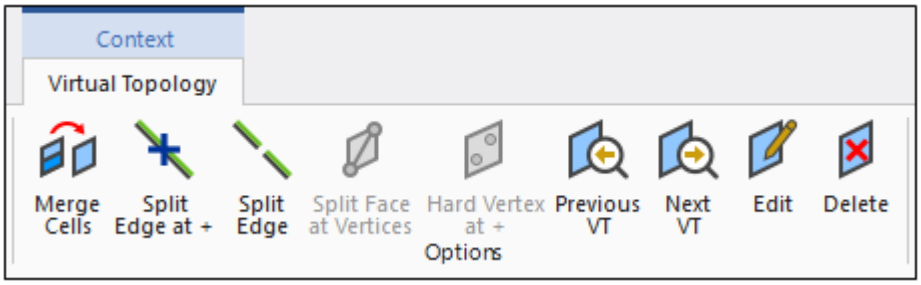
Option	Description
Connection Group	Inserts a **Connection Group** (p. 1212) object.
Spring	Inserts a **Spring** (p. 1395) object, either **Body-Ground** or **Body-Body**
Beam	Inserts a Beam object, either **Body-Ground** or **Body-Body**.
Bearing	Inserts a **Bearing** (p. 1413) object, either **Body-Ground** or **Body-Body**.
Spot Weld	Inserts a **Spot Weld** (p. 1407) object.
Interstage	Inserts an Interstage object..
End Release	Inserts an **End Release** (p. 1409) object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
Body Interactions	See the Body Interactions in Explicit Dynamics Analyses section for additional information.
AM Bond	Inserts an AM Bond object.
Contact	Inserts a specific type of Contact Region (p. 1234).
Contact Tool	Inserts a **Contact Tool** (p. 2079) object.
Solution Information	Insert a **Solution Information** (p. 1833) object.
Body-Ground	Enables you to insert and specify a certain type of Body-to-Ground Joint (p. 1298) object.
Body-Body	Enables you to insert and specify a certain type of Body-to-Body Joint (p. 1298) object.
Configure, **Set**, and **Revert** options and **Delta** field	Graphically configure the initial positioning of a joint. See the Example: Configuring Joints (p. 1380) example. The **Assemble** option performs the assembly of the model, finding the closest part configuration that satisfies all the joints. **Important:** When a model contains a **Point On Curve** (p. 1312) joint, the **Configure** and **Assemble** options (p. 51) are disabled for all the joints. This is also the case for a redundancy analysis that includes a **Point On Curve** joint.
Body Views	Toggles the display of parts and connections in separate auxiliary windows for contact regions, beams, bearings, joints, and spring connections.
Sync Views	When the **Body Views** option is selected, you can select this option synchronize the movements of your model in the **Geometry** window with the views of the auxiliary windows. and vice versa.

Virtual Topology Context Tab



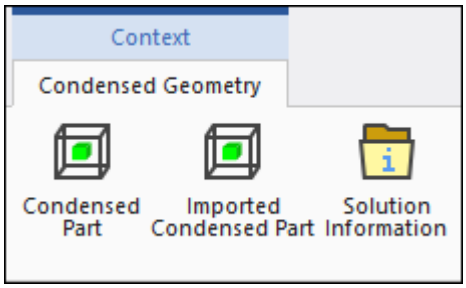
The Virtual Topology Context tab includes the following options:

Option	Description
Merge Cells	Creates Virtual Cell objects you can use to group faces or edges.
Split Edge at + and **Split Edge**	Create Virtual Split Edge objects that enable you to split an edge to create two virtual edges.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

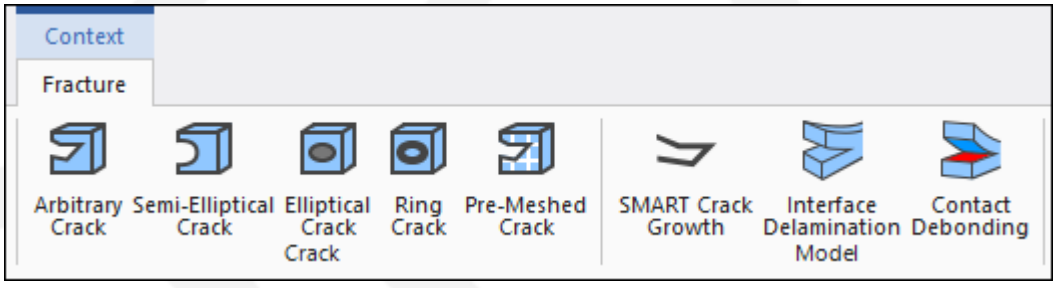
Option	Description
Split Face at Vertices	Creates Virtual Split Face objects to split a face along two vertices to create 1 to N virtual faces. The selected vertices must be located on the face that you want to split.
Hard Vertex at +	Creates Virtual Hard Vertex objects to define a hard point according to your cursor location on a face, and then use that hard point in a split face operation.
Previous VT/Next VT	Enable you to cycle through virtual topology entities in the sequence in which they were created. If any virtual topologies are deleted or merged, the sequence is adjusted automatically. See Cycling Through Virtual Entities in the Geometry Window.
Edit	Edits virtual topology entities.
Delete	Deletes selected virtual topology entities, along with any dependents if applicable.

Condensed Geometry Context Tab



The **Condensed Geometry** Context tab enables you to apply the objects associated with substructuring (p. 781), including the Condensed Part object, Imported Condensed Part, as well as a Solution Information (p. 1833) object.

Fracture Context Tab

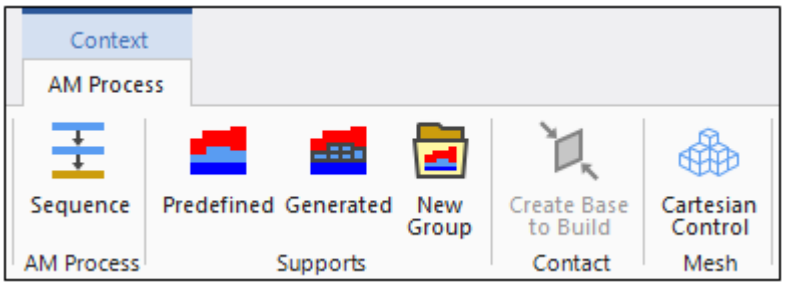


The **Fracture** Context tab enables you to insert the objects associated with a Fracture Analysis (p. 406), including different **Crack** (p. 424) types, SMART Crack Growth (p. 468), as well as progressive failure features (p. 476) in the form of Interface Delamination and Contact Debonding objects.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

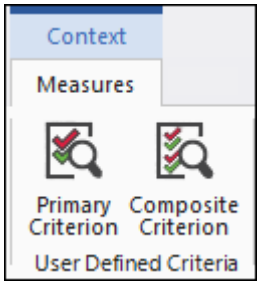
Published: 2023-10-23

AM Process Context Tab



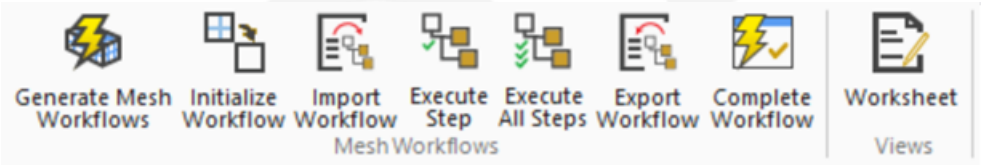
This tab displays when you insert an AM Process object into the **Outline**.

Measures Context Tab



This tab displays when you insert a **Measures** object into the **Outline**. You use the this object to insert User Defined Criteria (p. 2243).

Mesh Workflows Context Tab



The **Mesh Workflows Context** tab helps you to:

- Generate workflows from predefined steps that can be customized
- Initialize, import, execute, and export the workflows
- Visualize the workflow properties using the worksheet

The **Mesh Workflows** Context tab includes the following options:

Option	Description
Generate Mesh Workflows	Generate mesh workflows.
Initialize Workflow	Initialize mesh workflow, transferring selected input geometry to the mesh workflow operations. **Named Selections** scoped to the input geometry translate into corresponding **Labels** after initializing the workflow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Import Workflow	Import workflow steps from a .emx file. **Import workflow** is available after deleting steps and clearing data from the current workflow.
Execute Step	Initialize the workflow and execute the next step of the specified mesh workflow.
Execute All Steps	Initialize the workflow and execute all steps of the specified mesh workflow.
Export Workflows	Export the workflow steps as a template to a .emx file.
Complete Workflow	Complete the workflow by transferring generated data back to new mechanical geometry parts along with the corresponding part meshes. You cannot edit the specified mesh workflow type after completing the workflow.
Worksheet	Provides a view of the published mesh workflow operations, controls, and its properties.

Mesh Edit Context Tab

The **Mesh Edit** Context tab enables you to modify and create Mesh Connection objects that enable you to join the meshes of topologically disconnected surface bodies and also move individual nodes on the mesh. The **Mesh edit** Context tab includes the following options:

Option	Description
Mesh Connection Group	Inserts a Mesh Connection Group folder object.
Manual Mesh Connection	Inserts a **Mesh Connection Group** folder that includes a Mesh Connection object.
Contact Match Group	Inserts a Contact Match Group folder object.
Contact Match	Inserts a Contact Match folder object.
Node Merge Group	Inserts a Node Merge Group folder object.
Node Merge	Selects geometries and merge coincident mesh nodes.
Node Move	Selects and move individual nodes on the mesh. Requires mesh generation.
Pull	Creates a mesh volume extrusion.
Body Views	Only visible when Mesh Connection object selected. Toggle button to display parts in separate auxiliary windows.
Sync Views	Only visible when Mesh Connection object selected. Toggle button that you can use when the **Body Views** button is engaged. Any change to the model in the **Geometry** window is reflected in both auxiliary windows.

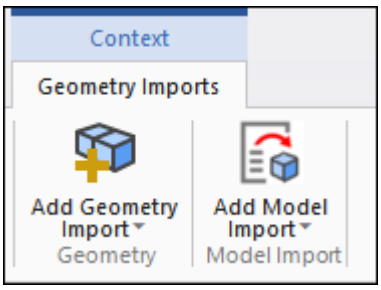
Published: 2023-10-23

Geometry Imports

The options of the **Geometry Imports** Context tab depend upon how you have open Mechanical as well as whether you have imported geometry.

Mechanical Opened Independently

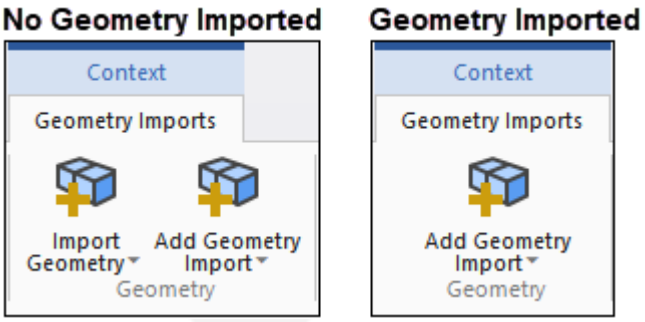
The following Context tab displays when you open Mechanical independently enabling you to open geometry or an external model file.



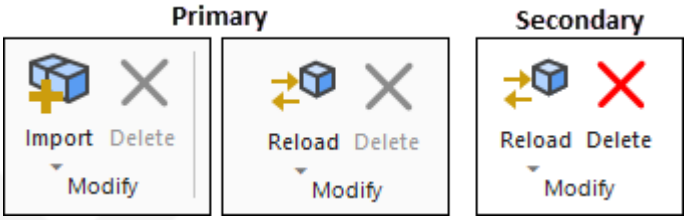
Both options include drop-down menus that provide a **From File** option to import files from a file location as well as a list of recently imported files that you can choose from.

Mechanical Opened from Workbench

As illustrated, if you have not imported a geometry, the option **Import Geometry** enables you to do so. The **Add Geometry Import** option imports secondary geometries into your analysis. All options include drop-down menus that provide a **From File** option to import models from a file location as well as a list of recently imported geometries that you can choose from.

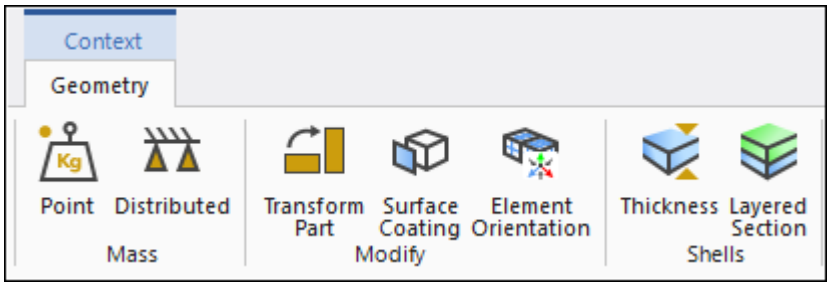


Similarly, when you select a child object (**Geometry Import** primary/secondary), the options of the primary object depend upon whether you have imported a geometry. For the secondary object, you use the **Reload** option to change your geometry. Or you can use the **Delete** option to remove the geometry from your analysis.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Geometry Context Tab



The **Geometry** context tab is active when you select the **Geometry** object in the Outline or any child objects (part/body) of the **Geometry** object. The tab includes the following options:

Option	Description
Modify Geometry (not illustrated)	For electronic computer-aided design (ECAD) models, displays the ECAD Import (p. 703) pane.
Point	Specifies a **Point Mass** (p. 901).
Distributed	Specifies a **Distributed Mass** (p. 902).
Transform Part	Becomes visible when you have a Part or Body selected. For the selected Part or Body, this option automatically scopes the geometry to a Part Transformation object.
Delete Part(s) (not illustrated)	Becomes visible when you have a Part or Body selected, enabling you to delete the selected part or body. Multiple part or body selection is supported.
Surface Coating	Specifies a **Surface Coating** (p. 2008).
Element Orientation	Specifies **Element Orientations** (p. 1008).
Imported Element Orientation	Available when you open Mechanical independently. Inserts an **Imported Element Orientation** folder object, an associated **Element Orientation** object, and displays the **External Data** dialog. You use this dialog to specify the desired external file(s) you wish to import.
Thickness	For surface bodies, enables you to add a Thickness object.
Imported Thickness	Available when you open Mechanical independently. Inserts an **Imported Thickness** folder object, an associated **Imported Thickness** object, and displays the **External Data** dialog. You use this dialog to specify the desired external file(s) you wish to import.
Layered Section	For surface bodies, enables you to add a **Layered Section** (p. 868) object to define layers applied to surfaces.

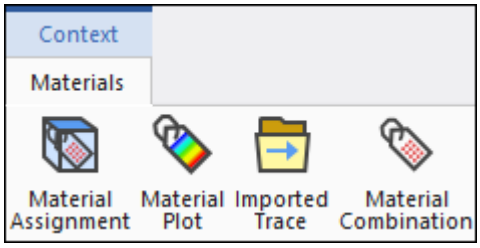
Imported Fields Context Tab

If the **Geometry** object includes an imported object, such as Imported Thickness or Imported Element Orientation, an **Imported Fields** Context menu displays when you select the imported object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Materials Context Tab



The **Materials** context tab is active when you select the Materials, **Material Assignment** (p. 1049), **Material Plot** (p. 1051), or **Material Combination** objects. Use this tab to employ the features related to the **Materials** object. Options include:

- Material Assignment (p. 1049)
- Material Plot (p. 1051)
- Material Combination (p. 1052)

Imported Fields Context Tab

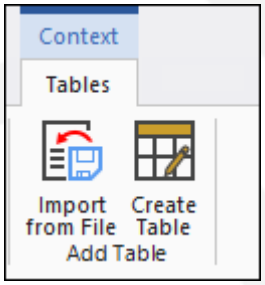
If you import Trace Mapping (p. 686) from an ECAD file, an Imported Trace group folder is placed under the Materials folder. This group folder displays the **Imported Fields** Context tab that includes the option **Trace**.

Imported Material Fields

If you import initial user-defined Field Variable values using the **External Data** (p. 736) system, an Imported Material Fields (p. 1055) group folder is placed under the **Materials** folder.

As a result of your data import, the folder contains an Imported Material Field object. You can specify additional **Imported Material Field** objects using the option of this tab. In addition, the **Variable Data** (p. 61) tab displays when **Imported Material Field** objects are selected.

Tables Context Tab

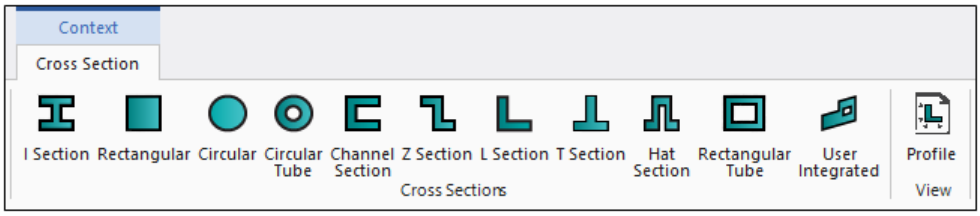


The **Tables** context tab is active when you select the Tables object. Use this tab to add tables for defining pressure, temperature, and convection loads. Options include:

- Import from File (p. 1107)
- Create Table (p. 1109)

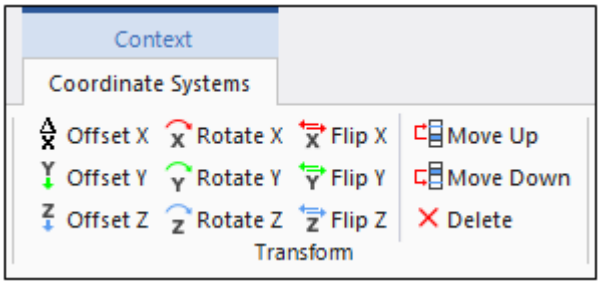
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Cross Section Context Tab



The **Cross Section** Context tab provides cross section type options that enable you to manually define a cross section for your line body model. There is also a **Profile** option that displays a window that enables you to view the cross section dimensions, during construction as well as when you are complete.

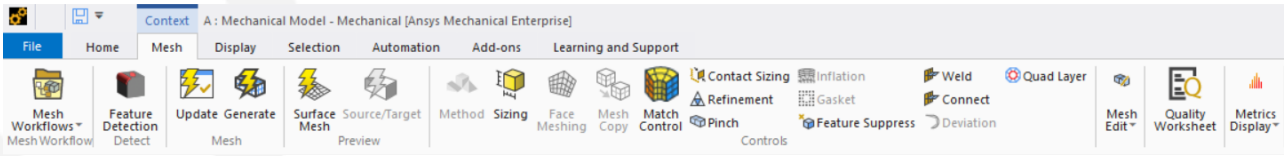
Coordinate Systems Context Tab



The **Coordinate Systems** Context tab is available when you have a user-defined Coordinate System object selected. It includes the following transformation options:

Option	Description
Offset X/Y/Z	Create an **Offset** in the **Transformations** category of the Details view. These options require to enter a value.
Rotate X/Y/Z	Create a **Rotate** transformation in the **Transformations** category of the Details view. These options require to enter a value.
Flip X/Y/Z	Create a **Flip** transformation in the **Transformations** category of the Details view. These options flip the coordinate system about a desired axis.
Move Up/Move Down	Scroll up or down through the **Transformations** category properties/transformations that you have created.
Delete	Deletes a property/transformation from the **Transformations** category.

Mesh Context Tab



The **Mesh Context Tab** includes the following options:

In the **Mesh Workflow** group, the following option is available:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
Mesh Workflows	Generate **Mesh Workflows** based on predefined workflows that can be customized.

In the **Detect** group, the following option is available:

Option	Description
Feature Detection	Detects feature based on Feature Detection (p. 1033).

In the **Mesh** group, the following options are available:

Option	Description
Update	Updates a cell that references the current mesh. This includes mesh generation as well as generating any required outputs.
Generate	Generates a mesh.

In the **Preview** group, the following options are available:

Option	Description
Surface Mesh	Enables you to preview the Surface Mesh.
Source/Target	Enables you to preview the source and target meshes for scoped bodies.

In the **Controls** group, the following options are available:

Option	Description
Method	Selects Method Control.
Sizing	Selects Sizing Control.
Face Meshing	Selects Face Meshing Control.
Mapped Meshing	Selects Mapped Meshing Control.
Mesh Copy	Selects Mesh Copy Control.
Match Control	Selects Match Control.
Contact Sizing	Selects Contact Sizing Control.
Refinement	Selects Refinement Control.
Pinch	Selects Pinch Control.
Inflation	Selects Inflation Group.
Gasket	Selects Gasket Mesh Control.
Feature Suppress	Selects Feature Suppress Control.
Weld	Selects Weld Control.
Connect	Selects Connect Control.
Deviation	Selects Deviation Control.
Quad Layer	Selects Quad Layer Control.

In the **Mesh Edit** group, the following options are available:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Mesh Connection Group	Selects Mesh Connection Group.
Contact Match Group	Selects Contact Match Group.
Node Merge Group	Selects Node Merge Group.
Mesh Edit	Selects Mesh Edit.
Mesh Numbering	Selects Mesh Numbering (p. 1035).
Manual Mesh Connection	Creates manual Mesh Connections.
Contact Match	Selects Contact Match.
Node Merge	Selects geometries and merges coincident mesh nodes.
Node Move	Selects Node Move.
Pull	Creates a mesh volume extrusion.

In the **Quality Worksheet** group, the following option is available:

Option	Description
Quality Worksheet	Displays the Mesh Quality Worksheet.

In the **Metrics Display** group, the following options are available:

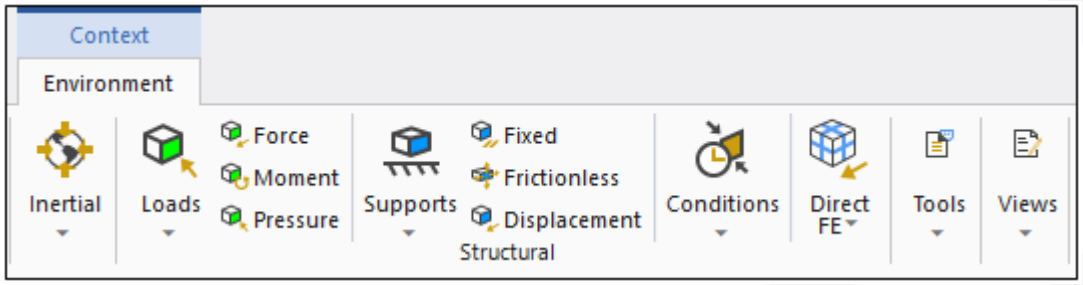
Option	Description
Metric Graph	Shows and/or hides the Mesh Metrics bar graph.
Edges	A drop-down menu options to change the display of your model, including: • **No Wireframe**: Displays a basic picture of the body. • **Show Elements**: Displays element outlines. These options are the same options that are available on the Meshing Edit Context Toolbar (p. 54).
Probe, **Max**, and **Min** (**Snap** and **Advanced**)	These are annotation display options. These options are not visible if the **Mesh** object **Display Style** property is set to the default setting, **Use Geometry Setting**. Selecting the **Max** and/or **Min** buttons displays the maximum and minimum values for mesh criteria (Element Quality, Jacobian Ratio, etc.) that you have selected. The **Probe** feature is also criteria-based. You place a **Probe** on a point on the model to display an annotation on that point. **Probe** annotations show the mesh criterion-based value at the location of the cursor.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
	See the Probe, Maximum, and Minimum (p. 71) topic below for more information.

Environment Context Tab



The **Environment** Context tab enables you to apply loads to your model. Tab groups and options vary depending on the type of analysis you are performing. For example, the groups and options for a **Static Structural** analysis is shown above.

Environment Context Tab Display Group for Variable Data

When your analysis includes imported boundary conditions (p. 1736) or imported thicknesses or you have specified spatial varying loads and displacements (p. 1769), the application displays contours or isoline representations of the associated variable data once you have generated the mesh on the model.

The **Display** group (shown below) becomes visible on the Environment Context Tab (p. 61) when variable data is available. The **Variable Data** drop-down menu provides the display options: **Smooth Contours**, **Contour Bands**, and **Isolines**. When you select the **Isolines** display option, the **Isoline Thickness** drop-down menu enables you to change the thickness of the displayed lines. Options include **Single** (default), **Double**, or **Triple**. The toolbar also contains options to display the **Maximum** and **Minimum** values of the imported data or spatial varying loading. You can toggle these min/max options on (default) and off.

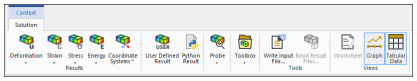
Note:

- The **Isolines** option is drawn based on nodal values. When drawing isolines for imported loads that store element values (**Imported Body Force Density**, **Imported Convection**, **Imported Heat Generation**, **Imported Heat Flux**, **Imported Pressure**, and **Imported Surface Force Density**), the program automatically calculates nodal values by averaging values of the elements to which a node is attached.
- This feature is not available for **Imported Loads** that are scoped to nodal-based **Named Selections**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- If you select multiple **Convection** load objects that include variable data, the application displays only one solid color for the scoped entities.

Solution Context Tab



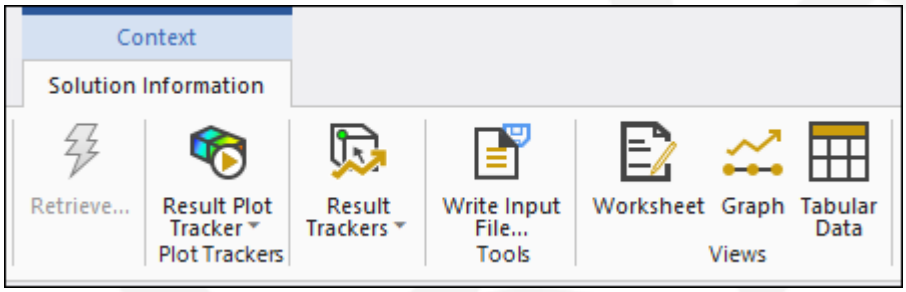
The **Solution** tab applies to Solution-level objects that either:

- Never display contoured results (such as the **Solution** object), or
- Have not yet been solved (no contours to display).

The options displayed on this tab are based on the type of analysis that is selected. The example shown above displays the solution options for a Static Structural analysis. Objects inserted using the **Solution** tab are automatically selected in the **Outline**.

The Applying Results Based on Geometry (p. 1969) section outlines which bodies can be represented by the various choices available in the drop-down menus of the Solution tab.

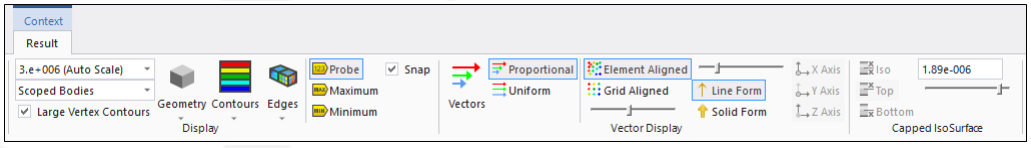
Solution Information Tab



Selecting the **Solution Information** (p. 1833) object displays a corresponding tab. The tab includes the **Retrieve** (p. 1795) option that you use to track background solution processes as well as the **Result Tracker** (p. 1844) and Result Plot Tracker options. The **Write Input File** option as well as some additional display options, **Worksheet**, **Graph**, **Tabular Data**, are also included on the tab.

Result Context Tab

The **Result** tab provides display options for your solved result objects.



The following subsections describe the options available on this tab.

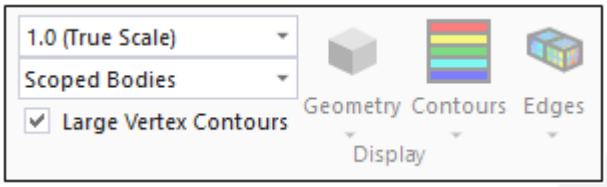
- Scaling Menus for Deformed Shapes (p. 63)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Geometry (p. 67)
- Contours (p. 67)
- Edges (p. 68)
- Probe, Maximum, and Minimum (p. 71)
- Vector Display (p. 74)
- Capped Isosurface (p. 2269)

Scaling Menus for Deformed Shapes

The **Display** group contains the following scaling options for deformations.

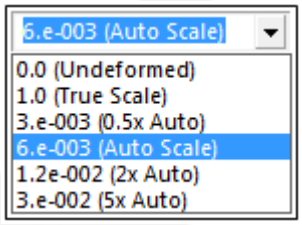


Review the following topics for additional information:

- Deformation Scale Menu (p. 63) and Relative Scaling (p. 65)
- Display Menu (p. 65)
- Large Vertex Contours (p. 67)

Deformation Scale Menu

For results with an associated deformed shape, the scaling menu provides display selections.



Scale factors precede the descriptions in parentheses in the list. The scale factors shown above apply to a particular model's deformation and are intended only as an example. Scale factors vary depending on the amount of deformation in the model. You can choose a preset option from the list, or you can enter a customized scale factor relative to the scale factors in the list.

For customized entries, the application follows a scheme where positive numbers affect the corresponding scaling differently than negative numbers. Positive numbers affect the **True Scale** factor (actual deformation) and negative numbers the **Auto Scale** factor (deformation is visible but not distorted). For example:

- A scale factor of +2.0 equates to 2 times the True Scale factor

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- A scale factor of -2.0 equates to 2 times the Auto Scale factor

Available scale factors include:

- `Undeformed` does not change the shape of the part or assembly.
- `True Scale` is the actual scale.
- `Auto Scale` scales the deformation so that it's visible but not distorting.
- The remaining options provide a wide range of scaling.

The system maintains the selected option as a global setting like other options in the Result tab. As with other presentation settings, figures override the selection. For results that are not scaled, the menu selection has no effect.

Note:

Most of the time, a scale factor selected by the application to create a deformed shape that will show a visible deflection to allow you to better observe the nature of the results. However, under certain conditions, the `True Scale` displaced shape (scale factor = 1) is more appropriate and is therefore the default if any of the following conditions are true:

- Rigid bodies exist.
- A user-defined spring exists in the model.
- Large deflection is on.

This applies to all analyses except for Modal and Eigenvalue Buckling analyses (in which case `True Scale` has no meaning).

Important:

Scaling of Rigid Body Part Displacements in Modal or Eigenvalue Buckling Analyses

Note the following restrictions that apply when scaling rigid part displacements during Modal or Eigenvalue Buckling analyses.

- (Currently) If you are performing a Modal or Eigenvalue Buckling analysis that includes rigid body parts, the application experiences a limitation while scaling and/or animating results.
- The motion of rigid parts in Mechanical is characterized by the changes in the:
  - Position of the center of mass, referred to as linear displacement.
  - Euler angles of the element coordinate system, referred to as angular displacement.

  Because of the difference in the nature of these concepts, a unified scaling algorithm that satisfies both scenarios has not yet been implemented for auto

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

scaling. With the `Auto Scale` option, Mechanical displays rigid parts as white asterisks at the centroid of the part. The application maintains the correct position of the rigid parts with respect to the flexible parts, however, the displayed asterisks do not indicate angular displacement or rotation.

- `True Scale` will not properly display the shapes in Modal or Buckling analysis and should not be used.
- For the best scaling results when working on a Modal analysis (where displacements are not true), use the `Auto Scale` option. If a given body's optimal scaling is `True` and another body's optimal scaling is `Auto Scale`, the graphical display of the motion of the bodies may not be optimal.

Important:

For the following analyses and/or configuration conditions, Mechanical sets the scale factor to zero so that the image of the finite element model does not deform.

- Random Vibration (PSD).
- Response Spectrum.
- Amplitude results for Harmonic Response analyses.
- When the By property of a result is set to:
  - **Maximum Over Time** or **Minimum Over Time**
  - **Time of Maximum** or **Time of Minimum**

Relative Scaling

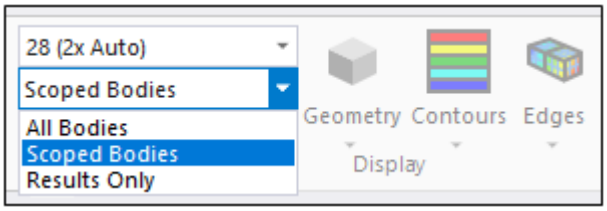
The menu provides the following "relative" scaling options. These options automatically scale deformations relative to preset criteria.

- **Undeformed**
- **True Scale**
- **0.5x Auto**
- **Auto Scale**
- **2x Auto**
- **5x Auto**

Display Menu

The **Display** drop-down menu enables you to view:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Option	Description	Example
All Bodies	Regions of the model not being drawn as a contour are plotted as translucent even for unscoped bodies as long as the bodies are *visible* (not hidden (p. 857))	Scoped Bodies	Default setting. Regions of the model not being drawn as a contour are plotted as translucent for scoped bodies only. Unscoped bodies are not drawn.	Results Only	Only the resultant contour or vector is displayed.	
Limitations

Note the following limitations for the display selections:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- The **Scoped Bodies** and **Results Only** options support geometry-based scoping (**Geometry Selection** property = **Geometry**) and **Named Selections** that are based on geometry selections or worksheet criteria.
- The **Scoped Bodies** and **Results Only** options do not support Construction Geometry features Path (p. 883) and Surface (p. 890).
- The **Results Only** option does not support the Explicit Dynamics Solver.
- For the **Scoped Bodies** option for results that are scoped across multiple entities (vertices, edges, faces, or volumes), all of these entities may not display because there are times when only the nodes of one of the shared entities are used in the calculation.

Large Vertex Contours

The **Large Vertex Contours** check box option is used for node-based result scoping. It toggles the size of the displayed dots that represent the results at the underlying mesh nodes on and off.

Geometry

You can observe different views from the **Geometry** drop-down menu, including:

Option	Description
Exterior	Displays the exterior results of the selected geometry.
IsoSurfaces	For contour results, displays a collection of surfaces of equal value of the chosen result, between its minimum and a maximum as defined by the legend settings. The application displays the interior of the model only.
Capped IsoSurfaces	Represents mainly a set of all points that equal a specified result value within the range of values for the result with additional features. This option provides three display selections. A display based on all points of a specified result, all points equal to and less than the specified result, and all points equal to and greater than the specified result value. Refer to Capped Isosurfaces (p. 2269) section for a description of the controls with this option. This view displays contours on the interior and exterior.
Section Planes	Displays planes cutting through the result geometry; only previously drawn Section Planes (p. 294) are visible.

Contours

The **Contours** drop-down menu enables you to change the way you view your results. Options include:

Option	Description
Smooth Contours	Displays gradual distinction of colors.
Contour Bands	Displays the distinct differentiation of colors.
Isolines	Displays a line at the transition between values.
Solid Fill	Displays the model only with no contour markings.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Edges

What is displayed by the options of the **Edges** drop-down menu, depends upon the selections you make in the other result display menus.

Option	Description
No Wireframe	Displays the result in its deformed state. The result's display is based on your selections in the **Geometry** and **Contours** menus (see above). **Example** Show Undeformed Wireframe	Displays the result with an undeformed wireframe overlay, as illustrated by the first image below. By default, this undeformed display is only supported for the **Exterior** option of the **Geometry** menu. The **IsoSurfaces**, **Capped IsoSurfaces**, and **Section Planes** options of the **Geometry** menu display the result with the wireframe overlay in a deformed state, as illustrated. **Geometry Menu Exterior** Option: Wireframe Not Deformed with Result  **Geometry Menu IsoSurfaces** Option: Wireframe Deformed with Result  You can change this default setting for the deformation display using the preferences of the **Options** dialog. Under the **Graphics** (p. 228) category, set the **Use Deformed Edge for Slice ISO Option** to **No**. For the **IsoSurfaces**, **Capped IsoSurfaces**, and

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
	Section Planes options, you can display the result in a deformed state and the wireframe overlay in an undeformed state, as illustrated below. **Geometry Menu IsoSurfaces** Option: Wireframe Not Deformed with Result  **Geometry Menu Capped IsoSurfaces** Option: Wireframe Not Deformed with Result  **Correcting Edge Display for Large Face Angles** You may see wireframe display issues for edges when the tolerance angle between two faces is insufficient. Using the Graphics (p. 228) category preference, **Maximum Face Angle to Preserve Edges**, you can increase this value to properly render the edge display. As illustrated below, note the display change when the angle is increased. **Face Angle 120°**  **Face Angle 130°** 
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Show Undeformed Model	Displays the result with a translucent overlay of the undeformed model, as illustrated below. By default, this undeformed display is only supported for the **Exterior** option in the **Geometry** menu. The **IsoSurface**, **Capped IsoSurface**, and **Section Planes** options display the result with the translucent overlay of the model in a deformed state, as illustrated. **Geometry Menu Exterior** Option - Translucent Overlay Not Deformed  **Geometry Menu IsoSurfaces** Option - Translucent Overlay Deformed with Result  As stated above, you can change this default setting for the deformation display using the preferences of the **Options** dialog. Under the **Graphics** (p. 228) category, set the **Use Deformed Edge for Slice ISO Option** to **No**. For the IsoSurface, Capped IsoSurface, aand Section Planes options, you can display the result in a deformed state and the translucent overlay of the model in an undeformed state, as illustrated. **Geometry Menu IsoSurfaces** Option: Translucent Overlay Not Deformed with Result  **Geometry Menu Capped IsoSurfaces** Option: Translucent Overlay Not Deformed with Result

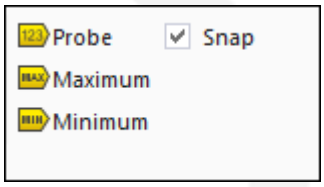
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
	Show Elements	Displays the result in its deformed state and includes mesh elements. The result's display is based on your selections in the **Geometry** and **Contours** menus. **Example** 
Probe, Maximum, and Minimum

You use the **Probe** option to interactively place probe annotations on your model. If you display the Graphics Annotations (p. 202) window, you can view the result value at the location of your probe annotation, the unit of the result, as well as the coordinate values for the probe. You use the **Maximum** and **Minimum** options to display (or hide) annotations of the maximum and/or minimum values for the selected result.

Note:

The **Maximum** and **Minimum** options consider only visible bodies. If you hide a body that includes one of these annotations, you could see a discrepancy between the minimum and maximum values displayed in the Details properties for the result versus the (new) location of the annotations.



The **Snap** option (active by default), automatically places probes on the nearest mesh node (the probe "snaps" to the node). For high order elements, this includes midside nodes as well as the centroids of element faces. Additionally, using the **Show Mesh Entity ID in Snap-Probe Labels** preference (also active by default) of the Graphics (p. 228) category in the **Options** dialog, the application automatically includes either the Node ID or the Element ID in the probe annotation label (see example

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

below). Furthermore, the **Graphics** category (under the Interactive and Min/Max Probes category (p. 231)) includes a property, **Show Detailed Information in Min/Max Probe Labels**, that enables you to also display additional information on the Min/Max probe, such as Node/Element ID and actual Min/Max values.

Tip:

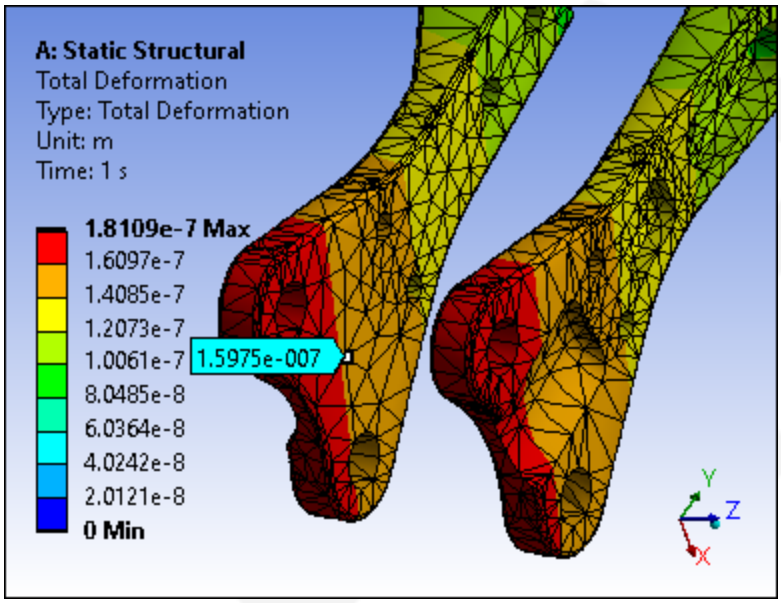
The application does not automatically save newly created probe annotations. You need to save the project manually.

Note:

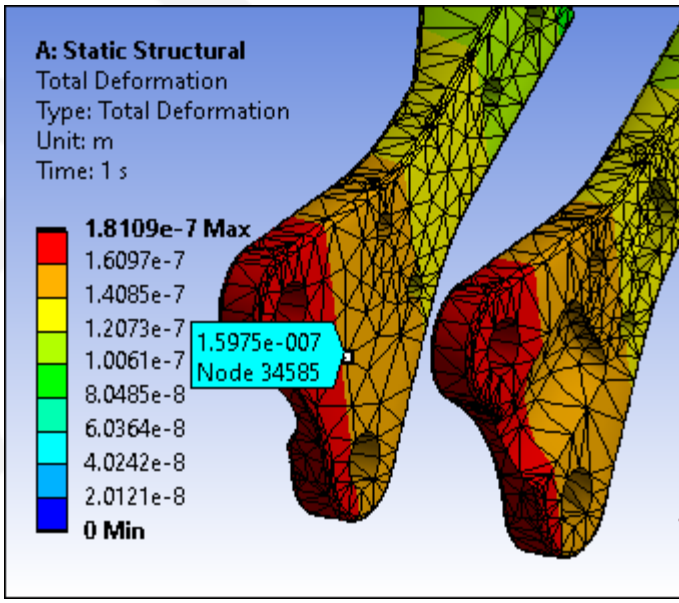
The **Snap** feature does not support the Geometry menu display options **IsoSurfaces**, **Capped IsoSurfaces**, or **Section Planes**.

Probe Labelling

Probe Label



Probe Label with Node ID

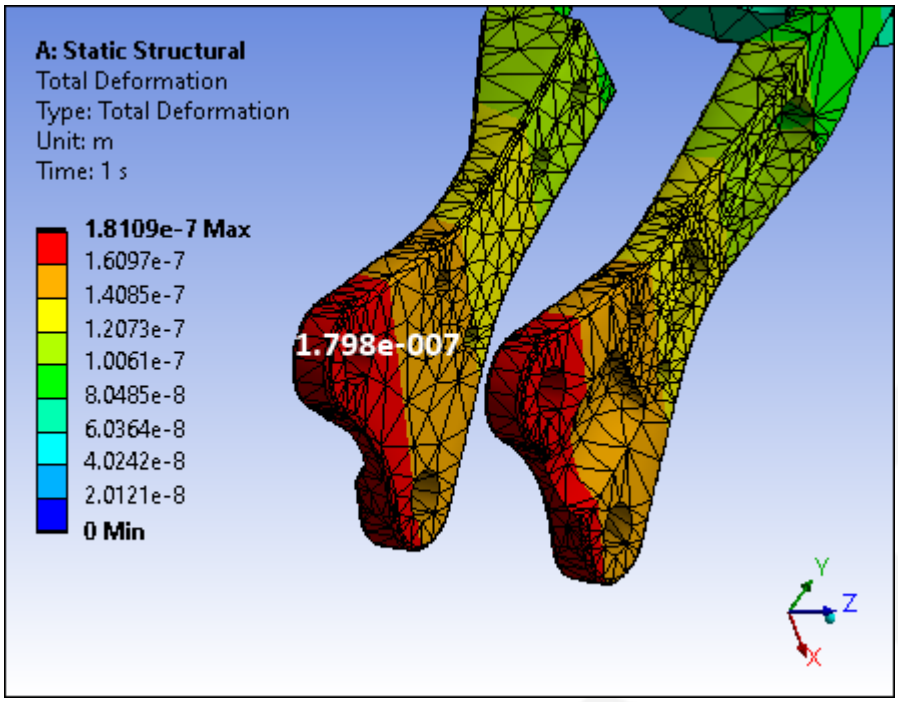


Probe Display Font

When the **Probe** option is selected and you move the cursor over your model, result values display. You can change the default display settings for the font using the **Probe Tool and Hit Point Coordinate (Windows Only)** preference of the **Graphics** (p. 228) category in the **Options** dialog. This preference enables you to change the attributes (font, size, style, color) of the font displayed (illustrated below is Bold Calibri Size 18).

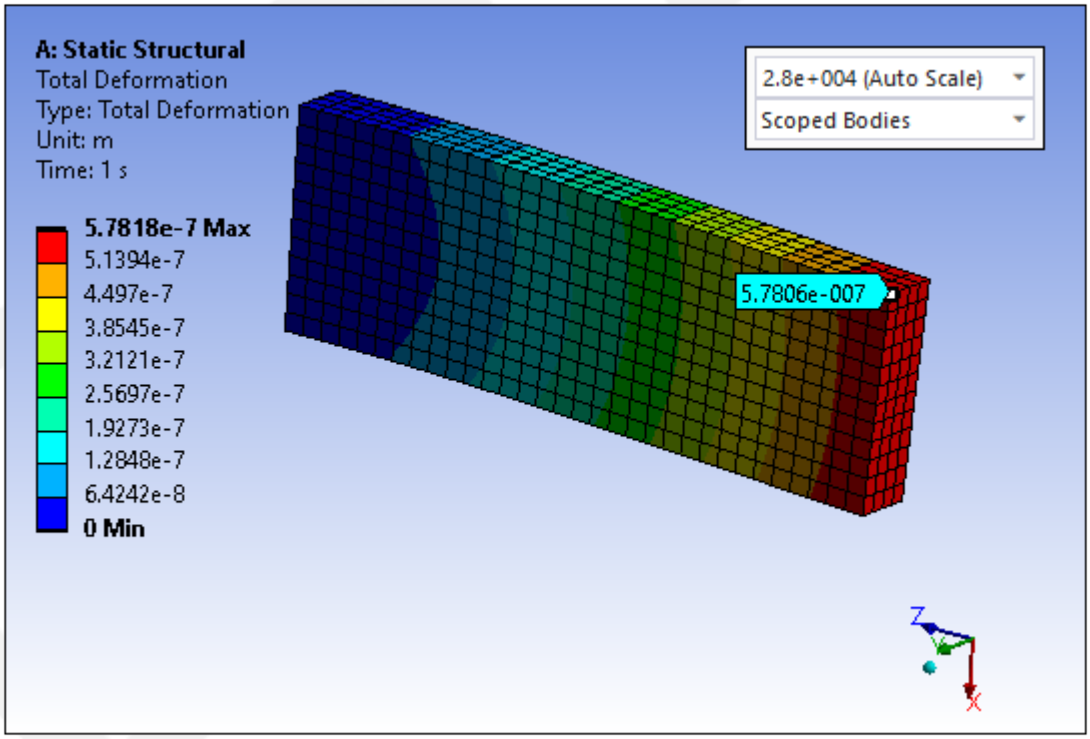
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

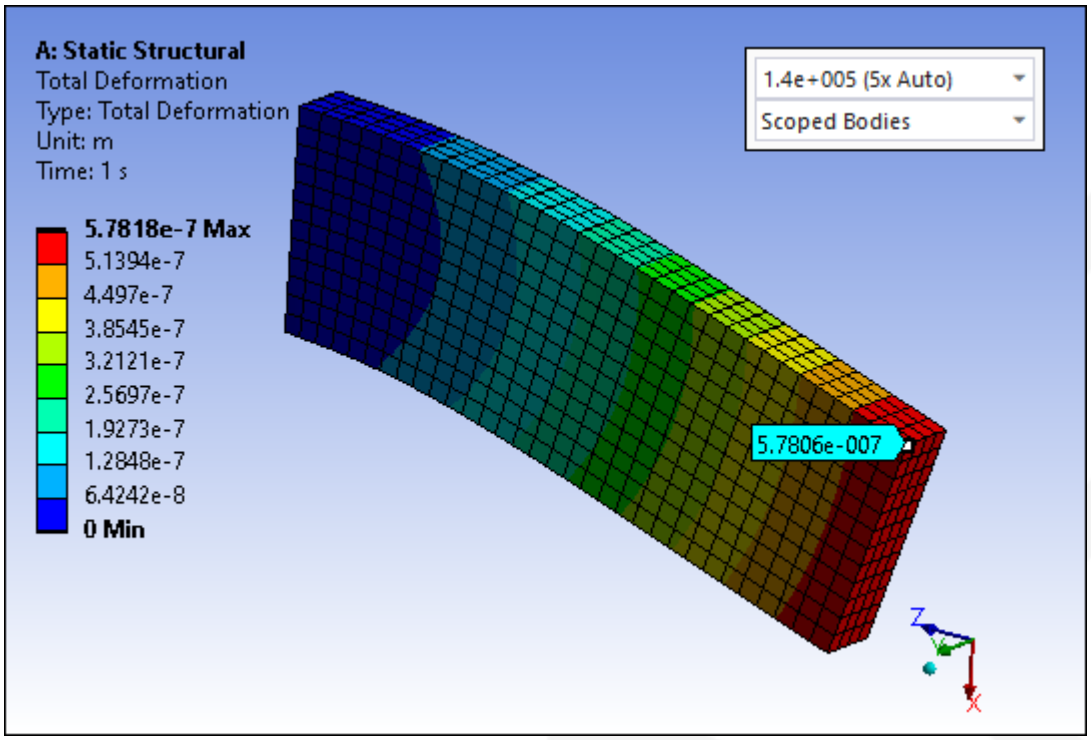


Probe Label and Scaling

Another **Graphics** (p. 228) category preference is the **Move Probe Labels with Deformation Scale Factor** setting. This preference is the default setting. It enables the probe to be "flexible" and move with the deformed mesh whenever you make a change to the Deformation Scale Factor, as illustrated below. If turned off, the application deletes probe labels whenever you make a change to the scale factor.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

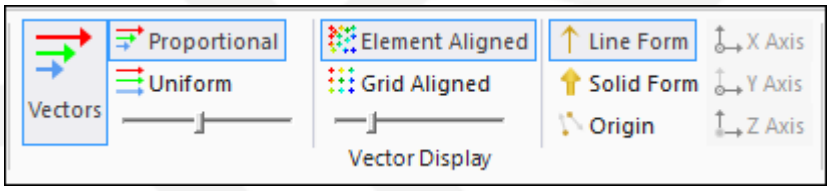


Note:

The application does not support the ability to flex a probe's location using the **Geometry** menu display options **IsoSurfaces**, **Capped IsoSurfaces**, or **Section Planes**. If you place a probe when any of these options are active and then change the scaling, the application automatically removes/deletes the probe labels.

Vector Display

Using the **Vector Display** group, you can display results as vectors. This group includes various options for controlling the display of the vectors.



Note:

These vector display options are also available for Element Orientations (p. 1008) and certain vector based-loads.

When you select the **Vectors** option, the following associated options may be used.

Option	Description
Proportional	Displays vector length proportional to the magnitude of the result.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
Uniform	Displays a uniform vector length, useful for identifying vector paths.
Element Aligned	Displays all vectors, aligned with each element.
Grid Aligned	Displays vectors, aligned on an approximate grid.
Length Slider	Controls the relative length of the vectors in incremental steps from 1 to 10 (default = 5), as displayed in the tool tip when you drag the mouse cursor on the slider handle.
Grid Slider	Controls the relative size of the grid, which determines the quantity (density) of the vectors. The control is in uniform steps from 0 [coarse] to 100 [fine] (default = 20), as displayed in the tool tip when you drag the mouse cursor on the slider handle. **Note:** This slider control is active only when the adjacent button is chosen for displaying vectors that are aligned with a grid.
Line Form	Displays vector arrows in line form.
Solid Form	Displays vector arrows in solid form.
Origin	Displays origin of the nodes included in the load and/or result.
X Axis/Y Axis/Z Axis	When solving principle stresses or principle strain, these buttons enable you to display (or hide) the vectors for Maximum Principal, Middle Principal, and Minimum Principal at each node. When solving Nodal Triads or Elemental Triads, these buttons enable you to display (or hide) the vectors for X Axis, Y Axis, and Z Axis at each node or element.

Vector Display Examples

Here are examples of uniform vectors identifying paths in line, solid, and origin form.

Line Form **Solid Form** **Origin Form**

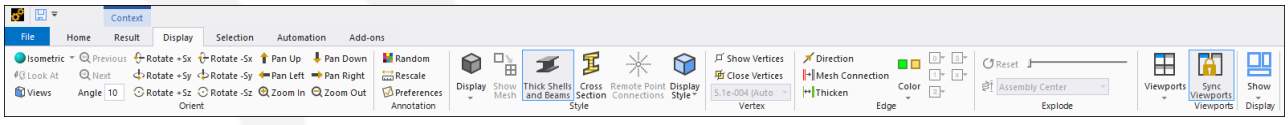
Display Tab

The **Display** tab contains options for moving your model within the **Geometry** window as well as a variety of display-based options such as wireframe, edge thickness, ply directions, etc.



This tab contains the following **Groups**.

- **Orient** (p. 79)
- **Annotation** (p. 79)
- **Style** (p. 80)

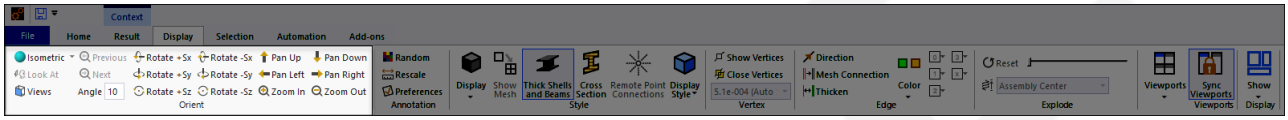
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Vertex** (p. 83)
- **Edge** (p. 84)
- **Explode** (p. 86)
- **Viewports** (p. 87)
- **Display** (p. 87)

Orient

The **Orient** group provides model orientation options.

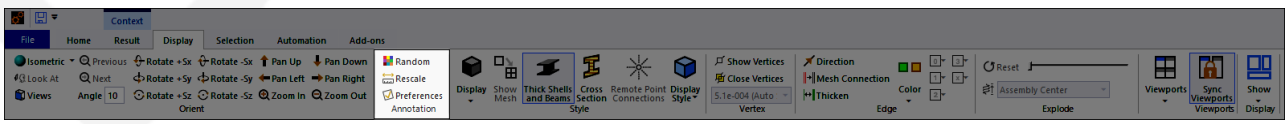


Options for this group include:

Option	Description
Isometric	Reorients your model into the isometric view. This option also includes the following drop-down menu options: • **Set**: Orient your model to a desired view and select this option to define a new default view for the **Isometric** option. • **Restore Default**: Resets the view of the **Isometric** option to the application default.
Look At	Centers your model in the **Geometry** window based in the currently selected face or plane.
Views	Provides a drop-down menu of options that enable you to change the viewpoint (front, back, right, etc.) of your model as well as an option to orient your model in the isometric view.
Previous/Next	Scrolls forward or backward from the last view displayed in the **Geometry** window.
Rotate ± X/Y/Z	Rotates your model in the **Geometry** window about the axis.
Pan Up/Down/Right/Left	Pans your model in the **Geometry** window.
Zoom In/Out	Zooms in or out of your model.

Annotation

The **Annotation** group enables you to make changes to how Annotations are displayed in the **Geometry** window as well as specify preferences.



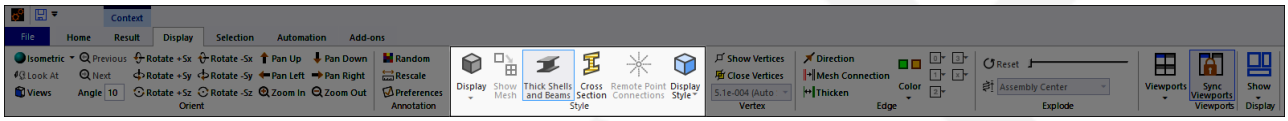
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Options for this group include:

Option	Description
Random	By default, the annotations for objects types (loads, supports, named selections, etc.) are shown by a unique color. That is, all loads are red and all supports are blue etc. Selecting the **Random** option, you change the colors used for annotations.
Rescale	Changes the size of annotation symbols, such as load direction arrows.
Preferences	Displays the **Preferences** (p. 310) dialog that you use to set preferences for the display of annotations.

Style

The **Style** group provides model display options such as wireframe, showing the mesh, etc.



Options for this group include:

Option	Description
Display	Provides a drop-down menu of the following model display options: • **Shaded Exterior and Edges**: Displays the model in the **Geometry** window with shaded exteriors and distinct edges. This option is mutually exclusive with Shaded Exterior and Wireframe. • **Shaded Exterior**: Displays the model in the **Geometry** window with shaded exteriors only. This option is mutually exclusive with Shaded Exterior and Edges and Wireframe. • **Wireframe**: Displays the model in the **Geometry** window with a wireframe display rather than a shaded one (recommended for seeing gaps in surface bodies). This option is mutually exclusive from the above two options. The Wireframe option not only applies to geometry, mesh, or named selections displayed as a mesh, but extends to probes, results, and variable loads to enable a better understanding of regions of interest. When Wireframe mode is set, just the exterior faces of the meshed models are shown, not the interior elements. **Note:** – When this option is on, green scoping is not drawn on probes. Also, elements are shown on probes and results, whereas the outline of the mesh is shown on isoline contour results.

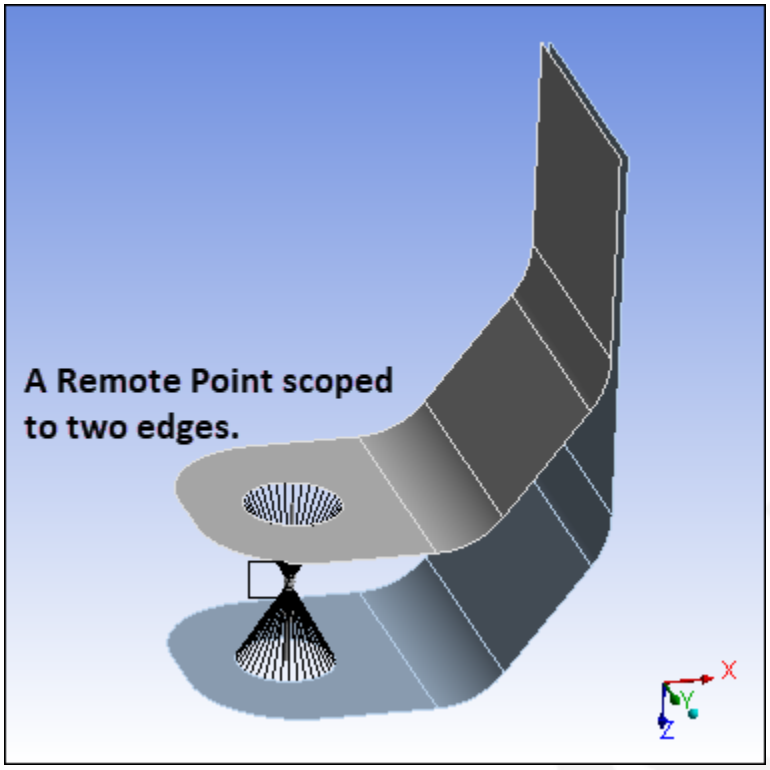
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

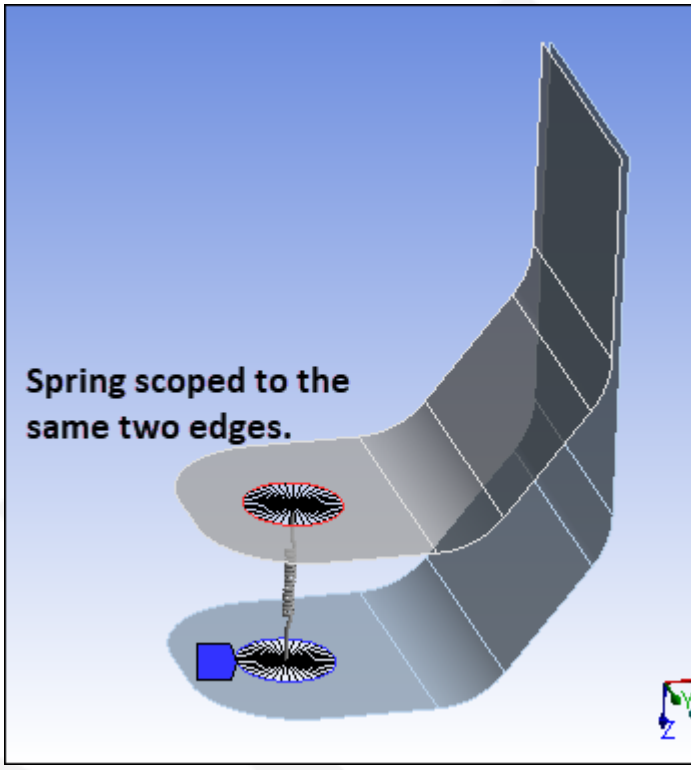
Published: 2023-10-23

Option	Description
	– Selecting any of the edges options (p. 68) on contour results automatically closes Wireframe mode.
Show Mesh	Displays your model's mesh regardless of the selected Outline object. When enabled, to make sure that Annotations display properly, also turn on Wireframe mode. See the related Note (p. 82) below.
Thick Shells and Beams	Displays the thickness of shells, beams, and particles, when viewing mesh or results. By default, this option is inactive. Review the Note (p. 82) below for additional display characteristics associated with this feature.
Cross Section	Displays line body cross sections as 3D geometry. See Viewing Line Body Cross Sections (p. 877) for details.
Remote Point Connections	Displays connection lines between geometry and Remote Points (p. 1089) or between supported remote boundary conditions (p. 1735) and Remote Points. See the example below. Once you have generated the mesh, the connection lines are drawn between the Remote Point and the nodes on the corresponding mesh of the underlying geometry or boundary condition. **Important:** Only the nodes that are contained inside of the Pinball Radius property setting are displayed.
Display Style	Provides a drop-down menu with options to display the parts and bodies of your model based on the available styles. For example, if an assembly is made of parts of different materials, you can color the parts based on the material; that is, all structural steel parts have the same color, all aluminum parts have the same color and so on. See the Color Coding of Parts (p. 858) topic.

Remote Point Connections Display Example

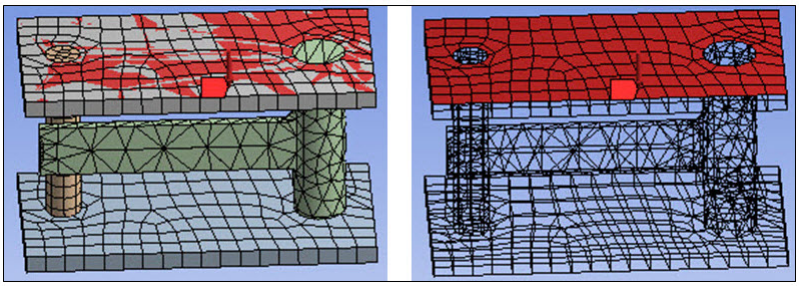
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23





Note:

As illustrated below, annotations may not always display properly when the **Show Mesh** option is activated. Turning on Wireframe mode accurately displays Annotations when **Show Mesh** is selected.



Note:

- **Displaying Shells for Large Deflections**: The display of shells may become distorted for large deformations such as in large deflection or during an Explicit Dynamics analysis. A workaround for this is to disable Shell Thickness by toggling the **Thick Shells and Beams** option. Or, set a variable, **UsePseudoShellDisp = 1**, using the **Variable Manager** option from the **File** tab. It may be necessary to toggle the deformation scaling from True Scale to Undeformed to True Scale again (see **Scaling Deformed Shape** in the Context Tabs (p. 47) section). Note that this option requires **True Scaling** to work properly.

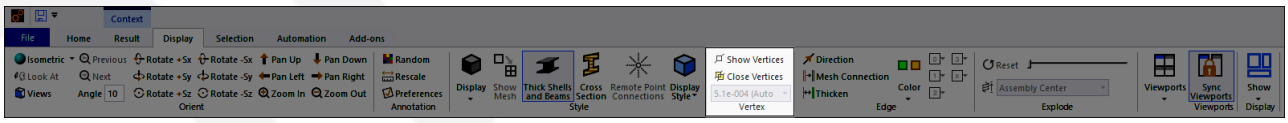
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Displaying Shells with Thickness on Geometry that Spans Large Angles**: The graphical representation of your meshed shell model may appear distorted when the shell spans a large angle, such as a 90° angle. Ordinarily, the application calculates an average of the normals between elements (based on a default setting of 180°). Given too large of an angle, a graphical abnormality may occur. Modify the default setting using the Graphics (p. 228) option in the **Options** (p. 217) dialog box. **60°** is the recommended setting to avoid the display of any graphical abnormalities.
- **Displaying Results on Very Thin Shell Bodies**: If you are viewing result contours of a very thin geometry, you could observe a graphical distortion as a result of colors from the back face of the geometry bleeding onto the front face of the geometry. This is a graphics-based limitation. In addition, turning off the **Thick Shells and Beams** option can cause the distortion to worsen.
- **Displaying Shells on Shared Entities**: The display of shells is done on a nodal basis. Therefore, graphics plot only 1 thickness per node, although node thickness can be prescribed and solved on a per elemental basis. When viewing shell thickness at sharp face intersections or a shared body boundary, the graphics display may become distorted.
- **Shell Element Display from Mesh Changes**. If you employ a feature that changes the model's mesh, such as the **Nonlinear Adaptive Region** or **Fracture**, you may see display errors for expanded shell elements as a result of the changing mesh. Disable the **Thick Shells and Beams** option to properly display the elements.
- **Displaying Contours and Displaced Shapes on Line Bodies**: The contour result on a line body are expanded to be viewed on the cross section shape, but only one actual result exists at any given node and as a result no contour variations across a beam section occur.
- **Display Pipes using Pipe Idealizations**: Although the solution will account for cross section distortions, the graphics rendering for the results display the cross sections in their original shape.

Vertex

The **Vertex** group provides vertex display options.



Options for this group include:

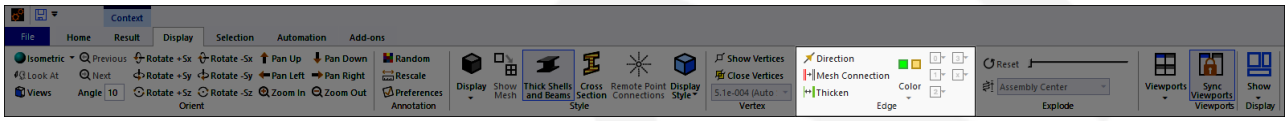
Option	Description
Show Vertices	Highlights all vertices on the model. This feature is especially useful when examining complex assemblies where vertices might normally be hidden from view. It can also be used to ensure that edges are complete and not segmented unintentionally.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
Close Vertices	Displays tightly clustered vertices on your model. This vertex display feature has an accompanying scale menu. When you select this option, a corresponding scale menu also activates and includes application generated tolerances as well as an option that enables you to enter a tolerance value. The application calculates the default tolerance (**Auto Scale**). This value is 0.1% of the diagonal measurement of your model's **Bounding Box** dimensions. Additional system options are factors of this base measurement and you can manually enter a tolerance using the **Custom Value** option. The **Custom Value** cannot exceed 5% of the model's **Bounding Box** dimensions. Based on the selected tolerance, the application highlights pairs of vertices that are closer to one another than the specified tolerance and draws segments between the vertices to further illustrate proximity.

Edge

The **Edge** group provides display options used to display the edges on your model, their connectivity, and how they are shared by faces. Also see the Preparing Assemblies of Surface Bodies (p. 861) section for more information.



Options for this group include:

Option	Description
Direction	Displays model edge directions. The direction arrow appears at the midpoint of the edge. The size of the arrow is proportional to the edge length.
Mesh Connection	Displays the edges using coloring schema, by taking into account the mesh connection information.
Thicken	For annotations scoped to lines (for example, annotations representing loads, named selections, point masses, and so on), enabling this option thickens these lines so they are more easily identifiable on the screen.
Color	The options of this drop-down menu highlight the edges of your model using specific colors. Options include: • **By Body Color**: Highlight the edges of your model using the colors assigned to the bodies. • **By Connection**: Highlight the edges of your model based on the number of element faces shared by the edge. Colors include blue (not shared, labeled “Free”), red (shared by one face, labeled “Single”), black (shared by two faces, labeled “Double”), pink (shared by three faces, labeled “Triple”) and yellow (edge shared by more than three faces, labeled “Multiple”). The legend for this option is titled “Edge/Face Connectivity.”

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
	• **By Body Connection**: Highlight the edges of your model based on edge-body connections. Colors include black (edge shared by one body, labeled Single), pink (edge shared by two bodies, labeled Double), and yellow (edge shared by more than three bodies, labeled "Multiple"). The legend for this option is titled "Edge/Body Connectivity." • **Black**: Highlight the edges of your model with black lines. This option turns off the edge-face connectivity display.
Free (edge display)	Displays drop-down menu with the following options: • **Hide Free**: Hides only edges not shared by any faces. • **Show Free**: Displays only edges not shared by any faces. • **Thick Free**: Displays only edges not shared by any faces at a different edge thickness compared to the rest of the model.
Single (edge display)	Displays drop-down menu with the following options: • **Hide Single**: Hides only edges that are shared by one face. • **Show Single**: Displays only edges that are shared by one face. • **Thick Single**: Displays only edges that are shared by one face at a different edge thickness compared to the rest of the model.
Double (edge display)	Displays drop-down menu with the following options: • **Hide Double**: Hides only edges that are shared by two faces. • **Show Double**: Displays only that are shared by two faces. • **Thick Double**: Displays only edges that are shared by two faces at a different edge thickness compared to the rest of the model.
Triple (edge display)	Displays drop-down menu with the following options: • **Hide Triple**: Hides only edges that are shared by three faces. • **Show Triple**: Displays only that are shared by three faces. • **Thick Triple**: Displays only edges that are shared by three faces at a different edge thickness compared to the rest of the model.
Multiple (edge display)	Displays drop-down menu with the following options: • **Hide Multiple**: Hides only edges that are shared by more than three faces. • **Show Multiple**: Displays only that are shared by more than three faces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
	• **Thick Multiple**: Displays only edges that are shared by more than three faces at a different edge thickness compared to the rest of the model.

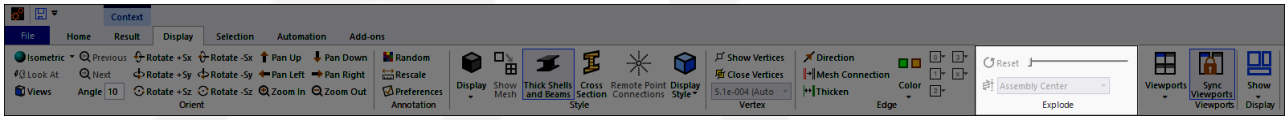
Note:

Note the following restrictions when you are using the **Edge** options on the mesh, as compared to their use on geometry:

- When you are using the **Edge Coloring** options when viewing the mesh, the application only draws the corner nodes to display the outline of the elements (mid-side nodes are ignored if available). You can use the Wireframe tool and also hide bodies to properly display the colored edges. And in doing so, you can see where mid-side nodes are located, if available.
- Not all of the buttons/options are functional, for example, **Double** always displays thin black lines. The width of the colored lines cannot be changed. They are always thick.
- During slicing, the colors of shared element edges are not drawn. They display as black and appear only when the selected section plane is losing focus in the slice tool pane.

Explode

The **Explode** group is a graphical display feature used to create imaginary distance between geometry bodies (only) of your model for viewing purposes.



Once the mesh is generated, this feature is not supported when you have the **Mesh** object selected or when the **Show Mesh** feature is turned on. In addition, when viewing the mesh, exploded geometry bodies, although not visible in the **Geometry** window, are still in an exploded state and passing the cursor over an exploded body will highlight the (otherwise invisible) body and it is also selectable at this time.

Reset Button

This button reassembles the parts of your model to their original position.

Explode View Factor Slider

This slider tool enables you to change the exploded distance between the parts from their original position.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Move Springs/Beams with Parts

The button for this option enables you to see an accurate representation of connections on your model, such as Springs and Beams, by showing the connections stretched from the assigned locations on the moving parts. Because the display is graphically accurate, the processing requirements are intensive. Use the default position (not active/depressed) when moving the slider for large models and when connection representations are not critical.

Assembly Center Drop-Down List

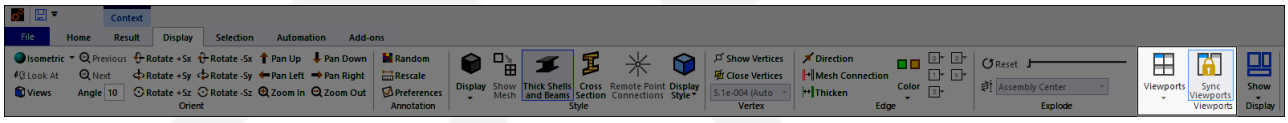
This drop-down list provides the available coordinate system options as well as the **Assembly Center** option (default setting) that defines the position in space from which the exploded view originates and the **Assembly Center (Visible)** option that accounts for the visible parts only. The **Global Coordinate System** is always an available option as well as any user-defined coordinate systems (p. 1192).

Note:

The explode view feature does not support the **Body Views** display, such as when you are displaying contact bodies in separate windows (p. 1270).

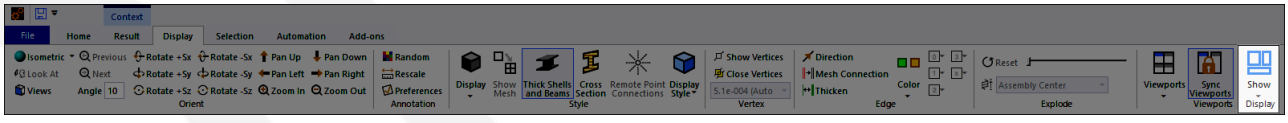
Viewports

The **Viewports** group enables you to split the **Geometry** window into multiple windows, synchronize the windows as desired, and/or capture an image of the currently displayed viewports. See the Using Viewports (p. 284) section for more information.



Display

The **Display** group contains the **Show** drop-down menu that provides several general display options, such as the ruler and legend.



Options of the menu include:

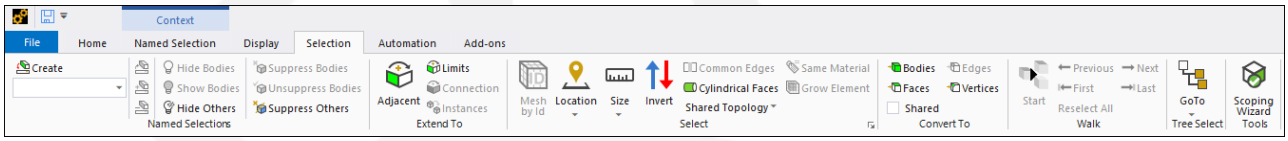
Option	Description
Ruler	Turns the **Geometry** window ruler on and off.
Legend	Turns the **Geometry** window legend on and off.
Triad	Turns the **Geometry** window triad on and off.
Show Mesh	Displays the model's mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Option	Description
All Coordinate Systems	Displays all the available coordinate systems defined on the model – default as well as user defined.
Visual Expansion	Toggles the visibility of either a single cyclic sector mesh or the full symmetry mesh in a cyclic symmetry analysis (p. 1147). Toggling this option can help preview before solving the density of nodes on the sector boundaries, or it can help confirm the expanded mesh in each case.
Erodes Nodes	Turns the visibility of eroded nodes for explicit dynamics analyses on or off.
Draw Face Mode	Displays a drop-down menu with options to change how faces are displayed as a function of back-face culling. Options include: • **Auto Face Draw**: Turning back-face culling on or off is program controlled. Using Section Planes is an example of when the application would turn this feature off. • **Draw Front Faces**: Forces face culling to stay on. Back-facing faces will not be drawn in any case, even if using Section Planes. • **Draw Both Faces**: Turns off back-face culling. Both front-facing and back-facing faces are drawn.

Selection Tab

The **Selection** tab facilitates the selection of geometric and/or mesh entities either through graphical picking or through some criterion-based selection feature, such as size or location.



Note:

The tab's functionality uses Ansys ACT. The relevant python modules (`selection.py` and `toolbar.py`) are available for review in the install folder: **aisol/DesignSpace/DSPages/Python**.

This tab contains the following **Groups**.

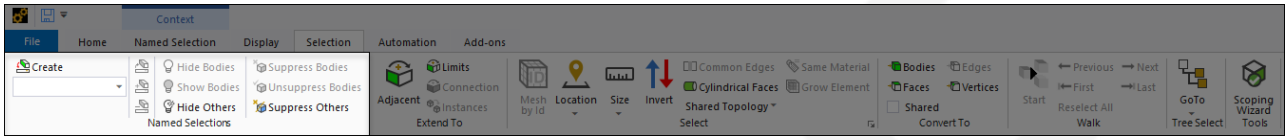
- **Named Selections** (p. 89)
- **Extend To** (p. 89)
- **Select** (p. 89)
- **Convert To** (p. 92)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Walk** (p. 93)
- **Tree Select** (p. 93)
- **Tools** (p. 93)

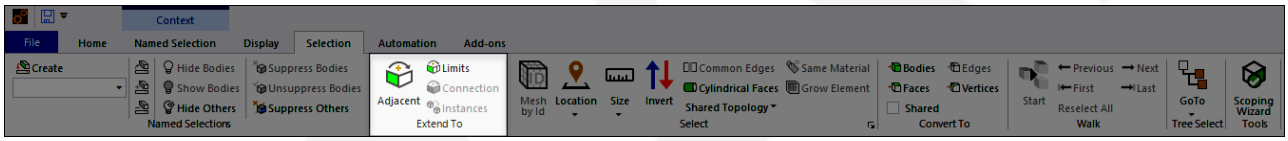
Named Selections

The **Named Selections** group enables you to select, add to, and remove items from existing user-defined named selections as well as modify visibility and suppression states. See the Applying Named Selections via the Ribbon (p. 1075) section for detailed description of the options.



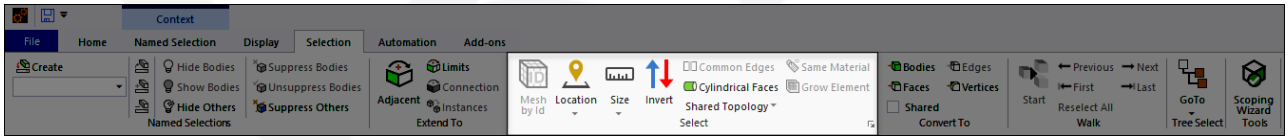
Extend To

The **Extend To** group enables you to add adjacent faces or edges, within angle tolerance, to the currently selected face or edge set, or adds tangent faces or edges within angle tolerance, to the currently selected face or edge set. See the Extend To (p. 264) topic for additional information about these options.



Select

The **Select** group provides options for making and/or manipulating geometry selections.



Note:

Many of these options are also available from the **Select By** menu on the Graphics Toolbar (p. 97).

Options for this group include:

Option	Description
Mesh by Id	Opens a dialog that enables you to select mesh nodes and mesh elements using their IDs once you have generated the mesh for your model. This feature is *modeless* and therefore enables you to work with the user interface while the dialog box is displayed. This feature is also available from the context (right-click) menu, **Select Mesh by ID (M)**, in the **Geometry**

Option	Description
	window. You can also activate the feature using the **M** key, when the **Geometry** window has focus. See the Selecting Nodes and Elements by ID (p. 279) section for more information.
Location **Note:** For a line body geometry, the location is estimated as the weighted arithmetic mean of the centroids of its edges. The weight is based on the edge lengths.	Displays a drop-down menu of the following options: • **Select All Entities With the Same X Location**: Adds all geometry entities in the model with the same X location in the Global Coordinate System as the current selection, to the current selection. • **Select All Entities With the Same Y Location**: Adds all geometry entities in the model with the same Y location in the Global Coordinate System as the current selection, to the current selection. • **Select All Entities With the Same Z Location**: Adds all geometry entities in the model with the same Z location in the Global Coordinate System as the current selection, to the current selection. • **Select All Coplanar Entities With the Same X Location**: Adds all geometry entities of the model that are in the same plane with the same X location, in the Global Coordinate System as the current selection, to the current selection. • **Select All Coplanar Entities With the Same Y Location**: Adds all geometry entities of the model that are in the same plane with the same Y location in the, Global Coordinate System as the current selection, to the current selection. • **Select All Coplanar Entities With the Same Z Location**: Adds all geometry entities of the model that are in the same plane with the same Z location, in the Global Coordinate System as the current selection, to the current selection.
Size	Displays a drop-down menu of the following options: • **Select All Entities With the Same Size**: Adds all geometry entities in the model with the same size as the current selection to the current selection. • **Select All Entities Smaller than Selection**: Adds all geometry entities in the model that are smaller than the current selection to the current selection. • **Select All Entities Smaller than**: Displays a dialog box that enables you to specify the type of geometric entity as well as a reference value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

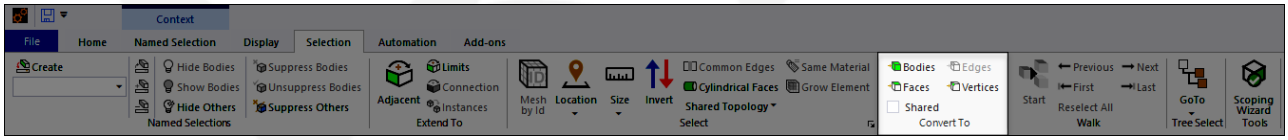
Published: 2023-10-23

Option	Description
	 The **Select** drop-down menu default option is **Bodies**. The application overrides this default if you have actively selected edges or faces. The default of the **Value** field equals the size of the current selection. The application adds all entities in the model for the given type that are smaller than the reference value to the current selection. Note that the units are based on the active unit system when the dialog was first launched and the type of entity. • **Select All Entities Larger than Selection**: Adds all geometry entities in the model that are larger than the current selection to the current selection. • **Select All Entities Larger than**: Displays a dialog box (shown above) that enables you to specify the type of geometric entity as well as a reference value. The application adds all entities in the model for the given type that are larger than the reference value to the current selection. The units are based on the active unit system . **Note:** These options are also available from the **Select By** > **Size** menu on the Graphics Toolbar (p. 97).
Invert	Selects all entities (face, edge, etc.) that are **not** currently selected. The option only selects entities of the same type. For example, if you have a face selected and select Invert, the application selects all the faces on your model *except* the face that you had selected.
Common Edges	Selects common edges of selected faces.
Cylindrical Faces	Selects all faces on the model that are cylindrical (they do not need to be full cylinders).
Shared Topology	Displays a drop-down menu of options, including, **All Edges** and **All Faces**. These options select any edge or face on the interior of a multi-body part.
Same Material	Selects all bodies with the same Material Assignment as the currently selected body.
Grow Element	Selects all elements adjacent to your current element selection. This option effectively grows the element selection by one layer of elements.
Set Tolerances	
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Description
	Opens a dialog box that enables you to specify a search tolerance for your geometric entity selections. The dialog fields include **Zero Tolerance** and **Relative Tolerance**. **Note:** Tolerance settings are only applicable when using the **Select All Entities With Same Size** option or a **Location** option (see above).  By default, the **Zero Tolerance** property is set to **`1.e-08`** and the Relative Tolerance value is **`0.001`**. Relative tolerance is a multiplying factor applied to comparisons. For example, if you want a tolerance of 1%, enter **`.01`** in the **Relative Tolerance** field. Tolerance values are dimensionless. All comparisons are done in the CAD unit system. Review the Adjusting Tolerance Settings for Named Selections by Worksheet Criteria (p. 1061) topic in the *Specifying Named Selections using Worksheet Criteria* section for additional information.

Convert To

The **Covert To** group enables you to change (convert) your currently selected geometric entity or mesh item to a different geometric entity or mesh item.



This group includes the following options:

Option	Description
Shared	Selects only geometric entities that are shared by all currently selected entities.
Bodies	Selects all bodies associated with your current selection of either faces, edges, vertices, elements, or nodes. The selection mode automatically changes to Body selection.
Faces	Selects all Faces associated with your current selection of either bodies, edges, vertices, elements, or nodes. For example, if your selection is a body or bodies, all faces on that body will be selected. The selection mode automatically changes to Face selection.
Edges	Selects all Edges associated with your current selection of bodies, faces, vertices, elements, or nodes. For example, if vertices are selected, any edges associated with the vertices will be selected. The selection mode automatically changes to Edge selection.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

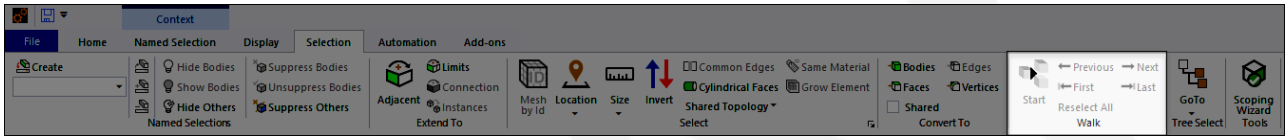
Option	Description
Vertices	Selects all Vertices associated with your current selection of either bodies, faces, edges, elements, or nodes. The selection mode automatically changes to Vertex selection.

Note:

These options, except for the **Shared** option, are also available from the **Convert** menu on the Graphics Toolbar (p. 97).

Walk

The **Walk** group enables you to highlight and zoom in on entities of your model. Once you select more than one geometric or mesh entity (using Graphics Toolbar (p. 97) options) from the **Geometry** window and select the **Start** option, the application automatically highlights and zooms in on each entity in turn as you use the navigation options. The feature supports all geometric and mesh (mesh generation required) selections, including Body, Face, Edge, Vertex, Node, Element Face, and Element.



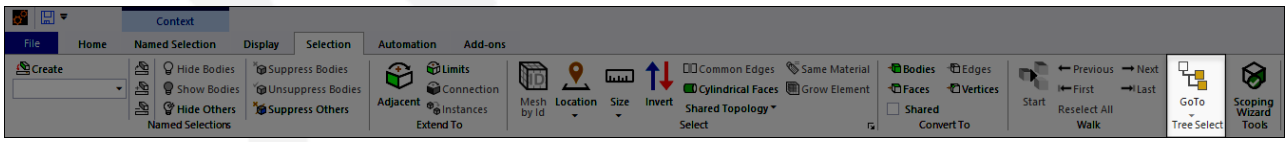
Once you have made selections and selected the **Start** option, the application caches each selected entity into memory. You then use the navigation options (**Previous**/**Next**/**First**/**Last**) to step through your selections. The cached selections are maintained until you make new selections and click the **Start** option.

Tip:

When the **Geometry** window has focus, the **Select All** (or **[Ctrl]**+**[A]**) context (right-click) menu option can be useful when using this feature.

Tree Select

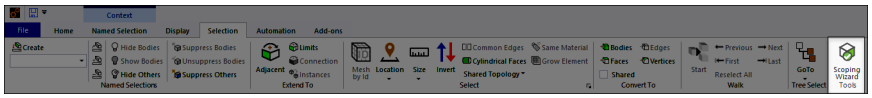
This group provides a drop-down menu of **Go To** options. These options correlate model selections to tree objects. Selecting an option highlights a tree object. See the Correlating Tree Outline Objects with Model Characteristics (p. 110) section for more information. The **Go To** options are also available from the context (right-click) menu of the **Geometry** (p. 129) window.



Tools

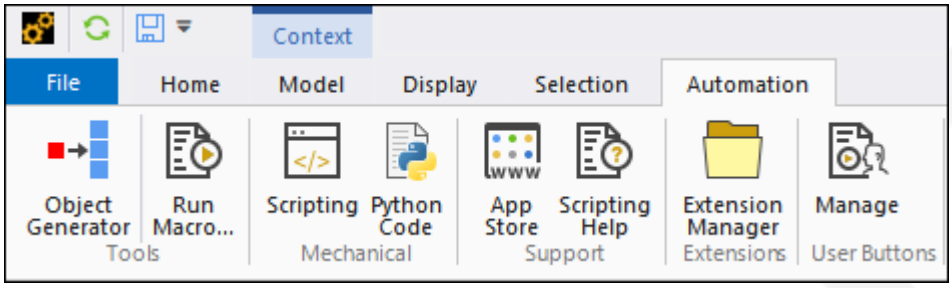
The **Tools** group contains the **Scoping Wizard** option. This option displays the **Scoping Wizard** (p. 147) pane. This feature enables you to reidentify an object's scoping lost because of a geometry update. Once identified, you can use the options of the feature to reestablish the original scoping.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



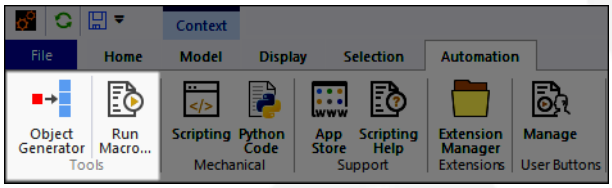
Automation Tab

The **Automation** tab provides productivity and customization features.



Tools

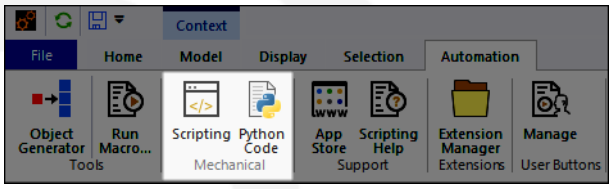
The **Tools** group contains the **Object Generator** (p. 2343) option as well as the **Run Macro** option that open a dialog box to locate a desired script file. Macros can be written in the Python (.py) programming language. For additional information, refer to the Scripting in Mechanical Quick Start Guide.



Mechanical

The **Mechanical** group includes the following options:

- **Scripting**: Launch the **Mechanical Scripting** pane.
- **Python Code**: Insert a Python Code object into the Outline.



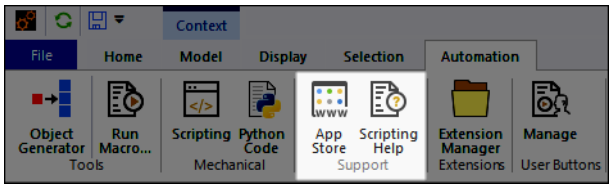
Support

The **Support** group includes the following options:

- **App Store**: Open the Ansys Application Store website.
- **Scripting Help**: Open the Scripting Introduction Help page.

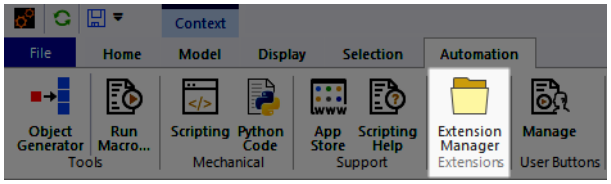
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



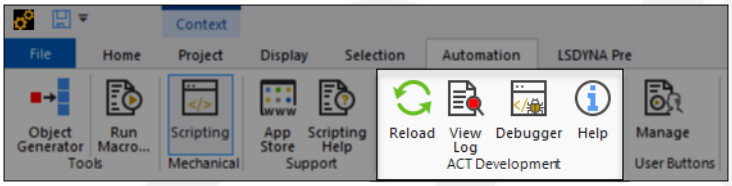
Extension Manager

When you open Mechanical independently (p. 323), the **Automation** tab contains an **Extension Manager** option. Use this feature to load/unload ACT extensions just as you would from the Manage Extensions in Workbench.



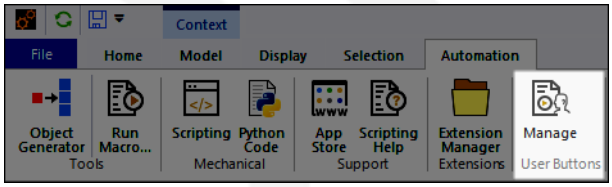
ACT Development

The **ACT Development** group displays when you have activated the debug mode. From Workbench, active **Debug Mode** using the options **Tools** > **Options** > **Extensions**. When you launch Mechanical independently, activate debug mode by selecting the **Extension Manager** option. This opens the Extension **Manager** pane. From this pane, select the gear icon and then select the **Debug Mode** checkbox.



User Buttons

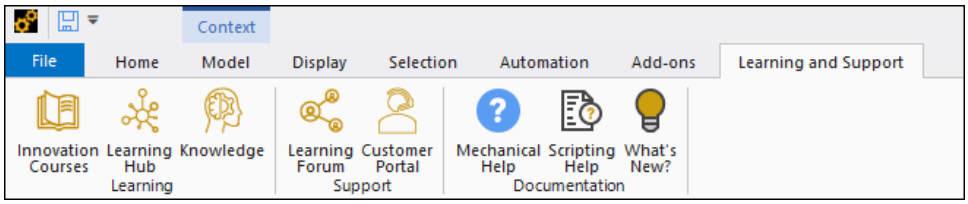
The **User Buttons** group enables you to create, edit, and manage custom options. Custom options are added to this group when created. See the Creating User Defined Buttons (p. 154) section for more information.



Learning and Support Tab

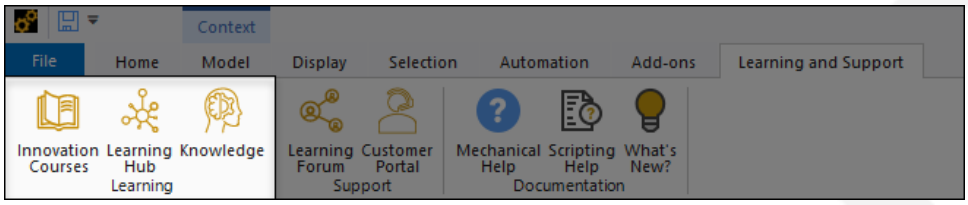
The **Learning and Support** tab contains links to various learning and support resources for Mechanical.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Learning

The **Learning** group provides access to learning resources.

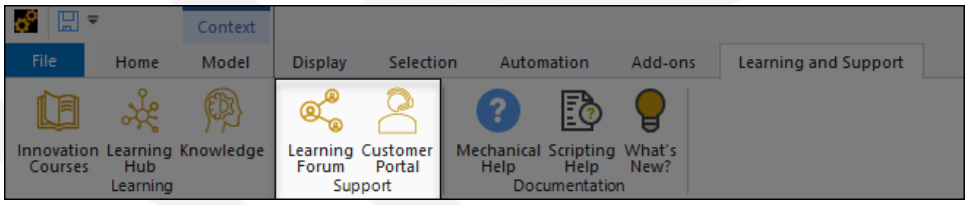


Options for this group include:

- **Innovation Courses**: This option links to free structural engineering courses in Ansys Innovation Space. These self-paced courses include videos, handouts, and quizzes to help reinforce physics and engineering fundamentals.
- **Learning Hub**: This option links to subscription-based virtual courses in Ansys Learning Hub. Within the hub, you can attend live or self-paced classes with dedicated learning rooms for discussions and continuous learning support from Ansys experts.
- **Knowledge**: This option links to free general learning materials for structural engineering in Ansys Innovation Space. The materials include expert-curated FAQs and short video tutorials to help answer simulation-related questions.

Support

The **Support** group provides access to support options.



Options for this group include:

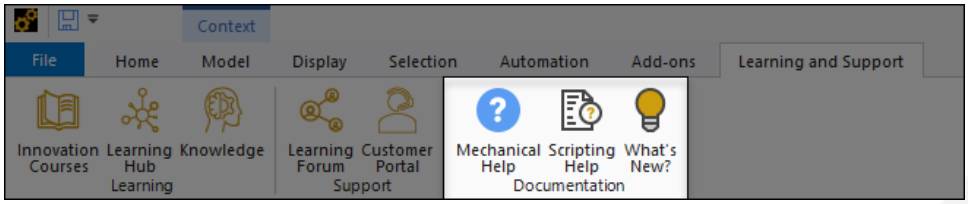
- **Learning Forum**: This option links to a public user forum for mechanical engineering discussions in Ansys Innovation Space. You can find answers to your questions and learn from the global Ansys user community.
- **Customer Portal**: This option links to a private support portal for commercial customers. You can receive technical support from Ansys during business hours. You can also log support requests, download product software, and manage licensing and subscriptions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Documentation

The **Documentation** group provides access to our product documentation for Mechanical.

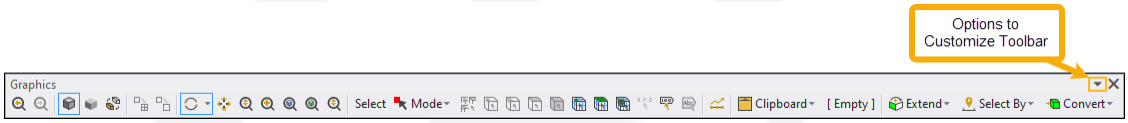


Options for this group include:

- **Mechanical Help**: This option links to the *Mechanical User's Guide (p. 1)* with detailed information about Mechanical's features.
- **Scripting Help**: This option links to the *Scripting in Mechanical Guide*. The guide provides an introduction to writing scripts that automate your routine tasks and information on using the ACT API to access and manipulate objects in the Mechanical tree.
- **What's New?**: This option provides information about the new Mechanical features at the current release.

Graphics Toolbar

The **Graphics** toolbar sets the selection/manipulation mode for the cursor in the **Geometry** window. The toolbar also provides commands for modifying a selection or for modifying the viewpoint. You can turn this toolbar on and off using the **Graphics Toolbar** option in the **Manage** option's drop-down menu located in the **Layout** (p. 47) group on the **Home** tab.



You can add or remove options from this toolbar using the Customization Menu shown below. You access this menu using the down-arrow drop-down menu at the far end of the toolbar.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Customization Menu	Option	Description
	Previous/Next	To return to the last view displayed in the Geometry window, click the Previous View button on the toolbar. By continuously clicking you can see the previous views in consecutive order. After displaying previous views in the Geometry window, click the Next View button on the toolbar to scroll forward to the original view.
	Shaded Exteriors and Edges	Displays the model in the Geometry window with shaded exteriors and distinct edges. This option cannot be used in combination with either the Shaded Exterior or Wireframe views.
	Shaded Exteriors	Displays the model in the Geometry window with shaded exteriors only. This option cannot be used in combination with either the Shaded Exterior and Edges or Wireframe views.
	Wireframe	Enable the **Wireframe** display mode. The model displays in the Geometry window with a wireframe display rather than a shaded (recommended for seeing gaps in surface bodies) display. The Wireframe option not only applies to geometry, mesh, or named selections displayed as a mesh, but extends to probes, results, and variable loads to enable a better understanding of regions of interest. When set, just the exterior faces of the meshed models are shown, not the interior elements. Selecting any of the edges options (p. 68) on contour results automatically closes Wireframe mode. **Note:** When active, green scoping is not drawn on probes. Also, elements are shown on probes and results, whereas the outline of the mesh is shown on isoline contour results.
	Show Mesh	Display the model's mesh. Enabling this option displays the model's mesh regardless of the selected tree object. When enabled, to make sure that Annotations display properly, also turn on Wireframe mode. See Note below.
	Rotate	Activates the model Rotate feature. Free

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Customization Menu	Option	Description
		rotation is the default behavior. See the rotation topic in the Manipulating the Model in the Geometry Window section for additional options associated with this selection.
	Pan	Reposition your model laterally in the Geometry window.
	Zoom	Displays a closer view of the body by dragging the mouse cursor vertically toward the top of the Geometry window, or displays a more distant view of the body by dragging the mouse cursor vertically toward the bottom of the Geometry window. **Note:** If you zoom in on a model at an extreme factor (over 10^5), you may see the graphical display of geometry edges or mesh element edges appear distorted. These display distortions are due to the limitations of the computer's architecture (precision of storing data) and the display screen resolution.
	Zoom To Fit	Fit the entire model in the Geometry window.
	Zoom To Selection	Zoom in on the currently selected item in the Geometry window.
	Toggle Magnifier Window On/Off	Displays a Magnifier Window, which is a shaded box that functions as a magnifying glass, enabling you to zoom in on portions of the model. When you toggle the Magnifier Window on, you can: • *Pan* the Magnifier Window across the model by holding down the *left* mouse button and dragging the mouse. • *Increase the zoom* of the Magnifier Window by adjusting the *mouse wheel*, or by holding down the *middle* mouse button and dragging the mouse upward. • *Recenter* or *resize* the Magnifier Window using a *right* mouse button click and choosing an option from the context

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Customization Menu	Option	Description
		menu. Recenter the window by choosing **Reset Magnifier**. Resizing options include **Small Magnifier**, **Medium Magnifier**, and **Large Magnifier** for preset sizes, and **Dynamic Magnifier Size On/Off** for gradual size control accomplished by adjusting the *mouse wheel*. Standard model zooming, rotating, and picking are disabled when you use the Magnifier Window.
	Select	Label only.
	Mode	Display a drop-down menu of options that define how geometry, node, or element selections are made: • **Single Select** • **Box Select** • **Box Volume Select** • **Lasso Select** • **Lasso Volume Select** These options are used in conjunction with the selection filters (p. 261) (**Vertex**, **Edge**, **Face**, **Body**, **Node**, **Element**) **Note:** Selection shortcuts: • When you place your cursor within the **Geometry** window, you can change your selection mode from **Single Select** to **Box Select** by holding the right mouse button and then clicking the left mouse button. • When you place your cursor within the **Geometry** window, and given a generated mesh, and the **Node** or **Element** selection

Published: 2023-10-23

Customization Menu	Option	Description
		option is active, holding the right mouse button and then clicking the left mouse button scrolls through the available selection options (single section, box selection, box volume, lasso, lasso volume).
	Smart Select	For **Single Select** mode, use this option to select or highlight vertices, edges, and faces on the model without needing to specify a selection filter (Vertex, Edge, or Face). Use the **[Ctrl]** key or hold down the left-mouse button to select multiple entities. When you make a selection, an icon displays that enables you to select the parent body for the current selection(s). This option supports the **Select All**, **Zoom To Selection**, and Mini Selection Toolbar (p. 264) features. This option does not currently support depth picking (p. 261).
	Vertex	Activate Vertex geometry selection option.
	Edge	Activate Edge geometry selection option.
	Face	Activate Face geometry selection option.
	Body	Activate Body geometry selection option.
	Node	Activate Node mesh selection option.
	Element Face	Activate Element Face mesh selection option.
	Element	Activate Element mesh selection option.
	Hit Point Coordinate	Available only if you are setting a location, for example, a local coordinate system. This option enables the exterior coordinates of the model to display adjacent to the cursor and updates the coordinate display as the cursor is moved across the model. If you click with the cursor on the model, a label displays the coordinates of that location. This feature is functional on faces only. It is not functional on edges or line bodies. **Note:** You can change the default display settings for the font (size, style, color) used with this

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Customization Menu	Option	Description
		feature by changing the settings of the **Probe Tool and Hit Point Coordinate (Windows Only)** preference in the Graphics (p. 228) category of the **Options** dialog.
	Label	Select and drag and drop an annotation label anywhere on the corresponding scoping. Not all objects support this option.
	Highlight Imported Data	For certain data imported through the External Model system, this option enables you to highlight the graphical representation of the data in the **Geometry** window. This option behaves just like you were selecting a row in the Worksheet for the imported data. See the User Interface Options (p. 910) topic in the *Importing Mesh-Based Databases* section for more information.
	Direction	Chooses a direction by selecting a single face, two vertices, or a single edge (enabled only when Direction field in the Details view has focus). See Pointer Modes (p. 258).
	All	Select all geometric entities of your model based on the current selection filter type (vertex, edge, face, or body). **Ctrl**+**A** also performs this action.
	Invert	Automatically select entities of the same type (face, edge, etc.) that are not currently selected. Any selection made before selecting this option is removed.
	Display Graph (p. 197)	Display the content of the **Graph** window in the **Geometry** window.
	Clipboard Information	To help you keep track of what is contained in the Clipboard, once you make selections (or add or change) the Clipboard menu displays the current number of entities contained in the Clipboard, such as 1 Body, as illustrated above. When no selections are contained in the Clipboard, this field contains the text string "Empty." Also note that the status bar displays active Geometry window selections.
	Extend	Adds adjacent faces (or edges) within angle tolerance, to the currently selected face (or edge) set, or adds tangent faces (or edges)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

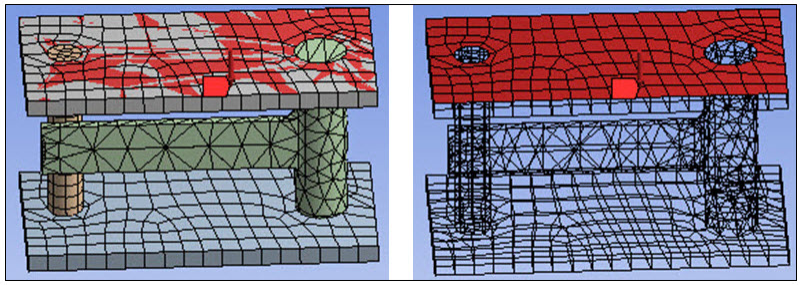
Customization Menu	Option	Description
		within angle tolerance, to the currently selected face (or edge) set. See the Extend Selection Menu (p. 264) topic for additional information about these options.
	Select By	Display a drop-down menu of selection options. See the **Select** group topic (p. 89) in the Selection Tab (p. 88) section for more information.
	Convert	Display a drop-down menu of options to change your currently selected geometric entity or mesh item to a different geometric entity or mesh item. See the **Convert To** group topic (p. 92) in the Selection Tab (p. 88) section for more information.
	Viewports	Split the Geometry window into multiple windows (p. 284).
	Sync Viewports	Synchronize the Viewports display in each window to reorient/move (pan, zoom, rotate) your model in each window simultaneously.
	Front/Back/Right/Left/Top/Bottom	These options reorient the display of your model.
	Look At	
	Accelerated Display (p. 289)	Improve the display time for mesh and result objects.
	Reset Toolbar	Reset the Graphics Toolbar to the default display configuration.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Customization Menu	Option	Description

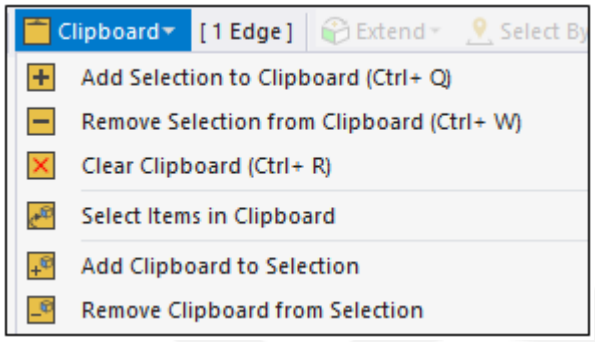
Note:

As illustrated below, annotations may not always display properly when the **Show Mesh** option is activated. Turning on Wireframe mode accurately displays Annotations when **Show Mesh** is selected.



Clipboard Menu

The **Clipboard** menu is a selection feature that enables you to make geometry and mesh selections in the **Geometry** window.



Using the options of this menu, you can create, change, add to, and overwrite the selections of the **Clipboard**. This feature enables you to select only one type of geometric (face/edge/body/vertex) or mesh (node/element) entity at a time. Once you have made your desired selections and included them in the **Clipboard**, these selections are available for use during your analysis. When desired, use the menu option **Select Items in Clipboard** in order to activate your clipboard selections. You can also change active selections using the menu options **Add Clipboard to Selection** or **Remove Clipboard from Selection**.

To help you keep track of what is contained in the **Clipboard**, once you make selections (or add or change) the **Clipboard** menu displays the current number of entities contained in the **Clipboard**, such as [1 Edge], as illustrated above. When no selections are contained in the **Clipboard**, this field

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

contains the text string "Empty." Also note that the status bar (p. 135) displays active **Geometry** window selections.

Note:

This feature does not currently support **Element Face** selection.

The **Clipboard** menu contains the following options:

- **Add Selection to Clipboard**: This option adds your current selection to the existing selection(s) contained in the clipboard. Default hotkey: **Ctrl**+**Q**.
- **Remove Selection from Clipboard**: This option removes your current selection from the existing selection(s) contained in the clipboard. Default hotkey: **Ctrl**+**W**.
- **Clear Clipboard**: This option clears clipboard selections. Default hotkey: **Ctrl**+**R**
- **Select Items in Clipboard**: This option replaces your current selection with the selection contained in the clipboard.
- **Add Clipboard to Selection**: This option adds the selection contained in the clipboard to your currently selected geometry or mesh.
- **Remove Clipboard from Selection**: This option removes the selection contained in the clipboard from your currently selected geometry or mesh.

Outline

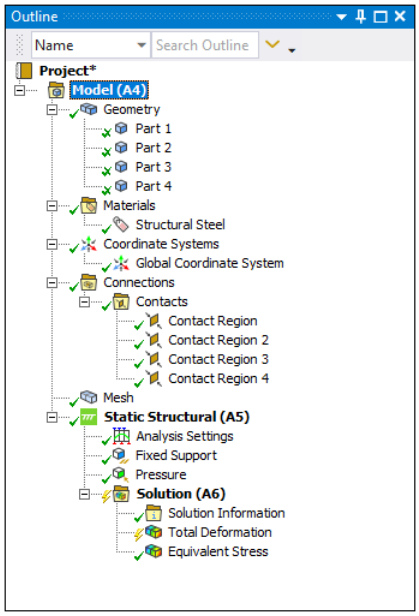
Go to a section topic:

- Outline Pane Overview (p. 105)
- Context Menu Options (p. 106)
- Object Details (p. 108)
- Additional Capabilities (p. 108)

Overview

You use the **Outline** pane, as illustrated below, to set up your model using the "objects" arranged in the tree structure. These objects guide you through the different steps (p. 323) of a simulation. By expanding the objects, you expose the details associated with the object, and you can use the corresponding tools and specification tables to further define your simulation. Refer to the Objects Reference section for a listing and description of all of the objects available in the application.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Important:

If your analysis includes an exceptionally large number of objects, the **Outline** content may appear incomplete. The application has a display limitation of 65,536 objects. If the number of objects exceeds this threshold, any additional objects are not displayed.

Note:

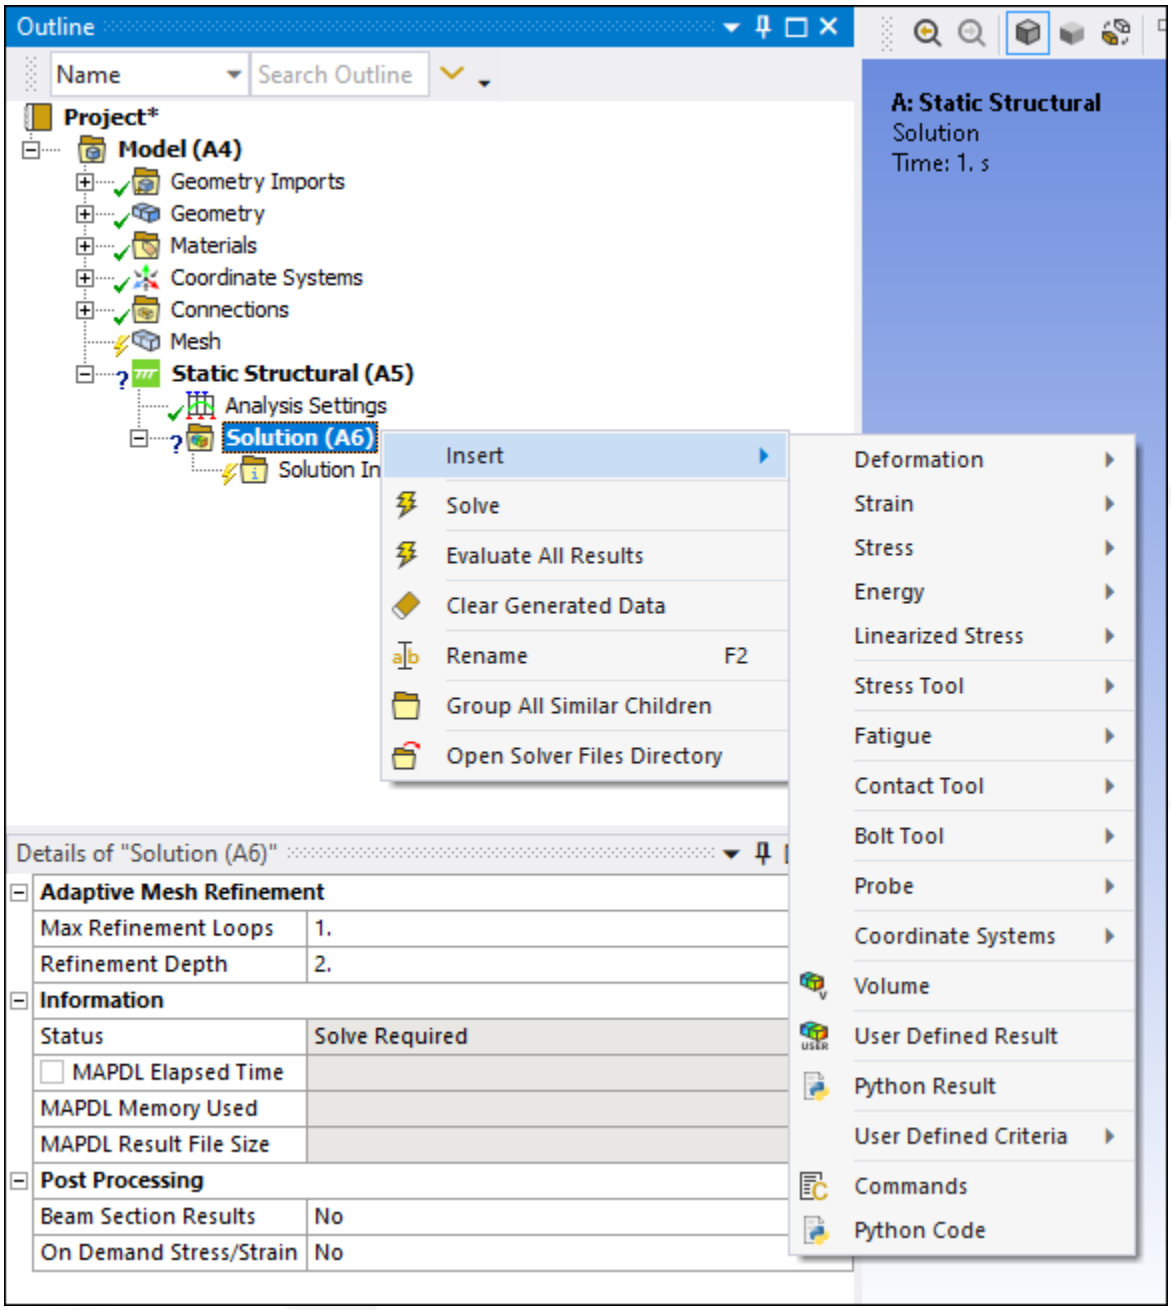
Numbers preceded by a space at the end of an object's name are ignored. This is especially critical when you copy objects or duplicate object branches. For example, if you name two force loads as **Force 1** and **Force 2**, then copy the loads to another analysis environment, the copied loads are automatically renamed **Force** and **Force 2**. However, if you rename the loads as **Force_1** and **Force_2**, the copied loads retain the same names as the two original loads.

Contextual Options

Each **Outline** object provides contextual (right-click) menus, as illustrated below. These menu options are generally based on the selected object. For example, if you select the **Solution** object, most of the menu options are specific to obtaining solution data or further defining the results of the simulation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Common Context Menu Options

Most of the context menus also provide a variety of common options, including:

- **Insert**: The **Insert** menu is specific to the object. You use the insert menu to add contacts, loads, results, etc.
- **Duplicate**: Duplicate the selected object, including scoping and Details definition.
- **Copy**/**Cut**: Copy or Cut the selected object.
- **Paste**: Paste supported objects (that you copied) within the active Mechanical session.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Copy To Clipboard**/**Paste From Clipboard**: Any object that is scoped to a geometric entity (mesh-based scoping is not supported), and that supports Copy/Cut, also supports copying and pasting to and from the clipboard. These options enable you to paste objects copied to the clipboard from one Mechanical session to another. These clipboard actions can only be performed once. The clipboard is cleared once pasted.
- **Delete**: Delete the selected object.
- **Rename**: Rename the selected object.
- Group (p. 208)/**Ungroup**: Group objects in the Outline as desired.
- Rename Based on Definition (p. 2283): The application automatically renames the object based on its type and scoping.

Tip:

The sections of the Objects Reference provide more information about the context menu options specific to the various objects.

Object Details

Selecting an object in the **Outline** displays attributes and controls for the selected object in the **Details** (p. 119) pane. The **Geometry** window displays your CAD model and, based on the object selected, displays pertinent information about object specifications and how they relate to the displayed geometry.

Additional Capabilities

The following topics present further details related to the **Outline** features.

Understanding the Tree Outline

Correlating Tree Outline Objects with Model Characteristics

Suppressing Objects

Filtering the Tree

Searching the Tree

Understanding the Tree Outline

The tree Outline uses the following conventions:

- Icons appear to the left of objects in the tree. Their intent is to provide a quick visual reference to the identity of the object. For example, icons for part and body objects (within the **Geometry** object folder) can help distinguish solid, surface and line bodies.
- A ⊞ symbol to the left of an item's icon indicates that it contains associated subitems. Click to expand the item and display its contents.
- To collapse all expanded items at once, double-click the Project name at the top of the tree.
- Drag-and-drop function to move and copy objects.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- To delete a tree object from the Outline (p. 105), right-click the object and select **Delete**. A confirmation dialog asks if you want to delete the object.
- Filter tree contents and expand the tree by setting a filter (p. 114) and then clicking the **Expand on Refresh** button.

Status Symbols

As described below, a small status icon displays to the left of the object icon in the Outline (p. 105).

Status Symbol Name	Symbol	Example
Underdefined		A load requires a nonzero magnitude.
Error		bad attachments may break during an Update.
Mapped Face or Match Control Failure		Face could not be mapped meshed, or mesh of face pair could be matched.
Ok		The object is defined properly and/or any specific action on the object is successful.
Needs to be Updated		Equivalent to "Ready to Answer!"
Hidden		A body or part is hidden.
Meshed		The symbol appears for a meshed body within the **Geometry** folder, or for a multibody part whose child bodies are all meshed.
Suppress		An object is suppressed.
Solve	  	*Yellow lightning bolt*: Item has not yet been solved. *Green lightning bolt*: Solve in progress. *Green check mark*: Successful solution. *Red lightning bolt*: Failed solution. An overlaid pause icon indicates the solution could resume with the use of restart points. *Green down arrow*: Successful background solution (p. 1803) ready for download. *Red down arrow*: Failed background solution (p. 1803) ready for download.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

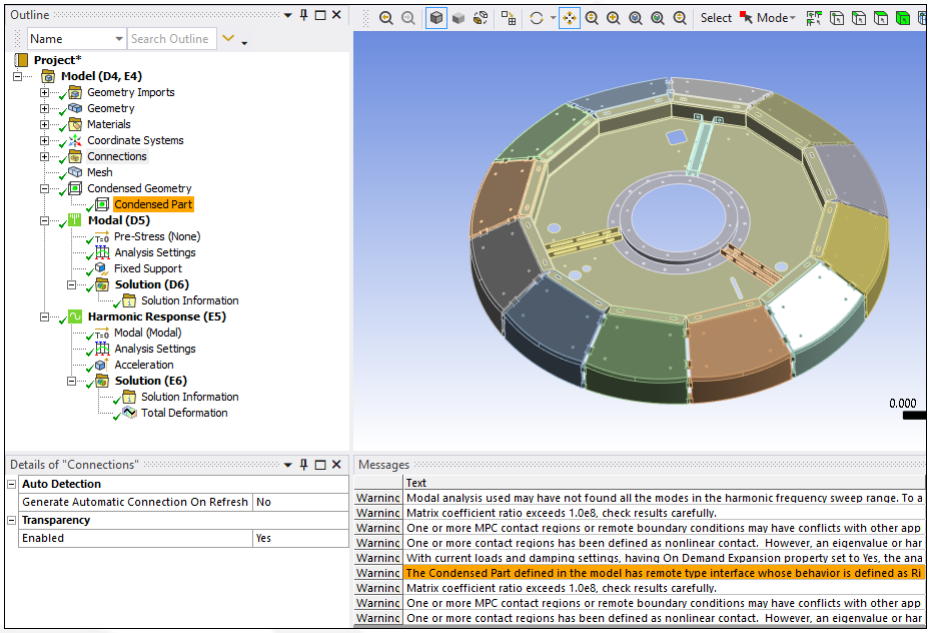
Status Symbol Name	Symbol	Example
		Yellow down arrow: You can download obsolete results from a background solution.

Note:

The state of an environment folder can be similar to the state of a **Solution** folder. The solution state can indicate either solved (check mark) or not solved (lightning bolt) depending on whether or not an input file has been generated.

Status Coloring

In addition to the status icons, you may see objects highlighted in orange to indicate that there is a potential problem related to the object or to a child-object. Objects highlighted in orange have a corresponding message in the Messages (p. 200) window. You can turn this feature off using the **Options** (p. 217) dialog box (see the Messages (p. 236) category).



Also see the Outline (p. 105) section.

Correlating Tree Outline Objects with Model Characteristics

The **Go To** feature provides you with instant visual correlation of objects in the tree as they relate to various characteristics of the model displayed in the **Geometry** window.

To activate this feature, right-click anywhere in the **Geometry** window, choose **Go To**, then choose an option in the context menu. In some cases (see table below), you must select geometry prior to choosing the **Go To** feature. The resulting objects that match the correlation are highlighted in the tree and the corresponding geometry is highlighted on the model. **Go To** options are also available from the Selection (p. 88) tab. For example, you can identify contact regions in the tree that are associated with a particular body by selecting the geometry of interest and choosing the **Contacts for**

Published: 2023-10-23

Selected Bodies option. The contact region objects associated with the body of the selected items will be highlighted in the tree and the contact region geometry will be displayed on the model.

Several options are filtered and display only if specific conditions exist within your analysis. The **Go To** options are presented in the following table along with their description and the conditions under which they appear in the context menu.

Go To Option	Description / Application	Required Conditions for Option to Appear
Corresponding Bodies in Tree	Identifies body objects in the tree that correspond to selections in the **Geometry** window.	At least one vertex, edge, face, or body is selected.
Hidden Bodies in Tree	Identifies body objects in the tree that correspond to hidden bodies in the **Geometry** window.	At least one body is hidden.
Suppressed Bodies in Tree	Identifies body objects in the tree that correspond to suppressed bodies in the **Geometry** window.	At least one body is suppressed.
Bodies Without Contacts in Tree	Identifies bodies that are not in contact with any other bodies. When you are working with complex assemblies of more than one body, it is helpful to find bodies that are not designated to be in contact with any other bodies, as they generally cause problems for a solution because they are prone to rigid body movements.	More than one body in an assembly.
Parts Without Contacts in Tree	Identifies parts that are not in contact with any other parts. When you are working with complex assemblies of more than one multibody part, it is helpful to find parts that are not designated to be in contact with any other parts. For example, this is useful when dealing with shell models which can have parts that include many bodies each. Using this feature is preferred over using the **Bodies Without Contact in Tree** option when working	More than one part in an assembly.

Published: 2023-10-23

Go To Option	Description / Application	Required Conditions for Option to Appear
	with multibody parts mainly because contact is not a typical requirement for bodies within a part. Such bodies are usually connected by shared nodes at the time of meshing.	
Contact Sizing Common to Selected Bodies	Identifies Contact Sizing controls that exist between the selected bodies. This option may be useful when you want to delete common contact sizing controls.	Two bodies are selected.
Contacts for Selected Bodies	Identifies contact region objects in the tree that are associated with selected bodies.	At least one vertex, edge, face, or body is selected.
Contacts Common to Selected Bodies	Identifies contact region objects in the tree that are shared among selected bodies.	
Joints for Selected Bodies	Identifies joint objects in the tree that are associated with selected bodies.	
Joints Common to Selected Bodies	Identifies joint objects in the tree that are shared among selected bodies.	
Springs for Selected Bodies	Identifies spring objects in the tree that are associated with selected bodies.	
Mesh Controls for Selected Bodies	Identifies mesh control objects in the tree that are associated with selected bodies.	
Mesh Connections for Selected Bodies	Highlights **Mesh Connection** objects in the tree that are associated with the selection.	At least one vertex, edge, face, or body is selected and at least one mesh connection exists.
Mesh Connections Common to Selected Bodies	Highlights **Mesh Connection** objects in the tree that are shared among selected bodies.	At least one vertex, edge, face, or body is selected.
Field Bodies in Tree	Identifies enclosure objects in the tree that are associated with selected bodies.	At least one body is an enclosure.

Published: 2023-10-23

Go To Option	Description / Application	Required Conditions for Option to Appear
Bodies With One Element Through the Thickness	Identifies bodies in the tree with one element in at least two directions (through the thickness). This situation can produce invalid results when used with reduced integration. See At Least One Body Has Been Found to Have Only 1 Element (p. 2364) in the troubleshooting section for details.	At least one body with one element in at least two directions (through the thickness).
Thicknesses for Selected Faces	Identifies objects with defined thicknesses in the tree that are associated with selected faces.	At least one face with defined thickness is selected.
Body Interactions for Selected Bodies	Identifies body interaction objects in the tree that are associated with selected bodies.	At least one body interaction is defined and at least on body is selected.
Body Interactions Common to Selected Bodies	Identifies body interaction objects in the tree that are shared with selected bodies.	At least one body interaction is defined and at least on body is selected.
Named Selections Containing to Selection	Highlight all Named Selection objects in the Outline that contain any of the currently selected geometric or mesh entities.	The selection filter (face, edge, element, etc.) must match the definition of the Named Selection. That is, Face selections are only applicable to face-based Named Selections and so on.
Named Selections Common to Selection	Highlight all Named Selection objects in the Outline that include all of the currently selected geometric or mesh entities.	The selection filter (face, edge, element, etc.) must match the definition of the Named Selection. That is, Face selections are only applicable to face-based Named Selections and so on.

Suppressing Objects

Suppression Behaviors

Mechanical provides an option to suppress tree Outline (p. 105) objects. This feature enables you to remove an individual object or multiple objects from the analysis. Any corresponding (scoped) objects are also affected. For example, when you suppress a part, the application automatically removes the part from the display, under-defines any object that is scoped to the part, and clears data from all solution objects.

This can be useful when you are applying different types of loading conditions. You can quickly include and/or remove conditions through suppression. Not all tree objects provide the suppression capability.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

For child objects of the **Geometry** and the **Environment** objects: the application removes suppressed objects from the solution process. You can also use the Grouping feature (p. 208) on the **Geometry** object to select and suppress (and unsuppress) one or more objects.

For the **Solution** object: the application clears result data for suppressed objects and the object is not included during any subsequent solution processing. You can use this feature to remove under-defined result objects and/or perform comparisons for different result types.

How to Suppress or Unsuppress Objects

If available, set the **Suppressed** option in the Details view (p. 119) to **Yes**. Conversely, you can unsuppress items by setting the **Suppressed** option to **No**.

You can also suppress/unsuppress these items through context menu options available via a right mouse button click. Included is the context menu option **Invert Suppressed Body Set**, which enables you to reverse the suppression state of all bodies (unsuppressed bodies become suppressed and suppressed bodies become unsuppressed). You can suppress the bodies in a named selection using either the context menu options mentioned above, or through the Named Selection (p. 89) group.

Another way to suppress a body is by selecting it in the Geometry window, then using a right mouse button click in the Geometry window and choosing **Suppress Body** in the context menu. Conversely, the **Unsuppress All Bodies** option is available for unsuppressing bodies. Options are also available in this menu for hiding or showing bodies. Hiding a body only removes the body from the display. A hidden body is still active in the analysis.

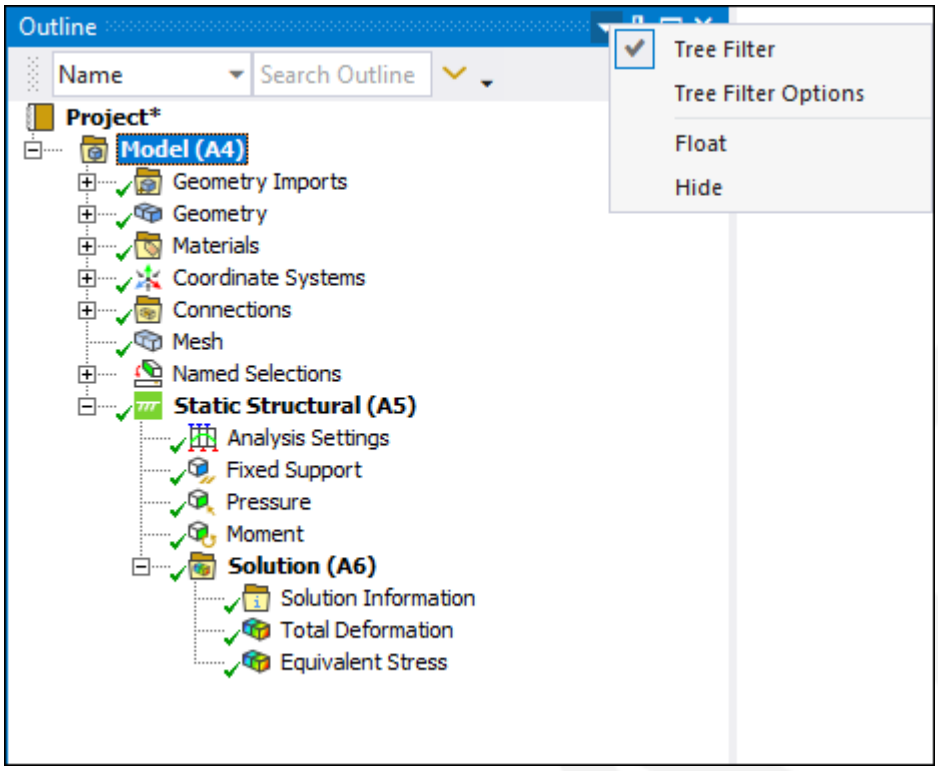
Filtering the Tree

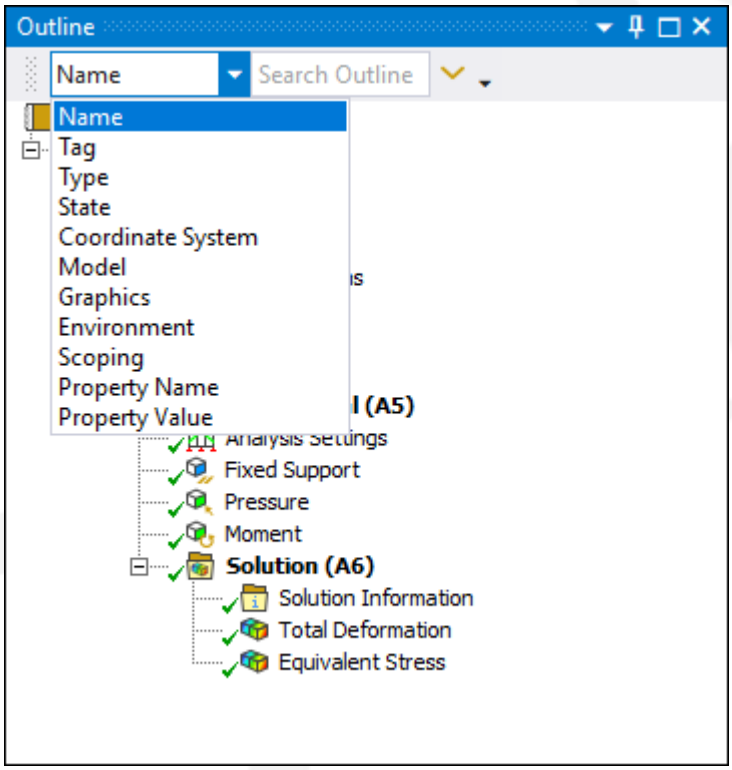
At the top of the **Outline** pane is the Tree Filter option. As illustrated below, this option has a search feature as well as associated filter options. The search feature filters objects based on criteria. The filter options can be hidden by right-clicking on a non-interactive region of the **Outline** pane, on the pane's title bar, or using the drop-down (arrow) menu on the pane's title bar.

DRAFT

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23





Filtering options include the following:

Filter Type	Description
Name	Filters the Outline for one or more specified search terms.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Filter Type	Description
Tag	Filters for Outline objects marked with one or more specified tag names. See the Tagging Objects (p. 2349) section.
Type	Provides a drop-down list of objects for which you can filter. The options include: • **All**: This default option displays all Outline objects and requires you to make a selection to initiate the filter process. • **Boundary Conditions** • **Commands** • **Comments** • **Connections** • **Figures** • **Images** • **Results**
State	Provides a drop-down list of filters for a selected state. State options include: • **All** • **Suppressed** • **Not Licensed** • **Underdefined** • **Ignored**
Coordinate System	Provides a drop-down list of all coordinate systems in the Outline. You can choose to filter **All** coordinate system objects or you can select an individual coordinate system object. The filter displays all objects within the Outline that employ the individually selected coordinate system. **Note:** *All* coordinate systems display in the filter. There are cases where an object does not have a coordinate system property in its Details view, but it does have an associated coordinate system as a requirement. As a result, it may appear as though an unaccounted for coordinate system is present. This is especially true for the Global Coordinate System.
Model	Provides a drop-down list of all source models (External Model, Mechanical Model, etc., including the source model's cell ID) that create an assembly. You can choose to filter **All** source models or you can select a specific model. The current system is

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Filter Type	Description
	the first item. This feature is only supported for models assembled in Ansys Mechanical 2024 R1 or greater.
Graphics	The default option, **All**, displays all Outline objects. The **Visible Bodies** option filters the Outline so that only visible bodies and objects *associated* with any visible body display. Objects independent of geometry, that is, those that do not require scoping, are always shown, such as Analysis Settings. The default setting for this selection can be modified using the **Options** dialog box. See the Specifying Options (p. 217) section of the Help under **Visibility** (p. 243).
Environment	For an analysis with multiple environments, this selection provides a drop-down list of all of the system's environments. You can choose to filter **All** (default) environments or you can select a specific environment. Once selected, all objects specific to the environment are displayed in the tree.
Scoping	The default option, **All**, displays all Outline objects. The **Partial** option filters the tree to only show objects that have partial scoping. These objects require your attention because scoping was lost due to upstream geometry updates.
Property Name	Filters Outline objects based on the name of a property, such as Magnitude, and displays objects containing the property name.
Property Value	Filters Outline objects based on the specified property value searched and displays objects containing the property value. You can also perform special query such as, "Property Name = Property Value." For example: "Formulation = MPC," or "Pinball Radius = 2," or "Solver Type = Direct."

Note:

Performing a search for an object that does not exist in the tree results in all objects being displayed.

Tree Filter Options

The filter options perform the following actions.

Refresh Search

Refreshes the search criteria that you have specified following changes to the environment.

Clear Search

Clear the filter and returns the tree to the full view.

Remove

Turned off by default. Depressing this button turns the feature on and off. When active, it removes the objects in question from the tree display.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Expand on Refresh

Selecting this option enables filtering updates to automatically display. The default setting is off. Select the button to turn the feature on and off. This option can be configured so that the filter will be automatically applied when bodies are hidden or shown. See the Specifying Options (p. 217) section of the Help under **Visibility** (p. 243).

Hide Folders

Selecting this option hides all grouping objects present in the tree. The default setting is off. Select the button to turn the feature on and off. If active, the grouping feature (p. 208) is unavailable and the tree displays in the default view, that is, no grouping.

Sort Ascending

Selecting this option sorts tree objects in alphanumeric order. This excludes most parent objects such as **Geometry**, **Coordinate Systems**, **Connections**, and **Named Selections** objects, however, child objects are sorted. For example, selecting this option would sort all contact regions, user- or system defined named selections, loading conditions, results, etc., in alphanumeric precedence.

Using the Filter Feature

To filter the Outline:

1. Select a filter type:
   - **Name**
   - **Tag**
   - **Type**
   - **State**
   - **Coordinate System**
   - **Model**
   - **Graphics**
   - **Environment**
   - **Scoping**
   - **Property Name**
   - **Property Value**
2. For the **Name**, **Tag**, **Property Name**, or **Property Value** options, you enter one or more search terms. For all other filters, select an option from the drop-down list to further specify your inquiry.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

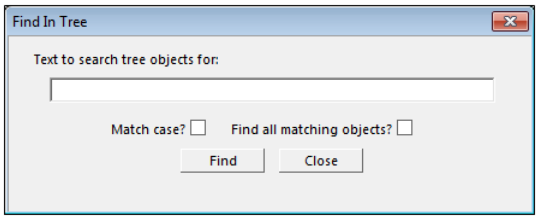
Published: 2023-10-23

3. Click the **Refresh Search** button (or press **Enter**) to execute your search. If you want to eliminate content from the tree, click the **Remove** button and then click **Refresh Search** to remove the requested objects.

4. When searching, the tree displays only objects matching your search criteria. If you enter multiple search terms, the tree shows only objects matching all of the specified terms. When removing objects, the requested objects do not display.

Searching the Tree

The **Find In Tree** option provided through the **Edit Menu** (or **F3** key) enables you to search tree objects whose names match your search criteria. The search tool is illustrated below.



Once you make an entry and click the **Find** button, the application highlights the first instance of the search string. The application will cycle through (highlight) each instance of the string as you continue to press the **Find** button. Furthermore, this cycle is sensitive to the order in which objects were generated, created, or renamed.

Search options may be case sensitive and you can search tree objects for all instances of a name/text-based string. The application highlights all objects in your specified string when you select the **Find all matching objects** option.

Details Pane

You use the **Details** pane to specify the attributes of an object selected in the Outline (p. 105). The pane provides categorized groups of properties for the selected object. You define the various properties in different ways. Some require you to make a selection in the **Geometry** window, others require a value, and so on. This is the primary entry point to properly define the environmental conditions of your simulation.

Here is an example of the **Details** pane for the Geometry object.

Published: 2023-10-23

For more information, see the topic below:

Features (p. 121)
Pausing Updates (p. 121)
Header (p. 122)
Categories (p. 122)
Undefined or Invalid Fields (p. 122)
Decision-Based (p. 123)
Text Entry (p. 124)
Numeric Values (p. 126)
Ranges (p. 126)
Increments (p. 127)
Scoping (p. 128)
Parameters (p. 128)
Options (p. 128)

Features

The **Details view** enables you to enter information that is specific to each section of the Outline. It automatically displays details for branches such as Geometry, Model, Connections, etc. Features of the Details pane include:

- Collapsible bold headings.
- Dynamic cell background color change.
- Row selection/activation.
- Auto-sizing/scrolling.
- Sliders for range selection.
- Combo boxes for boolean or list selection.
- Buttons to display dialog box (browse, color picker, etc.).
- Apply / Cancel buttons for geometry selection.
- Obsolete items are highlighted in red.

Pausing Updates

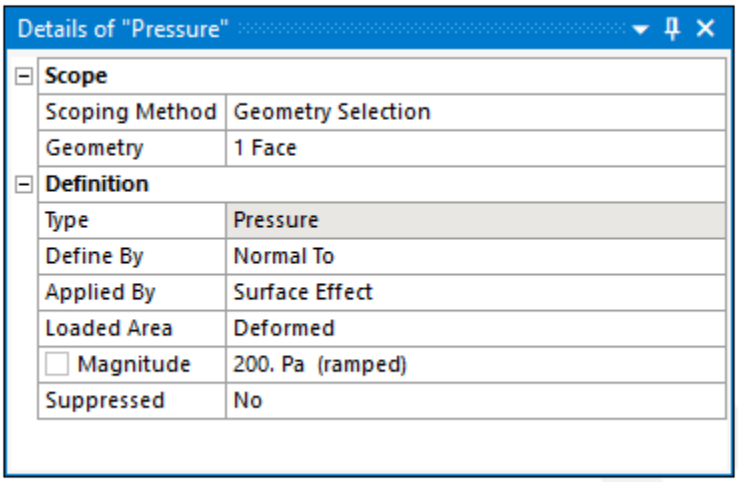
Certain actions instruct the application to update the content of the Details view pane. Depending upon the action, this can take an undesirable amount of time. The **Options** (p. 217) dialog preference **Pause View Update** enables you to halt Details view updates. This may be desirable until you have completed all desired actions when configuring an analysis. The options of this preference are **Yes** and **No** (default).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

When active, the title of the pane displays the message “Details view Update Paused.” You must change the setting in the **Options** dialog to deactivate the setting. The setting for this preference carries over to future Mechanical session if not changed.

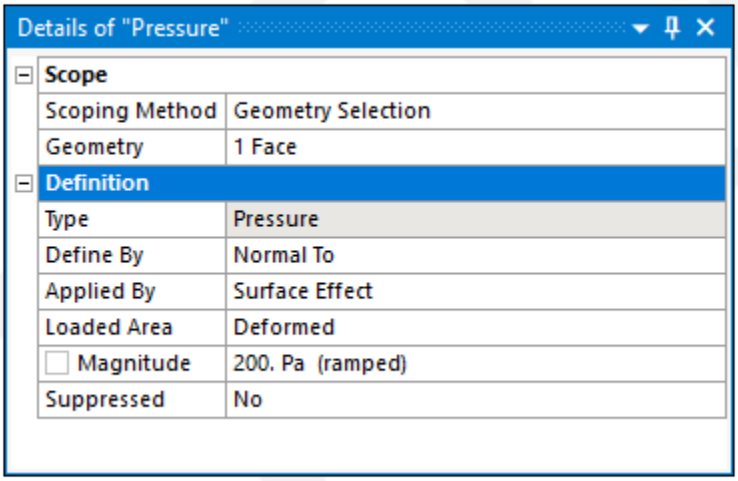
Header

The heading of the pane identifies the name of the selected object (contained in parenthesis), such as the "Pressure" load shown here. For certain objects, the heading may also display the type of object currently selected in addition to the object name.



Categories

The category label in the pane organizes associated properties. The **Definition** category, a common object category, is highlighted in the following example. Double-click a category's name to expand or collapse the category.

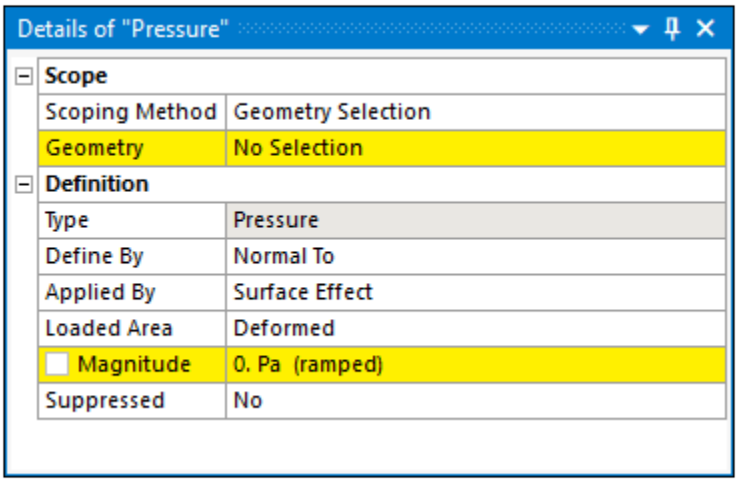


Undefined or Invalid Fields

Fields whose value is undefined or invalid are highlighted in yellow:

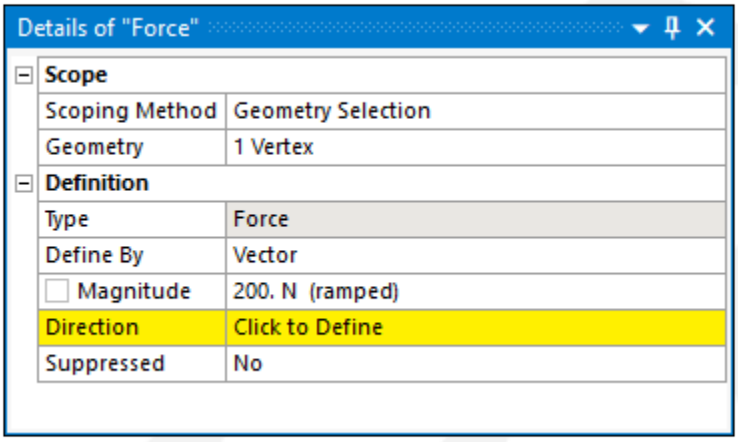
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

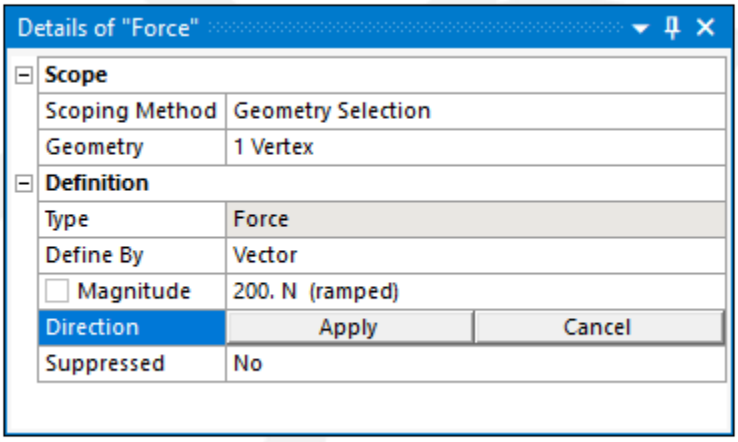
Published: 2023-10-23



Decision-Based

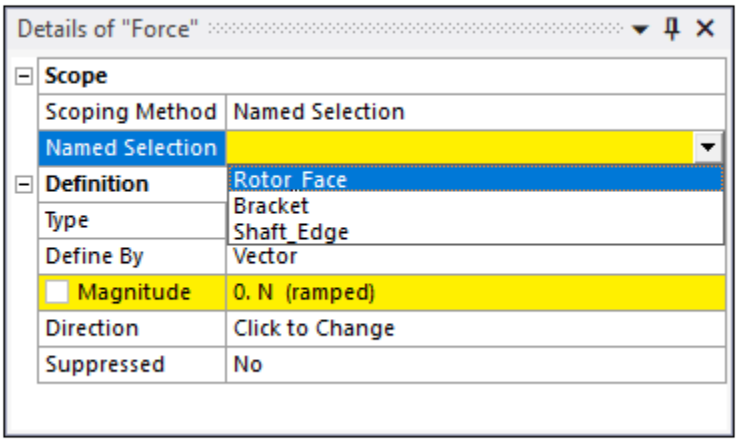
Some properties require a selection in order to specify an attribute, such as the **Direction** property shown here. This property requires additional specification actions that you then "Apply."



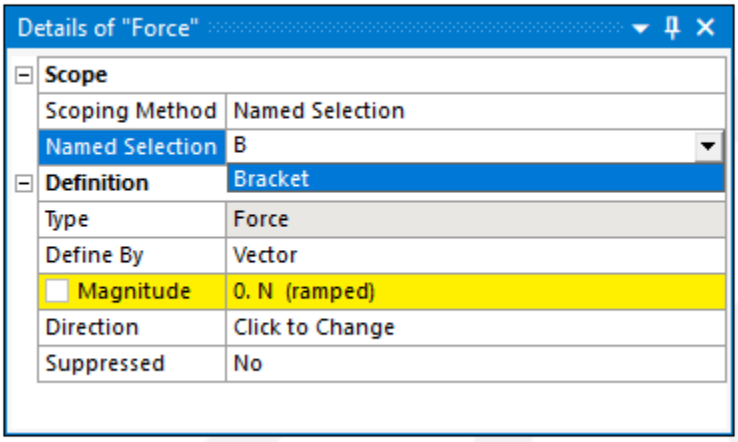


The properties associated with decision-based fields often provide a drop-down list of options, such as the list of Named Selections shown here.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



You can search these option-based fields. For example and as illustrated below, an "B" was entered in the field and the application filtered all of the options that included that letter. This search feature is not case sensitive. And, you can change disable this capability (turned on by default) under the **UI Controls** category of the Miscellaneous Options (p. 235).



Note:

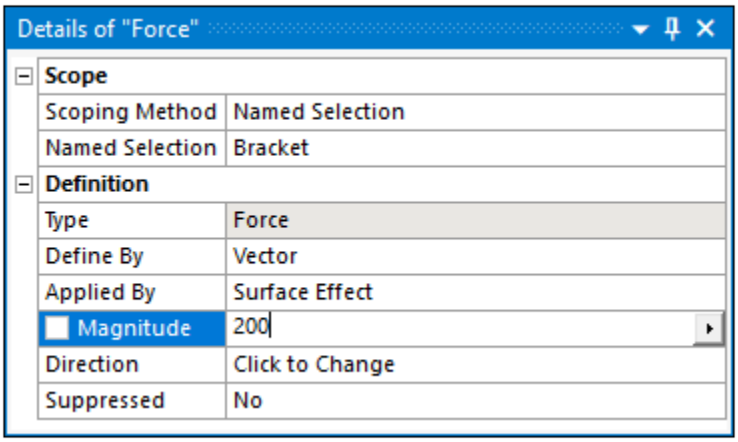
The left column always adjusts to fit the widest visible label. This provides maximum space for editable fields in the right column. You can adjust the width of the columns by dragging the separator between them.

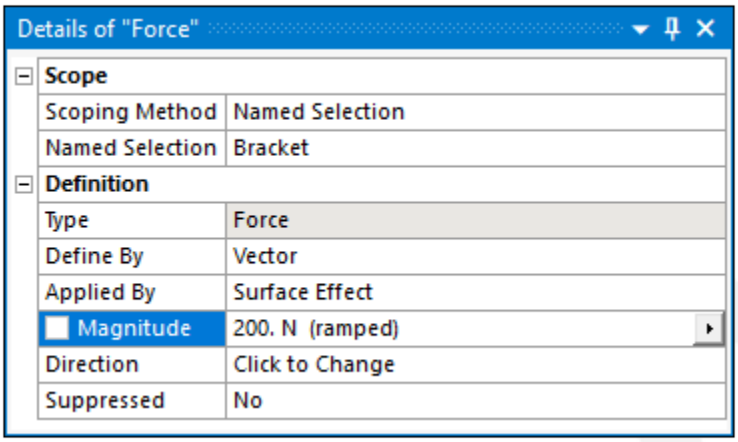
Text Entry

Text entry fields may be qualified as strings, numbers, or integers. Units are automatically removed and replaced to facilitate editing:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23





Inappropriate characters are discarded (for example, typing a Z in an integer field). A numeric field cannot be entered if it contains an invalid value. It is returned to its previous value.

Separator Clarification

Some languages use "separators" within numerical values whose meanings may vary across different languages. For example, in English the comma separator [,] indicates "thousand" ("2,300" implies "two thousand three hundred"), but in German the comma separator indicates "decimal" ("2,300" implies "two and three tenths", equivalent to "2.300" in English). To avoid misinterpretation of numerical values you enter that include separators, you are asked to confirm such entries before they are accepted.

For example, in English, if you enter "2,300", you receive a message stating the following:

"Entered value is 2,300. Do you want to accept the correction proposed below?

2300

To accept the correction, click **Yes**.

To close this message and correct the number yourself, click **No**.

Note:

If an invalid entry is detected, an attempt is made to interpret the entry as numerical and you receive the message mentioned above if an alternate value is found. If an invalid value

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

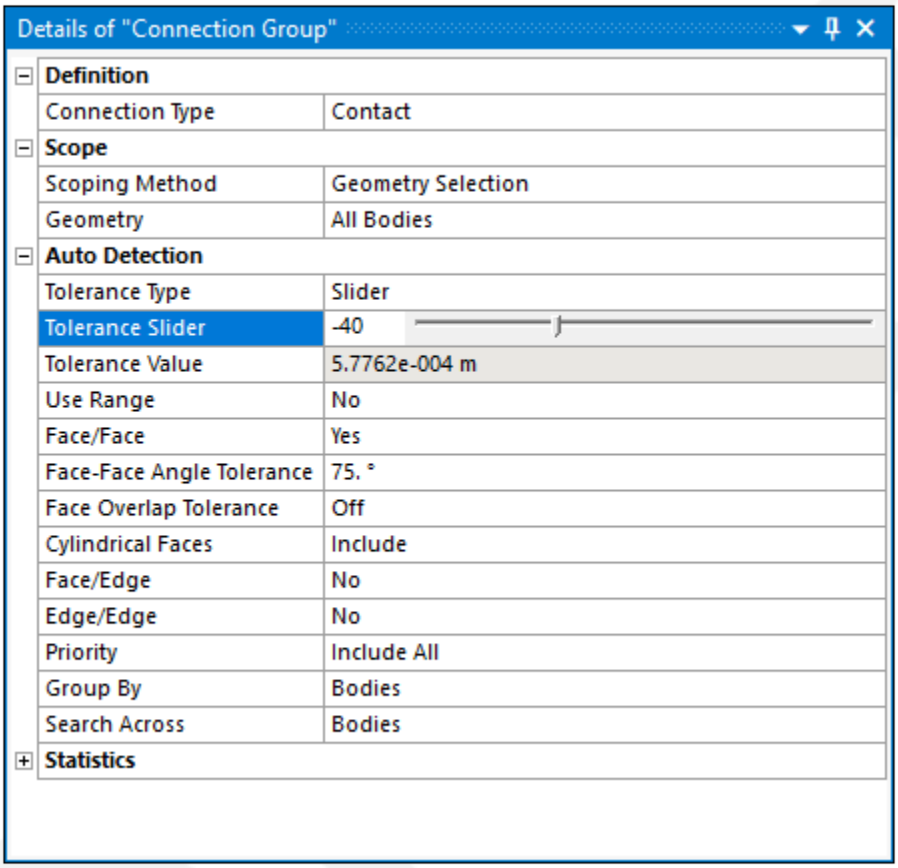
is entered, for example "a1.3.4", and no numerical alternative is found, the entry is rejected and the previous value is re-displayed.

Numeric Values

You can enter numeric expressions in the form of a constant value or expression, tabular data, or a function. See Defining Boundary Condition Magnitude (p. 1771) for further information.

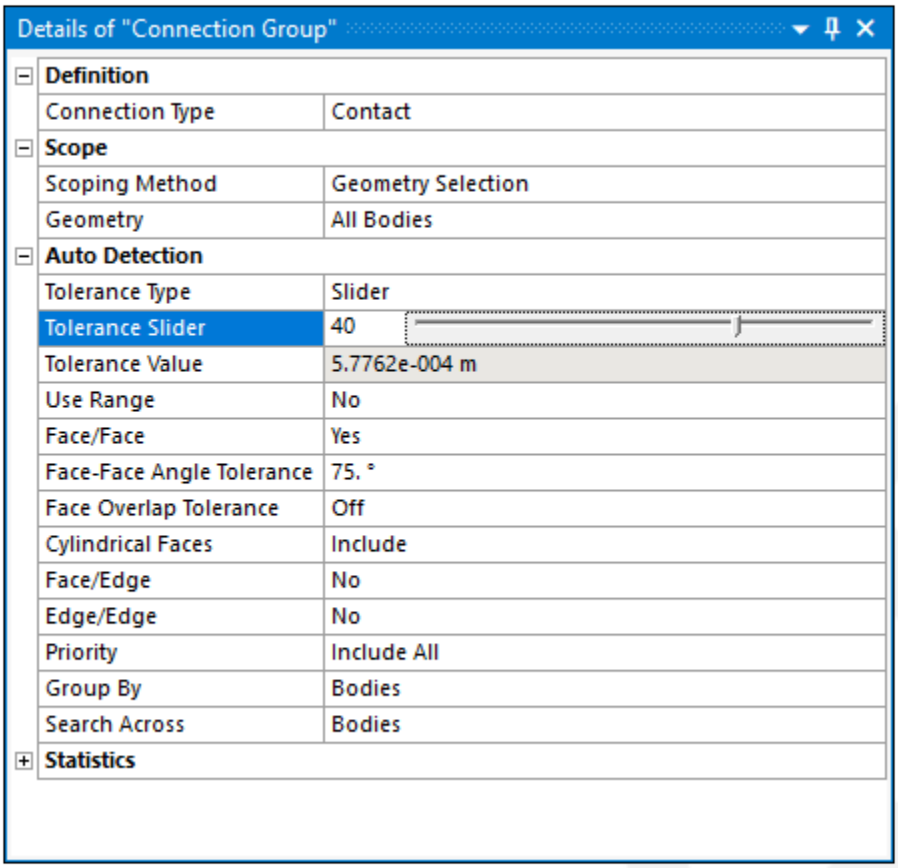
Ranges

If a numeric field has a range, a slider appears to the right of the current value. If the value changes, the slider moves. And when the slider moves, the value updates.



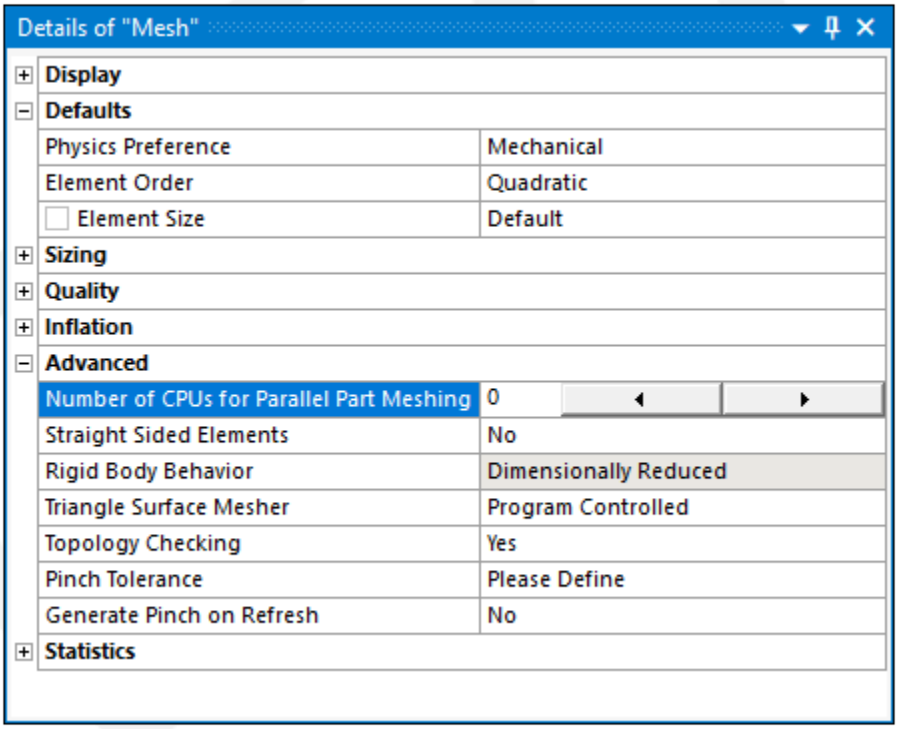
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Increments

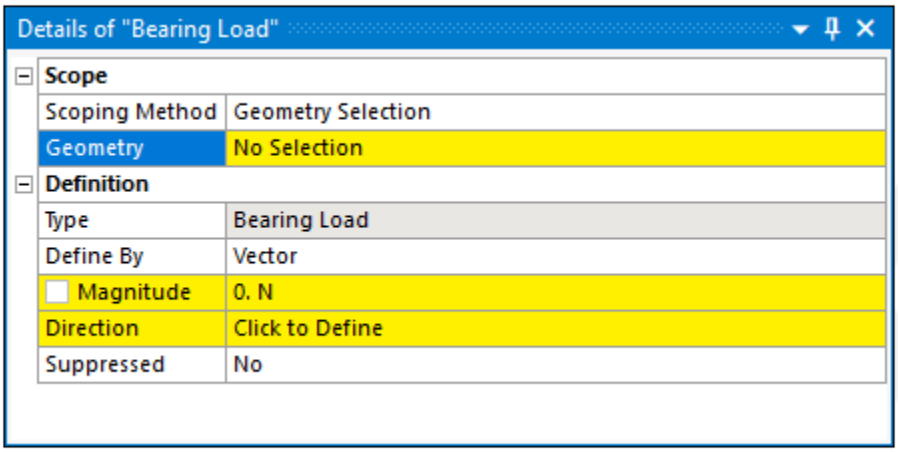
If a numeric field has an increment, a horizontal up/down control appears to the right of the current value. The arrow buttons enable you to increase/decrease the property's value.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Scoping

The **Scoping Method** and its associated properties, usually **Geometry** and **Named Selection**, may have selection requirements. For example, the application only supports face scoping for a Bearing Load (p. 1561). If you try to scope the load to any other geometric entity, or a Named Selection that is **not** face-based, the application presents an invalid state.



Parameters

Variables that you can parameterize display in the interface with a check box. Clicking the box activates the property as a parameter. For more information, see Parameterizing a Variable (p. 128).

Options

Option fields allow you to select one item from a short list. Options work the same way as Decision-Based (p. 123), but don't affect subsequent fields. Options are also used for boolean choices (true/false, yes/no, enabled/disabled, fixed/free, etc.) Double-clicking an option automatically selects the next item down the list.

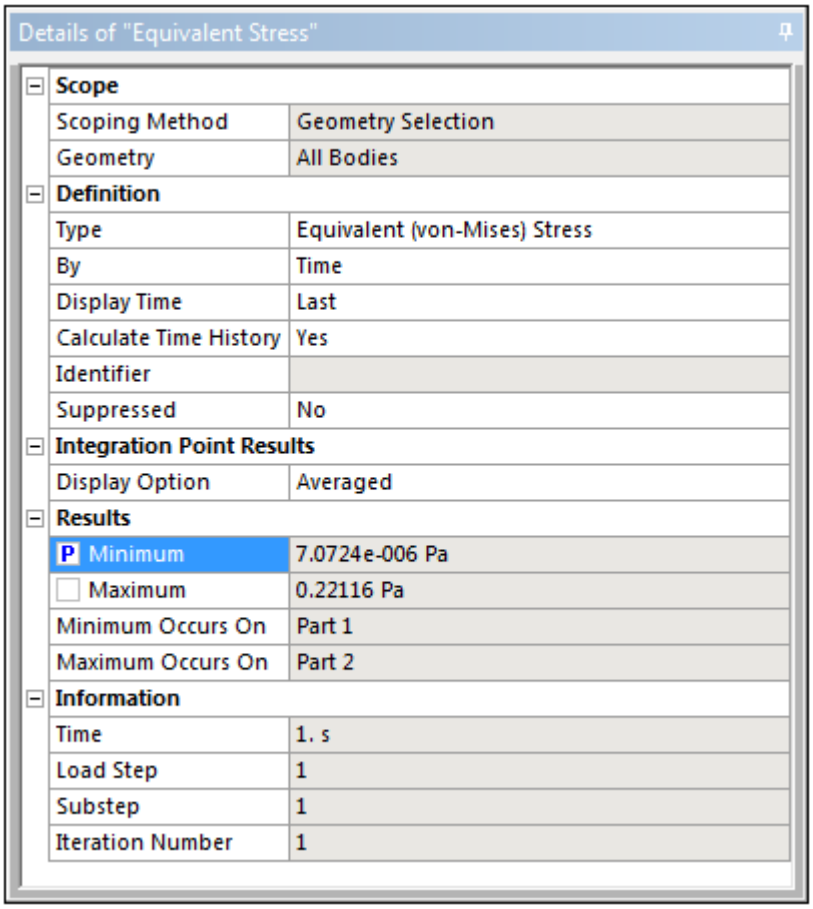
Selecting an option followed by an ellipsis causes an immediate action.

Parameterizing a Variable

Variables that you can parameterize display in the interface with a check box. Clicking the check box displays a blue capital "**P**", as illustrated below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



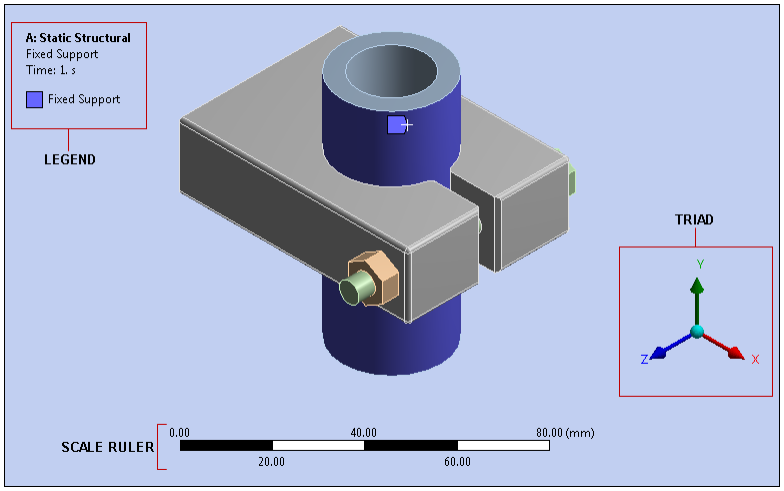
The boxes that appear in the Mechanical application apply only to the Parameter Workspace. Checking or clearing these boxes will have no effect on which CAD parameters are transferred to Design Exploration.

For more information, see Setting Parameters (p. 2337).

Geometry Window

The **Geometry** window/tab displays a 3D graphical representation of your model. All view manipulation, geometry selection, and graphics display of a model occurs in this window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The default components of the window, as illustrated above, include:

Legend

The information presented by the Legend varies, but in general, it provides information about the currently selected object or objects as well as the analysis type, and includes annotations. For the above example, a **Fixed Support** object is selected. The face to which the support is applied is shown via color coding.

You can reposition the legend by dragging and dropping it to a location in the window.

Scale Ruler

Based on the selected unit of measure, the ruler provides a reference for your geometry.

Triad

Shows the global XYZ coordinate triad. The axes are color-coded as follows:

- Red: X
- Green: Y
- Blue: Z

The Triad enables you to reorient the position of your model based on a desired axis as well as reset the isometric view (light blue ball). If you move your cursor around the triad, you will see an arrow appear that shows the direction that corresponds to the position of your cursor (+x, -x, +y, -y, +z, -z). If you click the arrow, it changes your view so that the axis indicated by the arrow is facing outward.

You can turn these options on and off using selections **Show** drop-down menu on the **Display** (p. 87) group on the **Display** tab.

Full Screen Mode

Mechanical offers a full screen mode so that you can view and/or present the results of your analysis by maximizing the **Geometry** window and hiding all other interface elements (by default). You activate

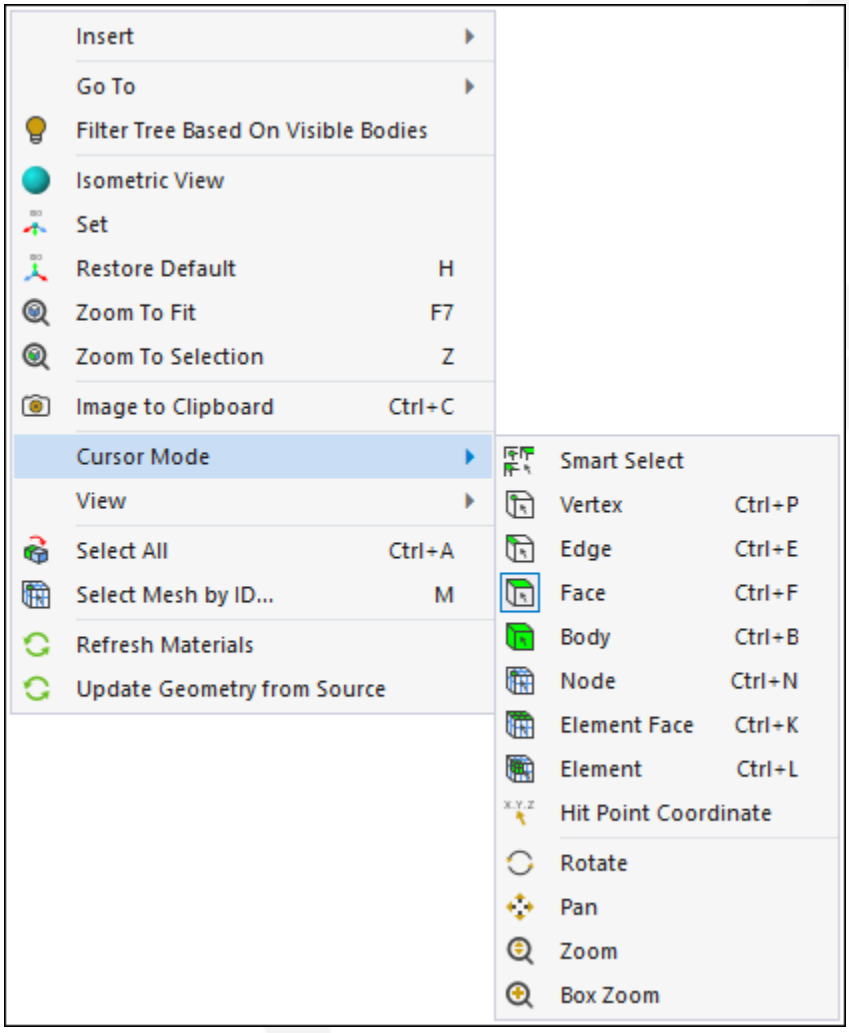
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

full screen mode by selecting the **Full Screen** option from the **Layout** (p. 47) group on the **Home** tab. Or, you can use the **F11** key when the **Geometry** window, the tree **Outline**, or the **Details** view have focus. The tab option and the **F11** key toggle the display on and/or off. Also note that you can use Key Assignments (p. 314) from when the Full Screen active to displays other interface panes, such as the **Outline**, if desired.

Contextual Menu Options

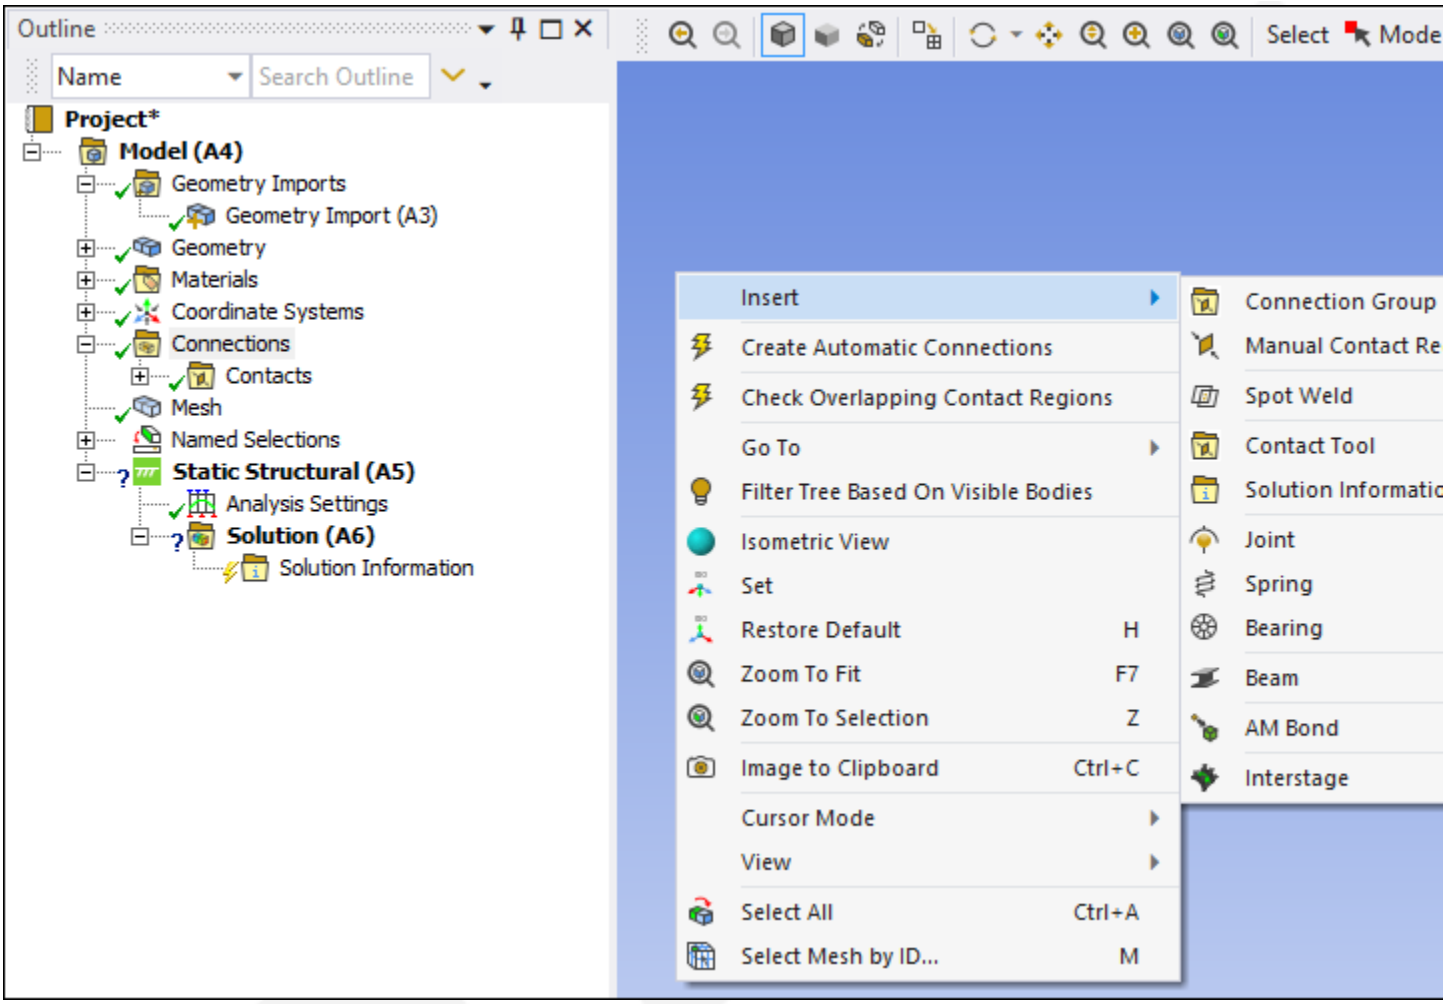
Right-clicking the mouse in the Geometry window provides a context menu with a variety of options. The common menu options and specifically, the **Cursor Mode** menu, are illustrated below. Furthermore, the menu displays additional options that are based on the object you have selected. For example, the **Insert** and **Go To** options shown below are often available and their menu selections depend upon the tree object that is selected.



Insert

The options of the **Insert** menu depend upon the object selected in the tree. For example, with the Connections object selected, right-click in the geometry window and then select **Insert** to display the menu of connection options illustrated below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Tip:

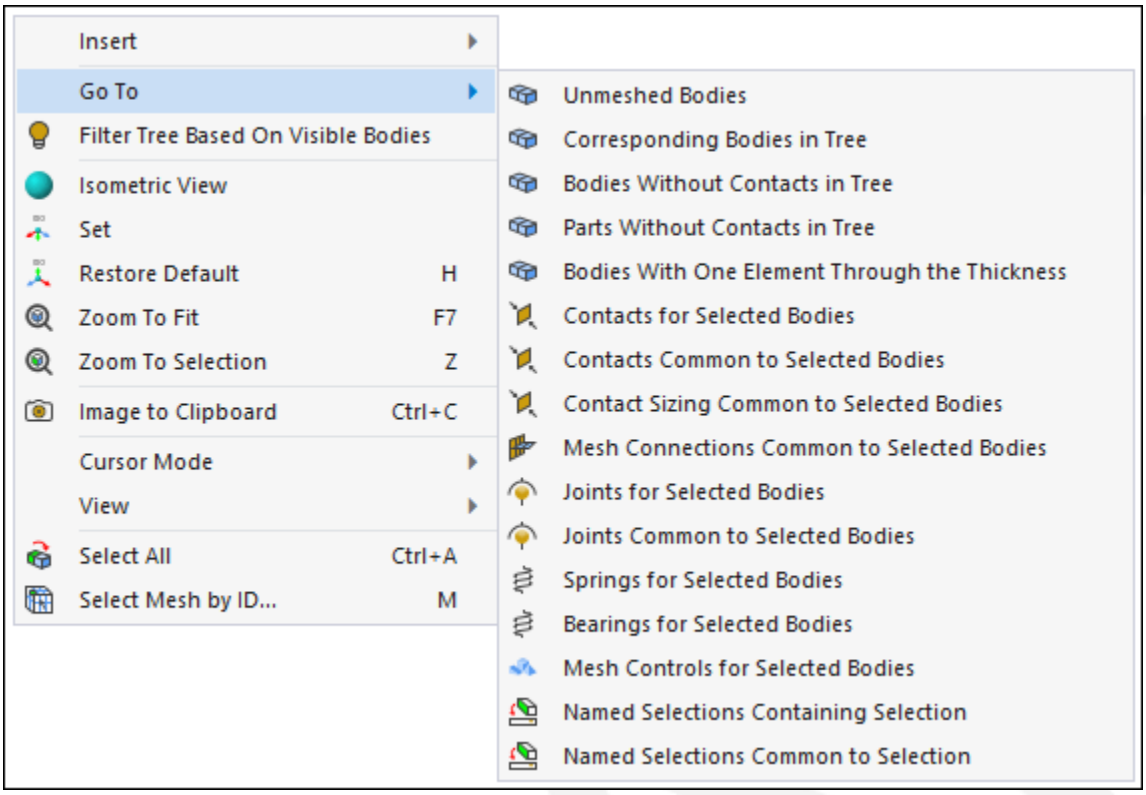
The Objects Reference section provides descriptions for all objects and their context menu options.

Go To

The options of the **Go To** menu depend upon the object selected in the tree. For example, with a geometric entity selected on the model, right-click in the geometry window and then select **Go To** to display the menu of options illustrated below. See the Correlating Tree Outline Objects with Model Characteristics (p. 110) section for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

Got To options are also available from the Selection (p. 88) tab.

Filter Tree Based on Visible Bodies

Filters the tree so that only visible bodies and objects associated with any visible body display.

Isometric View

Displays your model in the default isometric view.

Set

This option enables you can define a custom isometric viewpoint based on the current viewpoint. That is, you position your model where you would like it, using the other view options as desired, and then selecting this option establishes a new **Isometric View**.

Restore Default

This option resets the **Isometric View** to the application default.

Zoom To Fit

Fits the entire model in the Geometry window.

Zoom To Selection

Zoom in on the currently selected item (geometry/mesh/etc.) in the Geometry window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Image to Clipboard (Ctrl+C)

For the Windows platform, this option performs a snapshot of whatever is currently displayed in the **Geometry** window and copies it to the clipboard so that you can paste it into compatible applications.

Cursor Mode

This option provides a different method for selecting the cursor mode. See the Graphics Toolbar (p. 97) section of the Help for a description of each selection.

View

This option changes the viewpoint of your model. It operates much like the Triad.

Select All

Selects all items in the Model of the current selection filter type (vertex, edge, face, or body).

Select Mesh by ID (M)

This option enables you to select mesh nodes or elements using their ID (p. 279). This feature can be activated with the **M** key when the Geometry window is active. And, it also provides an option to create Named Selections for your selections.

Reset Body Colors

Reset the body colors back to the default color scheme.

Note:

As applicable and based on the object that you have selected in the tree, the contextual menu also provides options specific to that object.

Discrete Legends in the Mechanical Application

The following additional legends are available based on the object you have selected in the application.

- **Geometry Legend (p. 858)** : Content is driven by **Display Style** selection in the Details view panel.
- **Joint Legend (p. 1366)** : Depicts the free degrees of freedom characteristic of the type of joint.
- **Results Legend (p. 2284)** : Content is accessible via the right mouse when the legend for a solved object in the **Solution** folder is selected.

Displaying Shells for Large Deflections

The display of shells may become distorted for large deformations such as in large deflection, explicit dynamics analyses, etc. A workaround is to disable shell thickness by toggling **Thick Shells and Beams** option in the **Style** group (p. 80) of the **Display** tab. Or, set a Workbench variable, **`UsePseudoShellDisp`** = **`1`**, via the **Variable Manager**. It may be necessary to toggle the deformation

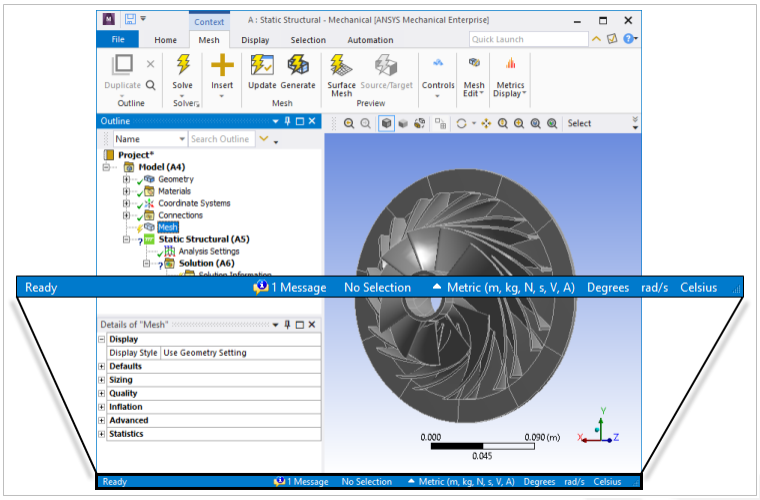
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

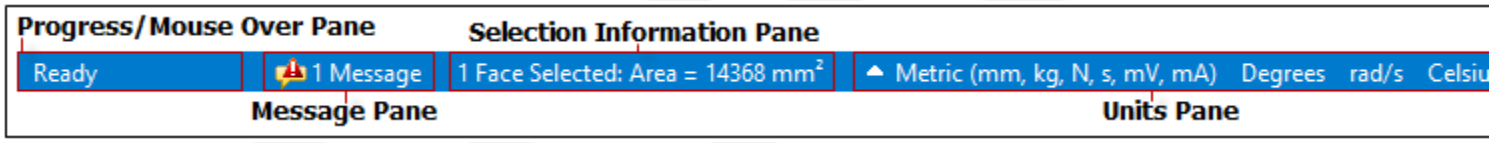
scaling (p. 63) from **True Scale** to **Undeformed** to **True Scale** again. Note that this option requires True Scaling to work properly.

Status Bar

The status bar provides information about your simulation.



Illustrated here, the status bar displays information panes. Generally, when information is available, you can single-click a pane to display an associated menu or window.



Go to a status bar component topic for more information about its purpose:

- Progress Pane (p. 135)
- Tooltip Display (p. 136)
- Application Messages (p. 137)
- Selection Information (p. 137)
- Units of Measure Pane (p. 138)
- License Read-Only Display (p. 138)
- Customize the Status Bar (p. 138)

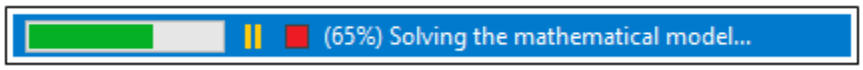
Progress Pane

This area of the status bar displays the progress of certain application processes, such as mesh generation and solution processing.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

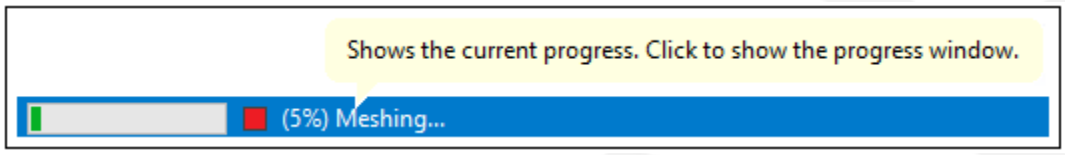
Progress Bar (**Interrupt** and **Stop** Options)

During an active process, the application displays a progress bar in the progress pane. And, depending on the process, it also provides an Interrupt (pause icon) option and/or Stop (red square icon) option. An example of the progress of a solution is illustrated blow. It includes both the Interrupt and Stop options.

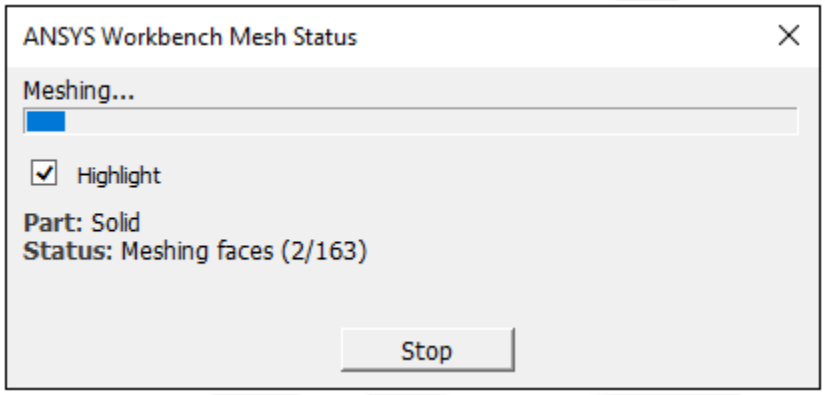


Progress Tool Tips (via Mouse Over)

During an active process, if you hover your mouse over the progress bar, a button, or the description (percentage, etc.) of the progress and process, a tool tip displays. An example of a mesh generation process is shown below.



Note that a single-click in the progress pane opens an associated progress window (shown here). This window is the legacy progress display for Mechanical.



Note:

Using the **UI Options** (p. 244) preference setting **Hide Progress Window**, you can choose to always display progress windows.

Tooltip Display

When you hover your mouse over an interface option, a tooltip displays in the bottom right corner of the bar. Here is an example of the tooltip for a mouse-over of the Solve button.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

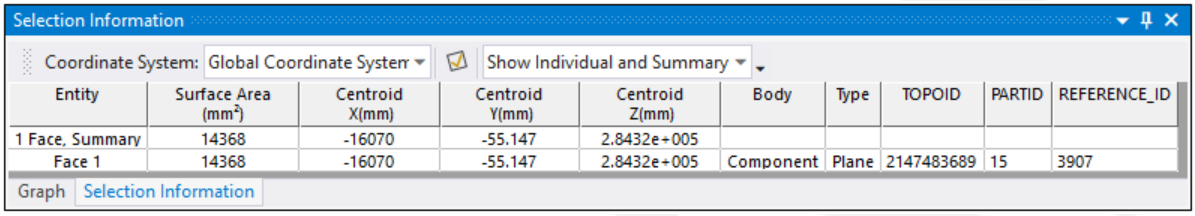
Application Messages

The status bar contains a pane that displays whether there are application generated messages (errors, warnings, and/or information). A single-click the pane to display the Message window (p. 200).

Selection Information

The **Selection Information** pane displays information about the currently selected geometric entity or entities. Such as area, length, or location. In the following example, the area of a single face is displayed.

A single-click the pane displays the Selection Information (p. 180) window.



Example Selection Information includes (but is not limited to):

- A selected node or element number if only one node/element is selected.
- The location of a node or vertex if one is selected.
- The combined volume of selected bodies, area of selected faces, and lengths of edges.
- The radius of a single circular edge or face that is selected.
- Angle between three nodes (always in degrees).
- The angle between two planar surfaces (always in degrees).
- The angle between two straight edges (always in degrees).

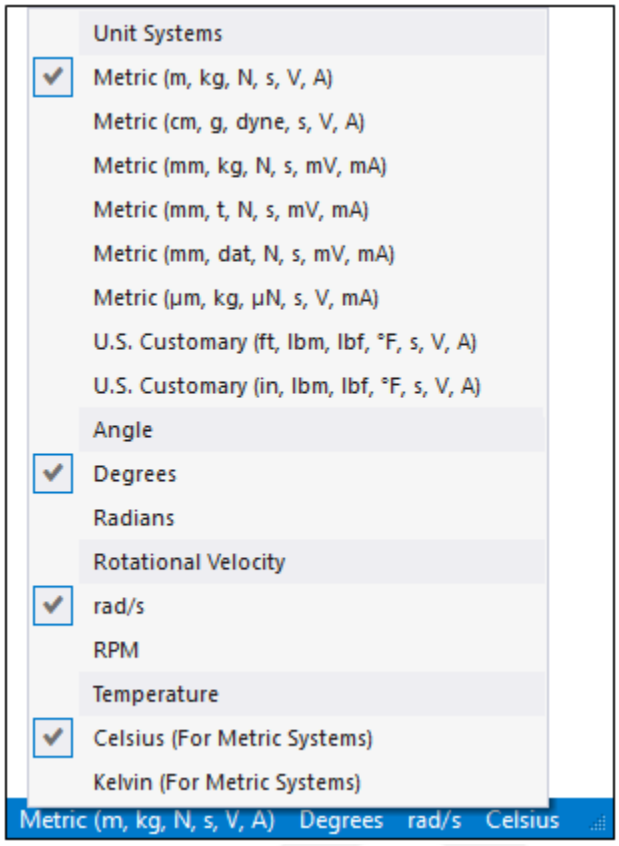
Note:

- If there is no associated information, the Selection Information pane indicates **No Selection**.
- Geometry calculations such as length and area are an approximation based on geometry information contained in either the CAD data or graphics tessellation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Units of Measure Pane

This pane displays the currently selected Unit systems. Selecting this pane displays the **Units** menu (p. 45) enabling you to change the current unit system.



License Read-Only Display

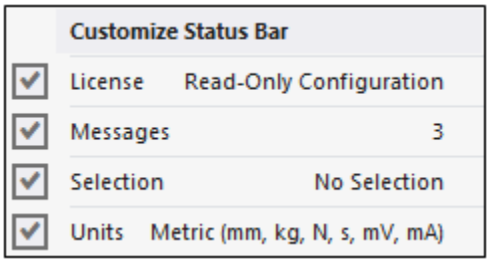
If a license is not available when you open Mechanical, the application automatically opens in **Read-Only Configuration** mode as illustrated below. Once a license becomes available and you activate it, the application automatically exits this read-only mode.

Customize the Status Bar

When you right-click the status bar, the following menu displays. Using this menu, you can select whether to hide (or show) certain status bar options.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Quick Launch

The **Quick Launch** tool enables you to quickly find a desired function, feature, or interface option, and, based on the search string, automatically select, insert, or launch the pertinent interface item/feature. As you type in the Quick Launch search box, results display in the following categories:

- **Ribbon** (@rib): This category presents interface options available from all current tabs as well as the current Context tab.
- **Context Tab** (@ctx): This category presents search results for all the of the application's Context tabs (current or otherwise not displayed).
- **Pane Toolbar** (@too): This category presents search results for application features and options that are contained in all application toolbars.
- **Preferences** (@opt): This category presents selections that open the **Options** dialog (p. 217) and automatically displays the corresponding property, enabling you to modify its setting (default or current).
- **Tree** (@tre): This category presents search results for objects contained in the **Outline** pane. This option is hidden by default. Enable this option using the **Tree Items** setting of the Default Quick Launch Result Categories (p. 246) preference of the **Options** dialog.

As listed above, each category has an accompanying shortcut (@rib, etc.). You can use these entries to search within a desired category only. For example, the entry "@rib Mesh" searches for options and features of the ribbon category related to the keyword Mesh.

When you highlight a listing in the **Ribbon** category, the accompanying text string "Take me there" also displays. When selected, the "Take me there" feature tells the application to point to the option on the interface and display a pop-window that describes the option. This feature is also available for the **Pane Toolbar** and **Context Tab** categories. For the **Context Tab** category, it only displays when an action can be performed on the currently selected object. For the **Pane Toolbar** and **Tree** categories, it highlights the search item on the interface.

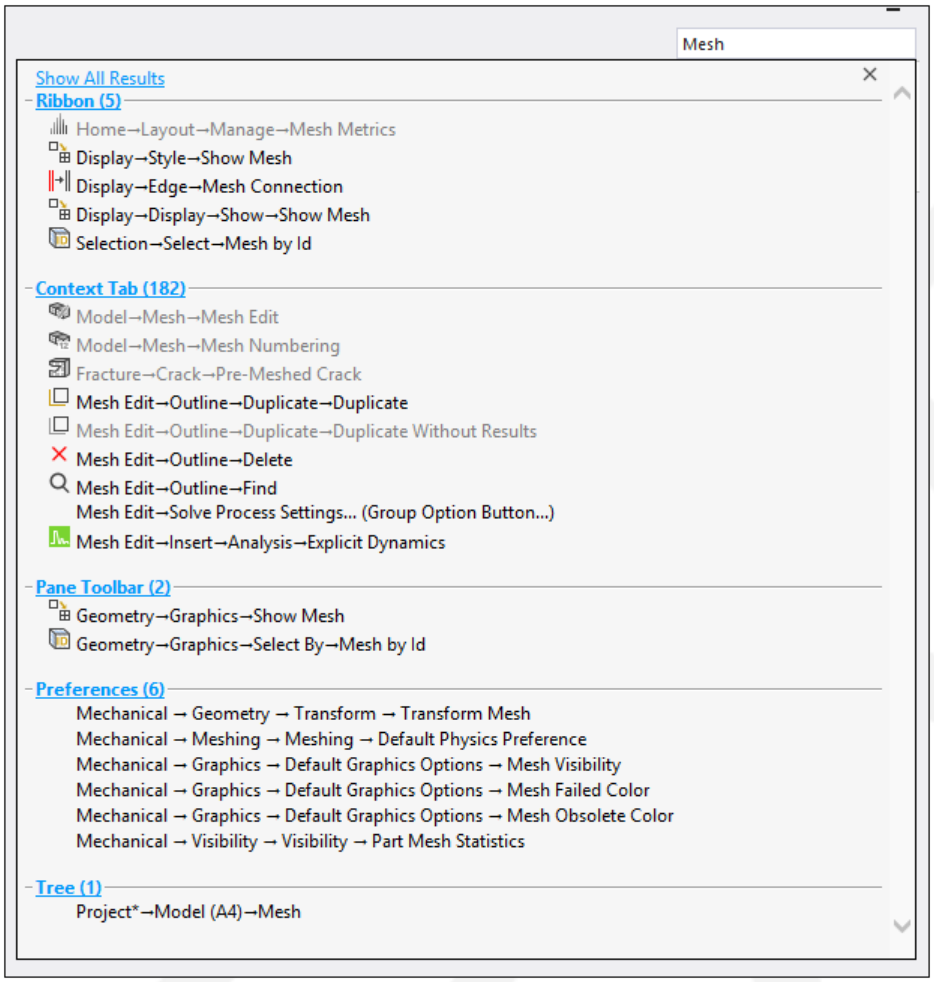
As illustrated below, some search listings display as bold and others are greyed-out. Greyed-out listing cannot be selected but suggest a potential path to your desired search item. Bold listings are selectable and cause the application to automatically take action. Example actions include the application automatically inserting or selecting an object in the **Outline** pane or highlighting a pertinent interface option. Note that bold listings may require that you have an appropriate object selected in order to successfully perform an action.

For example, if you have the Environment object selected and you search on "Pressure" and then select the Pressure listing from the Quick Launch menu, a Pressure load is automatically inserted below the

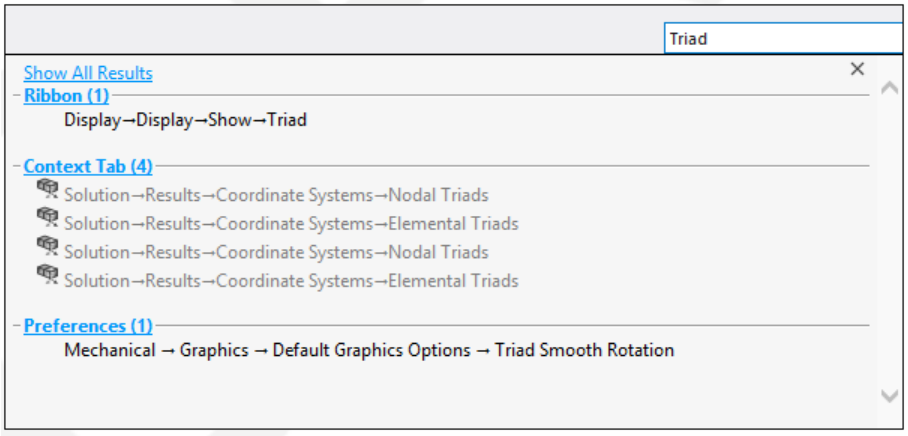
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Environment object. This is the same result as if you had performed the action via the Environment Context tab.

Bold Listings



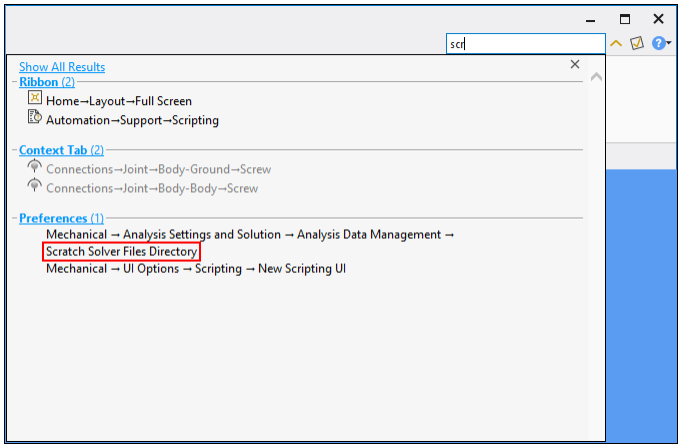
Greyed-Out Listings

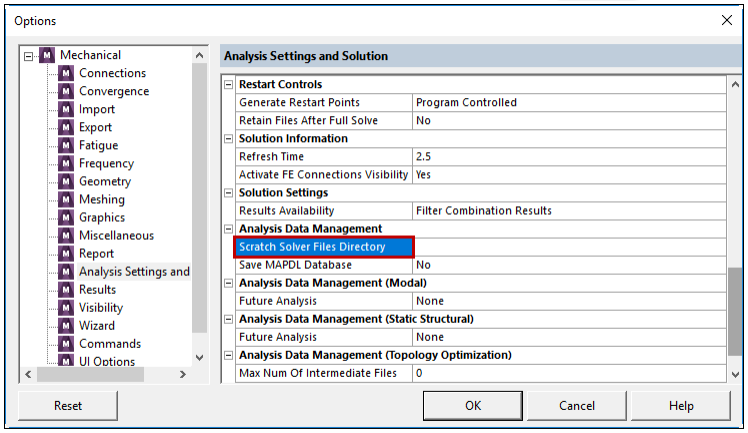


Preference Listings

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

These selections open the **Options** dialog (p. 217).





Help Menu

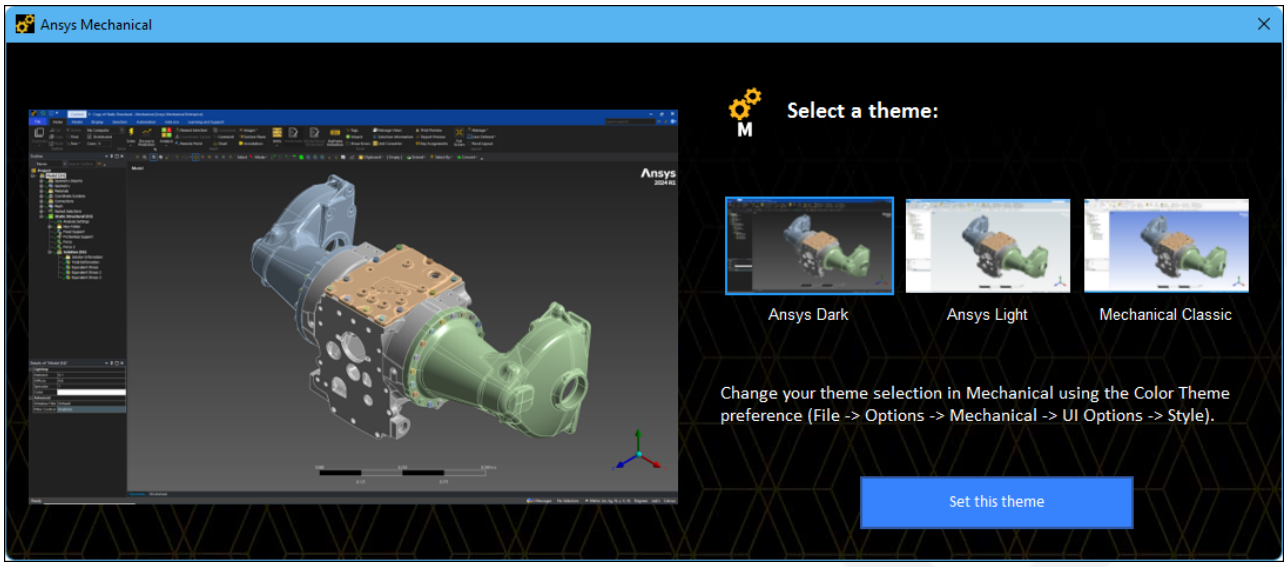
The **Help** drop-down menu provides the following options.

Function	Description
Mechanical Help	Displays the Help system in another browser window.
Mechanical Highlights - What's New? (Windows Platform Only)	This option displays an illustrated review (via the File (p. 37) tab) of the release's new features and capabilities.
Mechanical Release Notes	Open the release notes for the version of the application that you are running.
Usage Tips	This option opens a window that provides several instructional slides describing the new features and functions of the current release.
Scripting - Quick Start Guide	This option links to the introductory documentation for application scripting capabilities.
Ansys Product Improvement Program	This option launches the dialog for the Ansys Product Improvement Program and enables you to either accept or decline the invitation to participate in the program.
About Mechanical	Provides copyright and application version information.

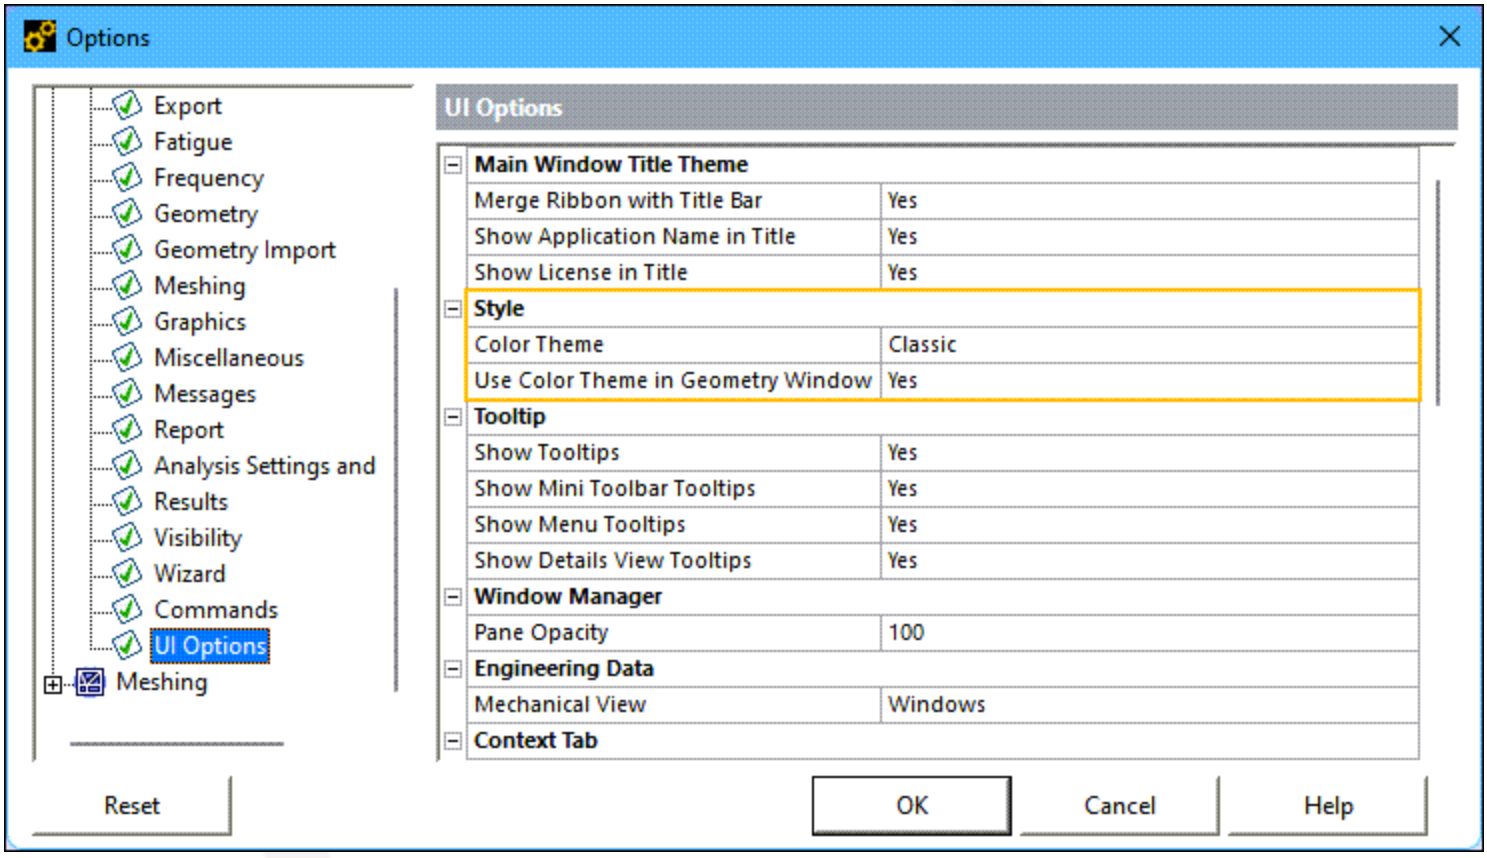
Color Theme

When you first install and launch the application, the following dialog displays so that you can select a theme. Options include **Ansys Dark**, **Ansys Light**, and **Mechanical Classic**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



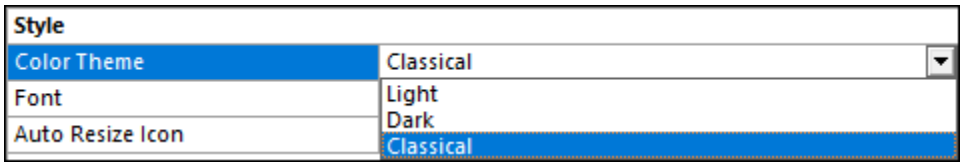
Using the Options (p. 217) dialog preferences of the Style (p. 244) category of the **UI Options** group, you can change the color theme (Dark and Light) of the interface.



Color Theme Preference

Following your initial selection, you can change the theme as desired using the **Color Theme** preference.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Use Color Theme in Geometry Window

Use this preference to select the background color of the **Geometry** window. If set to **Yes** (default), the application uses the background color of the selected **Color Theme** (light, dark, classic). Set to **No**, Mechanical uses the background colors selected in Workbench (**Tools** > **Options** > Appearance).

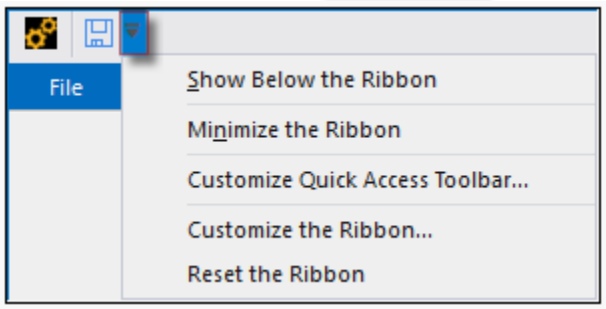
Ribbon Customization Options

The application offers features that enable you to modify the content of the tabs and the toolbar, including:

- Customizing Ribbon Content (p. 143)
- Customizing Toolbars (p. 145)

Customizing Ribbon Content

The ribbon interface includes a **Quick Access Toolbar** that you can modify. It is located in the upper felt corner of the window, right beside the Save icon (which is an option of the Quick Access Toolbar). Selecting the drop-down menu option displays the following menu.

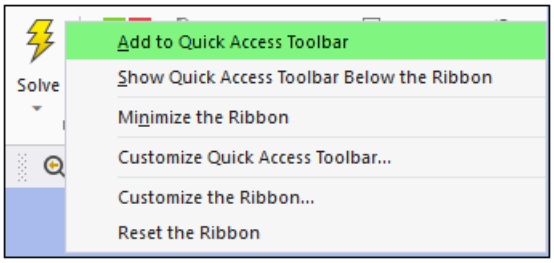


The options include:

- **Show Below the Ribbon** (or **Show Above the Ribbon**): Place the toolbar below the Tabs or return it to its default position.
- **Minimize the Ribbon**: Hide/show the ribbon.
- **Customize Quick Access Toolbar**: This option displays the **Customize** dialog. This dialog enables you to add options to the Quick Access Toolbar. See below (p. 144).
- **Customize the Ribbon**: modify the contents of the various tabs as well as create your own tabs and option groups. See below (p. 144).
- **Reset the Ribbon**: Reset the interface contents to default display settings.

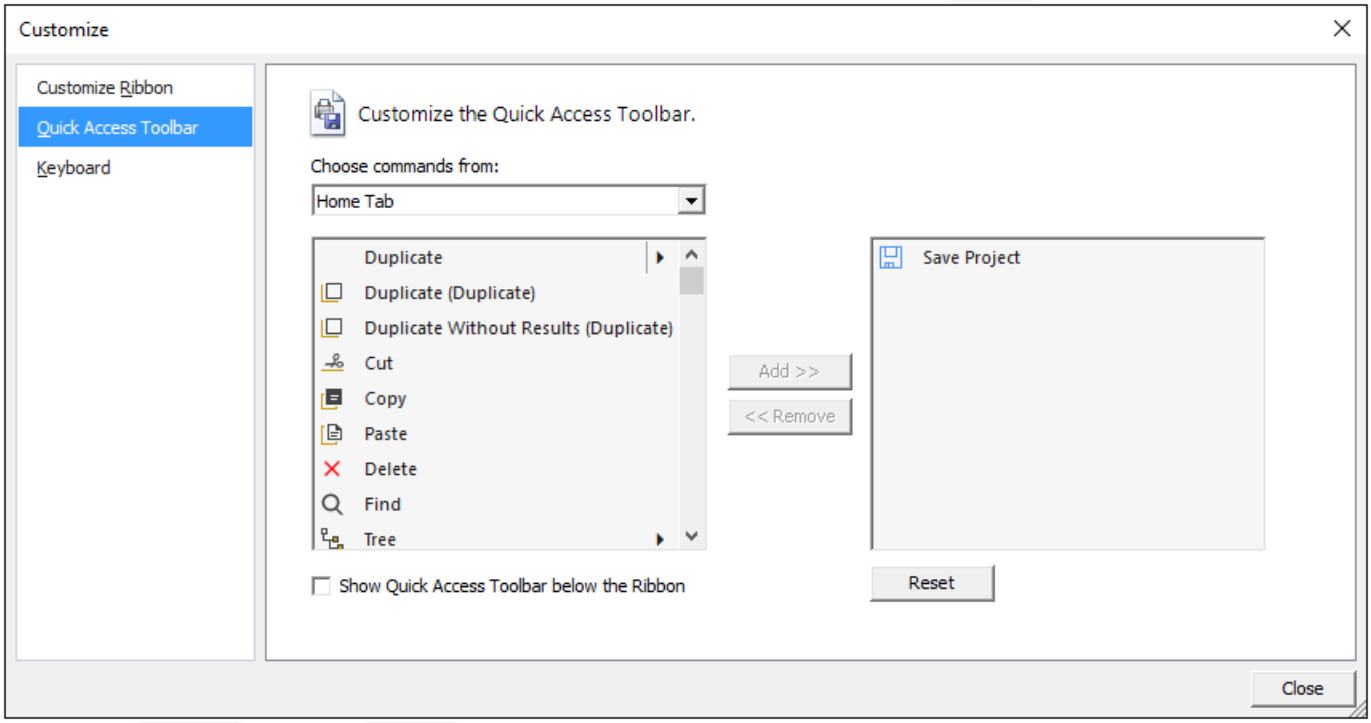
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Also note that you can highlight an interface option, right-click, and a select **Add to Quick Access Toolbar** to add the option.



Customize Quick Access Toolbar

When you select the **Customize Quick Access Toolbar** option, the following dialog appears. As you can see, the default Save option is already included. You select from the list of available commands to **Add**/**Remove** options to the Quick Access Toolbar. You can select options from all available tabs using the drop-down menu.



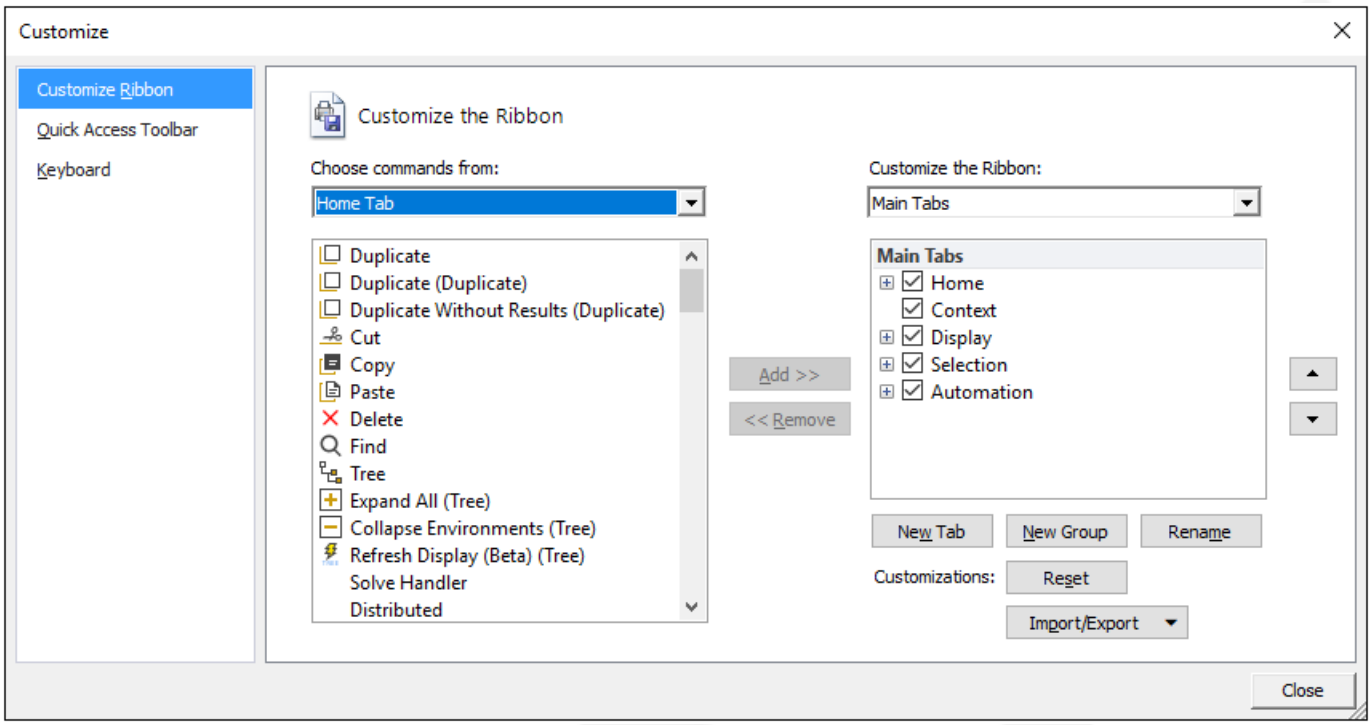
Customize the Ribbon

When you select the **Customize the Ribbon** option, the following dialog appears. A drop-down menu of tabs is available for your selection and the corresponding commands.

You can add existing options to the Groups of the Main Tabs or you can create a new customized Tab with custom Groups. Based on the Main Tab that you select in the right-side pane, if you create a **New Tab**, it is placed immediately after the currently selected option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

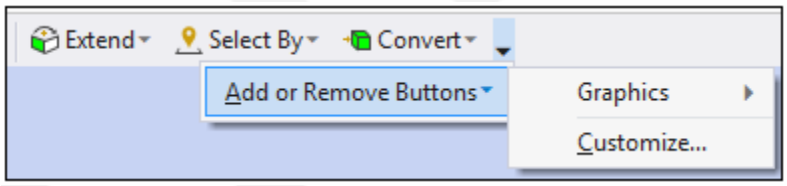


Note:

- You cannot remove system default tabs.
- If you deselected an ACT Extension in the Extension Manager or if the version of an extension is updated, any customization of the extension's Tab is automatically removed.

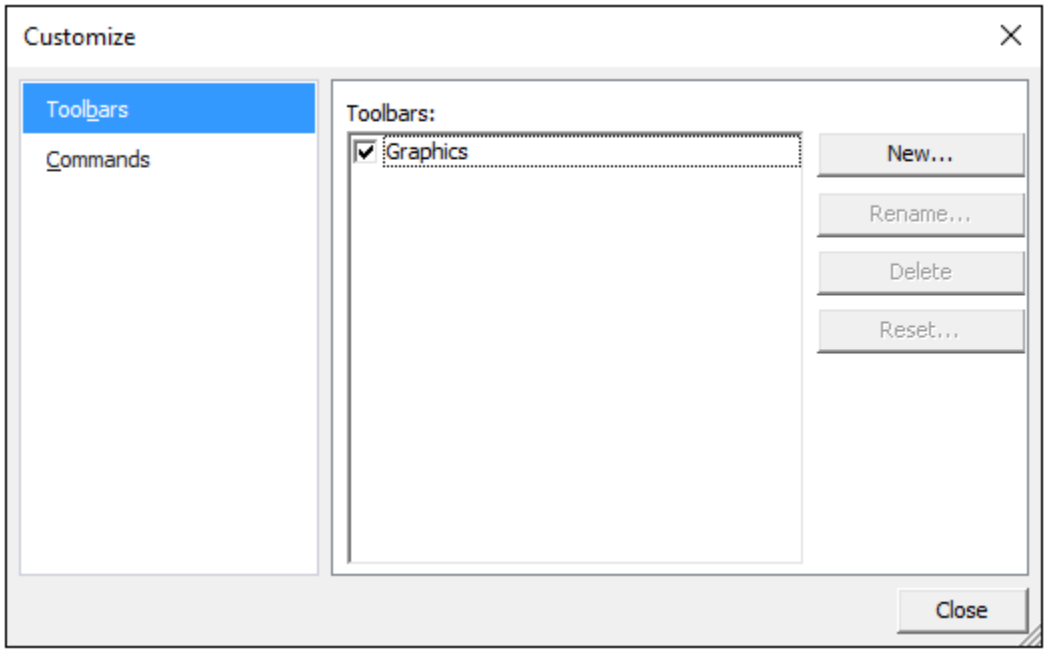
Customizing Toolbars

The various toolbars of the application, such as the Graphics Toolbar (p. 97) or the Manage Views (p. 292) window, offer an option to **Add or Remove Buttons**. You access this option using the down-arrow drop-down menu at the far end of the toolbar. An example of the Graphics Toolbar is illustrated below. When you select the **Add or Remove Buttons** option, an additional fly-out menu displays. Depending upon the toolbar or window that you have selected, the first option varies, but the common option is **Customize**.



Selecting the **Customize** option displays the following dialog.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

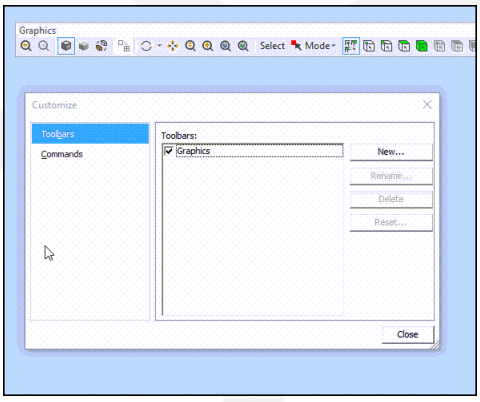


From this dialog, you create new toolbars or add options to the currently selected toolbar.

Add Options

In order to add options to the currently selected toolbar, you must first close the **Customize** dialog and detach the desired toolbar from the interface so that it is floating (as shown below). Then redisplay the **Customize** dialog, and 1) select the **Commands** option, 2) select from the available **Categories**, 3) drag-and-drop from the **Commands** pane to the toolbar.

Activating the **Show All Categories** setting of the **Options** dialog (**UI Options** (p. 244) > **Toolbar Customization**), you can display all options available in the application. This includes options from all toolbars from all panes, all commands from all Ribbon tabs, User Buttons, External ACT Extensions, etc. This gives you maximum flexibility for toolbar customization. This feature is set **No** by default. And, when turned off, any additions you make to a toolbar are cleared – the toolbar resets.

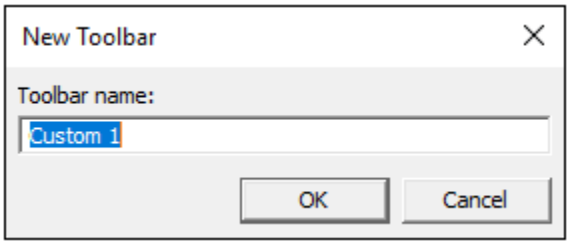


Create New Toolbar

To create a new toolbar, select the **New** button on the above dialog. An entry pane displays for you define a name for your toolbar.

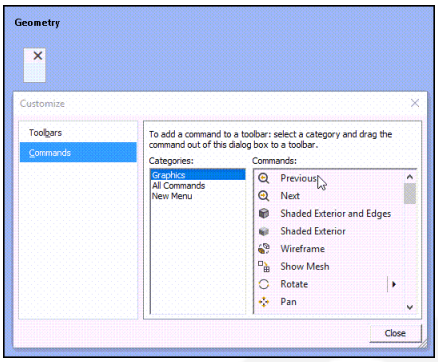
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



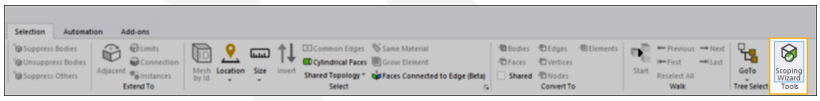
Once you define the name and click **Ok**, a blank toolbar displays (and includes down-arrow option), as illustrated bellow.

At this point you must close the **Customize** dialog and detach the new toolbar from the interface so that it is floating. Then, redisplay the **Customize** dialog, select the **Commands** option, and drag-and-drop **Commands** from the desired **Categories**. You can further build your new toolbar using the **New Menu** option that enables you to create a drop-down menu on the toolbar.



Scoping Recovery following Geometry Update

The **Scoping Wizard** option is available on the Selection (p. 88) tab of the ribbon. This feature automatically detects any geometry-based scoping that becomes lost following a geometry update. Once identified, you use the options of the feature to visualize and reestablish the original scoping. You turn the feature on (default) and off using the **Use Geometry Based Associativity** (p. 227) preference (**Options** > **Geometry**) dialog. In addition to the activation preference, there is an associated preference (**Automatic Scoping Update** (p. 227)) to have the application automatically correct geometry-based scoping that becomes lost following a geometry update.



Go to a section topic:

- Overview (p. 148)
- Feature Options (p. 149)
  - Wizard Pane Actions (p. 150)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

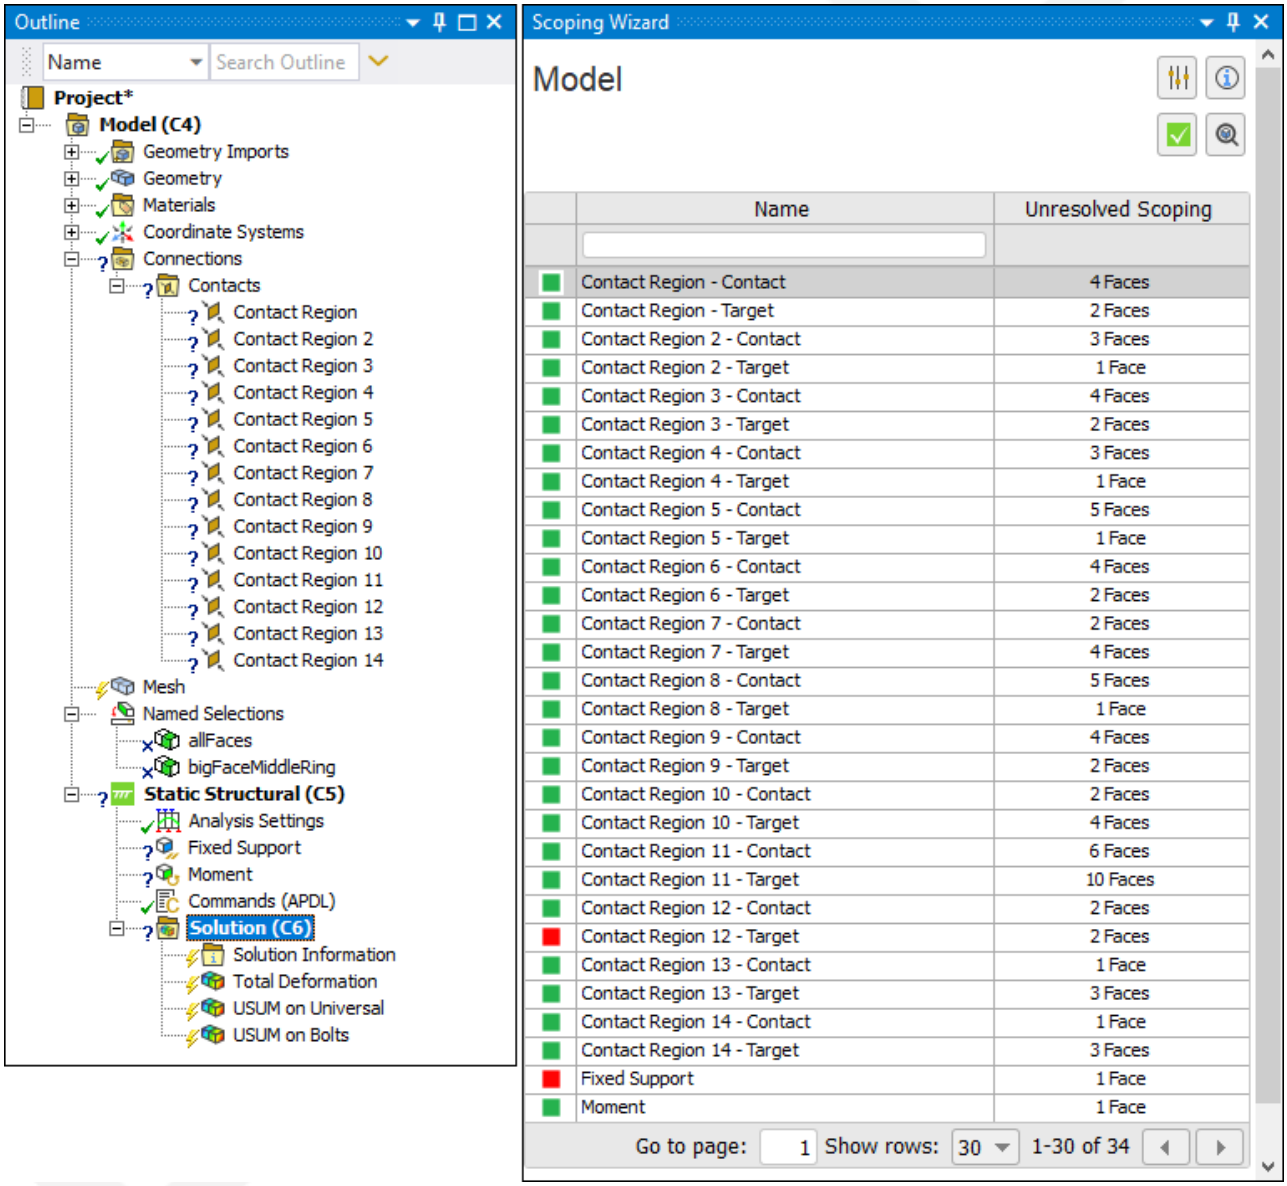
  - Context Menu Options (p. 150)
  - Color Codes and Annotations (p. 151)
- Display and Recovery Options (p. 152)

Overview

Selecting the ribbon option displays the **Scoping Wizard** worksheet pane, illustrated below, that lists all objects with unresolved scoping. Corresponding objects in the tree also display with an invalid state.

Important:

This feature does not recover mesh-based (node, element face, element) scoping.

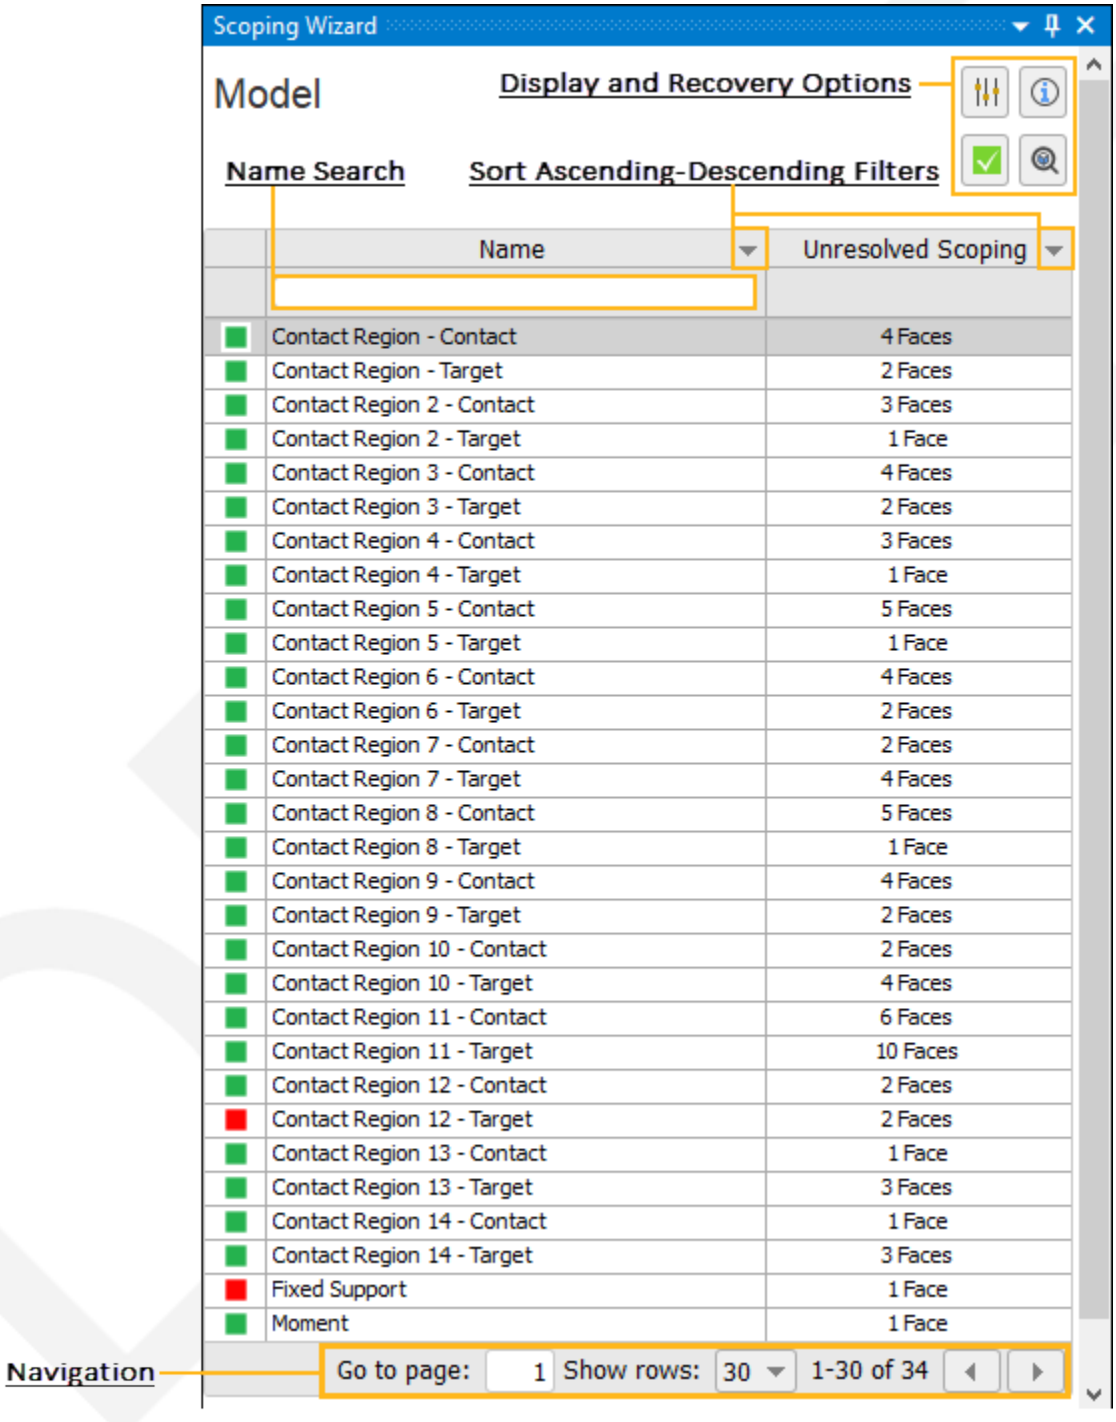


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Feature Options

The **Scoping Wizard** pane enables you to:

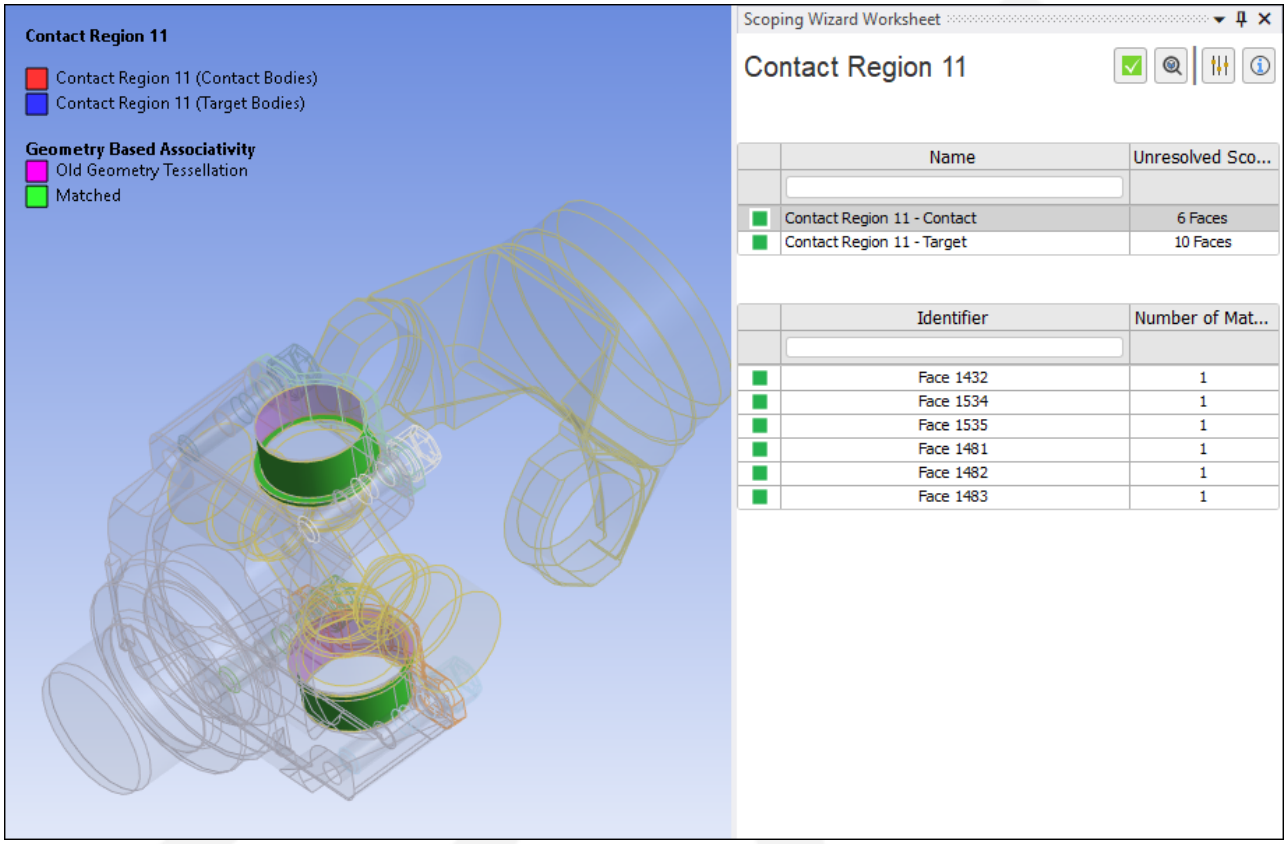
- Change display settings, fix scoping, show an information pane, and zoom on a scoping.
- View a list of unresolved objects.
- Filter the list based on object name or number of unresolved scopings (ascending/descending).
- Navigate through long lists of unresolved objects.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Wizard Pane Actions

If you double-click a table row, or select an unresolved object in the tree, the pane shows information specific to the object and its (unresolved) scoping. The following example shows a **Contact Region** that has lost scoping. The pane displays the object type/name (**Contact Region**), the number of unresolved geometric entities, whether the application identified a scoping match, and the original application-assigned ID for the entities. The first item in the worksheet is selected by default, and the parts are highlighted in the **Geometry** window.



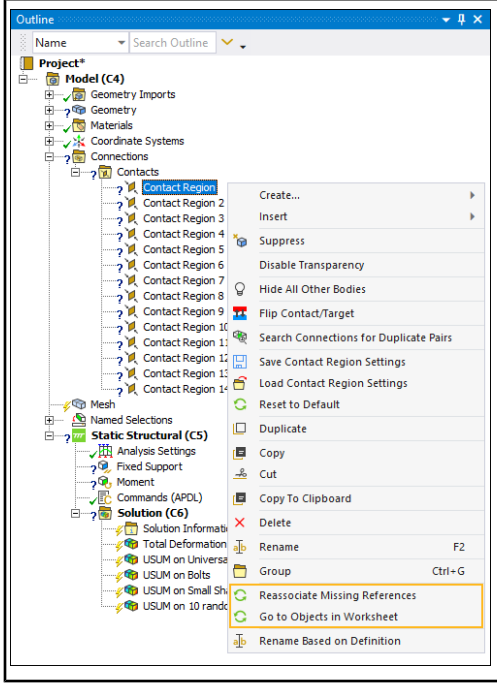
Context Menu Options

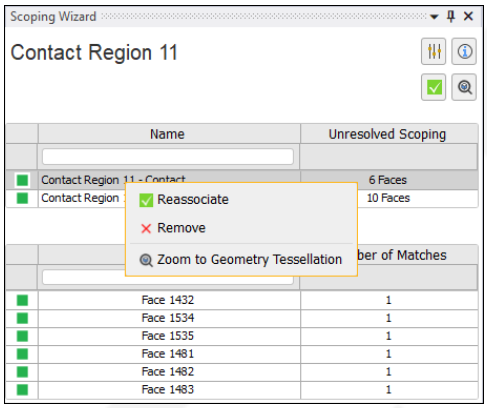
The feature also offers several context (right-click) menu options.

Outline Options	Worksheet Options
From the **Outline**, you can: • Reestablish the original scoping on individual objects using the **Reassociate Missing References** option • When the worksheet is not active/displayed, you can use the **Go to Objects in the Worksheet** option to open the worksheet and display information for the selected object.	Right-clicking on a row in the worksheet offers the following options: • **Reassociate**: Reestablish the original scoping. • **Remove**: Remove the row and its data from the worksheet. • **Zoom to Geometry Tessellation**: Zoom in on the body or part in the **Geometry** window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Outline Options	Worksheet Options
	




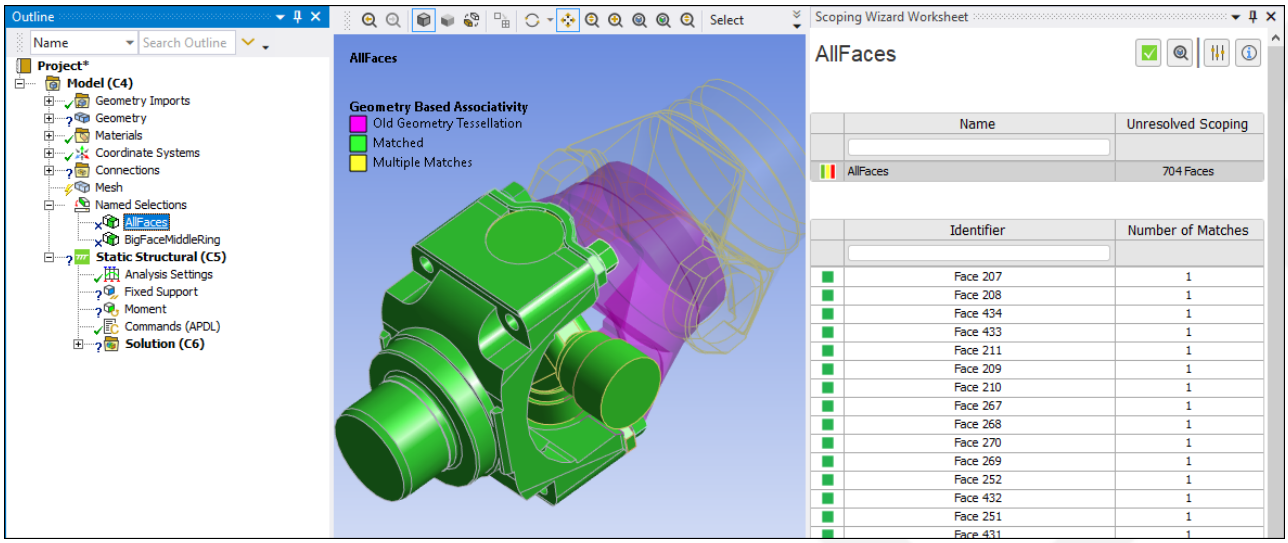
Note:

If you use the **Copy to Clipboard**/**Paste from Clipboard** options for an unresolved object, the associated data is copied and pasted between sessions and the application will automatically attempt to resolve any scoping.

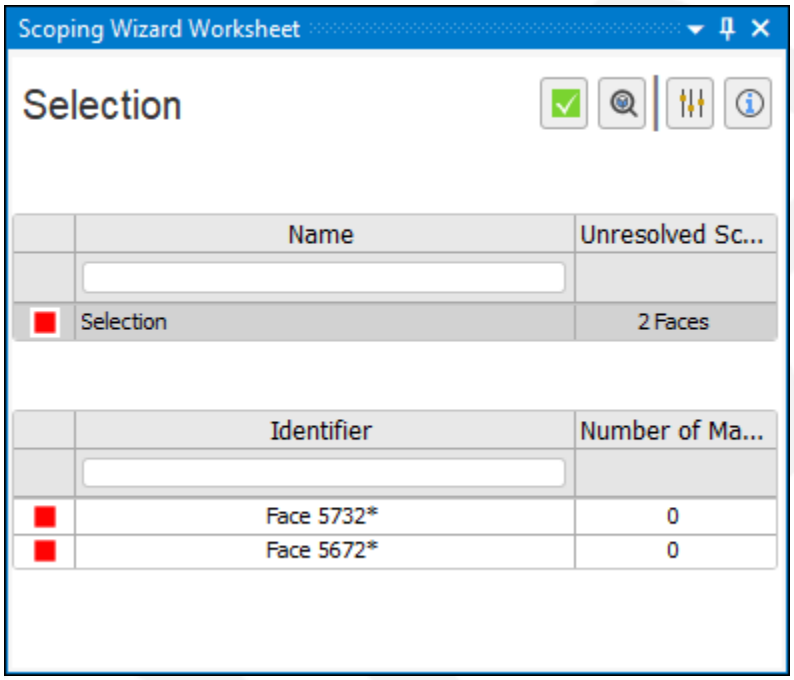
Color Codes and Annotations

The application displays reference annotations in the legend as well as highlights on the part(s) in the **Geometry** window, based on the state of the recovered reference. The application displays matched references display as green, multiple matches yellow, old geometry tessellation in purple, and if no match is available, the reference is drawn in red. Furthermore, the worksheet uses the color scheme to indicate if one or more of the conditions exists, such as the Named Selection, **AllFaces**, example shown in the table below that displays all three colors. See the Display and Recovery Options (p. 152) topic below for more information about annotations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



In addition, if a table entry appears with an asterisk, this indicates that the application could not find data associated with the reference. This can be the result of importing an older project, the use of virtual cells, or if you have turned the **Use Geometry Based Associativity** preference off.



Display and Recovery Options

At the top of the pane, there are options to take corrective action, zoom in on a geometry, or modify display settings, including:

Option	Description
Settings	Illustrated below, the **Settings** drop-down menu enables you to turn annotation display options on and off. This image shows the default display settings.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Option	Description
	 Options include: • **Bounding Box**: This option shows the bounding box of the old geometry tessellation for a selected item. Matched references are drawn in green, multiple matched references are drawn in yellow, and references that are not a match are drawn in red. • **Geometry Tessellation**: This option shows the full tessellation of the old geometry for a selected item. **Note:** The geometry tessellation references and the matched or multiple matched references display on top of one another and make it difficult to plainly see the old geometry tessellation. When the **Geometry** window is active, use the **[S]** key to turn off the display of matched or multiple matched references and only view the old geometry tessellation. • **Multiple Matches**: If the application determines that there are multiple potential matches, it highlights the original geometry as well as the new (multiple) geometries. For example, if two vertices in close proximity are potential matches, both will be highlighted as a Multiple Match. • **Matched**: The application determines that there is a new match for the original geometry selection. • **No Matches**: The application cannot determine a new match for the original geometry selection.
Information	This option displays a dialog that includes a description of the feature and its capabilities.
Fix All Scoping	This option automatically corrects all recovered scoping
Zoom to Geometry Tessellation	For the currently selected row in the wizard, or an object in the tree, this option zooms in on the body or part that the application has determined was associated with the original scoping.

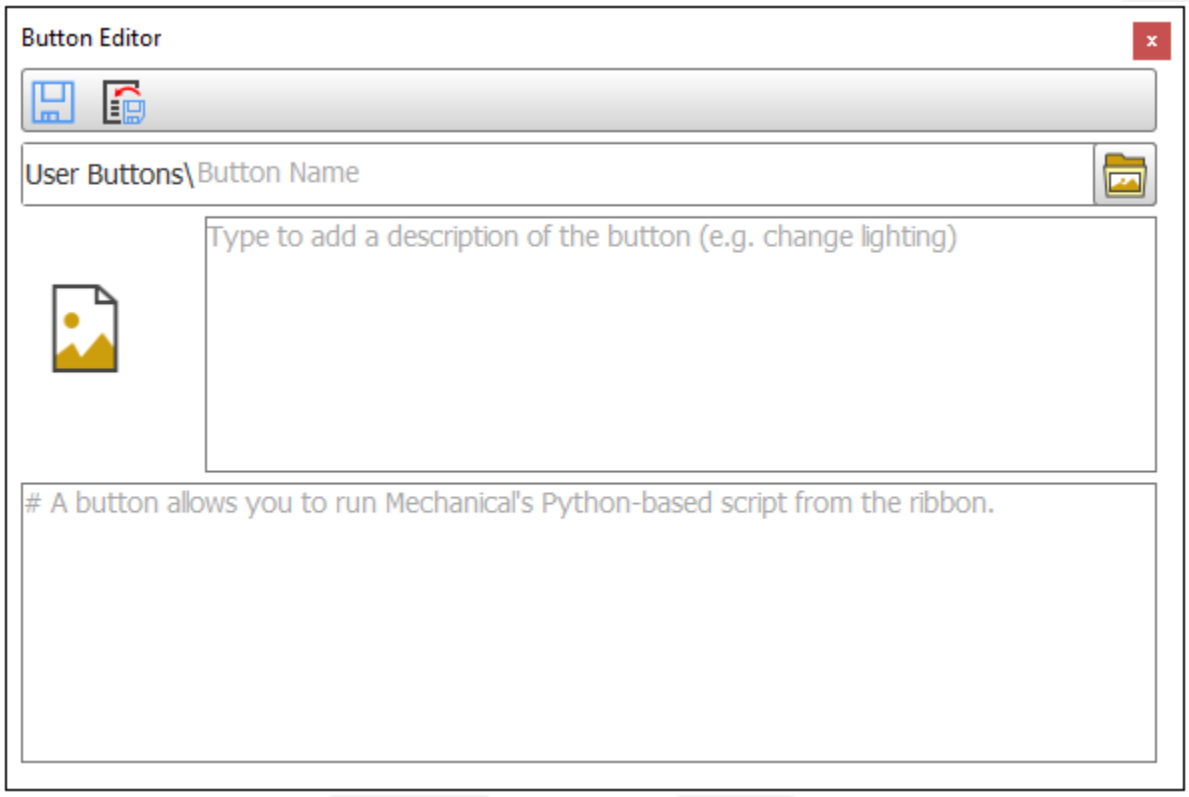
Published: 2023-10-23

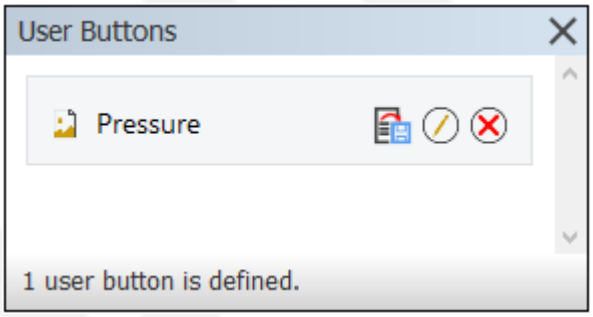
Creating User-Defined Buttons

The **User Buttons** group enables you to create, edit, manage, export and import, your own toolbar buttons. Selecting the **Manage** option opens the Button Editor.



This panel contains the following features and options:

- **Save**: This option saves button information and publishes it into the user group.
- **Import**: This option enables you to open and import an existing Python (`.py`) file that specifies a button. The content of the imported file populates the Button Editor dialog.
- **Name**: Enter a name (label) for the button.
- **Collection Editor**: The folder icon opens a panel that enables you to manage existing buttons. It contains option to edit, export, or delete the button.



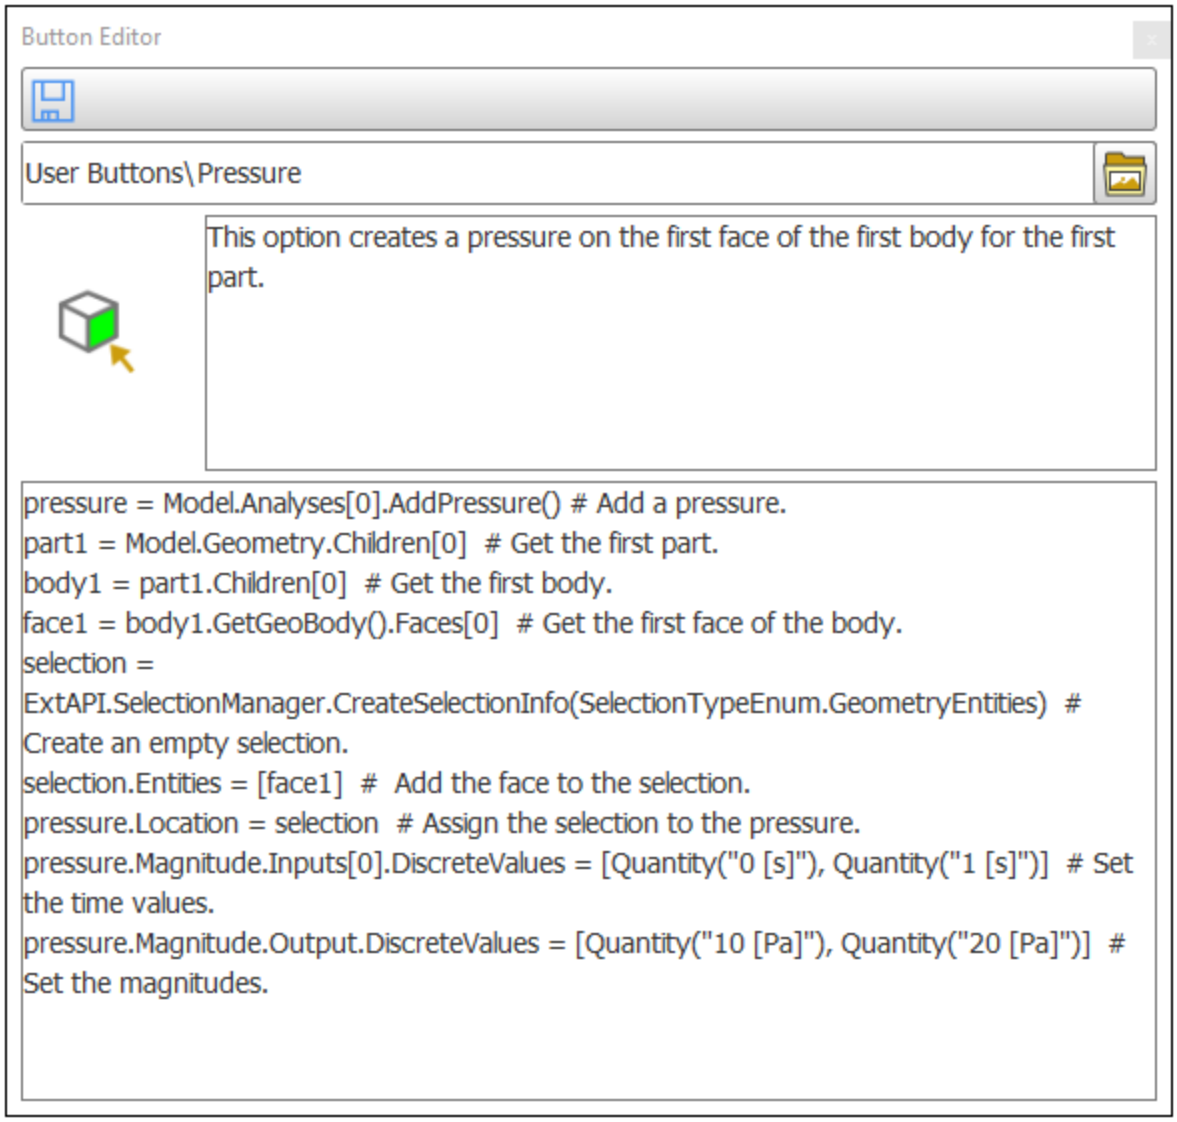
- **Image**: Select this icon to assign an image that to the button.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Description**: The description pane enables you to enter a description of what action the script performs - it is a tooltip.
- **Script**: You enter your python script into this pane.

Example

Here is an example to create of a Pressure load. You can find this example in the ACT Console.



The above example creates the following user-defined button.

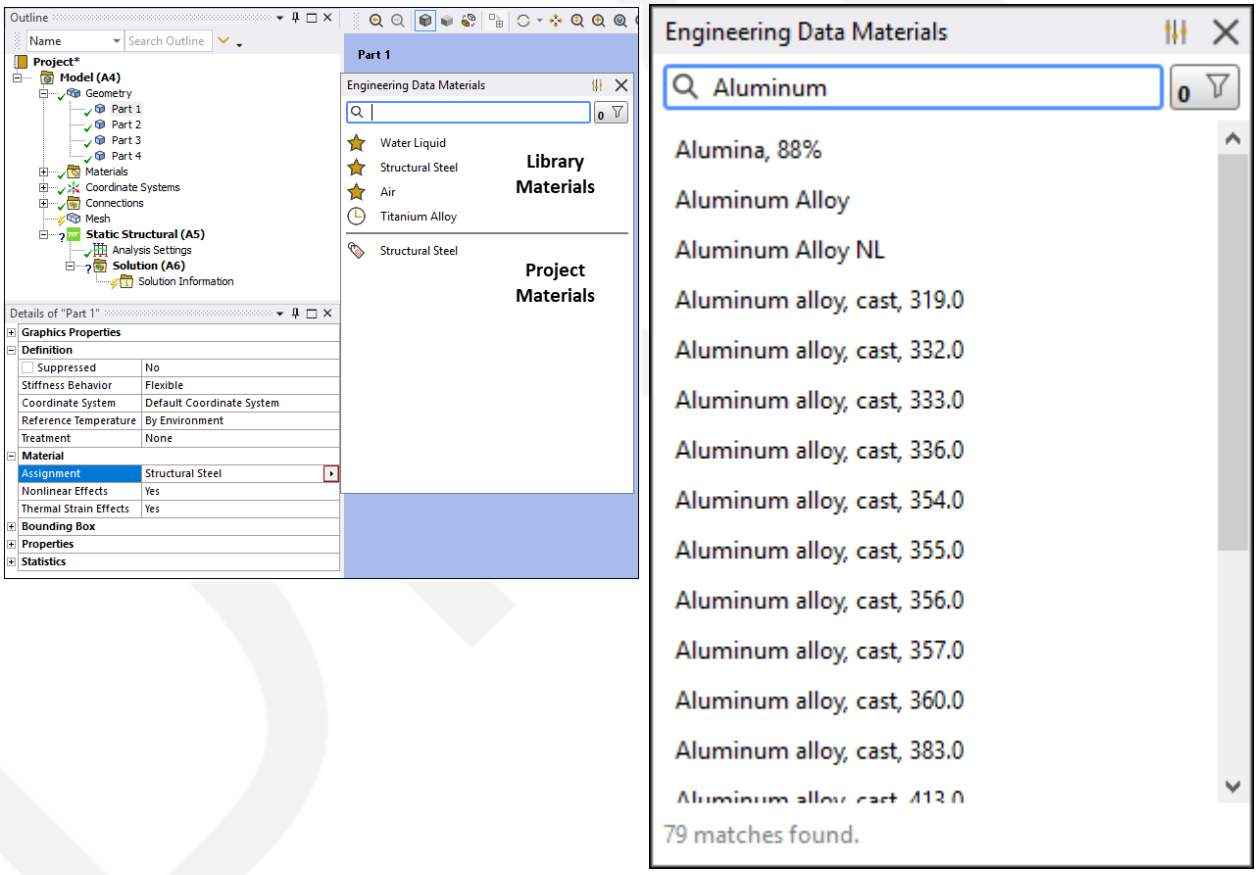
Engineering Data Material Window

The Engineering Data components of Mechanical enable Engineering Data information to be accessed and viewed within Mechanical. The available components include:

- Material Assignment (p. 156)
- Material Compare (p. 158)
- Material View (p. 165)

Material Assignment

The **Engineering Data Materials** pane is used to research and select material(s) to assign to specific application objects (p. 168) that require material assignment via the **Assignment** property. The pane can be accessed from the fly-out menu of the property. For example, as shown here, Parts (and/or Bodies) of the model require material assignment. By default, the pane lists favorites (star icon) and recent (clock icon) materials in the library portion of the pane, and project materials (material icon) from the Engineering Data workspace in the project portion of the pane. The search field (p. 159) can be used to find materials which match search criteria, in combination with filtering options (p. 159). A Material Card (p. 156) with common material properties can be viewed or used to access the complete material data to further assist in your search. When the desired material is found it can be selected for to assignment.

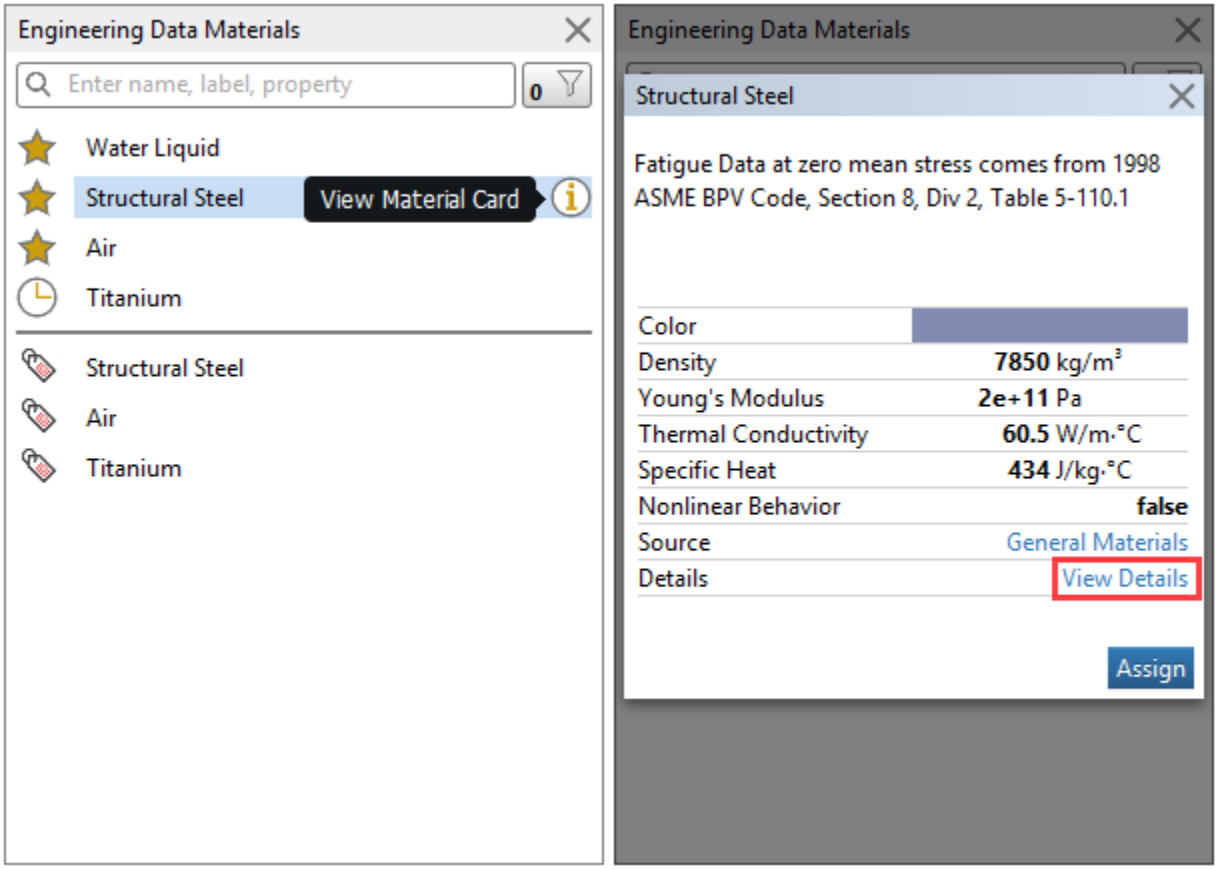


Material Card

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

As illustrated below, when you highlight a material in the fly-out menu, an information icon displays. Clicking this icon will display the material card. The material card displays common properties to provide a quick overview of the material. To view the complete details of the material, click **View Details**. If you are ready to assign the material to the selected object, click **Assign**. Selecting the **View Details** option displays the Material Assignment pane combined with the **Material View**.

Material Card



Material View

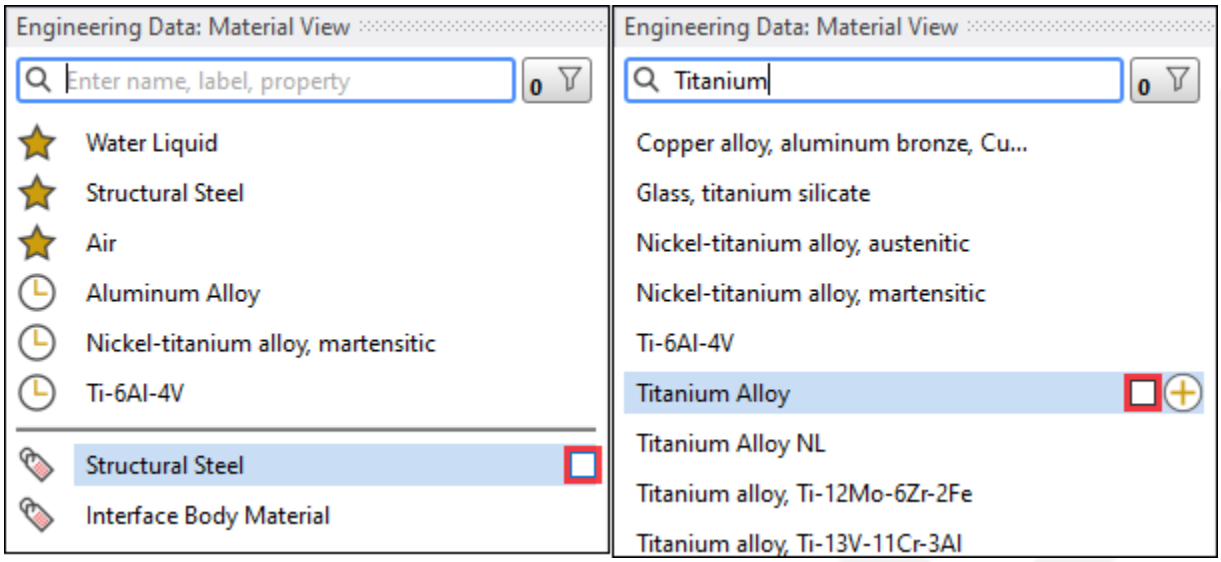
Comparing Materials

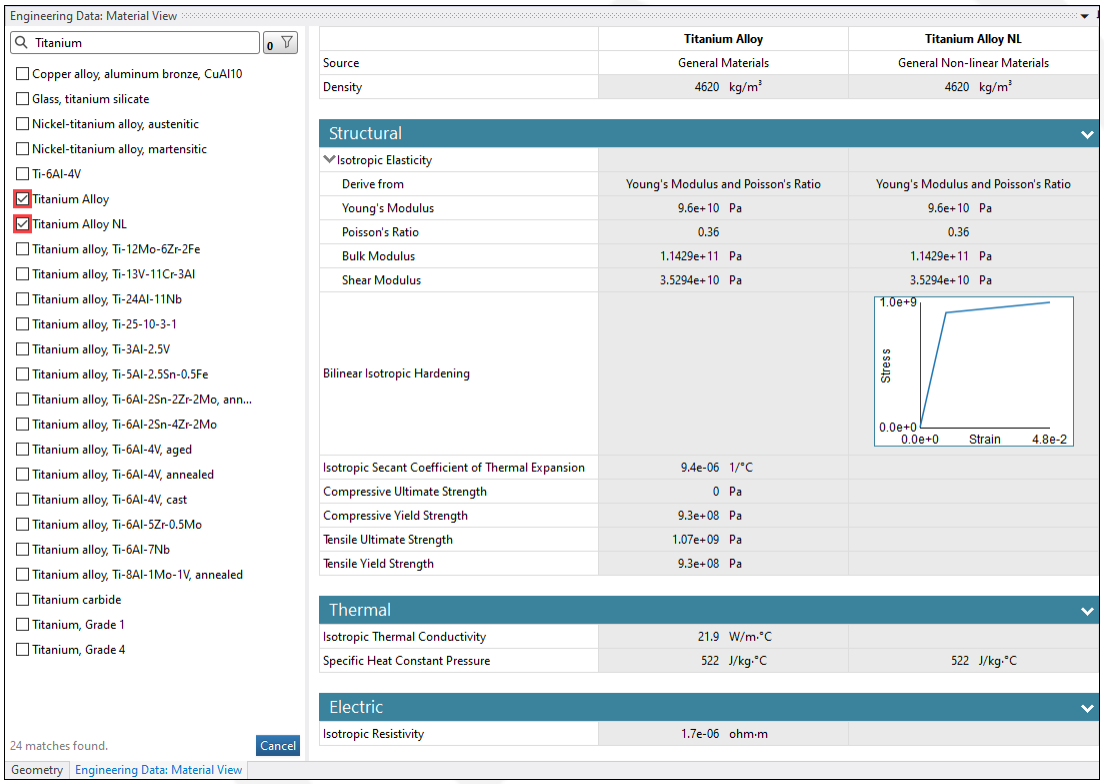
The materials added to your project, such as the default material Structural Steel, as well as the materials displayed when you perform a search, each provide a check box and a plus symbol when you hover the cursor over the material. The plus symbol (⊕) adds the material to the project.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



When you select a check box, or multiple check boxes, as show below, the application automatically displays material data to view and/or compare.



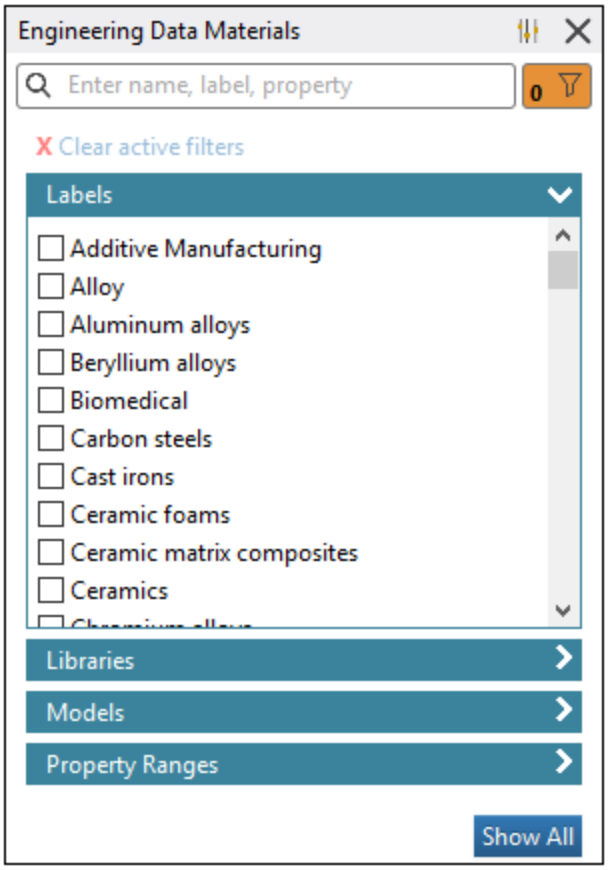
Search Field

The **Engineering Data Materials** panel provides the search field to enter filtering criteria. Each word in the field will be used to filter materials for selection (for example, criteria1 criteria2 criteria3). To return to the list of favorites, recent, and project materials; type the **[Backspace]** key in the empty field.

Filtering Options

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The **Engineering Data Materials** panel provides for additional filtering options by selecting the filter button (funnel icon). This displays the filtering options pane which allows selection of various filters.



On initial entry it is possible to show all the materials available to search by choosing **Show All**. Selections can be made in each of the criteria-based drop-down groups to narrow your search and then clicking on the **Search** button at the bottom of the panel. All criteria must be matched in a material for it to be returned in the search. Note that choices in the groups will be filtered as you select to avoid choosing invalid criteria. When available, clicking on **Clear active filters** will remove all filters.

Labels

The **Labels** group displays the labels attached to materials which correspond to industry-based categories for ease of selection. These same labels can be typed into the search field. Note that not all materials will be labeled.

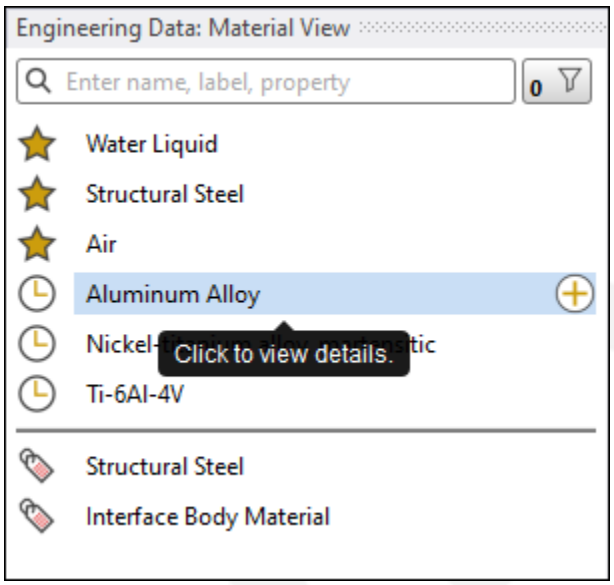
An option (**Click to view details.**) is also displays when you highlight a material in any of the material view panes.



Heading Components

Color Block

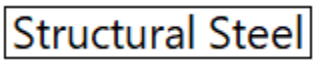
The color of the block indicates the color that will be used to display this material in a model. An imported material that doesn't have a color will be assigned a random color.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Name

The name of the material.



Edit

The edit (pencil) icon will navigate to the Engineering Data Workspace to allow data to be modified and/or parameterized. Once the edit is completed the material must be refreshed in Mechanical. The refresh can be accessed on the Materials group via right-click.

Label

The label tag will display the labels associated with a material when you hover to show the tooltip.

Library

The library icon will display the library that the material belongs to when you hover to show the tooltip.

Material Model Data

For each material, the window displays data for the material model. This data can be a value or charted data when there are field variables (S-N Curve). For variable data, you can select the graph to display additional data, such as the associated tabular data. The various material data is organized by physics type. Collapsible headings for Structural, Thermal, Electric, and Magnetic are common physics types.

Objects Supporting Material Assignment

The following objects support material assignment:

- Analysis Ply
- Beam Connection
- Bearing
- Contact Region
- Delamination
- Joint
- Load Conditions
- Parts and Bodies
- Point Mass
- Remote Point
- Spring
- Surface Coating

Windows Management

The Mechanical interface contains window panes that house graphics, outlines, tables, object details, and other views and controls. Window management features allow you to move, resize, tab-dock, and auto-hide window panes. A window pane that is "tab-docked" is collapsed and displayed at the side of the application interface. Auto-hide indicates that a window pane (or tab-docked group of panes) automatically collapses when not in use.

Auto-Hiding

Panes are either pinned or unpinned. Toggle this state by clicking the icon in the pane title bar. A pinned pane occupies space in the window. An unpinned pane collapses to a tab on the periphery of the window when inactive.

Published: 2023-10-23

To examine an unpinned pane, move the mouse pointer over the tab. This causes the pane to open on top of any other open window panes. Holding the mouse pointer over the tab keeps the tab visible. Clicking the tab activates the window pane (also causing it to remain visible). Pin the pane to restore it to its open state.

Moving and Docking

Drag a window's title bar to move and undock a window pane. Once you begin to drag the window, a number of dock targets (blue-filled arrows and circle) appear in the interface window. At this point you:

1. Move the mouse pointer over a target to preview the resulting location for the pane. Arrow targets indicate adjacent locations; a circular target enables tab-docking of two or more panes (to share screen space).
2. Release the button on the target to move the pane. You can abort the drag operation by pressing the **ESC** key.

Tip:

You can also double-click a window's title bar to undock the window and move it freely around the screen. Once undocked, you can resize the window by dragging its borders/corners.

Restore Original Window Layout

Select the **Reset Layout** option in the **Layout** group (p. 47) on the **Home** tab to return to the default/original pane configuration.

Preference Migration

The first time you run Ansys Workbench following the installation of a new version of the software, the application automatically migrates your user preferences to the new version. This includes preferences such as licensing settings, **Options** (p. 217) settings, solver preferences, user created buttons, Key Assignments, and Engineering Data settings.

To migrate preferences, the application creates a text file (`MigratePreferences.txt`) in the following directory:

Windows: C:\Users\John_Doe\AppData\Roaming\Ansys\<new_version>

Linux: ~/.ansys/<new_version>

If this file does not exist, the application migrates your preferences. Once the application has generated this text file, the migration no longer runs.

Turn Automatic Migration Off

You can turn migration off by:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Creating an empty file called %APPDATA%/Ansys/v<new_version>/MigratePreferences.txt before the first run.

  Or...

- Starting Workbench with (Target property) "RunWB2.exe -K Framework.MigratePreferences=off"

Remove Migrated Preference Data

You can remove the migrated user preference data by emptying the %APPDATA%/Ansys/v<new_version> directory and creating the empty file %APPDATA%/Ansys/v<new_version>/MigratePreferences.txt. Make sure that no Ansys product is running during this action.

Resource Prediction

The **Resource Prediction** option (**Home** Tab/**Solve** Group) displays a window that enables you to select an analysis and predict the computing resources needed to perform a solution for the environment. The application displays a prediction for time, memory, and disk space requirements. The prediction is displayed in green at the top of the page. When initiated, the progress of the calculation is displayed in the left corner of the Status Bar (p. 135). The progress bar includes a stop button to end the process.

Note:

- A successful prediction does not guarantee a successful solution.
- This feature presents estimates based on simulations with similar characteristics and should only be used as a reference. Your actual simulation may not solve as suggested.
- The prediction applies to the solution using distributed-memory parallel (DMP) processing.

Go to a section topic:

- Requirements and Limitations (p. 170)
- Static Structural Analysis Prediction (p. 171)
- Modal (stand-alone only) Analysis Prediction (p. 171)
- Resource Prediction under Solution Output (p. 172)

Requirements and Limitations

Review the following requirements and limitations:

- The mesh must be generated.
- Supports linear Static Structural and Modal (stand-alone) systems only.
- The resources predicted are the computational resources needed to perform one step.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- This feature is not supported on the Linux platform.

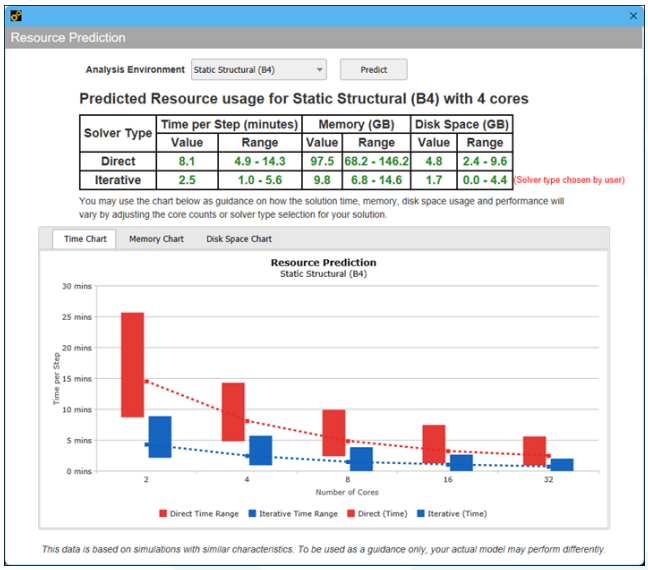
Static Structural Analysis Prediction

By default, a prediction is automatically performed for both the **Direct** and **Iterative** solver settings. The prediction display, as illustrated below, includes red text in parenthesis beside the option specified in the **Solver Type** property. If the **Solver Type** property is set to **Program Controlled**, then the red text indicates the option selected by the application.

Note:

Resource prediction using the iterative solver setting assumes convergence and it does not consider any impact if the solver setting switches from the iterative solver to the direct solver.

Time Chart Static Structural Analysis

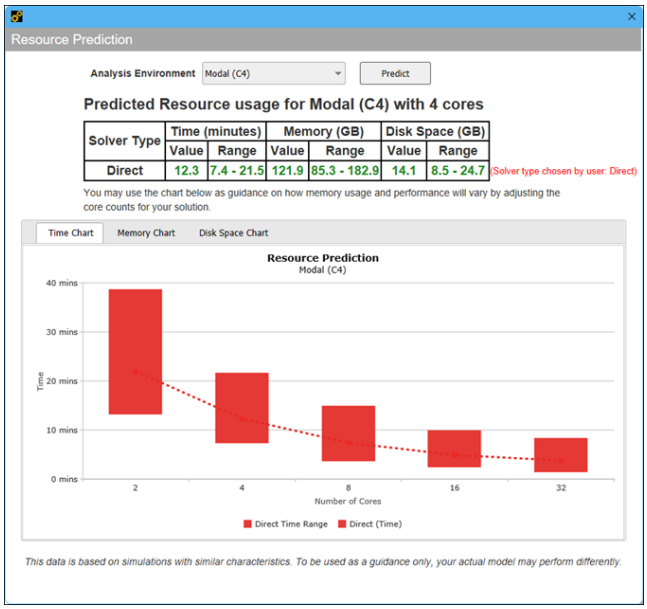


Modal (Stand-Alone Only) Analysis Prediction

A stand-alone Modal analysis supports resource prediction using the **Direct** setting for the **Solver Type** property only, either setting the option manually or through the use of the **Program Controlled** option.

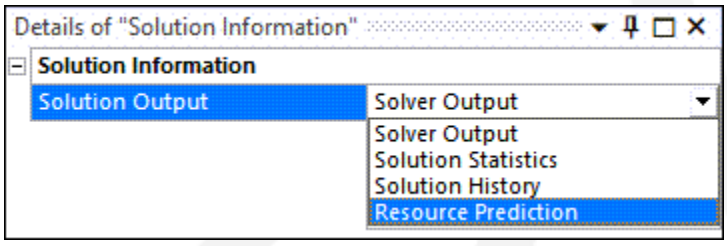
Time Chart for Modal Analysis

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Resource Prediction under Solution Output

The **Solution Output** property of the Solution Information (p. 1833) object provides a **Resource Prediction** option. When you write an input file or preform a solution, use this option to display resource predicted values in the Worksheet.

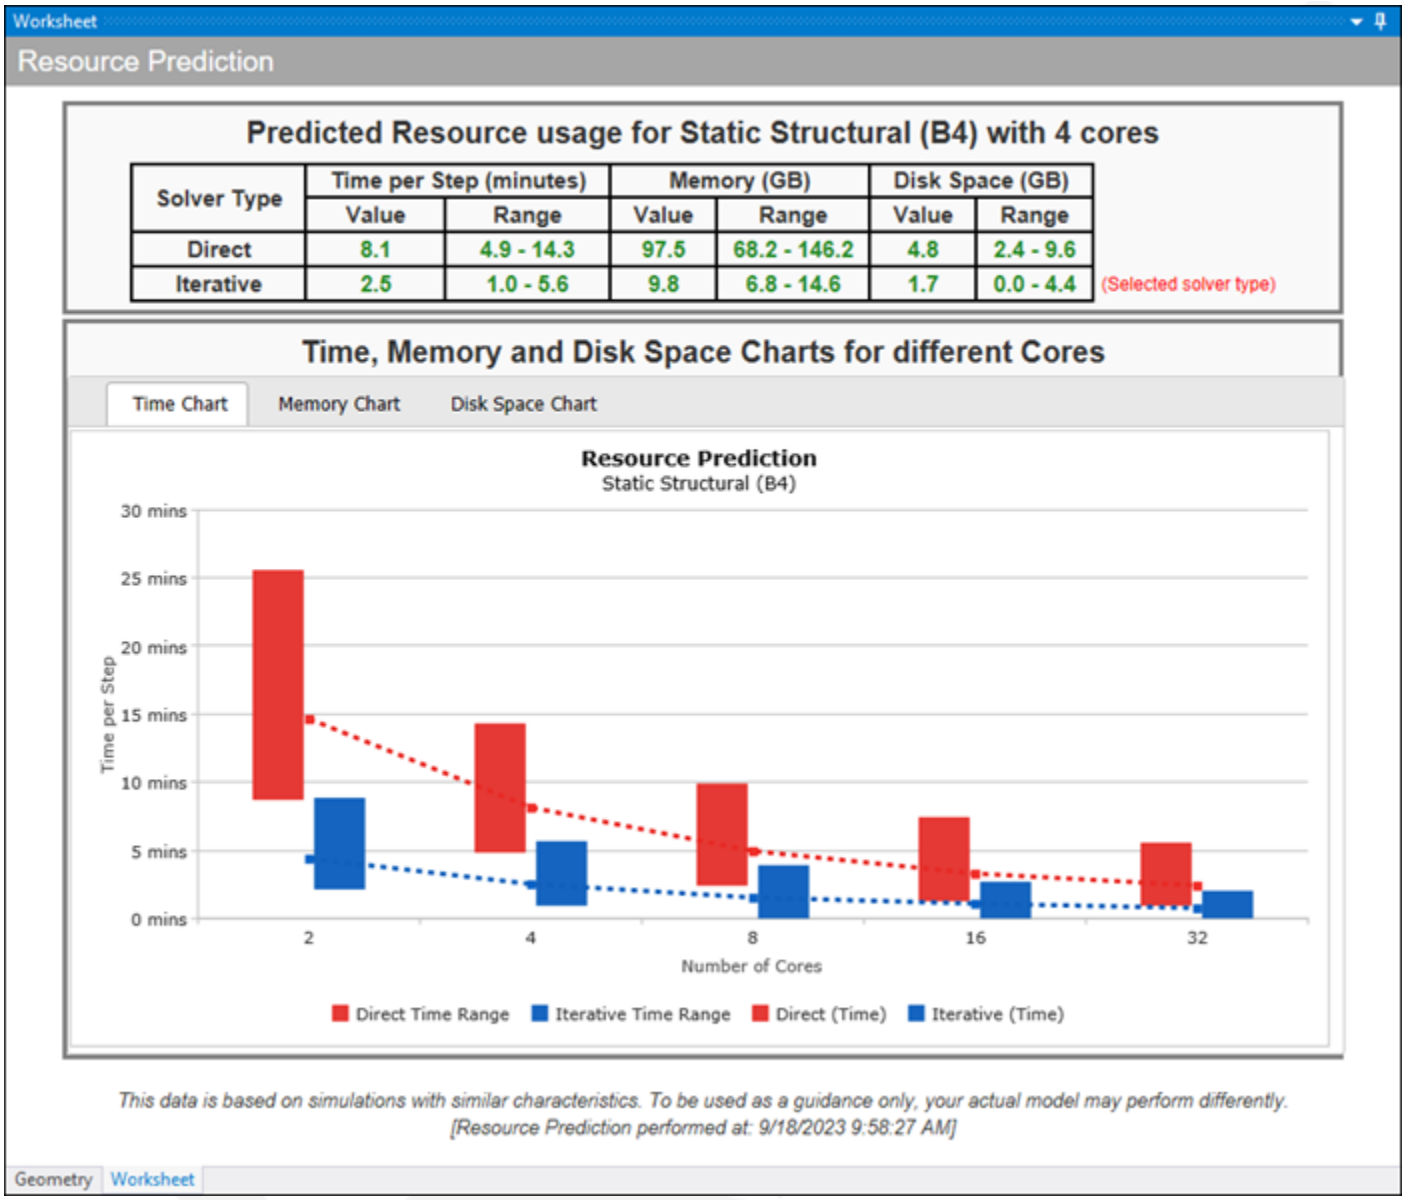


This option displays the following information:

- Predicted computational resources for the core count you specify, up to 32 cores.
- Time, Memory, and Disk Space charts that display how resources vary per core count.
- As applicable, suggestions as per predicted values.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

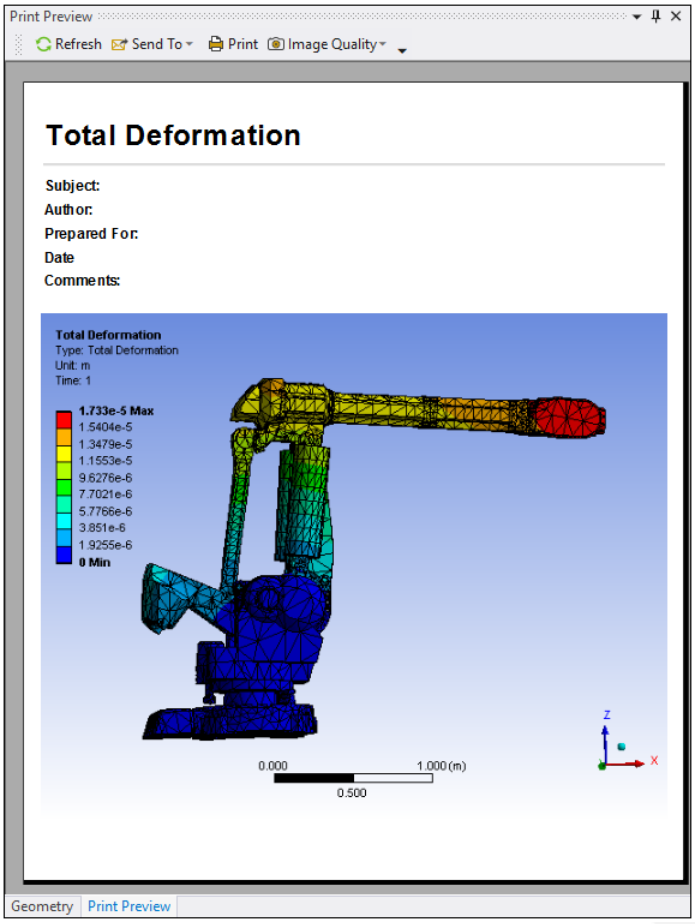
This feature only supports:

- Linear solutions for Static Structural analyses.
- Modal analyses for the **Direct Solver** setting of the **Solver Type** property (**Analysis Settings** > Solver Controls (p. 1428)), including when the **Program Controlled** setting selects **Direct Solver**.

Print Preview

The **Print Preview** option, selected from the **Tools** (p. 45) group on the **Home** tab, runs a script to generate an HTML page and an image for a selected object, such as the Deformation result shown below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The title block is an editable HTML table. The table initially contains the **Author**, **Subject**, **Prepared For** and **Date** information supplied from the Details of the **Project** tree node. To change or add this information, double-click inside the table. The information entered in the table does not propagate any changes back to the details view and is not saved after exiting the **Print Preview** tab.

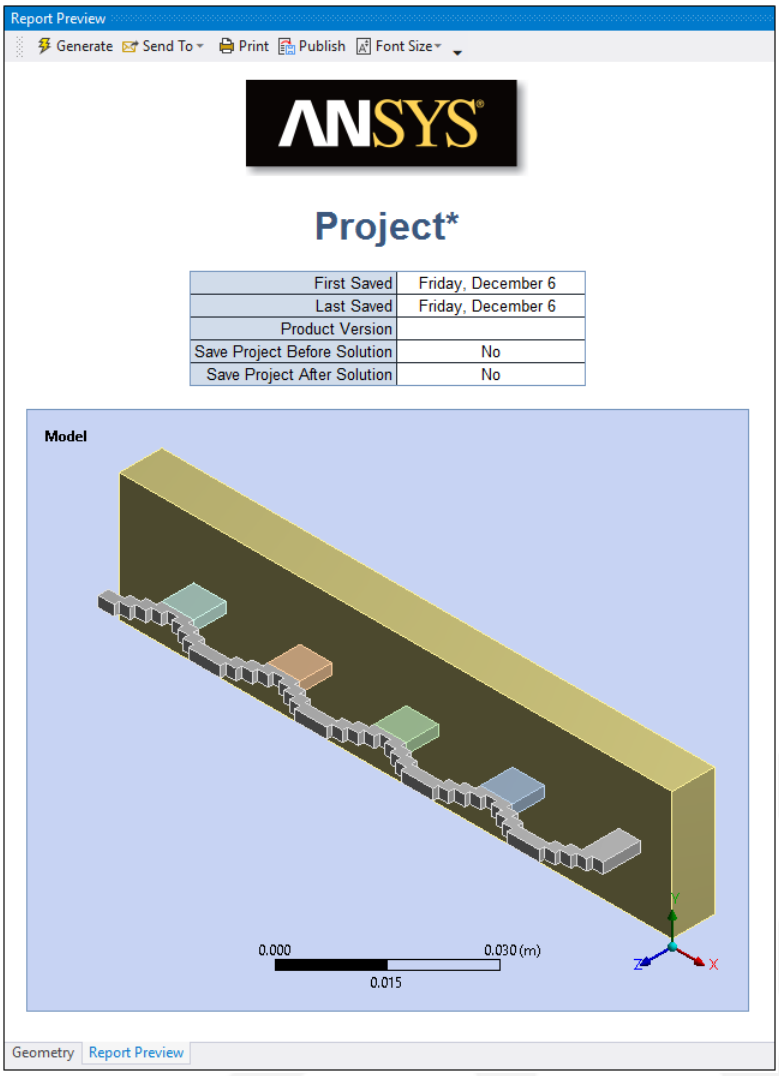
The image is generated in the same way as figures in **Report Preview**. The new **Print Preview** copies all current view settings, including those defined in the Options (p. 217), such as the **Font Magnification Factor**.

Report Preview

The **Report Preview** option, selected from the **Tools** (p. 45) group on the **Home** tab, enables you to create a report based on the analyses in the **Outline**. This report selects items in the **Outline**, examines the worksheets for it, then appends any material data used in the analysis. The report generation process starts immediately, and, once started, it must run to completion before you can begin working in the interface again.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



The generation process of the feature starts as soon as you select the option. Unlike prior report generators, this system works by extracting information from the user interface. It first selects each item in the **Outline**, then examines worksheets in a second pass, and finally appends any material data used in the analysis. The material data will be expressed in the Workbench standard unit system which most closely matches Mechanical's unit system. Once started the report generation process must run to completion. Avoid clicking anywhere else in Workbench during the run because this will stop the report process and may cause an error. This approach to reporting ensures consistency, completeness, and accuracy.

Important:

When running multiple Mechanical sessions, the application automatically overwrites any existing files (MHT, HTML, Word, or PPT) if you generate report outputs without first managing them with the Publish feature or by copying files to a new location.

Note:

Not all **Report Preview** options are available on the Linux platform.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

In addition to the Tables (p. 176) and Figures (p. 176) topics described below, this section examines:

Publishing the Report

Sending the Report

Comparing Databases

Customizing Report Content

Tables

Most tables in the report directly correspond to the **Details** of an object or set of related objects. **Object** names appear across the top of the tables.

By default, tables displays 12 columns. This setting increases the likelihood that tables will fit on the screen and on printed pages. In the **Report Options** (p. 237) dialog you can increase or decrease the setting for the number of columns you wish to display by default. For example, you may allow more columns if object names take up little space, if you have a high resolution screen, or print in landscape layout. The minimum is two columns, in which case no grouping of objects occurs and the Contents is equivalent to the **Outline**.

The system merges identical table cells by default. This reduces clutter and helps to reveal patterns. You can disable this feature in the **Report Options** (p. 237) dialog.

Note:

The **Report Preview** feature does not display table entries from the nonlinear joint stiffness matrix.

Figures and Images

Figures and Images appear in the report as specified in the **Outline**. The system automatically inserts charts as needed. The system creates all bitmap files in PNG format.

You may change the size of charts and figures in the **Report** (p. 237) preference in the default **Options** (p. 217) settings. For example, you may specify smaller charts due to few data points or bigger figures if you plan to print on large paper. For best print quality, increase the **Graphics Resolution** in the **Report** (p. 237) preference. In addition, you can increase legend font sizes using the **Font Magnification Factor** option under the **Graphics Options** (p. 228) preference.

Publishing the Report

Click the **Publish** option to save your report as a single HTML file that includes the picture files in a given folder, or as an HTML file with a folder containing picture files. The first option produces a single MHT file containing the HTML and pictures. MHT is the same format used by Internet Explorer when a page is saved as a "Web Archive". Only Internet Explorer 5.5 or later on Windows supports MHT. For the other two options, the HTML file is valid XHTML 1.0 Transitional.

Full support for MHT file format by any other browser cannot be guaranteed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Sending the Report

The **Send To** feature enables you to publish your report as:

- An email attachment. This option attaches a single MHT file automatically to your email application.

  Some email systems may strip or filter MHT files from incoming messages. If this occurs, email a ZIP archive of a published report or email the report from Microsoft Word.

- A Word document. This format is equivalent to opening a published HTML file in the application.

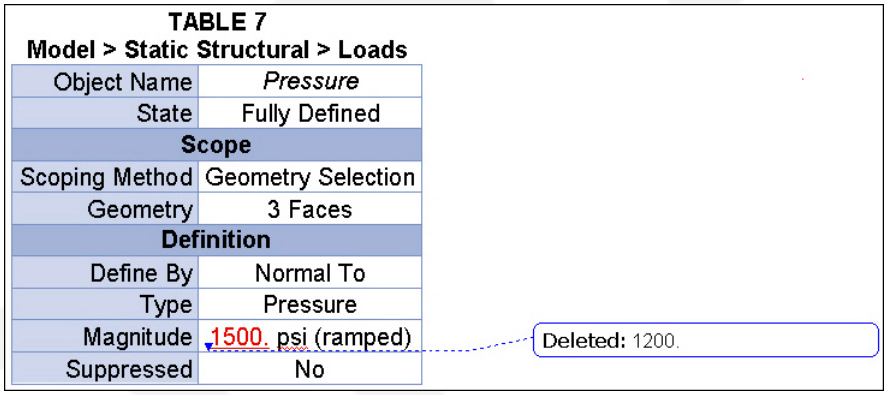
- A PowerPoint presentation (images only). A presentation is automatically created and includes the images (one per slide) of your analysis. It includes no other report information.

Note:

If you have multiple Mechanical sessions open, the application overwrites any reports that you have produced in the above formats if do not manage the reports with the **Publish** feature or by copying the files to a different location.

Comparing Databases

Because the report content directly corresponds to the user interface, it is easy to determine exactly how two databases differ. Generate a report for the first database, open it in Word, save and exit. Open the report for the second database in Word and choose **Compare Documents**. In the dialog, clear the **Find Formatting** box and select the first file. Word highlights the differences, as illustrated here:



Customizing Report Content

Report customization falls into two categories: preferences in the **Report Options** (p. 237) dialog and the ability to run a modified report generator from a local or network location. This ability to externalize the system is shared by the Mechanical Wizard (p. 321). It allows for modifications outside of the installation folder and reuse of a customized system by multiple users.

To run report externally:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

1. Copy the following folder to a different location: `Program Files\ANSYS Inc\v241\aisol\DesignSpace\DSPages\Language\en-us\Report2006`.
2. Specify the location under **Custom Report Generator Folder** in the **Report Options** (p. 237) (for example: \\server\copied_Report2006_folder).

The easiest customization is to simply replace `Logo.png`. The system uses that image on the wait screen and on the report cover page.

The file `Template.xml` provides the report skeleton. Editing this file allows:

- Reformatting of the report by changing the CSS style rules.
- Addition of standard content at specific points inside the report body. This includes anything supported by XHTML, including images and tables.

The file `Rules.xml` contains editable configuration information:

- Standard files to include and publish with reports. The first is always the logo; other files could be listed as the images used for custom XHTML content.
- Rules for excluding or bolding objects in the **Contents**.
- Rules for applying headings when objects are encountered.
- Selective exclusion of an object's details. For example, part Color (extracted as a single number) isn't meaningful in a report.
- Exclusion of **Graph** figures for certain objects. This overrides the other four criteria used to decide if a **Graph** figure is meaningful.
- Rules against comparing certain types of objects.
- Object states that are acceptable in a "finalized" report.
- Search and replace of **Details** text. For example, the report switches "Click to Change" to "Defined". This capability allows for the use of custom terminology.
- Insertion of custom XHTML content based on object, analysis and physics types, and whether the content applies to the details table, the chart or the tabular data. For example, report includes a paragraph describing the modal analysis bar chart.

All files in the `Report2006` folder contain comments detailing customization techniques.

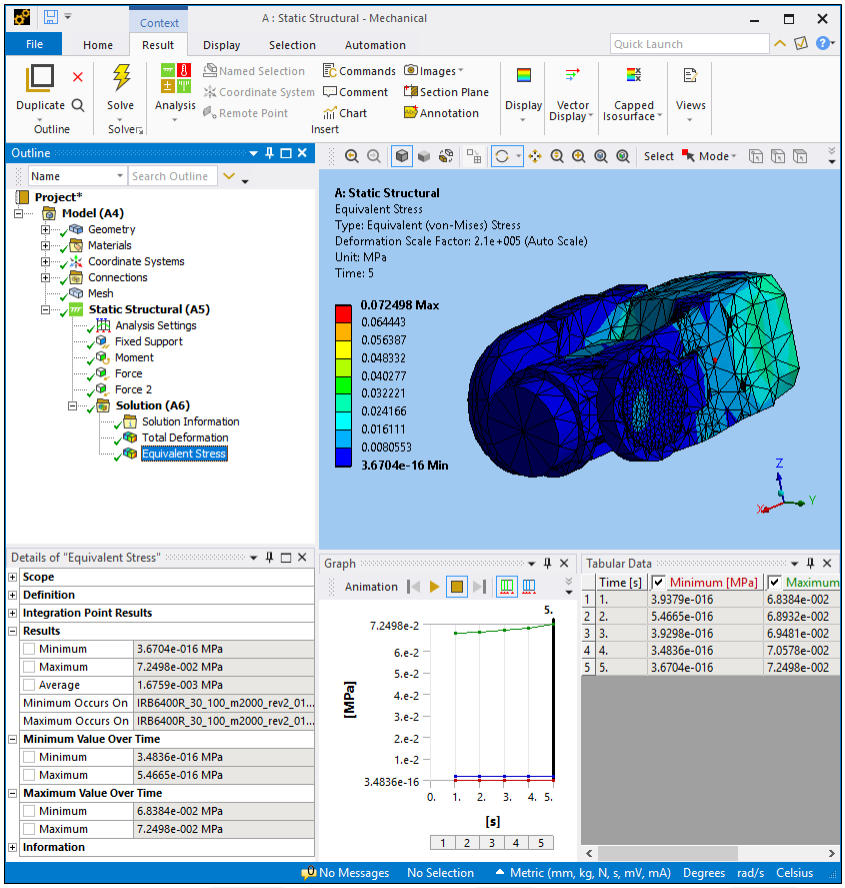
Full Screen Mode

The illustrations below depict the default layout of Mechanical as well as the full screen mode used to view/present your analysis. You activate full screen mode by selecting the **Full Screen** option from the **Layout** (p. 47) group on the **Home** tab. Or, you can use the **F11** key when the **Geometry** window, the tree **Outline**, or the **Details** view have focus. The tab option and the **F11** key toggle the display on and/or off.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When using this mode, the presentation inherits the active selection tool. For example, if you had the **Body** selection option active, it continues to be active in full screen mode. This includes other options such as **Wireframe** and **Show Mesh**. Based on the active selection filter, you can affect the model as desired. In addition, when in the full screen mode, you may find it useful to use the available keyboard shortcuts (Key Assignments (p. 314)). These options enable you to quickly change the selection options.



By default, full screen mode maximizes the display based on the largest resolution available for your computer monitor. This is useful when you if you want to maximize the display for a model when you have a smaller screen, such as laptop.

The tree **Outline** panel displays by default while presenting your analysis. You can use the Hotkey combination **Ctrl**+**O** to toggle the **Outline** on and off. You can also use the Hotkey combination **Ctrl**+**D** to toggle the **Details** view on and off.

Contextual Windows

Mechanical provides a number of feature-based windows. This section discusses the following:

Selection Information Window

Worksheet Window

Graph and Tabular Data Windows

Messages Window

Graphics Annotations Window

Section Planes Window

Mechanical Wizard Window

Selection Information Window

The **Selection Information** window provides a quick and easy way for you to interrogate and find geometric information on items that you have selected on the model.

The following topics are covered in this section:

Activating the Selection Information Window

Understanding the Selection Modes

Using the Selection Information Window

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

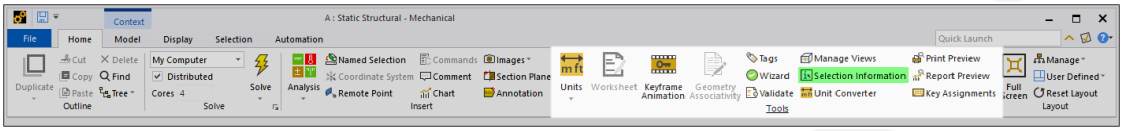
Published: 2023-10-23

Selecting, Exporting, and Sorting Data

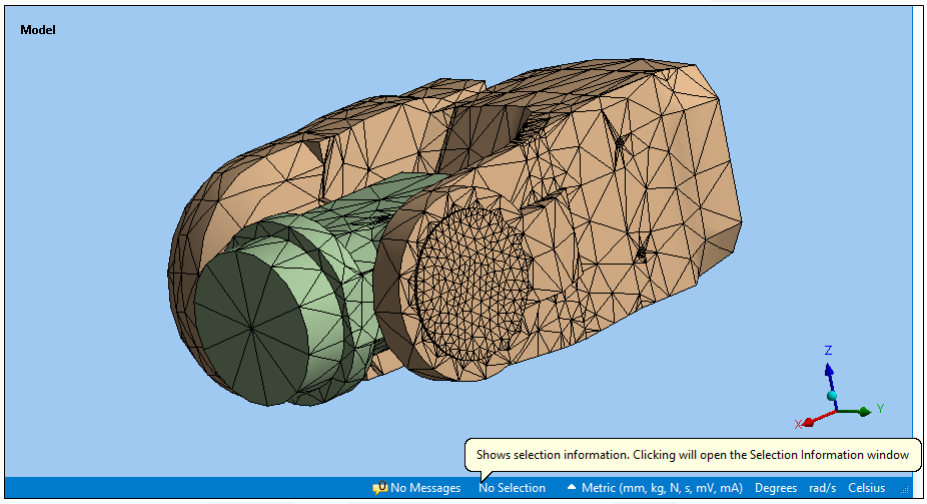
Activating the Selection Information Window

You can display the **Selection Information** window using any of the following methods:

- Select the **Selection Information** option in the **Tools** (p. 45) group on the **Home** tab (p. 40).



- Double-click the field on the status bar that displays the Selection field.



Understanding the Selection Modes

The supported selection modes are vertex, edge, face, body, node, and coordinate, as described below. Common reported information for each mode, except coordinate, includes x, y, z locations and if two selections are made, the distance between their centroids is reported.

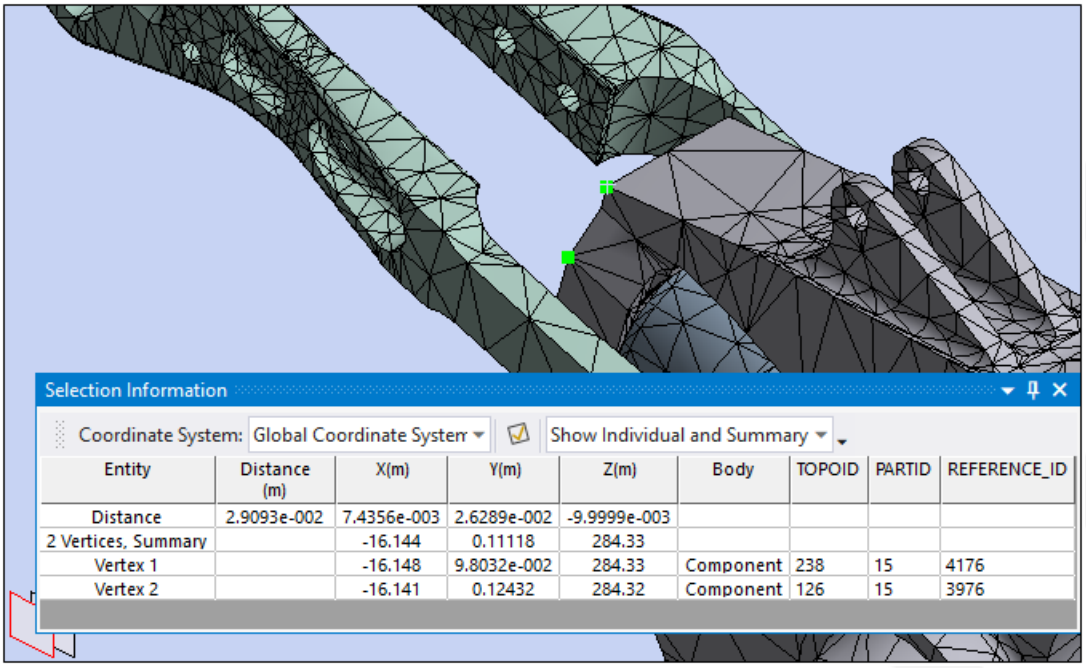
Note:

Selection Information may not be available for virtual entities.

Vertex

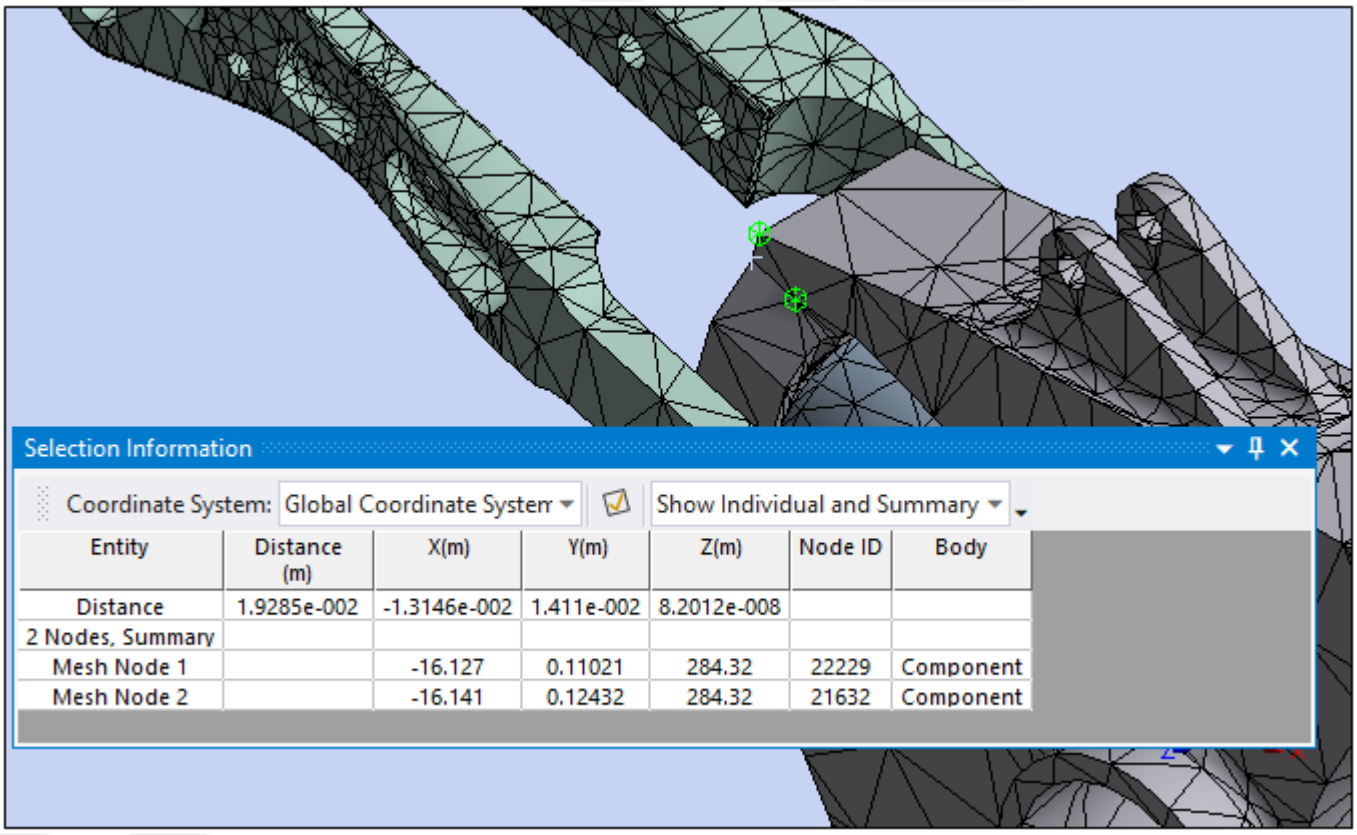
Individual vertex location and average location are reported. The bodies that the vertex attaches to are also reported.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Node

The information displayed for selected nodes is similar to a vertex with the addition of the Node ID.

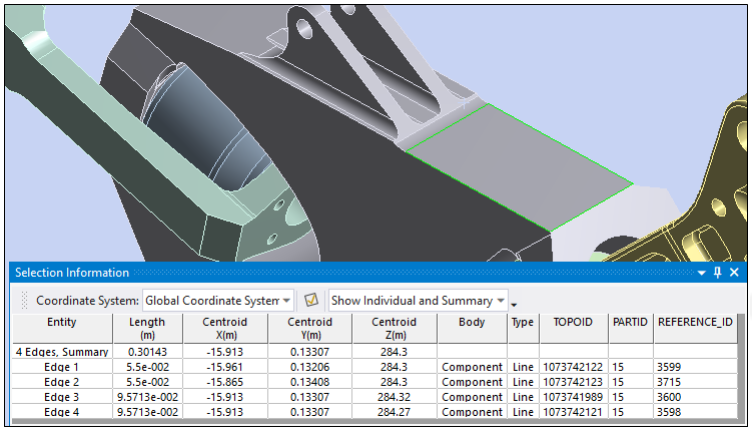


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Edge

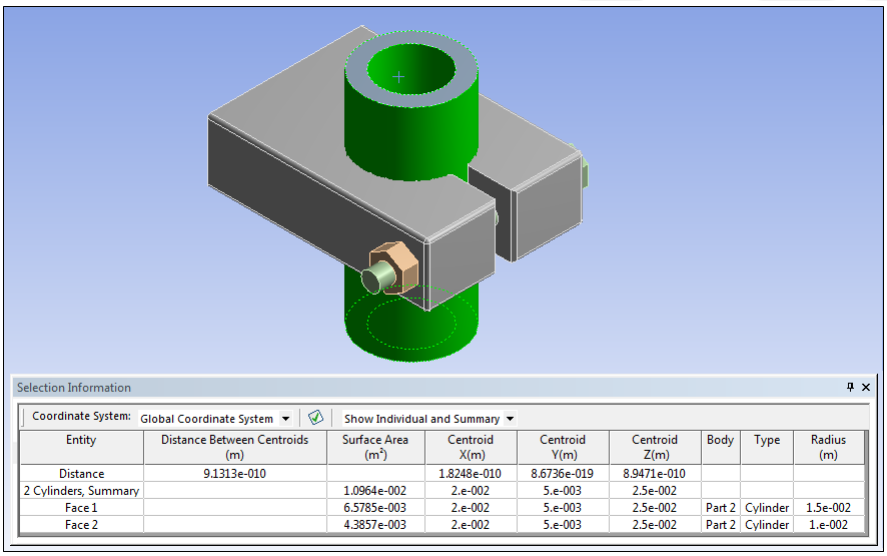
Combined and individual edge length and centroid are reported. The bodies that the edge attaches to are reported. The type of the edge is also reported. If an edge is of circle type, the radius of the edge is reported.



Entity	Length (m)	Centroid X(m)	Centroid Y(m)	Centroid Z(m)	Body	Type	TOPOID	PARTID	REFERENCE_ID
4 Edges, Summary	0.30143	-15.913	0.13307	284.3					
Edge 1	5.5e-002	-15.961	0.13206	284.3	Component	Line	1073742122	15	3599
Edge 2	5.5e-002	-15.865	0.13408	284.3	Component	Line	1073742123	15	3715
Edge 3	9.5713e-002	-15.913	0.13307	284.32	Component	Line	1073741989	15	3600
Edge 4	9.5713e-002	-15.913	0.13307	284.27	Component	Line	1073742121	15	3598

Face

Combined and individual area and centroid are reported. The bodies that the face attaches to are reported. The type of the face is reported. If a face is of cylinder type, the radius of the face is also reported.



Entity	Distance Between Centroids (m)	Surface Area (m^2)	Centroid X(m)	Centroid Y(m)	Centroid Z(m)	Body	Type	Radius (m)
Distance	9.1313e-010		1.8248e-010	8.6736e-019	8.9471e-010			
2 Cylinders, Summary		1.0964e-002	2.e-002	5.e-003	2.5e-002			
Face 1		6.5785e-003	2.e-002	5.e-003	2.5e-002	Part 2	Cylinder	1.5e-002
Face 2		4.3857e-003	2.e-002	5.e-003	2.5e-002	Part 2	Cylinder	1.e-002

Body

Combined and individual volume, mass, and centroid are reported. The body name is reported. Your choice of the mass moment of inertia in the selected coordinate system or the principal is also reported. The choice is provided in the **Selection Information Column Control** (p. 187) dialog box.

Important:

For a Surface Body, the Volume, Mass, and Moment of Inertia information for the Body selection are based on the original thickness value specified on the Surface Body object. This does not account for any Thickness object specifications. Thickness specifications overwrite the body thickness values when the application calculates thickness for any faces and/or surface bodies. Refer to the PRECISE MASS SUMMARY section from the Solution Information worksheet for solver calculated Mass values.

Coordinate

If there is a mesh present, the picked point location and the closest mesh node ID and location are reported.

Worksheet Window

The worksheet presents you with information about objects in the tree in the form of tables, charts and text, thereby supplementing the Details view. It is typically intended to summarize data for a collection of objects (for example, the **Connections** folder worksheet reveals the inputs for all contacts, joints and others) or to receive tabular inputs (for example, to specify the coefficients and the analyses to include in **Solution Combinations**).

Behavior

- **Dockable Worksheet**

  By default, when you select an applicable object in the tree, a dockable (p. 169)**Worksheet** window displays alongside the **Geometry** window, allowing you to review both at once. You may, however, disable the display of the **Worksheet** window using the **Worksheet** option (see below). This preference is persisted in future sessions of the product. There are specific objects that ignore the preference, as outlined below.

Worksheet Function	Worksheet Behavior When Object is Selected	Example Objects
Data input and display information	Automatically appears and gains focus	**Constraint Equation**, **Solution Combination**
Display information related to object settings	Automatically appears but does not gain focus	**Analysis Settings**
Display information related to objects within a folder	Appears only if display is turned on manually using the **Worksheet** option (see below)	**Geometry** folder, **Contact** folder

- **Worksheet Option**

  For tree objects that include an associated Worksheet, the **Worksheet** option of the **Views** group on the ribbon enables you to toggle the **Worksheet** window display on or off. The option is not available (grayed out) for objects that do not include a Worksheet.

  Worksheets designed to display many data items do not automatically display the data. The data readily appears however when you click the **Worksheet** button. This feature applies to the worksheets associated with the following object folders: **Geometry**, **Coordinate System**, **Contact**, **Remote Points**, **Mesh**, and **Solution**.

Features

- **Go To Selected items**

  This useful feature enables you to find items in either the tree or **Geometry** window that match one or more rows of the worksheet. If the worksheet displays a tabular summary of a number of objects, select the rows of interest, right-click, and choose **Go To Selected Items in Tree** to instantly highlight items that match the contents of the **Name** column (leftmost column). Control is therefore transferred to the tree or **Geometry** window, as needed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Viewing Selected Columns**

  When a worksheet includes a table with multiple columns, you can control which columns to display. To do so, right-click anywhere inside the table. From the context menu, check the column names of interest to activate their display. Some columns may ignore this setting and remain hidden should they be found inapplicable.

  To choose the columns that will display, right mouse click anywhere inside the worksheet table. From the context menu, click any of the column names. A check mark signifies that the column will appear. There are some columns in the worksheet that will not always be shown even if you check them. For example, if all contact regions have a **Pinball Region** set to **Program Controlled**, the **Pinball Radius** will not display regardless of the setting.

Graph and Tabular Data Windows

The **Graph** and **Tabular Data** windows enable you to review and modify the data, primarily associated with the objects and features listed below. When you select certain objects in the tree, the **Graph** window and **Tabular Data** window display beneath the **Geometry** window. Refer to the following topics for descriptions about the use of these windows as they relate to:

- Analysis Settings (p. 193)
- Loading Conditions (p. 193)
- Contour Results and Probes (p. 194)
- Display Graph Content in the Geometry Window (p. 197)
- Solution Steps and Substeps (p. 198)
- Charts (p. 199)
- Context Menu Options (p. 199)

Analysis Settings

For analyses with multiple steps, you can use these windows to select the step(s) whose analysis settings (p. 1417) you want to modify. The **Graph** window also displays all the loads used in the analysis.

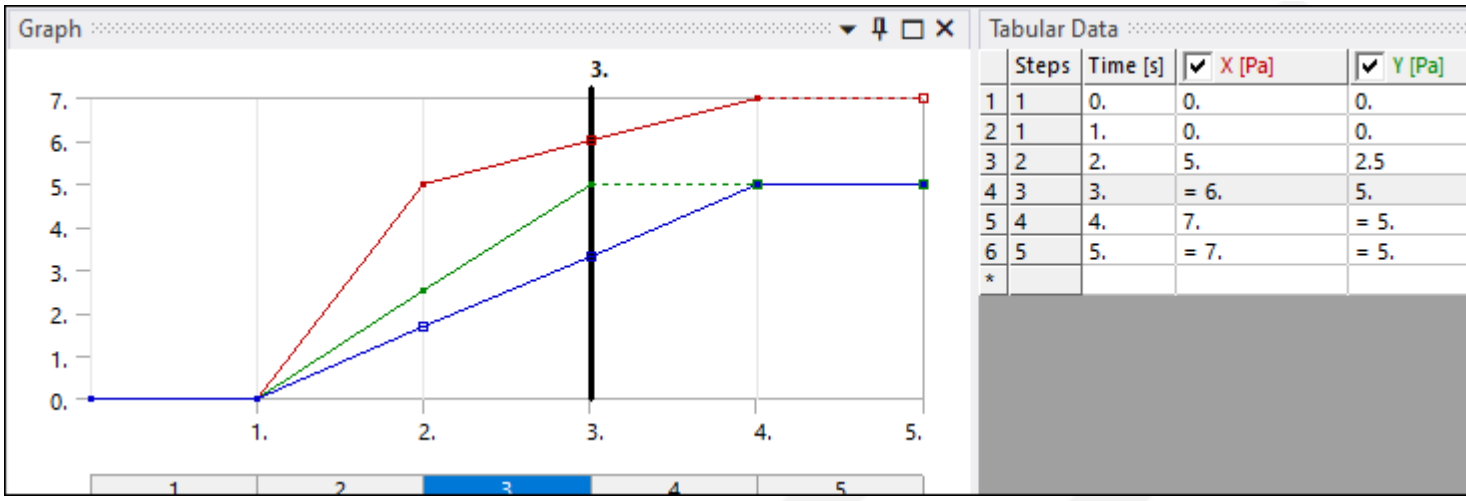
These windows are also useful when using restarts. See Using Solution Restarts (p. 1815) for more information.

Loading Conditions

Inserting a loading condition (p. 1497) updates the **Tabular Data** window with an entry table that enables you to enter data on a per-step basis. The **Graph** window updates as you make **Tabular Data** entries.

All new tabular data is entered into the row that begins with an asterisk (*) regardless of whether the time or frequency point is higher or lower than the last defined point in the table. The application automatically sorts the content of the table into ascending order. In addition, any **Tabular Data** values preceded by an equal sign (=) are not defined table values. These values are application interpolated values shown for reference.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



A check box is available in the column title for each component of a load in order to turn on or turn off the viewing of the load in the **Graph** window. Components are color-coded to match the component name in the **Tabular Data** window. Clicking on a time value in the **Tabular Data** window or selecting a row in the **Graph** window will update the display in the upper left corner of the Geometry window with the appropriate time value and load data.

As an example, if you use a Displacement (p. 1666) load in an analysis with multiple steps, you can alter both the degrees of freedom and the component values for each step by modifying the contents in the **Tabular Data** window as shown above.

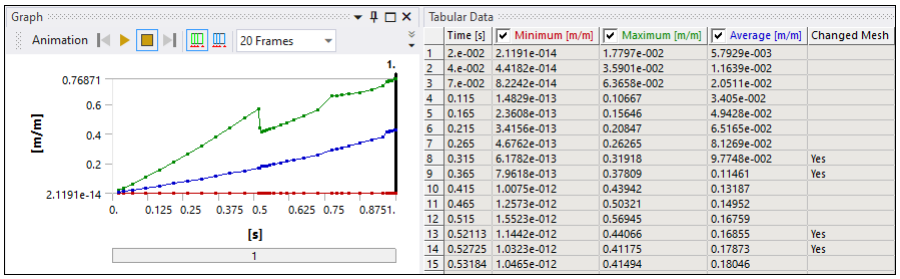
If you wish for a load to be active in some steps and removed in some other steps you can do so by following the steps outlined in Activating and Deactivating Loads (p. 1423).

Contour Results and Probes

For contour results (p. 1935) and probes (p. 1946), the **Graph** and **Tabular Data** windows display how the results vary over time. In addition, for result objects, the **Tabular Data** window usually displays the **Total**, as well as **Minimum** and **Maximum** values calculated on the specified geometry. The color of the column headers for these values corresponds to the colors displayed in the **Graph** window, red and green as illustrated below. You can animate your results in the **Graph** window for the specified result set domain. And, you can further specify a specific range to animate by dragging your mouse across graph content.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

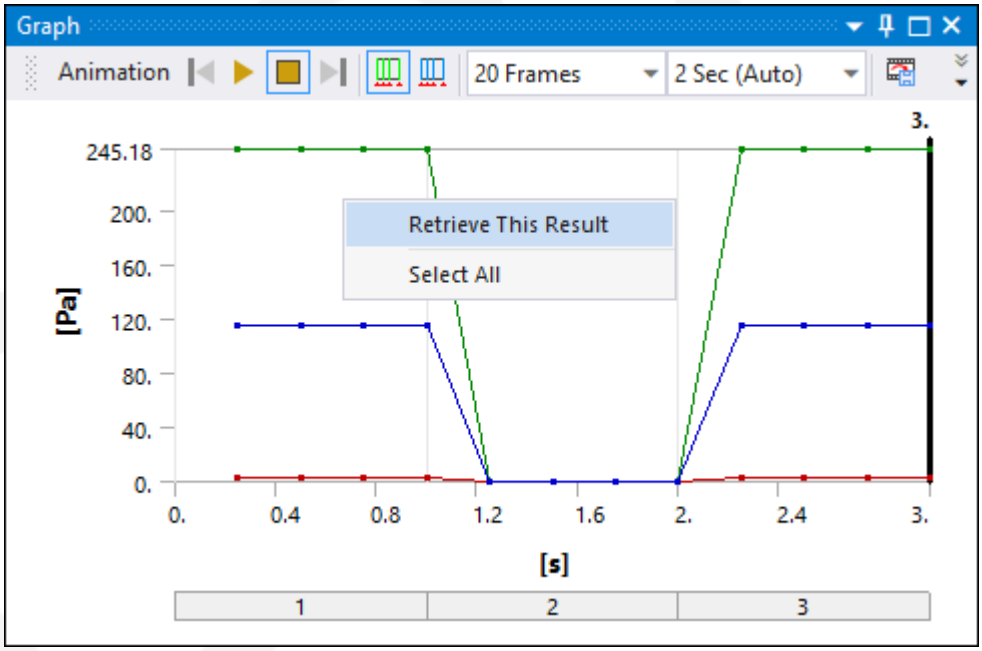
If you refine the mesh using the **Nonlinear Adaptive Region** (p. 1707) condition, the **Changed Mesh** column displays and indicates when mesh regeneration took place.

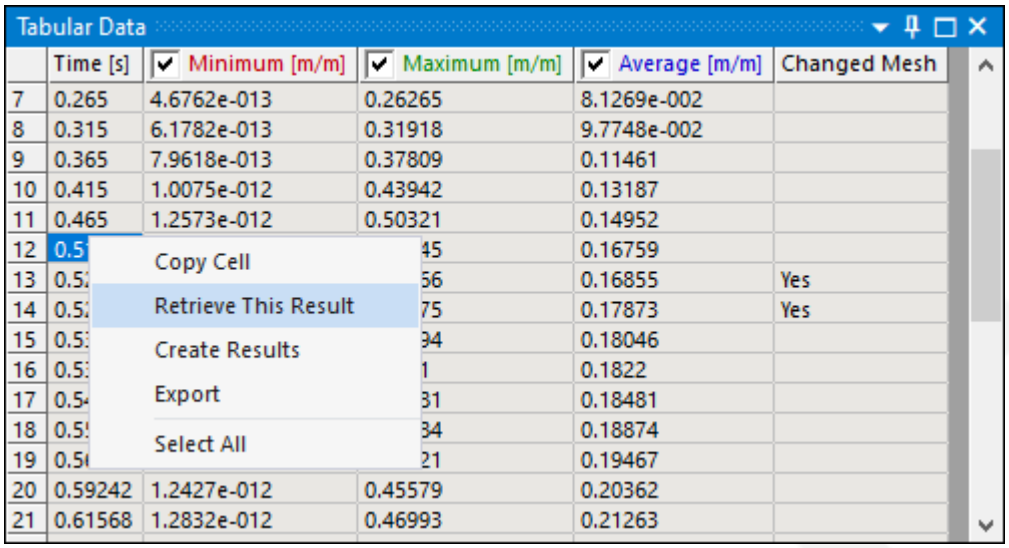
Important:

For results displayed in the **Tabular Data** window, if **0** (zero) displays for both the **Minimum** and **Maximum** values of a row, the result set may not contain result data. You can use the **Retrieve** option, discussed below, to view a result set in order to determine if any data exists for the set. If no data is available, the result contours in the **Geometry** window display as fully transparent.

Retrieving Results

To view the results in the **Geometry** window for a desired time point, select the time point in the **Graph** window or **Tabular Data** window, then right-click the mouse and select **Retrieve This Result**. The **Details** for the chosen result object also updates to the selected step.





Creating Results

The contextual (right-click) menu of the **Tabular Data** window also includes an option to **Create Results**. This feature enables you to select multiple rows in the table and create individual results for each selection. These new results are placed in a **Group** folder (p. 208) in the tree. The **Group** folder has the same name as the original result. Or, in the event the originally result was already grouped, the new results are added to this existing group.

Create Results Selection **Generated Results**

Display Graph Content in the Geometry Window

When the **Geometry** window has focus, you can select the **Display Graph** option on the Graphics Toolbar (p. 97), or use the keyboard key **G** or the context (right-click) menu option, to display the content (load and result data) of the **Graph** window in the **Geometry** window. This enables you to include the graph in image captures of a viewport. Once displayed, you can drag and drop the graph within the window. You can activate this feature in multiple viewports and it remains active until you select one of the **Display Graph** options to remove the graph. In addition, the animation and animation export options support this feature.

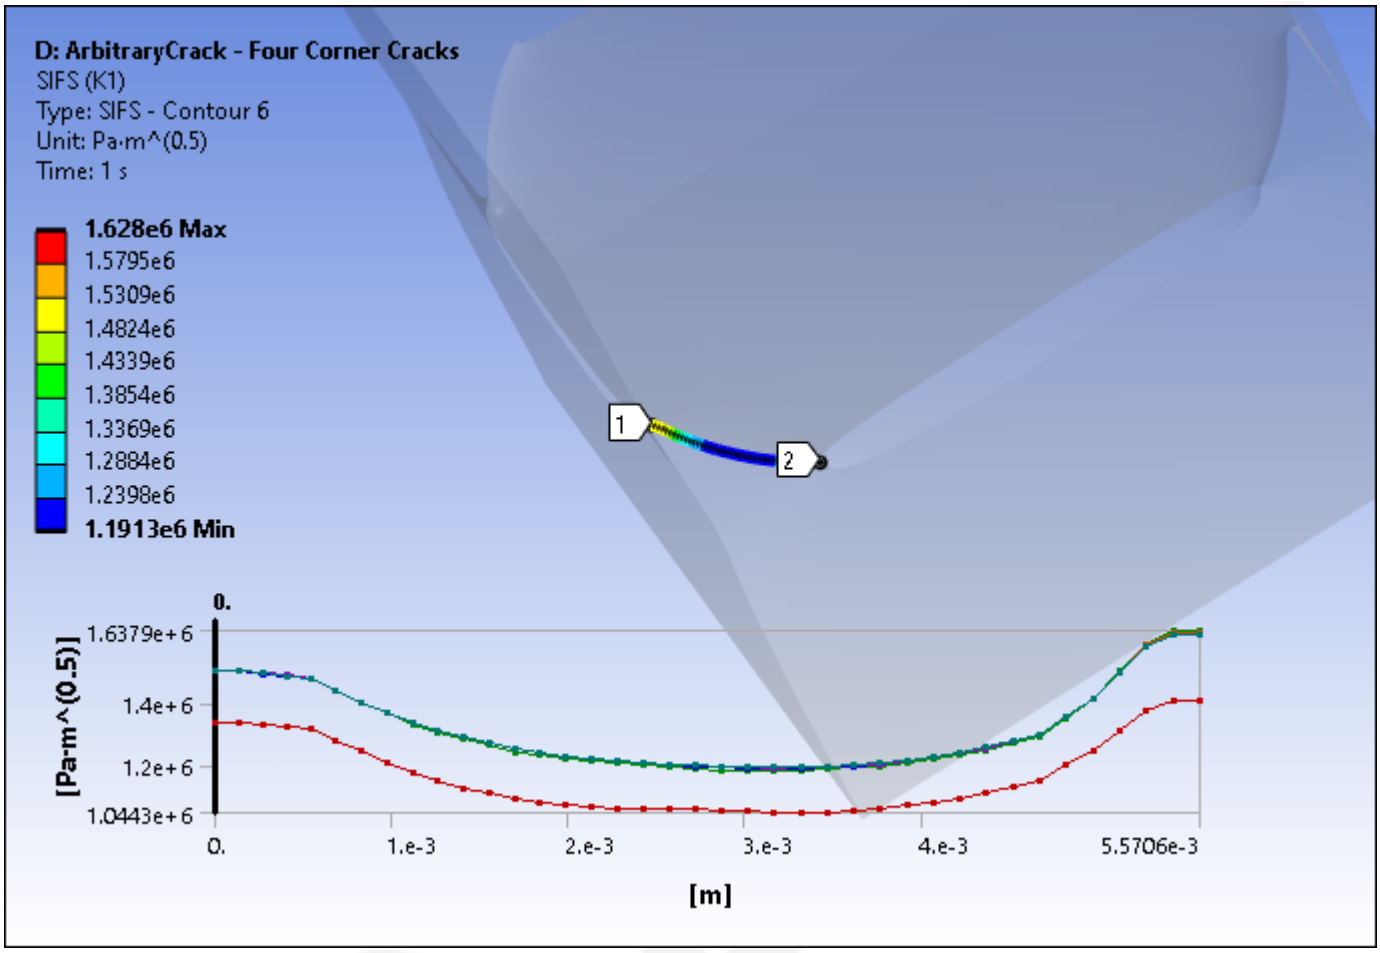
Published: 2023-10-23



Solution Steps and Substeps

During analyses that are using the Mechanical APDL solver, selecting the **Solution** object following the solution process for an analysis that includes multiple steps, the **Tabular Data** window displays the **Time** associated with each **Step** of the analysis as well as each **Substep** as applicable. The following examples of the **Tabular Data** window show these options for a deformation result.

Total Deformation Result Tabular Data **Solution Object Tabular Data**

Charts

With charts (p. 1929), the **Graph** and **Tabular Data** windows can be used to display loads and results against time or against another load or results item.

Context Menu Options

Presented below are some of the commonly used options available in a context menu that displays when you click the right mouse button within the **Graph** window and/or the **Tabular Data** window. The options vary depending on how you are using these windows (for example, loads vs. results).

- **Retrieve This Result**: As discussed above, for a selected object, this option retrieves and presents the result data at the selected time point you have selected in the **Graph** window or **Tabular Data** window.
- **Create Results**: As discussed above, this option create result objects for the rows that you select in the **Tabular Data** window and places the new results in a group folder.
- **Create Total Deformation Results**/**Create Equivalent Strain Results**/**Create Equivalent Stress Results**/**Create Temperature Results**: These options are available for **Tabular Data** content when the **Solution** object is selected for a solved analysis. These options enable you to create results for a selected row or multiple rows of data.
- **Insert Step**: Inserts a new step at the currently selected time in the **Graph** window or **Tabular Data** window. The newly created step will have default analysis settings. All load objects in the analysis will be updated to include the new step.
- **Delete Step**: Deletes a step.
- **Copy Cell**: Copies the cell data into the clipboard for a selected cell or group of cells. The data may then be pasted into another cell or group of cells. The contents of the clipboard may also be copied into Microsoft Excel. Cell operations are only valid on load data and not data in the **Steps** column.
- **Paste Cell**: Pastes the contents of the clipboard into the selected cell, or group of cells. Paste operations are compatible with Microsoft Excel.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Delete Rows**: Removes the selected rows. In the **Analysis Settings** object this will remove corresponding steps. In case of loads this modifies the load vs time data.
- **Select All Steps**: Selects all the steps. This is useful when you want to set identical analysis settings for all the steps.
- **Select All Highlighted Steps**: Selects a subset of all the steps. This is useful when you want to set identical analysis settings for a subset of steps.
- **Activate/Deactivate at this step!**: This enables a load to become inactive (deleted) in one or more steps. By default any defined load is active in all steps.
- **Zoom to Range**: Zooms in on a subset of the data in the **Graph** window. Click and hold the left mouse at a step location and drag to another step location. The dragged region will highlight in blue. Next, select **Zoom to Range**. The chart will update with the selected step data filling the entire axis range. This also controls the time range over which animation takes place.
- **Zoom to Fit**: If you have chosen **Zoom to Range** and are working in a zoomed region, choosing **Zoom to Fit** will return the axis to full range covering all steps.

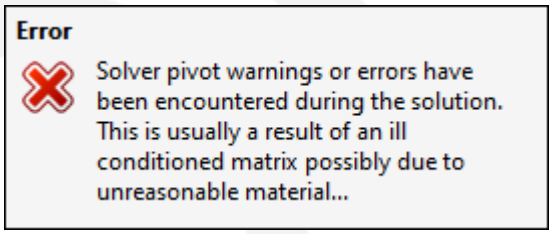
Messages Window

The **Messages Window** is a Mechanical application feature that prompts you with feedback concerning the outcome of the actions you have taken in the application. For example, Messages display when you resume a database, Mesh (p. 348) a model, or when you initiate a Solve (p. 355).

Messages come in three forms:

- **Error**
- **Warning**
- **Information**

As illustrated below, when the application issues a message, a window first displays the message for five seconds and then the pop-up is automatically hidden. You may change the default setting for the these messages in the Messages (p. 236) category of the Options preferences (p. 217). Change the **Pop-up Messages** setting to **No**. The default setting is **Yes**.

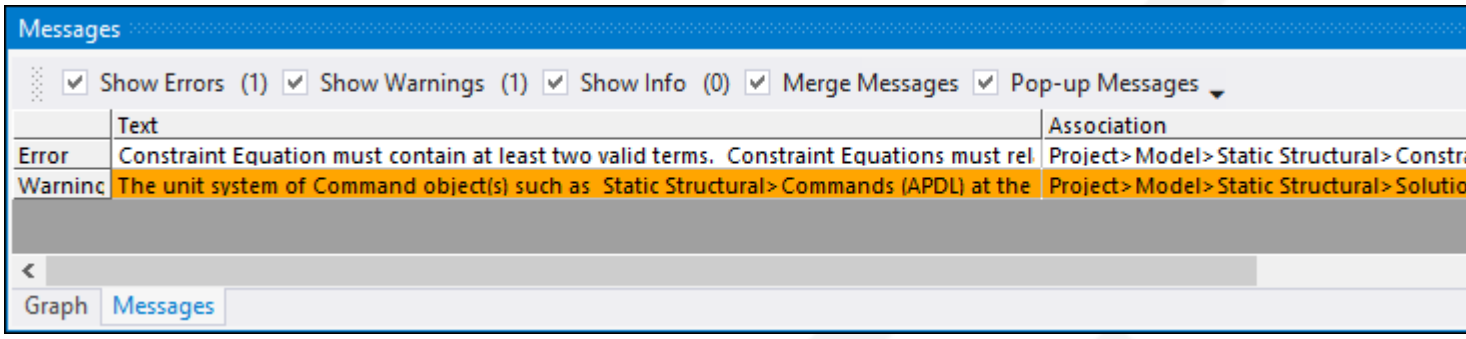


Note:

The Linux platform does not support the message pop-up feature.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

By default the **Messages** window is hidden. To display the window, open the **Manage** drop-down menu from the **Layout** (p. 47) group of the **Home** tab and select **Messages**. An example of the **Messages** window is shown below.



As shown here, the Status Bar provides a dedicated area to alert you should one or more messages become available to view. You can double-click this field to display messages.

Highlighted Messages

As illustrated above, messages may display with an orange highlight to indicate that there is a potential problem related to an object. The object corresponding to this message is also highlighted in the tree (p. 110). You can turn this feature off using the Options (p. 217) dialog box (see the Messages (p. 236) category).

Window Options

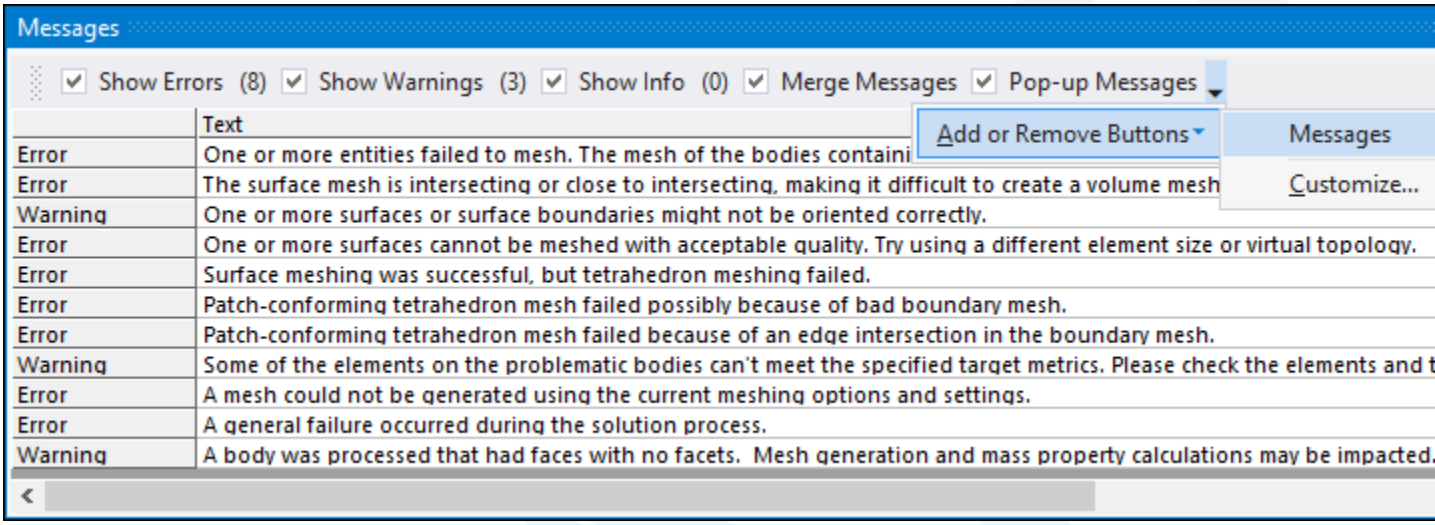
Once messages are displayed in the **Messages** window, you can:

- Double-click a message to display its contents in a pop-up window.
- You can filter messages using the display options listed below. Checking and clearing the options may change the order in which the window displays the messages. These options have associated preferences settings in the Messages (p. 236) category of the Options (p. 217) dialog that enables you to define the default setting.
  - **Show Errors**: Display or hide error messages. This field also lists the number of different error messages displayed in the Messages window. When you merge/unmerge messages, this value changes accordingly.
  - **Show Warnings**: Display or hide warning messages. This field also lists the number of different warning messages displayed in the Messages window. When you merge/unmerge messages, this value changes accordingly.
  - **Show Info**: Display or hide information-based messages. This field also lists the number of different information messages displayed in the Messages window. When you merge/unmerge messages, this value changes accordingly.
  - **Merge Messages**: Merge similar messages into one row. Unchecking this option will unmerge messages - all original messages are then displayed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

– **Pop-up Messages**: When selected, pop-ups display as expected. When you unselect this option, system generated messages do not display as a pop-up, but are included in the list of messages in the **Messages** window. You can double-click messages to display them as a pop-up dialog.

The filter toolbar also contains a drop-down menu option that enables you to hide/display any or all of the above filter options as well as reset the toolbar.



- Right-click one or more messages to display the following context menu options:

  – **Go To Object**: Selects the object in the tree which is responsible for the message.

  – **Show Problematic Geometry**: Highlights the geometries in the Geometry window that are causing the error or warning.

  – **Show Intersecting Surface Mesh**: This option creates a Named Selection of the problematic bodies and elements for your review.

  – **Show Message**: Displays the selected message in a popup window.

  – **Copy**: Copies the selected messages to the clipboard. You can also highlight a message and then press the key combination **Ctrl** + **C** to copy its contents to the clipboard.

  – **Delete**: Removes the selected messages. You can also use the **Delete** key to remove a selected message from the window.

  – **Refresh**: Refreshes the contents of the **Messages Window** as you edit objects in the Mechanical application tree.

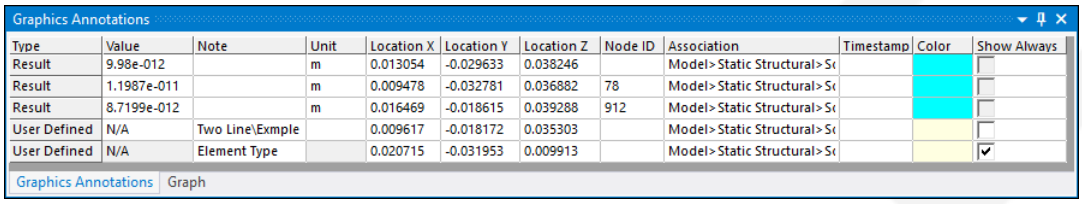
Graphics Annotations Window

The **Graphics Annotations** window, illustrated below, displays a table of user-defined annotations. The annotations are either a note that you place on your model using the **Annotation** (p. 42) option or the display of a specific result value at its coordinate location on your model, using the Probe (p. 71) option.

These annotations are labels that you place on your model that include a/an:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Value** (**Probe** only)
- **Note**
- Coordinates of the label (**Location X/Y/Z** columns)
- **Node ID** as applicable. **Node ID** values are included in the table for probe selections when the Snap (p. 71) option is selected (active by default).
- Object associated with the label (**Association** column).
- **Timestamp**
- Label color (**Color** column)
- Display option for user-defined annotations (not probes) that you can select to have that label remain displayed (**Show Always** column).



Go to a section topic:

- Application (p. 203)
- Annotation Types (p. 204)
- Graphics Annotations Window Features (p. 204)
  - Write Notes (p. 205)
  - Highlight Values (p. 205)
  - Display Node IDs (p. 206)
  - Move Labels (p. 206)
  - Change Probe Line Coloring (p. 207)
  - Change Label Color (p. 207)
  - Display Obscured Labels (p. 207)
  - Display Annotation Labels Continuously (p. 207)
  - Select Context Menu Options (p. 207)
  - Manually Delete Annotations (p. 208)

Application

The **Graphics Annotations** window displays automatically when you:

1. Place an annotation on your model. Select the **Annotation** option from the **Insert** group (p. 42) on the Home (p. 40) tab and then click a location on your model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Or...

Note:

The **Insert** group displays on numerous Context tabs.

2. Place a probe on your model. Select a result object, select the **Probe** option on the Result Context Tab (p. 62), and then click a location on your model.

Note:

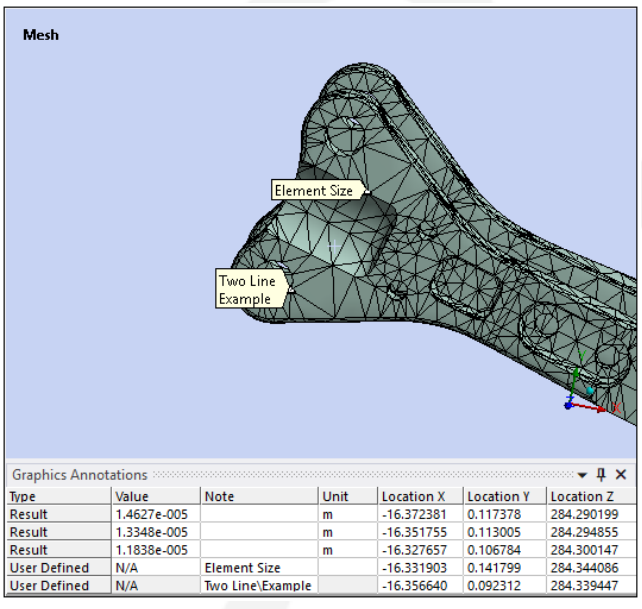
For the **Probes** feature:

- Annotations are not supported for results scoped to edges and vertices.
- Values are cleared if you re-solve your simulation.
- Values for positions inside of an element may differ from hand-calculated values, especially for certain user defined result expressions. See the limitations topic in the Interpolation of Result Values (p. 1937) section.

Annotation Types

Examples of the annotation types as displayed in the **Geometry** window are shown below.

User Defined Graphics Annotation



Graphics Annotations

Type	Value	Note	Unit	Location X	Location Y	Location Z
Result	1.4627e-005		m	-16.372381	0.117378	284.290199
Result	1.3348e-005		m	-16.351755	0.113005	284.294855
Result	1.1838e-005		m	-16.327657	0.106784	284.300147

Graphics Annotations Window Features

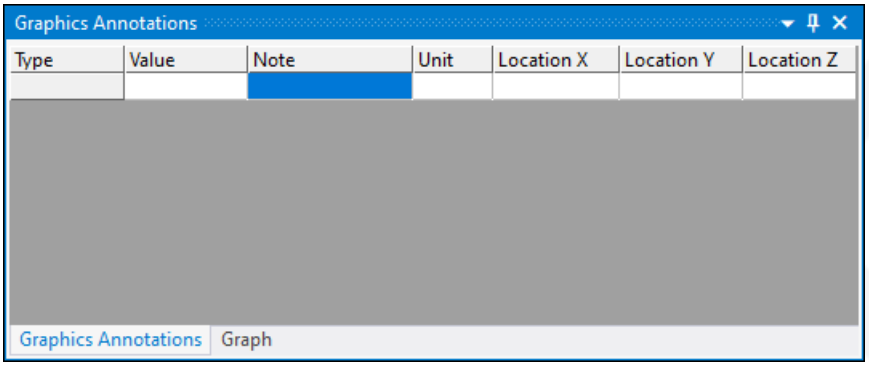
The **Graphics Annotations** window provides the following options once you have created annotations:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

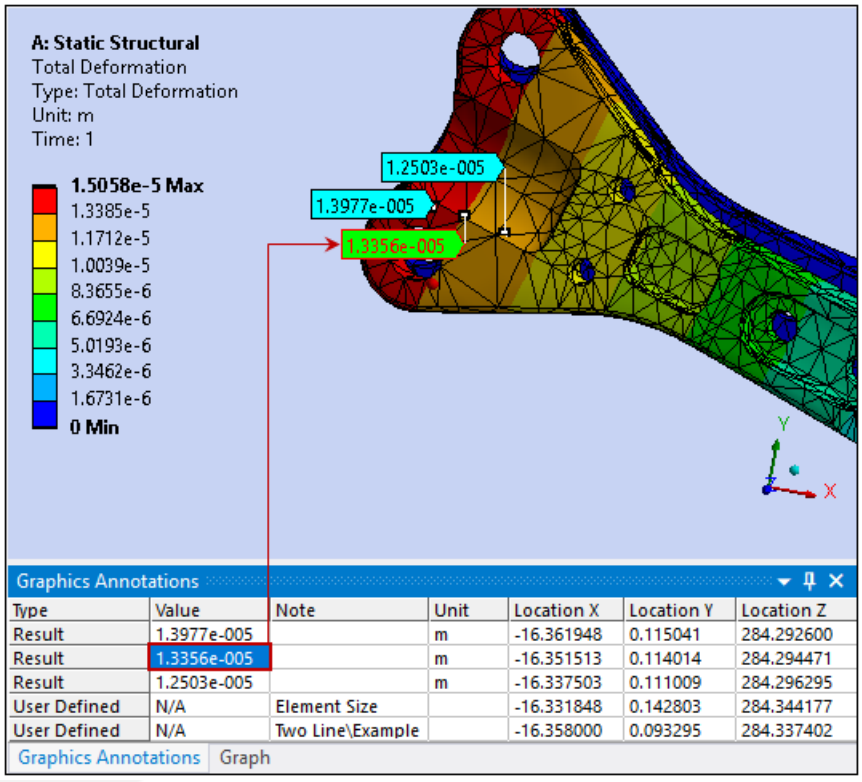
Write Notes

When you select the **Annotation** option in the **Insert** group (p. 42) and place the annotation on a point of your model, the **Graphics Annotations** window displays as shown below. The **Note** cell of the table is active and you can being to type your note. You can edit the text entry for a user-defined annotation by double-clicking the annotation's **Note** cell. Your text entries can span more than one line using the backslash (\) keyboard character. Note the "Two Line" note example above.



Highlight Values

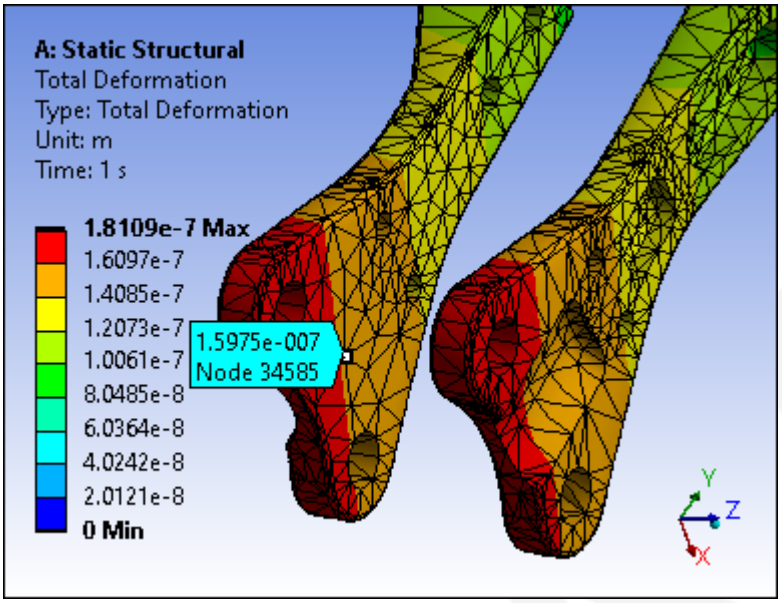
Selecting a table cell in the **Value** column (or a cell of the **Association** column) or selecting the annotation label in the **Geometry** window, highlights the annotation in the table as well as in the **Geometry** window. Note that for a user-defined annotations, the **Geometry** display switches to the corresponding object of the tree that includes the annotation, such as the Element Size example shown above.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Display Node IDs

Using the **Show Node ID in Snap-Probe Labels** preference of the **Graphics** (p. 228) category in the **Options** dialog, you can include the Node ID in the probe label, as illustrated below.



Move Labels

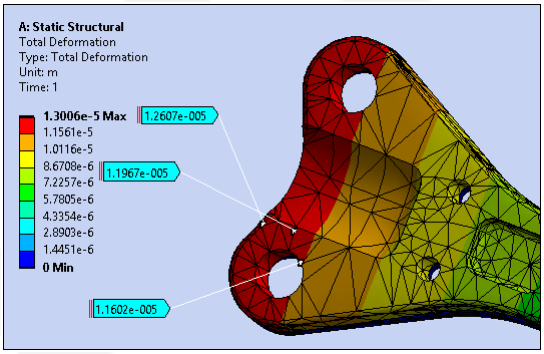
Selecting the **Label** option on the Graphics Toolbar (p. 97) enables you select and then drag-and-drop an annotation.

Moving a Text Label

You can only reposition a text label on the model. Once repositioned, the label will rotate and move in space with the model.

Moving a Probe Label

Probe labels can be moved anywhere within the **Geometry** window. As illustrated below, a white line directs you to the probe's location on the model. Also, two vertical red lines appear beside a label when it is moved. You can then freely drag-and-drop the annotation to a different location. Once moved, the label is stationary. If you rotate or move the model, the label remains in the same position in the window. As needed, you can simply return the annotation to the original position or drag-and-drop it to an new position in order to reposition it along with the model.



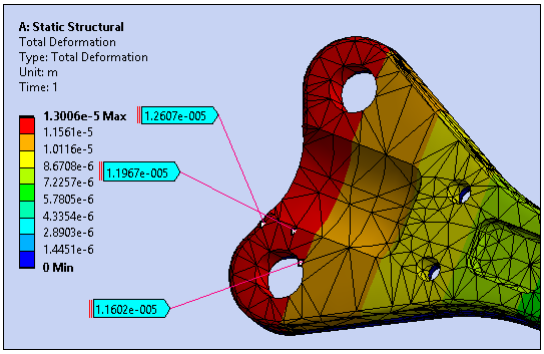
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

To return probe labels to their original position (the anchor of the probe always remains in the original position), select the annotation in the **Geometry** window or in the window and press the **Esc** key. You can select multiple probes using the **Ctrl** key.

Change Probe Line Coloring

You can change the color of the line connecting the probe label to its location on the model using the **Probe Line Color** property in the Graphics (p. 228) category of the Options (p. 217) dialog.



Change Label Color

When you double-click a cell in the **Color** column, a color selection pane displays that enables you to change the color of the label.

Display Annotation Labels Continuously

For user-defined annotations (not probes), you can select the check box under the **Show Always** column to have that label remain displayed regardless of the object or interface selection you make.

Display Obscured Labels

The Options (p. 217) dialog contains a Graphics (p. 228) category preference, **Obscured Label Display Style**, that enables you to change the display of an annotation label and/or probe that is not visible because of the orientation of your model. The options include **Solid** (default), **Translucent**, and **Hidden**. When a label or probe is on the opposite side of the model's current orientation, you can choose whether to have it show "through" the model using the Solid and Translucent options or not at all using the **Hidden** option.

Also note that the **Graphics** category includes an associated preference: **Unobscured Label Tolerance Factor**. For the **Translucent** or **Hidden** options, this tolerance enables you make small adjustments to make sure that a label behaves as expected in the event a label displays as obscured when it should not. For example, when a label's position is located slightly within a curved surface rather than directly on the surface. This is most likely a result of how the application calculates the location of a label. The tolerance range is between 0 and 1. Small incremental changes, such as 0.0001 can be appropriate to properly display obscured labels.

Select Context Menu Options

As illustrated below, the window provides a context menu when you make a table selection and then right-click the mouse.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Context Menu Options	Option Descriptions
	• **Copy**: copy the content contained in the row into the clipboard. • **Delete**: delete table selections. • **Delete All**: delete all table content. • **Reset Label Location**: return all selected probes to their original position. • **Export Text File**: export table content to a text file.

Manually Delete Annotations

To delete an annotation, select a row in the window or select the annotation label in the **Geometry** window, and then press the **Delete** key. You can select multiple probe labels or table cells using the **Ctrl** key.

Section Planes Window

The **Section Plane** window gives you access to the functionality for creating a cut or slice on your model so that you can view internal geometry, or mesh and results displays. For more information on this feature, see Creating Section Planes (p. 294).

Mechanical Wizard Window

The **Mechanical Wizard** window appears in the right side panel whenever you click the Mechanical Wizard button on the Home Tab (p. 40). For details, see Mechanical Wizard (p. 321).

Group Tree Objects

Mechanical enables you to organize and group certain objects in the **Outline** pane. Using context menu (right-click) options, the application provides a number of different options that you use to group objects.

Go to a section topic:

- Group Multiple Objects (p. 209)
- Group, Hide, and Suppress Geometry Objects (p. 211)
- Group All (p. 212)
- Group Loads by Load Vector (**Substructure Generation** Analysis Only) (p. 214)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

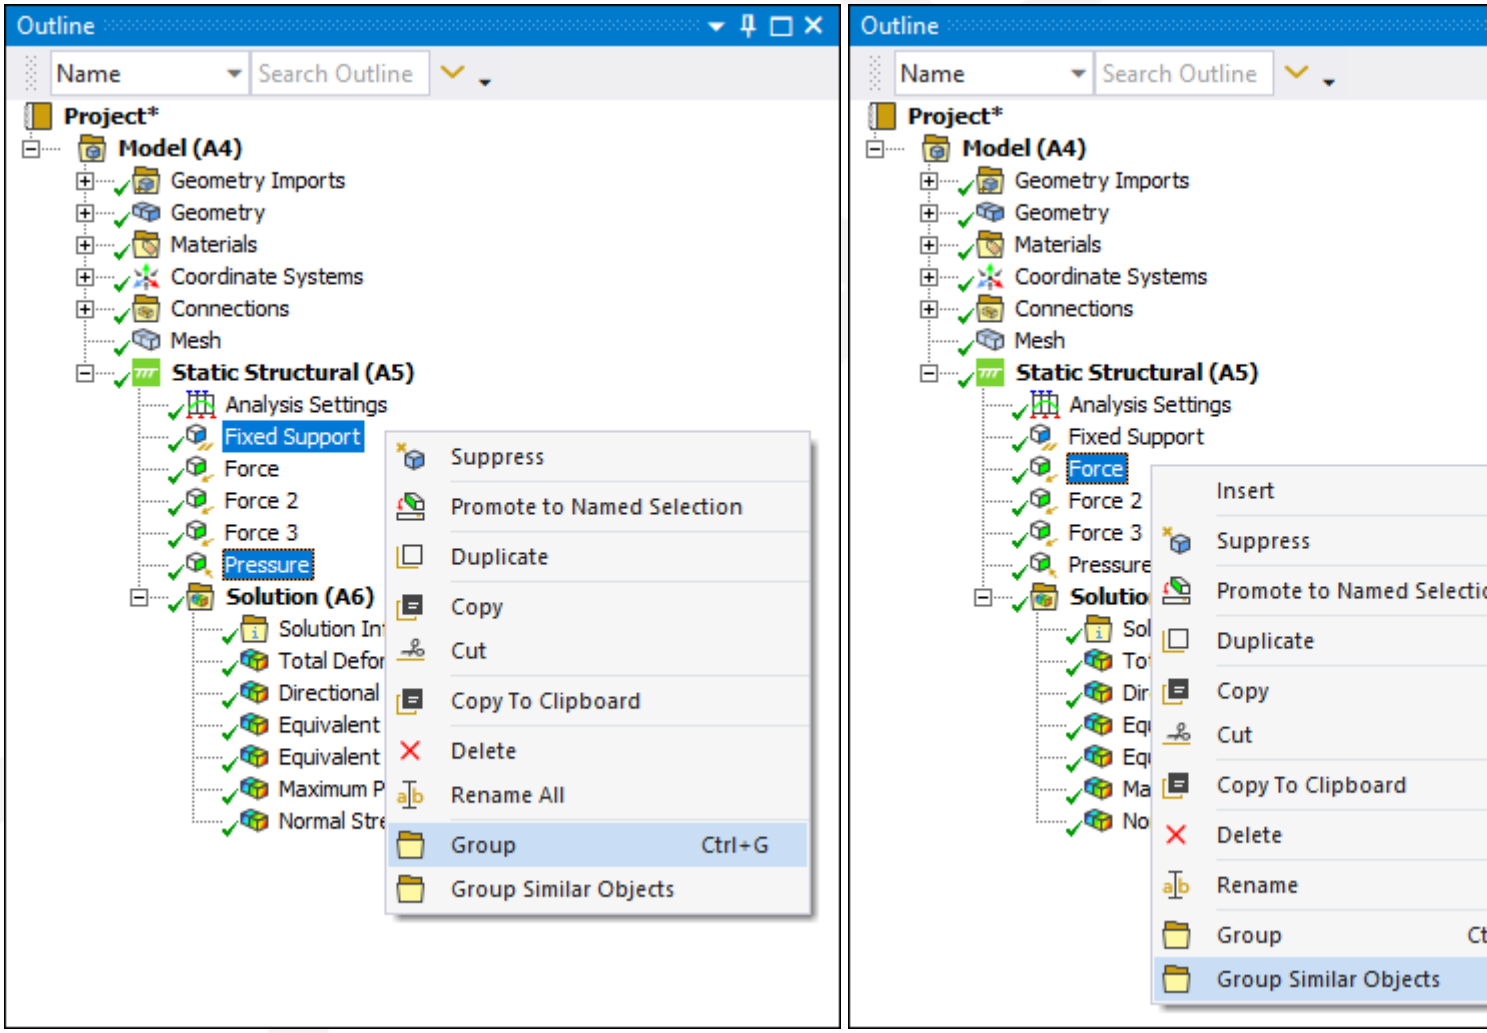
- Objects with Limited Grouping (p. 215)

Note:

For CAD files that include a hierarchy structure, the **Options** dialog preference setting, **Assembly Hierarchy**, enables you to automatically group parts and bodies under the **Geometry** object upon import. If you use this preference, you cannot change the setting once you have imported your geometry. This is due to a geometry update limitation.

Group Multiple Objects

Use the **Group** option when you individually select multiple objects to be grouped. The **Group Similar Objects** groups together objects of the same type (for example, Pressure, Displacement, etc.) and renames the group folder according to that type.

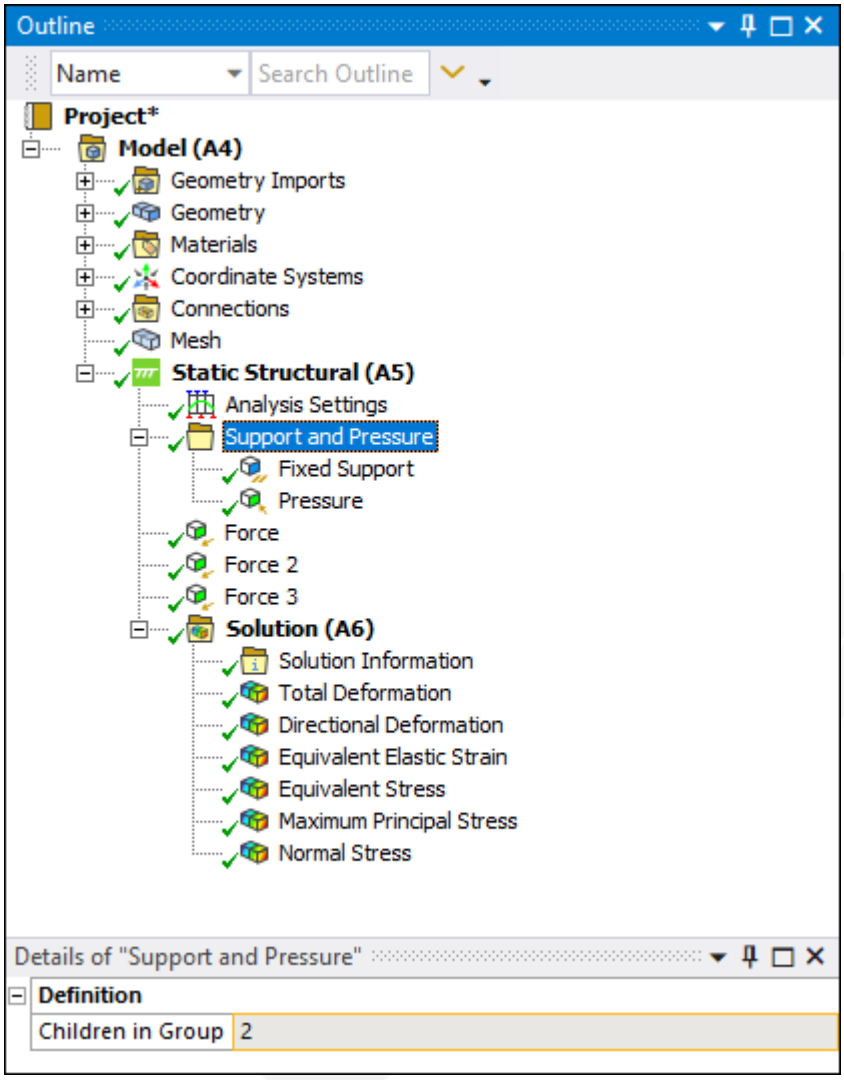


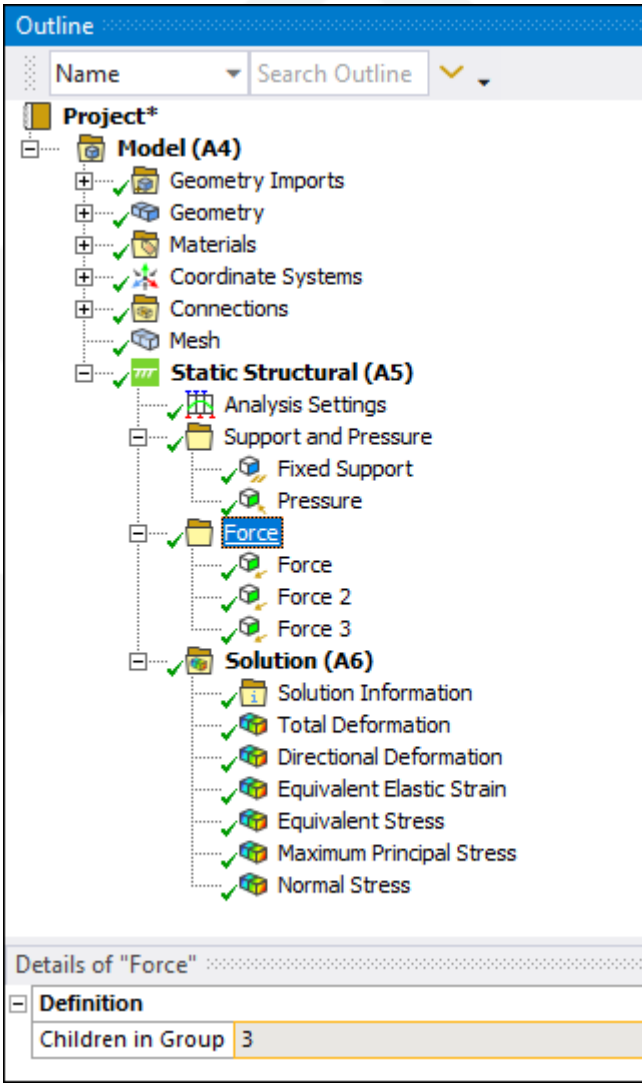
Note:

If you change and update your geometry, always verify your groupings. For example, using the Explode Part feature in DesignModeler alters Part IDs.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Once you create groups, you are prompted to rename the folder or you may accept the default name (**New Folder**). In the following example, the folder was named "Support and Pressure." The similar objects folder name is automatically created based on the object type, in this case, **Force**. Also note that this new object provides the Details view property **Children in Group** that displays the total number of objects contained in the new group.

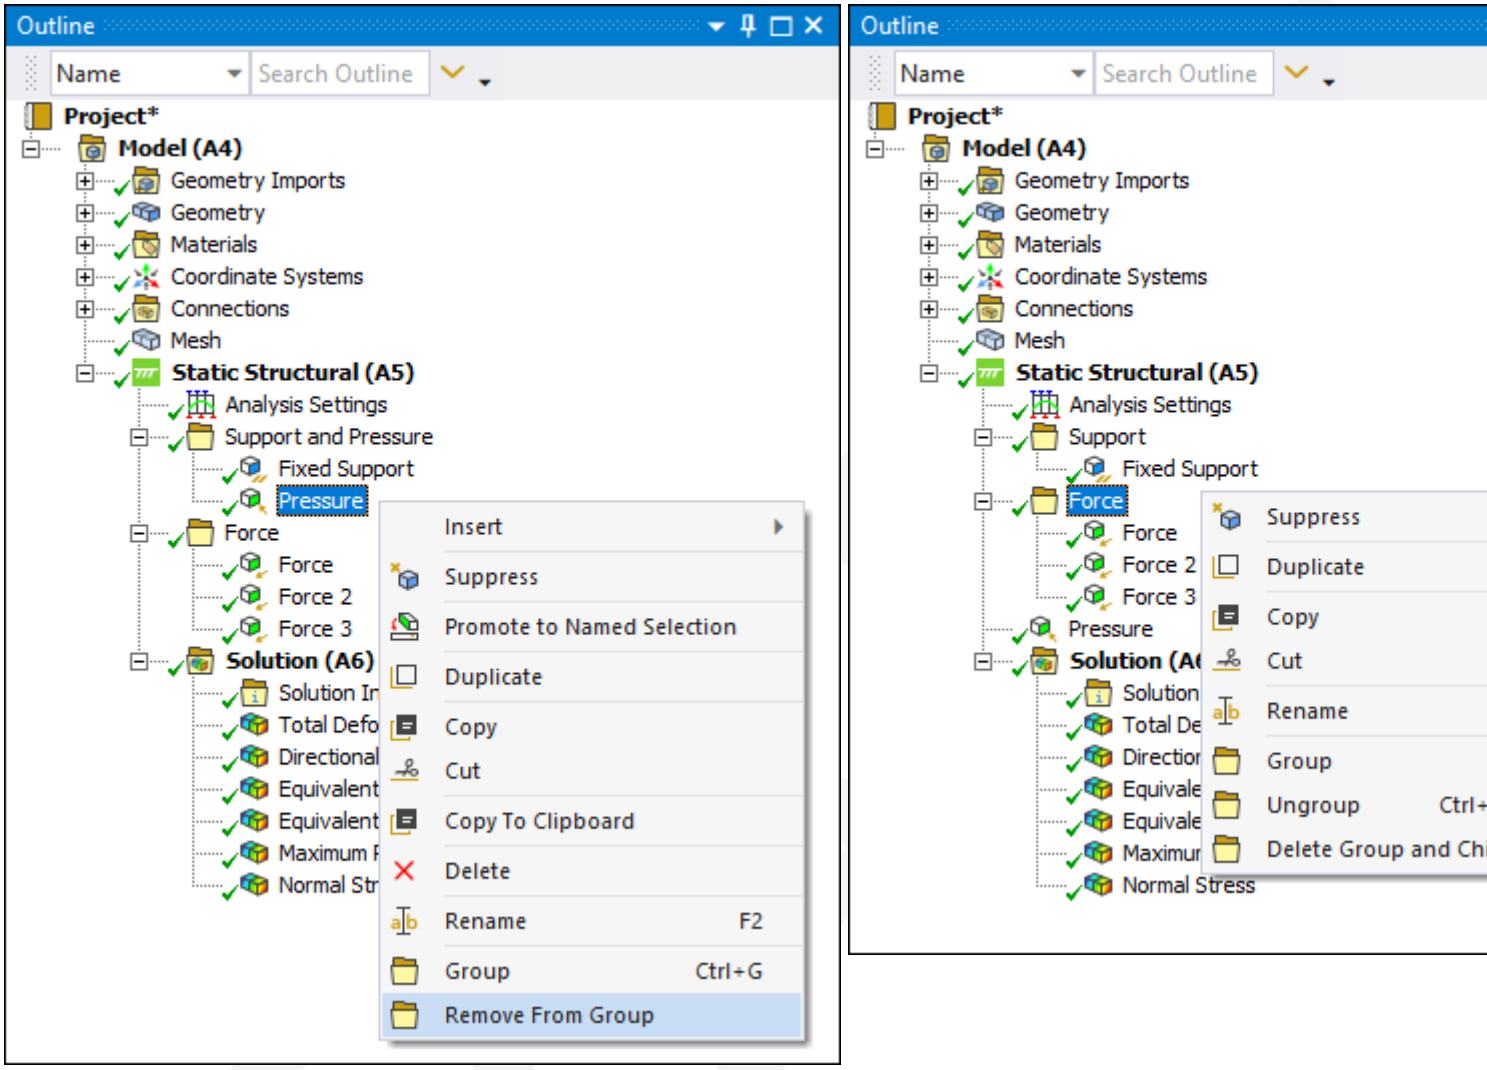




Once defined, options become available that enable you to **Suppress** (and **Unsuppress**) a group as well as remove objects from a group (**Remove From Group**), further group objects into sub-folders/groups (**Group**), **Ungroup** a particular folder, as well as delete a folder and its sub-folders (**Delete Group and Children** option or **[Delete]** key). You can also **Cut**, **Copy**, and **Duplicate** the content of a group folder. And in addition to the context menu options, you can drag-and-drop objects between folders.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

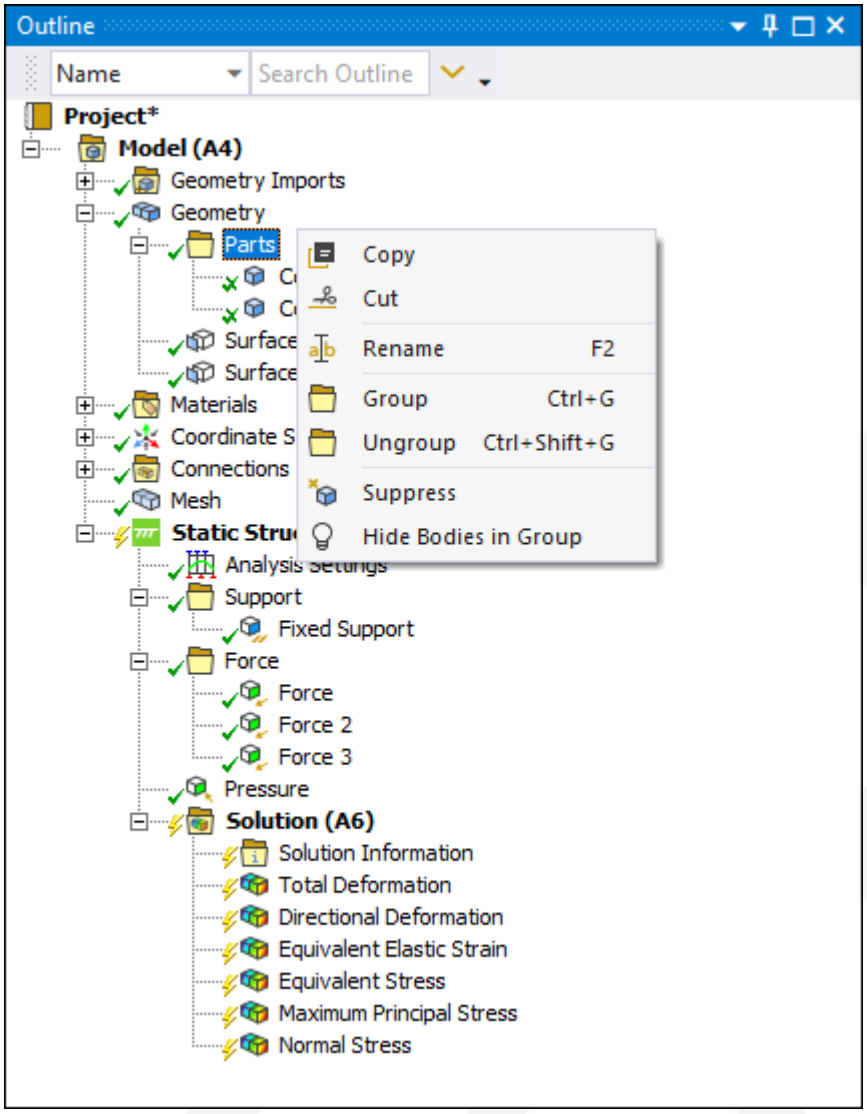
Published: 2023-10-23

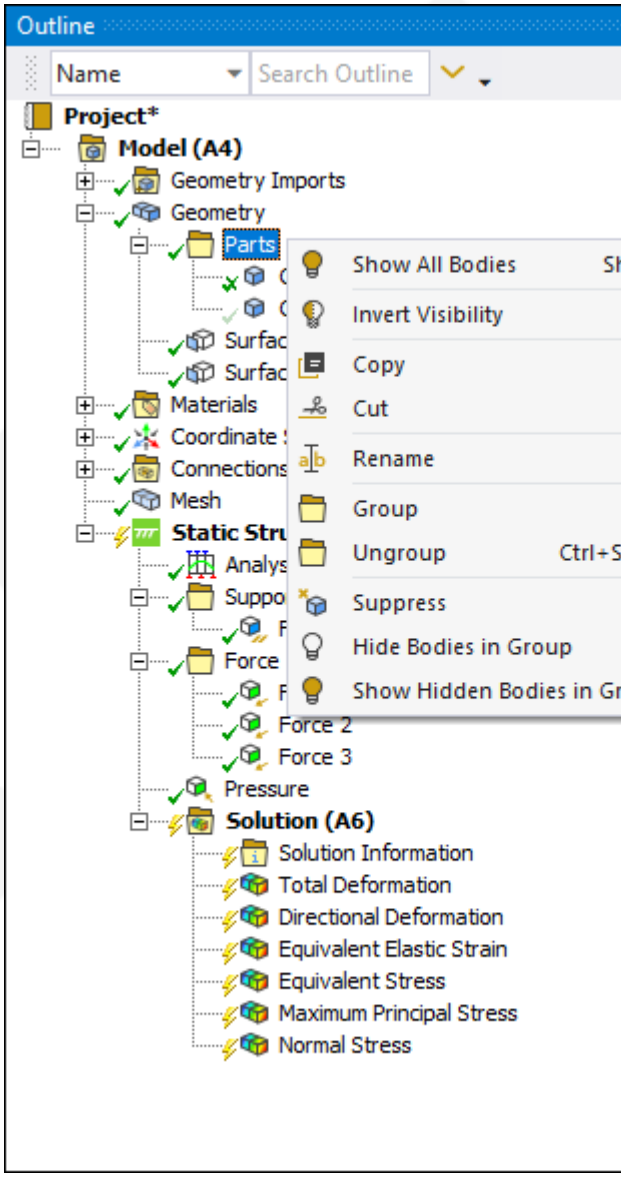


Group, Hide, and Suppress Geometry Objects

As illustrated below, the **Geometry** object offers additional grouping options that enable you to Hide and Show bodies inside and outside of a group as well as Suppress/Unsuppress (p. 113) bodies. The **F9** hotkey (p. 314) also enables you to hide selected bodies.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



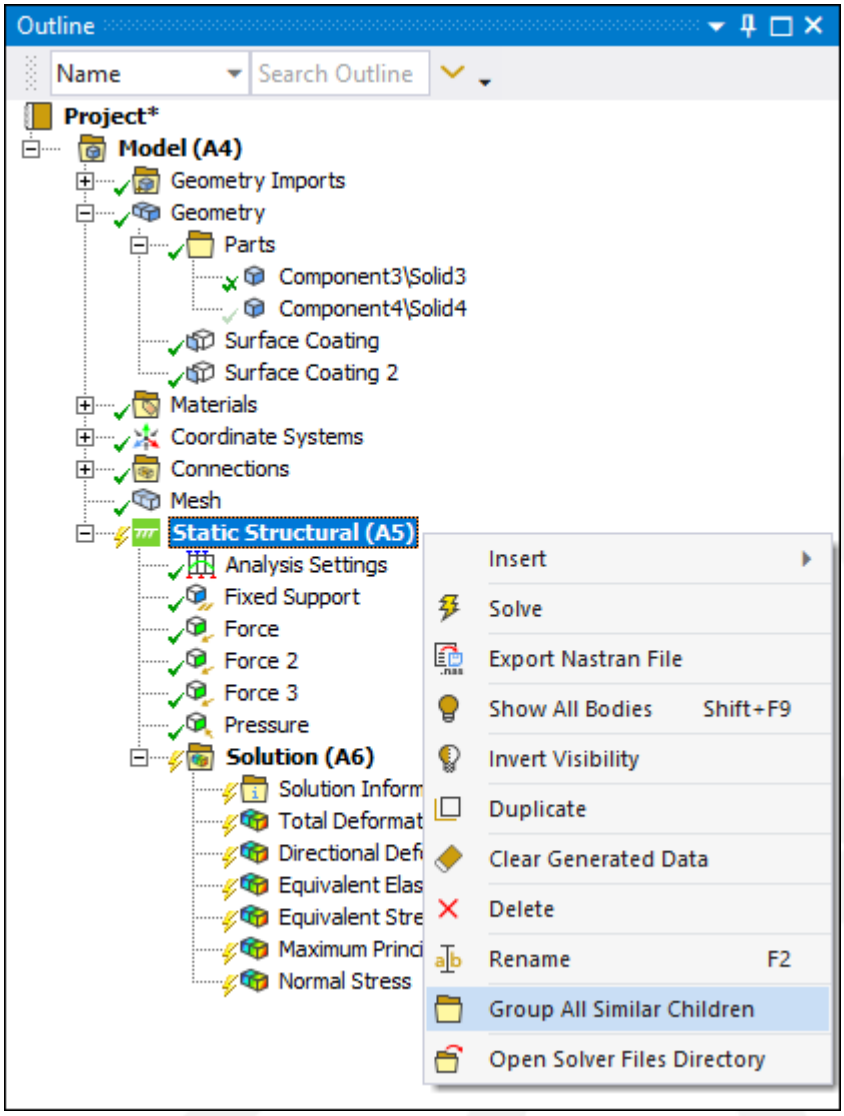


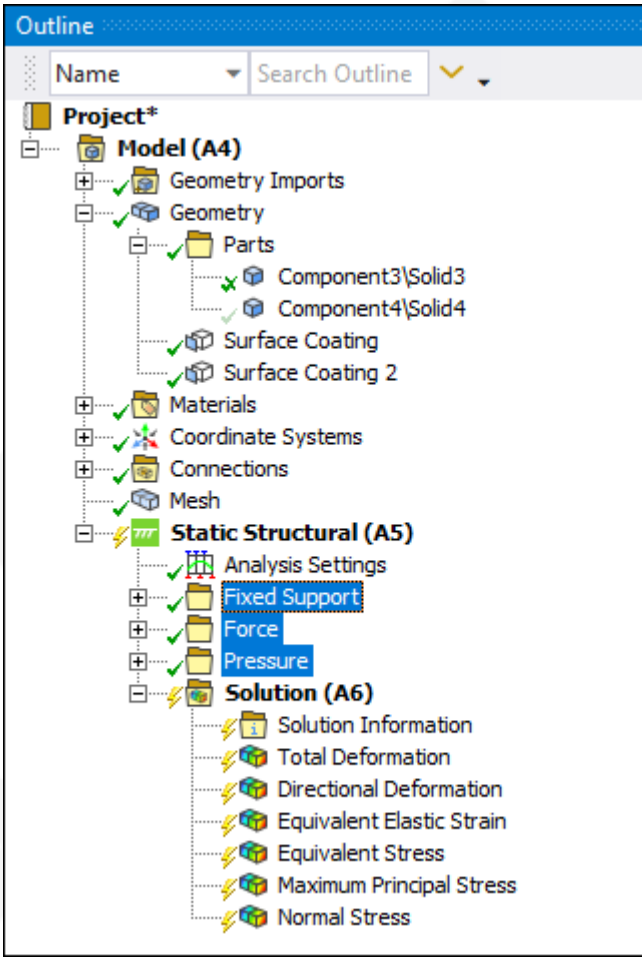
Group All

The **Mesh**, **Named Selection**, **Environment**, and **Solution** objects provide an option to **Group All Similar Children**. This option groups together the same type (for example, Mesh Method, Pressure, Stress result, etc.) of objects (that are not already included in a grouping) and automatically names the folder based on that type.

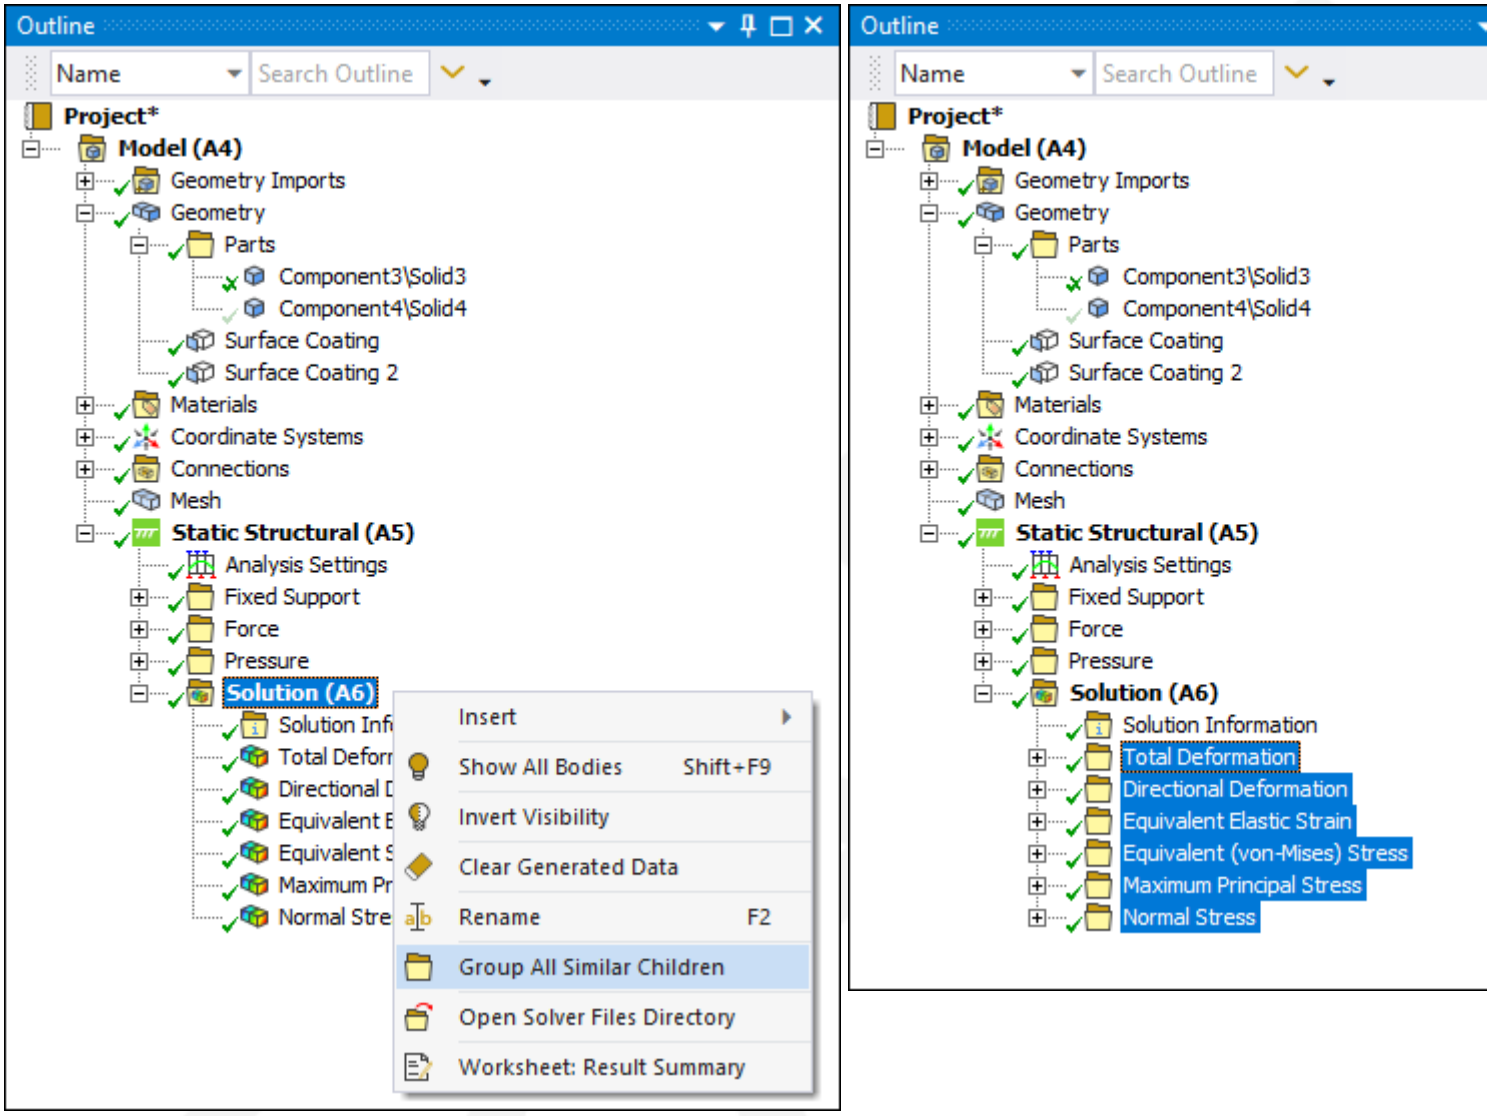
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23





Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

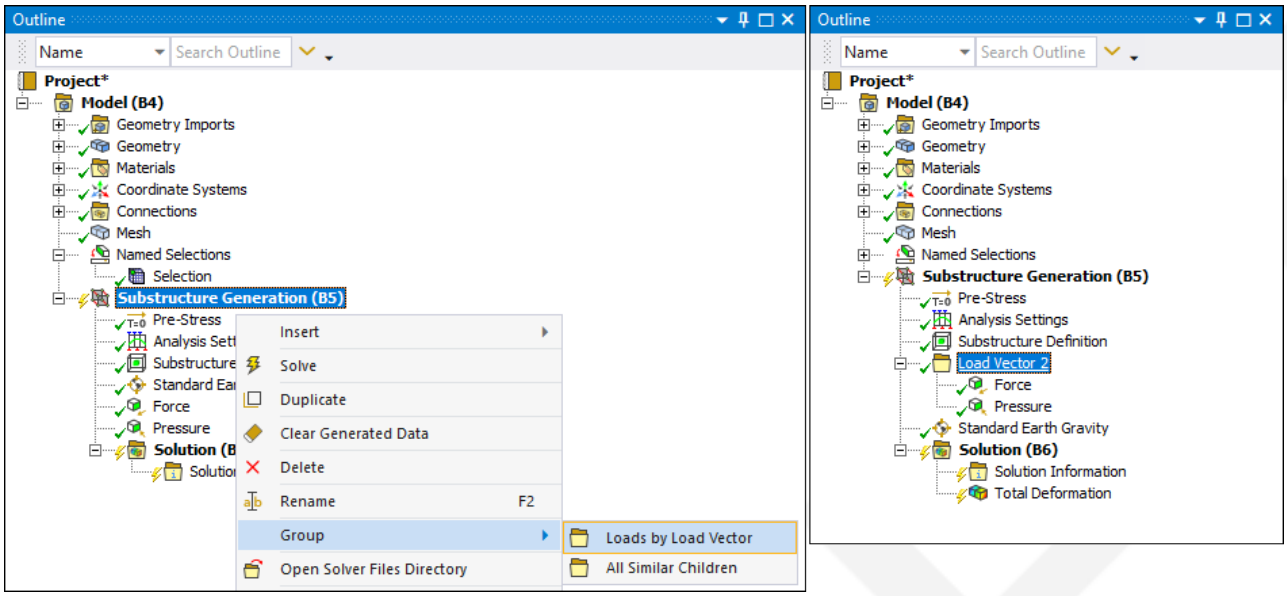


Group Loads by Load Vector (Substructure Generation Analysis Only)

For the boundary conditions supported by the Substructure Generation (p. 540) analysis, the Environment object provides the grouping option: **Loads by Load Vector**. This option automatically groups environment load objects that have the same **Load Vector Number**, as specified by the **Load Vector Controls** properties available from the boundary condition object. The application generates a folder based on the corresponding **Load Vector Number**, as illustrated below for load vector number **2**. Note that loads with the same load vector number that are already included in a group, are not added to the new group.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Objects with Limited Grouping

The following objects have limitations regarding grouping. This includes several objects that cannot be grouped.

- **Model** object children (except **Chart**) cannot be grouped. However, the child objects of these model-level children may be grouped.
- System generated Named Selections under the **Fracture** object cannot be grouped.
- **Gasket Mesh Control** objects under a **Part** object cannot be grouped.
- **Global Coordinate System**: this is the application defined Coordinate System and does not support grouping.
- **Reference Coordinate Systems**: These coordinate systems are *not* defined by the **Coordinate Systems** object and do not support grouping.
- **Analysis Settings**: grouping not supported.
- **Initial Conditions** (including child objects): grouping not supported.
- **Solution Information**: grouping not supported.

Interface Behavior Based on License Levels

The licensing level that you choose automatically enables you to exercise specific features and blocks other features that are not allowed. Presented below are descriptions of how the interface behaves when you attempt to use features not allowed by a license level.

- If the licensing level does not allow an object to be inserted, it will not show in the **Insert** menus.
- If you open a database with an object that does not fit the current license level, the database changes to "read-only" mode.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- If a Details view option is not allowed for the current license level, it is not shown.
- If a Details view option is not allowed for the current license level, and was preselected (either through reopening of a database or a previous combination of settings) the Details view item will become invalid and shaded yellow.

Note:

When you attempt to add objects that are not compatible with your current license level, the database enters a read-only mode and you cannot save data. However, provided you are using *any* license, you can delete the incompatible objects, which removes the read-only mode and enables you to save data and edit the database.

Environment Filtering

The Mechanical interface includes a filtering feature that only displays model-level items applicable to the particular analysis type environments in which you are working. This provides a simpler and more focused interface.

The environment filter has the following characteristics:

- Model-level objects in the tree that are not applicable to the environments under a particular model are hidden.
- The user interface inhibits the insertion of model-level objects that are not applicable to the environments of the model.
- Model-level object properties (in the Details view of objects) that are not applicable to the environments under the model are hidden.

The filter is enabled by default when you enter the Mechanical application. You can disable the filter by highlighting the **Model** object, clicking the right mouse button, and choosing **Disable Filter** from the context menu. To enable the filter, repeat this procedure but choose **Auto Filter** from the context menu. You can also check the status of the filter by highlighting the **Model** object and in the Details view, noting whether **Control** under **Filter Options** is set to **Enabled** or **Disabled**.

The filter control setting (enabled or disabled) is saved when the model is saved and returns to the same state when the database is resumed.

Application Preferences and Default Behaviors

You can specify certain application default settings and behaviors as well as create unique options. Select from and review the following for more information:

- Specifying Application Defaults and Preferences (p. 217)
- Creating User-Defined Buttons (p. 154)
- Setting Variables (p. 247)
- Using Macros (p. 248)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

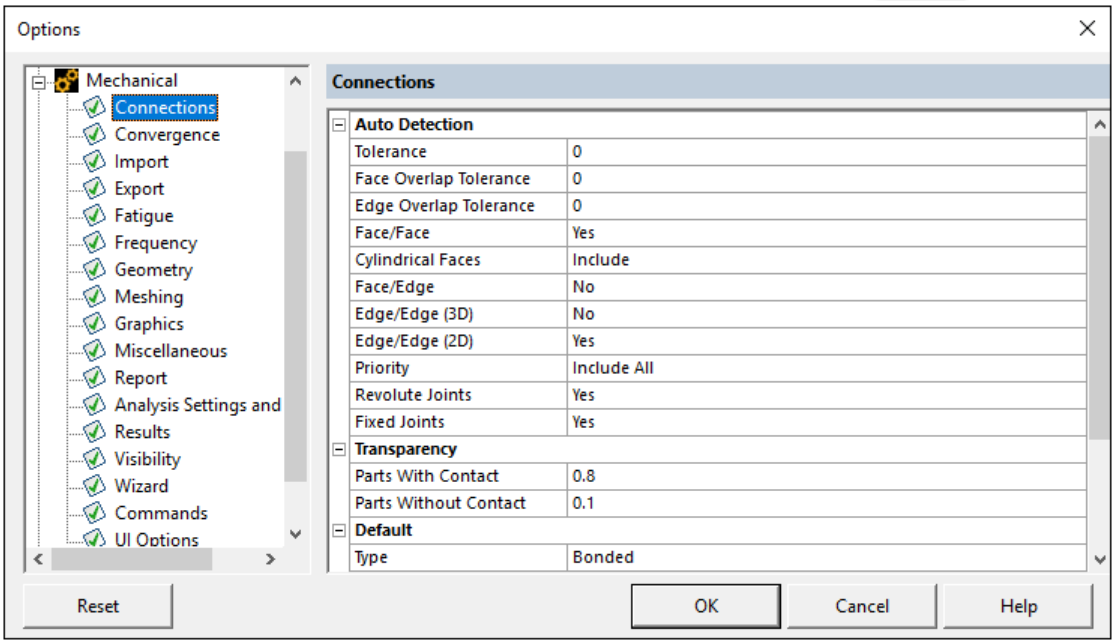
Specifying Application Defaults and Preferences

Using the **Options** dialog, you can control various behaviors and default functions of the application to better suit your uses. This feature essentially enables you to establish preferences for application behaviors and property settings.

Application

To open and make changes to **Options** settings:

1. Select the **File** tab and then **Options** (an option is also available beside the **Quick Launch** field on the title bar). A dialog box titled **Options** displays. Groupings associated with default behaviors for the application display under the Mechanical heading. These groups are referred to as categories. Within each category are various properties that you can change the settings for. For example, and as illustrated below, the **Connections** category is highlighted by default. Here you can see that you can specify a value for the **Face Overlap Tolerance** from the default of zero (0). These types of customizations can be very beneficial.



2. Select a desired category. Each category has associated properties.

3. Change any of the property settings by clicking directly in the field. You will first see a visual indication for the kind of interaction required in the field (examples are drop-down menus, secondary dialog boxes, direct text entries).

4. Click **OK**.

Important:

Option settings within a particular language are independent of option settings in another language. If you change any options from their default settings, then start a new Workbench

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

session in a different language, the changes you made in the original language session are not reflected in the new session. You are advised to make the same option changes in the new language session.

Note:

User Preferences File

The Mechanical application stores the configuration information from the **Options** dialog box in a file called a User Preference File on a per user basis. This file is created the first time you start the Mechanical application. Its default location is:

```
%APPDATA%\Ansys\v241\%AWP_LOCALE241%\dsPreferences.xml
```

Connections

The **Auto Detection** category enables you to change the default values for the following:

Note:

The auto contact detection on geometry attach can be turned on/off from the Workbench Options dialog box for the Mechanical application. See the Mechanical part of the Setting Ansys Workbench Options section of the Help.

- **Tolerance**: Sets the default for the contact detection slider; that is, the relative distance to search for contact between parts. The *higher* the number, the *tighter* the tolerance. In general, creating contacts at a tolerance of 100 finds fewer contact surfaces than at 0. The default is **0**. The range is from **-100** to **+100**.
- **Face Overlap Tolerance**: Sets the default tolerance for overlap of faces in contact; that is, the minimum percentage of overlap at which a contact pair is created for two overlapping faces. For example, if **Face Overlap Tolerance** is set to 25, a contact pair is created for each pair of faces for which at least 25% of one face overlaps the other. This setting enables the software to obtain more precise contact pairs during automatic contact generation based on a tolerance that is appropriate for your simulation type. The default is **0**, which means overlap checks are turned off. The range is from **0** to **100**.

  Note:

  The **Face Overlap Tolerance** value and the **Tolerance** value are evaluated together to determine which faces are considered to be in contact.

- **Face/Face**: Sets the default preference[1] (p. 220) for automatic contact detection between faces of different parts. The choices are **Yes** or **No**. The default is **Yes**.
- **Cylindrical Faces**: Set the default for separating flat surfaces from cylindrical faces for face/face contact. Options include **Include** (default), **Exclude**, and **Only**.
- **Face/Edge**: Sets the default preference[1] (p. 220) for automatic contact detection between faces and edges of different parts. The choices are:
  - **Yes**
  - **No** (default)
  - **Only Solid Edges**
  - **Only Surface Edges**
  - **Only Beam Edges**
- **Edge Overlap Tolerance**: Sets the default tolerance for overlap of an edge and a face in contact; that is, the minimum percentage of overlap at which a contact pair is created for an edge and a face that overlap. For example, if **Edge Overlap Tolerance** is set to 25, a contact pair is created

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

for an edge and a face when at least 25% of the edge overlaps the face. This setting enables the software to obtain more precise contact pairs during automatic contact generation based on a tolerance that is appropriate for your simulation type. The default is **0**, which means overlap checks are turned off. The range is from **0** to **100**.

- **Edge/Edge (3D)**: Sets the default preference[1] (p. 220) for automatic contact detection between edges of different parts in a three dimensional model. The choices are **Yes** or **No**. The default is **No**.

- **Edge/Edge (2D)**: Sets the default preference[1] (p. 220) for automatic contact detection between edges of different parts in a two dimensional model. The choices are **Yes** or **No**. The default is **Yes**.

- **Priority** (p. 1217): Sets the default preference[1] (p. 220) for the types of contact interaction priority between a given set of parts. The choices are:

  – **Include All** (default)

  – **Face Overrides**

  – **Edge Overrides**

- **Revolute Joints**: Sets the default preference for automatic joint creation (p. 1359) of revolute joints (p. 1299). The choices are **Yes** and **No**. The default is **Yes**.

- **Fixed Joints**: Sets the default preference for automatic joint creation (p. 1359) of fixed joints (p. 1298). The choices are **Yes** and **No**. The default is **Yes**.

[1] Unless changed here in the **Options** dialog box, the preference remains persistent when starting any Workbench project.

The **Transparency** category includes the following exclusive controls for this category. There are no counterpart settings in the Details view.

- **Parts With Contact**: Sets transparency (p. 1269) of parts in selected contact region so the parts are highlighted. The default is **0.8**. The range is from **0** to **1**.

- **Parts Without Contact**: Sets transparency of parts in non-selected contact regions so the parts are not highlighted. The default is **0.1**. The range is from **0** to **1**.

The **Default** category enables you to change the default values for the following:

- **Type**: Sets the definition type of contact (p. 1234). The choices are:

  – **Bonded** (default)

  – **No Separation**

  – **Frictionless**

  – **Rough**

  – **Frictional**

- **Behavior** (p. 1236): Sets the contact pair. The choices are:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - **Program Controlled** (default)
  - **Asymmetric**
  - **Symmetric**
  - **Auto Asymmetric**
- **Formulation**: Sets the type of contact formulation method (p. 1241). The choices are:
  - **Program Controlled** (default)
  - **Augmented Lagrange**
  - **Pure Penalty**
  - **MPC**
  - **Normal Lagrange**
- **Small Sliding**: This setting sets the default behavior for the **Small Sliding** (p. 1244) property. The options include **Program Controlled** (default), **Yes**, and **No**.
- **Update Stiffness**: Enables an automatic contact stiffness update (p. 1249) by the program. The choices are:
  - **Program Controlled** (default)
  - **Never**
  - **Each Iteration**
  - **Each Iteration, Aggressive**
- **Shell Thickness Effect** (p. 1232): This setting enables you to automatically include the thickness of surface bodies during contact calculations. The default setting is **No**.
- **Auto Rename Connections**: Automatically renames joint, spring, contact region, and joint condition objects when **Type** or **Scoping** are changed. The choices are **Yes** and **No**. The default is **Yes**.
- **Bushing Joint Worksheet View**: Enables you to set the default display (on or off) of the Worksheet for a Bushing Joint (p. 1303). Options include **Yes** (default) and **No**.

Convergence

The **Convergence** category enables you to change the default values for the following:

- **Target Change**: Change of result from one adapted solution to the next. The default is **20**. The range is from **0** to **100**.
- **Allowable Change**: This should be set if the criteria is the max or min of the result. The default is **Max**.

The **Solution** category enables you to change the default values in the Details view for the **Max Refinement Loops** property. This property enables you to change the number of refinement loops the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

application performs. The default is **1**. The range is from **1** to **10**. When performing an out of process (p. 1803) solution asynchronously, wherein the solve may finalize during another Workbench session, the application performs only one maximum refinement loop. As necessary, you must manually perform additional loops. To solve with a single user action, solve synchronously.

Import

The **Import** category enables you to specify preferences for when you import data into Mechanical. Currently, these preferences are for importing delamination interfaces from the Ansys Composite PrepPost (ACP) application.

- **Create Delamination Objects**: This option controls the automatic creation of Interface Delamination objects in Mechanical when importing layered section data from ACP. When Interface layers are specified in ACP, Interface Delamination objects corresponding to Interface Layers are automatically inserted into the Mechanical Tree Outline under the Fracture object. The default setting is **Yes**.
- **Delete Invalid Objects**: This option controls the deletion of Invalid Interface Delamination objects scoped to Interface Layers from ACP. When an Interface Layer specified in ACP is deleted, the corresponding Interface Delamination object is deleted in Mechanical when the project is refreshed. The default setting is **No**. This default setting suppresses invalid objects instead of automatically deleting them.

Export

The **Text File Export** category provides the following exclusive settings. There are no counterpart settings in the Details view.

- **File Encoding**: select either **ASCII** (default) or **UNICODE (Windows only)** as the encoding to use for exporting data.
- **Automatically Open Excel**: Excel will automatically open with exported data. The default is setting **Yes**.
- **Remove Duplicate Nodes**: When set to **Yes**, the application automatically removes any duplicate nodes when you export data to a text file (p. 249). The default setting is **No**.
- **Include Node Numbers**: Node numbers will be included in exported file. The default is setting **Yes**.
- **Include Node Location**: Node location can be included in exported file. The default is setting **No**.
- **Show Tensor Components**: Options include **Yes** and **No** (default). For the default setting **No**, the export data contains the principal stresses and strains (1, 2, and 3) as well as the three Euler angles. The export data for the **Yes** setting contains raw components of stress and strain (X, Y, Z, XY, YZ, XZ).
- **Show Additional Header**: Options include **Yes** and **No** (default). Prepend the exported file with the following header information:
  - Result File Name
  - Unit
  - Coordinate System

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - Environment Name
  - Time
  - Result Name
  - Result Type

The **STL Export** category provides the setting **Export Format**. This property sets the default for how STL files are exported, using either **Binary** (default) or **ASCII** format.

The **AVZ Viewer Option** category provides the property **Open AVZ Viewer**. When this property is set to **Yes**, the application automatically opens the Ansys Viewer (after you have saved the file) when you are exporting a result object using the contextual menu option **Ansys Viewer File (AVZ)**. When set to **No**, the application simply prompts you to save the AVZ file. This feature applies to result objects only.

The **Views** category provides the property **File Directory**. This property enables you to specify a default location to where you will export and/or import the graphical views (p. 292) that you have created, exported, or imported. Using the property's field, you enter a folder location, such as **`C:\Mechanical\Manage_Views`**. This location becomes the default folder location. By default, the application uses the automatically generated **`user_files`** folder.

Fatigue

The **General** category enables you to change the default values for the following:

- **Design Life**: Number of cycles that indicate the design life for use in fatigue calculations. The default is **1e9**.
- **Analysis Type**: The default fatigue method for handling mean stress effects. The choices are:
  - **SN - None** (default)
  - **SN - Goodman**
  - **SN - Soderberg**
  - **SN - Gerber**
  - **SN - Mean Stress Curves**

  The Goodman, Soderberg, and Gerber options use static material properties along with S-N data to account for any mean stress while Mean-Stress Curves use experimental fatigue data to account for mean stress.

The **Cycle Counting** category enables you to change the default values for the following:

- **Bin Size**: The bin size used for rainflow cycle counting. A value of 32 means to use a rainflow matrix of size 32 X 32. The default is **32**. The range is from **10** to **200**.

The **Sensitivity** category enables you to change the default values for the following:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Lower Variation**: The default value for the percentage of the lower bound that the base loading will be varied for the sensitivity analysis. The default is **50**.
- **Upper Variation**: The default value for the percentage of the upper bound that the base loading will be varied for the sensitivity analysis. The default is **150**.
- **Number of Fill Points**: The default number of points plotted on the sensitivity curve. The default is **25**. The range is from **10** to **100**.
- **Sensitivity For**: The default fatigue result type for which sensitivity is found. The choices are:
  - **Life** (default)
  - **Damage**
  - ***Factor of Safety***

Frequency

The **Modal** category enables you to change the Modal Analysis default values for the following:

- **Max Number of Modes**: The number of modes that a newly created frequency branch will contain. The default is **6**. The range is from **1** to **200**.
- **Limit Search to Range**: You can specify if a frequency search range should be considered in computing frequencies. The default is **No**.
- **Min Range (Hz)**: Lower limit of the search range. The default is value is **0.01** for Modal Acoustic analyses and **0.0** all other analysis types.
- **Max Range (Hz)**: Upper limit of the search range. The default is value is **100000000**.
- **Cyclic Phase Number of Steps**: The number of intervals to divide the cyclic phase range (0 - 360 degrees) for frequency couplet results in cyclic modal analyses.

The **Eigenvalue Buckling** category enables you to change the Eigenvalue Buckling Analysis default values in the Details view for the **Max Modes to Find** property. This property defines the number of buckling load factors and corresponding buckling mode shapes. The default value is **2**.

The **Harmonic** category enables you to change the default setting for the **Frequency Spacing** property. The options include:

- **Linear** (default)
- **Logarithmic**
- **Octave Band**
- **1/2 Octave Band**
- **1/3 Octave Band**
- **1/6 Octave Band**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **1/12 Octave Band**
- **1/24 Octave Band**

Geometry

The **Import** category provides the following properties:

- **Assembly Hierarchy**: Options include **Yes** and **No** (default). If your CAD file includes a hierarchy structure, the **Yes** setting enables Mechanical to automatically group the parts and bodies under the **Geometry** object.

  Note:

  If you group parts and bodies in SpaceClaim, you need to account for shared topology and the fact that shared topology creates multi-body parts. In this instance, the application groups multi-body parts together regardless of the assembly structure. You can use the **View Assembly Structure** tool to see how the SpaceClaim assembly structure is affected by Shared Topology in Mechanical. See the *SpaceClaim Documentation* (Workbench > Shared Topology > Viewing Tools > View Assembly Structure) for more information.

  Caution:

  You cannot change the **Assembly Hierarchy** setting once you have imported your geometry. This is due to a geometry update limitation.

- **Volume Calculation**. Options include **Analytical** (default) and **Faceted**. Using the **Faceted** option, the volume is calculated using the faceted (graphical) representation of the volume. This improves computation times. Note, however, that this setting could be less accurate (~0.1% depending on rendering quality or facet quality value) than the default setting.
- **Delete Missing Named Selections from CAD**: Options include **Yes** (default) and **No**. This setting deals with the interaction between the Named Selections you create in your CAD application and import into Mechanical. For either setting, you need to refresh your geometry from the source or refresh your project for Mechanical to be aware of any upstream changes.

  For the default **Yes** setting, if you delete a Named Selection in CAD and refresh your project, Mechanical automatically deletes the Named Selection from the Outline. In addition, any object scoped to the Named Selection becomes invalid.

  For the **No** setting, for any upstream deletion, instead of deleting the object from the Outline, it suppresses. Objects scoped to the Named Selection become invalid, however: the scoped object maintains the reference to the deleted Named Selection. That is, Mechanical keeps the name of the Named Selection in the appropriate property of the scoped object. This capability enables you to recreate the Named Selection in CAD and the application automatically reproduces downstream scoping once you refresh from the source application.

The **Geometry** category enables you to change the default values for the following:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Beam Cross Section (For Solver)**: Define the default setting to send user-defined cross-sections, to the Mechanical APDL solver, as either a **Pre-Integrated** (default) cross-section or as a **Mesh** section.
- **Nonlinear Material Effects**: Indicates if nonlinear material effects should be included (**Yes**), or ignored (**No**). The default is **Yes**.
- **Thermal Strain Calculation**: Indicates if thermal strain calculations should be included (**Yes**), or ignored (**No**). The default is **Yes**.
- **2D Tolerance**: For surface bodies, you use this property to set the tolerance used to validate that the imported geometry is two-dimensional (2D) by checking the value of the **Length Z** property, using CAD units, in the **Bounding Box** category. The default value for this property is 0.00001.
- **2D Axisymmetric Check**: When you import a 2D geometry (p. 878) and set its **Behavior** property to **Axisymmetric**, Mechanical automatically performs a check to make sure that the geometry lies only on the positive X axis. Certain CAD applications can automatically increase bounding box values and cause a geometry to appear in the negative X plane. This generates a system error that prohibits you from executing a solution. This property enables you to change a system generated error to a warning. **Options** include **Error** (default) and **Warning**. A **Warning** setting allows the application to attempt a solution.
- **Clear Mesh on Dimension Change**: When you change the setting (**3D** or **2D**) of the **Dimension** property (Body object) or if you change the setting of the **Analysis Type** property of the **Geometry** cell on the Workbench project page, also **3D** or **2D**, this preference instructs the application whether to automatically clear and regenerate the mesh. Options include **Yes** (default) and **No**.

Certain CAD applications automatically increase the bounding box size beyond the exact limits of the geometry and can cause the geometry to appear in the negative X plane. This causes Mechanical to generate an error and prohibit a solution. In this scenario, you can change the error setting to a warning in order to perform a solution. You use the **Geometry** (p. 225) preference **2D Axisymmetric Check** in the **Options** dialog to change this setting.

Note:

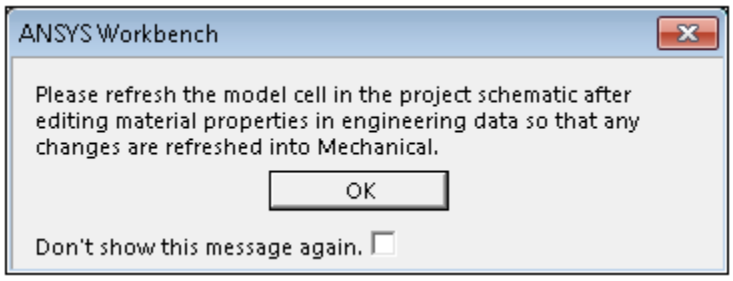
This setting applies only to newly attached models, not to existing models.

The **Material** category enables you to change the default values for the following:

- **Prompt for Model Refresh on Material Edit**: This setting relates to the material **Assignment** (p. 345) property. If you choose to edit a material or create/import a new material via this property, the application displays a message (illustrated below) reminding you to refresh the Model cell in the Workbench Project Schematic. The default setting is **Yes**. The message in Mechanical provides you with the option to not show the message again. This option is in addition to this method of changing this setting to **No**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



- **Assign Default Material to New Bodies Based on Update**: This setting relates to the default setting of the **Assign Default Material** property. The **Assign Default Material** property controls default material assignment when geometry is updated in Mechanical.

The **Geometry Based Associativity** category enables you to change the default values for the following:

- **Use Geometry Based Associativity**: Options include **Yes** (default) and **No**. When set to **Yes**, this preference instructs the application to retain available geometry data prior to a geometry update.
- **Automatic Scoping Update**: Options include **Yes** and **No** (default). When set to **Yes**, this preference enables the application to automatically correct geometry-based scoping that becomes lost following a geometry update.

Geometry Import

The **Geometry Import** category enables you to change the default settings of the properties associated with importing geometry into Mechanical. These are the same preferences that are available for the **Geometry** cell of an analysis system on the Workbench Project Schematic before you have specified a model to import. You should review the Geometry Preferences section of the *CAD Integration* documentation as well as the Geometry Import section of the *Workbench User's Guide* for additional information.

Meshing

The **Meshing** category enables you to change the value of **Default Physics Preference**. The physics preference that you choose here will be the default for all Mechanical systems, regardless of whether they are analysis systems or component systems. The choices are:

- **Mechanical** (default)
- **Nonlinear Mechanical**

Note:

The default physics preference that you can set in the Meshing application's **Options** dialog box has no effect on the default that is set for Mechanical systems.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Graphics

The **Default Graphics Options** category enables you to change the default values for the following:

- **Reset Views on Geometry Refresh**: Select whether geometry refreshes will reset the graphical view in Mechanical. The default setting is **No**.
- **Max Number of Annotations to Show**: A slider that specifies the number of annotations that are shown in the legend of the **Geometry** window. The range is adjustable from 0 to 50. The default is **10**.
- **Show Min Annotation**: Indicates if Min annotation will be displayed by default (for new databases). The default setting is **No**.
- **Show Max Annotation**: Indicates if Max annotation will be displayed by default (for new databases). The default setting is **No**.
- **Obscured Label Display Style**: Options include **Solid** (default), **Translucent**, and **Hidden**. When you have an annotation label applied on either the **Mesh** object or on a result object, or you have a probe label applied to a result, this preference lets you choose whether to have the label/probe show "through" the model when a label or probe is not visible because of the model's current orientation.
- **Unobscured Label Tolerance Factor**: There may be times when a label displays as obscured when it should not. This is most often a result of how the application calculates the location of a label. There are instances when a label's position will be located beneath the surface of a body. For the Translucent or Hidden options, this tolerance enables you make small adjustments to the tolerance factor to make sure that the label behaves as expected. The tolerance range is between 0 and 1. Small incremental changes, such as 0.0001, can be appropriate to properly display obscured labels.
- **Number of Local Min/Max Probes**: Specify the number of Min/Max probe labels (p. 2278) you wish to display for your result data. The default setting is **6**. The supported range is 1-20.
- **Contour Option**: Selects default contour option. The options include:
  - **Smooth Contour**
  - **Contour Bands** (default)
  - **Isolines**
  - **Solid Fill**
- **Flat Contour Tolerance**: Flat contours (no variation in color) display if the minimum and maximum results values are equal. The comparison of the minimum and maximum values is made using scientific notation with the number of significant digits to the right of the decimal point as specified with the flat contour tolerance setting (**3** to **9**). Increasing this tolerance enables you to display contours for an otherwise too narrow range of values. Decreasing this tolerance prevents insignificant range variations from being contoured. This setting has a default value of **3**.
- **Edge Option**: Selects default edge option for result display. The choices are:
  - **No Wireframe**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - **Show Undeformed Wireframe**
  - **Show Undeformed Model**
  - **Show Elements** (default)
- **Highlight Selection**: Indicates default face selection. The choices are:
  - **Single Side** (default)
  - **Both Sides**
- **Number of Circular Cross Section Divisions**: Indicates the number of divisions to be used for viewing line body cross sections (p. 877) for circular and circular tube cross sections. The range is adjustable from 6 to 360. The default is **16**.
- **Mesh Visibility**: Indicates if mesh is automatically displayed when the **Mesh** object is selected in the Tree Outline, or if it's only displayed when you select the **Show Mesh** button. The default is **Automatic**.
- **FE Annotation Color**: This option enables you to change the default coloring for FE related annotations (FE-based Named Selections and/or Objects scoped to Nodes (p. 269) or Elements (p. 276)). It also changes the color of the elements displayed for an Analysis Ply object.
- **Mesh Failed Color**: Set the color of the of the **Mesh Failed** annotation.
- **Mesh Obsolete Color**: Set the color of the of the **Mesh Obsolete** annotation.
- **Geometry Highlight Color**: Specify the default color used when a part or body is selected from the **Geometry** folder.
- **Level of Detail (Beta)**: This selection defines two separate behaviors: 1) the level of complexity for the graphical display of the model in the **Geometry** window and 2) the speed it to takes select objects in the **Outline**. See the beta documentation for this option.
- **Model Rotation Center**: This option enables you to change how the rotation feature behaves. Selections include:
  - **Click to Set** (default): Select a location on the model to be the center of rotation.
  - **On Mouse Down**: Select a location on the model to be the center of rotation. Rotation is available immediately - no additional mouse selections ("clicks") are required.
- **Shell Expansion Edge Angle**: This option enables you to change the setting for the angle used to determine whether adjacent element normals are averaged. This is applicable when shell thickness is being applied to the mesh to represent the actual thickness. The range is adjustable from 0 to 180. The default is **180**.
- **Line Body Thickness**: This option enables you to change how line bodies are displayed in the **Geometry** window. Selections include **Thin** (default) and **Thick**.
- **Mouse Rotation Mode**: This option enables you to change cursor rotation behaviors (p. 280) in the **Geometry** window when you are using the **Rotate** option on the Graphics toolbar (p. 97). Selections include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

  - **Free Rotate Only** (default): using this setting, the cursor provides free 360° model rotation.
  - **Axis Rotation Available**: specifying this setting activates the roll, yaw, and pitch cursor options.

- **Triad Smooth Rotation**: Active by default, this option instructs the application to compute the shortest path between model positions when using the **Triad** feature in order to facilitate smoother model rotations. Options include **Yes** (default) and **No**.
- **Show Coupled Physics Analysis**: For analyses that support the use of the Physics Region object, this preference enables you to display the bodies and/or parts associated with each properly defined **Physics Region** as a different color when the Environment object is selected. Options include **Yes** and **No** (default).
- **Consider Section Planes When Mesh Picking**: Options include **Yes** and **No** (default). Activating this preference enables you to select newly displayed finite element entities (nodes, elements, and element faces) from geometries within the model that were hidden before adding the specified Section Plane (p. 294). See the Selecting Mesh Entities Displayed by the Section Plane (p. 301) topic for additional information.
- **Animation Draw Option**: Options include **Yes** (default) and **No**. In older releases, the application first processed result animations and then displayed them instead of displaying the animation as it is being processed. As needed, you can revert to the previous display method by setting the this property to **No**.
- **Use Deformed Edge for Slice ISO Option**: Options include **Yes** (default) and **No**. This property applies to the **IsoSurfaces**, **Capped IsoSurfaces**, and **Section Planes** options of the **Geometry** menu (p. 67) and the **Show Undeformed Wireframe** and **Show Undeformed Model** options of the **Edges** menu, both of the Result (p. 62) Context tab, and how they work together. When you set this property to **No**, the **IsoSurfaces**, **Capped IsoSurfaces**, and **Section Planes** options display the selected result in a deformed state but a wireframe overlay (**Show Undeformed Wireframe**) of the model or a translucent overlay (**Show Undeformed Model**) of the model in an undeformed state.
- **Disable 2D Overlays** (Linux Platform Only): Options include **Yes** and **No** (default). When active, this option stabilizes the graphical display by preventing your model from disappearing during mouse movements. This option also turns off a variety of display features, such as the ability to highlight geometry selections (single, box select, lasso, etc.) prior to selecting a geometric entity, as well as graphics labels (such as interactive probe labels). These display and selection features operate properly, but do not provide pre-selection highlights and labels.
- **Mesh Translucency**: This preference defines the translucency of the displayed mesh. The slider option has a range of **0** (no translucency) to **1** (totally transparent). The default setting is **0**.
- **Maximum Face Angle to Preserve Edges**: When you have the **Edges** (p. 68) result display set to **Show Undeformed Wireframe**, you could experience display issues for edges when the tolerance angle between two faces is insufficient. This preference enables you to increase this tolerance. The default setting is **`120°`**. Supported entry range is **`0`** to **`180°`**.
- **Anti-Aliasing (MSAA)** (Windows Only): Options include **Off**, **Low (2x)**, **Medium (4x)**, and the default **High (8x)**. You use this preference to specify the desired sampling level for the display of the model in the **Geometry** window. The sampling process smooths the display of jagged edges. You can cycle through these settings using the key combinations **Shift**+**[1]** through **Shift**+**[4]**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Contour Edge Line Weight**: For results scoped to edges, this preference enables you to specify the thickness of edge result contours. It provides an entry field combined with a slider option. The setting range is **0** to **8**. The default setting is **5**.
- **Mesh Edge Coloring**: This preference enables you to change the color of mesh lines/edges from the default black to the mesh body's color in order to improve edge visibility for dense meshes. Options include **Yes** and **No** (default).

The **Interactive and Min/Max Probes** category enables you to change how Probe annotations (p. 71) behave and display. Options include:

- **Move Probe Labels with Deformation Scale Factor**: Options include **Yes** (default) and **No**. Enables probe labels to move with a deformed mesh when you make a change to the Deformation Scale Factor (p. 63). If set to **No**, the application deletes probe labels whenever you change to the scale factor.
- **Show Mesh Entity ID in Snap-Probe Labels**: Options include **Yes** (default) and **No**. Enables you to automatically display Node or Element IDs on probe annotations (p. 71) when the **Snap** option is selected.
- **Probe Line Color**: Set the color of the line that connects a probe label to its location on the model.
- **Show Detailed Information in Min/Max Probe Labels**: Options include **Yes** and **No** (default). When active, the application displays the min/max values as well as Node or Element ID on the probe annotation label.

The **Probe Tool and Hit Point Coordinate (Windows Only)** category enables you to change the default values for the attributes (font, size, style, color) of the font displayed for the **Probe** (p. 71) annotations. Options include:

- **Font**: Arial is the default font. Ten font types are available for selection.
- **Size**: The font size is in pixels. 18 is the is the default size. The size range is 10 to 30.
- **Style**: Styles include Regular (default), Bold, Italic, and Bold Italic.
- **Color**: White is the default color. A color palette displays when you select this option.

The **Lighting** category enables you to change the default values for the following properties of the Model object:

- **Ambient**: Default value is 0.1.
- **Diffuse**: Default value is 0.6.
- **Specular**: Default value is 1.
- **Color**: The default is white.
- **Force White Lighting for Results**. When you change the **Color** property of the Model object from white, this property enables you to make sure that load variation contours and result

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

contours will correspond to the color contours of the legend. Options include **Yes** and **No** (default).

Important:

Lighting preferences are project-based, therefore, when you change one of these default settings, you must close Mechanical and Workbench and then begin a new project. Once established, all future saved projects will include the preferences. Any previously saved projects will have the lighting defined when the project was saved.

The **Image Export** category defines the resolution, image content, background characteristics, and font size contained on the image when you save it as a file using the **Image to File** option in the **Image** drop-down menu on the **Insert** (p. 42) group Home (p. 40) tab, or when you create a **Figure** (p. 313), or when you prepare a **Print Preview** (p. 173) of an object or a **Report Preview** (p. 174). It includes the following properties:

- **Current Graphics Display**: Specify that the option is turned on or off: **Yes** (default) or **No**.
- **Graphics Resolution**: Defines default resolution setting. Options include:
  - **Optimal Onscreen Display (1:1)** (default)
  - **Enhanced Print Quality (2:1)**
  - **High Resolution Print Quality (4:1)**

Note:

The Ansys logo does not scale at higher resolution settings.

- **Image to Clipboard Uses Graphics Resolution**: Instructs the application to use the setting of the **Graphics Resolution** preference (described above) when you use the **Image to Clipboard** option of the **Images** drop-down menu (**Home** tab/Insert (p. 42) group). Settings for this preference include **Yes** and **No** (default).
- **Capture**: Defines whether the legend is included in the image. Options include:
  - **Image and Legend** (default)
  - **Image Only**
- **Background**: Defines the background coloring. Options include:
  - **Graphics Appearance Setting** (default): Mechanical setting or user-defined background color.
  - **White**
- **Show Preferences Dialog**: **Yes** (default) or **No**. This option determines whether a dialog box automatically displays when you select the **Image to File** option. The dialog box contains all of

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

the above options. If disabled using this option, the application saves the most recent settings that you have used.

- **Font Magnification Factor**: This setting changes the font size of the textual content contained in the legend. The magnification range for the font size is **0.5** to **1.5**. If you enter a value less than or greater than this range, the application will default to the corresponding minimum (**0.5**) or maximum (**1.5**) value. The default value is **1**. This setting also scales the contour color band.

- **Append Graph**: Options include **Yes** and **No** (default). When set to **Yes**, the application adds the content of the **Graph** window in to the captured image of the viewport. If there is no corresponding data in the **Graph**, the captured image is appended with a graph that includes no data. When set to **Yes**, the corresponding setting on the Image to File Preferences (p. 42) dialog is activated.

- **Composite Image Borders**: Options include **None** (default), **Interior**, **Exterior**, and **Interior and Exterior**. The application automatically adds the specified borders around/in-between the captured viewports or includes no borders. When you select one of the border options, the corresponding setting(s) on the Image to File Preferences (p. 42) dialog is/are automatically activated.

- **Probe Label Offset**: The options for this setting relate to how the application captures and saves images of results displayed in the **Geometry** window as well as how the application presents images on the **Print Preview** (p. 173) tab, when you have inserted Probe labels and then moved those probe labels (p. 207) on the screen. Options include:

  – **Respect User-Defined Offset** (default): This options ensures that probe labels maintain their location in the **Geometry** window when you are using the **Image to File** option contained in the **Image** drop-down menu on the **Insert** (p. 42) group Home (p. 40) tab or if you are using the **Print Preview** feature.

  – **Reset to Probe Anchor**: This options ensures that probe labels maintain their location in the **Geometry** window when you are using the **Image to File** option but only when the **Graphics Resolution** preference is a 1:1 ratio. Otherwise, the application places the probe labels in their original position. This option also places the probe labels in their original position if you employ the **Print Preview** feature.

Animation Export: This category contains the property **Legacy Animation Export**. Setting this property to **Yes** enables you to export AVI animation files using Microsoft Windows API on the Windows platform. The default setting is **No**.

The **Legend** category provides the control of the following:

- **Orientation**: Select a desire display orientation for the legend. Options include **Vertical** (default) and **Horizontal**.

- **Show Min/Max on Color Bar**: You use this setting to either display or hide (default) the legend's context menu (right-click) option **Show Min/Max on Color Bar**. Options include **Yes** and **No** (default).

- **Show Deformation Scale Factor**: You use this setting to either display (default) or hide the legend's context menu (right-click) option **Show Deformation Scale Factor**. Options include **Yes** (default) and **No**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Show Date and Time**: Options include **Yes** (default) and **No**. This control enables you turn off the display of the date and time in the **Geometry** window. The context (right-click) menu option **Date and Time** also changes this default setting.
- **Max Number of Labels to Shown in Legend**: A slider that specifies the number of annotations that are shown in the legend of the **Graph** window when you are using Charts (p. 1929). The range is adjustable from 0 to 50. The default is 10.

The **Performance** category provides the control of the following:

- **Accelerated Graphics for Mesh/Result Display**: See the Accelerated Graphics (p. 289) section for more information. Property options include:
  - **Program Controlled** (default): The application selects the graphical mode based on application settings and support status, such as analysis settings, the specified result, view options, etc. This is the recommended setting.
  - **Yes, if possible**: This setting forces the use of **Accelerated Graphics** wherever possible, even if only partially supported.
  - **No**: This setting disables the feature.
- **Animation Mode** (p. 2268). Options include:
  - **Program Controlled**: The application selects the animation mode based on the given analysis to balance performance and display features.
  - **Standard** (default): This setting uses the traditional animation process. It supports all display options without processing capabilities.
  - **Accelerated (Beta)**: This setting offers improved processing capabilities.
- **Use Faceted Lighting for Accelerated Graphics/Animation (Beta)**: This beta property enables you to modify the lighting. Options include **No** (default) and **Yes**. The **No** option specifies the standard lighting mode. This setting can cause issues with large deformation but maintains smooth lighting and is suitable for most models. The **Yes** setting uses an alternate faceted lighting mode. Lighting is done on a per-triangle basis resulting in a more jagged rendering of some models, but the lighting should be correct for any deformation.
- **Show Why Accelerated Graphics is Not Used**: Display an Information message for why Accelerated Graphics (or Accelerated Animation) is not used for the mesh and results when it is not possible. Options include **No** (default) and **Yes**.

Note:

Informational messages may display even when the Accelerated Graphics feature is disabled because this preference also supports Accelerated Animation. Accelerated Animation is controlled by the **Animation Mode** preference described above.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Edge Connectivity Display Mode**: This preference controls the internal algorithm used to compute and highlight the edges of your model when the By Connection (p. 84) option is selected. Options include **Accelerated** (default) and **Legacy**.

  Important:

  When set to **Accelerated**, hidden faces are not taken into consideration when computing the number of shared edges.

- **Show Accelerated Display Message in Graphics Window**: Turn the "Accelerated Display" label on and off. Options include **No** (default) and **Yes**.
- **Varying Loads (Optimization Options)**: Specify how varying loads display in the **Geometry** window. Options include **Accuracy** (default) and **Performance**. The **Accuracy** setting displays variable load contours normally. The **Performance** option displays colored discrete points on the model, based on legend colors, of the load variation. This option provides significantly faster redrawing times. The computational improvement may be desirable for models with a large number of parts/bodies.

Miscellaneous

The **Miscellaneous** property enables you to change the default values for the following:

- **Load Orientation Type**: Specifies the orientation input method for certain loads. This input appears in the **Define By** option in the Details view of the load, under **Definition**.
  - **Vector** (default)
  - **Component**
- **Reverse Displacement for Inverse Steps**: Options include **No** (default) and **Yes**.

Cross Sections

Unique Names:

The **Named Selections** category includes the preference **Unique Names (MAPDL Solver)**. Options include **Warning** (default) and **Error**. When the Mechanical APDL solver encounters a duplicate named selection it issues a Warning. This preference enables you to change the issuance to an **Error**. If set to **Error**, the application will stop the solution process and allow you to address the naming issue.

The **Image** category includes the **Image Transfer Type** control. There are no counterpart settings in the Details view. Using this control, you define the type of image file created when you send an image to Microsoft Word or PowerPoint,or when you select Print Preview. Options include:

- **PNG** (default)
- **JPEG**
- **BMP**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The **Post Processing (MAPDL Only)** category includes the control **Result File Caching**. This control is for results files written by the Mechanical APDL solver only. By holding substantial portions of a file in memory, caching reduces the amount of I/O associated with result file reading. The cache can, however, reduce memory that would otherwise be used for other solutions. Control options include:

- **System Controlled** (default): The operating system determines whether or not the result file is cached for reading.
- **Off**: There is no caching during the reading of the result file.
- **Program Controlled**: The Mechanical application determines whether or not the result file is cached for reading.

Note:

You need to close and then reopen Mechanical in order for changes to this preference to take effect.

The **Save Options** category includes the following controls for this category.

- **Save Project Before Solution**: Sets the **Yes** / **No** default for the **Save Project Before Solution** setting located in the Project Details panel. Although you can set the default here, the solver respects the latest **Save Project Before Solution** setting in the Details panel. The default for this option is **No**. Selecting **Yes** saves the entire project immediately before solving (after any required meshing). If the project had never been previously saved, you can now select a location to save a new file.
- **Save Project After Solution**: Sets the **Yes** / **No** default for the **Save Project After Solution** setting in the Project Details panel. The default for this option is **No** Selecting **Yes** Saves the project immediately after solving but before postprocessing. If the project had never been previously saved, nothing will be saved.

Note:

The save options you specify on the Project Details panel override the options specified in the Options dialog box and will be used for the current project.

Clipboard

Find Objects by Name on Paste:

The **Legend** category of the Miscellaneous option provides the control **Show Date and Time**. Options include **Yes** (default) and **No**. This control enables you turn off the display of the date and time in the **Geometry** window. The context (right-click) menu option **Date and Time** also changes this default setting.

Messages

The **Messages** category enables you to change the default values for the following:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Report Performance Diagnostics in Message**: Turn on messaging that reports the time it takes for certain processes to execute, such as the time it takes for contact detection, mesh generation, writing the input file, solution, etc. Options include **Yes** and **No** (default).
- **Pop-up Messages**: Turn pop-up messages in the Message Window (p. 200) on (**Yes**, default) or off (**No**).
- **Message Coloring**: Set whether to have the application highlight objects in the tree that are experiencing an issue. The objects as well as the corresponding message in the Messages window can be highlighted or you can select to highlight only Message window content. The available options include **On** (default), **Off**, and **Messages Window Only**.

  Note:

  You need to close and then reopen Mechanical in order for changes to this preference to take effect.

- **Show Info Messages**: Turn **Information** messages on or off. Options include **Yes** (default) and **No**.
- **Show Warning Messages**: Turn the automatic display of **Warning** messages on or off. Options include **Yes** (default) and **No**.
- **Merge Similar Messages**: Merge similar messages of the Messages (p. 200) window into one row. Options include **Yes** (default) and **No**. Changing this preference changes the setting of the **Merge Message** option of the **Messages** window if you close the application.

Report

The **Figure Dimensions (in Pixels)** category includes the following controls that allow you to make changes to the resolution of the report for printing purposes.

- **Chart Width** - Default value equals **600** pixels.
- **Chart Height** - Default value equals **400** pixels.
- **Graphics Width** - Default value equals **600** pixels.
- **Graphics Height** - Default value equals **500** pixels.
- **Graphics Resolution** - Resolution values include:
  - **Optimal Onscreen Display (1:1)**
  - **Enhanced Print Quality (2:1)**
  - **High-Resolution Print Quality (4:1)**

The **Customization** category includes the following controls:

- **Maximum Number of Table Columns**: (default = **12** columns) Changes the number of columns used when a table is created.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Merge Identical Table Cells**: merges cells that contain identical values. The default value is **Yes**.
- **Omit Part and Joint Coordinate System Tables**: chooses whether to include or exclude Coordinate System data within the report. This data can sometimes be cumbersome. The default value is **Yes**.
- **Include Figures**: specifies whether to include **Figure** objects as pictures in the report. You may not want to include figures in the report when large solved models or models with a mesh that includes many nodes and elements are involved. In these cases, figure generation can be slow, which could significantly slow down report generation. The default value is **Yes**.

  Note:

  This option applies only to **Figure** objects as pictures. **Graph** pictures, Engineering Data graphs, and result graphs (such as phase response in a harmonic analysis) are not affected and will appear regardless of this option setting.

- **Custom Report Generator Folder**: reports can be run outside of the Workbench installation directory by copying the Workbench **Report2006** folder to a new location. Specify the new folder location in this field. See the Customize Report Content (p. 177) section for more information.

Analysis Settings and Solution

The **Solver Controls** category enables you to change the default values for the following:

- **Solver Type**: Specifies which Mechanical APDL solver will be used. The choices are:
  - **Program Controlled** (default)
  - **Direct**
  - **Iterative**
- **Use Weak Springs**: specifies whether weak springs are added to the model. The **Program Controlled** setting automatically enables weak springs to be added if an unconstrained model is detected, if unstable contact exists, or if compression only supports are active. The choices include:
  - **Program Controlled**
  - **On**
  - **Off** (default)
- **Solver Pivot Checking (p. 1434)** : Sets the default for all new analyses created. Options include:
  - **Program Controlled** (default): enables the solver to determine the response.
  - **Warning**: Instructs the solver to continue upon detection of the condition and attempt the solution.
  - **Error**: Instructs the solver to stop upon detection of the condition and issue an error message.
  - **Off**: Pivot checking is not performed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The **Solver Control (Eigenvalue Buckling)** category provides the **Include Negative Load Multiplier** property. Options include **Program Controlled** (default), **Yes**, and **No**. This option enables you to evaluate either negative and positive load multipliers or only positive load multipliers. The **No** setting evaluates positive load multipliers given the load directions. The **Yes** setting evaluates positive load multipliers given the load directions as well as the negative load multipliers by flipping the load directions.

The **Output Controls (Static and Transient)** category enables you to change the default values for the following:

- **Stress** (Default setting = **Yes**)
- **Strain** (Default setting = **Yes**)
- **Nodal Forces** (Default setting = **No**)
- **Contact Miscellaneous** (Default setting = **No**)
- **General Miscellaneous** (Default setting = **No**)
- **Calculate Reactions** (Default setting = **Yes**)
- **Calculate Thermal Flux** (Default setting = **Yes**)

The **Output Controls (Modal)** category enables you to change the default value for the following:

- **Stress**: Writes stress results to the file, `file.mode`. Options include **Yes** (default) and **No**.
- **Strain**: Writes strain results to the file, `file.mode`. Options include **Yes** (default) and **No**.
- **Store Modal Results**: Options include **Program Controlled** (default), **No**, or **For Future Analysis**.

The **Options (Modal, Harmonic and Transient Mode Superposition)** category enables you to change the default settings for the following:

- **On Demand Expansion Option** property: This property is contained in the Options (p. 1447) category of the **Analysis Settings** object. Options include **Program Controlled** (default), **Yes**, and **No**. You use this property to improve solution performance and reduce result file sizes.
- **On Demand Mode Shapes** preference: Options include **Yes** (default) and **No**. When you set this preference and the **On Demand Expansion** property to **Yes**, the application automatically removes mode shape data from result files.

The **Options (Random Vibration)** category enables you to change the default value for the following:

- **Exclude Insignificant Modes**: When set to **Yes**, this property enables you to exclude modes for the mode combination based on the entry of the **Mode Significance Level** property. The default setting is **No**.
- **Mode Significance Level**: This property defines the threshold for the numbers of modes for mode combination. The default setting is **0** (all modes selected). Supported entries are between **0.0** and **1**. Displayed only when **Exclude Insignificant Modes** is set to **Yes**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The **Output Controls (Random Vibration)** category enables you to change the default value for the following:

- **Keep Modal Results**: include or remove modal results from the result file of Random Vibration analysis. The default setting is **No**.
- **Calculate Velocity**: Write Velocity results to the results file. The default setting is **No**.
- **Calculate Acceleration**: Write Acceleration results to the results file. The default setting is **No**.

The **Restart Controls** category enables you to change the default value for the following:

- **Generate Restart Points**: **Program Controlled** (default setting) automatically generates restart points. Additional options include **Manual**, that provides user-defined settings, and **Off**, which restricts the creation of new restart points.
- **Retain Files After Full Solve**: when restart points are requested, the necessary restart files are always retained for an incomplete solve due to a convergence failure or user request. However, when the solve completes successfully, you have the option to request to either keep the restart points by setting this field to **Yes**, or to delete them by setting this field to **No**.

Note:

You can control these settings in the Details view of the **Analysis Settings** object under Restart Controls (p. 1438), or in the **Options** dialog under the **Analysis Settings and Solution** preferences list. The setting in the Details view overrides the preference setting.

The **RSM** category includes the preference, **RSM Polling Delay (sec)**. This preference controls how often the processing from a remote solution is polled or queried for result data. The default setting is 5 seconds. The supported range is 1 to 6000 seconds. This feature does not prolong solution processing. Solution completion ends the polling process.

The **Solution Information** category enables you to change the default value of the following Details pane properties:

- **Refresh Time**: specifies how often any of the result tracking items under a Solution Information (p. 1833) object get updated while a solution is in progress. The default is **2.5 s**.
- **Activate FE Connection Visibility**: specifies the value of the **Activate Visibility** property. The default setting is **Yes**.

The **Analysis Data Management** category enables you to specify default settings for the following:

- **Scratch Solver Files Directory**: Use this option to specify a unique disk drive that the application will use to process the solution. Using this entry field, you must specify an existing disk location. If the entry is invalid, the application uses the default disk.
- **Save MAPDL Database**: Use this option to set the default value for the **Save MAPDL Database** control. Selections include **No** (default) or **Yes**. The setting of the **Future Analysis** control (see **Analysis Data Management** (p. 1484) Help section) can sometimes require the database file to be written. In this case, the **Save MAPDL Database** control is automatically set to **Yes**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Solver File Verbosity**: For loading conditions imported from External Model, this preference enables you to control how much information is written to the input file (`ds.dat`) and output file (`solve.out`) during the solution process. Options include:

  – **Minimum** (default): The application does not write comments to the input and solver file. This option provides faster processing time from the Mechanical APDL solver.

  – **Medium**: The application writes comments to the input file, but no comments are written (echoed) to the solver file.

  – **Verbose**: The application writes comments to the input and solver file.

The **Analysis Data Management (Modal)** category enables you to set the default value for the **Future Analysis** property. The options include **None** (default), **MSUP Analyses**, and **Topology Optimization**. If this property is set to **MSUP Analyses** or **Topology Optimization**, the application creates the files needed for future MSUP analyses or Topology Optimization. If this property is set to **None**, the files are not created in order to improve solution time and reduce file size.

The **Analysis Data Management (Static Structural)** category enables you to set the default value for the **Future Analysis** property. The options include **None** (default) or **Topology Optimization**. If this property is set to **Topology Optimization**, the application creates the files needed for Topology Optimization. If this property is set to **None**, the files are not created in order to improve solution time and reduce file size.

The **Analysis Data Management (Topology Optimization)** category enables you to set the default value for the **Max Num of Intermediate Files** property. It specifies the number of intermediate topology files you wish to retain for all iterations solved. A value of 1 indicates that the generated file is overwritten each iteration. The default value for the property is set to the text string "All Iterations" that equals a setting of zero (0).

The **Post Processing** category contains the **Distributed Post Processing** property. Options for the property include **Program Controlled** (default), **Yes**, and **No**.

The **Advanced (Static Structure)** category contains the **Inverse Solving** property. Options for the property include **No** (default) and **Yes**. This property species the default setting for the **Inverse Option** property of the **Advanced** (p. 1461) category in the **Analysis Settings** object.

The **Advanced** category contains the following properties:

- **Contact Split (DMP)**: Options for the property include **Program Controlled** (default), **On**, and **Off**. This property species the default setting for the **Contact Split (DMP)** property of the **Advanced** (p. 1461) category of the **Analysis Settings** object.

- **Contact Diagnostics for Modal and Harmonic**: Options for the property include **No** (default) and **Yes**. When you set this property to **Yes** and solve a stand-alone Modal or Harmonic Response analysis, Mechanical creates the CND file, `file.cnd`, that includes all the contact diagnostics information.

The **Solution History** category pertains to the content presented in the Worksheet when the Solution Output (p. 1833) property is set to **Solution History**. This category contains the following properties:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Maximum Solutions to Store**. This property specifies the default setting for the number of the solutions to be tracked. The default setting for this property is **10**. The minimum value is **1** and the maximum value is **50**.
- **Track Results**. This property specifies whether or not to collect and present result data. Options include **Yes** (default) and **No**.

Results

The **Default** category of the Results option provides the following controls:

- **Calculate Time History**: Sets the default value for calculation of time history. The default is **Yes**.
- **Auto Rename Results**: Automatically renames a result when the result **Type** is changed. The choices are **Yes** and **No**. The default is **Yes**.
- **Average Across Bodies**: Change the default setting of the property **Average Across Bodies**. The options are **Yes** and **No**. The default setting is **No**.
- **Prompt Before Deleting Results on Solve**: This control enables you to activate a confirmation prompt for the **Solve** option on the Solution folder's right-click context menu as well as the child object of the Solution folder (for example, result objects). The prompt only displays for analyses with existing solution data. The available options include:
  - **Failed and Restart Solution** (default): You are prompted when you attempt to re-solve a failed solution or for a solution with restart points.
  - **Never**: the confirmation prompt feature is turned off.
  - **Always**: you are always prompted when you select the right-click **Solve** option.

  Note:

  The **F5** hotkey does not support this function.

- **Update Dependent Expressions on Identifier Change**: Options include **Yes** and **No** (default). When you set this control to **Yes**, the application will attempt to automatically update downstream **Expression** property entries that include an Identifier (p. 1978) that was modified in an upstream system.

The **Cyclic Result Option** category of the Results option provides the **Allow Phase Sweep** control. Options include **No** (default) and **Yes**.

The **RSM File Manager** category of the Results option provides the **RSM Output Files Download** control. Options include **Show** and **Hide** (default).

The **Cyclic Solution Display** category of the Results option provides the following controls.

- **Number of Sectors**: For an analysis that includes a **Cyclic Region** object, this controls specifies the default setting of the **Number of Sectors** property of the **Solution** object. The default setting is 1.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Starting at Section**: For an analysis that includes a **Cyclic Region** object, this controls specifies the default setting of the **Starting at Section** property of the **Solution** object. The default setting is 1.

Visibility

The **Visibility** selection and category provides the **Part Mesh Statistics** setting. This setting enables you to display or hide the **Statistics** category in the Details view for Body and Part objects.

The **Tree Filtering** category provides the following controls:

- **Graphics**: **Never** (default) or **On Hide/Show Bodies**. Setting this option to **On Hide/Show Bodies** when the **Graphics** filter is active and set to **Visible Bodies**, causes the tree to automatically filter using that option whenever a body is hidden or shown so that only visible bodies and objects associated with any visible body display.
- **Expand**: **Yes** or **No** (default). Change the default setting of the **Expand on Refresh** button on the Filtering (p. 114) feature.

Wizard

The **Wizard Options** category includes the following exclusive controls for this category. There are no counterpart settings in the **Details** view.

- **Default Wizard**: This is the URL to the XML wizard definition to use by default when a specific wizard isn't manually chosen or automatically specified by a simulation template. The default is `StressWizard.xml`.
- **Flash Callouts**: Specifies if callouts will flash when they appear during wizard operation. The default is `Yes`.

The **Skin** category includes the following exclusive controls for this category. There are no counterpart settings in the **Details** view.

- **Cascading Style Sheet**: This is the URL to the skin (CSS file) used to control the appearance of the Mechanical Wizard. The default is `Skins/System.css`.

The **Customization Options** category includes the following exclusive controls for this category. There are no counterpart settings in the **Details** view.

- **Mechanical Wizard URL**: For advanced customization. See *Appendix: Workbench Mechanical Wizard Advanced Programming Topics* for details.
- **Enable WDK Tools**: *Advanced*. Enables the Wizard Development Kit. The WDK adds several groups of tools to the Mechanical Wizard. The WDK is intended only for persons interested in creating or modifying wizard definitions. The default is **No**. See the *Appendix: Workbench Mechanical Wizard Advanced Programming Topics* for details.

Note:

- URLs in the Mechanical Wizard follow the same rules as URLs in web pages.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- *Relative URLs* are relative to the location of the Mechanical Wizard URL.
- *Absolute URLs* may access a local file, a UNC path, or use HTTP or FTP.

Commands

The **Command Editor Options** category includes the following controls that enable you to change the presentation and operation of the **Commands (APDL) Object Worksheet**:

- **Font Size**: Specify the desired font size of the text in the window. The default setting is **11**.
- **Show Invisibles**: Show or hide formatting marks (spaces, paragraph symbol, etc.). The default setting is **No**.
- **Show Line Numbers**: Show or hide line numbers. The default setting is **Yes**.
- **Syntax Highlighting** (Mechanical APDL or Rigid Dynamics solvers only): Turn syntax highlighting on/off. The default setting is **On**.
- **Interactive Tooltips** (Mechanical APDL solver only): Turn the tooltip feature on/off. The default setting is **On**.

UI Options

The **UI Options** group includes the following categories that enable you to change certain interface display default settings.

Main Window Title Theme

For the Windows platform only, this category includes the following preferences:

- **Merge Ribbon with Title Bar**. Options include **Yes** (default) and **No**.

  This setting merges the title bar of the Mechanical interface with the ribbon in order to save space. When active, there is a potential display issue. If you are working in full screen mode (only) and you are running a lengthy process, it is possible that the application becomes unresponsive ("not responding"). In this situation, the Mechanical interface enlarges and covers your entire screen – including the Task Bar. This is undesirable. To eliminate this display limitation, given the required situation, disable the preference.

- **Shown Application Name in Title**: Options include **Yes** (default) and **No**. Turn the display of the application name shown in the title bar on and off.
- **Show License in Title**: Options include **Yes** (default) and **No**. Turn the display of the license currently in use in the title bar on and off.

Style

For the Windows platform only, this category includes the following preferences:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Color Theme**: When you first install and launch the application, you are prompted to select a desired theme. Options include **Light**, **Dark**, and **Classic**. At any time after this initial selection, you can change the theme using this preference.
- **Use Color Theme in Geometry Window**: Options include **Yes** (default) and **No**. Use this preference to select the background color of the **Geometry** window. If set to **Yes**, the application uses the background color of the selected **Color Theme**. Set to **No**, Mechanical uses the background colors selected in Workbench (**Tools** > **Options** > Appearance).
- **Font Size**: You use this preference to change the size of the font used in the Outline pane, Details pane, and the Ribbon. Options include **System Default**, **Normal**, **Large**, and **Extra Large**. The default setting is **Normal**.
- **Auto Resize Icons**: You use this preference to automatically change the size of ribbon icons when you modify the above **Font Size** preference. The default setting for this preference is **Yes**.

Tooltip

This category includes default settings for the following:

- **Show Tooltips**: Show/hide all tooltips for all available options. Options include **Yes** (default) and **No**. Setting this option to **No** hides all tooltips and the options below become ineffective.
- **Show Mini Toolbar Tooltips**: Show/hide tooltips for the Mini Selection Toolbar (p. 264). Options include **Yes** (default) and **No**.
- **Show Menu Tooltips**: Show/hide tooltips for options on right-click context menu. Options include **Yes** (default) and **No**.
- **Show Details View Tooltips**: Show/hide tooltips for the properties contained in the **Details** pane. Options include **Yes** (default) and **No**.

Window Manager

This category contains the **Pane Opacity** setting. This setting enables you to modify the transparency of the interface panes. The default setting is 100.

Engineering Data

This category contains the **Mechanical View** setting. Options include **None** and **Windows** (default). Selecting **None** returns the material assignment display and menu options to the previous layout and behavior.

Context Tab

This category includes the following settings:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Common Groups Visibility**. This setting enables you to hide the tab groups **Outline**, **Solve**, and **Insert** from Context tabs. By default, these groups are displayed on the various Context tabs. The options for this setting are **Show** (default) and **Hide**.

  Note:

  – This setting does not apply to the **Project**, **Named Selection**, **Remote Point**, and **Convergence** Context tabs as they only display these three groups.

  – If you select multiple objects in the **Outline**, these groups automatically display regardless of this setting. When the **Hide** setting is specified, the groups again become hidden once a single object is selected.

- **Edit and Combo Box Visibility**. Options include **Show** (default) and **Hide**. If you select the **Hide** option, the application hides all the editable and combo boxes available in context tabs and places them in a newly displayed ribbon tab titled "**Miscellaneous**". For this change to take place, you need to restart the Mechanical application.

- **Refresh Wait for Controls Deletion** (Windows Only). When you switch between objects in the **Outline** that have an associated context tab (Model, Mesh, Solution, etc.), the application uses a specific sequence for displaying the options and controls on the ribbon for each associated context tab. This preference optimizes this presentation sequence. Options include **Yes** (default) and **No**.

Mini Selection Toolbar

This category includes the **Mini Selection Toolbar Visibility** setting. This setting enables you to hide or display (default) the Mini Selection Toolbar (p. 264).

Progress

This category includes the setting: **Hide Progress Window**. This setting enables you to hide (default) or display the progress windows of certain application processes, such as attaching geometry, mesh generation, and the solution process. The progress for these processes is also displayed in the status bar (p. 135).

Scripting

This category includes the **New Scripting UI** setting. Based on a scripting interface update, the **Mechanical Scripting** interface is now the default. If desired, you can revert to the **ACT Console** interface using this setting. Mechanical must be restarted to implement the change.

Default Quick Launch Result Categories

The settings of this category, listed below, enable you to display or hide the Quick Launch pane groupings. These settings affect only the default search results. Results using the shortcut options "(@" symbol) are not affected. Setting options include **Show** and **Hide**. All settings are set to **Show** by default, except for the **Tree Items** setting that is set to **Hide**.

- **Ribbon Items**
- **Context Items**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Preference Items**
- **Pane Toolbar Items**
- **Tree Items**

Delay Loading

This category includes the **Tree** setting. Options include **Enable** and **Disable** (default). This preference tells the application to import, but not display, all upstream data associated with the geometry, contact conditions, and Named Selections. You simply expand (plus symbol) the corresponding object to display the geometry, etc. This can be a useful feature for models that include many parts, contact conditions, or Named Selections.

Pause View Update

This category includes the **Details** setting. This setting enables you to halt **Details** pane updates. The options of this preference are **Yes** and **No** (default).

Toolbar Customization

This category includes the **Show All Categories** setting. This setting enables you to display all of the options available in the application. All toolbars from all panes, all commands from all Ribbon tabs, User Buttons, External ACT Extensions, etc. This gives you maximum flexibility for toolbar customization. The options of this preference are **Yes** and **No** (default).

UI Controls

This category includes the following preferences:

- **Ribbon/Toolbar Refresh**. Options include **Automatic** (default) and **Manual**. Using the **Automatic** setting, the application refreshes the ribbon and toolbar controls every 100ms. If set to **Manual**, the application does not refresh automatically but rather refreshes only as a result of certain actions taken in the application. Refreshing the options of the application helps to ensure their proper display and operation.
- **Details View Combo Boxes**. This property enables you to change the default setting for the ability to search drop-down lists (p. 123) in the Details view. Options include **Searchable** (default) and **Non-Searchable**.

Setting Variables

Variables enable you to override default settings.

To set a variable:

1. Choose **Variable Manager** from the **Tools** menu.
2. Right-click in the row to add a new variable.
3. Enter a variable name and type in a value.
4. Click **OK**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Variable name	Supported Values	Description
`DSMESH OUTPUT`	filename	Writes mesher messages to a file during solve (default = no file written). If the value is a filename, the file is written to the temporary working folder (usually `c:\temp`). To write the file to a specific location, specify the full path.
`DSMESH DEFEATUREPERCENT`	a number between 1e-6 and 1e-3	Tolerance used in simplifying geometry (default = .0005).
`TreatModalAsComplex`	1	Mode shapes and contour colors are in sync for animated Modal results.
`contactAllowEmpty`	1	Allows the solution to proceed even if no contact elements are generated for a given Contact Region.
`UsePseudoShellDisp`	1	Display expanded shell thickness based on solver updated nodal locations (for shells with large deformations (p. 134)).
`edge contact type`	CONTA175 or CONTA177	Forcibly specifies the element type of edge contact (both for real contact and Remote Boundary Conditions (p. 1735)).

Status

The status box indicates if a particular variable is active or not. Checked indicates that the variable is active. Unchecked indicates that the variable is available but not active. This saves you from typing in the variable and removing it.

Using Macros

The Mechanical application enables you to execute custom functionality that is not included in a standard Mechanical application menu entry via its **Scripting** feature. The functionality is defined in a *macro* - a script that accesses the Mechanical application programming interface (API).

Macros can be written in the Python (.py) programming language. For additional information, refer to the Script Examples section of the Scripting in Mechanical Quick Start Guide. Macros cannot currently be recorded from the Mechanical application.

To access a macro from the Mechanical application:

1. Choose **Scripting** option (p. 94) from the **Support** group on the **Automation** tab.
2. Navigate to the directory containing the macro.
3. Select the macro.

Note:

Note: For the current release. Mechanical also supports macros written in the legacy languages Microsoft's JScript and VBScript. Several macro files are provided with the Ansys Workbench installation under **`\ANSYS Inc\v190\aisol\DesignSpace\DSPages\macros`**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Data Export

Mechanical enables you to export specifically supported analysis data to one or more of the following file types. Review the following topics based upon the desired export file format.

- General Export Procedure (p. 249)
- Exporting to Text and Delimited Files (p. 249)
- Stereolithography (STL) (p. 250)
- Ansys Viewer File (AVZ) (p. 251)
- Geometry (Part Manager Database) (p. 251)
- NASTRAN Bulk Data (p. 252)
- Ansys Sound (p. 253)
- Waveform Audio File (WAV) (p. 253)

See the Options Settings (p. 255) topic at the end of the section for some general export settings that are available using the **Options** dialog.

General Export Procedure

1. Select an object in the tree.
2. Click the **Worksheet** to give it focus (if applicable).
3. Right-click the selected object in the tree or on a selection in the **Tabular Data** window, select **Export**, and then select a file type as required.
4. Specify a file name and save the file. Based on the object type, the application may automatically open Excel, assuming you have the application.

Note:

You must right-mouse click the selected *object in the tree* to use this **Export** feature. On Windows platforms, if you have the Microsoft Office 2002 (or later) installed, you may see an **Export to Excel** option if you right-mouse click in the **Worksheet**. This is not the Mechanical application **Export** feature but rather an option generated by Microsoft Internet Explorer.

Exporting to Text and Delimited Files

You can export a variety of analysis data to a tab-delimited text file. This file format enables you to view the data in a text editor as well as Microsoft Excel. Mechanical supports exporting data from the following object types (without access to worksheet data):

- Contour Results (p. 2276)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Node-Based Named Selections (p. 1085)
- Element-Based Named Selections (p. 1085)
- Imported Loads (p. 1736)

Additionally, data from the following additional objects can be exported but requires worksheet data to be active:

Connections	Convergence	Geometry
Contact Group	Coordinate Systems	Mesh
Contact Initial Information	Fatigue Sensitivities	Solution
Contact Tool	Frequency Response	Thermal Condition

Stereolithography (STL)

The following objects enable you to export object information in **STL** file format, either as Binary (default) or ASCII. File size is the primary difference between the file formats. The binary format generates smaller files, however; it does not include information for the bodies of your model. The ASCII format preserves all body information during export. Using the Options (p. 217) dialog box, under the Export (p. 222) category, you can change the default setting for exporting in STL format.

- Geometry (ASCII format only (p. 223))
- Mesh
- Results and Result Tools (Group)

Important:

Mechanical obtains unit data from imported CAD models and displays the unit in the **Length Unit** property of the Geometry object. This is the unit system used by the STL export feature. When opening your exported STL file in a CAD application, make sure that the application is also using this unit system. For example, in SpaceClaim, set your unit system by selecting **File** > **SpaceClaimOptions** > **File Options** > **STL**, and then specify the appropriate unit system from the **Units** drop-down menu.

Note:

- When a model contains multiple bodies, Mechanical uses a nonstandard file format for the ASCII representation. In this case, the application separates the bodies.
- Files saved in the STL format can be viewed in appropriate STL supported applications, such as SpaceClaim. Currently for the **Mesh** object and for results-based objects (not including contour data), files exported in the ASCII format enable you to render individual parts of your model in SpaceClaim. Files in the binary format do not support this display capability.
- The display of an exported STL file, regardless of viewer type, is based on the scale you specify in the **Result** (p. 63) drop-down menu, on the **Solution** Context tab. That

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

is, if the scale is set to show deformations, the model is exported in the deformed shape.

- When you select **Top/Bottom** as the **Shell** setting in the Details view for a surface body and export the result contours (such as stresses and strains), the export file contains two results for every node on a shell element (p. 1993). The first result is for the bottom face and the second result is for the top face.

Ansys Viewer File (AVZ)

Mechanical enables you to export your mesh and/or a result object as an AVZ (.avz) file. The export operation creates a 3D model representation that you can display in the Ansys Viewer (installation required). The Ansys Viewer is a WebGL based 3D image viewer that you can use to visualize the exported mesh and results of your analysis without opening the Mechanical application. For results, you can inspect result values at specific locations by hovering the mouse over a point on your model. For result objects and as desired, you can automatically launch the Ansys Viewer by changing the default setting under the **Export** preference (p. 222) of the **Options** dialog.

Note:

Exporting results that include a customized legend may present legend/contour display inconsistencies in the viewer.

Geometry (Part Manager Database)

You can export the geometry (entirely or as parts) to a binary Part Manager Database (.pmdb) file by:

- Right-clicking on the **Geometry** object and then selecting **Export**>**Geometry**. The application writes the entire geometry to the `.pmdb` file. This option also writes any Named Selections created in Mechanical into the `.pmdb` file.

  Or...

- Right-clicking one or more bodies/parts, and then select **Export**>**Geometry**. The application writes the selected parts to the `.pmdb` file. If a selected body is part of a multi-body part, then the entire part is written to the file.

  Or...

- Right-clicking one or more bodies in the Geometry window and then selecting **Export**>**Geometry**. The application writes the selected parts to the `.pmdb` file.

Part Manager Database Requirements and Limitations

- Exporting the Geometry as a `.pmdb` file facilitates future geometry import into SpaceClaim, DesignModeler, as well as re-importing the file back into Mechanical.
- When exporting a geometry to a `.pmdb` file, the application exports all bodies, including suppressed bodies, to the file without maintaining their suppression status. Therefore, when you re-import the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

geometry, all of the bodies are unsuppressed. However, the application **does** export whether or not a you have hidden bodies. This means that suppressed bodies, which are typically hidden, appear hidden when you re-import the geometry. As a result, your geometry may have bodies that are hidden, because they were suppressed on export, but that are no longer suppressed.

- The application does not export supplemental model data created after the geometry was imported. This includes coordinate systems, work points, spot welds, or materials that you manually added during your Mechanical session.
- When defined, `.pmdb` files include geometry cross sections for line bodies in the exported file. Subsequent SpaceClaim and Mechanical sessions import the line body cross section data accordingly. However, DesignModeler does not support importing line body cross section data and as needed, requires you to redefine the cross sections if imported into DesignModeler.
- For any of the following that are exported as a Part Manager Database (.pmdb) file and then imported into a new Mechanical session, the application does not currently support re-meshing using normal mesh methods:
  - Geometries created from External Model
  - Deformation results
  - Parts created using the Mesh **Pull** feature

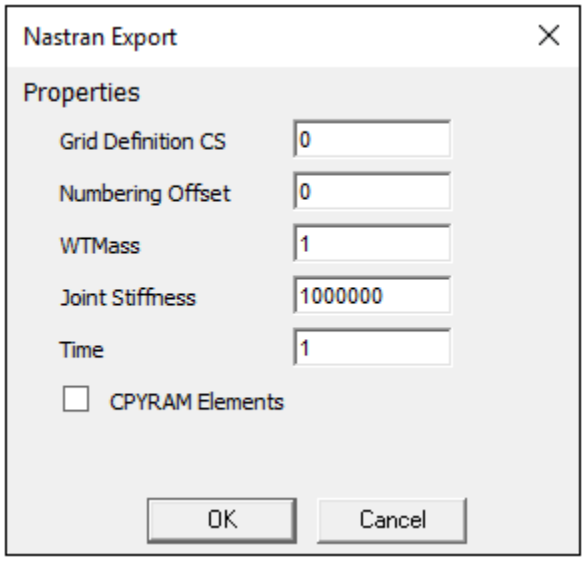
NASTRAN Bulk Data

For Static Structural and Modal analyses, you can export your simulation as a NASTRAN Bulk Data (.bdf, .dat, .nas) file.

When you select the Environment object, the option, **Export NASTRAN File** is available in the **Tools** group of the Environment Context Tab (p. 61). Based on your analysis type, one of the following dialogs displays. You use these property options to further define how you wish to export your simulation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

Also see the Writing NASTRAN Files (p. 1867) section for the steps to export your analysis as a NASTRAN (.nas) file.

Ansys Sound

Mechanical enables you to export a result to Ansys Sound software for sound synthesis, sound design, or psychoacoustics analysis. When exporting the result, the data is stored in an XML file, then Ansys Sound SAS is opened (if installed on the machine) and automatically opens this file. The option is supported for the following acoustics results:

- Equivalent Radiated Power Level
- ERP Level Waterfall Diagram
- Frequency Response Sound Power Level
- Far-field SPL Mic (when the **Definition Method** property is set to **Coordinates**)
- Far-field Sound Power Level
- Far-field Mic Waterfall Diagram
- Far-field Sound Power Level Waterfall Diagram

For more information, see the Ansys Sound documentation.

Waveform Audio File (WAV)

You can export the following acoustic-based result types to a Waveform Audio File (.wav) file:

- Equivalent Radiated Power Level

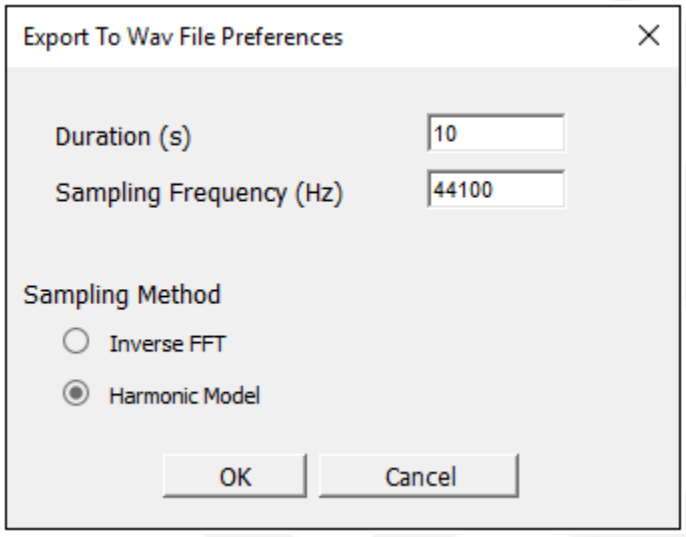
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- ERP Level Waterfall Diagram
- Frequency Response Sound Power Level
- Far-field SPL Mic (when the **Definition Method** property is set to **Coordinates**)
- Far-field Sound Power Level
- Far-field Mic Waterfall Diagram
- Far-field Sound Power Level Waterfall Diagram

Note:

Waterfall result types are only supported by the **Harmonic Model** sampling method described below.

For the above result types, the context (right-click) menu option **Export** > **Export to WAV File** opens the preference window shown below. The default settings are displayed.



The **Duration** and **Sampling Frequency** options are basic settings that enable you to specify the duration and sampling frequency of the audio file.

The **Sampling Method** options include:

- **Inverse FFT** (Fast Fourier Transform): This method generates a sound from a given spectrum using a Fourier transform. This method creates a sound sample based on the given input spectrum (level vs. frequency). This resulting sound sample has the same spectrum as the input. This method is recommended for broadband noise spectrum.
- **Harmonic Model**: This method generates a sound from a spectrum using sound synthesis from sinusoidal patterns. This method creates a sound sample based on the given input spectrum (level vs. frequency) that contains harmonic components at the same exact frequencies specified in the input spectrum. Each frequency has the same level as the specified input. This method is recommended for pure tones sounds.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Options Dialog Settings

The **Export** (p. 222) category of the **Options** dialog includes the following preferences that apply to exporting data.

Automatically Open Excel (**Yes** by default)

Remove Duplicate Nodes (**No** by default)

Include Node Numbers (**Yes** by default)

Include Node Location (**No** by default)

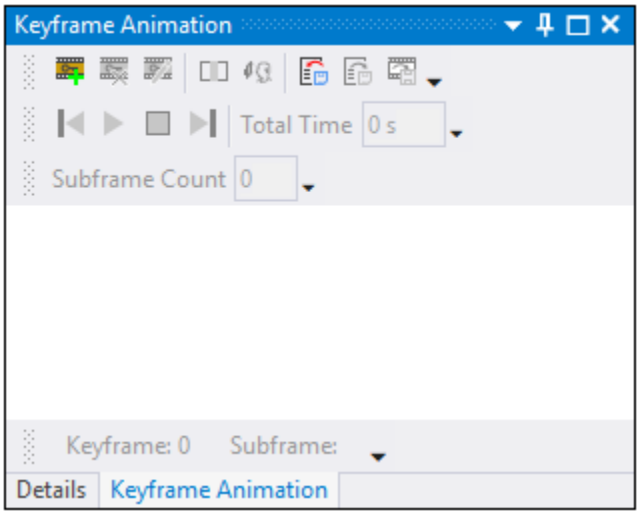
Keyframe Animation

Overview

The Keyframe animation feature enables you to string together snapshots of your model in the **Geometry** window to create an animation. Each Keyframe is a Start and End point that the application then links together by drawing Subframes (by default 30 Subframes) to create the animation. The application interpolates the transition from frame to frame to create a smooth animation. For example, you can create an animation of your model rotating.

Application

You create Keyframes using the **Keyframe Animation Views** window. To display (or close) the window, select the **Keyframe Animation** option from the **Tools** group (p. 45) on the **Home** tab. The window, as shown here, provides the interface for using the feature.



Create a Keyframe

To create Keyframes, you need to first position your model as desired in the **Geometry** window. Then, select the **Create a Keyframe** button in the **Keyframe Animation** window. A new entry displays in the window. The application assigns a numerical value to each Keyframe (**Keyframe 0**, **Keyframe1**, etc.). Each Keyframe is a snapshot of the model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Once you define a Keyframe animation in the window, you can double-click the Keyframe to view its position.

Modify a Keyframe

To change an existing Keyframe, select the Keyframe in the window, position your model as desired, and select the **Modify a Keyframe** button.

Delete a Keyframe

Select the Keyframe in the window and click the **Delete** button.

Save/Load/Export Animations

The window provides options to Save your defined Keyframes as an XML file, to load a saved XML files of Keyframes, and an export option that enables you to save your Keyframe animation as a video file (AVI, MP4, WMV, or GIF). Any **Subframe Count** and **Total Time** specifications apply to exported files types except the GIF format.

Insert Keyframe

Insert a new keyframe before the currently selected keyframe.

Apply Keyframe

Set the graphics window's camera settings to the currently selected keyframe's camera settings.

Note:

- When exporting your animation as a video file, make sure to keep the Mechanical application window is in front of any other desktop windows until the export process is complete. Opening other windows in front of the application window before the export process is complete could include those windows in the video capture.
- The GIF file format does not support the Workbench Gradient settings (the default setting). For this file format, the application automatically changes the Workbench appearance setting to Uniform. As a result, exported GIF files have a plain background compared to exported videos.

Frame Animation Control Options and Displays

The window provides the following options/displays:

- **Play**: Start or Resume the animation.
- **Pause**: Pause current animation
- **Stop**: Stop the animation
- **Previous**/**Next Frame**: These options move the animation backwards or forwards one frame at a time.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Subframe Count**: Specify the desired number of subframes (0 to 200) between each Keyframe. Subframes define the number of interpolations performed between each frame. This affects the smoothness or lack thereof of the animation. This setting applies to exported animations.
- **Total Time**: Specify a desired amount of time for your animation. This property defines presentation speed. This setting applies to exported animations.
- **Keyframe**: Read-only field that displays the Keyframe being displayed.
- **Subframe**: Read-only field that displays the subframes (per Subframe Count property) as the animation progresses. You can use the Previous/Next Frame options to view specific frames/subframes. Otherwise these fields automatically cycle through the animation.

Graphical Selection and Display

Here are some tips for working with graphics:

- You can use the ruler, shown at the bottom of the **Geometry** (p. 129) window, to obtain a good estimate of the scale of the displayed geometry or results (similar to using a scale on a geographic map). The ruler is useful when setting mesh sizes.
- You can activate the **Consider Section Planes When Mesh Picking** Graphics (p. 228) preference in order to select newly displayed finite element entities (nodes, elements, and element faces) from geometries within the model that were hidden before adding the specified Section Plane (p. 294). See the Selecting Mesh Entities Displayed by the Section Plane (p. 301) topic for additional information.
- Hold the control key to add or remove items from a selection. You can *paint select* faces on a model by dragging the left mouse button.
- Use the stack of rectangles in the lower left corner of the **Geometry** (p. 129) window to select faces hidden by your current selection.
- To multi-select one or more faces, hold the **Ctrl** key and click the faces you wish to select, or use **Box Select** to select all faces within a box. The **Ctrl** key can be used in combination with **Box Select** to select faces within multiple boxes.
- Use the options of the Selection Tab (p. 88) to make or manipulate geometry selections.
- Click the Using Viewports (p. 284) icon to view up to four images in the **Geometry** (p. 129) window.
- Controls are different for Graphs & Charts (p. 291).
- Mechanical supports 3Dconnexion devices. See the Platform Support section of Ansys.com for a complete list of 3Dconnexion products certified with the current release of Ansys applications.

Selecting Geometry

This section discusses cursor modes and how to select and pick geometry in the **Geometry** window. It includes information on the following:

Pointer Modes (p. 258)
Highlighting (p. 259)
Picking (p. 259)
Blips (p. 259)
Painting (p. 260)
Depth Picking (p. 261)
Selection Filters (p. 261)
Selection Modes (p. 262)
Mini Selection Toolbar (p. 264)
Extend To (p. 264)

For Help on how to select mesh nodes and elements, see the Selecting Nodes (p. 269) and Selecting Elements (p. 276) sections. Many of the same selection and picking tools are employed for mesh selections.

Pointer Modes

The pointer in the Geometry window is always either in a picking filter mode or a view control mode. When in a view control mode the selection set is locked. To resume the selection, repress a picking filter button.

The Graphics Toolbar (p. 97) offers several geometry filters and view controls as the default state, for example, face, edge, rotate, and zoom.

If a **Geometry** field in the Details Pane (p. 119) has focus, inappropriate picking filters are automatically disabled. For example, a pressure load can only be scoped to faces.

If the **Direction** field in the Details Pane (p. 119) has focus, the only enabled picking filter is **Select Direction**. **Select Direction** mode is enabled for use when the **Direction** field has focus; you never choose **Select Direction** manually. You may manipulate the view while selecting a direction. In this case the **Select Direction** button enables you to resume your selection.

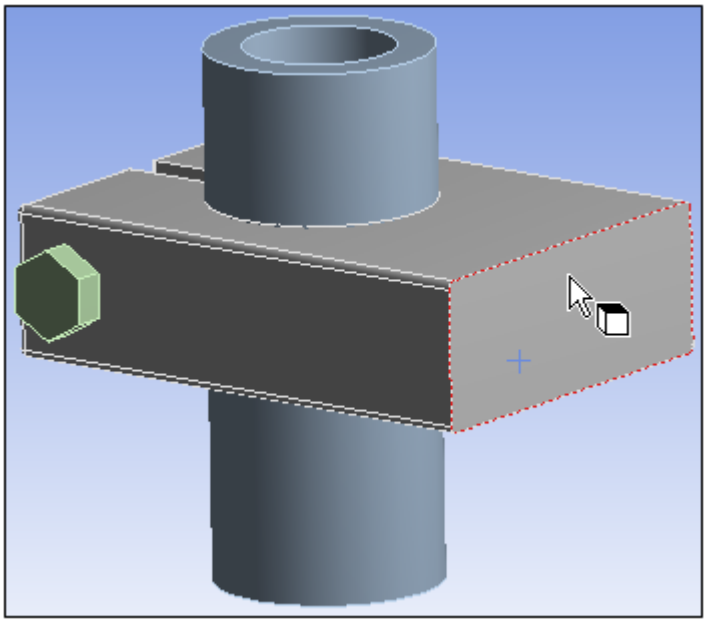
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Highlighting

Hovering your cursor over a geometry entity *highlights* the selection and provides visual feedback about the current pointer behavior, for example select faces, and location of the pointer, for example, over a particular face.

As illustrated here, the face edges are highlighted in colored dots.



Picking

A *pick* means you select or "click" on a visible geometric entity. A pick becomes the current selection, replacing previous selections. A pick in empty space clears the current selection.

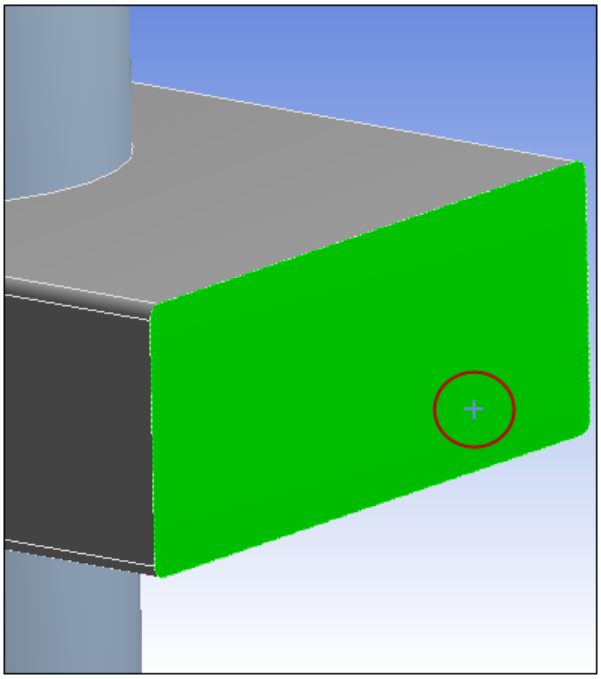
By holding the **Ctrl** key down, you can add additional selections or remove existing selections. Clicking in empty space with **Ctrl** depressed does not clear current selections.

For information on picking nodes, see Selecting Nodes (p. 269).

Blips

As illustrated below, when you make a selection on a model, a cross-hair “blip” appears.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The blip serves to:

- Mark a picked point on visible geometry.
- Represent a ray normal to the screen passing through all hidden geometry.

When you make multiple selections using the **Ctrl** key, the blip is placed at the last selection entity. Clicking in empty space clears your current selection, but the blip remains in its last location. Once you have cleared a selection, hold the **Ctrl** key down and click in clear space again to remove the blip.

Note:

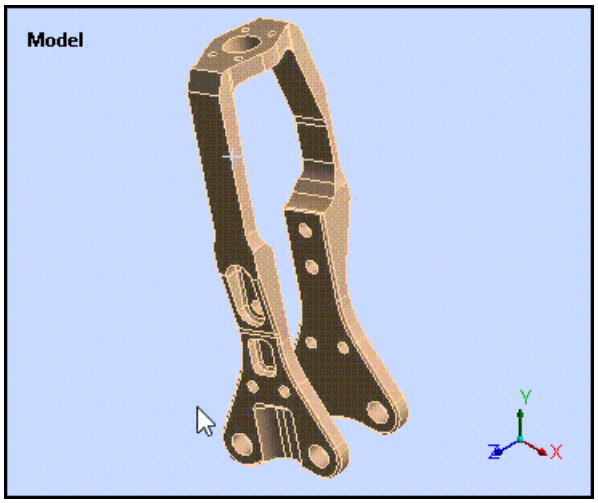
This is important for depth picking, a feature discussed below.

Painting

Painting means dragging the mouse on visible geometry to select more than one entity. A pick is a trivial case of painting. Without holding the **Ctrl** key down, painting picks all appropriate geometry touched by the pointer.

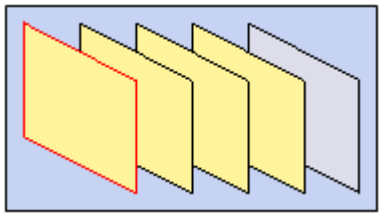
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Depth Picking

Depth Picking enables you to pick geometry through the Z-order behind the blip.



Whenever a blip appears above a selection, the Geometry window displays a stack of rectangles in the lower left corner. The rectangles are stacked in appearance, with the topmost rectangle representing the visible (selected) geometry and subsequent rectangles representing geometry hit by a ray normal to the screen passing through the blip, front to back. The stack of rectangles is an alternative graphical display for the selectable geometry. Each rectangle is drawn using the same edge and face colors as its associated geometry.

Highlighting and picking behaviors are identical and synchronized for geometry and its associated rectangle. Moving the pointer over a rectangle highlights both the rectangle its geometry, and vice versa. **Ctrl** key and painting behaviors are also identical for the stack. Holding the **Ctrl** key while clicking rectangles picks or unpicks associated geometry. Dragging the mouse (Painting (p. 260)) along the rectangles picks geometry front-to-back or back-to-front.

Selection Filters

When you are using your mouse pointer in the **Geometry** window, you are often selecting or viewing geometry entities or mesh selections. The Graphics Toolbar (p. 97) provides the geometry and mesh selection filters listed below. When you activate a filter, the specific entities (vertex, edge, face, body, node, or element) that you can select highlight as you pass your cursor over the entity. This helps you to make desired selections. You can use the filters with the options of the **Select Mode** drop-down list (that is, Single Select, Box Select, Box Volume Select, etc.).

Depressing the **Ctrl** key enables you to make multiple selections for a specific entity type. Furthermore, you can switch between modes (single, box, lasso, etc. as supported) and continue to add to your selection using the **Ctrl** key. You can release the **Ctrl** key while you change selection modes.

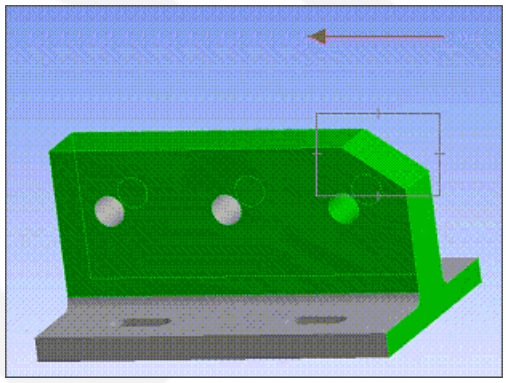
Selection Modes

The **Select Mode** option enables you to select items designated by the Selection Filters (p. 261) through the **Single Select** or **Box Select** drop-down menu options.

- **Single Select** (default): Click an item to select it.
- **Box Select**: Define a box that selects filtered items. When defining the box, the *direction* that you drag the mouse from the starting point determines what items are selected, as shown in the following figures:

  – Dragging to the *right* to form the box selects entities that are *completely* enclosed by the box.

  – **Visual cue:** 4 tick marks completely inside the box.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - Dragging to the *left* to form the box selects all entities that touch the box.
  - **Visual cue:** 4 tick marks that cross the sides of the box.

- **Box Volume Select**: Available for node-based Named Selections (p. 275) only. Selects all the surface and internal node within the box boundary across the cross-section. The line of selection is normal to the screen.
- **Lasso Select**: Available for node-based Named Selections (p. 275) only. Selects surface nodes that occur within the shape you define.
- **Lasso Volume Select**: Available for node-based Named Selections (p. 275) only. Selects nodes that occur within the shape you define.

Note:

Selection shortcuts:

- You can use the **Ctrl** key for multiple selections in both modes.
- You can change your selection mode from **Single Select** to **Box Select** by holding the right mouse button and then clicking the left mouse button.
- Given a generated mesh and that the **Mesh Select** option is active, holding the right mouse button and then clicking the left mouse button scrolls through the available selection options (single section, box selection, box volume, lasso, lasso volume).

Extend To (p. 264)

Selection Modes (p. 262)

For Help on how to select mesh nodes and elements, see the Selecting Nodes (p. 269) and Selecting Elements (p. 276) sections. Many of the same selection and picking tools are employed for mesh selections.

Pointer Modes

The pointer in the **Geometry** window is always either in a picking filter mode or a view control mode. When in a view control mode the selection set is locked. To resume the selection, repress a picking filter button. The Graphics Toolbar (p. 97) offers several geometry filters and view controls as the default state, for example, face, edge, rotate, and zoom.

If a **Geometry** field in the Details Pane (p. 119) has focus, inappropriate picking filters are automatically disabled. For example, a pressure load can only be scoped to faces.

If the **Direction** field in the Details Pane (p. 119) has focus, the only enabled picking filter is **Select Direction**. **Select Direction** mode is enabled for use when the **Direction** field has focus; you never choose **Select Direction** manually. You may manipulate the view while selecting a direction. In this case the **Select Direction** button enables you to resume your selection.

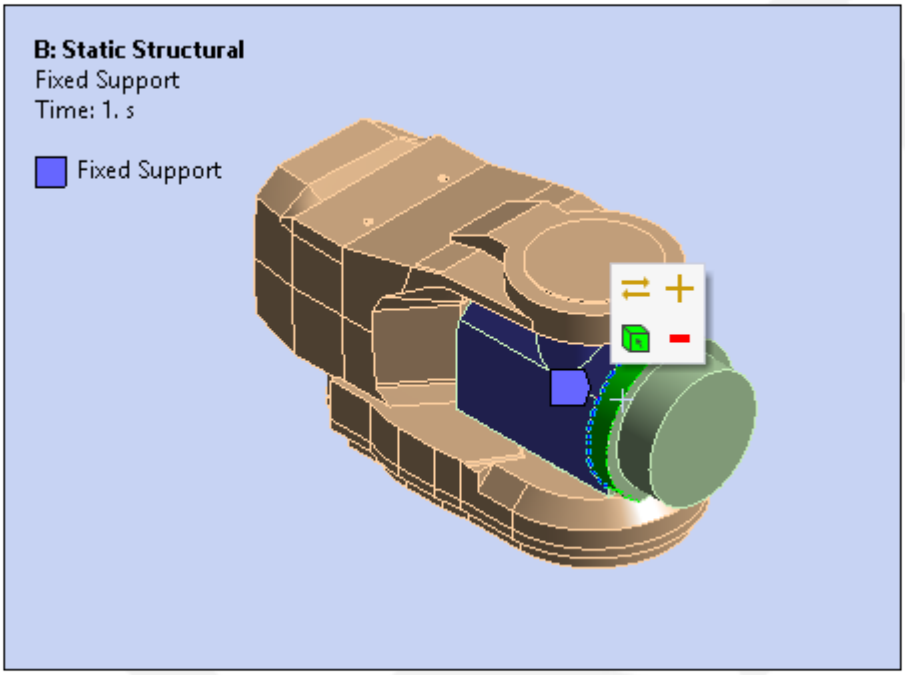
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Mini Selection Toolbar

When you are making geometric selections on your model, such as scoping contact conditions, boundary conditions, and/or results, a mini toolbar automatically displays in the **Geometry** window. This toolbar enables you to make selection changes "on the fly." Toolbar options include:

- **Apply Selection**: Replace scoping with the current geometry selection.
- **Add to**: Add the current geometry selection to the existing scoping.
- **Remove from**: Remove the current geometry selection from the existing scoping.

In addition, when you are using the Smart Select option (p. 97) option, an option to select the parent body of your current selection is also available on the toolbar.



Extend To

The **Extend To** group (p. 89), on **Selection** tab as well as the **Extend** drop-down menu on the Graphics Toolbar (p. 97), is enabled only for edge or face selection modes and only with a selection of one or more edges or faces. The following options are available in the drop-down menu:

Note:

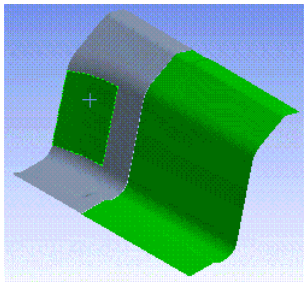
For all options, you can modify the angle used to calculate the selection extensions in the **WorkbenchOptions** dialog setting **Extend Selection Angle Limit** under Graphics Interaction.

Adjacent

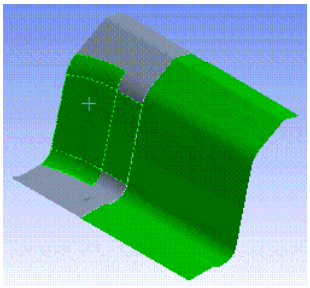
- For *faces*, the **Adjacent** option searches for faces adjacent to faces in the current selection that meet an angular tolerance along their shared edge.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

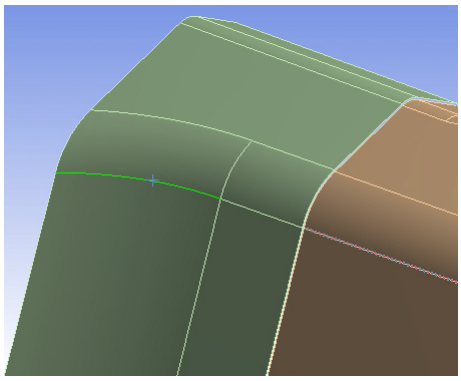


Single face selected in part on the left.

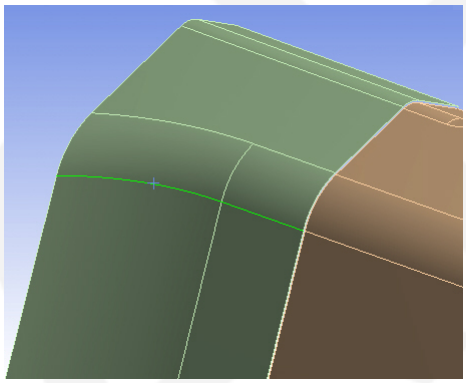


Additional adjacent faces selected after **Extend to Adjacent** option is chosen.

- For *edges*, the **Adjacent** option searches for edges adjacent to edges in the current selection that meet an angular tolerance at their shared vertex.



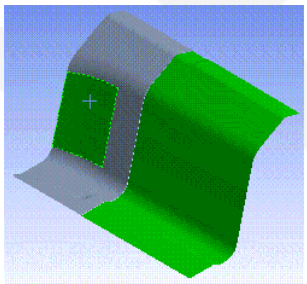
Single edge selected in part on the left.



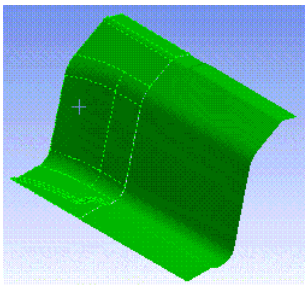
Additional adjacent edges selected after **Extend to Adjacent** option is chosen.

Limits

- For *faces*, the **Limits** option searches for faces that are tangent to the current selection as well as all faces that are tangent to each of the additional selections within the part. The selections must meet an angular tolerance along their shared edges.



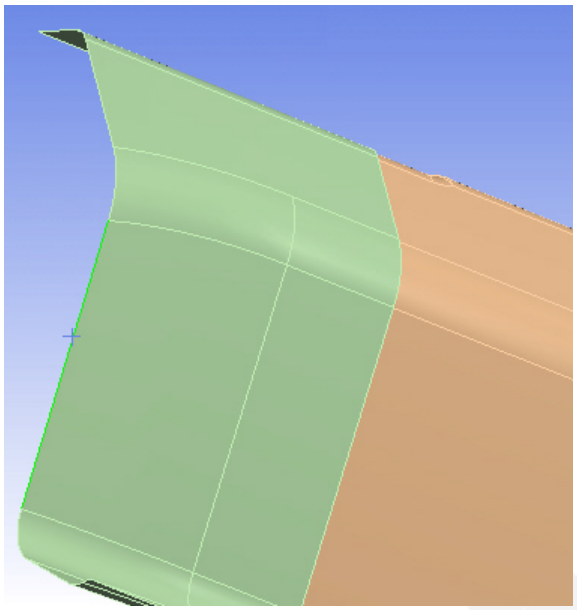
Single face selected in part on the left.



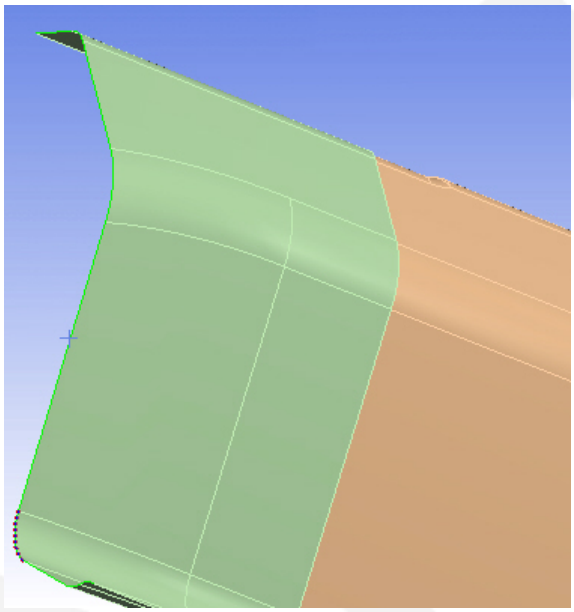
Additional tangent faces selected after **Extend to Limits** option is chosen.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- For *edges*, the **Limits** option searches for edges that are tangent to the current selection as well as all edges that are tangent to each of the additional selections within the part. The selections must meet an angular tolerance along their shared vertices.



Single edge selected in part on the left.



Additional tangent edges selected after **Extend to Limits** option is chosen.

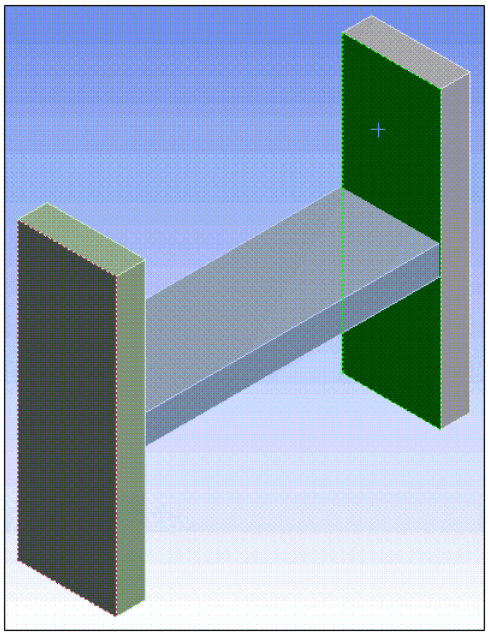
Instances

(Available only if CAD pattern instances are defined in the model): When a CAD feature is repeated in a pattern, it produces a family of related topologies (for example, vertices, edges, faces, bodies) each of which is named an "instance". Using **Instances**, you can use one of the instances to select all others in the model.

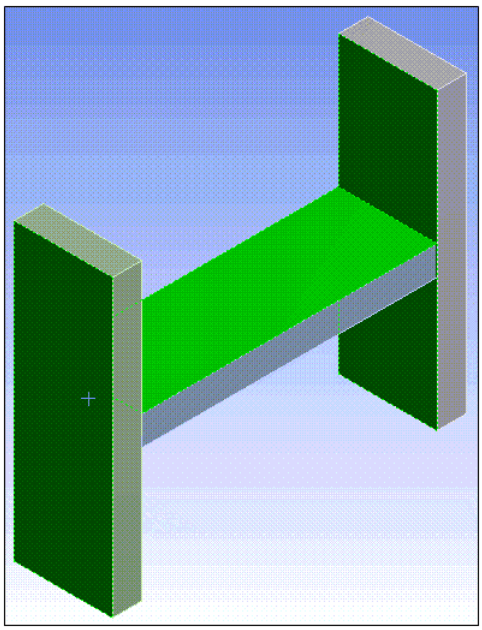
As an example, consider three parts that are instances of the same feature in the CAD system. First select one of the parts.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Then, choose **Instances**. The remaining two part instances are selected.



See CAD Instance Meshing for further information.

Connection

As described in Define Connections (p. 348), connections can be contact regions, joints, and so on.

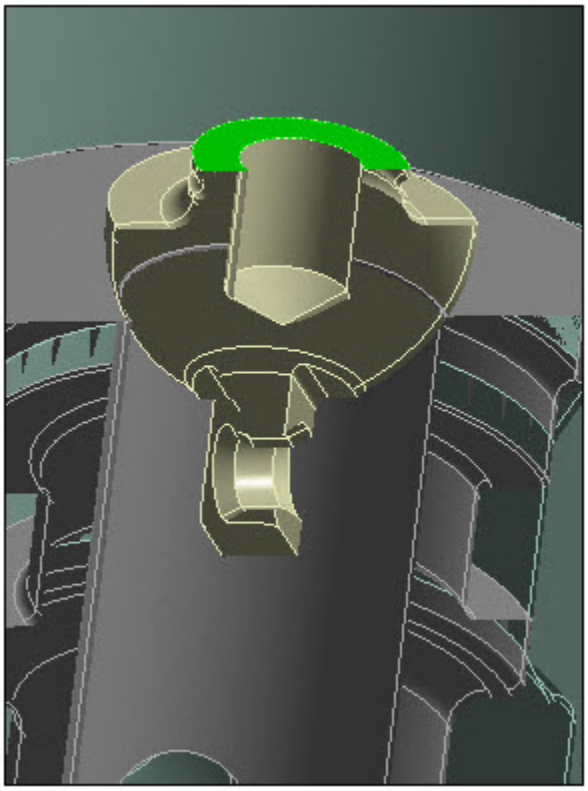
Connection searches for faces that are adjacent to the current selection as well as all faces that are adjacent to each of the additional selections within the part, up to and including all connections on the selected part. This does not include *all* faces that are part of a connection—it includes only those faces that are part of a connection and are also on the selected part.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

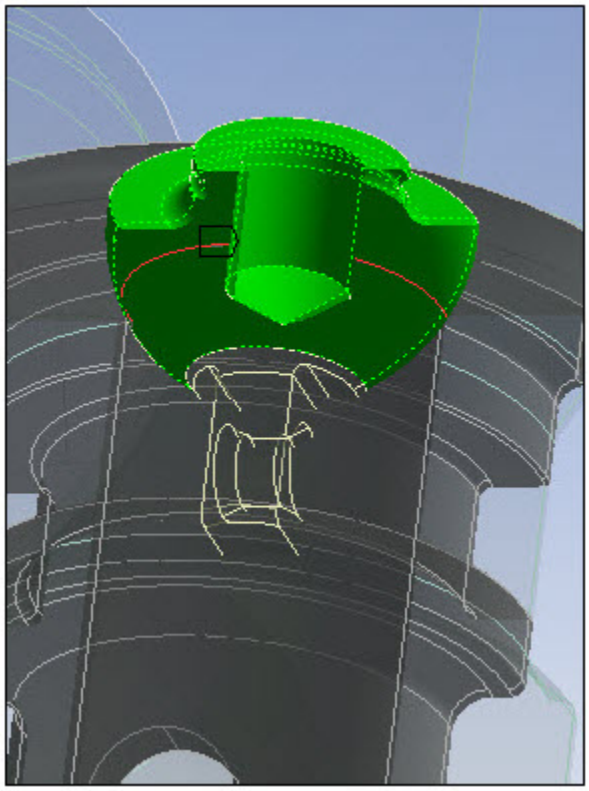
If an edge used by a connection is encountered, the search stops at the edge; a face across the edge is not selected. If there are no connections, all adjacent faces are selected. If the current selection itself is part of a connection, it remains selected but the search stops.

Note:

- The extent of the faces that will be included depends greatly on the current set of connections, as defined by the specified connections criteria (for example, **Connection Type**, **Tolerance Value**, and so on). By modifying the criteria and regenerating the connections, a different set of faces may be included. Refer to Connection Features and Operations (p. 1218) for more information.
- The figures below illustrate simple usage of the **Connection** option.



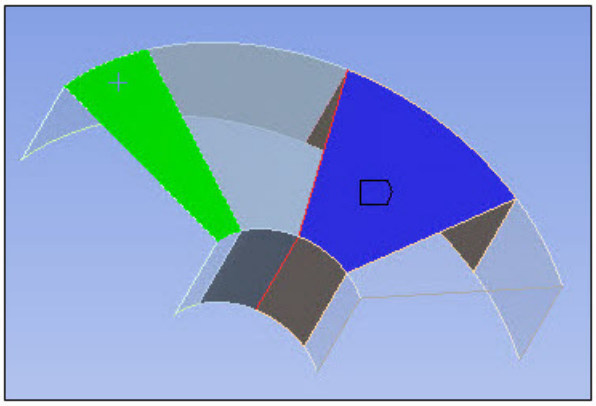
Single face selected in part.



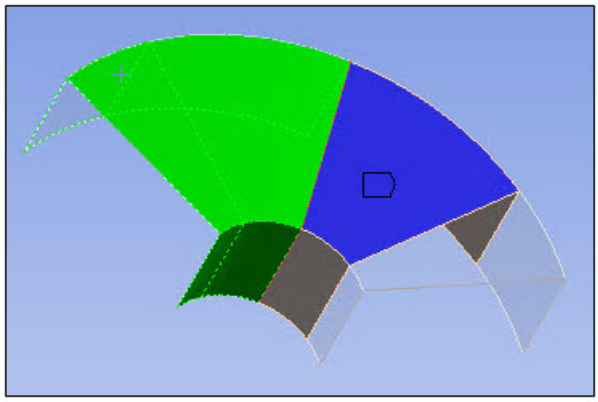
Additional connected faces selected after **Connection** option is chosen.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Single face selected in part. In this example, a multiple edge to single face connection is defined.



Additional connected faces selected after **Connection** option is chosen. When the connection is encountered, search stops at edge.

Selecting Nodes

As with geometry selection, you use many of the same selection tools for mesh nodes. Once you have generated the mesh on your model, you use picking tools to select individual or multiple nodes on the mesh. You use node selections to define objects such as a node-based coordinate system or node-based Named Selections (p. 1057) as well as examining solution information about your node selections. This section describes the steps to create node-based objects in Mechanical.

The following additional topics included in this section describe the uses for the node selection feature:

- Node Selection (p. 269)
- Selection Modes for Node Selection (p. 270)
- View Node Information (p. 272)
- Select Mesh Nodes on a Result Contour (p. 273)

Also see these sections for the steps to create node-based coordinate systems and Named Selections.

- Creating a Coordinate System by Direct Node Selection (p. 274)
- Specifying Named Selections by Direct Node Selection (p. 275)

Node Selection

To select individual nodes:

1. Generate a mesh by highlighting the **Mesh** object and clicking the **Generate Mesh** button.
2. From the Graphics Toolbar (p. 97), select the **Node** filter option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. As needed, choose the appropriate selection tool from the **Select Mode** drop-down list. For more information on the node-based selection modes, see Selection Modes for Node Selection (p. 270).

Note:

- When working with **Line Bodies**: Nodes can be selected using volume selection modes only (**Box Volume Select** or **Lasso Volume Select**).
- When working with **Line Bodies** and **Surface Bodies**: Ansys recommends that you turn *off* the **Thick Shells and Beams** option (**Display** tab (p. 78)). This option changes the graphical display of the model's thickness and as a result can affect how your node selections are displayed.

---

4. Select individual nodes or define the shape to select nodes. With your selections active, you can now define a coordinate system (p. 274) or named selection (p. 275) from selected nodes.

Selection Modes for Node Selection

Single Select	Selects individual nodes or a group of nodes on the surface.
Box Select	Selects all the surface nodes within the box boundary for all the surfaces oriented toward the screen.  
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

 Box Volume Select	Selects all the surface and internal nodes within the box boundary across the cross-section. The line of selection is normal to the screen.   Lasso Select	Is similar to the **Box Select** mode. Selects surface nodes that occur within the shape you define for surfaces oriented toward the screen.  
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Lasso Volume Select	Similar to **Box Volume Select** mode. Selects the nodes that occur within the shape you define.  
Tip:

- To select multiple nodes, press the **Ctrl** key or press the left mouse and then drag over the surface. You can also create multiple node groups at different locations using the **Ctrl** key.
- To select all internal and surface nodes, use the **Box Volume Select** or **Lasso Select** tool and cover the entire geometry within the selection tool boundary.
- The **Select All** (**Ctrl**+**A**) option is not available when selecting nodes.

View Node Information

You can view information such as the location of each selected node and a summary of the group of nodes in the **Selection Information** window. A brief description of the selected nodes is also available on the status bar of the application window. To view node id and location information:

1. Select the nodes you wish to examine.
2. Select the **Selection Information** option from the **Tools** (p. 45) group on the **Home** tab.

The following options are available as drop-down menu items in the **Selection Information** window.

Selection Information	Description
Coordinate System	Updates the **X**, **Y**, and **Z** information based on the selected coordinate system.
Show Individual and Summary	Shows both the node Summary and information on each node.
Show Individual	Shows information related to each node.
Show Summary	Shows only a summary of selected nodes.

For more information see the **Using the Selection Information Window** (p. 186) section.

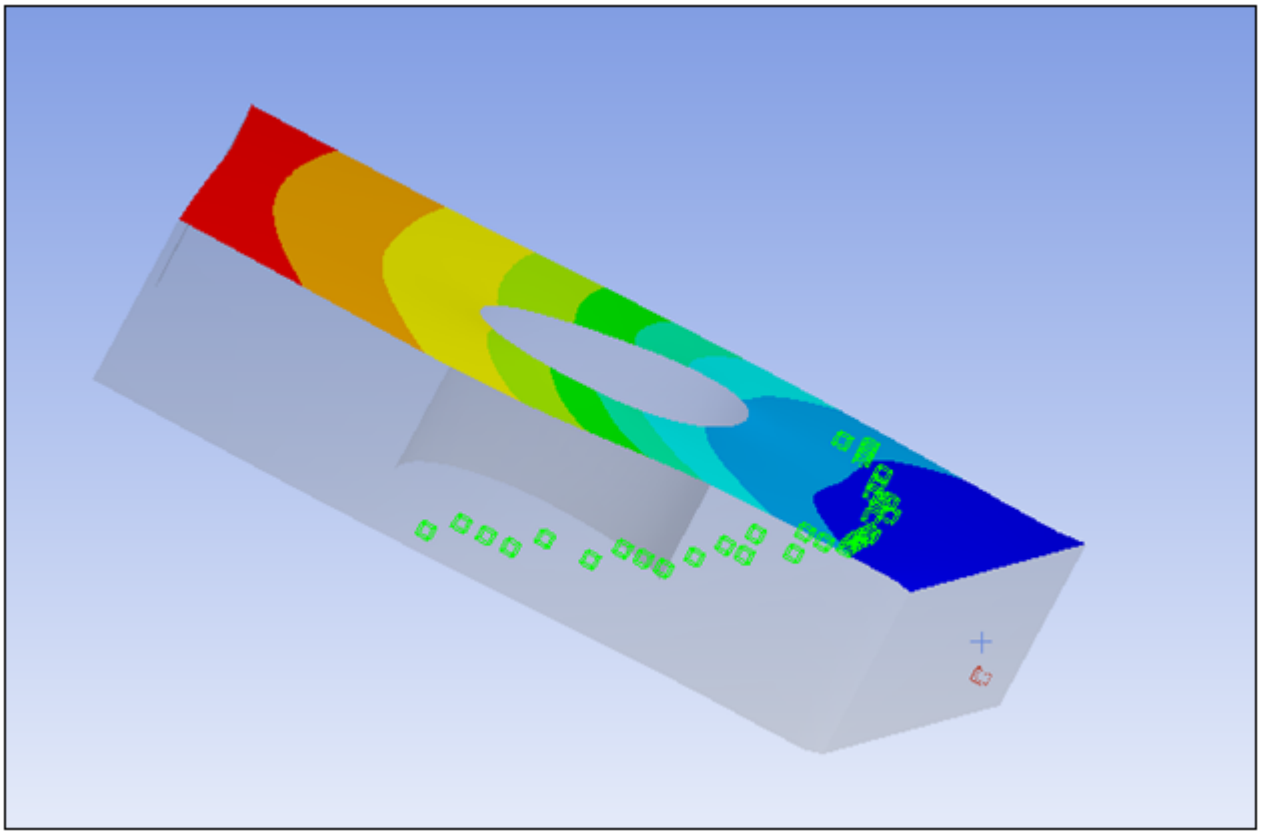
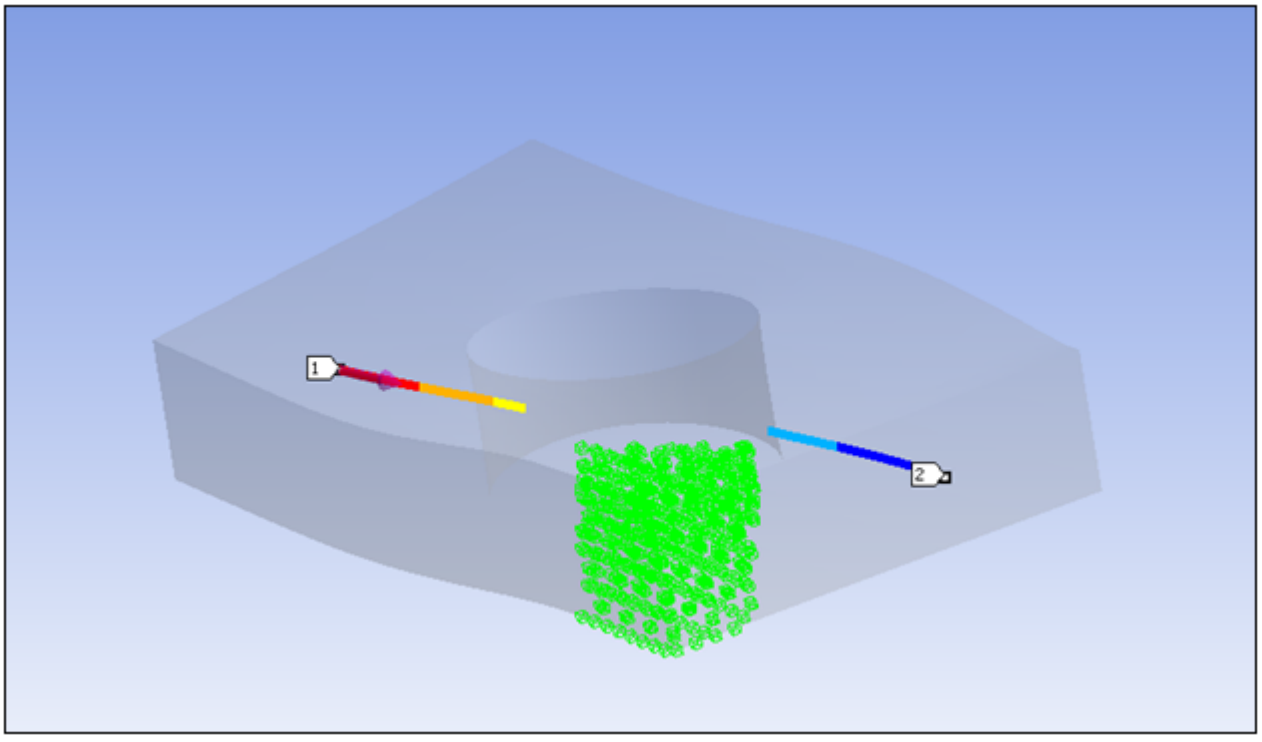
Published: 2023-10-23

Select Mesh Nodes on a Result Contour

Nodes (from the original mesh) can be selected even if they don't have values for the selected result, as in a path or surface scoped result.





Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The positions of selected nodes reported in the **Selection Information** window are those from non-deformed mesh.

Note:

If the graphics expansion is used (for shells and cyclic expansion, for example), the selection will work on the expanded graphics, while the reported node ID and position will be those in the non-expanded mesh. To eliminate confusion, switch the expansion off.

Creating a Coordinate System by Direct Node Selection

You can select one or more nodes and then create a coordinate system directly in the Geometry window. The new coordinate system is created at the location of the selected node or the centroid of multiple nodes using the (X, Y, Z) locations, rather than the nodes themselves, to ensure that the location does not change upon re-meshing.

To create a coordinate system from nodes in the Geometry window:

1. Using the **Node** selection filter on the Graphics Toolbar (p. 97), select a node.
2. Right-click the selected nodes and select **Create Coordinate System**.

   A new coordinate system is created at the location of the selected node or the centroid of multiple nodes.

If you re-mesh the body at this point, you will see that the coordinate system remains in the same location, as it is based on node location rather than node number.

Creating an Aligned Coordinate System

You can also select an individual node and create an aligned coordinate system on a solved vector principal stress or strain result.

Note:

While you cannot create an aligned coordinate system based on multiple nodes, you can create a local coordinate system at the centroid with an axis oriented in the direction of the global coordinate system.

To create an aligned coordinate system:

1. From the **Tree Outline**, select a **Vector Principal Stress** or **Vector Principal Strain** result.
2. Using the **Node** selection filter on the Graphics Toolbar (p. 97), select one or more nodes.
3. Right-click in the Geometry window and select **Create Aligned Coordinate System**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

A coordinate system is created. The Y-axis of the local coordinate system is oriented in the direction of *S1* (*direction of max. principal stress*).

Note:

Vector Principal Stress and **Vector Principal Strain** results cannot be applied to line bodies or a node located on a line body. As a result, any automatically generated (aligned) coordinate system would be incorrect.

Specifying Named Selections by Direct Node Selection

You create node-based Named Selections in the graphical viewer by scoping selections to single nodes, a group of surface nodes, or a group of nodes across a geometry cross-section.

Note:

You can make direct node selections when working with beams (line bodies) using the Worksheet (p. 1061). Direct graphical selection is also available using the **Node** selection filter on the Graphics Toolbar (p. 97).

To define node-based Named Selections:

1. Using the **Node** selection filter on the Graphics Toolbar (p. 97), select one or more nodes.

   Note:

   For accuracy, ensure that the selected node lies within the scoped area of the result

2. In the Geometry window, right-click the selected node or nodes and select **Create Named Selection**.
3. Enter a name for the Named Selection and click **OK**.

Note:

- If you select a large number of nodes (order of magnitude: 10,000), you are prompted with a warning message regarding selection information time requirements.
- Following a remesh or renumber, all nodes are removed from named selections. If named selections were defined with **Scoping Method** set to **Worksheet** and if the **Generate on Remesh** field was set to **Yes** in the **Details** view of the **Named Selection** folder, then the nodes are updated. Otherwise, node scoping does not occur and the named selection will be empty.

Selecting Elements and Element Faces

Once you have generated the mesh on your model, you can select one or more elements or element faces on your mesh using the **Element** or **Element Face** selection filter on the Graphics Toolbar (p. 97) as well as the options of the **Select Mode** drop-down menu. The following topics describe element-based selection methods and features:

- Selecting Elements or Element Faces (p. 276)
- Specifying Element and Element Face-Based Named Selections (p. 276)
- Viewing Element Information (p. 278)

Selecting Elements or Element Faces

To select elements/element faces:

1. Generate the mesh by highlighting the **Mesh** object and clicking the **Generate Mesh** button.
2. From the Graphics Toolbar (p. 97), select the **Element** or **Element Face** filter option.
3. As needed, choose the desired selection tool from the **Select Mode** drop-down menu on the Graphics Toolbar (p. 97).
4. Select an individual element or multiple elements. To select multiple elements:
   - Hold the **Ctrl** key and click the desired elements/element faces individually. You can also deselect elements/element faces by holding down the **Ctrl** key clicking an already selected element/element face.
   - Hold the left mouse button and drag the cursor across multiple elements/element faces.
   - Use the **Box Select** tool to select all elements/element faces within a box. The **Ctrl** key can also be used in combination with **Box Select** to select multiple boxes of elements/element faces.

Specifying Element and Element Face-Based Named Selections

To create an element or element face-based Named Selection (p. 1057):

1. Select individual or multiple elements/element faces as described above.
2. With your desired element/element face selections highlighted, right-click the mouse and select **Create Named Selection** from the context menu.
3. Enter a name for the Named Selection and click **OK**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

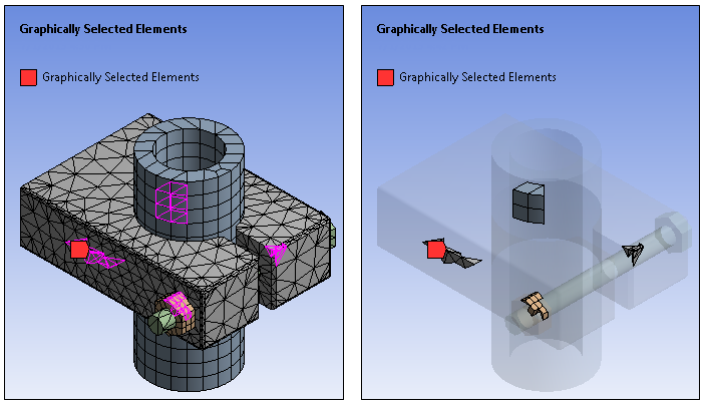
Published: 2023-10-23

Element-based Named Selections are written into the Mechanical APDL input file and this data can be used by the Command (p. 2303) object for further processing.

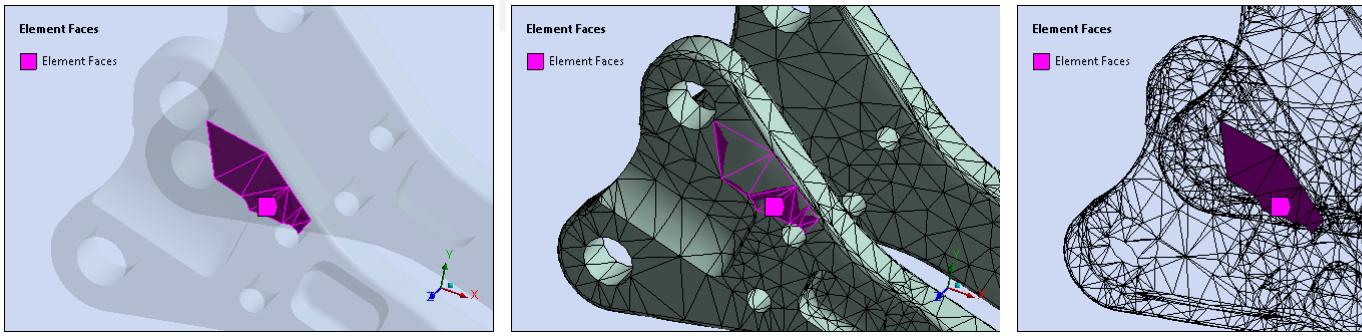
Note:

- An example element-based Named Selection is illustrated below. The example is named **Graphically Selected Elements**. When the **Show Mesh** feature is active, as illustrated in the first image, the elements of a named selection (or multiple named selections) are highlighted. Otherwise, the elements are drawn and the remained of the model is transparent, as illustrated in the second image.

Show Mesh On **Show Mesh Off**



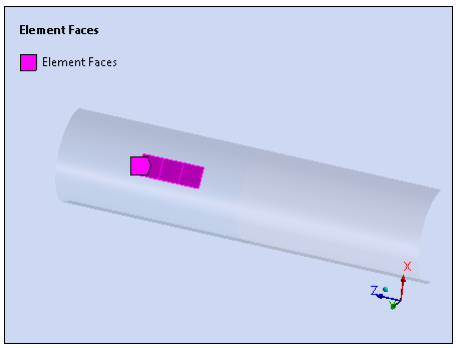
- For Element Face-based Named Selections, each selected face is displayed and each face is "filled" as illustrated in the first image shown below. This is different from Element-based selections that only highlight/display edges. When the **Show Mesh** feature is active, the element faces of a Named Selections may present "bleeding" on the annotation as illustrated in the second image shown below. You can turn on Wireframe mode to accurately display annotations when Show Mesh is selected, as illustrated in the third image.

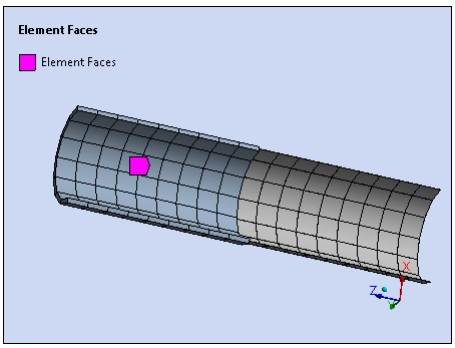


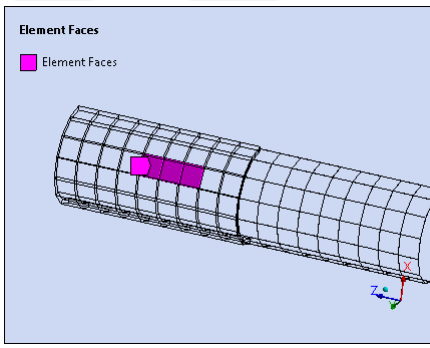
- When working with **Line Bodies** and **Surface Bodies**: Ansys recommends that you turn off the **Thick Shells and Beams** option (**Style** group of the **Display** tab). This option changes the graphical display of the model's thickness and as a result can affect how your element selections are displayed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

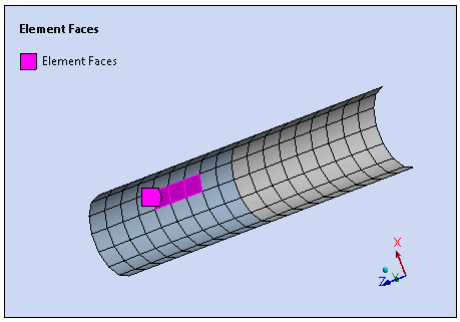
- For surface body Element Face-based Named Selections, the selected element faces can become invisible as a result of being hidden behind an expanded mesh as illustrated below in the first two images below. This issue can again be remedied using Wireframe mode to accurately display annotations when **Show Mesh** is selected, as illustrated in the third image.

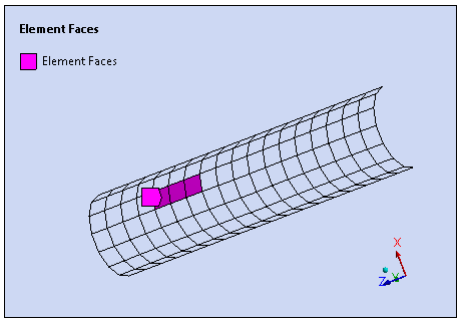






In addition, and as illustrated below in the first image below, not expanding the mesh (turn **Thick Shells and Beams** option off) displays the annotations properly. You can also use Wireframe mode, as illustrated in the second image below.

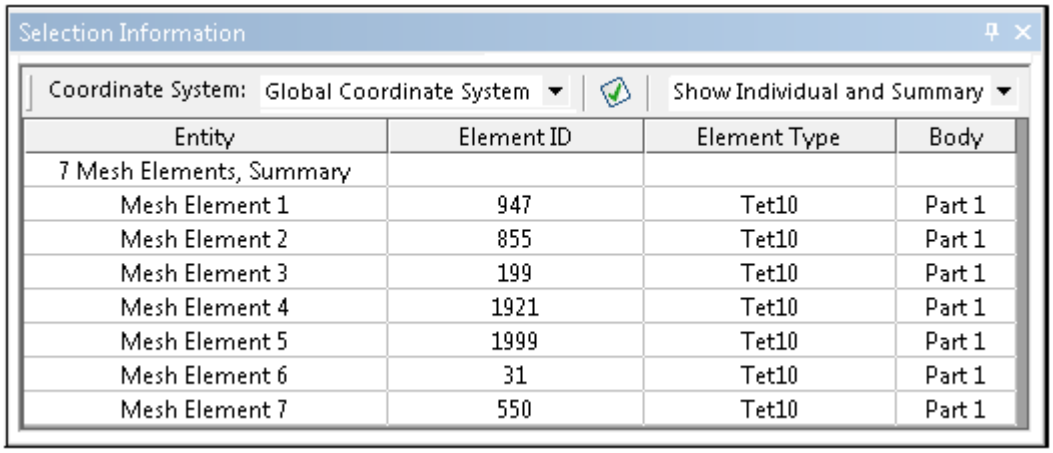




Viewing Element Information

As illustrated below, you can view information about your element/element face selections, such as Element Type, Element ID, as well as the body that the element is associated with using the **Selection Information** window. Once you have selected your desired element or elements, display the **Selection Information** window by selecting the **Selection Information** option from the **Tools** group (p. 45) on the **Home** tab.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Entity	Element ID	Element Type	Body
7 Mesh Elements, Summary			
Mesh Element 1	947	Tet10	Part 1
Mesh Element 2	855	Tet10	Part 1
Mesh Element 3	199	Tet10	Part 1
Mesh Element 4	1921	Tet10	Part 1
Mesh Element 5	1999	Tet10	Part 1
Mesh Element 6	31	Tet10	Part 1
Mesh Element 7	550	Tet10	Part 1

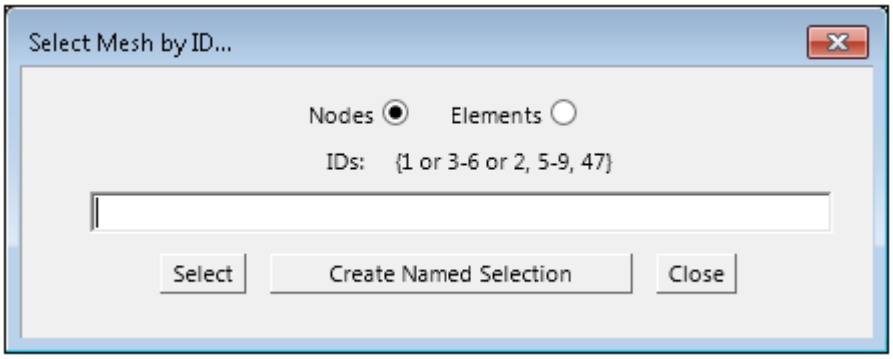
Note:

The status bar at the bottom of the application window also displays the number of elements/element faces you currently have selected.

For additional information, see the **Using the Selection Information Window** (p. 186) section.

Selecting Nodes and Elements by ID

Once you have generated the mesh for your model, the contextual menu (right-click) option, **Select Mesh by ID (M)**, is available from the **Geometry** window. You can also activate the feature using the **M** (p. 314) key, when the **Geometry** window has focus. As illustrated below, this dialog enables you to select mesh nodes and mesh elements using their IDs. This feature is modeless and therefore enables you to work with the user interface while the dialog box is displayed.



From this entry window, you can make comma separated entries of individual nodes (or elements), range entries by using a dash, and/or a combination of the two and then click the **Select** button. Range entries must increase in the appropriate order (for example, 1-10, not 10-1). The dialog displays messages regarding incorrect criteria as needed.

This feature works in tandem with the **Selection Information** window (p. 180), enabling you to view and verify your entries. Open the window to display information about your selections as you make them. In addition, the status bar displays your selections. You can double-click the status bar pane to activate the **Selection Information** window (p. 181). You can refer to the **View Node/Element In-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

formation topics in the Selecting Nodes (p. 269) and Selecting Elements (p. 276) sections of the Help for additional information.

Important:

- The application does not verify your ID entries. The application ignores any specified ID that does not exist.
- Exponential (for example, 1e6) notation is not supported.

Once you make your selections, you can create an associated Named Selection (p. 1057) by selecting the **Create Named Selection** button. For the newly created Named Selection, there will be a Worksheet (p. 1074) entry for each delimiter-separated set of nodes or elements.

Manipulating the Model in the Geometry Window

This section describes the tools to manipulate (rotate, pan, and zoom) your model in the Geometry window.

Panning the Model

Selecting the **Pan** option on the Graphics toolbar (p. 97) enables you to vertically and horizontally reposition your model in the **Geometry** window. Simply select the **Pan** button on the toolbar and click your mouse within the **Geometry** window to give it focus. Then, hold the left mouse button and reposition your model. In addition, once you have given the **Geometry** window focus, you can use the arrow key to reposition your model.

Note:

At any time while the **Pan** option is active, you can use the middle mouse button (or **[Ctrl]**+**[Arrows Keys]**) to rotate your model.

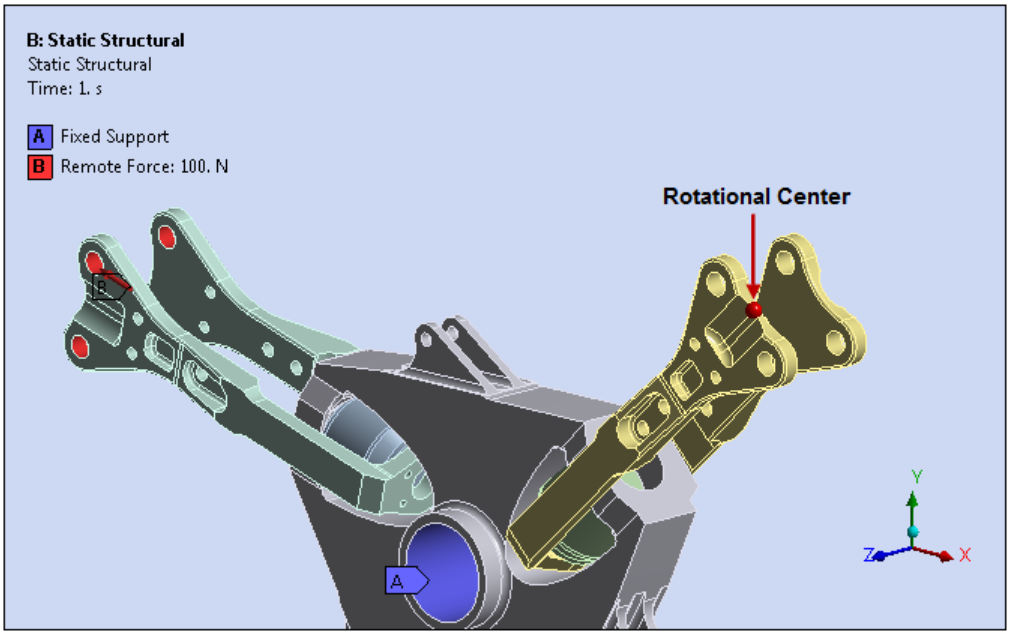
Rotating the Model

Selecting the **Rotate** option on the Graphics toolbar (p. 97) enables you to turn your model about a default or user-selected center using the left mouse button. This is a common application feature. By default, the rotational center is the center of your model.

To rotate about a specific point on the model, select a new point of rotation on your model with the left mouse button. This action recenters your model in the **Geometry** window and displays a red sphere that indicates the newly selected center of rotation. From this position, you can rotate your model freely about the new rotation point. To restore the default rotation point, simply click off of the model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Rotation Using the Middle Mouse Button

You can also, at any time, rotate your model in the **Geometry** window using the middle mouse button. With the middle mouse button, you can select a location on you model, hold the middle mouse button, and rotate your model about that point. Clicking off of the model returns the rotational center to the application default. Using this method, the application does not recenter the model in the window based on the newly selected center of rotation.

Note:

These middle mouse button options are always available when the Geometry window has focus.

On Mouse Down Set

For the left mouse button, you may change the default setting for the **Model Rotation Center** option in the Graphics (p. 228) category of the Options preference (p. 217) to **On Mouse Down Set**. Using this setting, with the **Rotate** feature active, the application does not recenter your model and you can immediately rotate it around the new point. When in this mode, your new selection becomes the default.

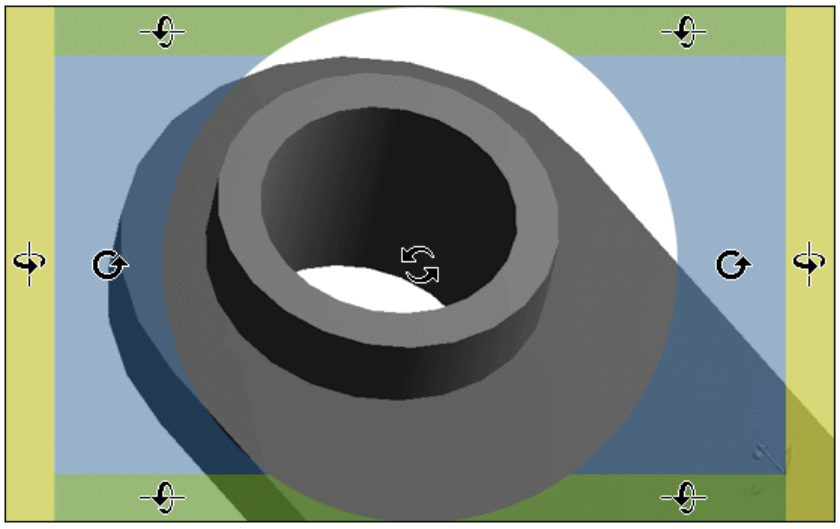
Rotation Behavior Based on Cursor Location

You may change the default setting for the **Mouse Rotation Mode** option in the Graphics (p. 228) category of the Options preference (p. 217) to **Axis Rotation Available**. Using this setting, with the **Rotate** feature active, the application activates the roll, yaw, and pitch cursor options in the **Geometry** window, as described below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Geometry Window Cursor Icon	Description
	Free rotation.
	Rotation around an axis that points out of the screen (roll).
	Rotation around a vertical axis relative to the screen (yaw axis).
	Rotation around a horizontal axis relative to the screen (pitch axis).

As illustrated below, the application displays these icons based upon where you position the cursor in the **Geometry** window.



Model Orientation using the Triad

The Triad, located in the lower right corner of the Geometry window, enables you to reorient the position of your model based on a desired axis as well as reset the isometric view (light blue ball). If you move your cursor around the triad, you will see an arrow appear that shows the direction that corresponds to the position of your cursor (+x, -x, +y, -y, +z, -z). If you click the arrow, it changes your view so that the axis indicated by the arrow is facing outward.

Zooming In and Out on Your Model

There are a number of Zoom options available in the Graphics toolbar:

- Selecting the **Zoom** button enables you to drag your left mouse button up and down in the **Geometry** window to zoom in and out on your model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Selecting the **Box Zoom** button displays a box selection area when you to drag your left mouse button. The application zooms in on this area in the **Geometry** window. Note that the smaller area that you select with this tool, the smaller area that is zoomed in upon.

Note:

- You can hold the **Shift** key and use the up and down arrow buttons respectively, to zoom in and out on your model.
- You can zoom in or out by rolling the mouse wheel.

Defining Direction

Orientation may be defined by any of the following geometric selections:

- A planar face (normal to).
- A straight edge.
- Cylindrical or revolved face (axis of).
- Two vertices.

This section discusses the following topics:

Direction Defaults (p. 283)
Highlighting Geometry in Select Direction Mode (p. 283)
Selecting Direction by Face (p. 284)

Direction Defaults

If you insert a load on selected geometry that includes both a magnitude and a direction, the **Direction** field in the **Details view** states a particular default direction. For example, a force applied to a planar face by default acts normal to the face. One of the two directions is chosen automatically. The load annotation displays the default direction.

Highlighting Geometry in Select Direction Mode

Unlike other picking filters (where one specific type of geometry highlights during selection) the **Select Direction** filter highlights any of the following during selection:

- Planar faces
- Straight edges
- Cylindrical or revolved faces
- Vertices

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

If one vertex is selected, you must hold down the **Ctrl** key to select the other. When you press the **Ctrl** key, only vertices highlight.

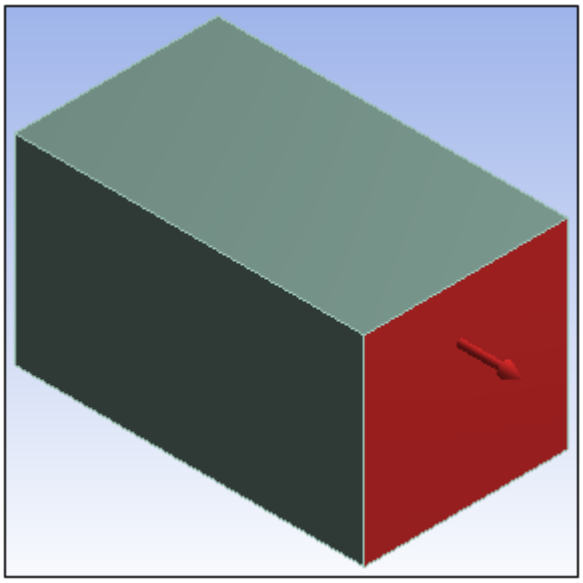
Selecting Direction by Face

The following figure shows the graphic display after choosing a face to define a direction. The same display appears if you edit the **Direction** field later.

- The selection blip indicates the hit point on the face.
- Two arrows show the possible orientations. They appear in the lower left corner of the Geometry Window (p. 129).

  If either arrow is clicked, the direction flips.

When you finish editing the direction, the hit point (initially marked by the selection blip) becomes the default location for the annotation. If the object has a location as well as a direction (e.g. Remote Force), the location of the annotation will be the one that you specify, not the hit point.



Note:

The scope is indicated by painting the geometry.

Using Viewports

The **Viewports** feature enables you to split the **Geometry** window into multiple windows, up to four, and perform independent actions in each window.

Got to a section topic:

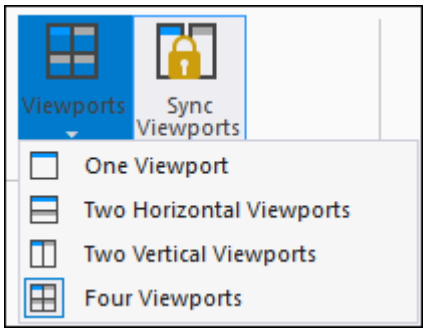
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Display Options (p. 285)
- Synchronize Viewports (p. 286)
- Capture Viewport Images (p. 286)
- Append Graph Window Data (p. 288)

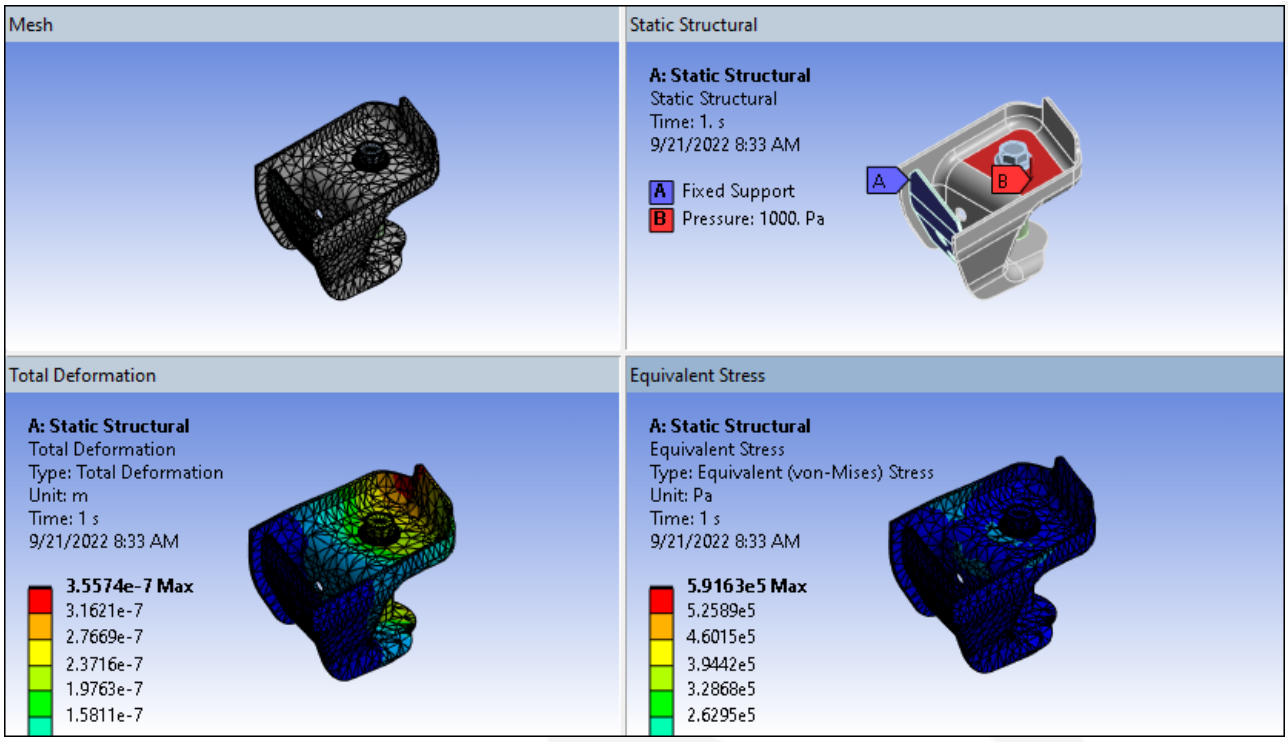
Display Options

As illustrated, the **Viewports** drop-down menu enables you to display one, two (horizontally or vertically), or four viewports in the **Geometry** window.



By default, the **Geometry** window displays one viewport/window. Once you select to display two or more viewports, the currently selected object displays in all viewport windows. You activate a viewport window by selecting it (clicking in the window or on the title bar). Once active, you can change the selected object, move your model, change property settings or scoping for the selected object, etc., *independent* of the other viewport windows displayed. For example, you can view loading conditions, results, Named Selections, contact conditions, and make changes to each separately.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Note:

A figure can be viewed in a single viewport only. If multiple viewports are created with the figure in focus, all other viewports display the parent of the figure.

Synchronize Viewports

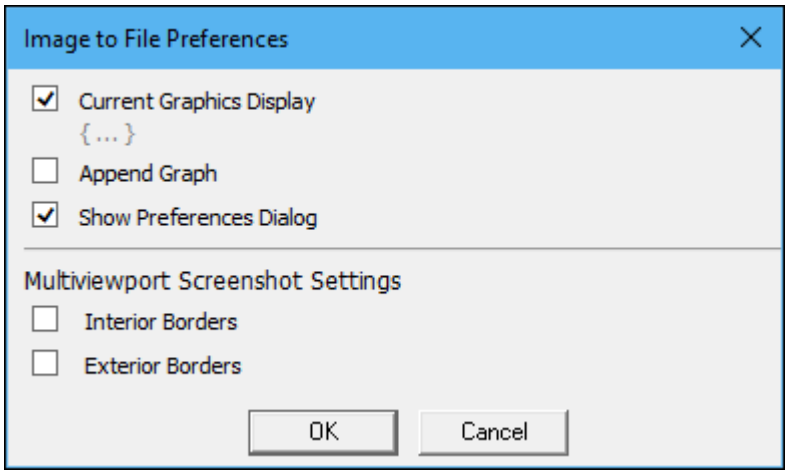
The ribbon group also includes the **Sync Viewports** option. The default setting is active. It enables you to synchronize the display in each window to reorient/move (pan, zoom, rotate) your model in each window simultaneously. When you have multiple orientations configured with the **Sync Viewports** option *inactive* and then you activate it, the viewport window that you select and manipulate first, becomes the window that all the other windows synchronize to.

Capture Viewport Images

The **Images** drop-down menu of the Insert (p. 42) group on the **Home** tab includes the option **Composite image to File**. This option acts the same as the Image to File (p. 42) option. It enables you to save the contents (viewports) of the **Geometry** window as an image file. When you select the option, a dialog displays that enables you to change image details such as resolution, appearance, and magnification.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

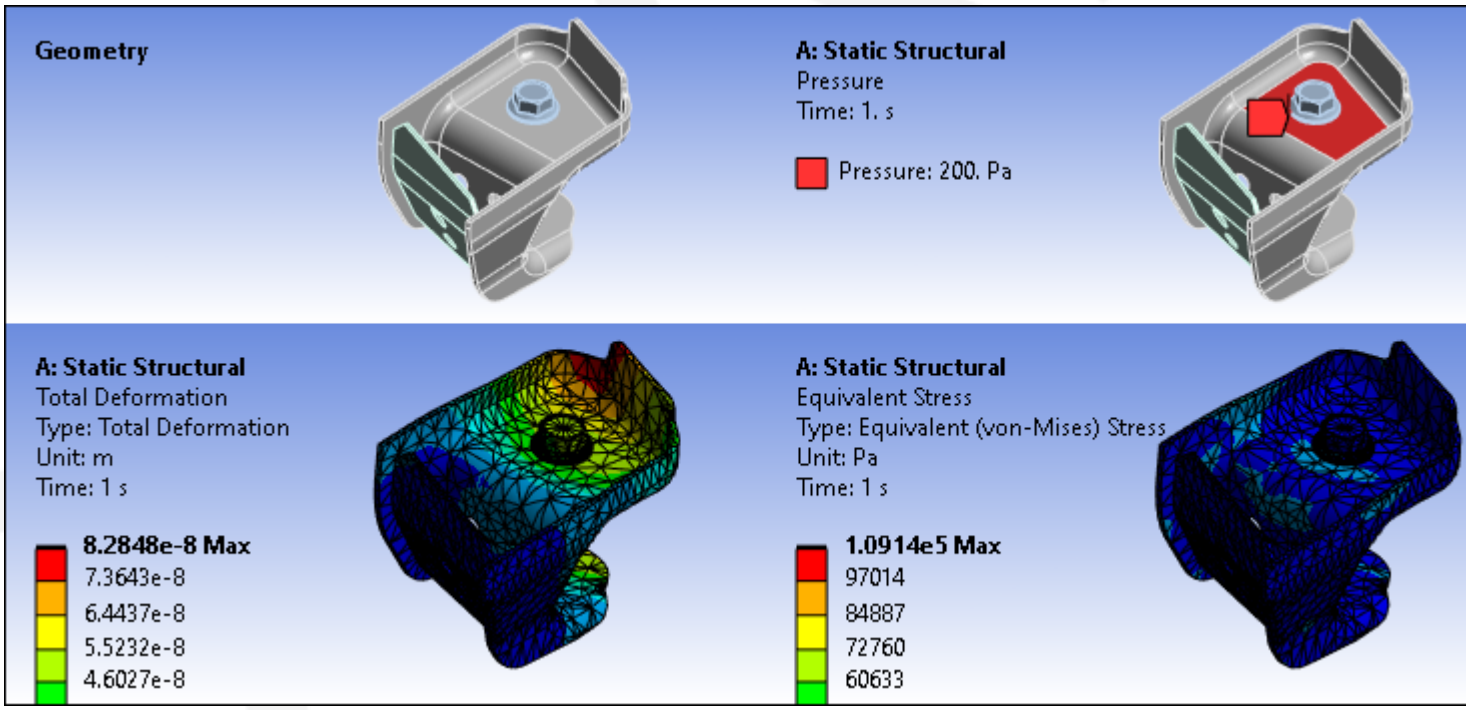
Published: 2023-10-23



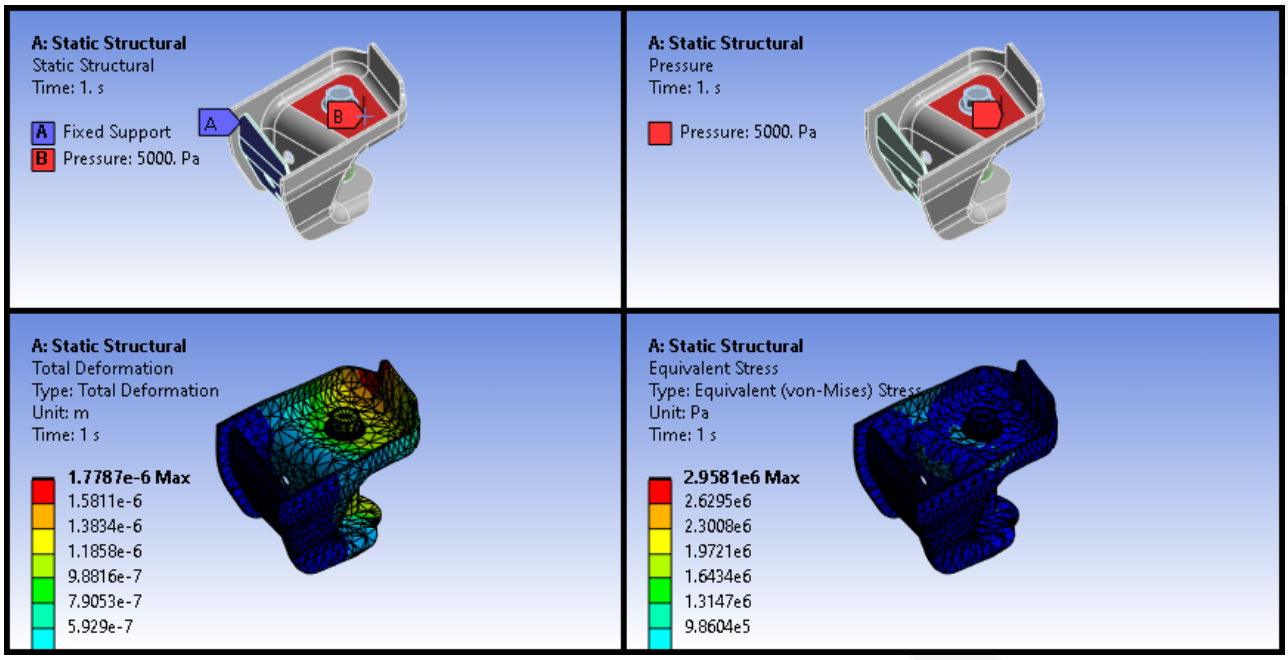
Note:

You can change the default settings for the dialog's options using the properties of the Image Export (p. 232) group of the **Graphics** category of the Options (p. 217) dialog.

The dialog also includes the options **Interior Borders** and **Exterior Borders** under the **Multiviewport Screenshot Settings** title that enables you to add borders around and in-between the viewports you capture. The following images show a comparison of these options when turned on and off.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

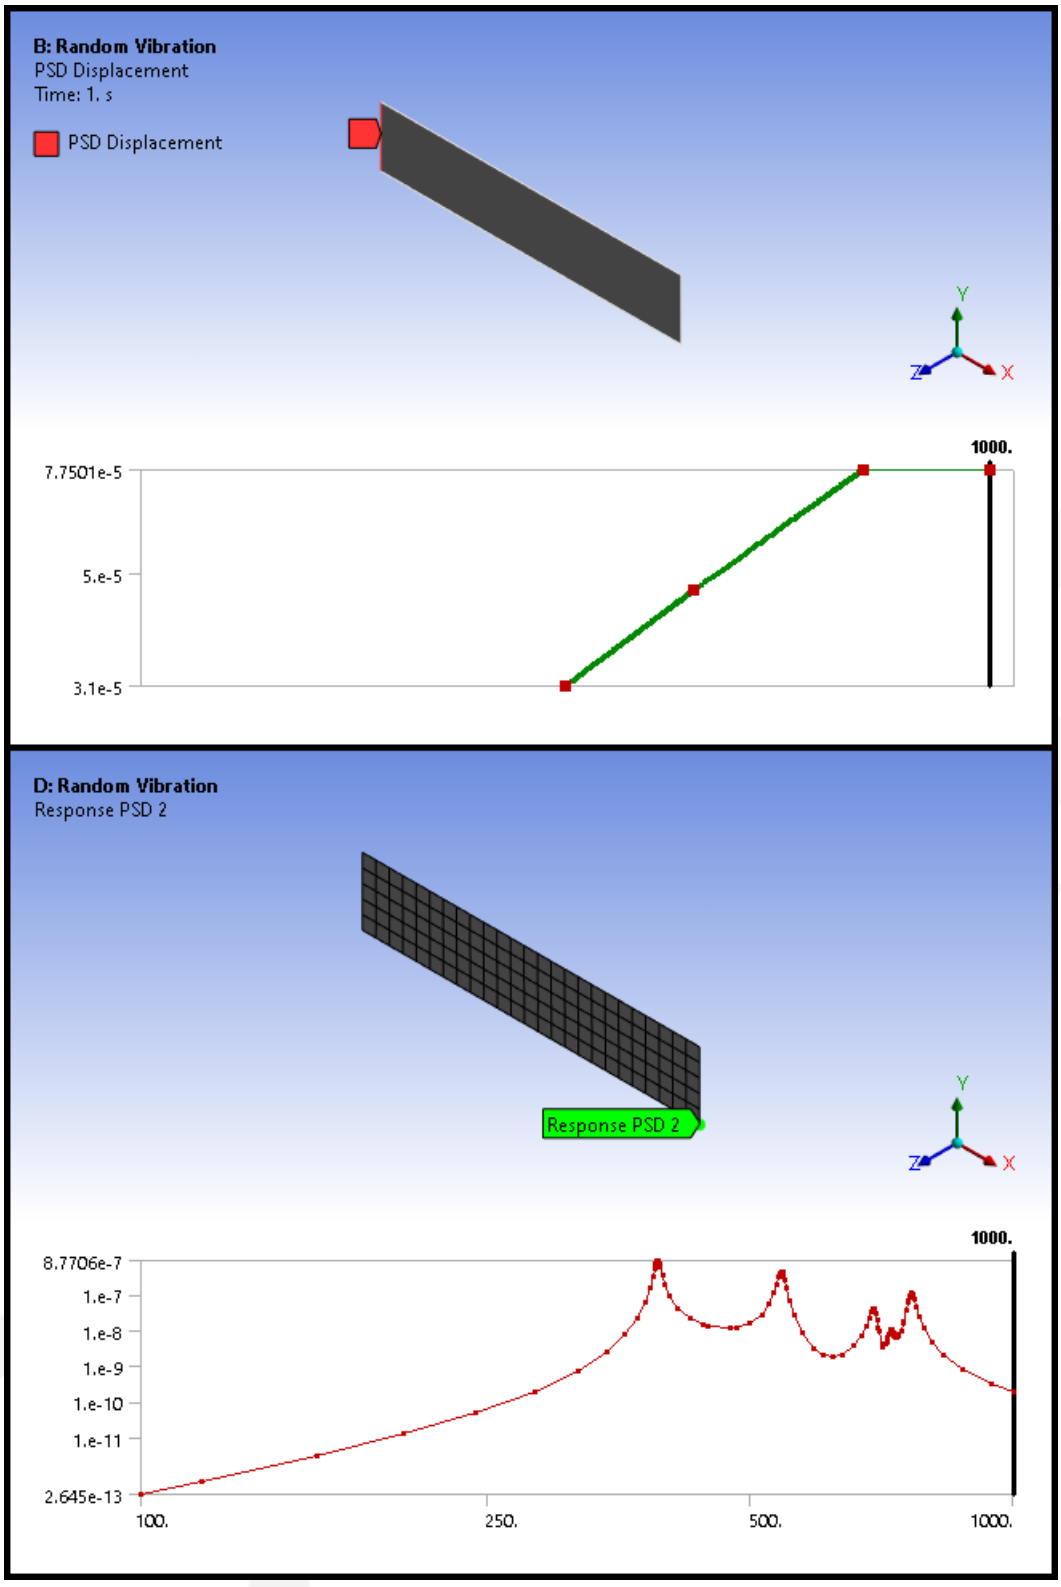


Append Graph Window Data

In addition, the dialog contains the check box **Append Graph**. As shown here, the application adds the content of the **Graph** window in the lower left-hand corner of the image. If there is no corresponding data in the **Graph** when this option is selected, the captured image is appended with a graph that includes no data.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Accelerated Graphics

If you are using a Windows system that supports OpenGL 4.3, the application automatically utilizes the **Accelerated Graphics** feature. This feature uses graphical display technology that produces a faster display of mesh and result objects when you first select the object, with even greater gains

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

when you select the object a second/third time. In addition to faster graphical display times, this feature provides more accurate color contours, a higher fidelity vector display, and a Smoothed Particle Hydrodynamics (SPH) display.

Important:

Although released, additional development is being made to the feature. Some application features and displays are not yet compatible with **Accelerated Graphics** and will automatically revert to previous display technology. Support in this regard is ongoing.

Note:

Once active, the label "Accelerated Display" is placed below the Ansys logo in the Geometry window.

Go to a section topic:

- Application (p. 290)
- Associated Preferences (p. 290)
- Cautions and Limitations (p. 291)

Application

Activate the feature using the **Accelerated Graphics for Mesh/Result Display** property in the Options (p. 217) dialog (Graphics (p. 228) preferences). Property options include:

- **Program Controlled** (default): The application selects the graphical mode based on application settings and support status, such as analysis settings, the specified result, view options, etc. This is the recommended setting.
- **Yes, if possible**: This setting forces the use of **Accelerated Graphics** wherever possible, even if only partially supported. However, this setting may produce graphical display issues for other features and displays options that are not yet supported by the feature. For large, complicated models, the benefits of the enhanced display may outweigh these display issues.
- **No**: This setting disables the feature.

Note:

You can also activate this feature from the Graphics Toolbar (p. 97).

Associated Preferences

This feature has the following associated preferences, included in the **Performance** category of the Graphics (p. 228) preferences of the Options dialog.

- **Show Accelerated Display Message in Graphics Window**: Turn the “Accelerated Display” label on and off. Options include No (default) and Yes.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Show Why Accelerated Graphics is Not Used**: Display an Information message for why Accelerated Graphics is not used for the mesh and results when it is not possible. Options include **No** (default) and **Yes**.
- **Use Faceted Lighting for Accelerated Graphics/Animation (Beta)**: This beta property enables you to modify the lighting. Options include **No** (default) and **Yes**. The **No** option specifies the standard lighting mode. This setting can cause issues with large deformation but maintains smooth lighting and is suitable for most models. The **Yes** setting uses an alternate faceted lighting mode. Lighting is done on a per-triangle basis resulting in a more jagged rendering of some models, but the lighting should be correct for any deformation.

Cautions and Limitations

Note the following when this feature is active:

- You may see minor graphical differences. For example, there could be slight differences in how the application displays translucency and higher resolution SPH symbol displays. These differences should not affect the accuracy of the display.
- The application uses an alternative system for rendering text. As a result:
  - You could see slight differences in text sizes and text placement compared to the graphical viewport in the legend, ruler, triad, etc.
  - You could see Unicode text (such as Japanese text) display limitations. For example, if the system name or a result name includes Unicode, or there are user labels that include Unicode text, this text may not render completely.
- The application does not yet support certain features, such as Section Planes and result probes. Processing contingencies for these features exist, however, you may see lag for larger models while using these features.

Controlling Graphs and Charts

The following controls are available for Graphs/Charts for Using Adaptive Convergence (p. 1852), and Fatigue Results (p. 2165) result items.

Feature	Control
Pan	Right Mouse Button
Zoom	Middle Mouse Button
Box Zoom	**Alt**+Left Mouse Button
Rotate (3D only)	Left Mouse Button
Perspective Angle (3D only)	**Shift**+Left Mouse Button
Display Coordinates (2D only)	**Ctrl**+Left Mouse Button along graph line

Tips for working with graphs and charts:

- Some features are not available for certain graphs.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Zoom will zoom to or away from the center of the graph. Pan so that your intended point of focus is in the center prior to zooming.
- If the graph has a Pan/Zoom control box, this can be used to zoom (shrink box) or pan (drag box).
- Double-clicking the Pan/Zoom control box will return it to its maximum size.

Managing Graphical View Settings

Using the **Manage View** option of the **Tools** group (p. 45) on the **Home** tab, you can save graphical views and return to a specific view at any time. This option displays an independent window that you use to work with the feature. The feature enables you to create a list of desired views. You can export your view list and import it into different projects and maintain a consistent model view between multiple projects.

This section discusses the following topics:

Creating a View
Applying a View
Renaming a View
Deleting a View
Replacing a Saved View
Exporting a Saved View List
Importing a Saved View List
Copying a View to Mechanical APDL

Creating a View

To save the current graphical view:

1. Click the **Create a View** option in the **Manage Views** window. A new entry with the naming convention of "View #" is created.
2. As desired, enter a new name for the view.

You can now return to this view at any time using this view entry.

Note:

You must save the project to save your created views in the **Manage Views** window.

Applying a View

Saved graphical views are listed in the **Manage Views** window. You can return to a saved view at any time.

To return to a saved graphical view:

1. In the **Manage Views** window, select the view.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click the **Apply View** button.

The **Geometry** window reflects the saved graphical view.

Renaming a View

To rename a saved graphical view:

1. In the **Manage Views** window, select the view you want to rename.
2. Click the **Rename** button, or press **F2**.
3. Enter the new view name.
4. Click the **Apply** button.

Deleting a View

To delete a saved graphical view:

1. In the **Manage Views** window, select the view you want to delete.
2. Click the **Delete** button.

Replacing a Saved View

To replace a saved view with the current graphical view:

1. In the **Manage Views** window, select the view you want to update.
2. Click the **Replace saved view based on current graphics** button.

Exporting a Saved View List

You can export a saved graphical view list to an XML file. This file can then be imported into other projects.

To export a saved view list:

1. In the **Manage Views** window, click the **Export** button.

   The **Save As** window appears.
2. Navigate to the file directory where you want to store the XML file and enter the desired file name.
3. Click **Save**.

Importing a Saved View List

Saved view lists can be exported to XML files. You can then import a saved view list from an XML file to a different project.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

To import a saved graphical view list:

1. In the **Manage Views** window, click the **Import** button.

   The **Open** window appears.

2. Select the file you want to import.

3. Click **Open**.

Copying a View to Mechanical APDL

You can copy a saved graphical view as a Mechanical APDL command and insert the command into a Mechanical APDL file. The view in Mechanical APDL will then be consistent with the selected graphical view.

To copy a graphical view to Mechanical APDL:

1. In the **Manage Views** window, right-click a view and select **Copy as MAPDL Command**.

2. Create or open an existing Commands (APDL) file.

3. Paste the new Mechanical APDL command into the file. The settings structure is:

   ```
   /FOC
   /VIEW
   /ANG
   /DIST
   ```

4. Select the **Solve** button, and the new view is available in the Commands (APDL) file.

Creating Section Planes

The **Section Plane** feature creates cuts or slices on your model so that you can view internal geometry, mesh, and/or result displays. The graphical display and operation of the feature varies depending upon whether you are displaying your model as geometry or if you are displaying the mesh or a result. You can create as many as six active Section Planes for a model. Once this maximum is met, you can add additional planes, but you cannot activate (or view) them until you have deactivated (unchecked) an existing plane and then activated the desired plane.

Tip:

Activate the Consider Section Planes When Mesh Picking (p. 228) preference in order to select newly displayed finite element entities (nodes, elements, and element faces) from geometries within the model that were hidden before adding the specified Section Plane. Review the Selecting Mesh Entities Displayed by the Section Plane (p. 301) topic at the end of the section to make sure that you understand the requirements and limitations of this feature.

Go to a section topic:

- Application (p. 295)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

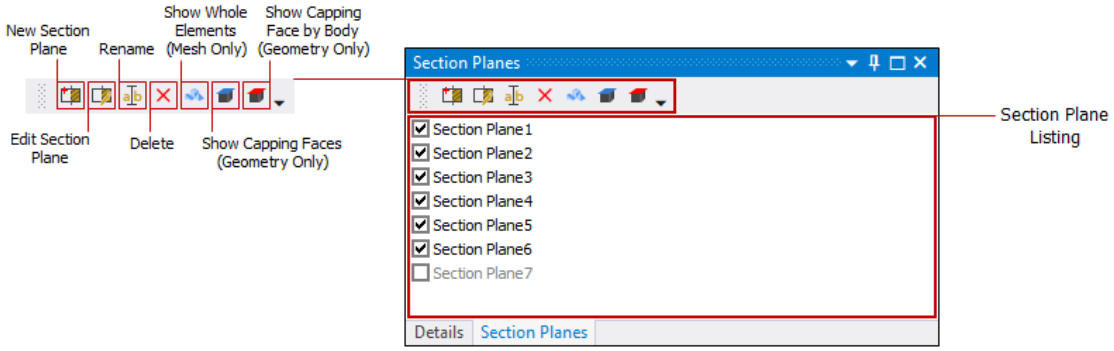
Published: 2023-10-23

- Section Plane Tools (p. 295)
  - New Section Plane (p. 296)
  - Edit Section Plane (p. 296)
  - Delete Section Plane (p. 298)
  - Rename Section Plane (p. 298)
  - Show Elements (p. 298)
  - Show Capping Faces (p. 299)
  - Show Capping Faces by Body Color (p. 300)
- Selecting Mesh Entities Displayed by the Section Plane (p. 301)

See the next two sections, Understanding Section Plane Display Differences (p. 303) and Working with Section Plane Results (p. 306), for information about display differences for section planes as well as display characteristics for when you apply a Section Plane to a result.

Application

Select the **Section Plane** option from the **Insert** group of the Home tab (p. 40) to open the **Section Planes** window illustrated below. The window displays a list of existing section planes (once created) and also provides the tools used to add, modify, or delete you section planes.



Note:

The Section Planes tool supports up to six (6) defined planes. Once you exceed six, unchecking an existing plane enables you to activate any defined planes greater than six.

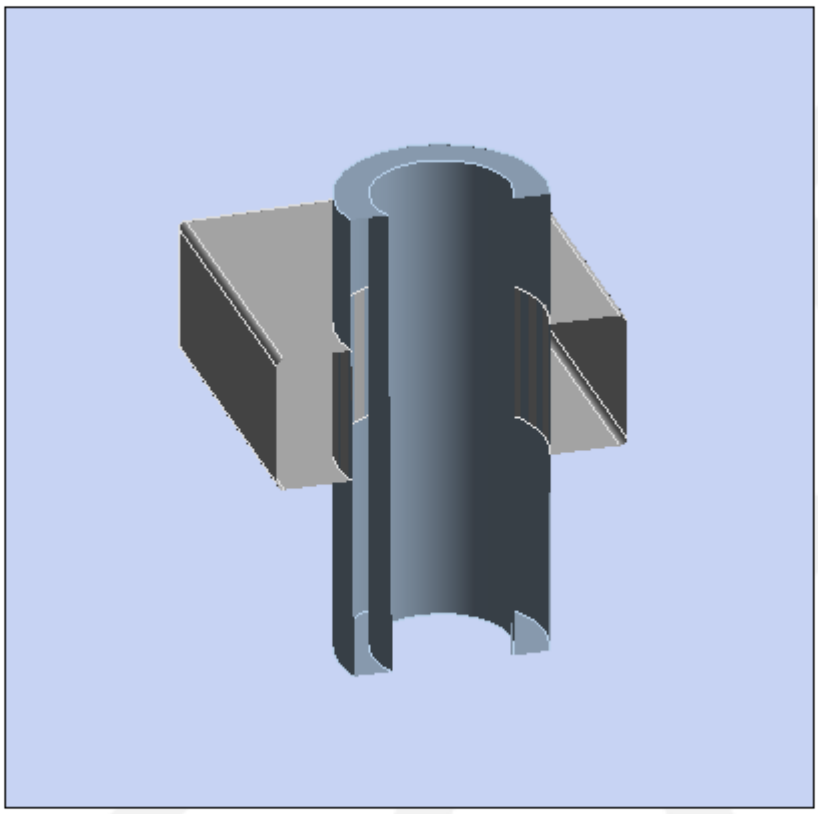
Section Plane Tools

The **Section Planes** window provides the following tools. You toggle these tools on and off by selecting the button.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

New Section Plane

Select this option and create a new Section Plane in the Geometry window. Drag the mouse pointer across the geometry where you want to create a section plane. The new section plane automatically displays in the Section Planes window with a default name of "**Section Plane #**." The checkmark next to the plane's name indicates it is an active section plane. You can construct additional Section Planes by clicking the New Section Plane button and dragging additional lines across the model. Note that activating multiple planes displays multiple sections.



Important:

Note that for incidences, such as very large models, where the accessible memory is exhausted, the New Section Plane tool reverts to a Hardware Slice Mode that prohibits the visualization of the mesh on the cut-plane.

Edit Section Plane

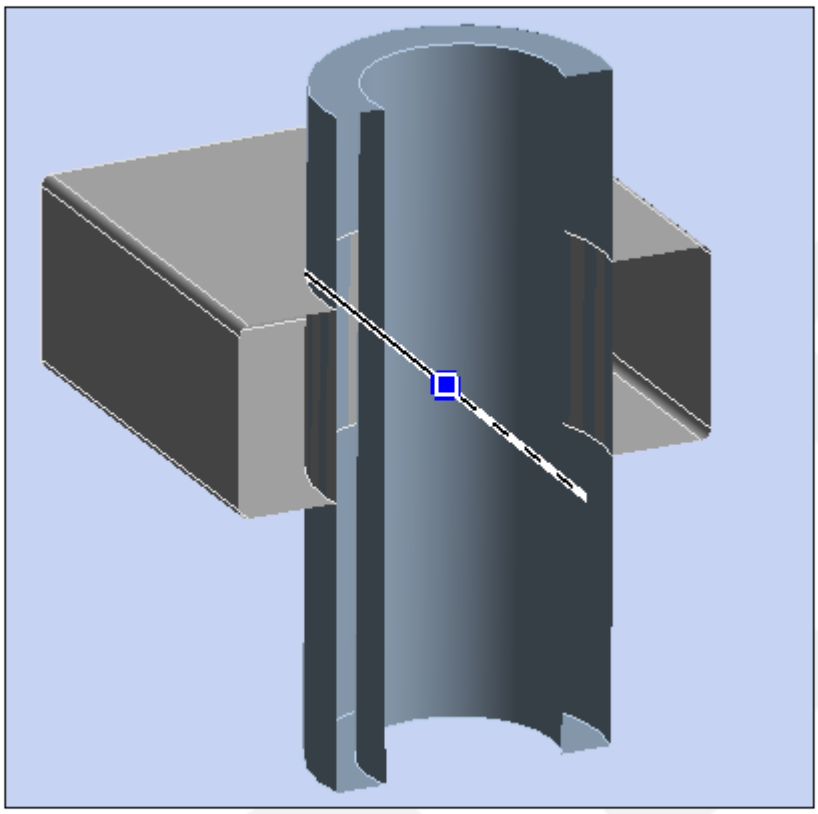
Highlight one of the Section Planes available in the window listing and then select this option to edit the highlighted section plane.

To edit a section plane:

1. In the **Section Planes** window, select the plane you want to edit.
2. Click the **Edit Section Plane** button. The section plane's anchor appears.
3. Drag the Section Plane or Capping Plane anchor to change the position of the plane.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can click the line on either side of the anchor to view the exterior on that side of the plane. The anchor displays a solid line on the side where the exterior is being displayed. Clicking the same side a second time toggles between solid line and dotted line, that is, exterior display back to section display.



This animation shows the result of dragging the anchor (not visible for PDF versions of the Help).

Published: 2023-10-23

Delete Section Plane

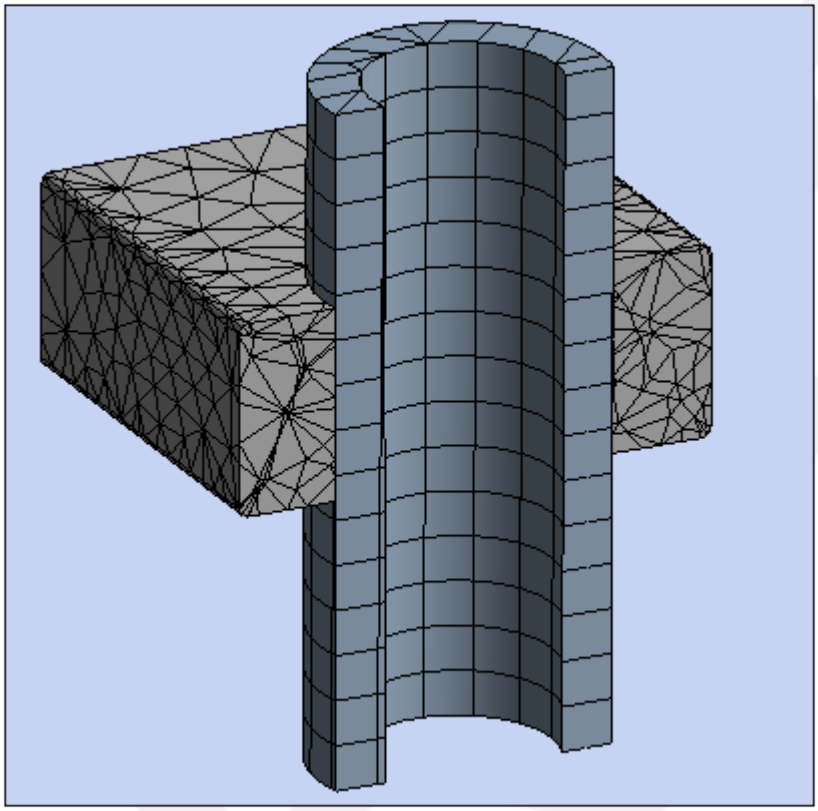
This option deletes a selected Section Plane from the listing.

Rename Section Plane

Select this option to rename a Section Plane.

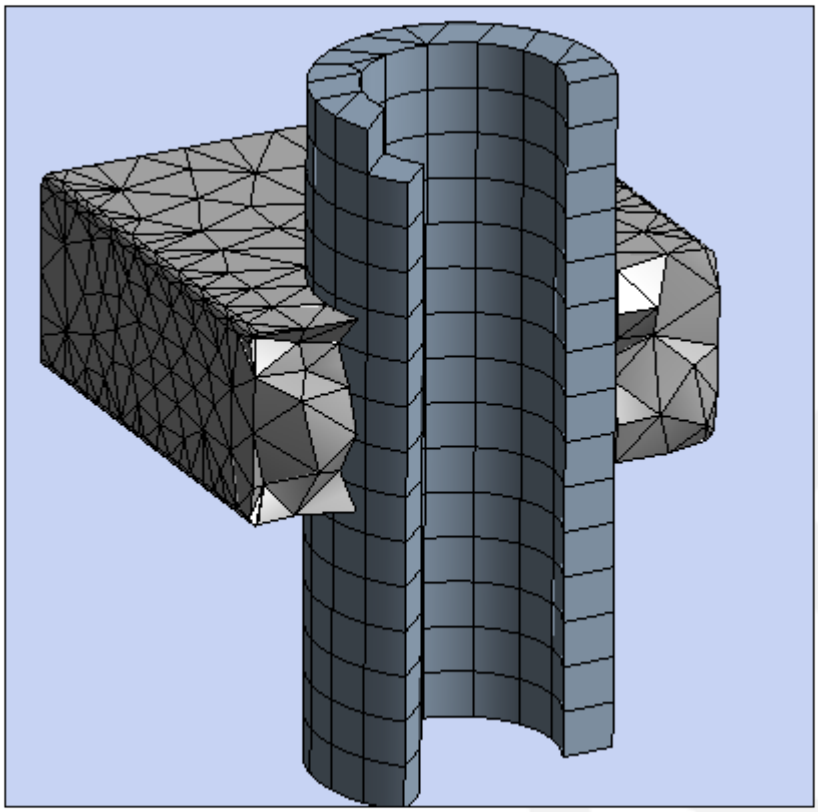
Show Elements

When you have the **Mesh** object selected or you have the **Show Mesh** feature activated, this selection causes any partially sliced elements to display entirely.



When you are viewing a Mesh display, you can use the **Show Whole Elements** button to display the adjacent elements to the section plane which may be desirable in some cases.

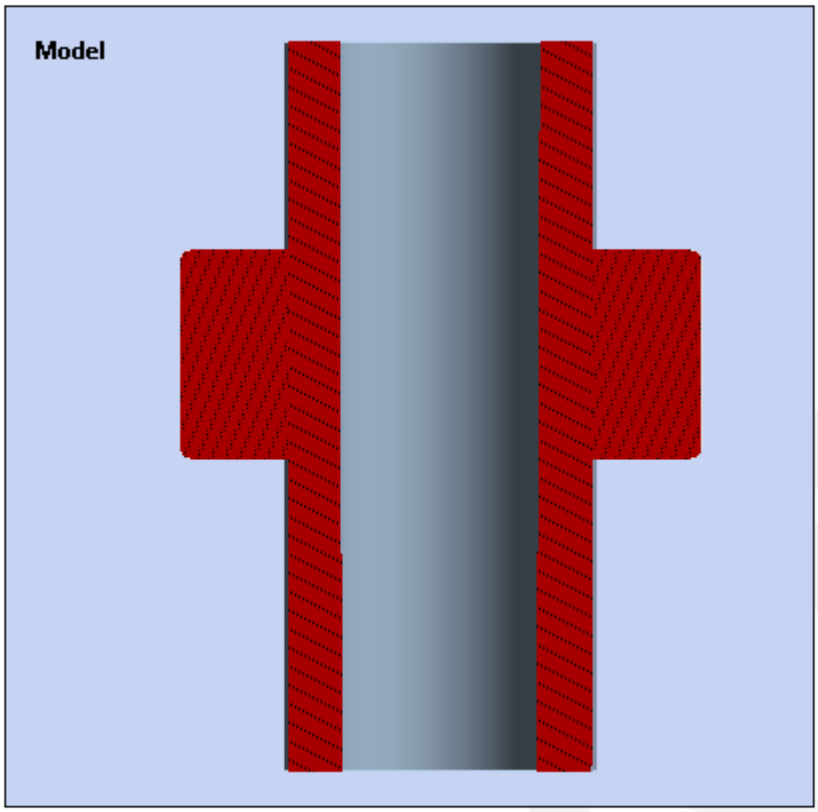
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.



Show Capping Faces

When *only one* Section Plane is contained in the window, by default, the slice is not capped and you can see the interior of the geometry. Selecting this option caps the geometry.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

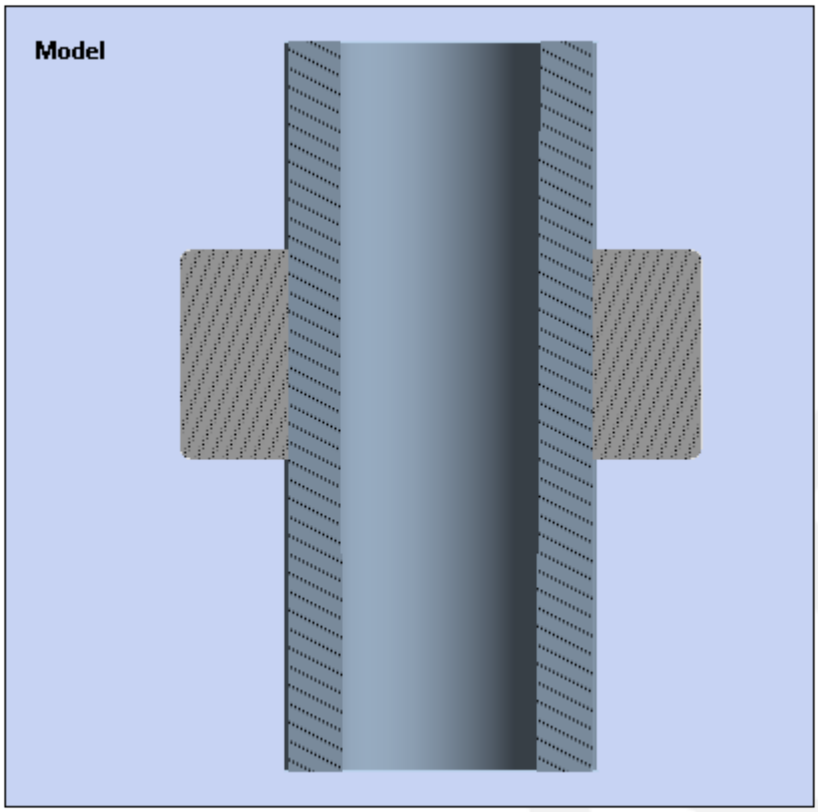


Show Capping Faces by Body Color

This selection works in tandem with the **Show Capping Faces** option. Selecting this option changes the color of the capped geometry surface to match the body color of the geometry.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

Certain objects that display geometry annotations may not correctly display capping. Examples include contact objects, joints, and objects displaying spatially varying loads.

Caution:

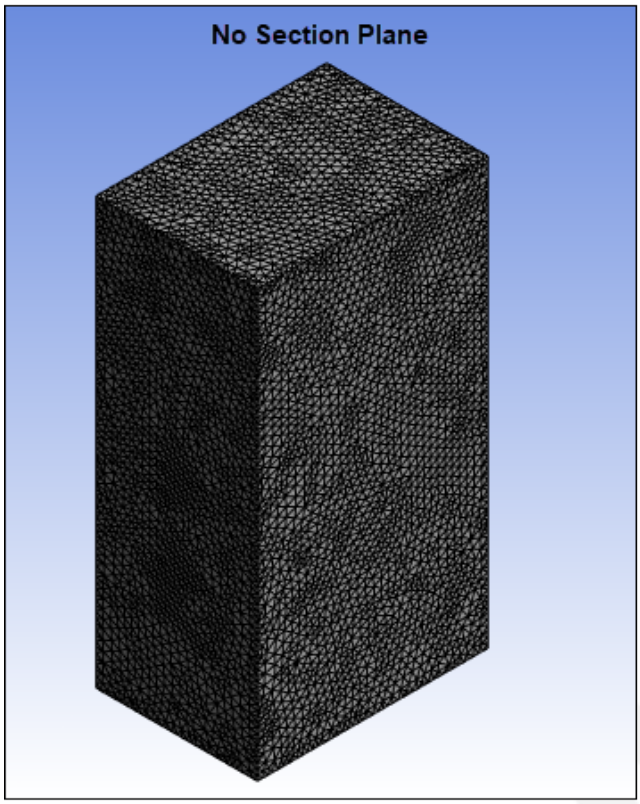
When using the **Section Planes** feature with shell bodies, make sure that the **Thick Shells and Beams** view option is turned on. Turning this view feature off changes the graphical display. The coloring for the top and bottom surfaces can degrade. So much so that the application could display both sides of a section plane simultaneously and as a result, the application could display inaccurate results.

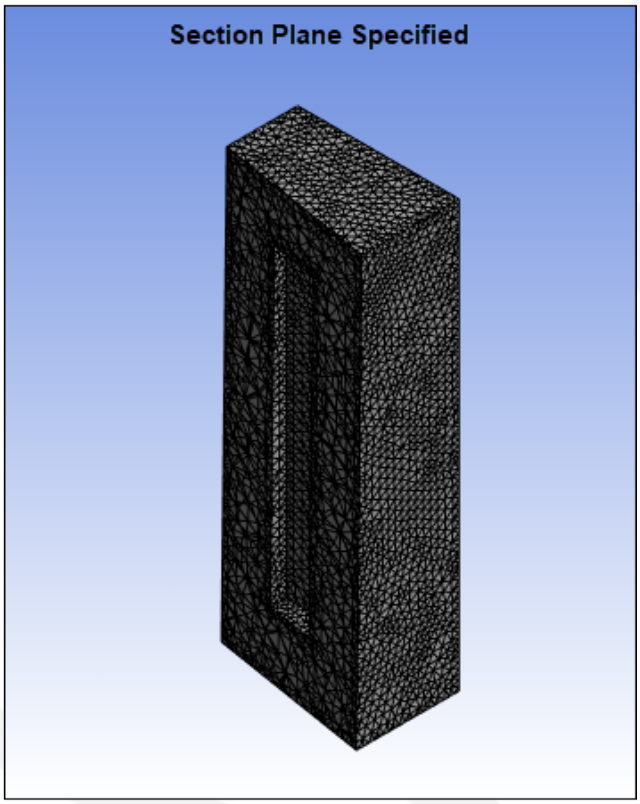
Selecting Mesh Entities Displayed by the Section Plane

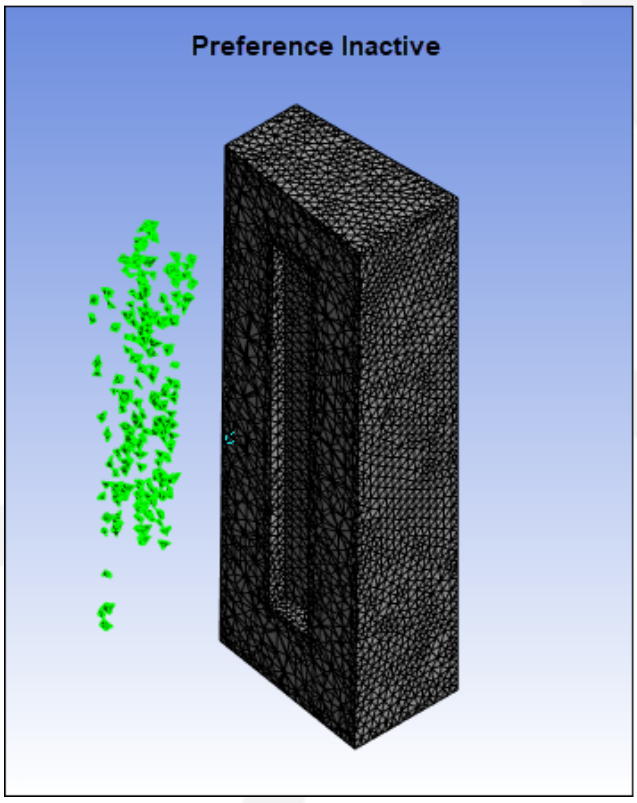
`

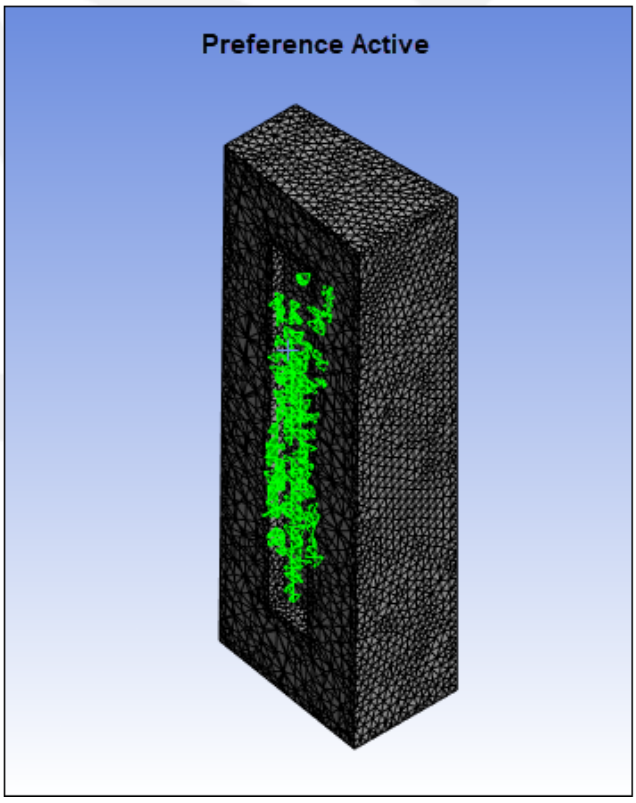
When you activate the Consider Section Planes When Mesh Picking (p. 228) preference, the application displays finite element entities (nodes, elements, and element faces) from geometries within the model that were not visible before adding the specified Section Plane. As illustrated below, in previous versions of the application, the application unexpectedly picked finite element entities on the hidden geometries (of the Section Plane). The application essentially did not recognize a Section Plane existed. This preference addresses the graphical selection limitation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23









Note:

This preference:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

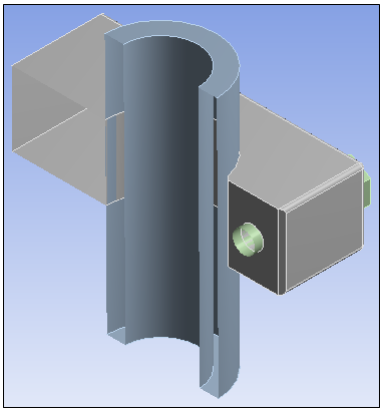
- Is supported for all active section planes.
- Does not support capped faces.
- Supports all selection modes: single, box, lasso and volume.
- Supports direct mesh selection on results.

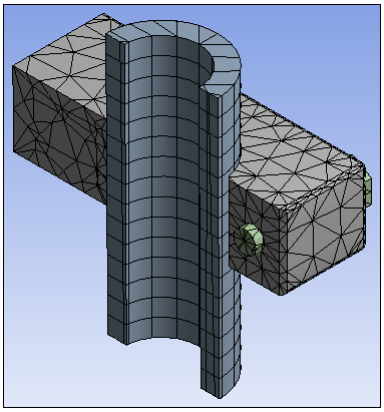
Understanding Section Plane Display Differences

The Section Plane acts differently depending if you are viewing a result, mesh, or geometry. When viewing a result or a mesh, the cut is performed by a software algorithm. When viewing geometry, the cut is performed using a hardware clipping method. This hardware clipping cuts away the model in a subtractive method. The software algorithm cuts away the model but always starts with the whole model. Examples of these methods are illustrated below.

Note:

The software algorithm always caps the surfaces created by the section plane as opposed to the hardware clipping method that may or may not cap the surface depending on the display options you have selected. See the Creating Section Planes (p. 294) section for the capping display options. When capping, the software algorithm creates a visible surface at the intersection of the object and the section plane.

Geometry Display	Mesh Display
	




In addition, and as illustrated in the examples below, **Section Planes** do not cut the orientation or element displays if you employ:

- Element Orientation (p. 1008) feature
- Element-based, element face-based, or node-based selections
- Named Sections scoped to elements, element faces, or nodes
- Hit Point selections

Working with Section Plane Results

View Options

When creating a Section Plane on a result, if the Section Plane feature is active, you can use the following options from the **Edges** drop-down menu on the Result Context Tab (p. 62):

- **Show Undeformed WireFrame**: displays the wireframe with the deformations added to the nodes. This is intended to help you interpret the image when you drag the anchor across smaller portions of the model.
- **Show Undeformed Model**: displays the portion of model behind the plane as a deformed gray scale image. In order to not clutter the graphics display in this situation, the application does **not** currently display undeformed bodies.

Deformation Scaling

When you create a Section Plane, the slice it creates is flat. If you create a Section Plane on a deformed shape and then change the scaling (p. 63) of the result, the Section Plane deforms accordingly and the plane may no longer be flat. Furthermore, if you select a different object in the tree and then return to the result that includes the Section Plane, the Section Plane re-plots as originally defined and creates new flat surface on the new deformation scale. As a result, the display of the result changes. This change can be significant.

Important:

When you are actively working with a **Section Plane**, the application disables back-face culling. Back-face culling is a computer graphics technique that discards polygons facing away from the camera and assumes the polygons to be occluded. Back-face culling is disabled to make sure that the application displays the cut section of the model correctly. Furthermore, this display necessity may cause color bleeding for coplanar polygons on shell models because the application draws both sides of the shell.

Viewing Annotations

Annotations provide the following visual information:

- Boundary of the scope region by coloring the geometry for edges, faces or vertices.
- An explicit vertex within the scope.
- A 3D arrow to indicate direction, if applicable.
- Text description or a value.
- A color cue (structural vs. thermal, etc.).

Note:

Custom annotations that you create using the Label (p. 308) feature remain visible even when you suppress the body.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

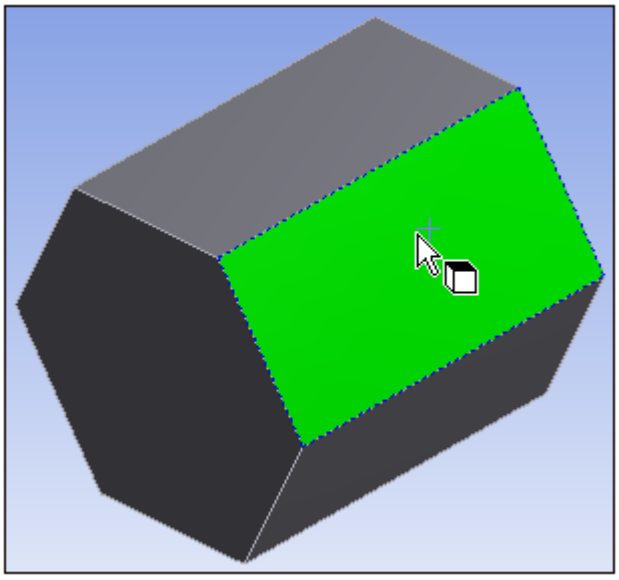
This section addresses the following types of annotations:

Highlight and Select Graphics (p. 307)
Scope Graphics (p. 307)
Annotation Graphics and Positioning (p. 308)
Annotations of Multiple Objects (p. 309)
Rescaling Annotations (p. 309)

In addition, you can also specify preferences for your annotations. For more information, see Specifying Annotation Preferences (p. 310).

Highlight and Select Graphics

You can interactively highlight and select topology, such as the face illustrated below. The topology selection highlights when you click it.



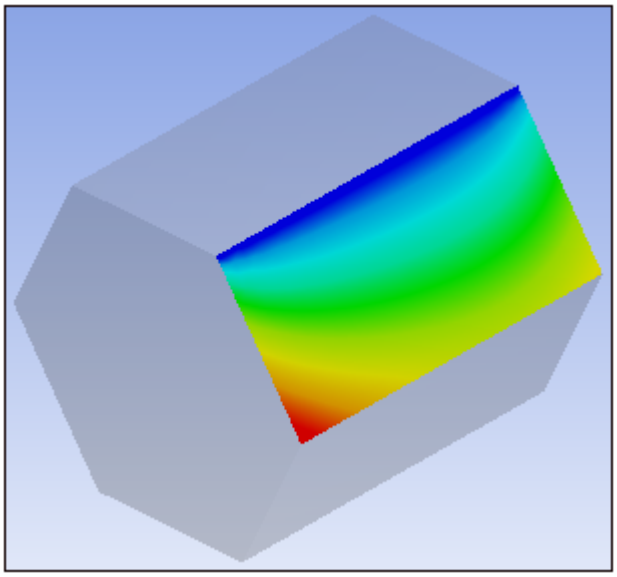
See Selecting Geometry (p. 258) for details on highlighting and selection.

Scope Graphics

In general, selecting an object in the Outline (p. 105) displays its Scope by painting the geometry and displays text annotations and symbols as appropriate. The display of scope via annotation is carried over into the Report Preview (p. 174) if you generate a figure.

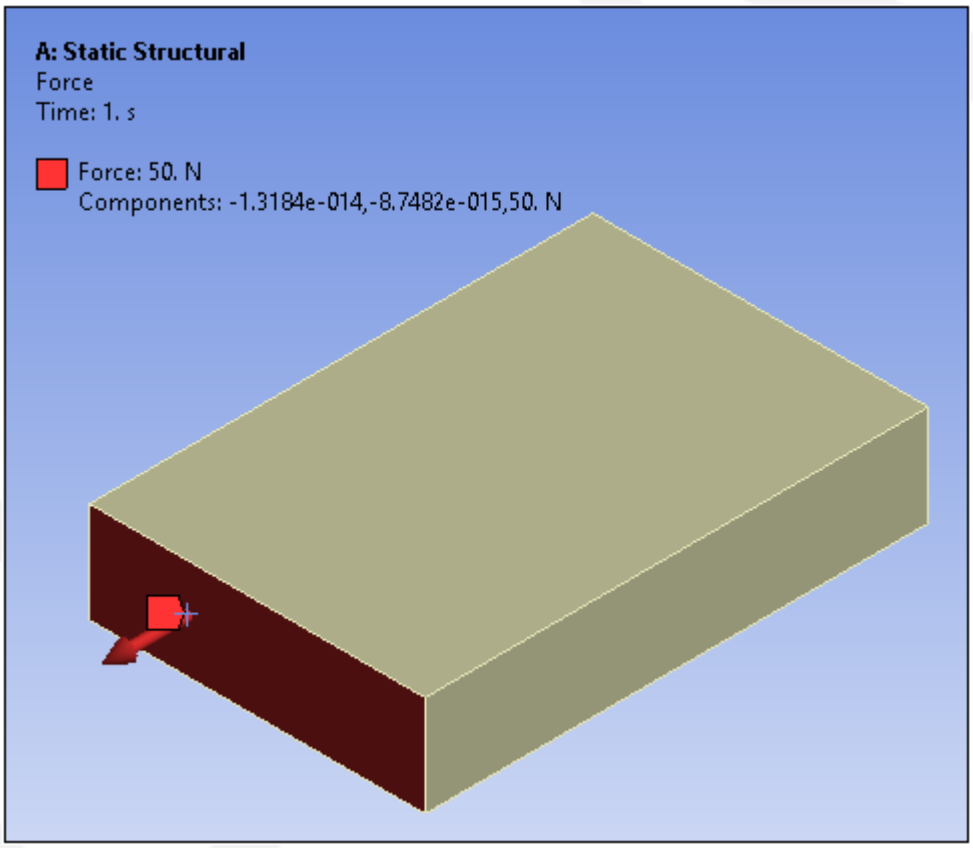
Contours are painted for results on the scoped geometry. No boundary is drawn.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Annotation Graphics and Positioning

A *label* consists of a block arrow cross-referenced to a color-coded legend. For vector annotations, a 3D arrow originates from the tip of the label to visualize direction relative to the geometry.



Use the pointer after selecting the **Label** option on the Graphics Toolbar (p. 97) for managing annotations and to drag the annotation to a different location within the scoping.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

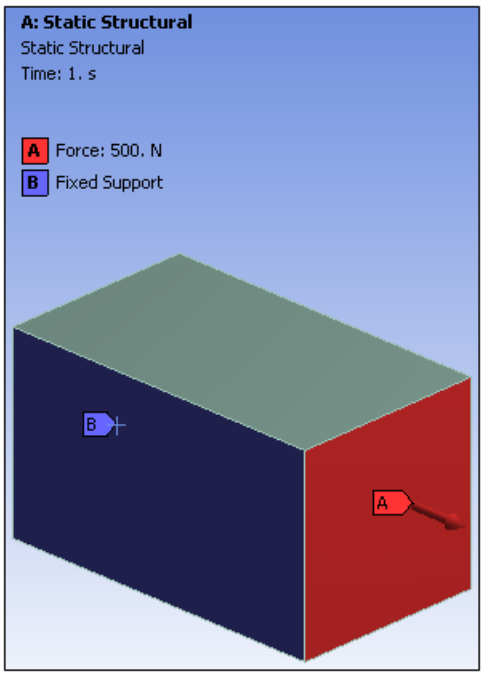
- If other geometry hides the 3D point, for example, the point lies on a back face, the block arrow is unfilled (transparent).
- The initial placement of an annotation is at the pick point. You can then move it by using the **Label** toolbar button for managing annotations.
- Drag the label to adjust the placement of an annotation. During the drag operation the annotation moves only if the tip lies within the scope. If the pointer moves outside the scope, the annotation stops at the boundary.

Annotations of Multiple Objects

When multiple individual objects or a folder (such as environment, contact, or named selections) are selected in the Outline (p. 105), an annotation for each one appears on the geometry. The default number of annotations shown is 10, but you can change it to any value from 0 to 50 using the **Max Number of Annotations to Show** property in the **Graphics** options (p. 228) of the **Options** dialog. For more information, see the Annotations (p. 79) topic in the *Selection Tab* section.

Note:

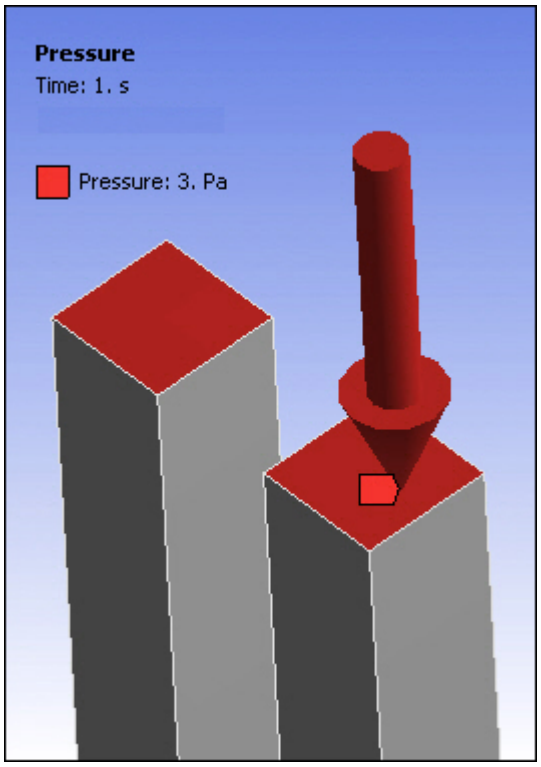
If you have a large number of objects, you may want to display each object as a different color. See the **Random** option of the Annotations (p. 79) group.

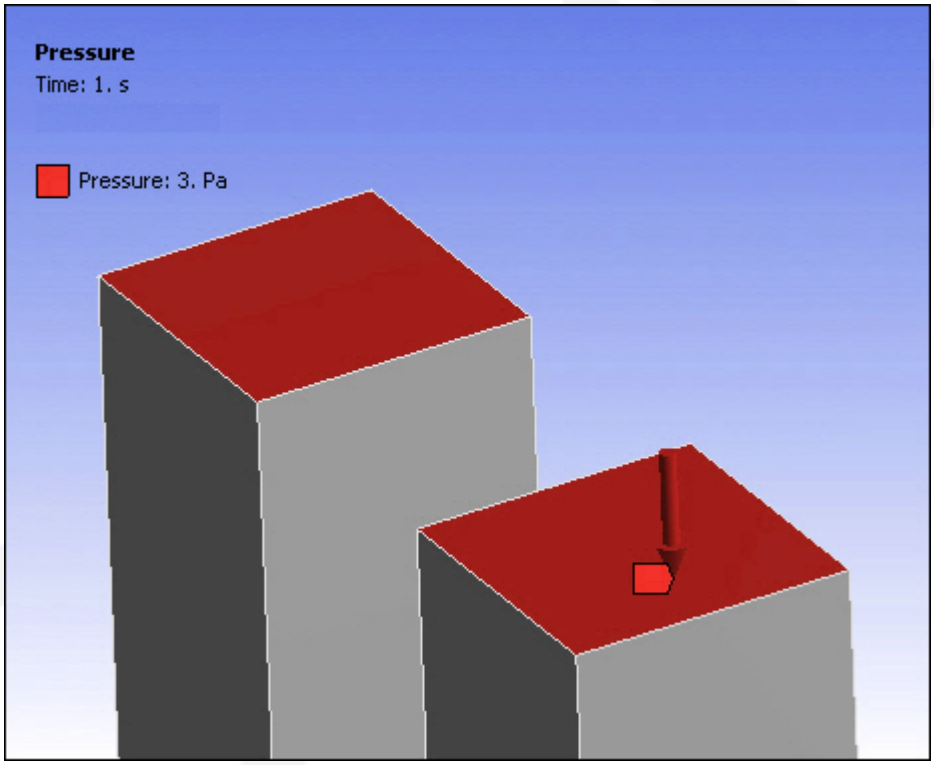


Rescaling Annotations

This feature modifies the size of annotation symbols, such as load direction arrows, displayed in the Mechanical application. For example, and as illustrated below, you can reduce the size of the pressure direction arrow when zooming in on a geometry selection. To change the size of an annotation, select the **Rescale** option in the **Annotation** group (p. 79) on the **Display** tab.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23





Specifying Annotation Preferences

The **Annotation Preferences** dialog box controls the visibility of all annotations, such as custom annotations and annotation labels, annotations on objects such as cracks, point masses, and springs.

To set your annotation preferences:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

1. Click the **Preferences** option in the **Annotation** (p. 79) group on the **Display** tab.

   The **Annotation Preferences** dialog box appears. By default, all annotations are selected, and thus set to visible.

2. Under **Basic Annotations**, select or clear the check boxes for the following options:

   - **View Annotations**: Toggles the visibility of annotations in the Geometry window.
   - **View User Defined Graphics Annotations**: Toggles the visibility of custom user annotation in the Geometry window.
   - **View Annotation Labels**: Toggles the visibility of annotation labels (p. 308) in the Geometry window.

3. Under **Remote Boundary Conditions**, select or clear the check boxes for the following options:

   - **Point Masses**: Toggles the visibility of annotations for point masses.
   - **Springs**: Toggles the visibility of annotations for springs.
   - **Beam Connections**: Toggles the visibility of annotations for beam connections.
   - **Bearings**: Toggles the visibility of annotations for bearings.

   Note:

   The size range for Point Masses and Springs is from 0.2-2 (Small-0.2, Default-1, Large-2).

4. Under **Remote Boundary Conditions**, slide the indicator to specify the size of the annotations for **Point Masses** and **Springs**.

5. Under **Additional Display Preferences**, select or clear the check boxes for the following options:

   - **Crack Annotations**: Toggles the visibility of annotations on crack objects.
   - **Individual Force Arrows on Surface Reactions**: Toggles the visibility of individual force arrows on surface reactions.
   - **Body Scoping Annotations**: Toggles the visibility of annotations on body scoping.

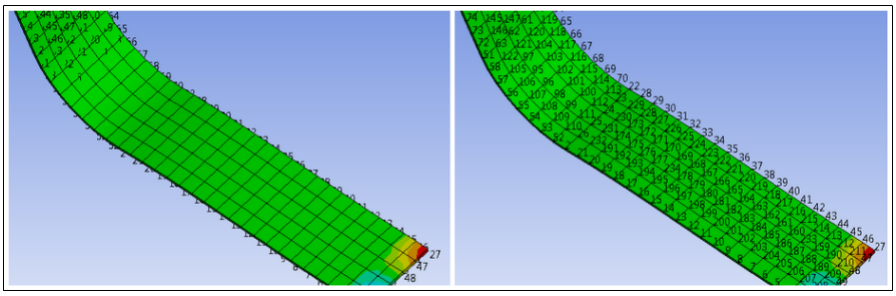
6. Under **Mesh Display**, select or clear the check boxes for the following options:

   - **Mesh Annotations**: Toggles the visibility of mesh node and mesh element annotations in Named Selection displays.
   - **Node Numbers**: Toggles the visibility of mesh node numbers in Named Selection, Mesh, and Result displays. This selection also provides options to specify a numerical range of which nodes to display. For example, display the nodes **1** (**Min**) through **200** (**Max**). An increment (**Inc**) property enables you to further define the range so that it selects

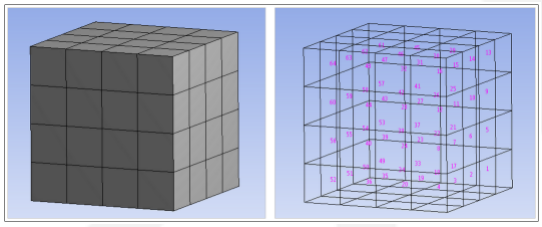
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

only every *N*th value (for example, every 5th node). The default Minimum value is **1** and the default Maximum value is **100000**.

Depending upon the number of nodes that you are displaying as well as how you have positioned your model in the Geometry window, **Node Numbers** may not fully display, as illustrated below. The **Rescale Annotation** option, available in the Graphics Toolbar (p. 97), adjusts the size of annotation symbols, as such, this option may improve the display issue.



- **Element Numbers**: Toggles the visibility of mesh element numbers in Named Selection, Mesh, and Result displays. This selection also provides options to specify a numerical range of which elements to display. Because Element Numbers are displayed at the centroid of the elements, Wireframe mode is required to properly display all Element Numbers.



- **Plot Elements Attached to Named Selections**: Toggles the visibility of elements for all items in the Named Selections group. For nodal Named Selections, this option shows the full elements, while for face or body Named Selections this option shows just the element faces. This option does not affect Line Bodies. You must have the **Show Mesh** button toggled off to see the elements in the Named Selection.

7. When you are finished specifying your annotation preferences, click **Apply Changes** to apply your preferences and leave the dialog box open, or click **OK** to apply and close.

Controlling Lighting

The **Details** view properties of the Model object provide lighting controls that affect the display in the **Geometry** window.

Note:

The application saves **Lighting** property settings with your analysis. Lighting changes propagate throughout the features of the application and are used when you export images.

Inserting Comments, Images, and Figures

You can insert Comment objects, Image objects, or Figure objects under various parent objects in the Mechanical tree to add text or graphical information that pertain specifically to those parent objects. Refer to their individual objects reference pages for descriptions. The use of a **Comment** and/or an **Image**, is essentially intuitive. However, for the **Image Plane from File** and the **Figure** options, there are additional capabilities and characteristics, as discussed below.

Image Plane

The **Image Plane from File** option enables you to import an image into Mechanical and place it on or around you model based on a coordinate system setting. The option is primarily used with the Construction Line (p. 895) feature to overlay and accurately sketch one or more line segments. However, you can use it any way you want. For example, you can place logos on your model, specify a background, set up physical rulers to help measure deformations. You may also wish to use it with an ACT extensions to generate images or 2D graphics that you can then programmatically/automatically render when you import a model into Mechanical.

Figure

Figures allow you to:

- Preserve different ways of viewing an object (viewpoints and settings).
- Define illustrations and captions for a report.
- Capture result contours, mesh previews, environment annotations etc., for later display in Report (p. 174).

Clicking the **Figure** button in the Home Tab (p. 40) creates a new **Figure** object inside the selected object in the Outline (p. 105). Any object that displays 3D graphics may contain figures. The new figure object copies all current view settings, including those defined in the Options (p. 217), such as the **Font Magnification Factor**, and gets focus in the **Outline** automatically.

View settings maintained by a figure include:

- Camera settings
- Result settings
- Legend configuration

A figure's view settings are fully independent from the global view settings. Global view settings are maintained independently of figures.

Figure Behaviors

- If you select a figure after selecting its parent in the Outline, the Geometry window transforms to the figure's stored view settings automatically (e.g. the graphics may automatically pan/zoom/rotate).
- If you change the view while a figure is selected in the Outline, the figure's view settings are updated.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- If you reselect the figure's parent in the Outline, the Geometry window resumes the global view settings. That is, figure view settings override but do not change global view settings.
- Figures always display the data of their parent object. For example, following a geometry Update and Solve, a result and its figures display different information but reuse the existing view and graphics options. Figures may be moved or copied among objects in the Outline to display different information from the same view with the same settings.
- You may delete a figure without affecting its parent object. Deleting a parent object deletes all figures (and other children).
- In the Outline (p. 105), the name of a figure defaults to simply **Figure** appended by a number as needed.
- You may enter a caption for a figure as a string in the figure's details. It is your responsibility to maintain custom captions when copying figures.
- For a result object that includes one or more **Figure** objects, if you clear (**Clear Generated Data** option) the parent object's data or re-solve the analysis, the application also clears any result settings of the child **Figure** objects. The application does maintain Camera settings and legend configurations, as noted above, such as the last viewing setting.

Hotkeys and Keyboard Shortcuts

Mechanical supports a variety of hotkeys and hotkey combinations that enable you to quickly execute actions. For example, the popular hotkey "N" is used to create Named Selections once you select a geometric or mesh entity.

Hotkey and keyboard actions are described in the following topics:

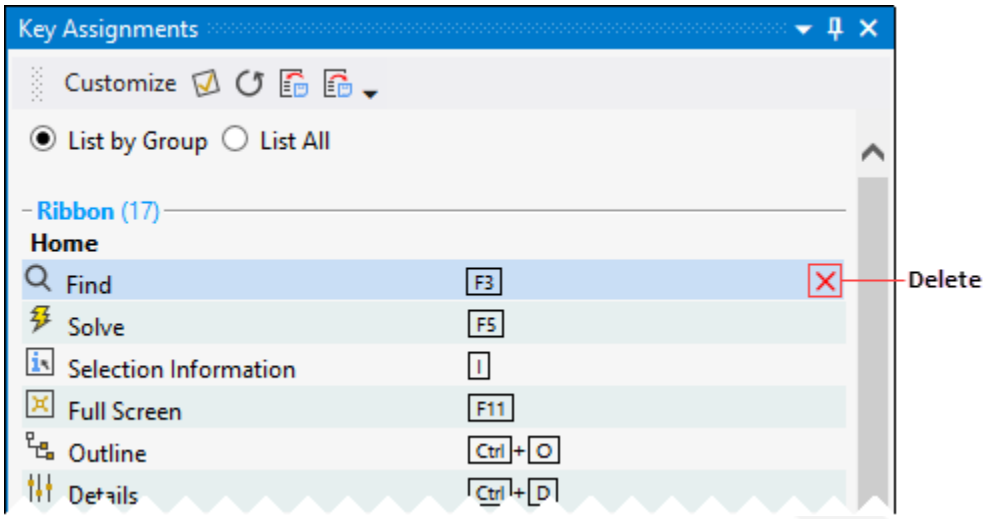
- Key Assignment Pane (p. 314)
- Ribbon Shortcuts (p. 315)
- Hotkeys and Hotkey Combination Descriptions (p. 316)
- Keyboard Number Pad Shortcuts (p. 320)

Key Assignment Pane

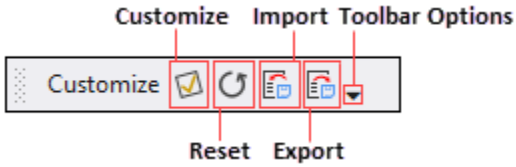
You use the **Key Assignments** pane, illustrated below, to view application assigned hotkeys. The option to display this window is available in the **Tools** (p. 45) group of the **Home** tab. Hotkeys are listed either by groups or you can list all available key assignments.

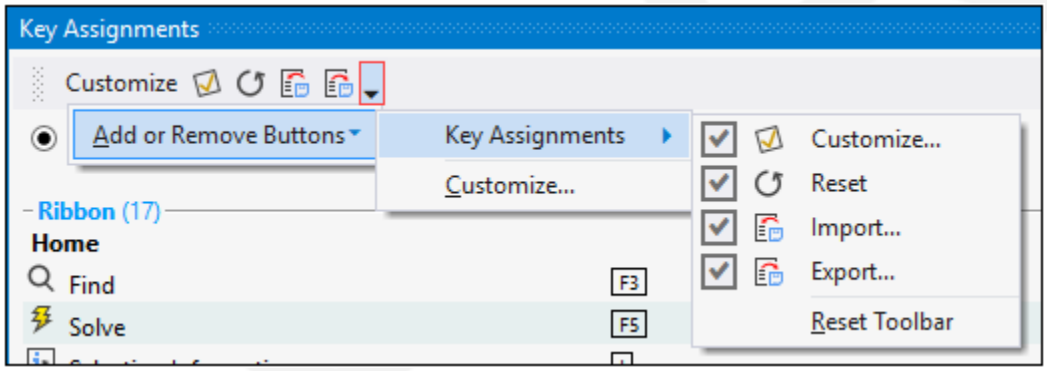
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



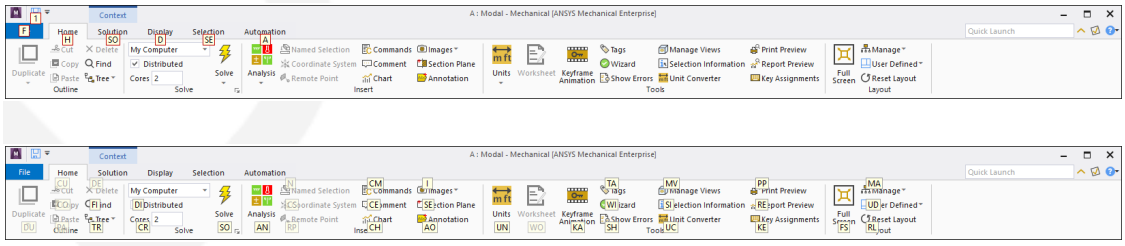
This window also provides a toolbar that includes 1) an option that opens the **Customize** (p. 143) dialog that enables you to modify hotkeys, 2) a reset option, 3) options to Import and Export user-defined key assignments, 4) a drop-down menu you can use to display or hide default options.





Ribbon Shortcuts

In addition to the options of the **Key Assignments** window, selecting the **[Alt]** key displays keyboard selection options. As illustrated below, when you select the **[Alt]** key, letters for each tab display. When you select one of these letters, additional options also display for the given tab.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Hotkeys and Hotkey Combination Descriptions

Application default hotkeys and their actions are described below.

Selection Filters

Ctrl+**P**: Activate **Vertex** selection.

Ctrl+**E**: Activate **Edge** selection.

Ctrl+**F**: Activate **Face** selection.

Ctrl+**B**: Activate **Body** selection.

Ctrl+**M**: Activate option to merge virtual topologies. Perform this key combination once you have selected one or more edges in order to merge adjacent faces into one or more virtual face(s) or select one or more faces to merge the faces into one or more virtual face(s).

Ctrl+**N**: Activate **Node** selection.

Ctrl+**K**: Activate **Element Face** selection.

Graphical Actions

G: When the **Geometry** window has focus, this key displays the content of the Graph (p. 194) window in the **Geometry** window. This feature is also available from the Graphics Toolbar (p. 97) and a context (right-click) menu.

H: When the **Geometry** window has focus, and you have modified the view of your model, for example, examining a part up-close, this key returns the view to the application default, Isometric View.

I: When the **Geometry** window has focus, this key toggles the display of the Selection Information (p. 180) Window on/off.

K: Create a local probe at the largest result value.

L: Create a local probe at the smallest result value.

M: When the **Geometry** window has focus, this key opens the Select Mesh By ID (p. 279) dialog box.

N: When the **Geometry** window has focus, this key opens the Named Selection (p. 1057) dialog window, enabling you to create a named Selection for the selected geometric or mesh entity.

Z: When the **Geometry** window has focus, this key zooms in on the selected entity (body, face, edge, vertex). If no geometric entity is selected in the **Geometry** window, this key acts the same as the **F7** (Zoom to Fit) option.

Ctrl+**A**: Selects all entities based on the active selection filter (bodies, faces, edges, vertices, nodes).

Ctrl+**C**: Copy the content of the graphics window into the clipboard. The content is available to paste (**Ctrl** + **V**) into a compatible application. Default image resolution settings can be changed using the **Graphics Resolution** option under the **Graphics** (p. 228) preference.

Ctrl+**D**: Display/hide the Details pane.

F4: This key enables you to move a vertex or a node to a new location. When you are using the Node Move feature, hold this key to reposition the desired node if you want to relax the node and move the node away from the geometry it is associated with.

F6: Toggle between the **Shaded Exterior and Edges**, **Shaded Exterior**, and **Wireframe** views.

F7: Executes the **Zoom to Fit** option (also available on the Graphics Toolbar (p. 97)).

F8: Hide selected faces.

F9: Hide selected bodies in **Geometry** window and hide/show selected bodies from the tree view.

F10: Maximize/Minimize the Ribbon.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Ctrl+**L**: Activate **Element** selection.

Ctrl+**Q**: This option adds your current clipboard (p. 104) geometry or mesh selection to the existing geometry or mesh selection(s).

Ctrl+**R**: This option clears all clipboard (p. 104) selections

Ctrl+**W**: This option removes your current clipboard (p. 104) geometry or mesh selection from the existing geometry or mesh selection(s).

Shift+**F1**: Activate **Extend to Adjacent** selection.

Shift+**F2**: Activate **Extend to Limits** selection.

Shift+**F3**: Activate

F11: When the **Geometry** window has focus, this key toggles the full screen display on/off.

Shift+**F8**: Show Hidden Face(s).

Ctrl+**F9**: Hide all other bodies.

Shift+**F9**: Show all bodies.

Arrow Keys: Pan your model in the Geometry (p. 129) window. The window needs to be the active interface element.

Ctrl+**Arrow Keys**: Rotate the model about the vertical or horizontal axis of the model's orientation in the **Geometry** window.

Shift+**[1]**: Turn the **Anti-Aliasing (MSAA)** preference **Off**.

Shift+**[2]**: Set the **Anti-Aliasing (MSAA)** preference to **Low (2x)**.

Shift+**[3]**: Set the **Anti-Aliasing (MSAA)** preference to **Medium (4x)**.

Shift+**[4]**: Set the **Anti-Aliasing (MSAA)** preference to **High (8x)** (default).

Shift+**W**: Increases the number of layers displayed on a mesh that includes poor quality elements. See the Check Mesh Quality section for more information.

Shift+**S**: Decreases the number of layers displayed on a mesh that includes poor quality elements. See the Check Mesh Quality section for more information.

Outline Pane Actions

These hotkeys require an object in the Outline pane to be selected or that the pane has focus:

F1: Open the Mechanical User's Guide to a section associated with the selected object.

F2: Rename a selected object.

F3: Open the search (Find In Tree) dialog box.

Ctrl+**G**: Group objects.

Shift+**Ctrl**+**G**: Ungroup objects.

Ctrl+**O**: Display/hide the Outline pane.

Ctrl+**S**: Save the project.

Solution/Retrieve Results

The **F5** key starts the solution process for a selected Environment or if you have an object selected in the tree that is above all of the properly defined environments, then all branches will be solved. This action is also available when the **Graphics** window has focus.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Extend to Connection selection.

Shift+**F4**: Activate **Extend to Instances** selection.

Ctrl+**U**: Retrieve current result data when you are using Result Plot Trackers.

Go To Options

Ctrl+**1**: Highlight the corresponding Bodies in tree.

Ctrl+**2**. Highlight the contacts for the selected bodies.

Ctrl+**3**: Highlight the contacts common to the selected Bodies

Ctrl+**4**: Highlight the corresponding Named Selections object in the tree.

Ctrl+**5**: Highlight all Named Selections common the to given Named Selection.

Ctrl+**6**: Highlight the Mesh Controls in the tree that are associated with the selected bodies.

DRAFT

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Animation Actions

The following hotkeys are available for the animation feature when the **Geometry** window has focus.

P: Plays and pauses the animation.

S: Stops the animation.

Shift+**Right/Left Arrow Key**: Reverse or advance the animation frame by frame.

Note:

For the **Standard Animation (SA)** setting, you can abort the animation creation process using the **ESC** key.

Use a Macro

Ctrl+**F7**: Display a Open dialog to

DRAFT

select and then run a macro file.

Note:

When you place your cursor within the **Geometry** window, and given a generated mesh, and the **Node** or **Element** selection option is active, holding the right mouse button and then clicking the left mouse button scrolls through the available **Select Mode** options (single section, box selection, box volume, lasso, lasso volume).

Keyboard Number Pad Shortcuts

Certain display functionalities are also available via the number pad on your keyboard provided the **NumLock** key is enabled. The numbers correlate to the following functionality:

0 = View Isometric

1 = +Z Front

2 = -Y Bottom

3 =+X Right

4 = Previous View

5 = Default Isometric

6 = Next View

7 = -X Left

8 = +Y Top

9 = -Z Back

. (dot) = Set Isometric

7 -X Left	8 +Y Top	9 -Z Back
4 ← Previous	5 Default Isometric	6 Next →
1 +Z Front	2 -Y Bottom	3 +X Right
0 View Isometric		. Set Isometric

Wizards

Wizards provide a layer of assistance above the standard user interface. They are made up of tasks or steps that help you interpret and work with simulations. Conceptually, the wizards act as an agent between you and the standard user interface.

Wizards include the following features:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- An interactive checklist for accomplishing a specific goal
- A reality check of the current simulation
- A list of a variety of high-level tasks, and guidance in performing the tasks
- Links to useful resources
- A series of Callout windows which provide guidance for each step

Note:

Callouts close automatically, or you may click inside a Callout to close it.

Wizards use hyperlinks (versus command buttons) because they generally represent links to locations within the standard user interface, to content in the help system, or to a location accessible by a standard HTML hyperlink. The status of each step is taken in context of the currently selected Outline (p. 105) object. Status is continually refreshed based on the Outline state (not on an internal wizard state). As a result you may:

- Freely move about the Outline (p. 105) (including between branches).
- Make arbitrary edits without going through the wizards.
- Show or hide the wizards at any time.

Wizards are docked to the right side of the standard user interface for two reasons:

- The Outline (p. 105) sets the context for status determination. That is, the wizards interpret the Outline rather than control it. (The user interface uses a top-down left-right convention for expressing dependencies.)
- Visual symmetry is maintained.

To close wizards, click the ×. To show/hide tasks or steps, click the section header. Options for wizards are set in the Wizard (p. 243) section of the **Options** dialog box (p. 217) under the Mechanical application.

The Mechanical Wizard (p. 321) is available for your use in the Mechanical application.

Mechanical Wizard

Display the Mechanical Wizard by selecting the wizard button in the **Tools** (p. 45) group on the **Home** (p. 40) tab. You can close the wizard at any time by clicking the close button at the top of the panel. To show or hide the sections of steps in the wizard, click the section header.

Note:

The Mechanical Wizard is not supported on the Linux platform.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Features of the Mechanical Wizard

The Mechanical Wizard works like a web page consisting of collapsible groups and tasks. Click a group title to expand or collapse the group; click a task to activate the task.

When activated, a task navigates to a particular location in the user interface and displays a callout with a message about the status of the task and information on how to proceed. Activating a task may change your tab selection, cursor mode, and Outline (p. 105) selection as needed to set the proper context for proceeding with the task.

You may freely click tasks to explore the Mechanical application. Standard tasks WILL NOT change any information in your simulation.

Callouts close automatically based on your actions in the software. Click inside a callout to close it manually.

Most tasks indicate a status via the icon to the left of the task name. Rest your mouse on a task for a description of the status. Each task updates its status and behavior based on the current Outline (p. 105) selection and software status.

Tasks are *optional*. If you already know how to perform an operation, you don't need to activate the task.

Click the **Choose Wizard** task at the top of the Mechanical Wizard to change the wizard goal. For example, you may change the goal from **Find safety factors** to **Find fatigue life**. Changing the wizard goal *does not* modify your simulation.

At your discretion, simulations may include any available feature not covered under **Required Steps** for a wizard. The Mechanical Wizard does not restrict your use of the Mechanical application.

You may use the Mechanical Wizard with databases from previous versions of the Mechanical application.

Types of the Mechanical Wizards

There are wizards that guide you through the following simulations:

- Safety factors, stresses and deformation
- Fatigue life and safety factor
- Natural frequencies and mode shapes
- Optimizing the shape of a part
- Heat transfer and temperatures
- Magnetostatic results
- Contact region type and formulation

Steps for Using the Mechanical Application

This section describes the overall workflow involved when performing any analysis in the Mechanical application. The following workflow steps are described:

- Create Analysis System
- Define Materials
- Attach Geometry/Mesh
- Define Part Behavior
- Create a Simulation Template
- Create a Geometry in Mechanical
- Define Substructures
- Define Connections
- Apply Mesh Controls and Preview Mesh
- Establish Analysis Settings
- Define Initial Conditions
- Apply Pre-Stress Effects for Implicit Analysis
- Apply Loads and Supports
- Perform Solution
- Review Results
- Create Report (optional)

Create Analysis System

There are multiple ways to open Ansys Mechanical and specify a desired analysis system.

Important

Unit System Behavior: Whenever you open a project from a previous session, the unit system specified in that session automatically becomes the active system in the new Mechanical session. A good habit is to verify the active unit system whenever you open a project.

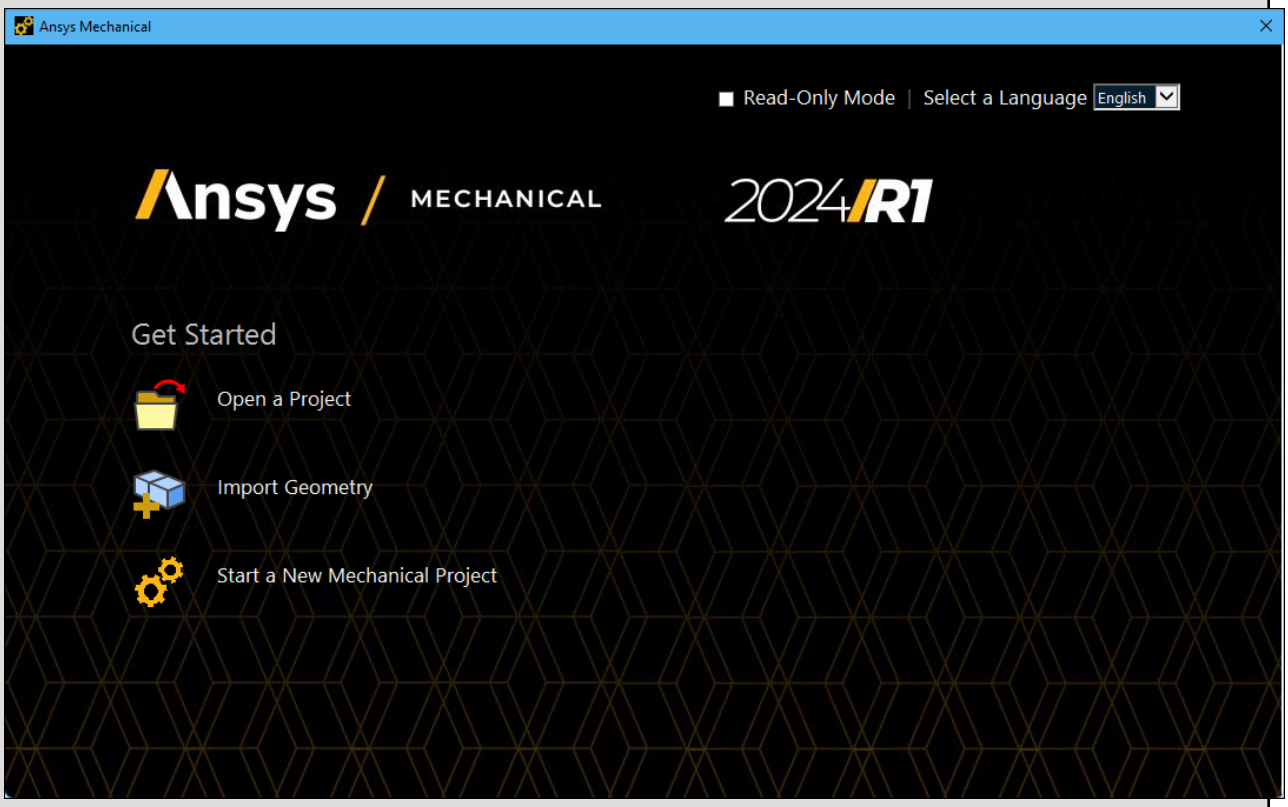
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Opening Mechanical from the Start Menu

To open Mechanical independently of Workbench and create an analysis system from within the application:

1. Open the **Ansys 2024 R1** menu of the **Start Menu** and select **Mechanical 2024 R1**.

2. Open an existing project, import a geometry, or open a new Mechanical project without a geometry. Supported project file types include `*.mechdb`, `*.mechpz`, `*.dsdb`, and `*.mechdat`. When opening Mechanical independently, `*.mechdb` is the default file type and `*.mechpz` is the archived file for this type.



Note:

The above dialog is the first instance of the pane for a newly installed version of the application. The color scheme of this dialog can be changed using the Options (p. 217) dialog preferences of the Style (p. 244) category of the **UI Options** group, you can change the color theme, from Dark to Light, or Classic.

3. If you do not open an existing project, select a desired analysis type from the **Analysis** drop-down menu of the Home (p. 42) Context tab (**Insert** group) for your new project.

Important:

Following a new installation of the product, if you open Mechanical independently, preferences from your previous installation are not automatically migrated. More im-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

portantly, when you subsequently open the Workbench application, preferences from your previous installation are automatically migrated. As a result, the application overwrites any options or preferences that you applied when previously opening Mechanical independently.

Opening Mechanical from Ansys Workbench

See the Working Through a System section of the Workbench User's Guide for the steps and background to create an analysis system in Workbench and open Mechanical. That section outlines the necessary workflow and supported analysis types.

Geometry Not Required

When configuring your analysis in Workbench, it is not necessary that you include geometry. You can simply skip the step of specifying a geometry and open Mechanical by double-clicking a supported cell, such as the **Model** cell, or right-clicking on a supported cell and selecting the **Edit** option. This can be done to create a template (p. 346) for use with multiple geometries.

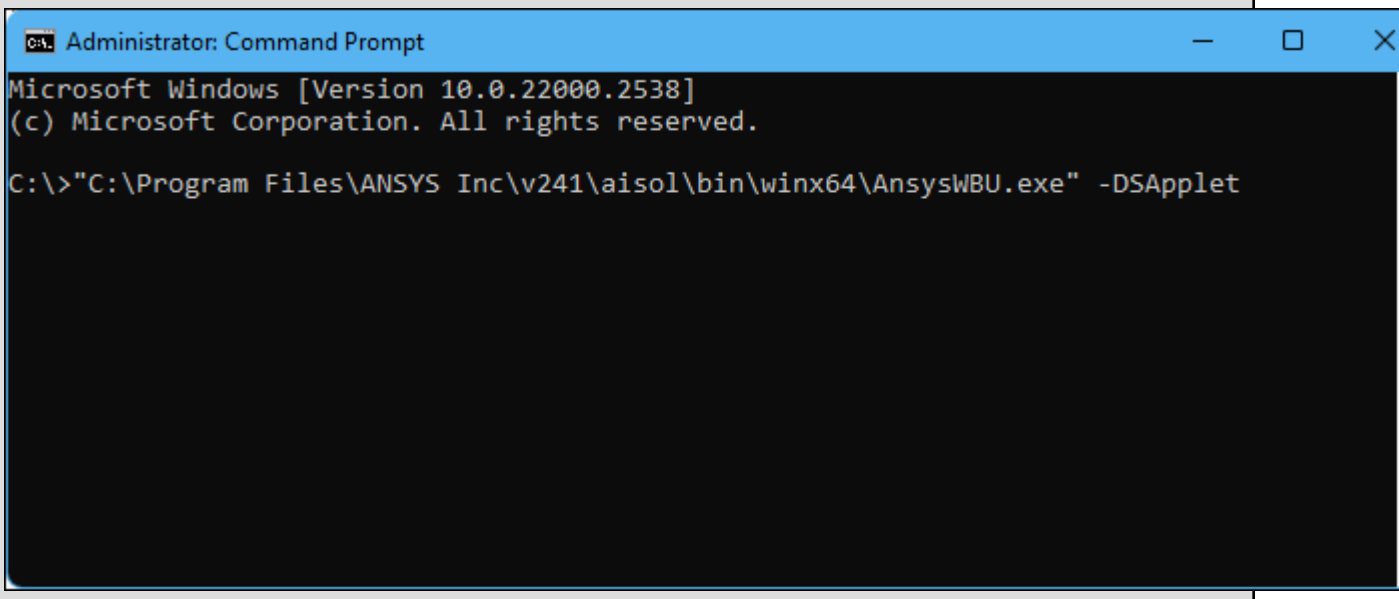
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Opening Mechanical from the Command Line on Windows

1. Open the **Command Prompt** window from the Windows **Start** menu.

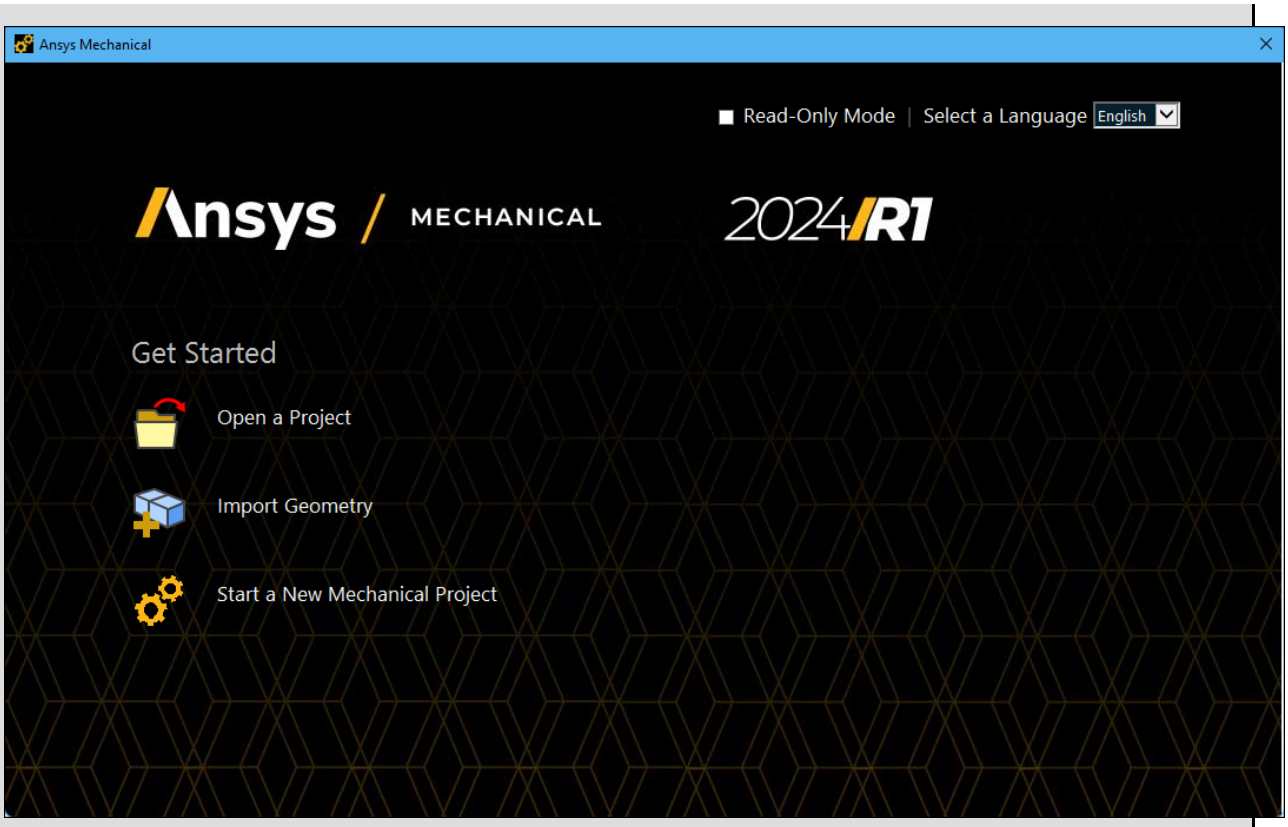
2. Enter (copy and paste) the following in the **Command Prompt** pane and press Enter to run the command. The example command has a file path of a typical installation location. Change the details of the file path to the specifics of your installation directory and add arguments as desired.

```
"C:\Program Files\ANSYS Inc\v241\aisol\bin\winx64\AnsysWBU.exe" -DSApplet
```



3. Open an existing project, import a geometry, or open a new Mechanical project without a geometry. Supported project file types include `*.mechdb`, `*.mechpz`, `*.dsdb`, and `*.mechdat`. When opening Mechanical independently, `*.mechdb` is the default file type and `*.mechpz` is the archived file for this type.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Note:

- Standalone supports the following project file types: `*.mechdb`, `*.dsdb`, and `*.mechdat`. The `*.mechdb` file type is new and unique to the standalone application.
- Once you select an option, this window disappears.

4. If you do not open an existing project, select a desired analysis type from the **Analysis** drop-down menu of the Home (p. 42) Context tab (**Insert** group) for your new project.

Command Line Arguments

Supported Command Line arguments include the following. These arguments are case **Insensitive**.

```
-AppModeMech                        to skip Start Page
-script "script_filename"           to run a script from a file
-file "filename"                    to open a Mechanical database or import a geometry file (see examples)
-b                                  to run script in batch mode
-x                                  to run script with auto exit
-ScriptArgs                         to pass arguments from the Command Prompt to the script
-readonly                           to open Mechanical in read-only mode
-language fr                        to specify the displaying language as French. Similarly, set it to en-us fo
                                        ja for Japanese (Windows platform only), and zh for Chinese (Windows pl

```

Opening Mechanical from the Command on Linux

Execute the following command in terminal from home directory to launch a Linux session:

```
./ansys_inc/v241/aisol/.workbench -DSApplet
```

Define Materials

Go to a section topic:

- Define Materials (p. 328)
- Overview of Part Behavior Based on Material Properties (p. 328)
- Material Dependent Damping Definition (Engineering Data and Mechanical) (p. 329)

Define Materials

You must use the Engineering Data Workspace to define and modify material properties as well as import material libraries. Typically, you access this workspace from the **Engineering Data** cell of a Mechanical analysis system included in the Project Schematic of Workbench.

Import Materials

For the Windows platform, when you open Mechanical, either from Workbench or independently, you can import materials or material libraries that are available in Engineering Data using the Assignment (p. 345) property of part and body objects.

In addition, when you open Mechanical independently, the Materials object provides the context (right-click) menu option **Import Materials** that enables you to import material files in `.xml` format.

Note:

Any changes you make to the local material libraries in Engineering Data, including material property changes, library additions, etc., will be reflected in Mechanical, whether opened through Workbench or independently once you have closed and reopened the applications.

Overview of Part Behavior Based on Material Properties

A part's response is determined by the material properties assigned to the part.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Depending on the application, material properties can be linear or nonlinear, as well as temperature-dependent.
- *Linear* material properties can be constant or temperature-dependent, and isotropic or orthotropic.
- Nonlinear material properties are usually tabular data, such as plasticity data (stress-strain curves for different hardening laws), Hyperelastic material data.
- To define temperature-dependent material properties, you must input data to define a property-versus-temperature graph.
- To define material-based damping properties, you must specify data in the Material Depending Damping property group. Mechanical supports material-based damping in addition to damping specified in the application. See below for a listing of the analysis types (p. 329) that support material-based damping.
- Although you can define material properties separately for each analysis, you have the option of adding your materials to a material library by using the **Engineering Data** tab. This enables quick access to and re-use of material data in multiple analyses.
- For all orthotropic material properties, by default, the Global Coordinate System is used when you apply properties to a part in the Mechanical application. If desired, you can also apply a local coordinate system (p. 1191) to the part.

Material Dependent Damping Definition (Engineering Data and Mechanical)

In the Engineering Data workspace, you can specify Material Depending Damping using the **Damping Ratio** and the **Constant Structural Damping Coefficient** properties.

These **Material Dependent Damping** properties have the same name as the properties in the Damping Controls (p. 1462) of Mechanical. The **Damping Ratio** property in Engineering Data generates the command **MP**,**DMPR**. In Mechanical, the **Damping Ratio** property generates the command **DMPRAT**. Similarly, the **Constant Structural Damping Coefficient** property defined in Engineering Data generates the command **MP**,**DMPS** and if defined in Mechanical, the property generates the command **DMPSTR**. The solver supports the use of these commands in combination or individually.

The following tables list the analysis types that support material-based damping defined in Engineering Data. Note that some analyses require specific settings or conditions in order to support material damping definitions. The Yes entries below indicate which command is written to the input file or whether both commands are written to the input file, based on certain settings/conditions.

	Modal (without Damping)	**Modal (Full Damped)**	**Modal (Reduced Damped)**
Damping Ratio (**MP**,**DMPR**)	Yes	No	No
Constant Structural Damping Coefficient (**MP**,**DMPS**)	No	Yes	Yes

	Harmonic Response (MSUP)	**Transient (MSUP)**
Damping Ratio (**MP**,**DMPR**)	Yes[a]	Yes[a]

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

	Harmonic Response (MSUP)	Transient (MSUP)
Constant Structural Damping Coefficient (**MP**,**DMPS**)	Yes[b]	Yes[b]

[a] This analysis type requires that you set the **Damped** property to **No** in the **Analysis Settings** of the upstream Modal Analysis. The **MP**,**DMPR** command is not sent again in the linked MSUP Harmonic/MSUP Transient analysis, as the application defines **Damping Ratio** (**MP**,**DMPR**) in the upstream Modal analysis. For a stand-alone MSUP Harmonic Response analysis, you define the **Damping Ratio** accordingly in the analysis.

[b] This analysis type requires that you set the **Damped** property to **Yes** in the **Analysis Settings** of the upstream Modal Analysis. The **MP**,**DMPS** command is not sent again in the linked MSUP Harmonic/MSUP Transient analysis, as the application defines the **Constant Structural Damping Coefficient** (**MP**,**DMPS**) in the upstream Modal analysis. For a stand-alone Full Harmonic Response analysis, you define the Constant Structural Damping Coefficient (MP,DMPS) accordingly in the analysis.

	Harmonic Response (Full)	Transient (Full)
Damping Ratio (**MP**,**DMPR**)	No	No
Constant Structural Damping Coefficient (**MP**,**DMPS**)	Yes[b]	Yes[b]

	Response Spectrum	Random Vibration
Damping Ratio (**MP**,**DMPR**)	Yes[a]	Yes[a]
Constant Structural Damping Coefficient (**MP**,**DMPS**)	No	No

[a] The application defines **Damping Ratio** (**MP**,**DMPR**) in the upstream Modal analysis. Therefore, there is no need redefine in this downstream analysis.

Attach Geometry/Mesh

There are several methods to open a geometry or mesh in the Mechanical application. Generally, you specify your geometry when you specify your analysis system on the Workbench **Project Schematic**. However, Mechanical also enables you to open the application *without* first specifying a geometry.

The following sections describe geometry and mesh import options as well as CAD related options and terminology:

Importing Geometry or Mesh from Workbench

Importing Geometries or Mesh from Mechanical

Updating Geometry from Within the Mechanical Application

CAD Interface Terminology

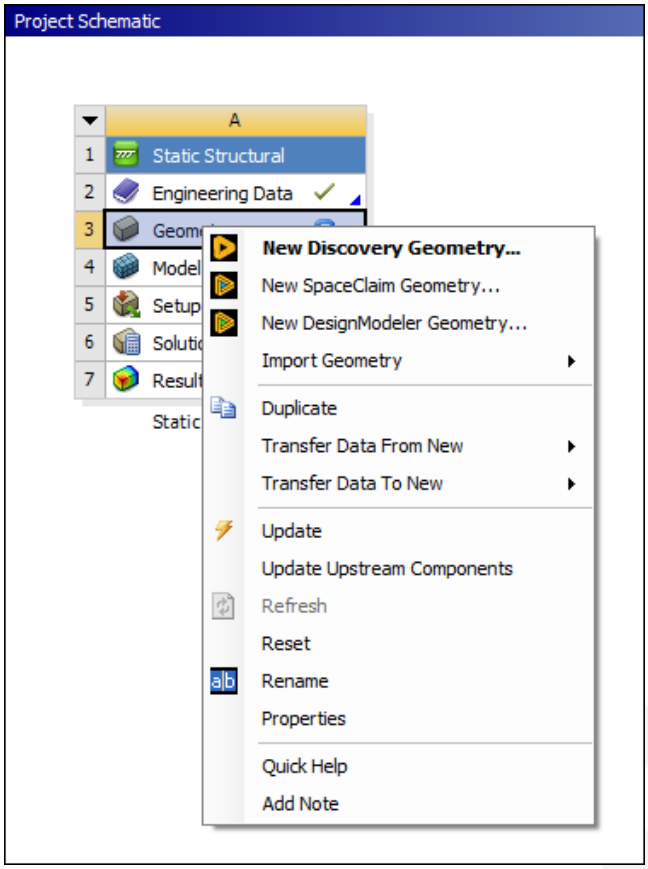
Importing Geometry or Mesh from Workbench

From Workbench, you open a geometry or mesh file as illustrated here:

Importing Geometry

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

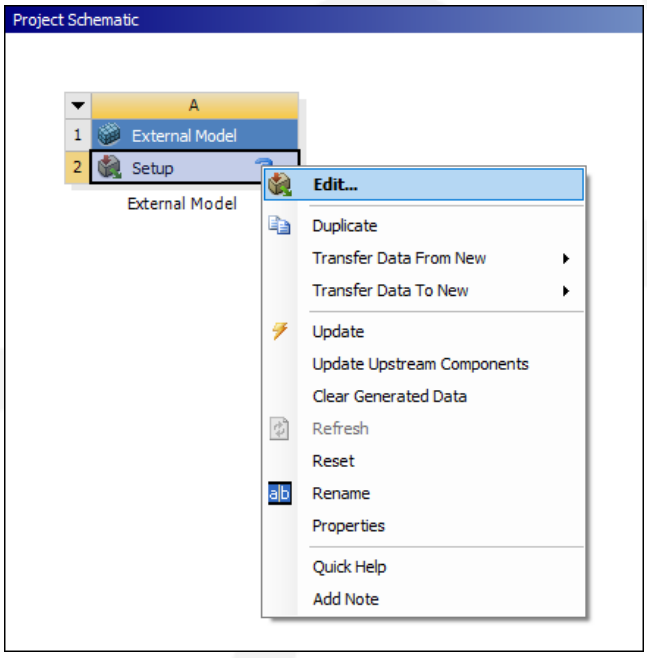
Published: 2023-10-23



Once you have inserted a Mechanical Model system or an analysis system, right-click the **Geometry** cell. The menu options enable you to:

- Open the Discovery application and specify your model.
- Open the SpaceClaim application and specify your model.
- Open the DesignModeler application and specify your model.
- Import a geometry from a supported CAD System (p. 2351) file using the **Import Geometry** option.

Importing Mesh

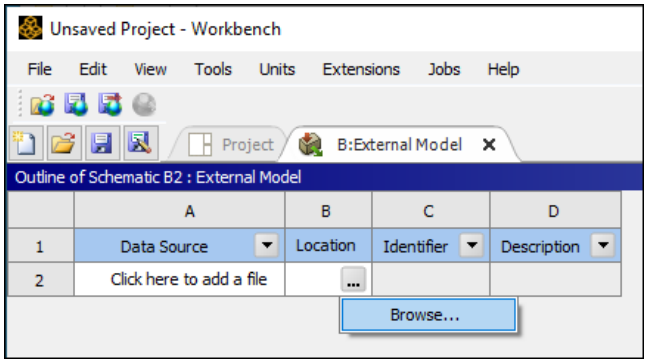


You can import mesh files using the **External Model** Component System.

1. Highlight the **Setup** cell and select **Edit**.
2. On the **External Model** tab, browse to your mesh file.

This feature imports Mechanical APDL common database (.cdb), Abaqus Input (.inp), NASTRAN Bulk Data (.bdf, .dat, .nas), Fluent Input (.msh, .cas), and ICEM CFD Input (.uns) files. For more

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



information, see the Importing Mesh-Based Geometry (p. 908) section.

Tip:

You can drag and drop a supported geometry or mesh file directly onto the **Project Schematic**. Based on the file type, the application automatically creates a **Geometry** system or an **External Model** system linked to a **Mechanical Model** system.

Note:

- If you create a link between the **Solution** cell of an analysis system and the **Model** cell of a downstream system, the application automatically transfers the resulting (deformed) geometry from the upstream analysis. See the Geometry from Deformation Results (p. 1022) section of the Help for more information.
- The Electronic Computer-Aided Design (ECAD) files, `Ansys EDB`, `ODB++`, and `IPC2851`, can be opened using the **Geometry** cell of the analysis system.

Importing Geometries or Mesh from Mechanical

The steps you use to import geometry or external model (mesh) files depend upon how you have opened the application.

Go to a section topic:

- Mechanical Opened Independently
  - Import Geometry (p. 333)
  - Import External Model (Mesh) File (p. 334)
- Mechanical Opened from Workbench
  - Import Primary Source (p. 335)
  - Import Secondary Source (p. 336)

Material Assignment

By default, when you first import your model into Mechanical, any bodies that do not include material assignment are assigned the application's default material. If you subsequently update your geometry from the source application, Mechanical does not assign

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

default materials to new bodies. If the geometry update includes a new body without an assigned material, the body becomes underdefined and requires you to specify a material.

Mechanical Opened Independently

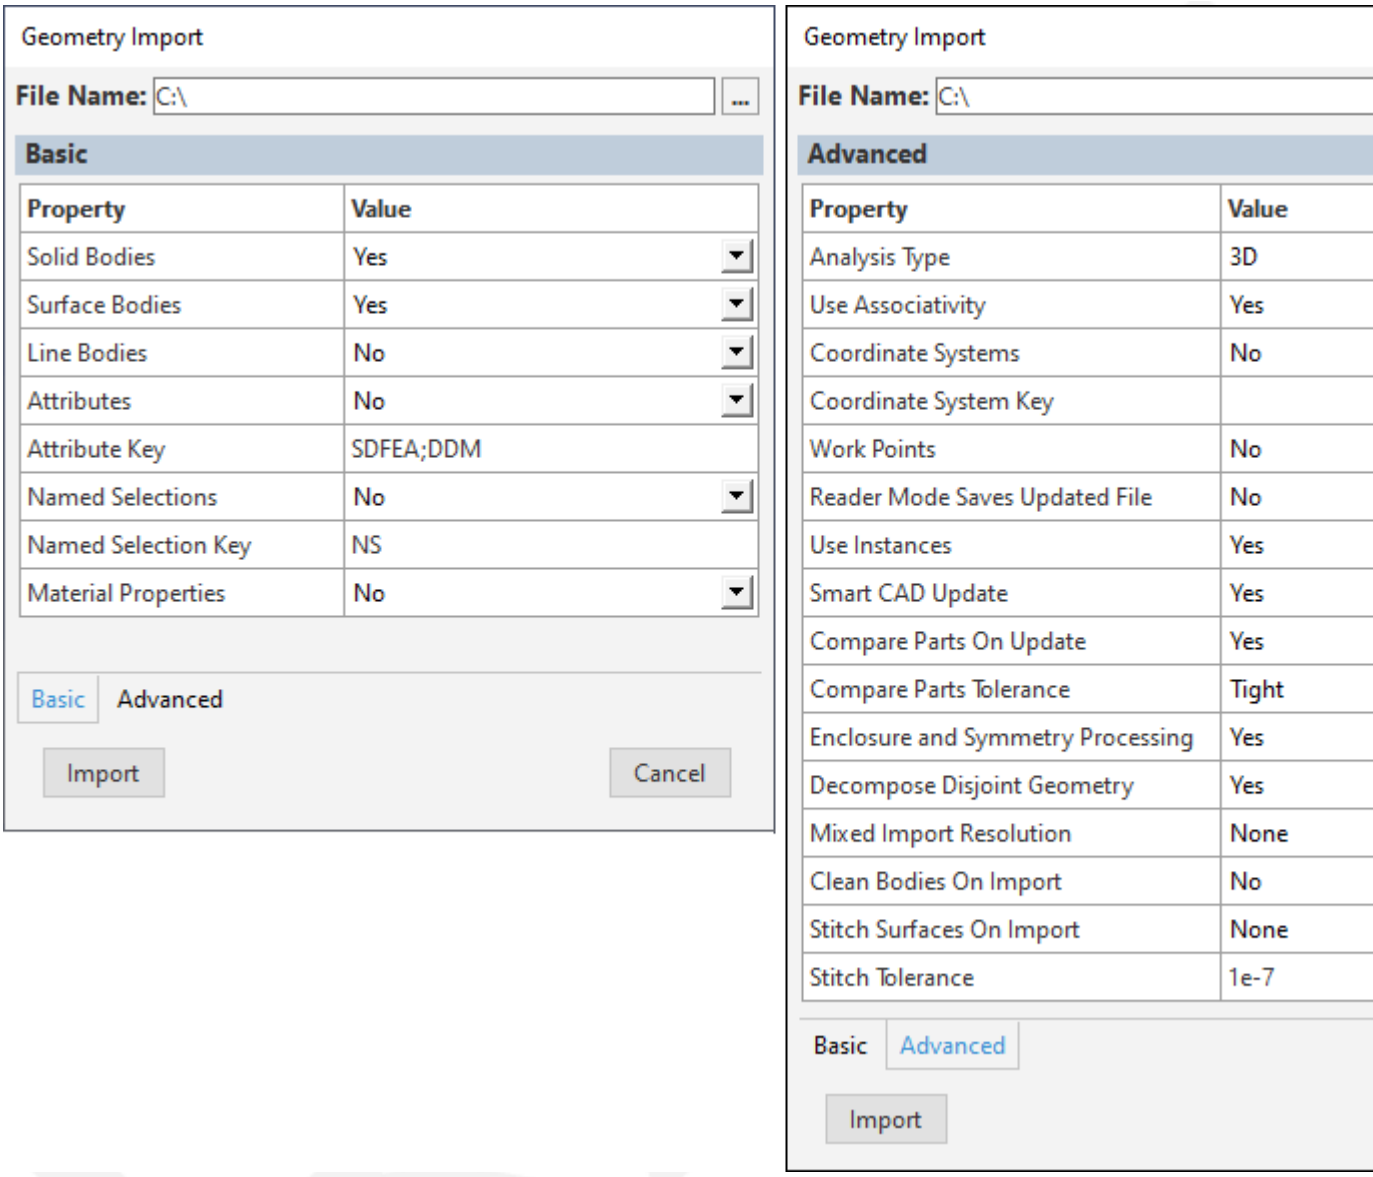
When you open Mechanical independently, you can import either geometry or an (external) model file.

Import Geometry

1. Select the **Geometry Imports** object.
2. Select the **Add Geometry Import** option from the **Geometry Imports** Context tab. The **Add Geometry Import** option includes a drop-down menu that lists recently imported files as well as the option **From File** that opens a dialog to select a file.
3. From the dialog, select a desired geometry file from the dialog.
4. The **Import Geometry** dialog displays automatically. This dialog includes two tabs: **Basic** and **Advanced**. Change property settings as needed and select the Import button.

DRAFT

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The application automatically imports the selected geometry and adds a Geometry Import object to the Outline. The application also updates the Geometry object with the imported parts/bodies.

Import External Model (Mesh) File

1. Select the **Geometry Imports** object.
2. Select the **Add Model Import** option from the **Geometry Imports** Context tab. The **Add Geometry Import** option includes a drop-down menu that lists recently imported files as well as the option **From File** that opens a dialog to select a file.
3. From the dialog, select a desired Mechanical APDL common database (`.cdb`) file.

Important:

This is the only supported file type.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

4. Specify Details pane properties as needed and then select the **Generate** option from the context tab. See the External Model section in the *Workbench User's Guide* for descriptions of the Details properties.

Once generated, the application updates the **Geometry** object with the imported parts/bodies as well as any additional finite element data. See the Importing Mesh-Based Geometry (p. 908) for more information about imported data types.

Mechanical Opened from Workbench

When you open Mechanical without a geometry, use the Geometry Imports folder and the child **Geometry Import** object to import geometries into Mechanical.

Import Primary Source

The "primary source" is the geometry imported from Workbench. For convenience, it can now be attached directly from Mechanical. The primary source uses the current **Basic**/**Advanced Geometry** Preference settings for the **Geometry** cell in Workbench.

Note:

If you have already imported geometry, a secondary source geometry is added instead. See the description below.

Select the **Geometry Imports** folder, and, using the Context tab (p. 55) **Geometry Imports**, either:

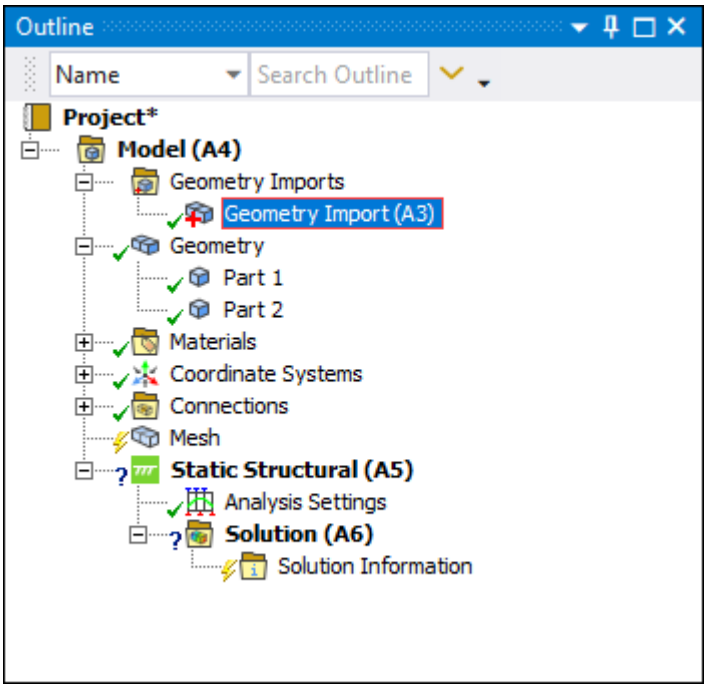
1. Click the **Import Geometry** option. A file selection dialog displays that enables you to select the desired file.

   Or...

2. Expand the drop-down list for the option to select a model from the list of recently imported geometries. For convenience, a **From File** option is also available.

If no other geometries are currently imported, the application automatically imports the selected geometry and updates the **Geometry Import (A3)** object. The application adds parts/bodies (for example, Part 1 and Part 2 shown below) as children to the **Geometry** object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Import Secondary Sources

Non-primary sources are referred to as "secondary" geometries/models. These are imported into Mechanical separately. Separate preferences can be specified for each import.

Once you have a model imported into Mechanical, you can add additional models using the **Geometry Imports** features. Use the steps below to add models to your analysis.

1. Select the **Geometry Imports** object, and using the Context tab (p. 55) **Add Geometry Import** option, either:

   a. Select the option. A dialog displays that enables you to navigate to the desired file.

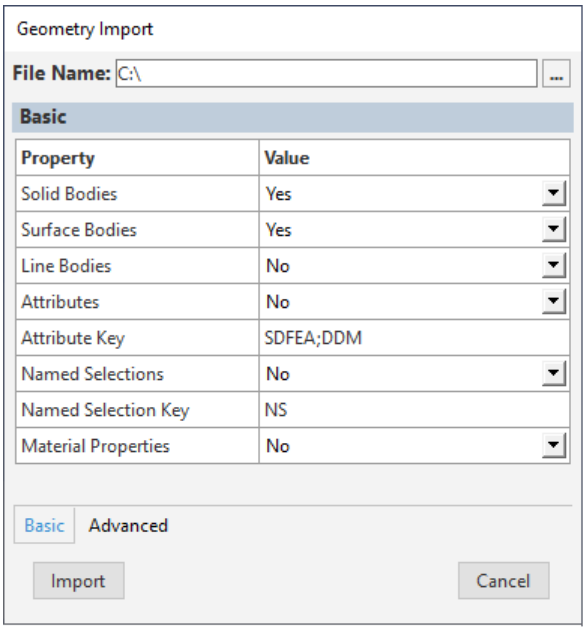
   Or...

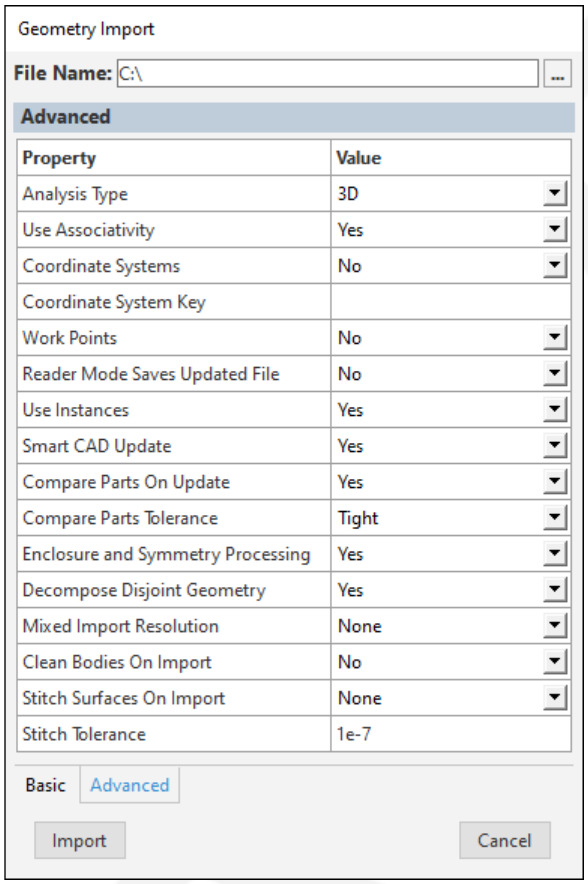
   b. Expand the drop-down list for the option to select a model from the list of recently imported geometries. For convenience, a **From File** option is also available.

2. As illustrated below, change the **Basic** and/or **Advanced** properties of the **Geometry Import** property pane. This property pane displays automatically.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

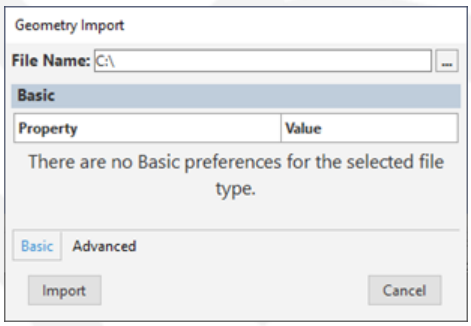
Published: 2023-10-23

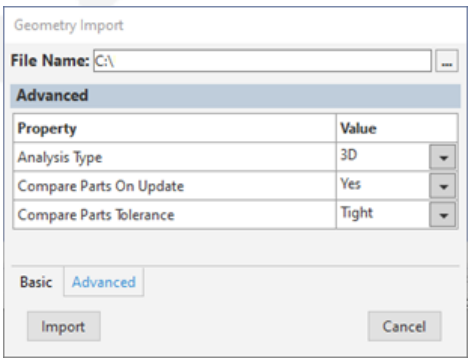




Note:

- Parameters are not supported for secondary imports.
- As illustrated, for DesignModeler and SpaceClaim files, the pane includes fewer properties.

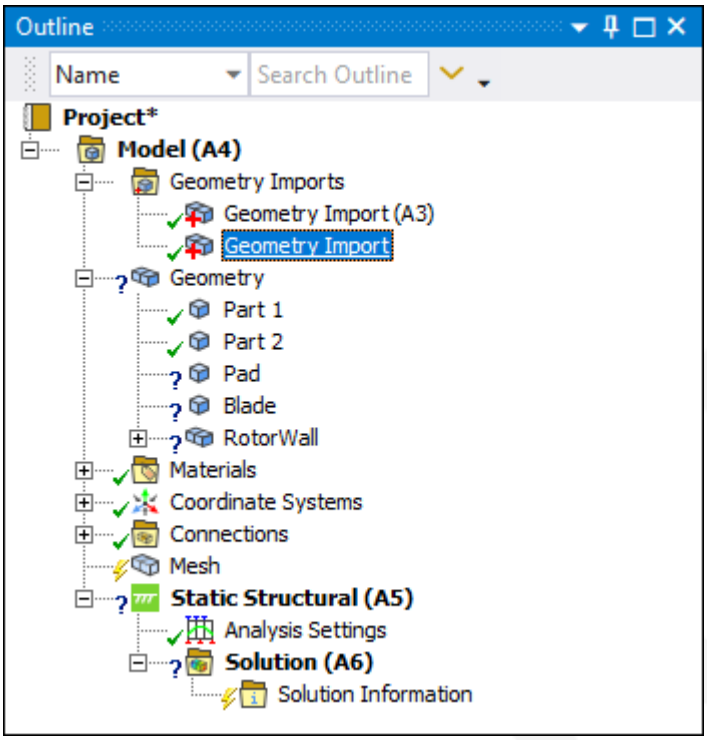




- In general, these are the same preferences that are available for the **Geometry** cell of an analysis system on the Workbench Project Schematic before you have specified a model to import. You should review the Geometry Preferences section of the *CAD Integration* documentation as well as the Geometry Import section of the *Workbench User's Guide* for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Select **Import**. A secondary **Geometry Import** object is automatically inserted into the outline, as illustrated below. The parts/bodies (shown below as Pad, Blade, and Rotor) are added as children to the **Geometry** object.



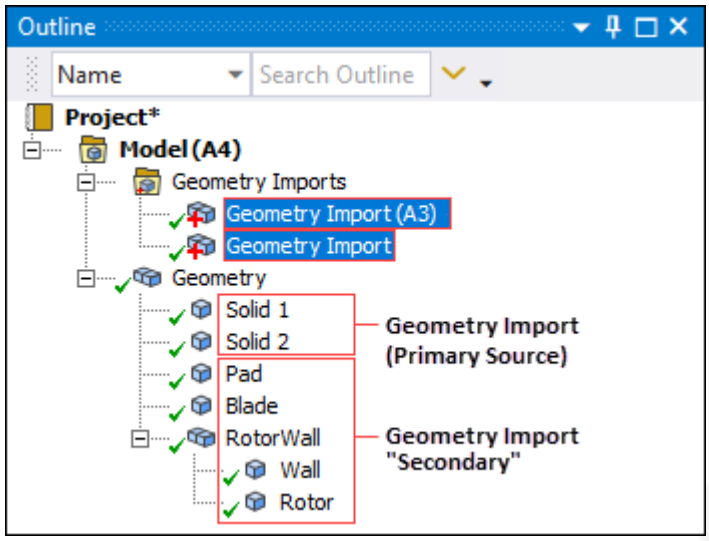
Important:

The application does not automatically assign materials to secondary imports. Note the "?" state for the above parts under the **Geometry** object. You need to manually specify a Material for the parts.

In the example below, you can see an example with parts and bodies under the **Geometry** object from multiple **Geometry Import** objects. Note that there is no separation or special treatment between parts/bodies from either Primary or Secondary sources.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Tip:

For convenience, you can display the context (right-click) menu on the **Geometry Import** objects and select the option **Go To** > **Corresponding Bodies in Tree**, to automatically select the parts/bodies for the import object. For CAD models, you can replace the geometry as desired using the Replace Geometry option on the Geometry Context tab.

Note:

Working with Model Assembly and Secondary Geometries

If you have an analysis that includes model assembly (p. 989), be sure to perform this operation before importing any secondary geometries. Existing secondary geometries are lost during the model assembly process.

Tip:

For Windows systems only, you can drag and drop a supported geometry or mesh file directly into the **Geometry** window. The application automatically attaches the model to the analysis system. For mesh files opened from Workbench, the application automatically inserts an upstream **External Model** system linked to your analysis system. Imported mesh files adopt the default unit system.

For CAD models, you can replace the primary and secondary source geometries using the **Reload** options.

Updating Geometry from Within the Mechanical Application

You can update all geometry by selecting the **Update Geometry from Source** context menu option, accessible by right-clicking on the **Geometry** tree object or anywhere in the **Geometry** window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The following update options are also available:

- Selective Update (p. 340)
- Smart CAD Update (p. 341)

Note:

The **Update Geometry from Source** option is not available if your analysis includes a secondary geometry.

Selective Update

Using the Geometry object right-click menu option **Update Selected Parts**>**Update: Use Geometry Parameter Values**, you can selectively update individual parts and synchronize the Mechanical model to the CAD model. This option reads the latest geometry and processes any other data (parameters, attributes, etc.) based on the current user preferences for that model.

Note:

Changes to either the number of turns or the thickness properties associated with a body do not update the CAD model.

This update feature only applies to part(s) that you select and other instances of the same part(s) that were previously imported. It does not import new parts added in the CAD system following the original import or last complete update. Assembly parameter values are always updated.

In addition, this feature is not a tool for removing parts from the Mechanical application tree, however; it will remove parts which have been selected for update in WB, but that no longer exist in the CAD model if an update is successful (if at least one valid part is updated).

The Update Selected Parts feature supports the associative geometry interfaces for:

- DesignModeler
- Autodesk Inventor
- CATIA V5
- Creo Elements/Direct Modeling
- Creo Parametric (formerly Pro/ENGINEER)
- Solid Edge
- NX
- SOLIDWORKS

With the exception of AutoCAD, executing the selective update feature on any unsupported interface will complete a full update of the model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Smart CAD Update

Using the Geometry Preferences, you enable the **Smart CAD Update**. Note that Geometry Preferences are supported by a limited number of CAD packages. See the **Project Schematic Advanced Geometry Options** table for details.

CAD Interface Terminology

The CAD interfaces can be run in either plug-in mode or in reader mode.

- **Attaching geometry in plug-in mode:** requires that the CAD system be running.
- **Attaching geometry in reader mode:** does not require that the CAD system be running.

Additional Geometry Import Procedures

The following table describes additional options for specifying and importing geometry into the application based on certain conditions.

Procedure	Condition	Procedural Steps
Specifying geometry options.	Optional task that can be done before attaching geometry.	1. In an analysis system schematic, perform either of the following: • Right-click the **Geometry** cell and choose **Properties** OR • Select the **Geometry** cell for your analysis and select **View** > **Properties**. 2. Specify Geometry properties as desired.
Attaching SpaceClaim geometry and/or mesh to the Mechanical application.	You have created and generated a geometry and/or mesh in SpaceClaim.	Double-click the **Model** cell. Mechanical opens and displays the geometry and/or mesh.
	SpaceClaim is not running. Your geometry and/or mesh is stored in an `.scdoc` file.	1. Select the **Geometry** cell in an analysis system schematic. 2. Browse to the `.scdoc` file by right-clicking the **Geometry** cell and selecting **Import Geometry** > **Browse**. 3. Double-click the **Model** cell. Mechanical opens and displays the geometry and/or mesh.
Attaching DesignModeler geometry to the	You have created and generated a geometry in DesignModeler.	Double-click the **Model** cell. Mechanical opens and displays the geometry.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Procedure	Condition	Procedural Steps
Mechanical application.	DesignModeler is not running. Your geometry is stored in an `.agdb` file.	1. Select the **Geometry** cell in an analysis system schematic. 2. Browse to the `.agdb` file by right-clicking the **Geometry** cell and selecting **Import Geometry** > **Browse**. 3. Double-click the **Model** cell. Mechanical opens and displays the geometry.
Attaching CAD geometry to the Mechanical application.	CAD system is running.	1. Select the **Geometry** cell in an analysis system schematic. 2. Right-click the **Geometry** cell listed to select geometry for import. 3. If required, set geometry options for import into the Mechanical application by highlighting the **Geometry** cell and choosing settings under **Preferences** in the Properties Panel. 4. Double-click the **Model** cell in the same analysis system schematic. The Mechanical application opens and displays the geometry.
	CAD system is not running. Geometry is stored in a native CAD system file, or in a CAD "neutral" file such as Parasolid or IGES.	1. Select the **Geometry** cell in an analysis system schematic. 2. Browse to the CAD file by right-clicking on the **Geometry** cell and selecting **Import Geometry**. 3. Double-click the **Model** cell in the **Project Schematic**. The Mechanical application opens and displays the geometry.
Open Mechanical without a geometry.	Specify the type of analysis you wish to perform.	Double-click the **Model** cell or right-click the cell and select **Edit**. Mechanical opens without a geometry. You can attach a geometry from within Mechanical as desired.

Define Part Behavior

After attaching geometry, you can access settings related to part behavior by right-clicking on the **Model** cell in the analysis system schematic and choosing **Edit**. The Mechanical application opens with the environment representing the analysis system displayed under the **Model** object in the tree.

An **Analysis Settings** object is added to the tree. See the Establish Analysis Settings (p. 349) overall step for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

An **Initial Condition** object may also be added. See the Define Initial Conditions (p. 349) overall step for details.

The Mechanical application uses the specific analysis system as a basis for filtering or making available only components such as loads, supports and results that are compatible with the analysis. For example, a **Static Structural** analysis type will allow only structural loads and results to be available.

Presented below are various options provided in the Details view for parts and bodies following import.

Stiffness Behavior

In addition to making changes to the material properties of a part, you may designate a part's **Stiffness Behavior** as being flexible, rigid, as a gasket, and can specify a line body as a stiff beam, essentially making the body rigid.

- Setting a part's behavior as rigid essentially reduces the representation of the part to a single point mass thus significantly reducing the solution time.
- A rigid part will need only data about the density of the material to calculate mass characteristics. Note that if density is temperature dependent, density will be evaluated at the reference temperature (p. 344). For contact conditions, specify Young's modulus.
- Flexible and rigid behaviors are applicable only to static structural, transient structural, rigid dynamics, explicit dynamics, and modal analyses.
- Gaskets can be defined in one of two ways:
  1. By setting the **Stiffness Behavior** as **Gasket**. In this case, a Gasket Mesh Control will be added as a child of the gasket body in the model tree. You need to define the source face of the gasket in the Gasket Mesh Control to define the gasket material orientation.
  2. By setting the **Stiffness Behavior** as **Flexible**. In this case, you need to define a Gasket Mesh Control in the mesh folder. The gasket mesh control in the mesh folder can be applied to multiple bodies, so if there are many gasket bodies this option may be a more convenient approach to setting up the gaskets.
- Gasket Bodies (p. 853) are only applicable to static structural analyses. The **Material Assignment** of gasket bodies should reference an appropriate gasket material.

Flexible is the default **Stiffness Behavior**. To change, simply select **Rigid**, **Gasket**, or **Stiff Beam** (for a line body only) from the **Stiffness Behavior** drop-down menu. Also see the Rigid Bodies (p. 852), Gasket Bodies (p. 853), and/or Stiff Beam (p. 856) sections.

Note:

Rigid behavior is not available for the Samcef or ABAQUS solver.

Coordinate Systems

The **Coordinate Systems** object and its child object, **Global Coordinate System**, is automatically placed in the tree with a default location of 0, 0, 0, when a model is imported.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

For solid parts and bodies: by default, a part and any associated bodies use the Global Coordinate System. If desired, you can apply a apply a local coordinate system (p. 1191) to the part or body. When a local coordinate system is assigned to a Part, by default, the bodies also assume this coordinate system but you may modify the system on the bodies individually as desired.

For surface bodies, solid shell bodies, and line bodies: by default, these types of geometries generate coordinates systems on a per element type basis. It is necessary for you to create a local coordinate system and associated it with the parts and/or bodies using the Coordinate System setting in the Details view for the part/body if you wish to orient those elements in a specific direction.

Reference Temperature

The default reference temperature is taken from the environment (**By Environment**), which occurs when solving. This necessarily means that the reference temperature can change for different solutions. The reference temperature can also be specified for a body and will be constant for each solution (**By Body**). Selecting **By Body** will cause the **Reference Temperature Value** field to specify the reference temperature for the body. It is important to recognize that any value set **By Body** will only set the reference temperature of the body and not actually cause the body to exist at that temperature (unlike the **Environment Temperature** entry on an environment object, which does set the body's temperature).

Note:

Selecting **By Environment** can cause the body to exist at that temperature during the analysis but selecting **By Body** will only ever effect reference temperature. So if the environment temperature and the body have a different specification, thermal expansion effects can occur even if no other thermal loads are applied.

Note:

If the material density is temperature dependent, the mass that is displayed in the Details view will either be computed at the body temperature, or at 22°C. Therefore, the mass computed during solution can be different from the value shown, if the **Reference Temperature** is the **Environment**.

Note:

When nonlinear material effects are turned off, values for thermal conductivity, specific heat, and thermal expansion are retrieved at the reference temperature of the body when creating the Mechanical APDL solver input.

Reference Frame

The Reference Frame determines the analysis treatment perspective of the body for an Explicit Dynamics analysis. The Reference Frame property is available for solid bodies when an Explicit Dynamics system is part of the solution. The valid values are **Langrangian** (default) and **Eulerian (Virtual)**. Eulerian is not a valid selection if **Stiffness Behavior** is set to **Rigid**.

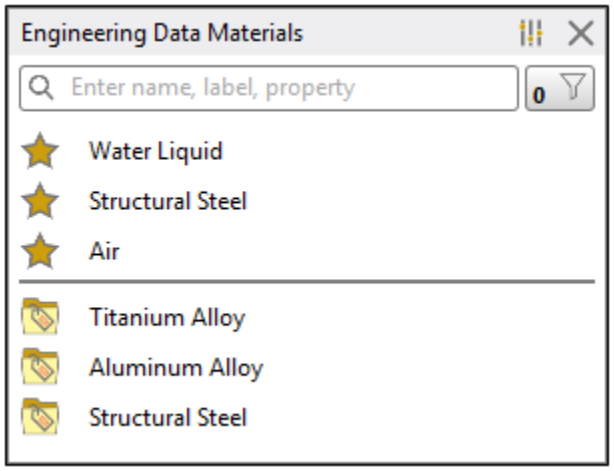
Published: 2023-10-23

Material Assignment

Once you have attached your geometry, you can change the material assigned to the parts and bodies of your model. When you select a Part or Body object in the Outline, there is an **Assignment** property available in the Details view for each. This property provides a selectable fly-out menu that opens that opens the following **Engineering Data Materials** window. By default, this window lists the materials included in the Engineering Data favorites, as symbolized with the star icon as well as any other materials that you made available from the Engineering Data workspace, such as titanium and aluminum alloy show below. Selecting a material from this window assigns it to the currently selected part or body.



When you edit the currently assigned material, create a material, or import a material, you work in the Material Data tab. Once you have completed any of those operations, you must refresh the **Model** cell in the Project Schematic to bring new data into Mechanical.

Note:

- The **Assignment** property can be designated as a parameter.
- To model a gasket, the material assignment should reference a valid Gasket Material Model.

Nonlinear Material Effects

You can also choose to ignore any nonlinear effects from the material properties.

- By default the program will use all applicable material properties including nonlinear properties such as stress-strain curve data.
- Setting **Nonlinear Effects** to **No** will ignore any nonlinear properties only for that part.
- This option will allow you to assign the same material to two different parts but treat one of the parts as linear.
- This option is applicable only for static structural, transient structural, steady state thermal and transient thermal analyses.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Thermal Strain Effects

For structural analyses, you can choose to have Workbench calculate a **Thermal Strain** (p. 2032) result by setting **Thermal Strain Effects** to **Yes**. Choosing this option enables the coefficient of thermal expansion to be sent to the solver.

Cross Section

When a line body is imported into the Mechanical application, the Details view displays the **Cross Section** field and associated cross section data. These read-only fields display the name and data assigned to the geometry in DesignModeler or the supported CAD system, if one was defined. See Line Bodies (p. 872) for further information.

Model Dimensions

When you attach your geometry or model, the model dimensions display in the Details Pane (p. 119) in the Bounding Box sections of the Geometry or Part objects. Dimensions have the following characteristics:

- Units are created in your CAD system.
- ACIS model units, if available during import and/or update, are used.
- Other geometry units are automatically detected and set.
- Assemblies must have all parts dimensioned in the same units.

Create a Simulation Template

You can open the Mechanical application without importing a geometry and specify any number of environmental conditions. To do so, select your desired analysis type in Workbench, select the **Model** cell, and open Mechanical. After you have defined all the desired aspects of your analysis, you can then save your simulation scenario. All without a geometry. This gives you the flexibility to simulate your scenario against different geometries.

The ability to define Worksheet-based Named Selections (p. 1061) in this situation has the most strategic benefit. Specifically, once you specify criterion-based Named Selections, you can scope a wide range of objects, such as, Remote Points, Coordinate Systems, loading conditions, support conditions, results, etc. Once you save your project, you can use with various models.

Limitations

Note the following conditions when importing a system that includes criteria-based Named Selections. For an existing template, if you import a system that contains a:

- Remote Point scoped to a criteria-based Named Selection, the Remote Point does may not update properly to include the location of the Named Selection. You can correct this condition by specifying an appropriate Coordinate System for the Remote Point instead of using the default Global Coordinate System setting.

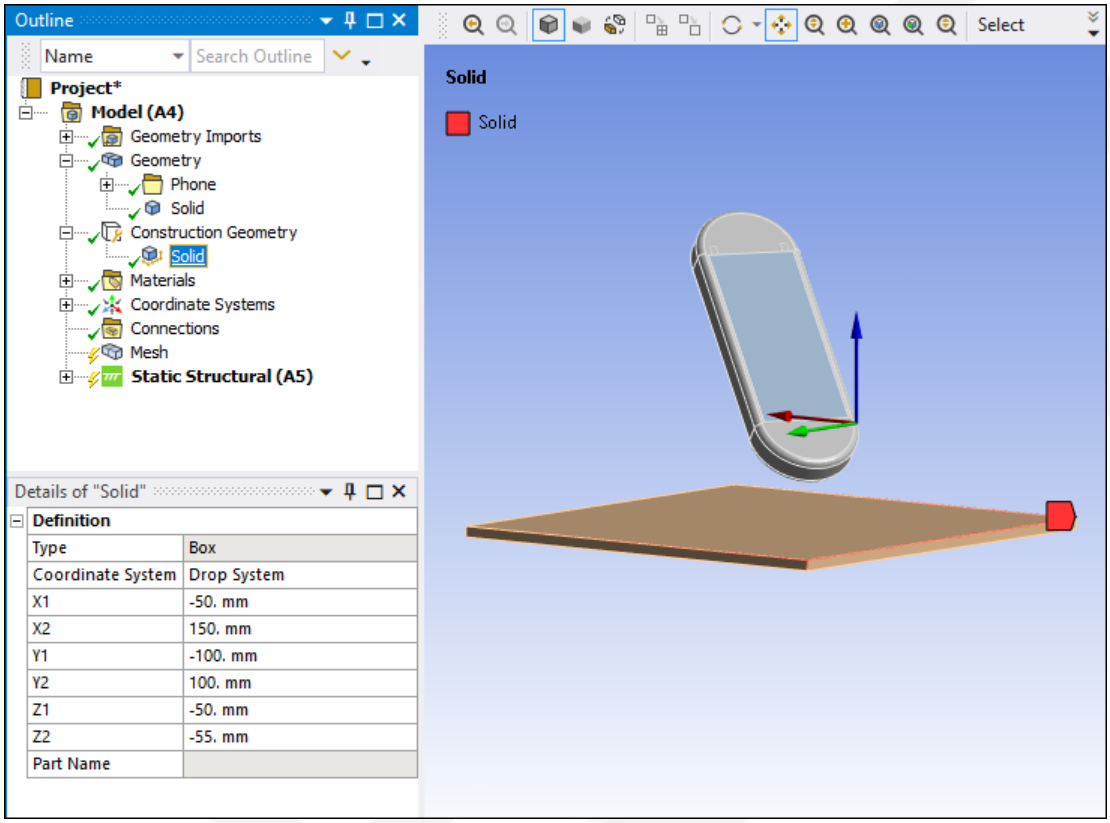
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- A loading condition scoped to criteria-based Named Selection and whose direction is defined by a **Vector**, the loading direction may not be updated after attaching the geometry. You can correct this condition by specifying the load by **Components**.

Create a Geometry in Mechanical

Using the **Construction Geometry** feature (**Solid** option), you can create and add a solid geometry within Mechanical. An example is illustrated below. The cellular telephone model is being dropped onto a solid body that was created in Mechanical. For more information, see the specifying a Solid (p. 892) section of the Help.



Define Substructures

Substructuring is a procedure that condenses a group of finite elements into one element represented as a matrix. The single-matrix element is called a superelement. You can use a superelement in an analysis as you would any other element type. By summarizing the mechanical behavior of the bodies, they can be assembled to synthesize the response of a more complex structure, or to model flexible bodies in the Rigid Dynamics solver.

See the Substructure Analysis (p. 781) section for more information about the use of this feature.

Supported Analysis Types

Substructuring currently supports the following analysis types:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Harmonic Response (p. 496) (MSUP only)
- Modal (p. 515)
- Random Vibration (p. 524)
- Response Spectrum (p. 533)
- Rigid Dynamics (p. 550)

Define Connections

Once you have addressed the material properties and part behavior of your model, you may need to apply connections to the bodies in the model so that they are connected as a unit in sustaining the applied loads for analysis. Available connection features are:

- **Contacts** (p. 1222): defines where two bodies are in contact or a user manually defines contact between two bodies.
- **Joints** (p. 1292): a contact condition in the application that is defined by a junction where bodies are joined together that has rotational and translational degrees of freedom.
- **Mesh Connections**: used to join the meshes of topologically disconnected surface bodies that reside in different parts.
- **Springs** (p. 1395): defines as an elastic element that connects two bodies or a body to "ground" that maintains its original shape once the specified forces are removed.
- **Bearings** (p. 1413): are used to confine relative motion and rotation of a rotating machinery part.
- **Beam Connections** (p. 1404): used to establish body to body or body to ground connections.
- **End Releases** (p. 1409) are used to release degrees of freedoms at a vertex shared by two or more edges of one or more line bodies.
- **Spot Welds** (p. 1407): connects individual surface body parts together to form surface body model assemblies.

Given the complex nature of bodies coming into contact with one another, especially if the bodies are in motion, it is recommended that you review the Connections (p. 1207) section of the documentation.

Apply Mesh Controls and Preview Mesh

Meshing is the process in which your geometry is spatially discretized into elements and nodes. This mesh along with material properties is used to mathematically represent the stiffness and mass distribution of your structure.

Your model is automatically meshed at solve time. The default element size is determined based on a number of factors including the overall model size, the proximity of other topologies, body curvature, and the complexity of the feature. If necessary, the fineness of the mesh is adjusted up to four times (eight times for an assembly) to achieve a successful mesh.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

If desired, you can preview the mesh before solving. Mesh controls are available to assist you in fine tuning the mesh to your analysis. Refer to the Meshing Help for further details.

To preview the mesh in the Mechanical Application:

See the Previewing Surface Mesh section.

To apply global mesh settings in the Mechanical Application:

See the Global Mesh Controls section.

To apply mesh control tools on specific geometry in the Mechanical Application:

See the Local Mesh Controls section.

To use virtual topology:

All virtual topology operations in the Mechanical application are described in the Virtual Topology section of the Meshing Help.

Establish Analysis Settings

Each analysis system includes an Analysis Settings object. You use this object to define a variety of solution options, such as step controls, solution type, large deflection, as well as specific output data to include in the result file. The properties available in the **Analysis Settings** Details pane vary based on the analysis type, and their settings can be critical to achieving a complete and accurate solution.

See the Analysis Settings for Most Analysis Types (p. 1417) section for a complete listing and description of all available properties.

Define Initial Conditions

Based on your analysis type, Mechanical enables you to begin your analysis with an initial specification using one of the object types described below. Initial specifications include Initial Conditions, links to an existing solved or associated environment, or an Initial Temperature. These objects are all default objects (included with) of the individual analysis types.

Analysis Type	Object	Description
Coupled Field Transient (p. 391) and Transient Structural (p. 665)	**Initial Conditions** folder	By default, a transient analysis is at rest. However, you can define velocity as an initial condition by inserting a **Velocity** object under the **Initial Conditions** folder.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Analysis Type	Object	Description
Explicit Dynamics	**Initial Conditions** folder: **Pre-Stress** object	Because an Explicit Dynamics analysis is better suited for short duration events, preceding it with an implicit analysis may produce a more efficient simulation especially for cases in which a generally slower (or rate-independent) phenomenon is followed by a much faster event, such as the collision of a pressurized container. For an **Explicit Dynamics** system, the **Initial Conditions** folder includes a **Pre-Stress** object to control the transfer of data from an implicit static or transient structural analysis to the explicit dynamics analysis. Transferable data include the displacements, or the more complete Material State (displacements, velocities, stresses, strains, and temperature). See Recommended Guidelines for Pre-Stress Explicit Dynamics for more information. An explicit dynamics analysis is at rest by default. However, for **Explicit Dynamics** and LS-DYNA systems, you can define velocity or angular velocity as initial conditions by inserting a **Velocity** object, a **Drop Height** object, or an **Angular Velocity** object under the **Initial Conditions** folder. If initial velocity, drop height, or angular velocity are defined in an LS-DYNA Restart, they override the velocities calculated at the end of the previous calculation.
Random Vibration (p. 524), Response Spectrum (p. 533), Harmonic Response MSUP (Mode-Superposition) linked (p. 509), or Transient (MSUP) linked (p. 674)	**Initial Conditions** folder: **Modal** object	A Random Vibration, Response Spectrum, Harmonic (Mode-Superposition - MSUP) linked or a Transient (MSUP) linked analysis *must* use the mode shapes derived in a Modal analysis.
Coupled Field Harmonic (p. 380) and Coupled Field Modal (p. 386)	**Pre-Stress** object	You can use the physics settings and results of an upstream Coupled Field Static analysis in downstream Coupled Field Harmonic and Coupled Field Modal analyses. Also see the Prestressed Coupled Field Harmonic Analysis (p. 382) and Prestressed Coupled Field Modal Analysis (p. 388) sections.
Eigenvalue Buckling (p. 487)	**Pre-Stress** object	An Eigenvalue Buckling analysis *must* use the stress-stiffening effects of a static structural analysis. See the Eigenvalue Buckling Analysis (p. 487) section for details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Analysis Type	Object	Description
Harmonic Response (p. 496) (Full)	**Pre-Stress** object	A Harmonic Response (p. 496) (**Full**) analysis linked to a Static Structural analysis can use the stress results to account for stress-stiffening effect. Also see the Harmonic Response (Full) Analysis Using Pre-Stressed Structural System (p. 506) section.
Modal (p. 515)	**Pre-Stress** object	A Modal analysis can use the stress results from a Static Structural analysis to account for stress-stiffening effect. See the Modal Analysis (p. 515) section for details.
Steady-State Thermal (p. 657)	**Initial Temperature** object	For a Steady-State Thermal analysis, you have the ability to specify an initial temperature.
Substructure Generation (p. 543)	**Pre-Stress** object	For a Substructure Generation analysis, an upstream Static Structural analysis (only) can be used to create pre-stress effects.
Transient Thermal (p. 680)	**Initial Temperature** object	For a Transient Thermal analysis, the initial temperature distribution should be specified.

Note:

When available in the **Outline**, you can apply temperatures from a Steady-State Thermal or a Transient Thermal analysis to a Static Structural, Transient Structural, or Electric analysis as a **Imported Body Temperature** load using the context (right-click) menu option **Import Load** that is available on the **Environment** object of the structural or electric analysis. The **Import Load** option provides a menu you can use to select the desired analysis you wish to link to. You can also perform this linking by dragging and dropping the Solution object of the Steady-State Thermal or a Transient Thermal analysis onto the Environment object of the structural or electric analysis. You can also apply **Heat Generation** from an Electric analysis to a Steady-State Thermal or Transient Thermal analysis using these methods.

Requirements/Usage

Depending upon the analysis type, an appropriate object is automatically added to the **Outline** enabling you to set an initial analysis specification:

- For a **Transient Structural** analysis, use the **Initial Conditions** object to insert **Velocity**. For an **Explicit Dynamics** analysis, use the **Initial Conditions** object to insert **Velocity**, **Angular Velocity**, and **Drop Height**. These values can be scoped to specific parts of the geometry.
- For a **Harmonic Response**, **Modal**, **Eigenvalue Buckling**, **Substructure Generation**, or **Explicit Dynamics** analysis, use the Details view of the **Pre-Stress** object to define the associated **Pre-Stress Environment** (p. 352). For an **Explicit Dynamics** analysis, use the Details view of this object to select either **Material State** (displacements, velocities, strains and stresses) or **Displacements** only modes, as well as the analysis time from the implicit analysis which to obtain the initial condition. For **Displacements** only, a **Time Step Factor** may be specified to convert nodal DOF displacements in the implicit solution into constant velocities for the explicit analysis according to the following expression:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Velocity = Implicit displacement/(Initial explicit time step x time step factor)

Note:

The **Displacements** only mode is applicable only to results from a linear, static structural analysis.

- For a **Random Vibration** or **Response Spectrum** analysis, you must point to a modal analysis using the drop-down list of the **Modal Environment** field in the Details view.
- For the **Steady-State** and **Transient Thermal** analyses, use the Details of the **Initial Temperature** object to scope the initial temperature value. For a Transient Thermal analysis that has a non-uniform temperature, you need to define an associated Initial Temperature Environment.
- The Details view of the Modal (Initial Conditions) object for linked Mode-Superposition Harmonic and Mode-Superposition Transient analyses displays the name of the pre-stress analysis system in the **Pre-Stress Environment** field, otherwise the field indicates **None** or **None Available**.

Apply Pre-Stress Effects for Implicit Analysis

Mechanical leverages the power of linear perturbation technology for all pre-stress analyses performed within Mechanical. This includes pre-stress Modal (p. 515) analyses, Full Harmonic Response analysis using a Pre-Stressed Structural System (p. 506) analyses, as well as Eigenvalue Buckling (p. 487) analyses.

The following features are available that are based on this technology:

- Large deflection static analysis followed by pre-stress modal analysis. Thus the static analysis can be linear or nonlinear including large deflection effects.

Note:

– If performing a pre-stress modal analysis, it is recommended that you always include large deflection effects to produce accurate results in the modal analysis.

– Pre-stress results should always originate from the same version of the application as that of the modal solution.

– Although the modal results (including displacements, stresses, and strains) will be correctly calculated in the modal analysis, the deformed shape picture inside Mechanical will be based on the initial geometry, not the deformed geometry from the static analysis. If you desire to see the mode shapes based on the deformed geometry, you can take the result file into Mechanical APDL.

- True contact status as calculated at the time in the static analysis from which the eigen analysis is based.
- Support for cyclic analysis.
- Support for multiple result sets in the static analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

For a pre-stressed eigen analysis, you can insert a **Commands** object (p. 2303) beneath the **Pre-Stress** initial conditions object. The commands in this object will be executed just before the first solve for the pre-stressed modal analysis.

Pressure Load Stiffness

If the static analysis has a pressure load applied "normal to" faces (3D) or edges (2-D), this could result in an additional stiffness contribution called the "pressure load stiffness" effect. This effect plays a significant role in follow-on Modal analyses, Eigenvalue Buckling analyses, and in Harmonic Response (Full) analyses, however, the effect can be more prominent in an Eigenvalue Buckling analysis.

Different buckling loads may be predicted from seemingly equivalent pressure and force loads in a buckling analysis because in the Mechanical application a force and a pressure are not treated the same. As with any numerical analysis, we recommend that you use the type of loading which best models the in-service component. For more information, see the *Mechanical APDL Theory Reference*, under *Structures with Geometric Nonlinearities> Stress Stiffening> Pressure Load Stiffness*.

Restarts from Multiple Result Sets

A property called **Pre-Stress Define By** is available in the Details view of the **Pre-Stress** object in the eigen analysis. It is set to **Program Controlled** by default which means that it uses the last solve point available in the parent static structural analysis as the basis for the eigen analysis. There are three more read only properties defined in the Details view of the **Pre-Stress** object – **Reported Loadstep**, **Reported Substep** and **Reported Time** which are set to **Last**, **Last**, and **End Time** or **None Available** by default depending on whether or not there are any restart points available in the parent static structural analysis. These read only properties show the actual load step, sub step and time used as the basis for the eigen analysis.

You can change **Pre-Stress Define By** to **Load Step**, and then another property called **Pre-Stress Loadstep** will appear in the Details view. **Pre-Stress Loadstep** gives you an option to start from any load step in the static structural analysis. If you use this property, then Mechanical will always pick the last substep available in that load step. You can see the actual reported substep and time as read only properties. The input value of load step should be less than or equal to the number of load steps in the parent static structural analysis. Loadstep **0** stands for the last load step available.

You can change **Pre-Stress Define By** to **Time**, and then another property called **Pre-Stress Time** will appear in the Details view. **Pre-Stress Time** gives you an option to start from any time in the static structural analysis. If there is no restart point available at the time of your input, then Mechanical will pick the closest restart point available in the static structural analysis. You can see the actual reported load step, sub step and time as read only properties. The input value of time should be non-negative and it should be less than the end time of parent static structural analysis. Time **0** stands for end time of the parent analysis. If there is no restart point available in the input loadstep and the number of restart points in the parent analysis is not equal to zero, then the following error message appears:

"There is no restart point available at the requested loadstep. Change the restart controls in the parent static structural analysis to use the requested loadstep."

Note:

If you use **Pre-Stress Time**, then Mechanical will pick the closest restart point available. It may not be the last sub step of a load step; and if it is some intermediate substep in a load

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

step, then the result may not be reproducible if you make any changes in the parent static structural analysis or you solve it again.

If there is no restart point available in the parent static structural analysis, then **Reported Loadstep**, **Reported Substep** and **Reported Time** are set to **None Available** regardless of the user input of **Load Step/Time** but these will be updated to correct values once the analysis is solved with the correct restart controls for the parent structural analysis.

Contact Status

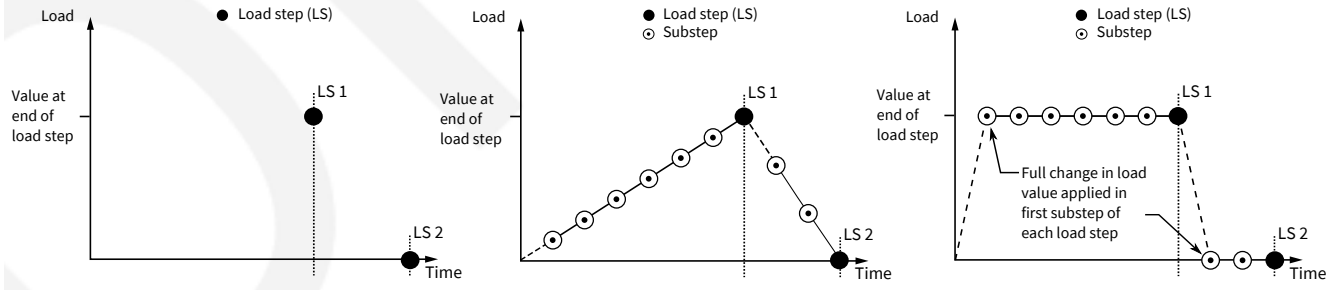
You may choose contact status for the pre-stressed eigen analysis to be true contact status, force sticking, or force bonded. A property called **Contact Status** is available in the Details view of the **Pre-Stress** object in the eigen analysis. This property controls the CONTKEY field of the Mechanical APDL **PERTURB** command.

- **Use True Status** (default): Uses the current contact status from the restart snapshot. If the previous run for parent static structural is nonlinear, then the nonlinear contact status at the point of restart is frozen and used throughout the linear perturbation analysis.
- **Force Sticking**: Uses sticking contact stiffness for the frictional contact pairs, even when the status is sliding (that is, the no sliding status is allowed). This option only applies to contact pairs whose frictional coefficient is greater than zero.
- **Force Bonding**: Uses bonded contact stiffness and status for contact pairs that are in the closed (sticking/sliding) state.

Apply Loads and Supports

You apply loads and support types based on the type of analysis. For example, a stress analysis may involve pressures and forces for loads, and displacements for supports, while a thermal analysis may involve convections and temperatures.

Loads applied to static structural, transient structural, rigid dynamics, steady-state thermal, transient thermal, magnetostatic, electric, and thermal-electric analyses default to either step-applied or ramped. That is, the values applied at the first substep stay constant for the rest of the analysis or they increase gradually at each substep.



(a) Load as specified in two load steps

(b) Load as applied - ramped (KBC,0)

(c) Load as applied - stepped (KBC,1)

You can edit the table of load vs. time and modify this behavior as needed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

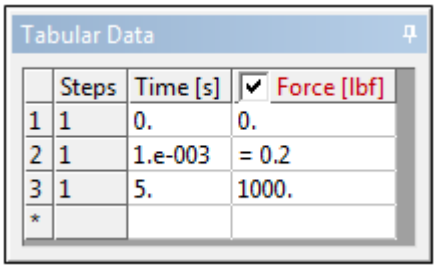
By default you have one step. However you may introduce multiple steps at time points where you want to change the analysis settings such as the time step size or when you want to activate or deactivate a load. An example is to delete a specified displacement at a point along the time history.

You do not need multiple steps simply to define a variation of load with respect to time. You can use tables or functions to define such variation within a single step. You need steps only if you want to guide the analysis settings or boundary conditions at specific time points.

When you add loads or supports in a static or transient analysis, the **Tabular Data** and **Graph** windows appear. You can enter the load history, that is, Time vs Load tabular data in the tabular data grid. Another option is to apply loads as functions of time. In this case you will enter the equation of how the load varies with respect to time. The procedures for applying tabular or function loads are outlined under the Defining Boundary Condition Magnitude (p. 1771) section.

Note:

- You can also import or export load histories from or to any pre-existing libraries.
- If you have multiple steps (p. 1492) in your analysis, the end times of each of these steps will always appear in the load history table. However you need not necessarily enter data for these time points. These time points are always displayed so that you can activate or deactivate the load over each of the steps. Similarly the value at time = 0 is also always displayed.
- If you did not enter data at a time point then the value will be either a.) a linearly interpolated value if the load is a tabular load or b.) an exact value determined from the function that defines the load. An "=" sign is appended to such interpolated data so you can differentiate between the data that you entered and the data calculated by the program as shown in the example below. Here the user entered data at Time = 0 and Time = 5. The value at Time = 1e-3, the end time of step 1, is interpolated.



To apply loads or supports in the Mechanical Application:

See the Setting Up Boundary Conditions (p. 1497) section.

Perform Solution

Mechanical uses the same solver kernels that Ansys Mechanical APDL (MAPDL) uses. At the Solve step, Mechanical passes its data to the appropriate MAPDL solver kernel, based on the type of analysis to be performed. That kernel then passes the solution data back to Mechanical, where you are able to look

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

at the results. Because the same solver kernels are used, you will obtain the same results from Mechanical that you would if doing the same analysis in MAPDL.

Based on the analysis type, the following solvers are available in Mechanical:

- **Mechanical Ansys Parametric Design Language (MAPDL) Solver**.
- **Ansys Rigid Dynamics Solver**: only available for Rigid Dynamics Analysis.
- **LS-DYNA Solver**: only available for Explicit Dynamics analysis.
- **Explicit Dynamics Solver**: only available for Explicit Dynamics analysis.
- **Samcef Solver**: only available for Static Structural, Transient Structural, Steady-State Thermal, Transient Thermal, Modal, and Eigenvalue Buckling analyses.
- **ABAQUS Solver**: only available for Static Structural, Transient Structural, Steady-State Thermal, Transient Thermal, and Modal analyses.

You can execute the solution process on your local machine or on a remote machine such as a powerful server you might have access to. The Remote Solve Manager (RSM) feature allows you to perform solutions on a remote machine. Once completed, results are transferred to your local machine for post processing. Refer to the Solve Modes and Recommended Usage (p. 1803) section for more details.

Solution Progress

Because nonlinear or transient solutions can take significant time to complete, a progress pane is displayed in the status bar (p. 135) to indicate the overall progress of solution. More detailed information on solution status can be obtained from the **Solution Information** object (p. 1833) contained under the **Solution** folder. The **Solution Information** object enables you to:

- View solver output.
- Monitor output such as convergence criteria for nonlinear problems.
- Diagnose possible reasons for convergence difficulties by plotting Newton-Raphson residuals.
- Monitor certain result items, such as displacement or temperature.

Solve References for the Mechanical Application

See the Understanding Solving (p. 1791) section for details on the above and other topics related to solving.

Review Results

The analysis type determines the results available for you to examine after solution. For example, in a structural analysis, you may be interested in equivalent stress results or maximum shear results, while in a thermal analysis, you may be interested in temperature or total heat flux. The Using Results (p. 1927) section lists various results available to you for postprocessing.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

To add result objects in the Mechanical application:

1. Highlight a **Solution** object in the tree.
2. Select the appropriate result from the Solution Context Tab (p. 62) or use the right-mouse click option.

To review results in the Mechanical application:

1. Click a result object in the tree.
2. After the solution has been calculated, you can review and interpret the results in the following ways:
   - Contour results (p. 62) - Displays a contour plot of a result such as stress over geometry.
   - Vector Plots (p. 74) - Displays certain results in the form of vectors (arrows).
   - Probes (p. 1946) - Displays a result at a single time point, or as a variation over time, using a graph and a table.
   - Charts (p. 1929) - Displays different results over time, or displays one result against another result, for example, force vs. displacement.
   - Animation (p. 2260) - Animates the variation of results over geometry including the deformation of the structure.
   - Stress Tool (p. 2058) - to evaluate a design using various failure theories.
   - Fatigue Tool (p. 2066) - to perform advanced life prediction calculations.
   - Contact Tool (p. 2079) - to review contact region behavior in complex assemblies.
   - Beam Tool (p. 2087) - to evaluate stresses in line body representations.

Note:

Displacements of rigid bodies are shown correctly in transient structural and rigid dynamics analyses. If rigid bodies are used in other analyses such as static structural or modal analyses, the results are correct, but the graphics will not show the deformed configuration of the rigid bodies in either the result plots or animation.

Note:

If you resume a Mechanical model from a project or an archive that does **not** contain result files, then results in the **Solution** tree can display contours but restrictions apply:

- The result object cannot show a deformed shape; that is, the node-based displacements are not available to deform the mesh.
- The result object cannot animate.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Contours are **not** available for harmonic results that depend upon both real and imaginary result sets.

See the Using Results (p. 1927) section for more references on results.

Create Report (optional)

Workbench includes a provision for automatically creating a report based on your entire analysis. The documents generated by the report are in HTML. The report generates documents containing content and structure and uses an external Cascading Style Sheet (CSS) to provide virtually all of the formatting information.

Report References for the Mechanical Application

See the Report Preview (p. 174) section.

Analysis Types

You can perform analyses in the Mechanical application using pre-configured analysis systems (as listed below). Each analysis description assumes that you are familiar with the analysis type as well as with the information presented in Steps for Using the Mechanical Application (p. 323) section, specifically the Create Analysis System (p. 323) topic. The availability of features for an analysis may differ based on the solver you select.

Also note that it is not necessary to specify a geometry or mesh, or even an analysis type to initiate a simulation. Mechanical provides options to perform these actions *after* you have opened the application.

Adaptivity Analyses

Coupled Field Analysis Types

Electric Analysis

Explicit Dynamics Analysis

Fracture Analysis

Linear Dynamics Analysis Types

Magnetostatic Analysis

Rigid Dynamics Analysis

Static Structural Analysis

Transient Structural Analysis Using Linked Modal Analysis System

Transient Thermal Analysis

Special Analysis Topics

In addition, you can enhance your analysis and add capabilities using the **Commands** Object (p. 2303) to execute Mechanical APDL commands in the Mechanical application.

Adaptivity Analyses

Mechanical enables you to perform nonlinear adaptive analyses using the **Nonlinear Adaptive Region** and **Geometry Based Adaptivity** options found in the Conditions (p. 1697) drop-down menu of the **Environment** context tab.

Nonlinear adaptivity is a capability of the solution process that enables the application to adapt to changing conditions during a nonlinear analysis. The solution process uses a feedback mechanism to discretely and continuously adjust internal parameters automatically so that you can obtain an accurate and convergent solution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

You use these conditions to either change the mesh during the solution process or to model the boundary geometry accurately during mesh adaptivity:

Nonlinear Adaptive Region

Geometry Based Adaptivity

Nonlinear Adaptive Region

The **Nonlinear Adaptive Region** condition enables you to change the mesh during the solution phase to improve precision without incurring a great deal of computational penalties. The Nonlinear Adaptive Region feature is completely automatic. It does not require any user input during the solution phase. It acts as a remesh controller based on certain criteria. The criteria determine whether or not the mesh requires modification and, if so, which parts need to be modified. This feature is based on load stepping, requiring you to define a number of steps for your analysis, while also allowing you to activate and/or deactivate the feature on a per step basis.

This condition may be useful for nonlinear problems that experience convergence difficulties or accuracy issues because of elemental distortions. Large deformation problems are best suited to the use of the condition. However, it is also useful for cases where large deformation is small but requires mesh adaptation to better capture the physics and give a more accurate solution. Review the Nonlinear Mesh Adaptivity Usage Considerations section of the *Nonlinear Adaptivity Analysis Guide* for more information about analysis cases when the feature can be useful.

Requirements

The **Nonlinear Adaptive Region** condition requires the **Store Results At** property to be set to **All Time Points** in the **Output Controls** category of the **Analysis Settings**.

Preprocessing Support Limitations

Note the following preprocessing limitations for this condition.

- When there is a hexahedral mesh for a multibody part, the Nonlinear Adaptive Region can only be scoped to a single body.
- The Nonlinear Adaptive Region is not supported if your model is a multibody part or multibody assembly with a mixture of linear and quadratic elements.
- It is not supported for Convergence.
- Cannot be used in combination with the following features/conditions on the same part:
  - Cyclic Symmetry
  - Beam Contact Formulation
  - Contact Behaviors: Auto Asymmetric
  - Point Mass, Beam Connection, Joints, Spring, and Bearing
  - Spatially varying boundary conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Not supported if the analysis includes a Pressure or an Imported Pressure that have the following combination of settings:
  - **Applied By** property set to **Direct** option.
  - **Loaded Area** property set to **Initial**.
  - **Large Deflection** property (Analysis Settings > Solver Controls) set to **On**.
- Cannot be used in combination with the following boundary conditions:
  - Coupling
  - Constraint Equation
  - Remote Displacement, Remote Force, and Moment specified with the **Behavior** property set to **Beam**.
- Cannot be used in combination with Weak Springs (p. 1433) (COMBIN14 element).
- The following materials properties are not supported:
  - Cast Iron
  - Concrete
  - Cohesive Zone
  - Damage Initiation Criteria and Damage Evolution Law
  - Microplane
  - Shape Memory Alloy
  - Swelling
- When linking analyses, you cannot apply the solution phase modified mesh to the linked system.
- When using the **Nonlinear Adaptive Region** during the restart of an analysis, the **Nonlinear Adaptive Region** object does not support Named Selections if your model contains a mesh change prior to the restart point.
- If your analysis failed to converge and you are adding a new **Nonlinear Adaptive Region** object, it is necessary that the contact object property, **Behavior**, was set to either **Symmetric** or **Asymmetric** for the initial solution that was processed.
- When the **Mesh** option is specified for the **Criterion** property:
  - does not support high order elements for 2D analyses.
  - does not support self-contact for 3D analyses.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Post Processing Support Limitations

Because this condition causes mesh changes during the course of the solution process, there are result scoping limitations.

- Only **Body** scoping is permitted (for bodies whose meshes will change). Therefore, if you scope any result or probe on a vertex, edge, or face of a body that experiences a mesh change, the analysis will not solve. This limitation is a result of the base mesh of the body being represented by nodes only. This limitation also applies to probes scoped to boundary conditions (via **Location Method** property).
- Element selection on a result is not supported. However, if you 1) have an element-based named selection and 2) activate the **Preserve During Solve** property, you can specify results for the named selection using the **Solver Component Names** option of the Solution Quantities and Result Summary (p. 1961) page of the **Worksheet** (accessed via the Solution object).
- If you have a result object selected, certain mesh-based features are not available, including mesh selection filters (nodes (p. 269), elements, and element faces (p. 276)), as well as the ability to display a Node ID in the probe label (p. 206), and Selecting Nodes and Elements by ID (p. 279).
- Does not support the multiple result set options (p. 1990) of the **By** property: **Maximum Over Time**/**Time of Maximum** or **Minimum Over Time**/**Time of Minimum**.
- Penetration plot following remesh may show the curve discontinuity.
- Is not supported when transferring the deformed geometry (p. 1022) and mesh of a **Deformation** result.
- When using the Deformation result tracker (p. 1847) to graph displacement, note there is a display limitation for the graph. The tracker reads and displays data contained in the `jobname.nlh` file. This file contains incremental displacement data collected after re-meshing occurs. That is, the re-meshed model is considered as a new reference.

Analysis Types

Nonlinear Adaptive Region is available for Static Structural (p. 652) analyses.

For additive manufacturing Inherent Strain simulations, a special case of nonlinear mesh adaptivity is available in which simulation time is reduced by *coarsening* elements in previously deposited layers, thereby reducing the total number of elements. See Using Adaptive Meshing (AM Octree) for details.

Common Characteristics

The following section outlines the common characteristics that include application requirements of the condition, support limitations, as well as loading definitions and values.

Dimensional Types

- 3D Simulation: *Supported*.
- 2D Simulation: *Supported*.

Geometry Types: Geometry types supported for the **Nonlinear Adaptive Region** condition include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Solid: *Supported*.
- Surface/Shell: **Not Supported**.
- Wire Body/Line Body/Beam: **Not Supported**.

Topology: The following topology selection options are supported for **Nonlinear Adaptive Region**.

- Body: *Supported*.
- Face: **Not Supported**.
- Edge: **Not Supported**.
- Vertex: **Not Supported**.
- Nodes: **Not Supported**.
- Element Face: **Not Supported**.
- Elements: *Supported* for element-based Named Selections only.

Note:

– Elements must be of the same element type, material, nodal orientation, and element orientation.

– If two regions with different element or material attributes require re-meshing, you must impose nonlinear adaptive regions separately.

– The application does not support mixed order Tetrahedral mesh elements defined on one region or when used with multiple regions.

Condition Application

To apply a **Nonlinear Adaptive Region**:

1. On the **Environment** Context tab: click **Conditions**>**Nonlinear Adaptive Region**. Or, right-click the **Environment** tree object or in the **Geometry** window and select **Insert**>**Nonlinear Adaptive Region**.
2. Specify the **Scoping Method**.

Note:

You can scope multiple Nonlinear Adaptive Regions to the same entity to give yourself more control on multiple load step settings that are local to the Nonlinear Adaptive Region condition.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Specify the **Criterion** property: options include **Energy**, **Box**, and **Mesh**. The **Mesh** option is the recommended setting.

   Following your selection, properly specify the associated properties.

   Note:

   Once you select an option for the Criteria property, the **Analysis Settings** category Nonlinear Adaptivity Remeshing Controls (p. 1440) becomes available and you may modify the available properties as needed.

4. When the condition is defined, the **Graph** and **Tabular Data** windows provide a right-mouse click option to **Deactivate** (or **Activate**) the condition for a desired load step. No remeshing will occur at the deactivated load step as the NLADAPTIVE command is set to OFF. The default setting is **Activated**. For a restart analysis, the application sets the newly added **Nonlinear Adaptive Region** to **Deactivated**.

   Note:

   You may wish to review the **Activation/Deactivation of Loads** topic in the Step Controls (p. 1418) section of the Help. The **Nonlinear Adaptive Region** condition is displayed in the graph for the **Analysis Settings** object.

Details View Properties

The selections available in the Details view are described below.

Category	Properties/Options/Description
Scope	**Scoping Method**, options include: • **Geometry Selection**: Default setting, indicating that the condition is applied to a geometry or geometries, which are chosen using a graphical selection tools. – **Geometry**: Visible when the **Scoping Method** property is set to **Geometry Selection**. Displays the type of geometry (Body) and the number of geometric entities (1 Body, 2 Bodies) to which the condition has been applied using the selection tools.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Category	Properties/Options/Description
	• **Named Selection**: Indicates that the geometry selection is defined by a **Named Selection**. – **Named Selection**: Visible when the **Scoping Method** property is set to **Named Selection**. This field provides a drop-down list of available user-defined element-based (only) Named Selections. You may wish to review the **Mechanical APDL References and Notes** at the bottom of the page for specific command execution information regarding these selections.
Definition	**Criterion**: Options included **Energy**, **Box**, or **Mesh**. **Energy** If **Energy** is selected, you need to enter an **Energy Coefficient**. **Energy Coefficient**: This criterion checks the strain energy of any element that is part of the defined component using the following calculation. A component is defined as the assembly of all scoped elements. $E_e \geq c_1 \cdot E_{Total} / NUME$ where: • E_e = strain energy of single target element. • c_1 = user input energy coefficient. • E_{total} = total strain energy of the component. • NUME = number of elements of the component. If this criterion is satisfied at an element, the program refines the element. A smaller **Energy Coefficient** improves the potential to trigger the mesh regeneration for the same loads. **Box** If **Box** is selected, the following additional properties require entries: • **Coordinate System** (default is **Global Coordinate System**): defines the minimum values of the box. • **Length X**: defines the diagonal length on global X axis. • **Length Y**: defines the diagonal length on global Y axis. • **Length Z** (for 3D): defines the diagonal length on global Z axis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Category	Properties/Options/Description
	Mesh (3D Analysis) For 3D analyses, if you select the **Mesh** option, the **Tetrahedral** and **Hex-Dominant** categories display. **Tetrahedral** The **Options** property displays. Available options include **Skewness**, **Jacobian Ratio**, or **Skewness and Jacobian Ratio** (default. If the **Options** property is set to either **Skewness** or **Skewness and Jacobian Ratio**, you need to enter a **Skewness Value** for the mesh elements. The element skewness is defined as: Skewness = $(V_{reg} - V_{el}) / V_{reg}$ Where: V_{el} is the volume of the element under calculation and V_{reg} is the volume of the standard tetrahedral linear element located in the same sphere as the element under calculation. When the element under calculation has an ideal shape (that of a standard tetrahedral element), $V_{reg} = V_{el}$ and **Skewness Value** = 0. When the element under calculation has the least ideal shape (that of a flat element), $V_{el} = 0$ and **Skewness Value** = 1. Therefore, for the linear tetrahedral element, **Skewness Value** is always between 0 and 1, with 1 being a flat element. The default value is **0.9**. The recommended **Skewness Value** is approximately **0.85** to **0.9**. When the **Option** property is set to **Jacobian Ratio** or **Skewness and Jacobian Ratio**, you need to enter a **Jacobian Ratio Value** for the mesh elements. This value defines the maximum Jacobian ratio at element integration points. The default value is **`0.1`**. **Hex-Dominant** If the body selected in the scoping includes hexahedral mesh, then this category and its properties are applicable to solution processing. The application uses an initial hexahedral-dominant mesh which is converted to a tetrahedral mesh during the solution process once the category's criterion is met. For a tetrahedral only mesh, application ignores this category and its properties. For this category: • The **Options** property is read-only and the application sets it to **Shape**. • The **Maximum Corner Angle** property has the default setting of **`155°`**. The entry range for this property is **`0°`** - **`180°`**. An

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Category	Properties/Options/Description
	element is re-meshed when any of its corner angles reach this specified value. **Mesh (2D Analysis)** For 2D analyses: • The **Options** property is read-only and the application sets it to **Shape**. • The **Maximum Corner Angle** property has the default setting of **160°** (recommended). The entry range for this property is **0°** - **180°**. An element is re-meshed when any of its corner angles reach this specified value. All the following common criteria properties are available for all **Criterion** property options as well as 2D analyses: • **Check At**: Options included **Equally Spaced Points** or **Specified Recurrence Rate**. • **Value**: This property further defines the **Check At** property. The default value is **1**. • **Time Range**: options included **Entire Load Step** or **Manual**. When specified as **Manual**, you need to enter a **Start Time** and **End Time**. The **End Time** value must be larger than the **Start Time** value. **Suppressed**: Include (**No** - default) or exclude (**Yes**) the condition.

Initial Mesh Load Specifications

You can apply the following boundary conditions directly to the initial mesh generated for each load step rather than on the newly generated mesh only by setting the object's **Apply To Initial Mesh** property to **Yes**.

- Imported Displacement (p. 1746)
- Imported Body Temperature (p. 1740)
- Imported Pressure (p. 1752)

For more information, see the Initial-Mesh Loading and Constraint section in the *Nonlinear Adaptivity Analysis Guide* of the Mechanical APDL documentation.

View Changed Mesh Results

Following the solution process, to determine if the mesh was changed:

- Select the **Solution** object or a **Result** object, the **Tabular Data** window displays the substeps with a changed mesh (**Changed Mesh** column = **Yes**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Select the **Solution Information** object and set the **Solution Output** property to **Force Convergence**. A chart displays. Remesh Points are shown by solid orange vertical lines.
- Create a **User Defined Result** (p. 2194) (using the **PNUMELEM** Expression) to view the new elements that have relatively larger element identities than the original element identities. You can duplicate this result and specify a **Result Set** (**By** property) for a result prior to a remesh and one at a remesh point, and using the **Viewports** (p. 284) feature, directly compare the (before and after) elements in the graphics window.

Mechanical APDL References and Notes

The following Mechanical APDL commands, element types, and considerations are applicable for this condition.

- The **Nonlinear Adaptive Region** is applied with the **NLADAPTIVE** command.
- When the **Scoping** property is defined as **Geometry**, the **Nonlinear Adaptive Region** condition uses the **CM** command to create the **Nonlinear Adaptive Region** component.
- When the **Scoping** property is defined as a **Named Selection**, the **Nonlinear Adaptive Region** condition uses the **CMBLOCK** command to create the **Nonlinear Adaptive Region** component.
- The **CMSEL**,**ALL** command and the **ESEL**,**ALL** command are issued at beginning of the **NLADAPTIVE** command.
- During a Structural Analysis, the **Nonlinear Adaptive Region** is applied using the PLANE182 (2-D Low Order), PLANE183 (2-D High Order), SOLID285 (3-D Linear Tetrahedral), and SOLID187 (3-D Quadratic Tetrahedral) element types.
- When a **Nonlinear Adaptive Region** is scoped to a body/element, the associated part is meshed with SOLID285 element type if they are linear tetrahedral or SOLID187 element type if they are quadratic tetrahedral.
- When a **Nonlinear Adaptive Region** is deactivated for certain steps, the **NLADAPTIVE** command is set to be **OFF** in the corresponding load steps. Relatively, an activated Nonlinear Adaptive Region sets the **NLADAPTIVE** command to be **ON**.
- When a **Nonlinear Adaptive Region** is applied, the **ETCONTROL ,SET** command is **not** issued.

Note:

For additional guidance about how to best use this feature, see the Mesh Nonlinear Adaptivity Hints and Recommendations section in the *Mechanical APDL Advanced Analysis Guide*.

Nonlinear Adaptive Region Solving Limitations

The purpose of nonlinear adaptive region is to repair a distorted mesh in order to overcome convergence problems caused by the distortion. It is effective only when the mesh distortion is caused by a large, nonuniform deformation. Nonlinear adaptive region cannot help if divergence occurs for any other reason such as unstable material, unstable structures, or numerical instabilities.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Unstable Material

Most nonlinear material models, especially those employing hyperelastic materials, have their own applicable ranges. When a deformation is too large or a stress state exceeds the applicable range, the material may become unstable. The instability can manifest itself as a mesh distortion, but nonlinear adaptive region cannot help in such cases. While it is sometimes difficult to determine when material is unstable, you can check the strain values, stress states, and convergence patterns. A sudden convergence difficulty could mean that material is no longer stable. The program also issues a warning at the beginning of the solution indicating when hyperelastic material could be unstable, although such a warning is very preliminary and applies only to cases involving simple stress states.

Unstable Structures

For some geometries and loads, a deformation may cause a "snap-through," or local buckling. Such behavior can also manifest itself as a mesh distortion, but one that nonlinear adaptive region cannot repair. The effect is usually easy to detect by closely checking the deformed region or the load-versus-time (displacement) curve.

Numerical Instabilities

A condition of numerical instability can occur when a problem is nearly overconstrained. The constraints can include kinematic constraints such as applied displacements, couplings, and constraint equations, and volumetric constraints introduced by fully incompressible material in mixed u-P elements. In many cases, numerical instability is apparent even in the early stages of an analysis.

Geometry Based Adaptivity

The **Geometry Based Adaptivity** condition enables you to model the boundary geometry accurately during mesh adaptivity by placing the new nodes and elements on the model boundary geometry during remeshing. This is different from conventional mesh adaptivity applied through the Nonlinear Adaptive Region (p. 360) object, where the new nodes and elements on the boundary are placed on the old mesh facets during remeshing. The use of this object cannot be combined with the use of the **Nonlinear Adaptive Region** feature. The application generates an error if both objects are present in an analysis.

Note:

Review the Nonlinear Mesh Adaptivity for Geometry-Preserving Adaptive Analysis (NLAD-GPAD) documentation in the *Mechanical APDL Nonlinear Adaptivity Analysis Guide* for more information.

Go to a section topic:

- Requirements (p. 370)

- Postprocessing Limitations (p. 371)
- Analysis Types (p. 372)
- Common Characteristics (p. 372)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Condition Application (p. 373)
- Details Properties (p. 374)

Requirements

The **Geometry Based Adaptivity** condition requires the **Large Deflection** property to be set to **Off** in the **Solver Controls** category of the **Analysis Settings**. As a result, the application specifies this condition as described in the **NLMESH** section of the *Mechanical APDL Command Reference*. Furthermore, you cannot create **Command (ADPL)** object entries that activate the **Large Deflection** property.

Refinement via general remeshing is supported with energy-based (**NLADAPTIVE,,,ENERGY**), or position-based (**NLADAPTIVE,,,BOX**) criteria only.

Note:

Refinement through splitting is not supported in **Geometry Based Adaptivity**.

The **Geometry Based Adaptivity** condition enables you to change the mesh during the solution phase to improve precision without incurring a great deal of computational penalties. The feature is completely automatic. It does not require any user input during the solution phase. It acts as a remesh controller based on certain criteria. The criteria determine whether or not the mesh requires modification and, if so, which parts need to be modified. This feature is based on load stepping, requiring you to define a number of steps for your analysis, while also allowing you to activate and/or deactivate the feature on a per step basis.

Review the Nonlinear Mesh Adaptivity for Geometry-Preserving Adaptive Analysis (NLAD-GPAD) section of the *Nonlinear Adaptivity Analysis Guide* for more information about analysis cases when the feature can be useful.

Modelling Limitations

Note the following preprocessing limitations for this condition.

- This condition only supports linear and quadratic tetrahedral elements (SOLID187 and SOLID285).
- The geometry-based adaptivity is not supported if your model is a multibody part or multibody assembly with a mixture of linear and quadratic elements.
- It does not supported the use of the Convergence object.
- Cannot be used in combination with the following features/conditions on the same part:
  - Cyclic Symmetry
  - Beam Contact Formulation
  - Contact Behaviors: Auto Asymmetric
  - Point Mass, Beam Connection, Joints, Spring, and Bearing
  - Spatially varying boundary conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Not supported if the analysis includes a Pressure or an Imported Pressure that have the following combination of settings:
  - **Applied By** property set to **Direct** option.
  - **Loaded Area** property set to **Initial**.
  - **Large Deflection** property (Analysis Settings > Solver Controls) set to **On**.
- Cannot be used in combination with the following boundary conditions:
  - Coupling
  - Constraint Equation
  - Remote Displacement, Remote Force, and Moment specified with the **Behavior** property set to **Beam**.
- Cannot be used in combination with Weak Springs (p. 1433) (COMBIN14 element).
- The following materials properties are not supported:
  - Cast Iron
  - Concrete
  - Cohesive Zone
  - Damage Initiation Criteria and Damage Evolution Law
  - Microplane
  - Shape Memory Alloy
  - Swelling
- When linking analyses, you cannot apply the solution phase modified mesh to the linked system.
- When using the **Geometry Based Adaptivity** during the restart of an analysis, the **Geometry Based Adaptivity** object does not support Named Selections if your model contains a mesh change prior to the restart point.
- If your analysis failed to converge and you are adding a new **Geometry Based Adaptivity** object, it is necessary that the contact object property, **Behavior**, was set to either **Symmetric** or **Asymmetric** for the initial solution that was processed.

Postprocessing Limitations

Because this condition causes mesh changes during the course of the solution process, there are result scoping limitations.

- Only **Body** scoping is permitted (for bodies whose meshes will change). Therefore, the evaluation of those results or probes will fail which will be scoped on a vertex, edge, or face of a

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

body that experiences a mesh change. This limitation also applies to probes scoped to boundary conditions (via **Location Method** property).

- Element selection on a result is not supported. However, if you 1) have an element-based named selection and 2) activate the **Preserve During Solve** property, you can specify results for the named selection using the **Solver Component Names** option of the Solution Quantities and Result Summary (p. 1961) page of the **Worksheet** (accessed via the Solution object).
- If you have a result object selected, certain mesh-based features are not available, including mesh selection filters (nodes (p. 269), elements, and element faces (p. 276)), as well as the ability to display a Node ID in the probe label (p. 206), and Selecting Nodes and Elements by ID (p. 279).
- Does not support the multiple result set options (p. 1990) of the **By** property: **Maximum Over Time**/**Time of Maximum** or **Minimum Over Time**/**Time of Minimum**.
- Penetration plot following remesh may show the curve discontinuity.
- Is not supported when transferring the deformed geometry (p. 1022) and mesh of a **Deformation** result.

Analysis Types

Geometry Based Adaptivity is available for Static Structural (p. 652) analyses.

Common Characteristics

The following section outlines the common characteristics that include application requirements of the condition, support limitations, as well as loading definitions and values.

Dimensional Types

- 3D Simulation: *Supported*.
- 2D Simulation: **Not Supported**.

Geometry Types: Geometry types supported for the **Geometry Based Adaptivity** condition include:

- Solid: *Supported*.
- Surface/Shell: **Not Supported**.
- Wire Body/Line Body/Beam: **Not Supported**.

Topology: The following topology selection options are supported for **Geometry Based Adaptivity**.

- Body: *Supported*.
- Face: **Not Supported**.
- Edge: **Not Supported**.
- Vertex: **Not Supported**.
- Nodes: **Not Supported**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Element Face: **Not Supported**.
- Elements: **Not Supported**.

Note:

- Elements must be of the same element type, material, nodal orientation, and element orientation.
- If two regions with different element or material attributes require re-meshing, you must impose geometry-based adaptivity regions separately.
- The application does not support mixed order Tetrahedral mesh elements defined on one region or when used with multiple regions.

Condition Application

To apply a **Geometry Based Adaptivity**:

1. On the **Environment** Context tab: click **Conditions**>**Geometry Based Adaptivity**. Or, right-click the **Environment** tree object or in the **Geometry** window and select **Insert**>**Geometry Based Adaptivity**.
2. Specify the **Scoping Method**.

   Note:

   You can scope multiple Geometry Based Adaptivity objects to the same entity to give yourself more control on multiple load step settings that are local to the Nonlinear Adaptive Region condition.

3. Specify the **Criterion** property: options include **Energy** and **Box**.

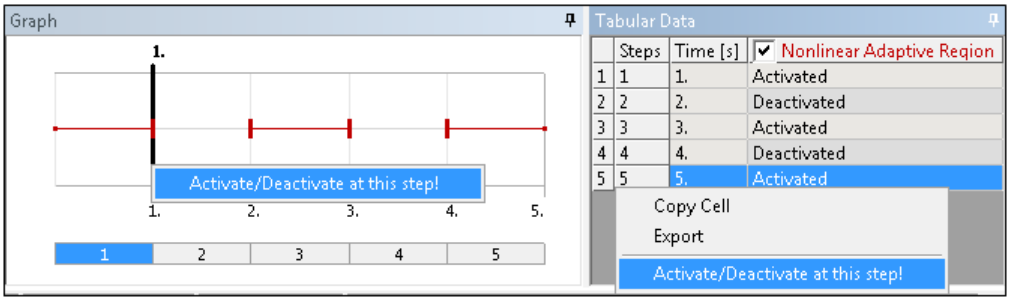
   Following your selection, properly specify the associated properties.

   Note:

   Once you select an option for the **Criteria** property, the **Analysis Settings** category Adaptivity Remeshing Controls (p. 1440) becomes available and you may modify the available properties as needed.

4. When the condition is defined, the **Graph** and **Tabular Data** windows provide a right-mouse click option to **Deactivate** (or **Activate**) the condition for a desired load step. No remeshing will occur at the deactivated load step as the NLADAPTIVE command is set to OFF. The default setting is **Activated**. For a restart analysis, the application sets the newly added **Geometry Based Adaptivity** to **Deactivated**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Note:

You may wish to review the **Activation/Deactivation of Loads** topic in the Step Controls (p. 1418) section of the Help. The **Geometry Based Adaptivity** condition is displayed in the graph for the **Analysis Settings** object.

Details Properties

The selections available in the Details are described below.

Category	Properties/Options/Description
Scope	**Scoping Method**, options include: • **Geometry Selection**: Default setting, indicating that the condition is applied to a geometry or geometries, which are chosen using a graphical selection tools. – **Geometry**: Visible when the **Scoping Method** property is set to **Geometry Selection**. Displays the type of geometry (Body) and the number of geometric entities (1 Body, 2 Bodies) to which the condition has been applied using the selection tools. • **Named Selection**: Indicates that the geometry selection is defined by a **Named Selection**. – **Named Selection**: Visible when the **Scoping Method** property is set to **Named Selection**. This field provides a drop-down list of available user-defined Named Selections. You may wish to review the **Mechanical APDL References and Notes** at the bottom of the page for specific command execution information regarding these selections.
Definition	**Criterion**: Options included **Energy** and **Box**. **Energy** If **Energy** is selected, you need to enter an **Energy Coefficient**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Category	Properties/Options/Description
	Energy Coefficient: This criterion checks the strain energy of any element that is part of the defined component using the following calculation. A component is defined as the assembly of all scoped elements. $E_e \geq c_1 \cdot E_{Total} / NUME$ where: • E_e = strain energy of single target element. • c_1 = user input energy coefficient. • E_{total} = total strain energy of the component. • NUME = number of elements of the component. If this criterion is satisfied at an element, the program refines the element. A smaller **Energy Coefficient** improves the potential to trigger the mesh regeneration for the same loads. **Box** If **Box** is selected, the following additional properties require entries: • **Coordinate System** (default is **Global Coordinate System**): defines the minimum values of the box. • **Length X**: defines the diagonal length on global X axis. • **Length Y**: defines the diagonal length on global Y axis. • **Length Z** (for 3D): defines the diagonal length on global Z axis. All the following common criteria properties are available for all **Criterion** property options as well as 2D analyses: • **Check At**: Options included **Equally Spaced Points** or **Specified Recurrence Rate**. • **Value**: This property further defines the **Check At** property. The default value is **1**. • **Time Range**: options included **Entire Load Step** or **Manual**. When specified as **Manual**, you need to enter a **Start Time** and **End Time**. The **End Time** value must be larger than the **Start Time** value. **Suppressed**: Include (**No** - default) or exclude (**Yes**) the condition.

Mechanical APDL References and Notes

For additional guidance for how to use this feature, see the NLAD-GPAD Best Practices section of the *Mechanical APDL Nonlinear Adaptivity Analysis Guide*.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Initial Mesh Load Specifications

You can apply the following boundary conditions directly to the initial mesh generated for each load step rather than on the newly generated mesh only by setting the object's **Apply To Initial Mesh** property to **Yes**.

- Imported Displacement (p. 1746)
- Imported Body Temperature (p. 1740)
- Imported Pressure (p. 1752)

For more information, see the Initial-Mesh Loading and Constraint section in the *Nonlinear Adaptivity Analysis Guide* of the Mechanical APDL documentation.

View Changed Mesh Results

Following the solution process, to determine if the mesh was changed:

- Select the **Solution** object or a **Result** object, the **Tabular Data** window displays the substeps with a changed mesh (**Changed Mesh** column = **Yes**).
- Select the **Solution Information** object and set the **Solution Output** property to **Force Convergence**. A chart displays. Remesh Points are shown by solid orange vertical lines.
- Create a **User Defined Result** (p. 2194) (using the **PNUMELEM** Expression) to view the new elements that have relatively larger element identities than the original element identities. You can duplicate this result and specify a **Result Set** (**By** property) for a result prior to a remesh and one at a remesh point, and using the **Viewports** (p. 284) feature, directly compare the (before and after) elements in the graphics window.

Coupled Field Analysis Types

Introduction

The Coupled Field analyses in Mechanical enable you to simulate interaction between multiple physics types. The availability of analysis settings, boundary conditions, results, etc. is based on the specified physics as well as the analysis type you select. For example, if you specify a Coupled Field Static analysis, all common features are available for structural physics, such as Force, Deformation, etc. Supported physics configurations include:

	Coupled Field Harmonic	Coupled Field Modal	Coupled Field Static	Coupled Field Transient
Structural	✓	✓	✓	✓
Acoustics	✓	✓	✓	✓
Electric	✓[a]	✓[a]	✓[b]	✓[b]
Thermal			✓	✓

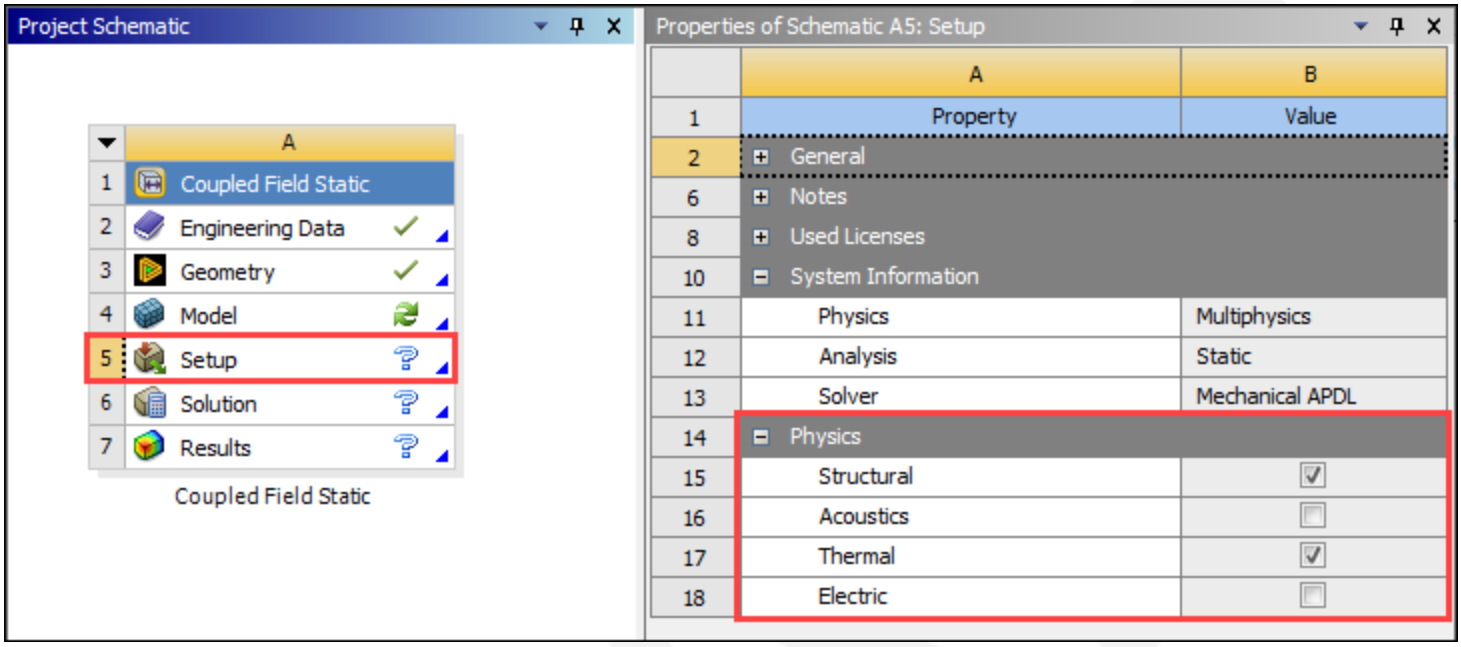
[a] Supports charge-based formulation only.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

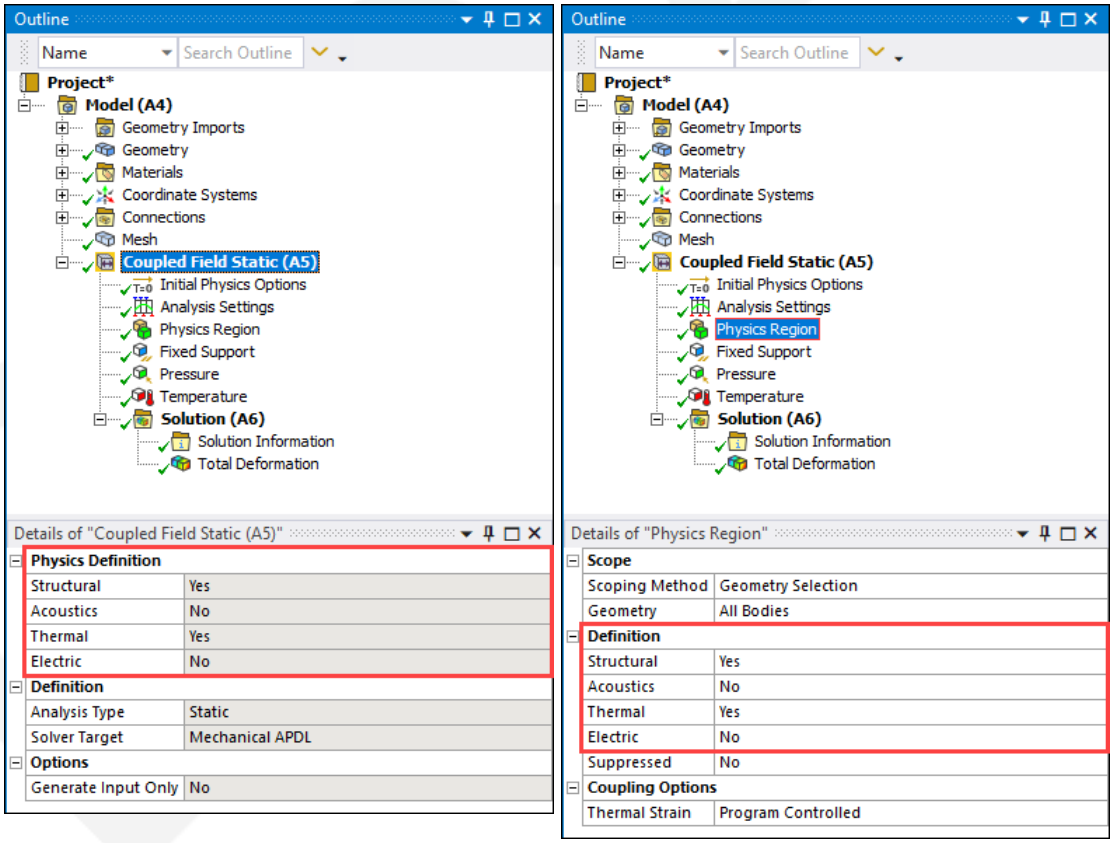
Published: 2023-10-23

[b] Supports charge-based and current-based formulation.

You can view the physics specified for your Coupled Field analysis from the properties of the **Setup** cell in Workbench.



And, in Mechanical, you can view the selected physics from the Environment object, and you can view and change the physics definition using the Physics Region object.



Coupling

The following table shows the interaction between the types of physics available in the application and the analysis types. You specify the interaction between the physics types and the analyses using either the 1) **Physics Region**, such as Thermal Strain, or through 2) coupling conditions, such as Plastic heating, or 3) the application always includes Piezoelectric coupling via Structural-Electric charge interaction.

Physics	Coupled Field Harmonic	Coupled Field Modal	Coupled Field Static	Coupled Field Transient
Structural Thermal	Not Supported		Thermal strain Thermoplasticity Thermoviscoelasticity	Thermal strain Thermoelastic Damping Thermoplasticity Thermoviscoelasticity
Electrostatic Structural	Electrostatic Force[a]	Electrostatic Force[a]	Electrostatic Force	Electrostatic Force
Structural-Acoustics	Fluid Solid Interface	Fluid Solid Interface	Fluid Solid Interface	Fluid Solid Interface
Structural Electric (Charge)	Piezoelectric	Piezoelectric	Piezoelectric	Piezoelectric
Thermal Electric (Conduction)			Joule Heating Seebeck Peltier	Joule Heating Seebeck Peltier

[a] Requires prestress Coupled Field Static.

Important:

The **Element Control** property of the Geometry object is, by default, set to **Program Controlled**. This setting allows the application to choose the best Mechanical APDL element options (KEYOPTS). For example, if your coupled field analysis includes nonlinearities, the application could automatically (and without your knowledge):

- Change the structural-thermal coupling from **Strong** to **Weak**.
- Specify that all coupling types use a uniform reduced integration scheme instead of Full Integration (as defined by the Brick Integration Scheme (p. 857) property of Part/Body objects).

As a result, to make sure that the application does not automatically change the element options, use the **Manual** setting for the **Element Control** property.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

See the Automatic Selection of Element Technologies and Formulations section of the Mechanical APDL Element Reference for more information.

Note:

- The **Physics Region** supports the activation of more than two physics types and therefore, coupling. In this case, there is a cumulative effect for each individual physics interaction with the other supported physics.
- If a body has more than two physics associated with its scoping, the interaction of the physics types is a combination of two different physics interactions.
- You can set the **Thermal Strain** property, of **Physics Region** object, to **Strong** (Matrix) coupling or **Weak** (Load Vector) coupling. Review the Coupled Effects section of the Coupling documentation in the *Mechanical APDL Theory Reference* for more background information.
- You can specify Thermoplasticity and Thermoviscoelasticity using the Plastic Heating (p. 1715) and Viscoelastic Heating (p. 1717) coupling conditions. Review the Thermoplasticity and Thermoviscoelasticity sections of the Coupling documentation in the *Mechanical APDL Theory Reference* for more background information.
- Joule Heating is considered as a load vector. Review the Thermoelectrics section of the Coupling documentation in the *Mechanical APDL Theory Reference* for more background information.
- For Piezoelectric coupling, the Piezoelectric matrix must be defined in the Engineering Data Workspace. You may want to review the Piezoelectrics section of the Coupling documentation in the *Mechanical APDL Theory Reference* for more background information.
- Currently, linear elements generated by the application use element SOLID226 (a high-order element) with the mid-side nodes dropped, **except** for structural-thermal analyses. For structural-thermal analyses, the application uses element SOLID225.

Coupled Field Harmonic Analysis

This analysis enables you to simulate the following physics types, independently or in combination, in a harmonic environment:

- Stand-alone Acoustics physics
- Piezoelectric Coupling
- Coupling of Structural and Acoustics physics
- Piezoelectric coupling with Acoustics physics

Note:

Piezoelectric analyses couple structural and electric physics with materials that have natural properties, such as quartz and ceramics.

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Points to Remember

- You can use an upstream Coupled Field Static (p. 391) analysis to prestress a Coupled Field Harmonic (p. 382) analysis.
- When beginning the analysis, you need to properly define the Physics Region object(s). The **Physics Region** object(s):
  - Is automatically included.
  - Requires each body of the model to be specified by a physics.
  - Defines the physics of the entire system/analysis.
  - Specifies physics type per body as needed.
  - Needs to be scoped to at least one body with more than one physics type or to an acoustic body.

This section assumes that you have an understanding of the general workflow for performing a simulation. As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview of the workflow.

Define Physics Region(s)

For this analysis, the physics types available for the **Physics Region** object include:

- Structural
- Acoustics

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Electric (Charge)

When **Structural** property is set to **Yes** and **Electric** property is set to **Charge**, the **Coupling Option** category, that includes the **Piezoelectric** property displays and indicates that the region is a piezoelectric region (read-only setting of **Yes**).

You can add **Physics Region** objects as desired by:

1. Highlighting the **Environment** object and selecting the **Physics Region** option on the Environment Context Tab (p. 61) or right-click the Environment object or within the **Geometry** window and select **Insert** > **Physics Region**.

2. Define all of the properties for the new object.

For additional information, see the Physics Region object reference section.

Specify Analysis Settings

The analysis type supports the following Analysis Settings (p. 1417):

- **Options** (p. 1447)
- **Advanced** (p. 1461)
- **Output Controls** (p. 1473)
- **Analysis Data Management** (p. 1484)

Apply Loads and Supports

The Environment Context tab (p. 61) provides the various groups of loads, supports, and conditions. In addition, the following **Electric** loads and boundary conditions are specific to **Coupled Field Harmonic** analysis:

- **Electric Charge** (p. 1625)
- **Voltage** (p. 1627) (Supports Phase Angle using Beta Options)
- **Voltage (Ground)** (p. 1633)
- **Voltage Coupling** (p. 1700)

See the Boundary Conditions (p. 1500) section for additional information.

Results

Note that for many results, the default setting for geometry selection is either **All Structural Bodies**, **All Acoustic Bodies**, or **All Electric Bodies**, depending on the given result type.

When you select the Solution (p. 62) Context tab, it provides the common result options as well as **Electric** (p. 2162) results. The Electric result drop-down menu contains the following results that are specific to this analysis:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Total Electric Flux Density**
- **Directional Electric Flux Density**

In addition, the Probes (p. 2163) drop-down menu includes **Charge Reaction** and **Impedance** probes and the Frequency Response (p. 2164) drop-down menu includes **Voltage**, **Charge Reaction**, and **Impedance** chart options. These result options are unique to this analysis type.

See the Using Results (p. 1927) section for more information.

Prestressed Coupled Field Harmonic Analysis

Mechanical enables you to specify an upstream Coupled Field Static (p. 391) analysis whose effects are used to perform a downstream Coupled Field Harmonic analysis. The supported physics combinations include:

- Coupling of Structural and Acoustics physics
- Piezoelectric Coupling
- Piezoelectric coupling with Acoustics physics
- Coupling of Electrostatic and Structural physics
- Electrostatic Structural coupling with Acoustics physics
- Electrostatic Structural coupling with Piezoelectric coupling

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Points to Remember

- To perform a prestressed Coupled Field Harmonic analysis you need to first perform a Coupled Field Static (p. 391) analysis, and properly link it to the downstream coupled field analysis.
- When beginning the analysis, you need to properly define the Physics Region object(s). The **Physics Region** object(s):
  - Is automatically included.
  - Requires each body of the model to be specified by a physics.
  - Defines the physics of the entire system/analysis.
  - Specifies physics type per body as needed.
  - Needs to be scoped to at least one body with more than one physics type or to an acoustic body.
- Any change to the physics settings in the upstream analysis will be automatically reflected in the downstream analysis

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- The **Thermal** physics type is not supported. If this physics type is active in the upstream analysis, the downstream analysis will be invalid.

This section assumes that you have an understanding of the general workflow for performing a simulation. As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview of the workflow.

Create Analysis System

Because this analysis is linked to (and based on) structural responses, a **Coupled Field Static** analysis is a prerequisite. This setup enables the two analysis systems to share resources, such as Engineering Data, Geometry, and the boundary condition type definitions that are defined the in the structural analysis.

From the **Toolbox**, drag a **Coupled Field Static** template to the Project Schematic. Then, drag a **Coupled Field Harmonic** template directly onto the **Solution** cell of the structural template.

Tip:

You can create a pre-stress environment in a **Coupled Field Harmonic** system that is already open in Mechanical by:

1. Selecting the **Coupled Field Static** option from the **Analysis** drop-down menu on the **Home** (p. 40) (or displayed) tab.
2. Setting the **Pre-Stress Environment** property (of the **Pre-Stress** object) to the **Coupled Field Static** system.

Specify Analysis Settings

The downstream Coupled Field Harmonic analysis supports the following Analysis Settings (p. 1417):

- **Options** (p. 1447)
- **Rotordynamics Controls** (p. 1490)
- **Advanced** (p. 1461)
- **Output Controls** (p. 1473)
- **Damping Controls** (p. 1462)
- **Analysis Data Management** (p. 1484)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Define Initial Conditions

The Pre-Stress object of the **Coupled Field Harmonic** analysis must point to the linked **Coupled Field Static** analysis.

Note:

- All structural loads, including Inertial (p. 1500) loads, such as Acceleration and Rotational Velocity, are deleted from the Harmonic analysis portion of the simulation once the loads are applied as initial conditions (p. 349). This is a result of the **Load Control** property of the Pre-Stress object being set (by default) to the **Keep All Displacements as Zero**. You can modify this to property to control load generation. See the description of the **Load Control** property in the Pre-Stress object reference for more information. Also see the Mechanical APDL command **PERTURB,HARM,,,DZEROKEEP** for more details.
- For **Pressure** boundary conditions in the Static Structural analysis: if you define the load with the **Normal To** option for faces (3D) or edges (2-D), you could experience an additional stiffness contribution called the "pressure load stiffness" effect. The **Normal To** option causes the pressure acts as a follower load, which means that it continues to act in a direction normal to the scoped entity even as the structure deforms. **Pressure** loads defined with the **Components** or **Vector** options act in a constant direction even as the structure deforms. For a same magnitude, the "normal to" pressure and the component/vector pressure can result in significantly different results in the follow-on Full-Harmonic Analysis. See the Pressure Load Stiffness (p. 353) topic in the Applying Pre-Stress Effects for Implicit Analysis (p. 352) Help Section for more information about using a pre-stressed environment.
- If displacement loading is defined with **Displacement**, **Remote Displacement**, **Nodal Displacement**, or **Bolt Pretension** (specified as **Lock**, **Adjustment**, or **Increment**) loads in the Static Structural analysis, these loads become fixed boundary conditions for the Harmonic solution. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution. If you define a **Nodal Displacement** in the Harmonic analysis at the same location and in the same direction as in the Structural Static analysis, it overwrites the previous loading condition and/or boundary condition in the Harmonic solution.
- If a voltage is defined in the Coupled Field Static analysis, all non-zero voltages are set to zero for the Harmonic solution. If you define voltage at the same location in the Harmonic solution, the previous loading is overwritten.

Apply Loads and Supports

The Environment Context tab (p. 61) provides the following for the prestressed Coupled Field Harmonic analysis:

Inertial	Acoustic Excitations
Acceleration (p. 1501) (Phase Angle is not supported.)	Mass Source Surface Velocity

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Acoustic Loads

- Temperature
- Impedance Sheet
- Static Pressure

Acoustic Boundary Conditions

- Pressure
- Impedance Boundary
- Absorption Surface
- Radiation Boundary
- Absorption Element
- Free Surface
- Thermo-Viscous BLI Boundary
- Rigid Wall
- Symmetry Plane
- Port
- Far-field Radiation Surface

Electric

- Voltage (p. 1627) (can be scoped to **Voltage Coupling** defined in upstream Coupled Field Static[a])
- Voltage (Ground) (p. 1633)
- Voltage Coupling (p. 1700)

- Diffuse Sound Field
- Incident Wave Source
- Port in Duct

Note:

Incident Wave Source and Port in Duct must use a Port defined in the Harmonic Acoustics analysis.

Direct FE

- Nodal Force (p. 1721)
- Nodal Pressure (p. 1724) (Phase Angle is not supported.)
- Nodal Displacement (p. 1728) - At least one non-zero Component is required for the boundary condition to be fully defined.

These load can only be scoped to node-based Named Selection and only support constant loading.

Note:

Any other boundary conditions must be defined in the prerequisite (parent) static Analysis, such as Support Type boundary conditions.

[a] If you apply a **Voltage** load, without the use of **Voltage Coupling** scoping option, to any of the geometries included in the **Voltage Coupling** condition defined in the upstream system, the entities will no longer be coupled and will be overwritten.

Results

See the Using Results (p. 1927) section for descriptions of all supported result types.

All results generally default to the corresponding physics setting, that is, **All Acoustic Bodies**, **All Structural Bodies**, or **All Electric Bodies**. You can individually scope most results to mesh or geometric entities on bodies.

Published: 2023-10-23

Coupled Field Modal Analysis

This analysis enables you to simulate the following physics types, independently or in combination, in a modal environment:

- Stand-alone Acoustics physics
- Coupling of Structural and Acoustics physics
- Piezoelectric Coupling
- Piezoelectric coupling with Acoustics physics

Note:

Piezoelectric analyses couple structural and electric physics with materials that have natural properties, such as quartz and ceramics.

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Points to Remember

- You can use an upstream Coupled Field Static (p. 391) analysis to prestress a Coupled Field Modal (p. 388) analysis.
- When beginning the analysis, you need to properly define the Physics Region object(s). The **Physics Region** object(s):
  - Is automatically included.
  - Requires each body of the model to be specified by a physics.
  - Defines the physics of the entire system/analysis.
  - Specifies physics type per body as needed.
  - Needs to be scoped to at least one body with more than one physics type or to an acoustic body.

This section assumes that you have an understanding of the general workflow for performing a simulation. As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview of the workflow.

Define Physics Region(s)

For this analysis, the physics types available for the **Physics Region** object include:

- Structural
- Acoustics

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Electric (Charge)

When **Structural** property is set to **Yes** and **Electric** property is set to **Charge**, the **Coupling Option** category, that includes the **Piezoelectric** property displays and indicates that the region is a piezoelectric region (read-only setting of **Yes**).

You can add **Physics Region** objects as desired by:

1. Highlighting the **Environment** object and selecting the **Physics Region** option on the Environment Context Tab (p. 61) or right-click the Environment object or within the **Geometry** window and select **Insert** > **Physics Region**.
2. Define all of the properties for the new object.

For additional information, see the Physics Region object reference section.

Specify Analysis Settings

The analysis type supports the following Analysis Settings (p. 1417):

- **Solver Controls** (p. 1428)
- **Rotordynamics Controls** (p. 1490)
- **Options** (p. 1447)
- **Advanced** (p. 1461)
- **Damping Controls** (p. 1462)
- **Output Controls** (p. 1473)
- **Analysis Data Management** (p. 1484)

Apply Loads and Supports

The Environment Context tab (p. 61) provides the various groups of loads, supports, and conditions. In addition, the following **Electric** loads and boundary conditions are specific to **Coupled Field Modal** analyses:

- **Voltage (Ground)** (p. 1633)
- **Voltage Coupling** (p. 1700)

See the Boundary Conditions (p. 1500) section for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Results

Note that for many results, the default setting for geometry selection is either **All Structural Bodies**, **All Acoustic Bodies**, or **All Electric Bodies**, depending on the given result type.

Important:

To evaluate the Electric Field Intensity or Electric Flux Density results, be sure that you set the properties that compute the elemental results (Stress, Strain, etc.) in the **Output Controls** of the **Analysis Settings** to **Yes**.

See the Using Results (p. 1927) section for more information.

Prestressed Coupled Field Modal Analysis

Mechanical enables you to specify an upstream Coupled Field Static (p. 391) analysis whose effects are to be used to perform a downstream Coupled Field Modal analysis. The supported physics combinations include:

- Coupling of Structural and Acoustics physics
- Piezoelectric Coupling
- Piezoelectric coupling with Acoustics physics
- Coupling of Electrostatic and Structural physics
- Electrostatic Structural coupling with Acoustics physics
- Electrostatic Structural coupling with Piezoelectric coupling

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Points to Remember

- To perform a prestressed **Coupled Field Modal** analysis you need to first perform a **Coupled Field Static** analysis, and properly link it to the downstream coupled field analysis.
- When beginning the analysis, you need to properly define the Physics Region object(s). The **Physics Region** object(s):
  - Is automatically included.
  - Requires each body of the model to be specified by a physics.
  - Defines the physics of the entire system/analysis.
  - Specifies physics type per body as needed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - Needs to be scoped to at least one body with more than one physics type or to an acoustic body.

- Any change to the physics settings in the upstream analysis will be automatically reflected in the downstream analysis
- The **Thermal** physics type is not supported. If this physics type is active in the upstream analysis, the downstream analysis will be invalid.

This section assumes that you have an understanding of the general workflow for performing a simulation. As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview of the workflow.

Create Analysis System

Because this analysis is linked to (and based on) structural responses, a **Coupled Field Static** analysis is a prerequisite. This setup enables the two analysis systems to share resources, such as Engineering Data, Geometry, and the boundary condition type definitions that are defined the in the structural analysis.

From the **Toolbox**, drag a **Coupled Field Static** template to the Project Schematic. Then, drag a **Coupled Field Modal** template directly onto the **Solution** cell of the structural template.

Tip:

You can create a pre-stress environment in a **Coupled Field Modal** system that is already open in Mechanical by:

1. Selecting the **Coupled Field Static** option from the **Analysis** drop-down menu on the **Home** (p. 40) (or displayed) tab.
2. Setting the **Pre-Stress Environment** property (of the **Pre-Stress** object) to the **Coupled Field Static** system.

Specify Analysis Settings

The downstream Coupled Field Modal analysis supports the following Analysis Settings (p. 1417):

- **Options** (p. 1447)
- **Solver Controls** (p. 1428)
- **Rotordynamics Controls** (p. 1490)
- **Advanced** (p. 1461)
- **Output Controls** (p. 1473)
- **Analysis Data Management** (p. 1484)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Define Initial Conditions

The Pre-Stress object of the Coupled Field Modal analysis must point to the upstream Coupled Field Static analysis.

Note:

- When you perform a pre-stressed Modal analysis, the support conditions from the static analysis are used in the Modal analysis. You cannot apply any new supports in the Modal analysis portion of a pre-stressed modal analysis. When you link your Modal analysis to a Structural analysis, all structural loading conditions, including Inertial loads, such as Acceleration and Rotational Velocity, are deleted from the Modal portion of the simulation. This is a result of the **Load Control** property of the Pre-Stress object being set (by default) to the **Keep All Displacements as Zero**. You can modify this to property to control load generation. See the description of the **Load Control** property in the Pre-Stress object reference for more information. Also see the Mechanical APDL command **PERTURB,MODAL,,,DZEROKEEP** for more details.
- For a Pressure (p. 1521) load in the Coupled Field Static analysis: if you define the load with the **Normal To** option for faces (3D) or edges (2-D), you could experience an additional stiffness contribution called the "pressure load stiffness" effect. The **Normal To** option causes the pressure to act as a follower load, which means that it continues to act in a direction normal to the scoped entity even as the structure deforms. **Pressure** loads defined with the **Components** or **Vector** options act in a constant direction even as the structure deforms. For the same magnitude, the "normal to" pressure and the component/vector pressure can result in significantly different modal results in the follow-on Modal Analysis. See the Pressure Load Stiffness (p. 353) topic in the Applying Pre-Stress Effects for Implicit Analysis (p. 352) section for more information about using a pre-stressed environment.
- If displacement loading is defined with either the Displacement (p. 1666), Remote Displacement (p. 1674), Nodal Displacement (p. 1728), or Bolt Pretension (p. 1566) (specified as a Lock, Adjustment, or Increment) in the Static Structural analysis, these loads become fixed boundary conditions for the Modal solution. If the Modal solution is followed by a Harmonic solution, these displacement loads become fixed boundary conditions for the Harmonic solution as well. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution.

Apply Loads and Supports

The Environment Context tab (p. 61) provides the following for the prestressed Coupled Field Modal analysis:

Acoustic Loads	Acoustic Boundary Conditions
Temperature	Pressure
Impedance Sheet	Impedance Boundary
	Absorption Surface

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Static Pressure	Radiation Boundary
	Absorption Element
	Free Surface
	Thermo-Viscous BLI Boundary
	Rigid Wall
	Symmetry Plane
	Port
	Far-field Radiation Surface

Any structural and/or electric support used in the Coupled Field Static analysis persists. Therefore, you are not allowed to add new support in the pre-stressed Coupled Field Modal analysis.

Results

See the Using Results (p. 1927) section for descriptions of all supported result types.

All results generally default to the corresponding physics setting, that is, **All Acoustic Bodies**, **All Structural Bodies**, or **All Electric Bodies**. You can individually scope most of the results to mesh or geometric entities on bodies.

Coupled Field Static Analysis

The Coupled Field Static analysis simulates the steady state interaction of different physics types (see below). This section assumes that you have an understanding of the general workflow for performing a simulation. See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-thermal solutions as well as some examples.

This analysis enables you to simulate the following physics types, independently or in combination, in a static environment:

- Coupling of Structural and Thermal physics
- Coupling of Structural and Acoustics physics
- Piezoelectric (charge-based) coupling
- Piezoelectric (charge-based) coupling with Acoustics physics
- Coupling of Thermal and Electric conduction physics
- Coupling of Structural and Thermoelectric conduction
- Stand-alone Electrostatic
- Coupling of Electrostatic and Structural physics
- Electrostatic Structural coupling with Acoustics physics

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Electrostatic Structural coupling with Piezoelectric coupling

Note:

Piezoelectric (charge-based) analyses couple structural and electric physics with materials that have natural properties, such as quartz and ceramics.

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Points to Remember

When beginning the analysis, you need to properly define the:

- The application automatically inserts an Initial Physics Options object in order to specify an initial and reference temperature for the analysis.
- To simulate the thermoviscoelasticity coupling effect, the **Viscoelastic Heating** condition (p. 1717) must be scoped to a body whose material assignment includes the Viscoelastic material properties **Prony Shear Relaxation** and **Prony Volumetric Relaxation**, as defined in Engineering Data.
- To simulate the thermoplasticity coupling effect, the **Plastic Heating** (p. 1715) condition object can be added and must be scoped to bodies whose material properties has the Plasticity effects
- When performing an Electrostatic Structural analysis:
  - Set the **Large Deflection** property (**Analysis Settings** > Solver Controls (p. 1428)) to **On**.
  - Specify your mesh using a single layer of low-order elements (no mid-side nodes) to avoid air mesh distortion. A quadrilateral mesh that collapses uniaxially typically works best.
- When you specify a **Physics Region** using only the **Electric** property, set to **Charge** (electrostatic elements), make sure that the material assigned to the scoped bodies includes relative permittivity definition.
- When your analysis includes electrostatic elements, the application automatically sets the electric charge reaction sign to negative. See the SOLID122 section (or PLANE121 and SOLID123) of the *Mechanical APDL Element Reference* for this KEYOPT setting.
- When performing a standalone Electrostatic analysis, the application automatically specifies the **Contact Region** object property, Small Sliding (p. 1244) as **No**. This applies to all contact conditions.

As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Recommendation for Contact Stiffness

When your analysis couples electrostatic and structural physics and a contact condition is defined, using the default setting (**Program Controlled**) for the **Formulation** property, and the bodies in contact have higher stiffness differences between them, Ansys recommends that you manually specify the **Normal Stiffness** property using the **Absolute Value** option. When selected, the **Normal Stiffness Value** property displays. You define the entry as follows:

Absolute Value = SMAX/(SC x D)

Where:

SMAX (Electrostatic Force per unit area) = (x V^2)/(2D^2)

V = Potential difference across the air gap.

D = Thickness of the air gap (minimum value).

= The absolute permittivity of the air gap.

SC (scale factor) = 1e-4 (refine for higher accuracy).

Review the description of the Normal Stiffness (p. 1249) property for additional information.

Define Initial Physics Options

Specify the temperature settings and values of the **Initial Physics Options** object. You use the **Initial Physics Options** object to specify the initial temperature and reference temperature of the parts/bodies specified as either Thermal or Structural (using the Physics Region object) during a Coupled Field Static (p. 391) analysis. For the Structural Settings, you specify a Reference Temperature. Typically for most other analysis types in Mechanical, you define a Reference Temperature from the Environment object.

Define Physics Region(s)

During a Coupled Field analysis, a **Physics Region** object is automatically included. All of the bodies of the model must have a physics type specified by a **Physics Region** object. You use this object to specify the geometry bodies that belong to the supported physics types. By default, the **Structural** and **Thermal** properties are set to **Yes**. The **Coupled Field Static** analysis provides the following physics types.

- **Structural**
- **Acoustics**
- **Thermal**: Note that when the **Structural** and **Thermal** properties are set to **Yes** (default settings), the **Coupling Options** category displays. This category includes the **Thermal Strain** property. You use this property to specify the thermoelasticity coupled effects included through the **Thermal Strain**. Options include **Program Controlled**, **Strong**, and **Weak**.
- **Electric**: The options for this property include **No**, **Charge**, and **Conduction**. Review the Physics Region object reference page for property descriptions.

You can add **Physics Region** objects as desired by:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

1. Highlighting the **Environment** object and selecting the **Physics Region** option on the Environment Context Tab (p. 61) or right-click the Environment object or within the **Geometry** window and select **Insert** > **Physics Region**.
2. Define all of the properties for the new object.

For additional information, see the Physics Region object reference section.

Specify Analysis Settings

The analysis type supports the following Analysis Settings:

- Step Controls (p. 1418)
- Solver Controls (p. 1428)
- Rotordynamics Controls (p. 1490)
- Restart Controls (p. 1438)
- Restart Analysis (p. 1437)
- Radiosity Controls (p. 1446)
- Nonlinear Controls (p. 1468)

> **Note:**
>
> To improve convergence for thermal-electric coupling, set the **Nonlinear Controls** property, **Line Search**, to the **On** setting.

- Output Controls (p. 1473)
- Analysis Data Management (p. 1484)
- Visibility (p. 1491)

Apply Loads and Supports

The Environment Context tab (p. 61) provides the various groups of loads, supports, and conditions, including various Acoustic loads and boundary conditions (p. 1520) and the following **Electric** loads and boundary conditions are specific to **Coupled Field Static** analyses:

- **Electric Charge** (p. 1625)
- **Voltage** (p. 1627) (Supports Phase Angle)
- **Voltage (Ground)** (p. 1633)
- **Current** (p. 1630)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

In addition, and depending upon physics definitions, the following Conditions (p. 1697) are specific to Coupled Field Static analyses:

- **Voltage Coupling** (p. 1700)
- **Plastic Heating** (p. 1715)
- **Viscoelastic Heating** (p. 1717)

See the Boundary Conditions (p. 1500) section for additional information.

Results

The Solution Context tab (p. 62) provides the various groups of result options. The analysis supports Structural (p. 2092), Thermal (p. 2155), and Electric (p. 2163) Probes. For many result objects, the default setting for geometry is either **All Structural**, **All Electric**, **All Acoustics** or **All Thermal Bodies**, depending on the given result type.

See the Using Results (p. 1927) section for more information.

Coupled Field Transient Analysis

This analysis enables you to simulate the following physics types, independently or in combination, in a transient environment:

- Coupling of Structural and Thermal physics
- Coupling of Structural and Acoustics physics
- Coupling of Thermal and Electric Conduction physics
- Coupling of Structural and Thermoelectric Conduction
- Stand-alone Acoustics physics
- Piezoelectric (charge-based) Coupling
- Piezoelectric coupling (charge-based) with Acoustics physics
- Coupling of Electrostatic and Structural physics
- Electrostatic Structural coupling with Acoustics physics
- Electrostatic Structural coupling with Piezoelectric coupling

Note:

Piezoelectric analyses couple structural and electric physics with materials that have natural properties, such as quartz and ceramics.

See the Application Examples and Background (p. 400) section for an overview of types of problems that use coupled structural-electric solutions as well as some examples. Also see the Acoustics Analysis Overview section for more detailed information about performing an acoustics analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Points to Remember

- The application automatically inserts an Initial Physics Options object for this analysis type.
- The **Physics Region** object(s):
  - Is automatically included.
  - Requires each body of the model to be specified by a physics.
  - Defines the physics of the entire system/analysis.
  - Specifies physics type per body as needed.
  - Needs to be scoped to at least one body with more than one physics type or to an acoustic body.
- To simulate the thermoviscoelasticity coupling effect, the **Viscoelastic Heating** condition (p. 1717) must be scoped to a body whose material assignment includes the Viscoelastic material properties **Prony Shear Relaxation** and **Prony Volumetric Relaxation**, as defined in Engineering Data.
- To simulate the thermoplasticity coupling effect, the **Plastic Heating** (p. 1715) condition object can be added and must be scoped to bodies whose material properties has the Plasticity effects
- When performing an Electrostatic Structural analysis:
  - Set the **Large Deflection** property (**Analysis Settings** > Solver Controls (p. 1428)) to **On**.
  - Specify your mesh using a single layer of low-order elements (no mid-side nodes) to avoid air mesh distortion. A quadrilateral mesh that collapses uniaxially typically works best.

As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the of general analysis workflow.

Recommendation for Contact Stiffness

When your analysis couples electrostatic and structural physics and a contact condition is defined, using the default setting (**Program Controlled**) for the **Formulation** property, and the bodies in contact have higher stiffness differences between them, Ansys recommends that you manually specify the **Normal Stiffness** property using the **Absolute Value** option. When selected, the **Normal Stiffness Value** property displays. You define the entry as follows:

Absolute Value = SMAX/(SC x D)

Where:

SMAX (Electrostatic Force per unit area) = (x V^2)/($2D^2$)

V = Potential difference across the air gap.

D = Thickness of the air gap (minimum value).

= The absolute permittivity of the air gap.

SC (scale factor) = 1e-4 (refine for higher accuracy).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Review the description of the Normal Stiffness (p. 1249) property for additional information.

Define Initial Physics Options

Specify the temperature settings and values of the **Initial Physics Options** object. You use the **Initial Physics Options** object to specify the initial temperature and reference temperature of the parts/bodies specified as either Thermal or Structural (using the Physics Region object) during a Coupled Field Transient (p. 395) analysis. For the thermal field, you specify an Initial Temperature as either Uniform or Non-Uniform (Transient only). For the Structural Setting, you specify a Reference Temperature. Typically for most other analysis types in Mechanical, you define a Reference Temperature from the Environment object.

Important:

Currently, the Coupled Field Transient analysis only supports the **Uniform Temperature** option for the **Initial Temperature** property. However, the **Non-Uniform Temperature** setting is available when Beta Options are active.

Specify Analysis Settings

The analysis type supports the following Analysis Settings:

- Step Controls (p. 1418) (see below)
- Solver Controls (p. 1428)
- Restart Controls (p. 1438)
- Radiosity Controls (p. 1446)
- Nonlinear Controls (p. 1468)

Note:

To improve convergence for thermal-electric coupling, set the **Nonlinear Controls** property, **Line Search**, to the **On** setting.

- Output Controls (p. 1473)
- Damping Controls (p. 1462)
- Analysis Data Management (p. 1484)
- Visibility (p. 1491)

For a **Coupled Field Transient** analysis when the **Time Integration** property is set to **On** (default), based on the active physics of the environment, the following additional properties display and enable you to specify whether to turn a physics field on or off:

- **Structural Only**: Options include **Off** and **On** (default).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Thermal Only**: Options include **Off** and **On** (default) .
- **Electric Only**: Options include **Off** and **On** (default). Supported only for **Electric (Conduction)** physics only.

Note:

For the **Acoustics** and **Electric (Charge)** physics properties, **Time Integration** property is automatically set to **On**.

Note:

For thermal-electric coupling and stand-alone acoustics physics, the application uses the Newmark Time integration method. For all other coupling and physics combinations, application uses the HHT time integration method. See the Transient analysis section of the Mechanical APDL Theory Reference for more information.

Define Physics Region(s)

During a Coupled Field analysis, a **Physics Region** object is automatically included. All of the bodies of the model must have a physics type specified by a **Physics Region** object. You use this object to specify the geometry bodies that belong to the supported physics types. By default, the **Structural** and **Thermal** properties are set to **Yes**.

The **Coupled Field Transient** analysis provides the following physics types.

- **Structural**
- **Acoustics**
- **Thermal**: Note that when the **Structural** and **Thermal** properties are set to **Yes** (default settings), the **Coupling Options** category displays. This category includes the following properties:
  - **Thermal Strain**. You use this property to specify the thermoelasticity coupled effects included through the thermal strain. Options include **Program Controlled** (default), **Strong**, and **Weak**.
  - **Thermoelastic Damping**: Either **On** or **Off** (default).
- **Electric**: The options for this property include **No**, **Charge**, and **Conduction**. Review the Physics Region object reference page for property descriptions.

You can add **Physics Region** objects as desired by:

1. Highlighting the **Environment** object and selecting the **Physics Region** option on the Environment Context Tab (p. 61) or right-click the Environment object or within the **Geometry** window and select **Insert** > **Physics Region**.
2. Define all of the properties for the new object.

For additional information, see the Physics Region object reference section.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Apply Loads and Supports

The Environment Context tab (p. 61) provides the various groups of loads, supports, and conditions, including various Acoustic loads and boundary conditions (p. 1520) and the following **Electric** loads and boundary conditions:

- **Electric Charge** (p. 1625)
- **Voltage** (p. 1627)
- **Voltage (Ground)** (p. 1633)
- **Current** (p. 1630)

In addition, and depending upon physics definitions, the following Conditions (p. 1697) are available:

- **Voltage Coupling** (p. 1700) (Electric)
- **Plastic Heating** (p. 1715) (Structural-Thermal)
- **Viscoelastic Heating** (p. 1717) (Structural-Thermal)

As needed, see the Boundary Conditions (p. 1497) section for additional information.

Results

The Solution Context tab (p. 62) provides the various groups of result options. The analysis supports Structural (p. 2092), Thermal (p. 2155), and Electric (p. 2163) Probes. For many result objects, the default setting for geometry is either **All Structural**, **All Electric**, **All Acoustics** or **All Thermal Bodies**, depending on the given result type.

See the Using Results (p. 1927) section for more information.

Limitations

General Limitations

Currently, Coupled Field analyses do not support the following features/capabilities:

- Fracture
- Solution Combination
- Fatigue Combination
- Fatigue Tool
- Condensed Parts
- General Axisymmetric Symmetry

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Analysis Type Limitations

Coupled Field Harmonic

The **Coupled Field Harmonic** analysis does not support the **MSUP** setting for the **Solution Method** property and cannot include an upstream pre-stress system.

Piezoelectric Analysis (Harmonic or Modal)

For a Piezoelectric analysis (Harmonic or Modal), any specifications in the Damping Controls (p. 1462) (**Analysis Settings**) do not contribute to the damping energy or associated losses. Instead, you need to specify damping in the Engineering Data workspace by defining the properties of the Material Dependent Damping group and/or **Damping Factors**.

Coupled Field Transient

The **Coupled Field Transient** analysis does not support the Mode-Superposition (MSUP) solution method. As a result, it cannot be linked to an upstream Coupled Field Modal analysis.

External Model Limitations

Note the following limitations associated with importing data from an **External Model** system:

- You can import structural and thermal data for **Coupled Field Static** and **Coupled Field Transient** analyses only.
- The lower-order 2D elements is not supported.

Boundary Condition Limitations

Boundary conditions cannot be imported from a Harmonic Response analysis to a Coupled Field Harmonic analysis.

And, when importing data from an External Data (p. 736) system, only the following imported loads (p. 1736) are supported:

- Imported Heat Flux
- Imported Temperature
- Imported Body Temperature (Imported Thermal Condition)

Application Examples and Background

Coupled Piezoelectric

You can employ piezoelectric solutions for problems such as:

- Direct piezoelectric effects for sensing technology and the converse effects for actuation technology.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Active noise control (ANC) and active vibration control (AVC) to minimize sound energy radiated by structures by using smart piezoelectric materials.
- Piezoelectric energy harvesting (PEH) to transform the kinetic energy of vibration and pressure into electric power.
- Non-destructive evaluation of structures looking at wave signatures, for example, diagnostic signs of construction defects by using piezoelectric materials as sensors and transducers.

Specific coupled structural-electrical engineering applications include:

- **Ultrasound Imaging**: Piezoelectric transducers are used in ultrasound imaging as a transmitter or receiver.
- **Oil and Gas Logging**: Piezoelectric transmitters and receivers are used extensively (in addition to acoustic-structural modeling) to ping the well casing and understand well integrity.
- **Underwater Sonar Application**: Piezoelectric material are used for wave generation and for receiving and interpreting the signals.
- **BAW/SAW Waveguides**: Piezoelectric waveguides are used to filter signals exploiting the resonance/antiresonance with applications in 5G technology.
- **Touchscreen Sensors**: Piezoelectric layers can act as pressure and force sensors. It can provide accurate, high-frequency, and rapid response. And it is widely used in industrial and aerospace applications.
- **Piezoelectric MEMS Microphones**: Piezoelectric microphones can provide large capacitance and it does not require bias voltage or backplate. It is also useful for prototyping microphones with unconventional geometries.
- **Piezoelectric Mass Sensor**: Piezoelectric devices are used for highly sensitive mass sensing by observing the shift in resonant frequencies.
- **Piezoelectric Gyroscopes**: Piezoelectric material induced vibrations in MEMS gyroscopes can be used for orientation measurements due to added Coriolis effect during rotation.
- **Piezoelectric Motors**: Ultra-sensitive piezoelectric linear and rotary motors can be used for nanometer scale precision on positioning with applications in various dynamic control applications.
- **Micro-Electro-Mechanical System (MEMS) Gyroscope**: As a part rotates, the Coriolis force will create an electrical current. MEMS gyroscopes are ultra-small, ultra-lightweight, and quick response.

Coupled Structural-Thermal

You can employ coupled structural-thermal solutions for problems such as:

- Large mechanical deformations where contact is established between surfaces late in the solution. These contact conditions form new heat flow pathways.
- Internal heat generation because of mechanical deformations.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Heat generation due to relative sliding between contacting surfaces.
- Thermal properties problems where materials are dependent on the mechanical solution and vice-versa.
- Fracture or delamination problems where the material or structure undergoes deformations that modify heat flow pathways.
- Nonlinear thermal boundary conditions where the non-linearity is dependent on the Mechanical solution.
- Pressure and gap cases that depend on contact thermal properties.

Specific coupled structural-thermal engineering applications include:

- **Brake Pad Heating**: Relative sliding between the disc and brake pads cause significant frictional heat generation.
- **Plastic Seals**: Large plastic deformation of seals cause temperatures to rise because of plastic heating. This may lead to relaxation in contact pressure. In addition, when subjected to cyclic pressure loads, the contact surfaces may generate frictional heating.
- **Arc Welding**: High temperature material deposition (through element birth) and subsequent cooling may lead to distortions in the final geometrical shape because of thermal expansion/contraction.
- **Friction Stir Welding**: The process relies on frictional heat generation between the tool and the workpiece, this necessitates using coupled thermal-structural analysis.
- **Cancerous Tissue Ablation**: RF waves are used for internal heat generation in cancerous cells leading to ablation. Coupled thermal-structural analysis may be utilized in addition to model this effect (in addition to element death).
- **Metal Forming**: Plastic heat generation in regions undergoing large plastic deformations may result in contraction/expansion leading to distortion of the final part.
- **Vibration Isolation Pads**: For high frequency applications there may be an increase in temperature due to viscoelastic heating in vibration isolation pads leading to change in material response and reduced fatigue life.
- **Threaded Connectors**: For high temperature applications local plastic heating near the threads and frictional heating can lead to increase increased temperature, causing reduced fatigue life because of thermomechanical fatigue.
- **High-frequency Resonators**: Thermoelastic damping may affect the harmonic response of the resonators, coupled field thermal-structural solutions allow for including this effect.
- **Hyperelastic Seal Fatigue**: For high frequency loading, viscoelastic heating may lead to changes in material behavior and also reduce fatigue life, coupled thermal-structural solutions allow for including this effect.
- **Thermal Barrier/Coating Ablation**: Surface heat generation at the coating surfaces (such as in ceramic thermal protection systems in space shuttle) causes the surface to ablate. Coupled

thermal-structural analysis may be utilized in addition to model this effect (in addition to element death).

Electric Analysis

Introduction

An electric analysis supports Steady-State Electric Conduction. Primarily, this analysis type is used to determine the electric potential in a conducting body created by the external application of voltage or current loads. From the solution, other results items are computed such as conduction currents, electric field, and joule heating.

An Electric Analysis supports single and multibody parts. Contact conditions are automatically established between parts. In addition, an analysis can be scoped as a single step or in multiple steps.

An Electric analysis computes Joule Heating (p. 2162) from the electric resistance and current in the conductor. This joule heating may be passed as a load to a Thermal analysis (p. 657) simulation using an Imported Load (p. 1736) if the Electric analysis Solution data is to be transferred to Thermal analysis. Similarly, an electric analysis can accept a Thermal Condition (p. 1740) from a thermal analysis to specify temperatures in the body for material property evaluation of temperature-dependent materials.

Points to Remember

A steady-state electric analysis may be either linear (constant material properties) or nonlinear (temperature dependent material properties). Additional details for scoping nonlinearities are described in the Nonlinear Controls (p. 1468) section.

Once an Electric Analysis is created, Voltage (p. 1627) and Current (p. 1630) loads can be applied to any conducting body. For material properties that are temperature dependent, a temperature distribution can be imported using the Thermal Condition (p. 1740) option.

In addition, equipotential surfaces can be created using the Coupling Condition (p. 1698) load option.

Preparing the Analysis

Create Analysis System

Published: 2023-10-23

Step Controls (p. 1418)

These properties are used to specify the end time of a step in a single or multiple step analysis.

Multiple steps are needed if you want to change load values, the solution settings, or the solution output frequency over specific steps. Typically you do not need to change the default values.

Output Controls (p. 1473)

These properties allow you to specify the time points at which results should be available for postprocessing. A multi-step analysis involves calculating solutions at several time points in the load history. However you may not be interested in all of the possible results items and writing all the results can make the result file size unwieldy. You can restrict the amount of output by requesting results only at certain time points or limit the results that go onto the results file at each time point.

Analysis Data Management (p. 1484)

Common **Analysis Data Management** properties are available for this analysis type.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

There is no initial condition specification for an Electric analysis.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are supported in a Steady-State Electric analysis:

- Voltage (p. 1627)
- Current (p. 1630)
- Coupling Condition (p. 1698) (Electric)
- Thermal Condition (p. 1594)

Solve

General *Basic general information about this topic (p. 355)*

Published: 2023-10-23

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the model during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Applicable results are all electric result types (p. 2162).

Once a solution is available, you can contour the results (p. 62) or animate the results (p. 2260) to review the responses of the model.

For the results of a multi-step analysis that has a solution at several time points, you can use probes (p. 1946) to display variations of a result item over the steps.

You may also wish to use the Charts (p. 1929) feature to plot multiple result quantities against time (steps). For example, you could compare current and joule heating. Charts can also be useful when comparing the results between two analysis branches of the same model.

Explicit Dynamics Analysis

Ansys Explicit Dynamics is a transient explicit dynamics Workbench application that can perform a variety of engineering simulations, including the modeling of nonlinear dynamic behavior of solids, fluids, gases and their interaction. Additionally, the LS-DYNA ACT extension is available to analyze a model using the LS-DYNA solver. Detailed information for running an Explicit Dynamics analysis can be found in the Explicit Dynamics Analysis Guide.

Fracture Analysis

Fracture analysis deals with the computation of fracture parameters that help you design within the limits of catastrophic failure of a structure. Fracture analysis assumes the presence of a crack in the structure. The fracture parameters computed are Stress Intensity Factors (SIFS), J-Integral (JINT), Energy Release Rates, Material Force, T-Stress and C*-Integral.

When a crack is associated with a SMART Crack Growth (p. 468) you can also compute Equivalent SIFS Range fracture results and time history results (Fracture Probes (p. 2127)) on any crack front node.

A Fracture analysis requires that you define a crack using an available crack definition. Since fracture parameter calculation requires knowledge of the mesh characteristics around the crack, the mesh must be generated before solving for fracture parameters. Fracture parameter computation is only applicable to Static Structural and Transient Structural analyses.

The following sections further describe the aspects of a Fracture Analysis as well as additional features available in the Fracture object of the application.

Fracture Analysis Workflows

Limitations of Fracture Analysis

Fracture Meshing

Cracks

SMART Crack Growth

Interface Delamination and Contact Debonding

Multi-Point Constraint (MPC) Contact for Fracture

Solving a Fracture Analysis

Extracting Fracture Results from a Result File

Additional topics include:

Fracture Results (p. 2066)

Fracture Probes (p. 2127) (Supported when a crack is associated with a SMART Crack Growth.)

Mechanical APDL References

See the *Fracture Analysis Guide* in the Mechanical APDL documentation for additional information about fracture analyses. You may also wish to review the Fracture Analysis Benchmarks section. This section provides a set of benchmark examples that you can use to evaluate fracture-analysis capabilities. The benchmark results are compared with results from reference calculations, handbook solutions, and experimental testing.

Fracture Analysis Workflows

A Fracture analysis can be performed in two stages:

1. Defining a crack and computing fracture parameters.

Fracture parameters help to design engineering structures within limits of catastrophic failure. You can define a crack and compute the needed fracture parameters using the following methods:

- Define Crack Location using the Semi-Elliptical Crack, Elliptical Crack, or Ring Crack Object (p. 408).
- Define an Arbitrary Crack using a Surface Body (p. 410).
- Imported Crack Mesh (Pre-Meshed Crack) (p. 412).

2. Analyze/study the crack growth.

You can study the crack growth phenomenon using the SMART Crack Growth (p. 468) object. This object provides the following crack growth options:

- **Fatigue**: Use this option to model structures subjected to cyclic loading. Fatigue crack growth model used is Paris' law.
- **Static**: For this option, crack growth modeling is based on selected fracture parameters (SIFS or J-Integral) and criteria.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

For additional technical information, refer to the Understanding Crack-Growth Mechanics section in the *Mechanical APDL Fracture Analysis Guide*.

This section describes the typical workflow for computing fracture parameters in the static structural analysis that contains cracks. The typical workflows are shown below:

Note:

For all workflows, the static structural analysis supports imported thermal loads from both steady-state thermal or transient thermal analysis by linking the set up cell of the static structural analysis to the upstream steady-state thermal or transient thermal analysis.

Define Crack Location using the Semi-Elliptical Crack/Elliptical Crack/Ring Crack Object

The steps shown below describe setting up the fracture analysis when using a Semi-Elliptical Crack, Elliptical Crack, or Ring Crack object.

Note:

You can also use these steps to compute fracture parameters in a Transient Structural analysis that contains cracks.

1. In Ansys Workbench, insert a Static Structural analysis in the project schematic.
2. Select a geometry.
3. Launch Mechanical.
4. Define a coordinate system location for the crack you will define. Note the following:
   - For semi-elliptical cracks, the specified coordinate system must be located on one of the surfaces of a solid body.
   - For elliptical and ring cracks, the specified coordinate system must be located inside of a solid body.
5. Align the axes of the coordinate system of the crack such that the direction of the specified coordinate system's Y-Axis is normal to the crack surface

   For Semi-Elliptical cracks lying on curved surfaces, ensure that the coordinate system's X-Axis is normal to the surface of the body at the coordinate system location. See Creating a Coordinate System Based on a Surface Normal (p. 1196) for details on how to orient such a coordinate system on a curved surface.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

6. Insert a **Fracture** folder in the **Outline**.

> **Note:**
>
> If you have an import base mesh that is hex-dominant, set **Re-mesh Hex-dominant to Tetrahedral** property of the **Fracture** folder to **On**. This setting automatically re-meshes an imported hex-dominant base mesh, on the solid body of a **Semi-Elliptical Crack** object, to a tetrahedral mesh. The resulting mesh is used to generate the initial crack mesh for the fracture parameters calculation and **SMART Crack Growth**.

7. Insert a **Semi-Elliptical Crack**, or an **Elliptical Crack**, or a **Ring Crack** object under the **Fracture** folder.
8. Specify the properties of the specified crack.
9. Generate the mesh by right-clicking the **Fracture** folder and selecting **Generate All Crack Meshes**.
10. Apply loads and boundary conditions. As needed, apply pressure on the crack face using a Nodal Pressure (p. 1724). Nodal pressure can be scoped using the automatically generated crack face Named Selection created under the crack object.
11. Ensure the **Fracture** setting under **Fracture Controls** (p. 1445) in the Analysis Settings is turned **On**.
12. Solve the simulation.
13. Insert the Fracture Tool and specify the desired crack using the **Crack Selection** property.
14. Insert desired fracture results under the **Fracture Tool**.
15. Post-process the fracture results.
16. Export to Excel or copy/paste from the chart if necessary.

Supplementary Steps to Define Semi-Elliptical Crack/Elliptical Crack/Ring Crack Object on Imported Base Mesh

Use the following steps to configure your simulation on the **Project Schematic** in order to specify an **Semi-Elliptical Crack**/**Elliptical Crack**/**Ring Crack** object on a mesh imported from External Model or Mechanical Model (p. 989).

External Model

1. From Ansys Workbench, insert an **External Model** system into the **Project Schematic**.
2. Open the **Setup** cell of the **External Model** tab and select the desired .cdb-based mesh that contains a solid body with tetrahedron/hex-dominant mesh. Return to the Project page and update the system.
3. Insert a **Static Structural** analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

4. Connect the fully-defined **External Model** upstream system to the downstream **Static Structural** analysis.

5. Launch Mechanical from the **Static Structural** system and then follow the steps from the above **Define Crack Location using the Semi-Elliptical Crack/Elliptical Crack/Ring Crack Object** topic, beginning with Step 4.

Mechanical Model

1. From Ansys Workbench, insert a **Mechanical Model** system into the **Project Schematic**.

2. Using the **Geometry** cell, specify solid body/bodies needed to define the crack.

3. Open the **Model** cell of the **Mechanical Model** system and mesh the solid bodies with either tetrahedron/hex-dominant mesh.

4. Return to the **Project** page and update the **Mechanical Model** system.

5. Insert a **Static Structural** analysis.

6. Connect the fully-defined **Mechanical Model** upstream system to the downstream **Static Structural** analysis.

7. Launch Mechanical from the **Static Structural** system and then follow the steps from the above **Define Crack Location using the Semi-Elliptical Crack/Elliptical Crack/Ring Crack Object** topic, beginning with Step 4.

Define an Arbitrary Crack using a Surface Body

The steps shown below describe how to set up a fracture analysis using the **Arbitrary Crack** object during a Static Structural analysis. You can follow same steps to set up fracture analysis for a Transient Structural Analysis.

1. From Ansys Workbench, insert a Static Structural analysis into the **Project Schematic**.

2. Input the geometry, which has a surface body (and will represent crack surface).

3. Launch Mechanical.

4. Create a Coordinate System. The Y axis must be directed towards the normal of the crack's top face and the X axis helps to determine the crack extension direction.

5. Insert a **Fracture** folder in to the tree **Outline**.

Note:

If you have an import base mesh that is hex-dominant, set **Re-mesh Hex-dominant to Tetrahedral** property of the **Fracture** folder to **On**. This setting automatically re-meshes an imported hex-dominant base mesh, on the solid body of a **Arbitrary Crack** object, to a tetrahedral mesh. The resulting mesh is used to generate the initial crack mesh for the fracture parameters calculation and **SMART Crack Growth**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

6. Using the Fracture Context Tab (p. 52) or the context menu (right-click the folder), insert an **Arbitrary Crack** object into the **Fracture** folder.
7. Specify the properties of the Arbitrary Crack object.
8. Right-click the **Fracture** folder and select **Generate All Crack Meshes** to generate the mesh.
9. Apply loads and boundary conditions. As needed, apply pressure on the crack face using the Nodal Pressure (p. 1724) boundary condition. You can scope this boundary condition using the automatically generated crack-face Named Selection created under the object.
10. Make sure that the **Fracture** property under the **Fracture Controls** (p. 1445) of the Analysis Settings is turned to **On**.
11. Solve.
12. Add the Fracture Tool and scope it to the **Arbitrary Crack** object and add desired fracture results.
13. Post process the fracture results.
14. Export to Excel or copy/paste from the chart if necessary.

Supplementary Steps to Define Arbitrary Crack on Imported Base Mesh

Use the following steps to configure your simulation on the **Project Schematic** in order to specify an **Arbitrary Crack** on a mesh imported from **External Model**.

1. From Ansys Workbench, insert an External Model system into the **Project Schematic**.
2. Open the **External Model** tab and select the desired .cdb-based mesh that contains a solid body (that may also contain a surface body to define the crack shape) with tetrahedron mesh. Return to the Project page and update the system.

   Note:

   If the imported .cdb- based mesh file contains a surface body that can be used to define the crack shape, you can jump to Step 6.

3. Insert a Mechanical Model system.

   Note:

   If the imported .cdb-based mesh doesn't contain a surface body, then the **Mechanical Model** system is required to import the surface body (including its mesh) individually for later use when defining the Arbitrary Crack surface.

4. Using the **Geometry** cell of the Mechanical Model system, specify a surface body. This surface body represents crack surface. The crack surface must intersect with at least one face of the solid body specified in the External Model system and must not be embedded inside of the solid body.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

5. Update the Mechanical Model system
6. Insert a **Static Structural** analysis.
7. Connect the fully-defined External Model and Mechanical Model (if defined above) upstream systems to the downstream **Static Structural** analysis.

Note:

Review Assembling External Models and Mechanical Models (p. 989) section for additional information.

---

8. Launch Mechanical from the **Static Structural** system and then follow the steps from the above **Define an Arbitrary Crack using a Surface Body** topic, beginning with Step 4.

Important:

- Arbitrary Crack mesh generated on an imported base mesh could affect the existing mesh (nodal and element) based Named Selection objects.
- When you have an Arbitrary Crack specified on an imported base mesh, the application of imported loads or constraints is not supported because the Arbitrary Crack mesh generation could affect the existing mesh (nodes) during remeshing.

Imported Crack Mesh (Pre-Meshed Crack)

This workflow describes using the Pre-Meshed Crack object for the computation of fracture parameters in 2D and 3D analysis using imported crack mesh. You can follow same steps to set up a Fracture analysis for a Transient Structural Analysis.

1. From Ansys Workbench, insert an External Model system into the Project Schematic.
2. Open the **External Model** tab and select the desired .cdb-based mesh that contains the crack mesh and its definition. Return to the Project page and update the system.
3. Insert a **Static Structural** analysis in the Project Schematic.
4. Connect the **Setup** cell of the External Model system to **Model** cell of the Static Structural system.
5. Launch Mechanical.
6. Create a Coordinate System with a Y axis perpendicular to the crack faces.
7. Insert a **Fracture** folder in the **Outline**.
8. Insert a **Pre-Meshed Crack** object under the **Fracture** folder.
9. Specify the **Pre-Meshed Crack** object details.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

10. Associate the **Pre-Meshed Crack** object with the newly created Coordinate System.
11. Apply load and boundary conditions.

> **Note:**
>
> You cannot apply Pressure loads to the crack face. You can only apply Nodal Pressures (p. 1724) on a structured mesh via node-based Named Selections for the nodes defining the crack face.

12. Ensure the **Fracture** setting under **Fracture Controls** (p. 1445) in the Analysis Settings is turned **On**.
13. Solve.
14. Add the Fracture Tool and desired fracture results.
15. Post process the fracture results.
16. Export to Excel or copy/paste from the chart if necessary.

> **Note:**
>
> In 2D, you can draw the crack in the same model using DesignModeler and generate the crack mesh using the mesh connection feature.

Limitations of Fracture Analysis

This section describes the limitations for the generation of a crack mesh on the supported crack types (semi-elliptical, elliptical, ring, or arbitrary). In addition, it describes the limitations in the computation of fracture parameters for these crack types, including the Pre-Meshed Crack object.

1. A Fracture analysis does not support adaptive mesh refinement.
2. For **Arbitrary Crack**, **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack Corner Crack**, **Edge Crack**, **Through Crack**, and **Cylindrical Crack** objects, crack meshing requires that the base mesh is a quadratic tetrahedron mesh. Linear elements may exist farther away from the buffer zone on the same body to which these cracks are scoped.
3. Only 3D analyses support semi-elliptical, elliptical, ring, and arbitrary cracks.
4. You can scope a **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, **Corner Crack**, **Edge Crack**, **Through Crack**, or **Cylindrical Crack** to one solid body only.
5. You should define Semi-Elliptical cracks on the surfaces of a solid body only, and the crack cannot span more than one face.
6. When the crack dimensions of an **Elliptical Crack** or a **Ring Crack** intersect with the free surfaces of the solid body, the application only supports the **Tetrahedrons** option of the **Mesh Method** property.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

7. The **Stiffness Behavior** property of the geometry scoped to a **Arbitrary Crack**, **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, **Corner Crack**, **Edge Crack**, **Through Crack**, or **Cylindrical Crack** must be set to **Flexible**.

8. You can scope an **Arbitrary Crack** to one solid body only. And, you can only scope the **Crack Surface** property of the crack to a single surface body.

9. The scoped crack front nodal selection of the **Pre-Meshed Crack** object must exist in geometries with a flexible stiffness behavior definition.

10. It is not recommended that you specify a Part Transformation (p. 1014) on a body that includes an **Arbitrary Crack**. This could lead to the application detecting an incorrect extension direction for the crack front nodes.

11. Arbitrary Cracks can only be meshed with the Tetrahedrons Mesh Method (**Mesh Method** set to **Tetrahedrons**).

12. Fracture parameter computations based on the VCCT technique are only supported for lower order crack mesh. Hence, VCCT based fracture parameter computations are only supported for **Pre-Meshed Crack** object.

13. In order to retain restart points when the **Fracture** property (**Analysis Settings** > Fracture Controls (p. 1445)), is set to **On**, you must set the **Generate Restart Points** property (**Analysis Settings** > Restart Controls (p. 1438) to **Manual**.

14. Solution restarts are not supported if you are computing fracture parameters for **SMART Crack Growth**.

15. The semi-elliptical, elliptical, ring, or arbitrary crack top and bottom face nodes are not connected through any constraint equation. Therefore, the nodes of the top face can penetrate the bottom face or vice versa based on the applied loads and constraints. In these scenarios, you may need to create a constraint equation between crack faces for the solution using the Commands (APDL) object.

16. The graphical view of a **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, **Corner Crack**, **Edge Crack**, **Through Crack**, or **Cylindrical Crack** may differ from the generated mesh. For more information, see the section on Cracks (p. 424).

17. The **Arbitrary Crack**, **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, **Corner Crack**, **Edge Crack**, **Through Crack**, or **Cylindrical Crack** objects are not supported in combination with the following features:

    - Cyclic Region
    - Structural Linear Periodic Symmetry Region
    - Interface Delamination

18. Interpolated displacements for the facets in a surface construction object may fail to demonstrate the proper deformation of a Semi-Elliptical crack. For more information, see Surface Displays and Fracture (p. 1961).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

19. In order to use the Fracture Tool to extract the fracture results and probe results from the results file of another analysis using the **Read Result Files** option, it is necessary that the meshes from both systems, including the crack mesh, match.

20. Fracture parameter calculations based on domain integrations such as SIFs, J-integral, or Material Force are not supported when contact elements exist inside the domain. The calculations may become path-dependent unless the contact pressure is negligible.

21. If you have a Hyperelastic material assigned in the analysis, only Material Force fracture results are supported.

Fracture Meshing

The Meshing application supports fracture meshing capabilities enabling you to insert multiple surface cracks and/or multiple embedded cracks (Elliptical and Ring) into the body mesh. This fracture mesh can then be used to analyze crack fronts in Static Structural and Transient structural analyses. Fracture meshing uses a Fracture object that can contain multiple Arbitrary Crack, Semi-Elliptical, Elliptical Crack, and/or Ring Crack objects.

Go to a section topic:

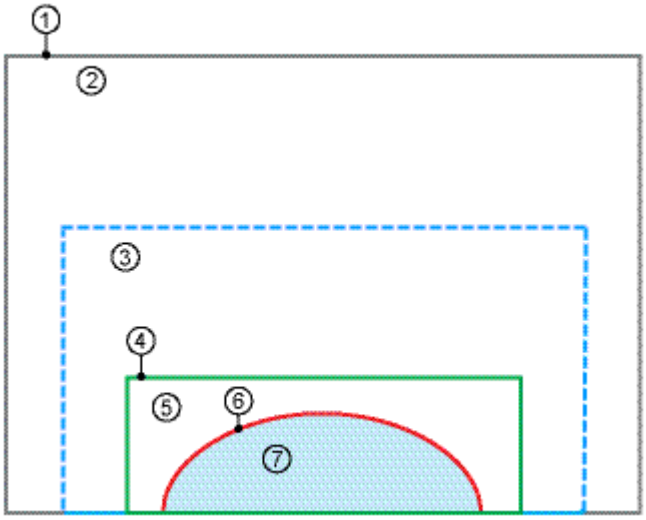
- Overview (p. 415)
- Characteristics and Limitations of Fracture Meshing (p. 416)
  - General (p. 417)
  - For Semi-Elliptical Cracks (p. 419)
  - For Arbitrary Cracks (p. 421)

Overview

The following figure illustrates many of the components of fracture meshing that are discussed throughout this section. This figure is a sliced top view of a semi-elliptical crack.

Overview of Fracture Meshing Components

DRAFT



1. Body to which the semi-elliptical crack is scoped.
2. Base mesh, which always consists of quadratic tetrahedron elements. For the generation of fracture mesh, the base mesh inside and surrounding the region of the buffer zone (3) must be a quadratic tetrahedron mesh. However, non-tetrahedron/linear mesh may exist farther away from the buffer zone on the same body to which the semi-elliptical crack is scoped.
3. Buffer zone, which is always filled with quadratic tetrahedron elements.
4. Interface between the buffer zone (3) and the fracture affected zone (5), illustrated by the green line. Contact pair 1 is defined at the interface between the elements in the buffer zone and the elements in the fracture affected zone.
5. Fracture affected zone, which is filled with quadratic elements (hex and wedge).
6. Crack front, located along the crack shape and illustrated by the red line. The crack shape is semi-elliptical.
7. Discontinuity planes, illustrated by the light blue shading. Consist of two planes at the same location (the crack front plane).

For semi-elliptical, elliptical, or ring cracks, you use the **Mesh Method** property to specify the mesh as either **Hex Dominant** (default) or **Tetrahedrons**.

Note:

When you specify the **Mesh Method** property as **Tetrahedrons** to mesh a **Semi-Elliptical Crack**, **Elliptical Crack**, or **Ring Crack**, the application does not create the **Fracture Affected Zone** (Step 5) and as a result the Interface (Step 4) does not exist. All other components remain the same.

Characteristics and Limitations of Fracture Meshing

Note the following information when using fracture meshing:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

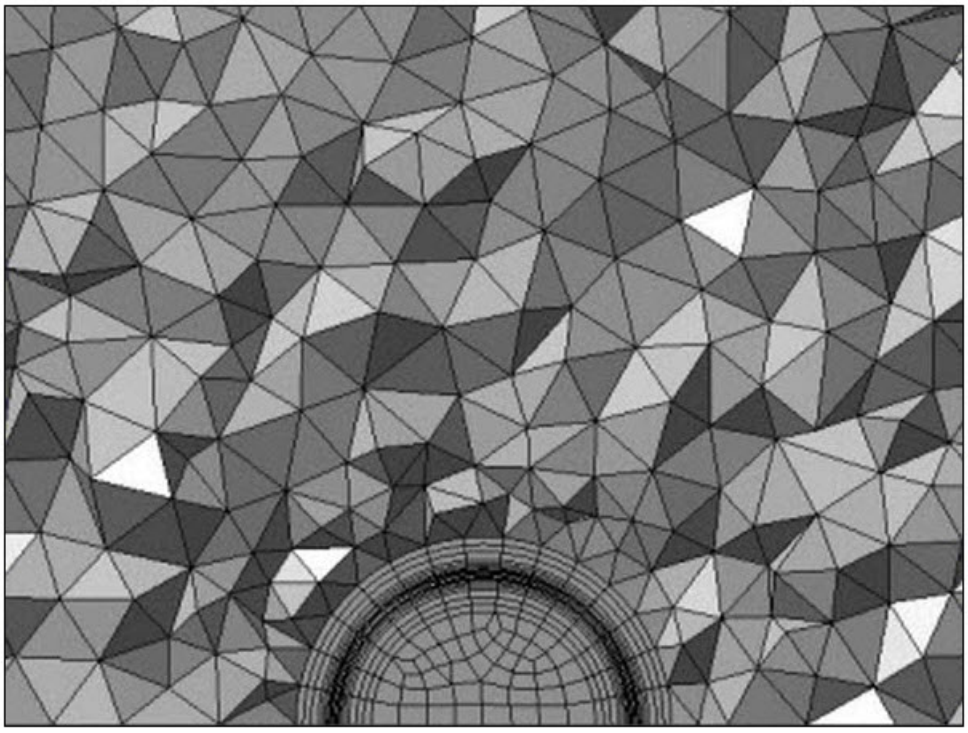
General

- Fracture meshing is a post mesh process which occurs during a separate step after the base mesh is generated. If you do not generate a base mesh before you invoke **Generate All Crack Meshes**, the base mesh is generated first and the crack meshing occurs in a separate step after base meshing is complete.
- When the **Mesh Method** property is set to **Tetrahedrons**, then meshing a Semi-Elliptical, Elliptical crack, Ring crack, and/or Arbitrary crack does not generate contact pairs in the interface region of the crack mesh and base mesh.

Note:

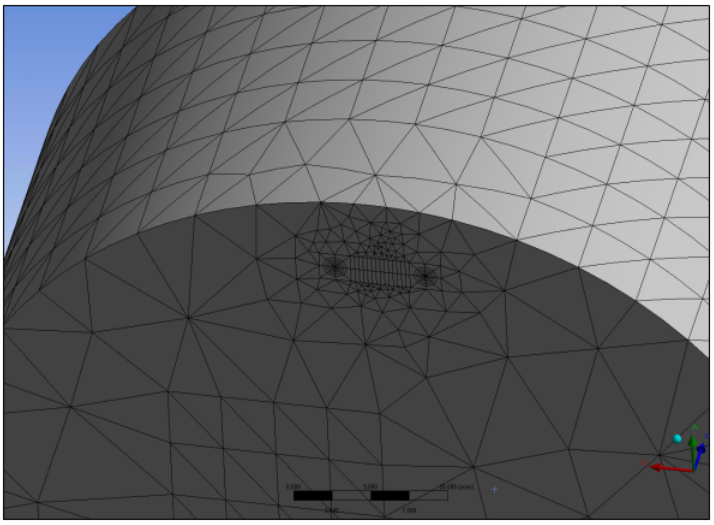
When the free surfaces of a solid body intersect with either an **Elliptical Crack** or a **Ring Crack**, the **Hex Dominant** setting for the **Mesh Method** property is not supported.

- For Semi-Elliptical, Elliptical, or Ring cracks with a Tetrahedron mesh, the **Largest Contour Radius** and **Mesh Contours** properties affect the crack mesh only when the **Front Element Size** property is set to **Default**. These properties do not have an effect on the crack mesh when the **Front Element Size** property is user defined. For Arbitrary cracks the **Largest Contour Radius** and **Mesh Contour** properties do not have an effect on the crack mesh.
- For the base mesh inside and surrounding the region of the buffer zone, fracture meshing supports quadratic tetrahedron elements only. Linear elements may exist farther away from the buffer zone on the same body to which the semi-elliptical, elliptical, ring, or arbitrary crack is scoped.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Fracture meshing is a part-based meshing operation. It is supported for all part/body-based tetrahedron mesh methods.
- Fracture meshing does not support insertion of a crack that spans multiple bodies.
- The fracture mesh overrides the settings of the base mesh. You can insert a semi-elliptical crack and/or arbitrary crack on topology to which a sizing control, match control, or mapped Face Meshing control is already applied. However, fracture meshing does not respect sizing controls. It will also eliminate or disable a match or mapped Face Meshing control. For example and as illustrated below, fracture meshing has overwritten a mapped Face Meshing control.



- Fracture meshing does not support mesh refinement.
- Fracture meshing is supported for static structural and transient structural analyses only.
- Crack insertion does not alter the geometry/topology of a model.
- For Error Limits, fracture meshing supports the **Standard Mechanical** option only.
- Once inserted, the Fracture folder object:
  - Cannot be suppressed.
  - Can only be deleted if the folder is empty.
- **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, and **Arbitrary Crack** objects can be suppressed, deleted, or duplicated. When a crack definition changes after meshing, only the Fracture object in the tree **Outline** is invalidated.
- The plane for semi-elliptical, elliptical, and ring cracks, always lies in the X-Z plane of the specified coordinate system.
- The major radius of the semi-elliptical crack/elliptical crack/ring crack grows in the Z direction. The minor radius of the elliptical crack/ring crack grows in the X direction of the specified coordinate system, and the minor radius grows of the semi-elliptical crack in the positive X direction of the specified coordinate system.

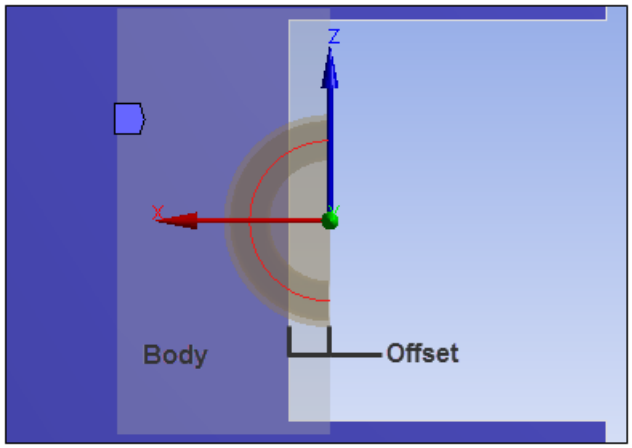
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

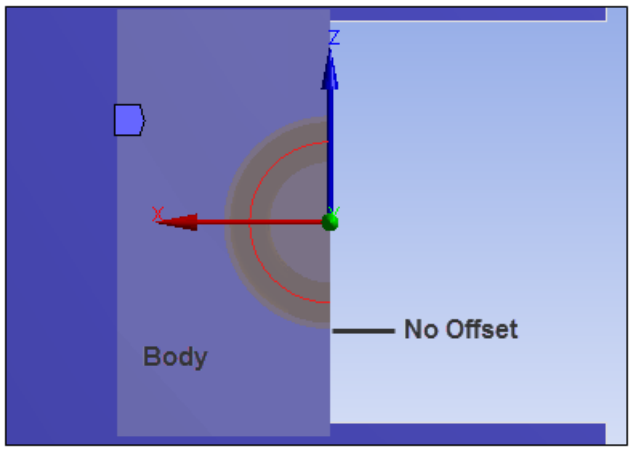
- When you use the Part Transform (p. 1014) feature on a meshed model that has a crack specified on a part, each time you change the Part Transform, the application clears the mesh on the body with cracks and requires re-mesh of the crack-based body.

For Semi-Elliptical Cracks

- Fracture meshing supports semi-elliptical crack insertion on planar surfaces and curved surfaces. For curved surfaces, you can insert semi-elliptical cracks on convex or concave surfaces. If you try to insert a single crack that extends across a surface that has both types of curves, crack insertion may fail.
- Fracture meshing does not support semi-elliptical crack insertion at a corner.
- The specified coordinate system should lie on the surface of the body to which the semi-elliptical crack is scoped. If it does not, and the **Project to Nearest Surface** property is set to **Yes**, the software projects the coordinate system onto the body's surface and modifies the center of the ellipse, as shown below.

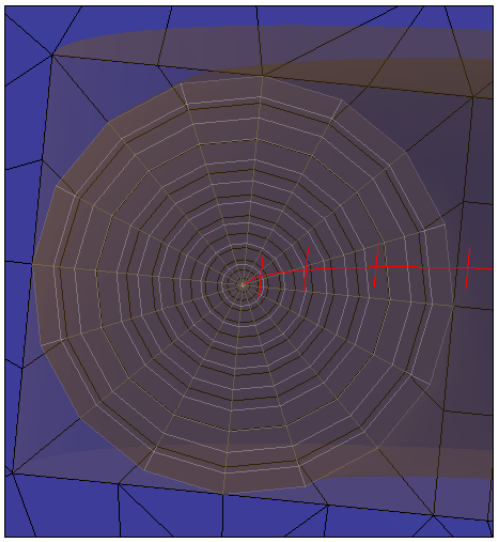


In this case, you will need to define the **Hit Point Normal** and orient the primary axis. The center of the ellipse is moved in the X direction so the major radius of the semi-elliptical crack grows in the Z direction, and the minor radius grows in the positive X direction of the specified coordinate system. The offset projects back to the surface of the body, making the offset close to 0. The illustration below shows the resultant mesh. For more information on creating a coordinate system aligned with a hit point, see the Creating a Coordinate System Based on a Surface Normal (p. 1196) section of the help.

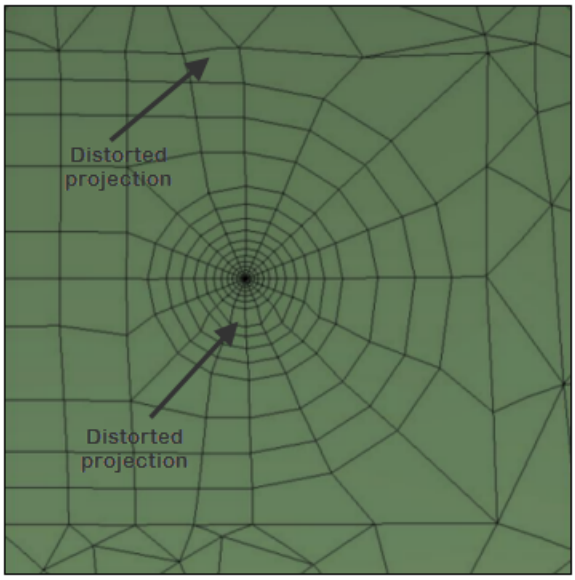


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- You can use the **Annotation Preferences** dialog box to toggle the visibility of annotations for cracks. For details, refer to the Probe, Maximum, and Minimum (p. 71) section of the help.
- As illustrated by the figure below, the mesh generated for the mesh contours (black lines) will not necessarily match the preview of the mesh contours (white lines).



- When cracks are inserted in curved surfaces, the projection of the crack template on the surface may be slightly distorted on the template, as shown in the following figure.

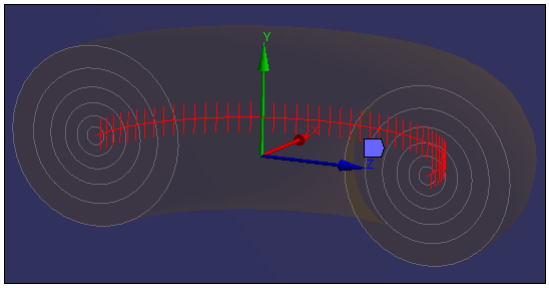


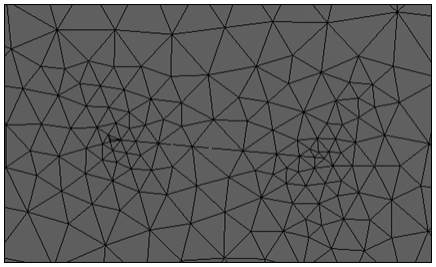
- Illustrated below is the graphics preview of a semi-elliptical crack that uses the Tetrahedrons Mesh Method. The graphics preview always shows the structured hex dominant shape irrespective of the mesh method selection. It does not accurately represent the generated crack mesh as compared to the generated crack mesh image. However, you can use the preview to examine the effect of the mesh parameters on the generated crack mesh.

Graphics Preview	**Generated Crack Mesh - Tetrahedrons Mesh Method**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

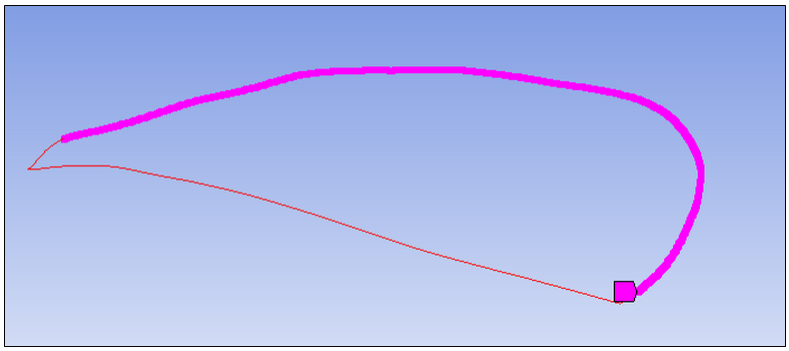
Published: 2023-10-23





For Arbitrary Cracks

- Arbitrary cracks only support crack mesh generation using **Tetrahedrons** as the **Mesh Method**.
- Arbitrary crack supports both planar and non-planar crack.
- Arbitrary cracks support surface, embedded, through, and corner cracks.
- Fracture meshing of Arbitrary cracks automatically detects proper intersection points between the crack surface body and its scoped geometry selection to extract the crack front. The image shown below shows that even if the crack surface is extended beyond the surface of the scoped geometry selection, the crack front nodes only include the intersection points and the points that are located inside of the surface.



- When generating the mesh for an Arbitrary crack, it is required that the coordinate system is selected such that the crack surface is located on both sides of the Z axis and that the crack top face is located in the positive Y axis.
- You can define multiple cracks on the same body as long as their buffer zones do not intersect.
- The arbitrary crack mesh illustrated below displays the tetrahedrons as the mesh method used to generate non-planar crack mesh. The crack front nodes of the generated crack mesh are extracted from the intersection points of the crack surface to the cylinder body.

Defining an Edge Crack
Defining a Through Crack
Defining a Cylindrical Crack
Defining a Pre-Meshed Crack
Special Handling of Named Selections for Crack Objects

Crack Overview

A crack is characterized by its shape, crack front/tip, crack discontinuity plane, crack normal, and crack direction. A crack front in three dimensional analyses represents the line of separation of the discontinuous crack surface. The same is represented by a crack tip in two dimensional analyses. A crack inside Ansys Mechanical can be defined using a **Semi-Elliptical Crack** object, an **Elliptical Crack** object, a **Ring Crack** object, or an **Arbitrary Crack** object, or a **Pre-Meshed Crack** object. These objects can be inserted under the **Fracture** folder.

Arbitrary Crack objects use a surface body selection to define an arbitrary crack shape in three dimensional analyses. The exterior edges of the surface body define the crack front and the surface itself defines the discontinuous crack plane. **Semi-Elliptical Crack**/**Elliptical Crack**/**Ring Crack** objects uses the geometric parameters to define the semi-elliptical/elliptical/ring crack shape and crack front in three dimensional analyses. These geometric inputs along with additional input parameters on the arbitrary crack and semi-elliptical/elliptical/ring crack object defines the region and shape of the generated crack mesh. Internally, the crack mesh generation is performed after the creation of the base mesh. By default, the crack mesh generation automatically creates a node-based named

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

selection for the crack front under the **Semi-Elliptical Crack**/**Elliptical Crack**/**Ring Crack**/**Arbitrary Crack** objects.

A **Pre-Meshed Crack** definition assumes that the crack meshes, representing the discontinuity or flaw in the structure, have already been generated. That is, the pre-meshed crack does not internally generate the crack mesh using Fracture Meshing (p. 415), as other crack objects do, but instead assumes that the crack mesh has been generated beforehand. A **Pre-Meshed Crack** object uses a node-based named selection to analyze crack front; this nodal named selection is required for the computation of fracture parameters. If a geometric edge represents a crack front, you must first convert it to a node-based named selection using the Worksheet criteria before it can be used by the Pre-Meshed Crack (p. 465) object. See the next section, **Defining a Pre-Meshed Crack (p. 465)**, for more information on the Pre-Meshed Crack.

The orientation of the crack plays a vital role in the fracture parameter calculations. **Semi-Elliptical Crack**/**Elliptical Crack**/**Ring Crack** and **Pre-Meshed Crack** objects supports planar cracks where the crack normal can be defined using a single coordinate system. The orientation of a **Semi-Elliptical Crack**/**Elliptical Crack**/**Ring Crack** object is reflected by its **Crack Coordinate System**, while the orientation of a **Pre-Meshed Crack** object is reflected by its Coordinate **System** property setting. The orientation must be defined such that the y-axis is normal to the crack surface while the x-axis helps align the crack extension direction. **Arbitrary Cracks** on the other hand supports both planar and non-planar cracks. The orientation of an **Arbitrary Crack** object is reflected by its **Coordinate System** property setting. A single coordinate system cannot define the crack normal for non-planar cracks which is varying along the crack front. Hence, the Y axis of the **Coordinate System** property setting is directed towards the crack top face normal and X axis helps align the crack extension direction.

Note:

When you insert a Commands (APDL) object under a crack, the object provides a **Crack Front Selection** property that enable you to execute commands specific crack front definitions. Property options include **All** (default), **First**, **Last**, and **By Number**. When you select the **By Number** option, an additional property displays: **Crack Front Number**. The default value for this property is **All**. You can use it to specify a desired value using the entry tool that displays when you select the field.

Tip:

To achieve coordinate system alignment to the face normal, create your coordinate system as described in Creating a Coordinate System Based on a Surface Normal (p. 1196) and assign the created coordinate system to the **Semi-Elliptical Crack** object. You can also set the **Align with Face Normal** property to **Yes** to generate a crack mesh whose coordinate system is aligned to the face normal and that is reflected by the **SECrack Coordinate System** object that is added under the **Semi-Elliptical Crack** object. Otherwise, the **Semi-Elliptical Crack** object's coordinate system can be at an inclination to the face normal direction. For the **Pre-Meshed Crack** and **Arbitrary Crack** objects, the origin of the coordinate system must be located on the open side of the crack.

Note: The graphical view of the semi-elliptical crack may differ from the mesh generated. Possible reasons include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- A crack definition unsuitable for valid mesh creation may result in some layers being "peeled off" to create a valid mesh.
- The crack contour may be shrunk to fit into the mesh domain.
- The crack coordinate system may be changed to align it to surface normal.
- The center of the crack may be changed to create the crack on the surface.
- The crack is meshed with gradation from the contour center to the outside results in difficulty distributing the crack mesh.
- The offset of the crack is not suitable for the crack contour, resulting in a contour that must be reduced to ensure all element contours fit into the template.

Defining an Arbitrary Crack

The steps for defining an Arbitrary crack are presented here.

1. Select the **Model** object in the Tree Outline.
2. Insert a Fracture object into the tree **Outline** by right-clicking on the **Model** object and selecting **Insert** > **Fracture** from the context menu. Alternatively, select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

3. Insert an Arbitrary Crack object into the tree by right-clicking on the **Fracture** object and selecting **Insert** > **Arbitrary Crack** from the context menu. Alternatively, click the **Arbitrary Crack** option from the **Crack** group of the **Fracture Context Tab** (p. 52).
4. An Arbitrary Crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details View, and then click **Apply**.
5. To further define the **Arbitrary Crack**, use the following Details pane properties. As you specify values for the properties, the image in the **Geometry** window previews the entered data. An example of Arbitrary crack definition, including an image of the crack on the model, is illustrated below.

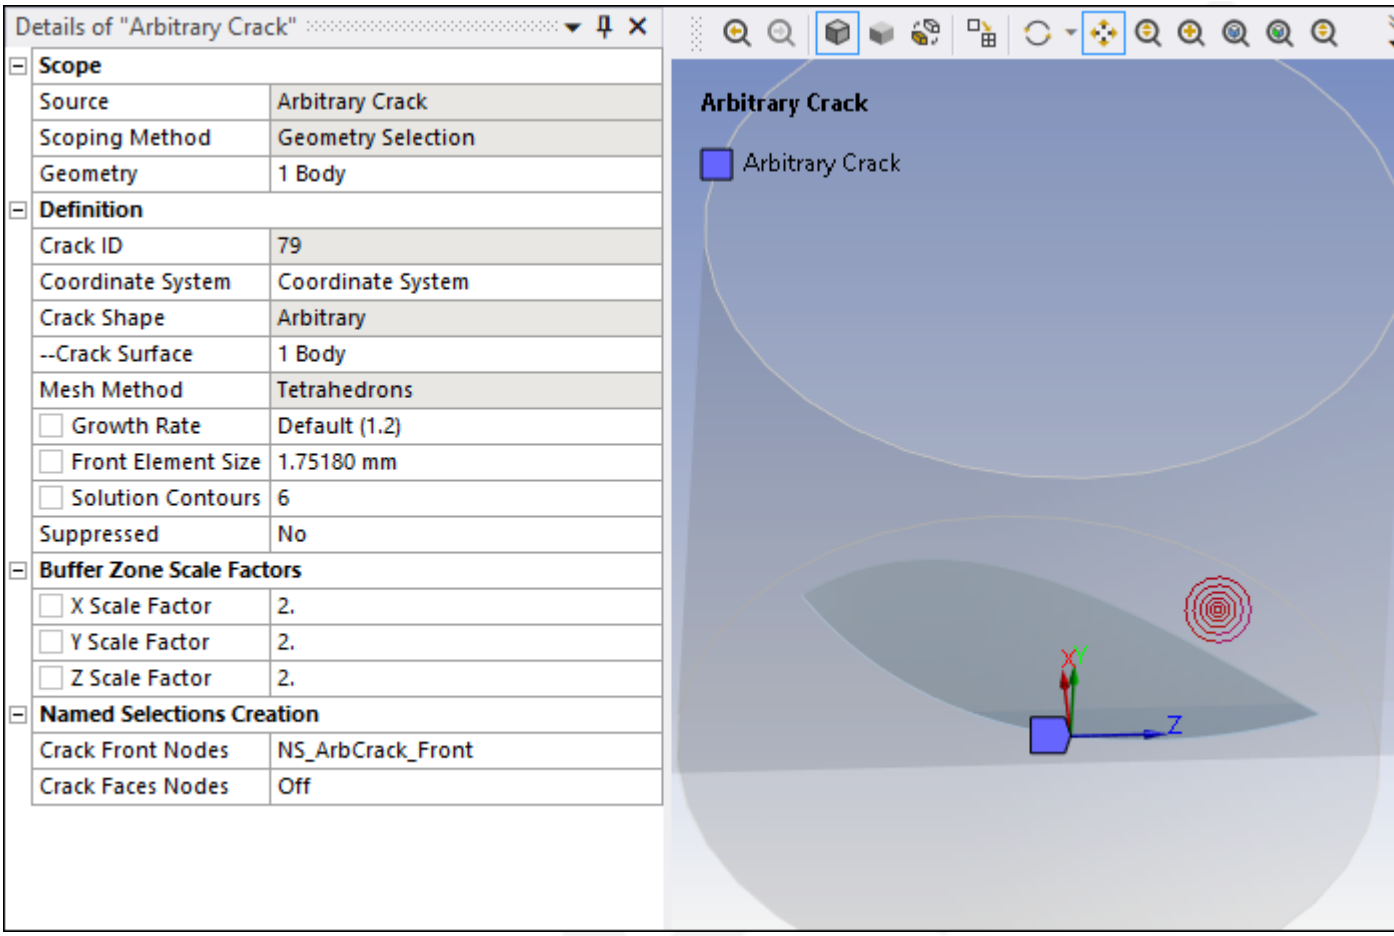
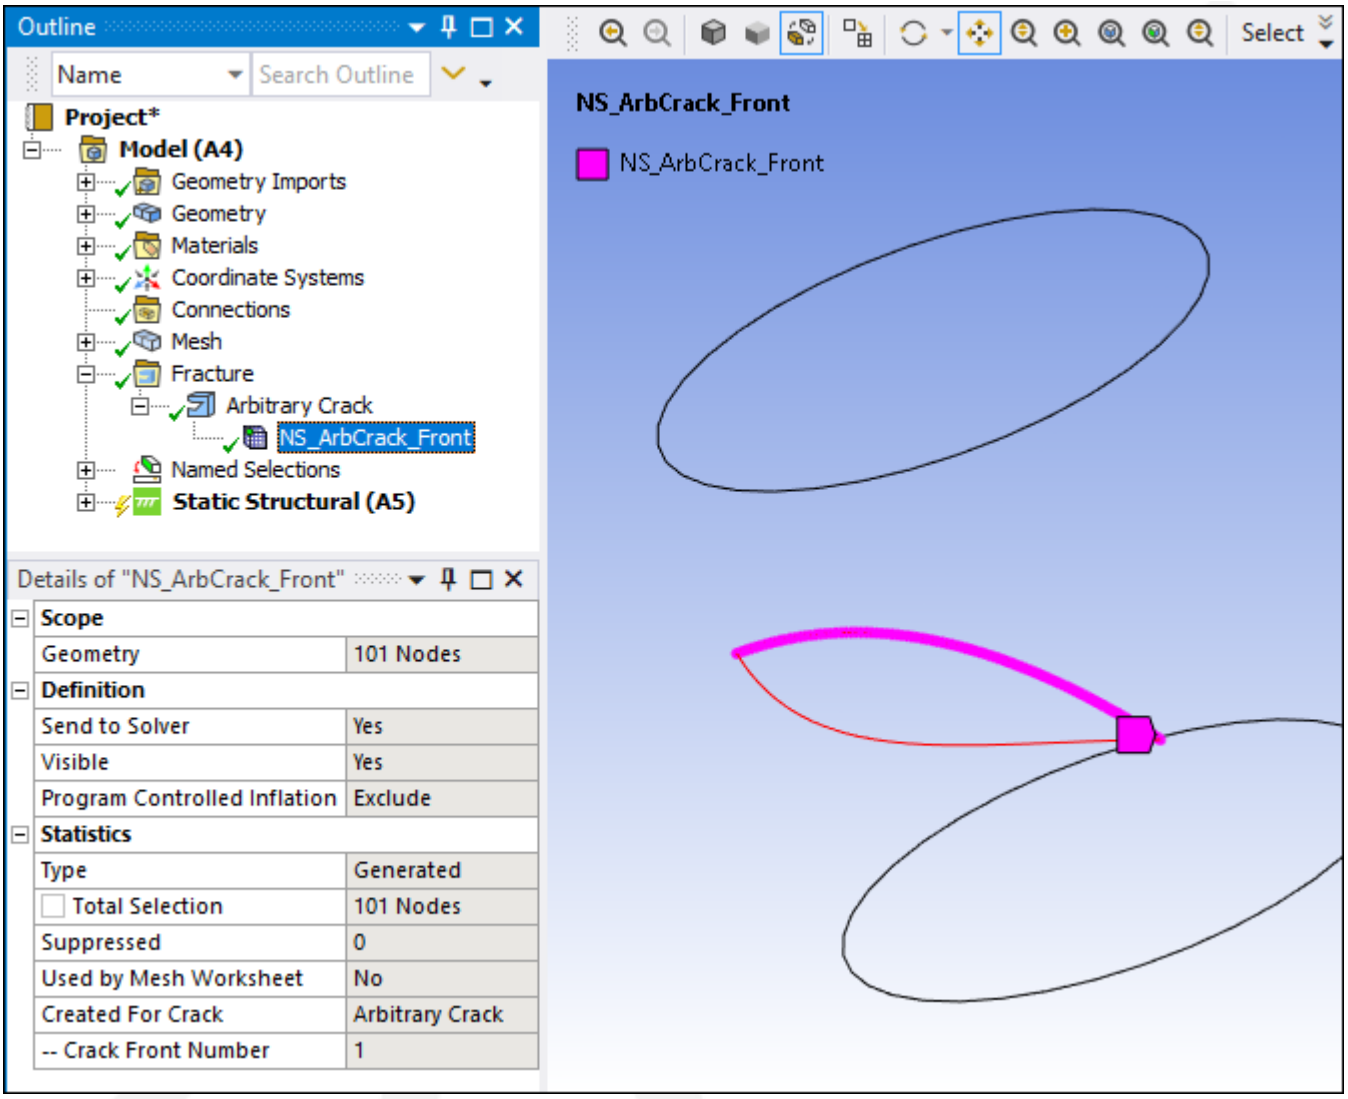
Published: 2023-10-23



As defined by the application generated Named Selection, the portion of the curve located inside the cylinder, including the intersection points, defines the shape of the crack front.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



- **Crack ID**: A read-only property that displays a unique system generated identification number ID for the crack object. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: This property specifies the coordinate system that defines the orientation of the crack. The Y axis of the specified coordinate system must be directed towards the normal of the crack's top face.
- **Crack Shape**: Read-only property set to **Arbitrary**.
- **Crack Surface**: You use this property to specify the surface body to be used as the crack surface. This surface body can be on a surface or embedded within the solid body, or it can intersect with the free surfaces of the solid body. This generates an arbitrary crack that is a surface crack, shaped as an ellipse, a ring, a cylinder, it can be a through-crack that cuts through a solid body, or a corner crack that intersects at multiple corners of the solid body.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

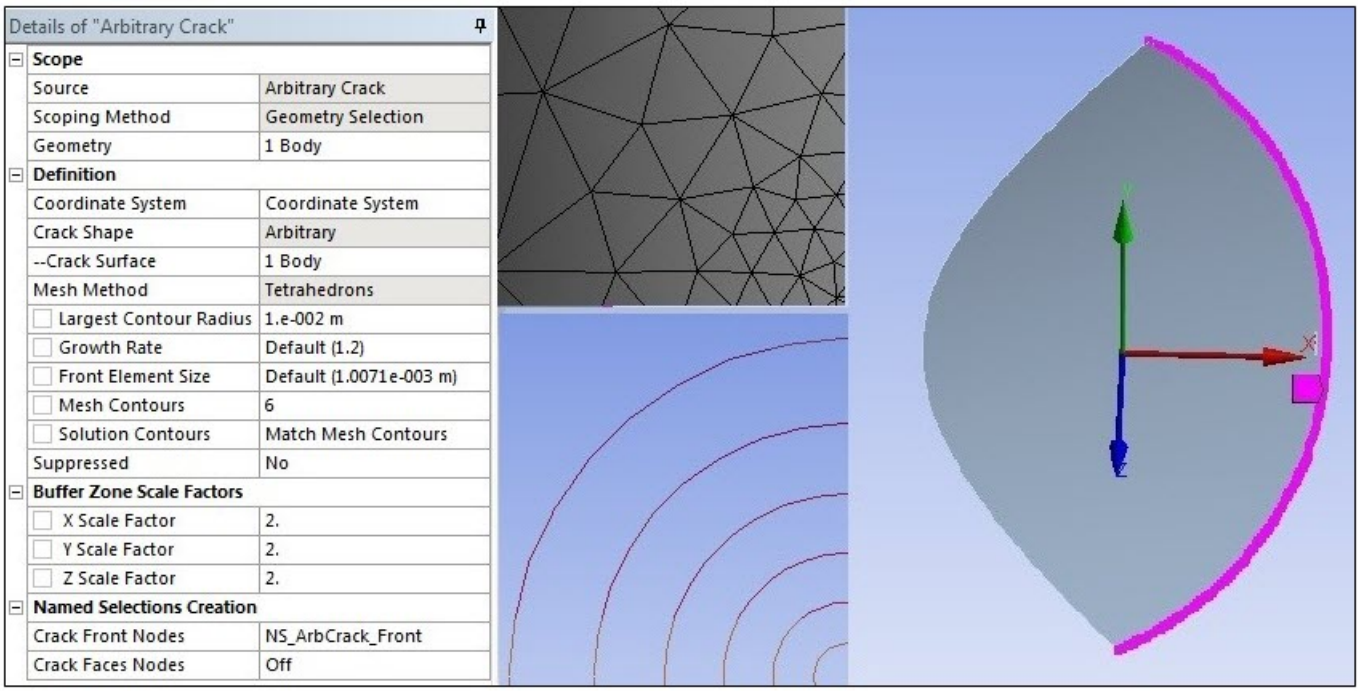
Published: 2023-10-23

- **Mesh Method**: Read-only property set to **Tetrahedrons**.

> **Note:**
>
> When this crack intersects with the free surfaces of a solid body, the **Hex Dominant** setting is not supported.

- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**. If you specify a **Front Element Size** value, this property is not applicable.
- **Growth Rate** Specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size** Specifies the element size for the crack front. The default value is computed using the values of **the Largest Contour Radius** property and the **Growth Rate** property.
- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. Your entry must be equal to or greater than **1**. The default value is **6**. If you specify a **Front Element Size** value, this property is not applicable.

  The **Geometry** window can display only a maximum of 100 mesh contours, but you can specify a higher value and fracture meshing will respect it.



> **Note:**
>
> You can use the graphics preview of an arbitrary crack to examine the relative effect of the mesh parameters on the generated crack mesh. The first mesh contour's

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

radius shown as a bull's-eye view in **Geometry** window is equal to specified **Front Element Size**. The mesh contours grow at the rate of the specified **Growth Rate** value as seen in the image. Also, the generated crack mesh is an unstructured tetrahedron mesh and may not accurately compare to all the mesh parameters seen in the **Geometry** window.

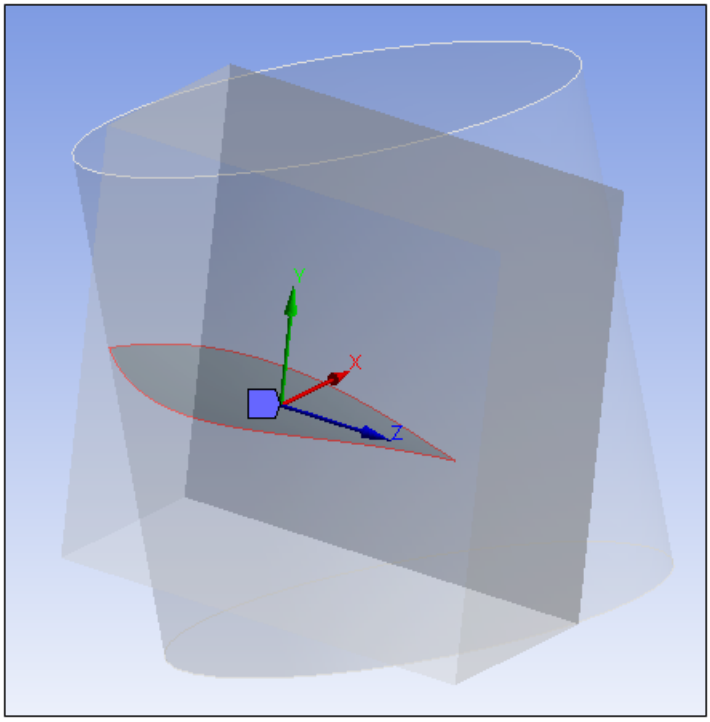
- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of the **Mesh Contours** property, and cannot be greater than **99**. By default, the value is set to **Match Mesh Contours**, indicating that the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the **Arbitrary Crack** object. The default is **No**.

  The **Arbitrary Crack** object is suppressed automatically if both the scoped body and scoped crack surface are suppressed.
- **Buffer Zone Scale Factors**: Control the size of the buffer zone in the X, Y, and Z directions, relative to the crack surface geometry dimensions. For each scaling parameter, use the slider to set a value from **2** to **50**. The default value is **2**. The maximum dimension among the three dimensions of the crack surface geometry is multiplied by the corresponding scale factors to create a buffer zone:
  - **X Scale Factor**
  - **Y Scale Factor**
  - **Z Scale Factor**

  As illustrated here, buffer zone scale factor annotations are not drawn in the negative X direction. That is, half of the cuboid is drawn to depict the buffer zone scale factors, but the half of the cuboid in the negative X direction is not drawn.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



The remaining properties pertain to Named Selections that are created automatically when the fracture mesh is generated, as described in Step 6 below. To ensure associativity to the corresponding **Arbitrary Crack** object, the following default naming convention is used for these Named Selections.

The following naming convention is used for Named Selections for crack objects with the name **Arbitrary Crack**:

- **NS**_ *ArbCrack* _**Front**
- **NS**_ *ArbCrack* _**TopFace**
- **NS**_ *ArbCrack* _**BottomFace**

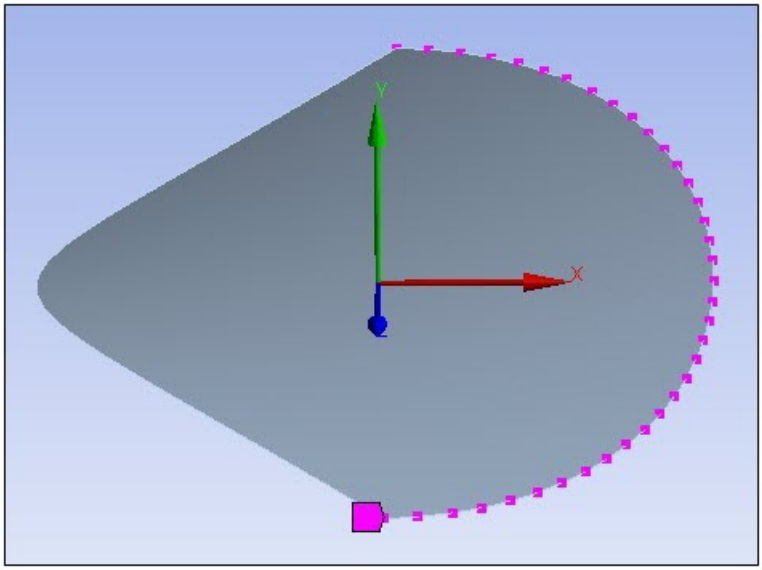
For example, for an **Arbitrary Crack** object named **Arbitrary Crack 4**, the default names are **NS_ArbCrack 4_Front**, **NS_ArbCrack 4_TopFace**, and **NS_ArbCrack 4_BottomFace**.

The Named Selections controls are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*ArbCrack*_**Front**). Contains nodes used for postprocessing of fracture parameter results.

  As shown, the X axis helps determine the extension direction of the crack front node.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Important:

For cracks with multiple crack fronts, the **Crack Front Nodes** property, under **Named Selection Creation** category, only modifies the first crack front name if you have already generated the mesh. However, the application applies the property value to all crack fronts if you are generating the mesh for the first time or if the mesh is re-generated.

- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous.

  The default is **Off**. If **On**, the following additional fields appear:

  – **Top Face Nodes**: Identifies the Named Selection that is created automatically for the top face (**NS**_*ArbCrack*_**TopFace**). This face is discontinuity plane 1. Contains nodes used for applying a pressure to the top face.

  – **Bottom Face Nodes**: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*ArbCrack*_**BottomFace**). This face is discontinuity plane 2. Contains nodes used for applying a pressure to the bottom face.

6. Select the **Fracture** object or **Arbitrary Crack** object in the tree **Outline**, right-click, and select **Generate All Crack Meshes**.

   - When the fracture mesh is generated, the requested Named Selections are inserted into the tree Outline under the **Arbitrary Crack** object with which they are associated.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Click **Show Mesh** on the Graphics Toolbar (p. 97) to display the fracture mesh.

Note:

Mesh near arbitrary crack is projected to facets if the geometry is faceted. Thus, if you see mesh being projected slightly away from the geometry, it might be because of the coarseness of geometry facets.

Defining a Semi-Elliptical Crack

The steps for defining a semi-elliptical crack are presented here.

1. Select the **Model** object in the Tree Outline.
2. Insert a Fracture object into the tree by right-clicking on the **Model** object and selecting **Insert** > **Fracture** from the context menu. Alternatively, select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

3. Insert a Semi-Elliptical Crack object into the Tree by right-clicking on the **Fracture** object and selecting **Insert** > **Semi-Elliptical Crack** from the context menu. Alternatively, click the **Semi-Elliptical Crack** from the **Crack** group of the **Fracture Context Tab** (p. 52).
4. A semi-elliptical crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details View, and then click **Apply**.
5. To further define the semi-elliptical crack, use the following controls. These controls appear in the Details View of the **Semi-Elliptical Crack** object. As you specify values for the controls, the image in the **Geometry** window previews the entered data.

   The following figure shows an example of a semi-elliptical crack definition and its corresponding image. The semi-elliptical curve defines the shape of the crack front, as shown by the red line.

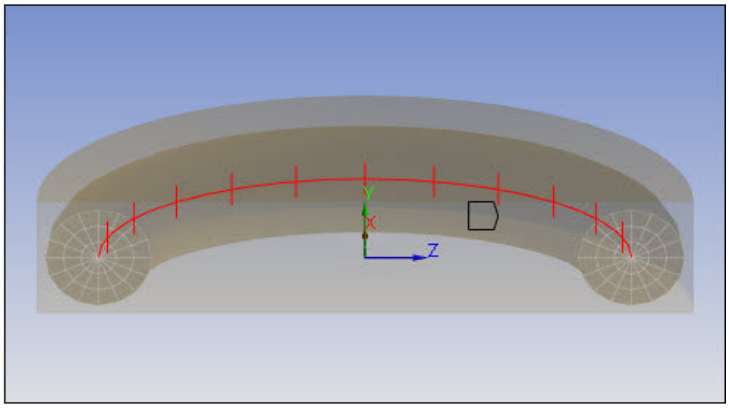
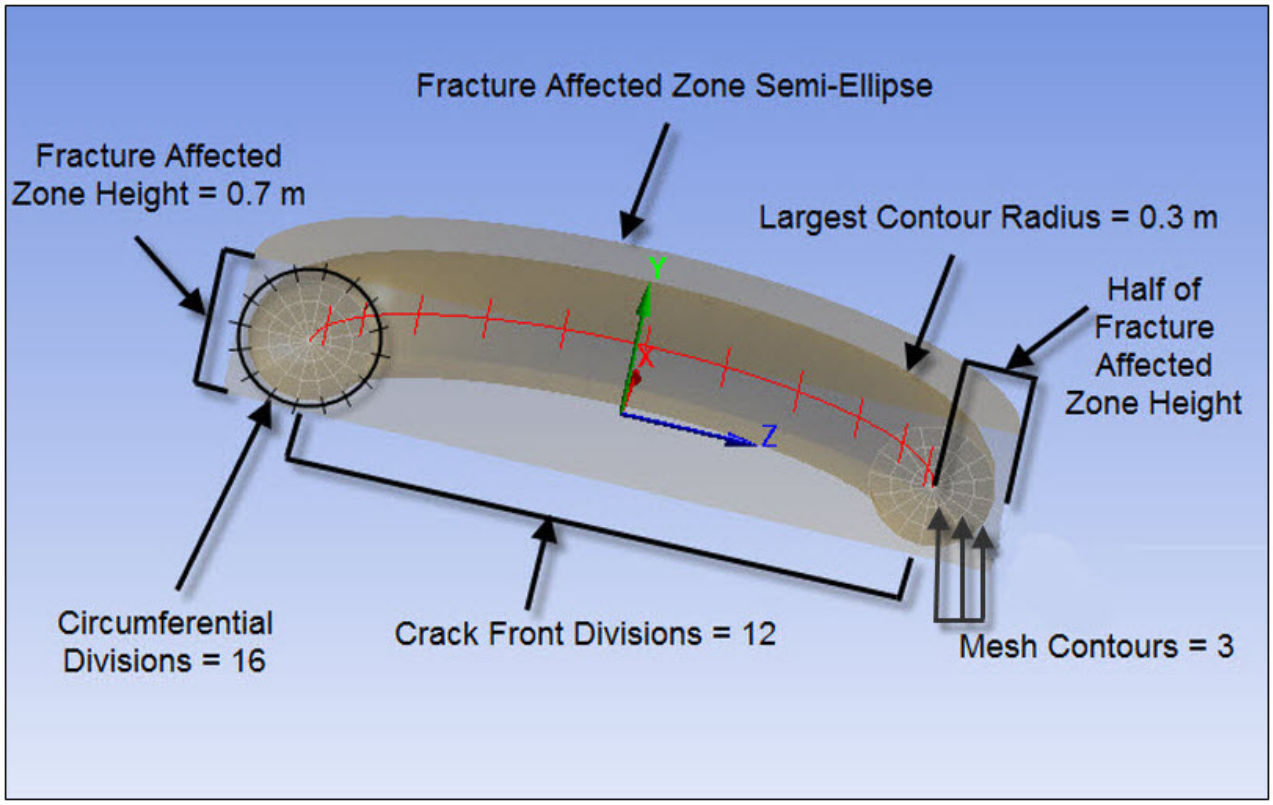
Align with Face Normal	Yes
Project to Nearest Surface	Yes
Crack Shape	Semi-Elliptical
--Major Radius	1.5 m
--Minor Radius	1. m
Mesh Method	Hex Dominant
Largest Contour Radius	0.3 m
Crack Front Divisions	12
Fracture Affected Zone	Manual
Fracture Affected Zone Height	0.7 m
Circumferential Divisions	16
Mesh Contours	3
Solution Contours	Match Mesh Contours
Suppressed	No
Buffer Zone Scale Factors	
Named Selections Creation	



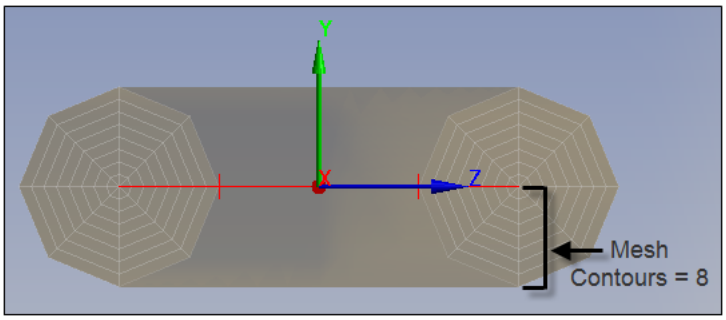
This figure provides a more detailed illustration of the fracture affected zone defined above. Notice that the values shown in the image below correspond to the Details View settings above.



This figure shows the detail of a crack for which **Mesh Contours** is set to **8**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



- **Crack ID**: A read-only property that displays a unique system generated identification number ID for the crack object. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: This property specifies the coordinate system that defines (along with the **Align with Face Normal** and **Project to Nearest Surface** properties) the position and orientation of the crack. The Y axis of the specified coordinate system defines the crack plane normal. The coordinate system that you create must be a Cartesian coordinate system (**Type** property) and its origin cannot lie outside the bounding box of the body scoped to the crack.
- **Align with Face Normal**: This property defines the orientation of the **SECrack Coordinate System** object by aligning the primary axis of the coordinate system specified in the **Coordinate System** property to the normal of the nearest surface. The default setting is **Yes**. Setting this property to **No** excludes the capability of this property.
- **Project to Nearest Surface**: This property defines the origin of the **SECrack Coordinate System** by projecting the origin of the coordinate system specified in the **Coordinate System** property to the nearest surface. The default setting is **Yes**. Setting this property to **No** excludes the capability of this property.

Note:

The meshing process automatically creates the **SECrack Coordinate System** object as a child of the **Semi-Elliptical Crack** object from the inputs of the **Coordinate System**, the **Align with Face Normal**, and the **Project to Nearest Face** properties.

- **Crack Shape**: Read-only and set to **Semi-Elliptical**.
- **Major Radius**: Specifies the major radius, which defines the size of the crack shape along the Z axis (that is, the width of the crack). Enter a value greater than 0.
- **Minor Radius**: Specifies the minor radius, which defines the size of the crack shape along the X axis (that is, the depth of the crack). Enter a value greater than 0.
- **Mesh Method**: This property enables you to select the mesh method to be used to mesh the semi-elliptical crack. Options include **Hex Dominant** (default) and **Tetrahedrons**.
- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.

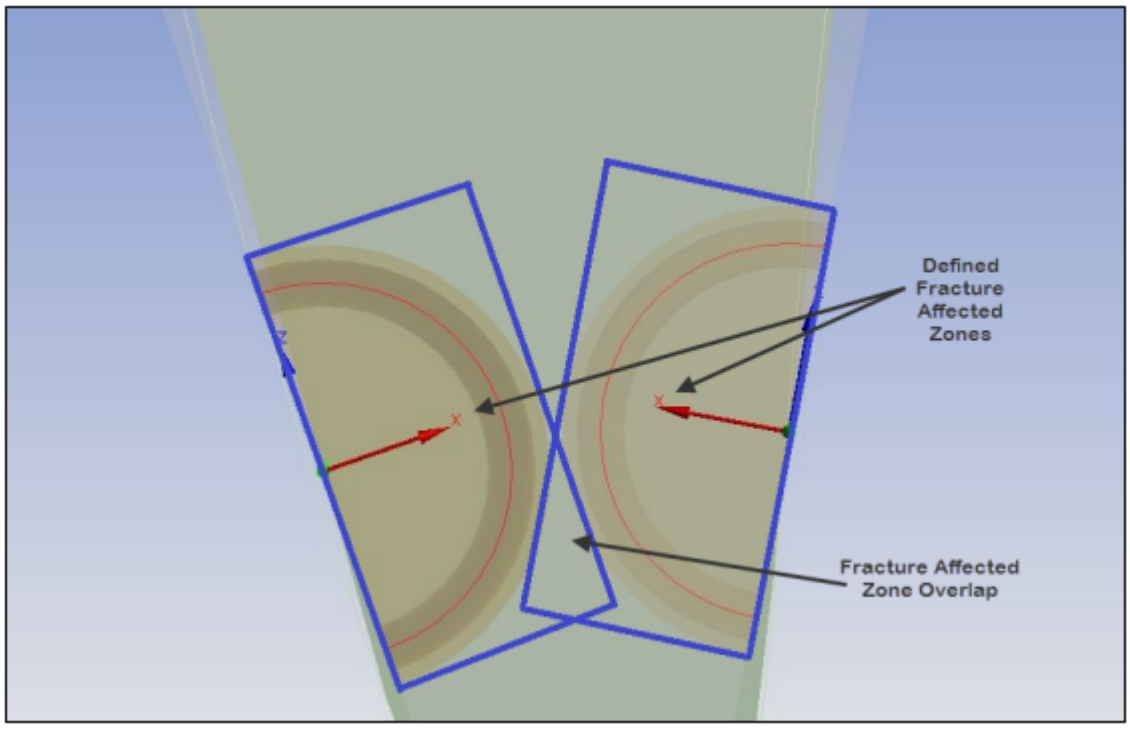
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Growth Rate** (**Mesh Method** set to **Tetrahedrons** only): Specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size** (**Mesh Method** set to **Tetrahedrons** only): Specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.
- **Crack Front Divisions** (**Mesh Method** set to **Hex Dominant** only): Specifies the number of divisions for the crack front. Your entry must be equal to or greater than **3**. The default is **15**.
  - The **Geometry** window can display only a maximum of 999 crack front divisions, but you can specify a higher value and fracture meshing will respect it.
- **Fracture Affected Zone** (**Mesh Method** set to **Hex Dominant** only): The fracture affected zone is the region that contains a crack. The **Fracture Affected Zone** control determines how the fracture affected zone height is defined:
  - **Program Controlled**: The software calculates the height, and **Fracture Affected Zone Height** is read-only. This is the default.
  - **Manual**: You enter the height in the **Fracture Affected Zone Height** field.
- **Fracture Affected Zone Height** (**Mesh Method** set to **Hex Dominant** only): This value specifies two things: 1) the height of the **Fracture Affected Zone**, which is in the Y direction of the crack coordinate system; and 2) the distance in totality by which the **Fracture Affected Zone** is extended in the positive and negative Z direction of the crack coordinate system from the crack front extremities.

  The shape of a Fracture Affected Zone is rectangular, regardless of the shape of the crack. Although buffer zones may overlap, care should be taken when defining multiple cracks that the zones do not overlap, as shown here, or the crack generation will fail.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



- **Circumferential Divisions** (**Mesh Method** set to **Hex Dominant** only): Specifies the number of circumferential divisions for the crack shape. The value you enter must be a multiple of 8, and must be 8 or greater. The default is 8.

  – The **Geometry** window can display only a maximum of 360 circumferential divisions, but you can specify a higher value and fracture meshing will respect it.

- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be 1 or greater. The default is 6.

  – The **Geometry** window can display only a maximum of 100 mesh contours, but you can specify a higher value and fracture meshing will respect it.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.

- **Suppressed**: Toggles suppression of the **Semi-Elliptical Crack** object. The default is **No**.

  – The **Semi-Elliptical Crack** object is suppressed automatically if the scoped body is suppressed.

- **Buffer Zone Scale Factors**

  It controls the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

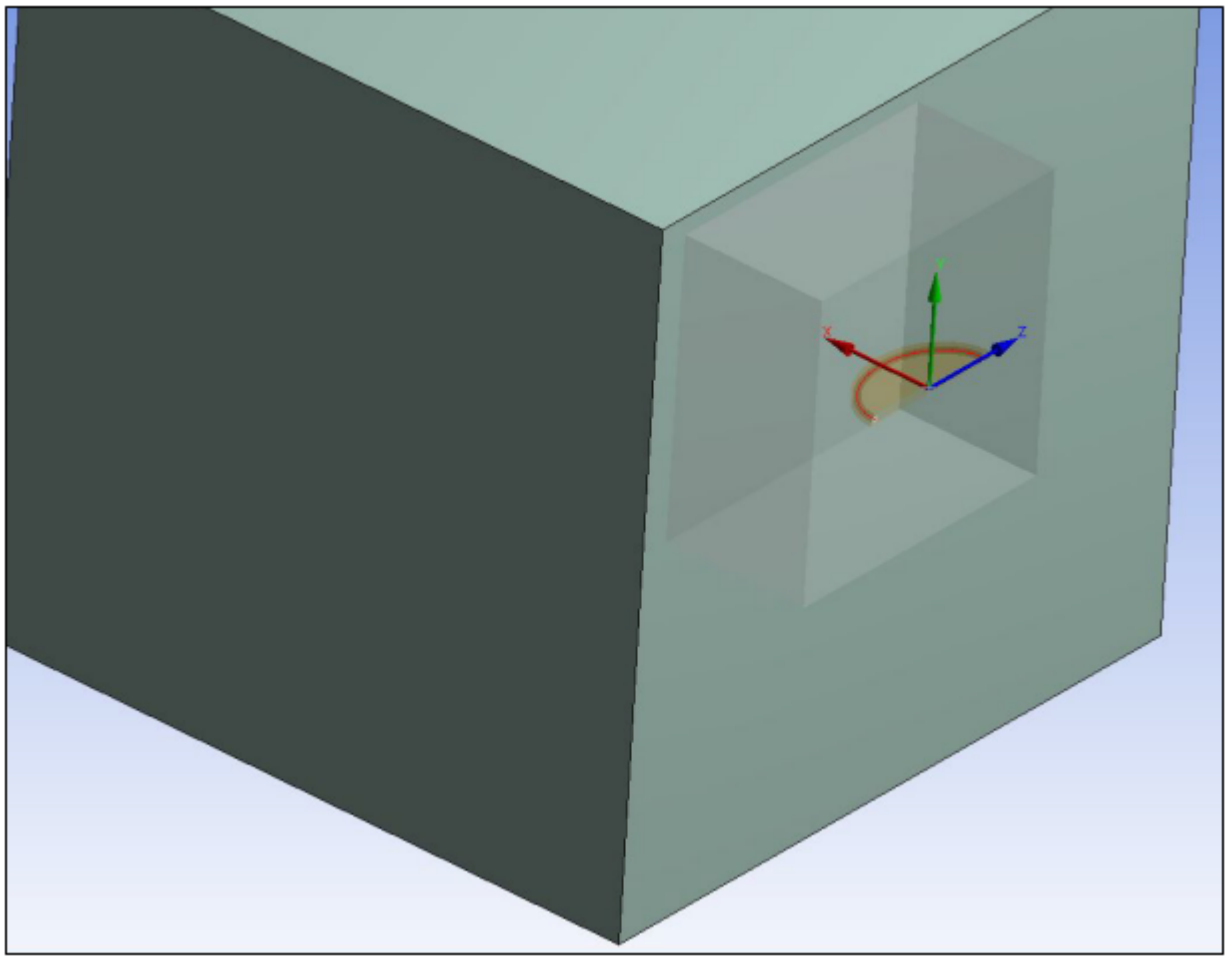
corresponding scale factors to create a buffer zone. When the **Mesh Method** is **Hex-Dominant**, the crack dimensions also include fracture-affected zones.

– **X Scale Factor**

– **Y Scale Factor**

– **Z Scale Factor**

As illustrated here, buffer zone scale factor annotations are not drawn in the negative X direction. That is, half of the cuboid is drawn to depict the buffer zone scale factors, but the half of the cuboid in the negative X direction is not drawn.



The remaining controls pertain to Named Selections that are created automatically when the fracture mesh is generated, as described in Step 6 below. To ensure associativity to the corresponding **Semi-Elliptical Crack** object, the following default naming convention is used for these Named Selections.

The following naming convention is used for Named Selections for crack objects with the name **Semi-Elliptical Crack**:

- **NS_** *SECrack* **_Front**
- **NS_** *SECrack* **_TopFace**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

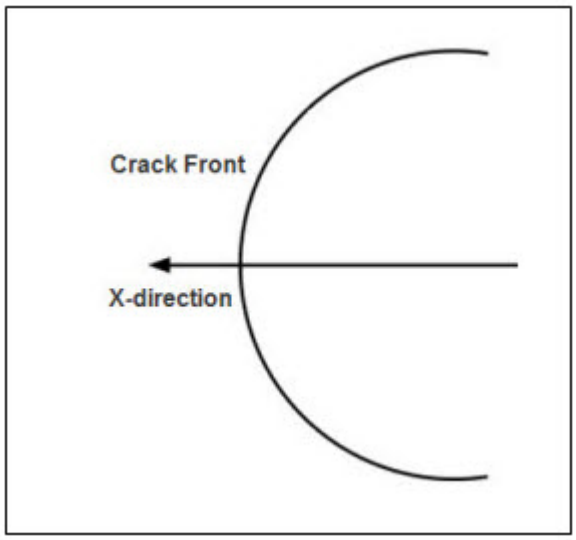
- **NS**_ *SECrack* _**BottomFace**
- **NS**_ *SECrack* _**Contact1**
- **NS**_ *SECrack* _**Target1**

For example, for a **Semi-Elliptical Crack** object named **Semi-Elliptical Crack 4**, the default names are **NS_SECrack 4_Front**, **NS_SECrack 4_TopFace**, **NS_SECrack 4_BottomFace**, **NS_SECrack 4_Contact1**, and **NS_SECrack 4_Target1**.

The Named Selections controls are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*SECrack*_**Front**). Contains nodes used for postprocessing of results.

  As shown, the crack front is always perpendicular to the X axis.



- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous.

  The default is **Off**. If **On**, the following additional fields appear:

  – **Top Face Nodes**: Identifies the Named Selection that is created automatically for the top face (**NS**_*SECrack*_**TopFace**). This face is discontinuity plane 1. Contains nodes used for applying a pressure to the top face.

  – **Bottom Face Nodes**: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*SECrack*_**BottomFace**). This face is discontinuity plane 2. Contains nodes used for applying a pressure to the bottom face.

- **Contact Pairs Nodes** (**Mesh Method** set to **Hex Dominant** only): Determines whether Named Selections are created automatically for the contact and target faces of the contact pair. The default is **Off**. If **On**, the additional fields listed below appear. Fracture meshing creates contact pair 1 between the fracture affected zone and the buffer zone.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Contact 1 Nodes**: Identifies the Named Selection that is created automatically for contact face 1 (**NS**_*SECrack*_**Contact1**). Contains nodes located on the contact face. The contact nodes are selected at the interface from the buffer zone of the base mesh.
- **Target 1 Nodes**: Identifies the Named Selection that is created automatically for target face 1 (**NS**_*SECrack*_**Target1**). Contains nodes located on the target face. The target nodes are selected at the interface from the fracture affected zone of the hex dominant mesh.

6. Select the **Fracture** object or **Semi-Elliptical Crack** object in the Tree Outline, right-click, and select **Generate All Crack Meshes**.
   - When the fracture mesh is generated, the requested Named Selections are inserted into the Tree Outline under the **Semi-Elliptical Crack** object with which they are associated.
   - Click **Show Mesh** on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining an Elliptical Crack

This section describes the steps to create an **Elliptical Crack**. You use elliptical cracks to insert embedded void cracks into a solid body.

Procedure

To define an **Elliptical Crack**:

1. Select the **Model** object.
2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

3. Insert a **Elliptical Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Elliptical Crack**. You can also select the **Elliptical Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.
4. A elliptical crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.
5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Examples entries are illustrated below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

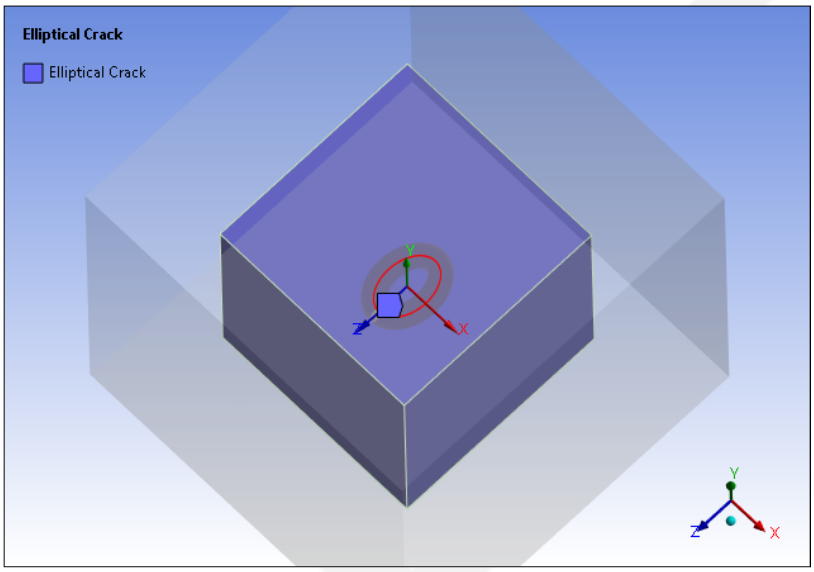
--Bottom Face Nodes	NS_Elliptical Crack_BottomFace



Crack categories and properties include:

Definition

- **Crack ID**: A read-only property that displays a unique system generated identification value. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: Specify the coordinate system that defines the orientation of the crack. The Y axis of the specified coordinate system must be directed towards the normal of the crack plane and the crack plane always lies in the X-Z plane of the specified coordinate system.
- **Crack Shape**: Read-only property set to **Elliptical**.
- **Major Radius**: Specifies the major radius, which defines the size of the crack shape along the Z axis (that is, the width of the crack). Enter a value greater than 0.
- **Minor Radius**: Specifies the minor radius, which defines the size of the crack shape along the X axis (that is, the depth of the crack). Enter a value greater than 0.
- **Mesh Method**: This property enables you to select the mesh method to be used to mesh the crack. Options include **Hex Dominant** (default) and **Tetrahedrons**.

  Note:

  When this crack intersects with the free surfaces of a solid body, the **Hex Dominant** setting is not supported.

- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Growth Rate**: This property is only visible when the **Mesh Method** property is set to **Tetrahedrons**. It specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.

- **Front Element Size**: This property is only visible when the **Mesh Method** property is set to **Tetrahedrons**. It specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.

- **Crack Front Divisions**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. It specifies the number of divisions for the crack front. Your entry must be equal to or greater than **3**. The default value is **30**.

  Note:

  The maximum number of crack front divisions the **Geometry** window can display is 999. However, you can specify a higher value and the application will process it accordingly.

- **Fracture Affected Zone**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. This is the region that contains a crack. This property defines the height of the fracture affected zone. Property options include:

  – **Program Controlled** (default): The application calculates the height. When selected, the **Fracture Affected Zone Height** property is read-only.

  – **Manual**: You manually specify the height in the **Fracture Affected Zone Height** property when using this option.

- **Fracture Affected Zone Height**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. This value specifies two things: 1) the height of the **Fracture Affected Zone**, which is in the Y direction of the crack coordinate system; and 2) the distance in totality by which the **Fracture Affected Zone** is extended in the positive and negative Z direction of the crack coordinate system from the crack front extremities.

  The shape of a Fracture Affected Zone is rectangular, regardless of the shape of the crack. Although buffer zones may overlap, you should use care when defining multiple cracks so that the zones do not overlap.

  Important:

  The crack generation process will fail if buffer zones overlap.

- **Circumferential Divisions**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. It specifies the number of circumferential divisions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

for the crack shape. The value you enter must be a multiple of 8, and must be 8 or greater. The default is 8.

Note:

The maximum number of circumferential divisions the **Geometry** window can display is 360. However, you can specify a higher value and the application will process it accordingly.

- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than 1. The default setting is 6.

Note:

The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the **Elliptical Crack** object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Buffer Zone Scale Factors

This category includes the following properties:

- **X Scale Factor**
- **Y Scale Factor**
- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone. When the **Mesh Method** property is set to **Hex-Dominant**, the crack dimensions also include fracture-affected zones.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

below). To ensure the Named Selections accurately correspond to the **Elliptical Crack** object, the application uses the following naming convention:

- **NS**_*EllipticalCrack*_**Front**
- **NS**_*EllipticalCrack*_**TopFace**
- **NS**_*EllipticalCrack*_**BottomFace**
- **NS**_*EllipticalCrack*_**Contact1**
- **NS**_*EllipticalCrack*_**Target1**

For example, for a **Elliptical Crack** object named **Elliptical Crack 4**, the default names are **NS_EllipticalCrack 4_Front**, **NS_EllipticalCrack 4_TopFace**, **NS_EllipticalCrack 4_BottomFace**, **NS_EllipticalCrack 4_Contact1**, and **NS_EllipticalCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*EllipticalCrack*_**Front**). Contains nodes used for postprocessing of results.
- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*EllipticalCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*EllipticalCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

- **Contact Pairs Nodes**: This property displays when the **Mesh Method** property is set to **Hex Dominant**. It determines whether Named Selections are created automatically for the contact and target faces of the contact pair. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Contact 1 Nodes: Identifies the Named Selection that is created automatically for contact face 1 (**NS**_*EllipticalCrack*_**Contact1**). It contains nodes located on the contact face. The contact nodes are selected at the interface from the buffer zone of the base mesh.

  Target 1 Nodes: Identifies the Named Selection that is created automatically for target face 1 (**NS**_*EllipticalCrack*_**Target1**). It contains nodes located on the target

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

face. The target nodes are selected at the interface from the fracture affected zone of the hex dominant mesh.

Note:

Fracture meshing creates contact pair 1 between the fracture affected zone and the buffer zone.

6. Select the **Fracture** object or **Elliptical Crack** object, right-click, and select **Generate All Crack Meshes**.

   When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Elliptical Crack** object with which they are associated.

   Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining a Ring Crack

This section describes the steps to create an **Ring Crack**. You use ring cracks to insert embedded void cracks of a hallow disc shape into a solid body.

Procedure

To define a ring crack:

1. Select the **Model** object.
2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

3. Insert a **Ring Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Ring Crack**. You can also select the **Ring Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.
4. A ring crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.
5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Examples entries are illustrated below.

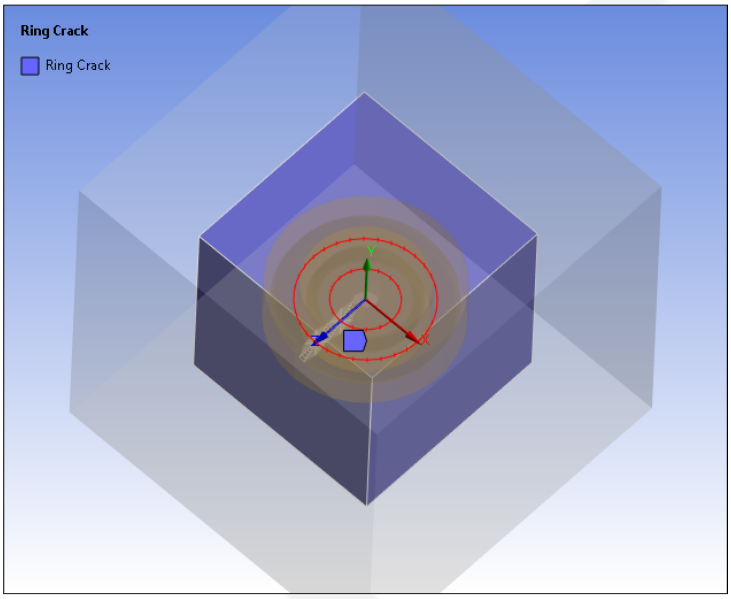
Details of "Ring Crack"

Scope	
Source	Analytical Crack
Scoping Method	Geometry Selection
Geometry	1 Body
Definition	
Crack ID	87
Coordinate System	Coordinate System
Crack Shape	Ring
--Outer Major Radius	6. mm
--Outer Minor Radius	6. mm
--Inner Major Radius	3. mm
--Inner Minor Radius	3. mm
Mesh Method	Hex Dominant
Largest Contour Radius	2. mm
Outer Crack Front Divisions	32
Inner Crack Front Divisions	16
Fracture Affected Zone	Program Controlled
Fracture Affected Zone Height	5.2028 mm
Circumferential Divisions	8
Mesh Contours	6
Solution Contours	Match Mesh Contours
Suppressed	No
Buffer Zone Scale Factors	
X Scale Factor	2.
Y Scale Factor	2.
Z Scale Factor	2.
Named Selections Creation	
Crack Front Nodes	NS_RingCrack_Front
Crack Faces Nodes	On
--Top Face Nodes	NS_RingCrack_TopFace
--Bottom Face Nodes	NS_RingCrack_BottomFace
Contact Pairs Nodes	Off



Crack categories and properties include:

Definition

- **Crack ID**: A read-only property that displays a unique system generated identification value. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: Specify the coordinate system that defines the orientation of the crack. The Y axis of the specified coordinate system must be directed towards the normal of the crack plane and the crack plane always lies in the X-Z plane of the specified coordinate system.
- **Crack Shape**: Read-only property set to **Ring**.
- **Outer Major Radius**: Specifies the outer major radius, which defines the size of the crack shape along the Z axis (that is, the width of the crack). Enter a value greater than 0.
- **Outer Minor Radius**: Specifies the outer minor radius, which defines the size of the crack shape along the X axis (that is, the depth of the crack). Enter a value greater than 0.
- **Inner Major Radius**: Specifies the inner major radius, which defines the size of the inner crack shape along the Z axis (that is, the width of the crack). Enter a value greater than 0.
- **Inner Minor Radius**: Specifies the inner minor radius, which defines the size of the inner crack shape along the X axis (that is, the depth of the crack). Enter a value greater than 0.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Mesh Method**: This property enables you to select the mesh method to be used to mesh the crack. Options include **Hex Dominant** (default) and **Tetrahedrons**.

  Note:

  When this crack intersects with the free surfaces of a solid body, the **Hex Dominant** setting is not supported.

- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.
- **Growth Rate**: This property is only visible when the **Mesh Method** property is set to **Tetrahedrons**. It specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Outer Front Element Size**: This property is only visible when the **Mesh Method** property is set to **Tetrahedrons**. It specifies the element size for the outer crack front. The default value is computed using crack length. Specify a value greater than 0.
- **Inner Front Element Size**: This property is only visible when the **Mesh Method** property is set to **Tetrahedrons**. It specifies the element size for the inner crack front. The default value is computed using crack length. Specify a value greater than 0.
- **Outer Crack Front Divisions**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. It specifies the number of divisions for the outer crack front. Your entry must be equal to or greater than 3. The default is 30.

  Note:

  The maximum number of crack front divisions the **Geometry** window can display is 999. However, you can specify a higher value and the application will process it accordingly.

- **Inner Crack Front Divisions**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. It specifies the number of divisions for the inner crack front. Your entry must be equal to or greater than 3. The default is 30.
- **Fracture Affected Zone**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. This is the region that contains a crack. This property defines the height of the fracture affected zone. Property options include:
  - **Program Controlled** (default): The application calculates the height. When selected, the **Fracture Affected Zone Height** property is read-only.
  - **Manual**: You manually specify the height in the **Fracture Affected Zone Height** property when using this option.
- **Fracture Affected Zone Height**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. This value specifies two things: 1) the height of

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

the **Fracture Affected Zone**, which is in the Y direction of the crack coordinate system; and 2) the distance in totality by which the **Fracture Affected Zone** is extended in the positive and negative Z direction of the crack coordinate system from the crack front extremities.

The shape of a Fracture Affected Zone is rectangular, regardless of the shape of the crack. Although buffer zones may overlap, you should use care when defining multiple cracks so that the zones do not overlap.

Important:

The crack generation process will fail if buffer zones overlap.

- **Circumferential Divisions**: This property is only visible when the **Mesh Method** property is set to **Hex Dominant**. It specifies the number of circumferential divisions for the crack shape. The value you enter must be a multiple of 8, and must be equal to or greater than 8. The default is 8.

  Note:

  The maximum number of circumferential divisions the **Geometry** window can display is 360. However, you can specify a higher value and the application will process it accordingly.

- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than 1. The default setting is 6.

  Note:

  The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.

- **Suppressed**: Toggles suppression of the **Ring Crack** object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Buffer Zone Scale Factors

This category includes the following properties:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **X Scale Factor**
- **Y Scale Factor**
- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone. When the **Mesh Method** property is set to **Hex-Dominant**, the crack dimensions also include fracture-affected zones.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6 below). To ensure the Named Selections accurately correspond to the **Ring Crack** object, the application uses the following naming convention:

- **NS**_*RingCrack*_**Front**
- **NS**_*RingCrack*_**Front2**
- **NS**_*RingCrack*_**TopFace**
- **NS**_*RingCrack*_**BottomFace**
- **NS**_*RingCrack*_**Contact1**
- **NS**_*RingCrack*_**Target1**

For example, for a **Ring Crack** object named **Ring Crack 4**, the default names are **NS_RingCrack 4_Front**, **NS_RingCrack 4_Front2**, **NS_RingCrack 4_TopFace**, **NS_RingCrack 4_BottomFace**, **NS_RingCrack 4_Contact1**, and **NS_RingCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack fronts (**NS**_*RingCrack*_**Front** and **NS_RingCrack 4_Front2**). Contains nodes used for postprocessing of results.

> **Important:**
>
> For cracks with multiple crack fronts, the **Crack Front Nodes** property, under **Named Selection Creation** category, only modifies the first crack front name if you have already generated the mesh. However, the application applies the property value to all crack fronts if you are generating the mesh for the first time or if the mesh is re-generated.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*RingCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*RingCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

- **Contact Pairs Nodes**: This property displays when the **Mesh Method** property is set to **Hex Dominant**. It determines whether Named Selections are created automatically for the contact and target faces of the contact pair. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Contact 1 Nodes: Identifies the Named Selection that is created automatically for contact face 1 (**NS**_*RingCrack*_**Contact1**). It contains nodes located on the contact face. The contact nodes are selected at the interface from the buffer zone of the base mesh.

  Target 1 Nodes: Identifies the Named Selection that is created automatically for target face 1 (**NS**_*RingCrack*_**Target1**). It contains nodes located on the target face. The target nodes are selected at the interface from the fracture affected zone of the hex dominant mesh.

Note:

Fracture meshing creates contact pair 1 between the fracture affected zone and the buffer zone.

---

6. Select the **Fracture** object or **Ring Crack** object, right-click, and select **Generate All Crack Meshes**.

   When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Ring Crack** object with which they are associated.

   Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining a Corner Crack

This section describes the steps to create a **Corner Crack**. You use this crack type to create a crack at any corner of a solid body. This crack must intersect at least two faces of the solid body.

Procedure

To define a **Corner Crack**:

1. Select the **Model** object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

Note:

Only one **Fracture** object is valid per **Model**.

---

3. Insert a **Corner Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Corner Crack**. You can also select the **Corner Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.

4. A corner crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.

5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Example entries are illustrated below.

Details of "Corner Crack"

Scope	
Source	Analytical Crack
Scoping Method	Geometry Selection
Geometry	1 Body
Definition	
Crack ID	86
Coordinate System	Origin
Crack Shape	Corner
--Major Radius	4. mm
--Minor Radius	2. mm

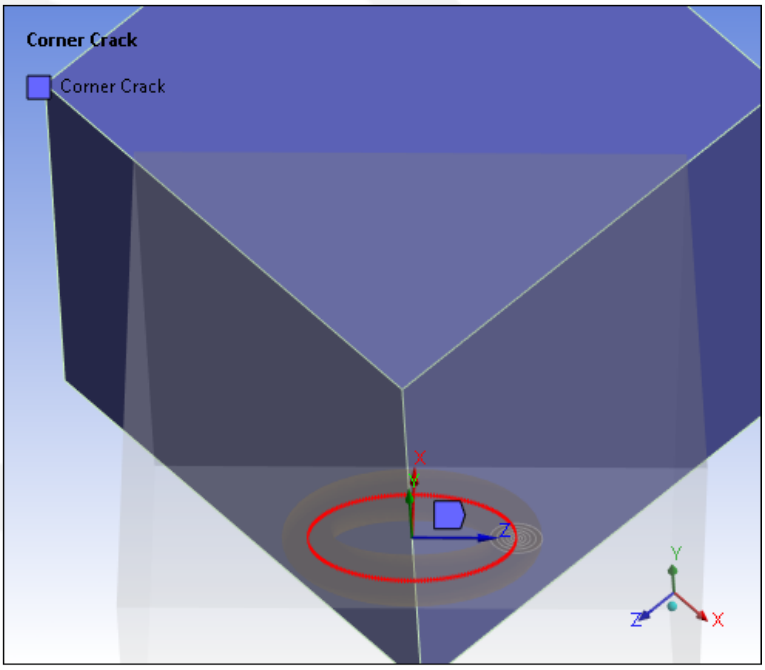
Y Scale Factor	2.
Z Scale Factor	2.
Named Selections Creation	
Crack Front Nodes	NS_CornerCrack_Front
Crack Faces Nodes	Off



Crack categories and properties include:

Definition

- **Crack ID**: A read-only property that displays a unique system generated identification value. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: Specify the coordinate system that defines the orientation of the crack. The Y axis of the specified coordinate system must be directed towards

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

the normal of the crack plane and the crack plane always lies in the X-Z plane of the specified coordinate system.

- **Crack Shape**: Read-only property set to **Corner**.
- **Major Radius**: Specifies the major radius, which defines the size of the crack shape along the Z axis (that is, the width of the crack). Enter a value greater than 0.
- **Minor Radius**: Specifies the minor radius, which defines the size of the crack shape along the X axis (that is, the depth of the crack). Enter a value greater than 0.
- **Mesh Method**: This is a read-only property set to **Tetrahedrons**, the only supported method.
- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.
- **Growth Rate**: This property specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size**: This property specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.
- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than 1. The default setting is **6**.

Note:

The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the crack object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Buffer Zone Scale Factors

This category includes the following properties:

- **X Scale Factor**
- **Y Scale Factor**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6 below). To ensure the Named Selections accurately correspond to the **Corner Crack** object, the application uses the following naming convention:

- **NS**_*CornerCrack*_**Front**
- **NS**_*CornerCrack*_**TopFace**
- **NS**_*CornerCrack*_**BottomFace**
- **NS**_*CornerCrack*_**Contact1**
- **NS**_*CornerCrack*_**Target1**

For example, for a **Corner Crack** object named **Corner Crack 4**, the default names are **NS_CornerCrack 4_Front**, **NS_CornerCrack 4_TopFace**, **NS_CornerCrack 4_BottomFace**, **NS_CornerCrack 4_Contact1**, and **NS_CornerCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*CornerCrack*_**Front**). Contains nodes used for postprocessing of results.
- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*CornerCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*CornerCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

6. Select the **Fracture** object or **Corner Crack** object, right-click, and select **Generate All Crack Meshes**.

When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Corner Crack** object with which they are associated.

Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Published: 2023-10-23

Defining an Edge Crack

This section describes the steps to create an **Edge Crack**. You can define this crack type on any face of a solid in order to cut into the face of the solid body.

Procedure

To define an **Edge Crack**:

1. Select the **Model** object.
2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

3. Insert a **Edge Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Edge Crack**. You can also select the **Edge Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.
4. A edge crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.
5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Example entries are illustrated below.

Published: 2023-10-23

- **Depth**: Specifies the depth of the crack. Enter a value greater than **0**.
- **Growth Rate**: This property specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size**: This property specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.
- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than 1. The default setting is **6**.

> **Note:**
>
> The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the crack object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Buffer Zone Scale Factors

This category includes the following properties:

- **X Scale Factor**
- **Y Scale Factor**
- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6 below). To ensure the Named Selections accurately correspond to the **Edge Crack** object, the application uses the following naming convention:

- **NS**_*EdgeCrack*_**Front**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **NS**_*EdgeCrack*_**TopFace**
- **NS**_*EdgeCrack*_**BottomFace**
- **NS**_*EdgeCrack*_**Contact1**
- **NS**_*EdgeCrack*_**Target1**

For example, for a **Edge Crack** object named **Edge Crack 4**, the default names are **NS_EdgeCrack 4_Front**, **NS_EdgeCrack 4_TopFace**, **NS_EdgeCrack 4_BottomFace**, **NS_EdgeCrack 4_Contact1**, and **NS_EdgeCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*EdgeCrack*_**Front**). Contains nodes used for postprocessing of results.
- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*EdgeCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*EdgeCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

6. Select the **Fracture** object or **Edge Crack** object, right-click, and select **Generate All Crack Meshes**.

   When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Edge Crack** object with which they are associated.

   Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining a Through Crack

This section describes the steps to create a **Through Crack**. You use this crack type to define a crack that cuts through a solid body from one surface to the other.

Procedure

To define a **Through Crack**:

1. Select the **Model** object.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

   Only one **Fracture** object is valid per **Model**.

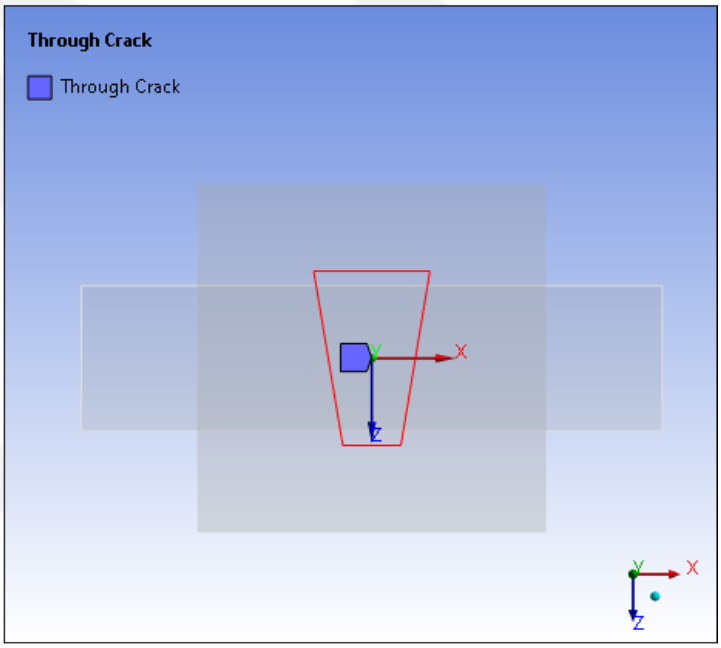
3. Insert a **Through Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Through Crack**. You can also select the **Through Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.

4. A through crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.

5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Example entries are illustrated below.

Details of "Through Crack"

Scope	
Source	Analytical Crack
Scoping Method	Geometry Selection
Geometry	1 Body
Definition	
Crack ID	102
Coordinate System	Coordinate System
Crack Shape	Through
Start Width	4. mm
End Width	2. mm
Mid Width	3. mm
Depth	6. mm
Mesh Method	Tetrahedrons
Largest Contour Radius	2. mm
Growth Rate	Default (1.2)
Front Element Size	Default (0.20141 mm)
Mesh Contours	6
Solution Contours	Match Mesh Contours
Suppressed	No
Buffer Zone Scale Factors	
X Scale Factor	2.
Y Scale Factor	2.
Z Scale Factor	2.
Named Selections Creation	
Crack Front Nodes	NS_ThroughCrack_Front
Crack Faces Nodes	Off



Crack categories and properties include:

Definition

- **Crack ID**: A read-only property that displays a unique system generated identification value. The application uses this identifier when creating solution identifiers for fracture parameters.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Coordinate System**: Specify the coordinate system that defines the orientation of the crack. The Y axis of the specified coordinate system must be directed towards the normal of the crack plane and the crack plane always lies in the X-Z plane of the specified coordinate system.
- **Crack Shape**: Read-only property set to **Through**.
- **Start Width**: Specifies the width at the start of the crack. Enter a value greater than **0**.
- **End Width**: Specifies the width at the end of the crack. Enter a value greater than **0**.
- **Mid Width**: Specifies the width at the centre of the start and end of the crack. Enter a value greater than **0**.
- **Depth**: Specifies the depth of the crack. Enter a value greater than **0**.
- **Mesh Method**: This is a read-only property set to **Tetrahedrons**, the only supported method.
- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.
- **Growth Rate**: This property specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size**: This property specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.
- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than 1. The default setting is **6**.

  Note:

  The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the crack object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Buffer Zone Scale Factors

This category includes the following properties:

- **X Scale Factor**
- **Y Scale Factor**
- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6 below). To ensure the Named Selections accurately correspond to the **Through Crack** object, the application uses the following naming convention:

- **NS**_*ThroughCrack*_**Front**
- **NS**_*ThroughCrack*_**TopFace**
- **NS**_*ThroughCrack*_**BottomFace**
- **NS**_*ThroughCrack*_**Contact1**
- **NS**_*ThroughCrack*_**Target1**

For example, for a **ThroughCrack** object named **ThroughCrack 4**, the default names are **NS_ThroughCrack 4_Front**, **NS_ThroughCrack 4_TopFace**, **NS_ThroughCrack 4_BottomFace**, **NS_ThroughCrack 4_Contact1**, and **NS_ThroughCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*ThroughCrack*_**Front**). Contains nodes used for postprocessing of results.
- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*ThroughCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*ThroughCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

6. Select the **Fracture** object or **Through Crack** object, right-click, and select **Generate All Crack Meshes**.

   When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Through Crack** object with which they are associated.

   Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining a Cylindrical Crack

This section describes the steps to create an **Cylindrical Crack**. You use the cylindrical crack option to insert a crack, with a cylindrical shape, into a solid body.

Procedure

To define an **Cylindrical Crack**:

1. Select the **Model** object.
2. Insert a Fracture object by right-clicking on the **Model** object and selecting **Insert** > **Fracture**. You can also select the **Fracture** option from the **Define** group on the Model Context Tab (p. 48).

   Note:

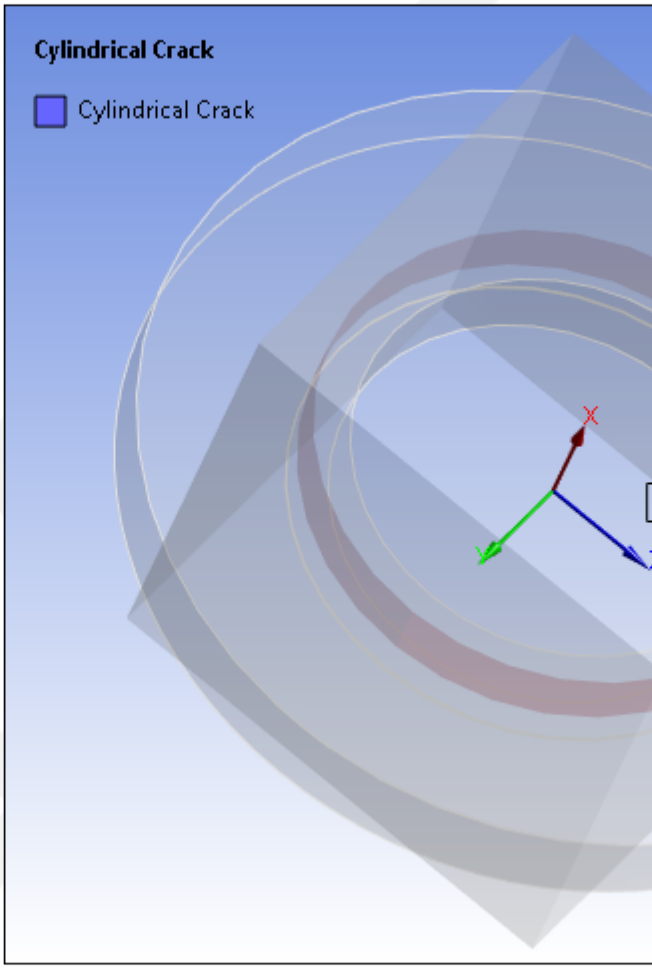
   Only one **Fracture** object is valid per **Model**.

3. Insert a **Cylindrical Crack** object by right-clicking on the **Fracture** object and selecting **Insert** > **Cylindrical Crack**. You can also select the **Cylindrical Crack** option from the **Crack** group of the **Fracture** (p. 52) Context Tab.
4. A cylindrical crack definition must always be scoped to a single solid body. Use the **Body** selection filter to pick a body in the **Geometry** window, click the **Geometry** field in the Details, and then click **Apply**.
5. Specify the properties of the crack. As you specify property values, the entries are reflected on the model in the **Geometry** window. Examples entries are illustrated below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Details of "Cylindrical Crack"

Scope	
Source	Analytical Crack
Scoping Method	Geometry Selection
Geometry	1 Body
Definition	
Crack ID	169
Coordinate System	Coordinate System
Crack Shape	Cylindrical
--Major Radius	0.6 m
--Minor Radius	0.6 m
--Height	0.15 m
Mesh Method	Tetrahedrons
Largest Contour Radius	2.5e-002 m
Growth Rate	Default (1.2)
Front Element Size	2.5e-002 m
Mesh Contours	6
Solution Contours	Match Mesh Contours
Suppressed	No
Buffer Zone Scale Factors	
X Scale Factor	2.
Y Scale Factor	2.
Z Scale Factor	2.
Named Selections Creation	
Crack Front Nodes	NS_CylindricalCrack_Front
Crack Faces Nodes	On
--Top Face Nodes	NS_CylindricalCrack_TopFace
--Bottom Face Nodes	NS_CylindricalCrack_BottomFace



Crack categories and properties include:

Definition

- **Crack ID**: A read-only property that displays a unique system generated identification value. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: Specify the coordinate system that defines the orientation of the crack. The X axis of the specified coordinate system must be directed towards the axis of the cylindrical crack and the first crack front always lies in the Y-Z plane of the specified coordinate system.
- **Crack Shape**: Read-only property set to **Cylindrical**.
- **Major Radius**: Specifies the major radius, which defines the size of the crack shape along the Y axis. Enter a value greater than **0**.
- **Minor Radius**: Specifies the minor radius, which defines the size of the crack shape along the Z axis. Enter a value greater than **0**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Height**: Specifies the height of the cylindrical crack to be inserted. The height is defined from the origin of the coordinate system (starting face of the cylinder) to the other end of the cylinder.

  Important:

  If the specified height is less than the gap between the origin of the coordinate system and the free surface of the solid geometry, the mesh generates two crack fronts and two crack surfaces. Otherwise, the mesh generates a single crack front and two crack surfaces.

- **Mesh Method**: This is a read-only property set to **Tetrahedrons**, the only supported method.
- **Largest Contour Radius**: Specifies the largest contour radius for the crack shape. Enter a value greater than **0**.
- **Growth Rate**: It specifies the factor with which the mesh layers will grow along the radius of the crack. Specify a value greater than **1**. The default value is **1.2**. The recommended value is equal to or greater than **1.1**.
- **Front Element Size**: It specifies the element size for the crack front. The default value is computed using crack length. Specify a value greater than **0**.
- **Mesh Contours**: Specifies the number of mesh contours for the crack shape. The value you enter must be equal to or greater than **1**. The default setting is **6**.

  Note:

  The maximum number of mesh contours the **Geometry** window can display is 100. However, you can specify a higher value and the application will process it accordingly.

- **Solution Contours**: Specifies the number of mesh contours for which you want to compute the fracture result parameters. The value you enter must be less than or equal to the value of **Mesh Contours**, and cannot be greater than 99. By default, the value is **Match Mesh Contours**, indicating the number of **Solution Contours** is equal to the number of **Mesh Contours**. Entering 0 resets the value to **Match Mesh Contours**.
- **Suppressed**: Toggles suppression of the **Cylindrical Crack** object. The default is **No**. The application automatically suppresses the crack object if the scoped body becomes suppressed.

Buffer Zone Scale Factors

This category includes the following properties:

- **X Scale Factor**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Y Scale Factor**
- **Z Scale Factor**

These properties control the size of the buffer zone in the X, Y, and Z directions, relative to the dimensions of the crack. For each scaling parameter, use the slider to set a value from **2** to **50**. The default is **2**. The maximum dimension among the three directions of the crack is multiplied by the corresponding scale factors to create a buffer zone.

Named Selection Creation

The **Named Selection Creation** category of the **Details** displays Named Selections automatically created by the application following fracture mesh generation (Step 6 below). To ensure the Named Selections accurately correspond to the **Cylindrical Crack** object, the application uses the following naming convention:

- **NS**_*CylindricalCrack*_**Front**
- **NS**_*CylindricalCrack*_**TopFace**
- **NS**_*CylindricalCrack*_**BottomFace**
- **NS**_*CylindricalCrack*_**Contact1**
- **NS**_*CylindricalCrack*_**Target1**

For example, for a **Cylindrical Crack** object named **Cylindrical Crack 4**, the default names are **NS_CylindricalCrack 4_Front**, **NS_CylindricalCrack 4_TopFace**, **NS_CylindricalCrack 4_BottomFace**, **NS_CylindricalCrack 4_Contact1**, and **NS_CylindricalCrack 4_Target1**.

The properties of this category are defined as follows:

- **Crack Front Nodes**: Identifies the Named Selection that is created automatically for the crack front (**NS**_*CylindricalCrack*_**Front**). Contains nodes used for postprocessing of results.
- **Crack Faces Nodes**: Determines whether Named Selections are created automatically for the crack's top face and bottom face. These faces are both located in the XZ plane and are discontinuous. Options include **Off** (default) and **On**. If set to **On**, the following additional properties appear:

  Top Face Nodes: Identifies the Named Selection that is created automatically for the top face (**NS**_*CylindricalCrack*_**TopFace**). This face is discontinuity plane 1. It contains nodes used for applying a pressure to the top face.

  Bottom Face Nodes: Identifies the Named Selection that is created automatically for the bottom face (**NS**_*CylindricalCrack*_**BottomFace**). This face is discontinuity plane 2. It contains nodes used for applying a pressure to the bottom face.

6. Select the **Fracture** object or **Cylindrical Crack** object, right-click, and select **Generate All Crack Meshes**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When the fracture mesh is generated, the requested Named Selections are automatically inserted into the Outline under the **Cylindrical Crack** object with which they are associated.

Select the **Show Mesh** option on the Graphics Toolbar (p. 97) to display the fracture mesh.

Defining a Pre-Meshed Crack

A Pre-Meshed Crack is based on a previously-generated mesh and uses a node-based named selection to analyze crack fronts. In addition to cracks modeled in CAD and meshed manually in the Mechanical Application, this feature is also useful when you have a pre-existing mesh generated from an external source and imported to the existing database. The referenced named selection must contain references only to nodes.

Selecting the named selection is done through the Details view of the Pre-Meshed Crack object by selecting from the list of valid named selections in the Crack Front (Named Selection) property. Named selections that contain only nodes are offered as choices.

Important:

To properly define a **Pre-Meshed Crack** object, you need to create the necessary node-based Named Selections and generate all crack meshes in advance. For more information on named selections, see Working with Named Selections (p. 1057). As an alternative, a geometric based named selection can be converted into a node-based based named selection using the Worksheet. For more information, see Specifying Named Selections using Worksheet Criteria (p. 1061).

To define a pre-meshed crack:

1. Select the **Model** object in the Tree Outline.
2. Insert a **Fracture** object into the Tree by right-clicking the **Model** object and selecting **Insert** > **Fracture**.

   Note:

   Only one **Fracture** object is valid per **Model**.

   ---

3. Insert a **Pre-Meshed Crack** object into the Tree by right-clicking the **Fracture** object and selecting **Insert** > **Pre-Meshed Crack**. You can also select the **Pre-Meshed Crack** option from the **Crack** group of the **Fracture** Context Tab.
4. In the **Details View**:

   For 2D Analysis

   Specify the node-based named selection for the **Crack Tip (Named Selection)** property. This property defines the nodes to which the crack definition will be scoped.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

For 3D Analysis

- Specify the node-based named selection for the **Crack Front (Named Selection)** property. This property defines the nodes to which the crack definition will be scoped.
- As desired, set the Crack Faces Nodes property to **On**. This property enables you to specify a crack top face and bottom face using node-based Named Selections. The default setting is **Off**. When set to **On**, the following additional properties display:
  - **Top Face Nodes**: Specify the top face (nodes) of the crack by selecting a valid node-based named selection from the drop-down list.
  - **Bottom Face Nodes**: Specify the bottom face (nodes) of the crack by selecting a valid node-based named selection from the drop-down list.

5. To further define the crack, use the following controls in the **Details View**.

- **Crack ID**: A read-only property that displays a unique system generated identification number ID for the crack object. The application uses this identifier when creating solution identifiers for fracture parameters.
- **Coordinate System**: Specifies the coordinate system that defines the position and orientation of the crack. The Y axis of the specified coordinate system defines the crack surface normal. The origin of the coordinate system represents the open side of the crack. You can select the default coordinate system or a local coordinate system that you have defined. The default is the **Global Coordinate System**. The valid coordinate system must be of type Cartesian.
- **Solution Contours**: Specifies the number of contours for which you want to compute the fracture result parameters.
- **Symmetry**: Specifies the crack symmetry about a line (in 2D analysis) or about a plane (in 3D analysis). The default is **No**.
- **Suppressed**: Toggles suppression of the **Pre-Meshed Crack** object. The default is **No**.

Note:

The **Pre-Meshed Crack** object is suppressed automatically if the scoped body is suppressed.

Special Handling of Named Selections for Crack Objects

Crack objects dynamically generate Named Selections during crack mesh generation. The Named Selections generated for **Arbitrary Crack**, **Semi-Elliptical Crack**, **Elliptical**, or **Ring** crack objects are a special type of Named Selection and have the following distinct properties:

- Named Selections for **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, or **Arbitrary Crack** objects are not inserted into the Named Selections branch of the Tree Outline. They appear in

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

the Outline under the **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack** or **Arbitrary Crack** objects with which they are associated.

- You may rename a Named Selection by editing its name in the Details of the **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack** or **Arbitrary Crack** objects or by right-clicking the Named Selection in the tree Outline and selecting **Rename**. Use caution when renaming the Named Selection associated with the crack front (**NS**_*SECrack*_**Front**). If the name is not unique when compared to other Named Selections, the crack definition sent to the solver may contain the wrong set of crack front nodes.

  Important:

  For cracks with multiple crack fronts, the **Crack Front Nodes** property, under **Named Selection Creation** category, only modifies the first crack front name if you have already generated the mesh. However, the application applies the property value to all crack fronts if you are generating the mesh for the first time or if the mesh is re-generated.

- For a **Ring Crack**, two crack front named selections are created at the outer and inner intersection of the crack with the solid body.
- An **Arbitrary Crack** defined using an embedded or intersecting crack surface body could generate more than one crack front.
- You cannot insert, duplicate, copy, delete, or merge these Named Selections.
- You may scope nodal-based loads to these Named Selections.
- By default, nodal Named Selections show nodes attached to them in the **Geometry** window. To plot elements attached to these nodal Named Selections, refer to Specifying Annotation Preferences (p. 310) section of the help.
- If you delete **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, or **Arbitrary Crack** objects, all associated Named Selections are deleted.
- If you suppress **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, or **Arbitrary Crack** objects, the nodal selection of each associated Named Selection is cleared and the state of each Named Selections becomes suppressed.
- All Named Selections for **Semi-Elliptical Crack**, **Elliptical Crack**, **Ring Crack**, or **Arbitrary Crack** objects are sent to the solver. **Send to Solver** is always set to **Yes** and is read-only.
- If Named Selections for **Crack Faces Nodes** and/or **Contact Pairs Nodes** have been created and you subsequently set the fields to **Off**, the corresponding Named Selections are deleted when a new crack mesh is generated.

Published: 2023-10-23

- See the Working with Named Selections (p. 1057) section of the Help for additional information.

Note:

For information about common fracture meshing problems and troubleshooting, see Fracture Meshing Problems (p. 2380).

SMART Crack Growth

You use the **SMART Crack Growth** object to simulate fatigue or static crack growth in engineering structures. SMART is a remeshing-based method for crack growth simulation. SMART stands for Separating, Morphing, Adaptive, and Remeshing Technology. SMART automatically uses a combination of morphing, adaptive, and remeshing methods to update mesh changes to simulate static or fatigue crack growth during the solution process. The mesh changes occur around the crack-front region only, leading to a computationally efficient solution of the crack-growth problem. See the following subsections for more information.

SMART Crack Growth Application

SMART Crack-Growth Assumptions and Limitations

Note:

When you define **SMART Crack Growth**, the application stores fracture results for time points based on the setting of the **Analysis Settings** > Output Controls (p. 1473) property **Store Results At** (p. 1481).

Important:

If the **Store Results At** property is not set to the **All Time Points** option, the **Crack Extension** and **Total Number of Cycles** probe results will be inaccurate. This is because these values are derived from the summation of results stored in the results file instead of the summation of results over all solved sub-steps. Therefore, Ansys recommends that you set the **Store Results At** property to **All Time Points** for accurate **Crack Extension** and **Total Number of Cycles** probe results. Furthermore, Ansys recommends that you use this property to specify time points, even if you issue additional **OUTRES** commands through the **Commands (APDL)** object.

Note:

- For additional technical information on this feature, refer to the SMART Method for Crack-Growth Simulation section in the *Mechanical APDL Fracture Analysis Guide*.
- For specific information about the properties of the object, see the SMART Crack Growth object reference page.
- For a video example of the feature, see the Fatigue Crack Growth Analysis using SMART Crack Growth Tutorial.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

SMART Crack Growth Application

The following procedure describes the steps to define a **SMART Crack Growth** object. The procedure assumes that you have already inserted a Fracture folder and defined the prerequisite crack. This crack can be any of the supported crack types. The feature supports the definition of multiple **SMART Crack Growth** objects when your model contains multiple cracks.

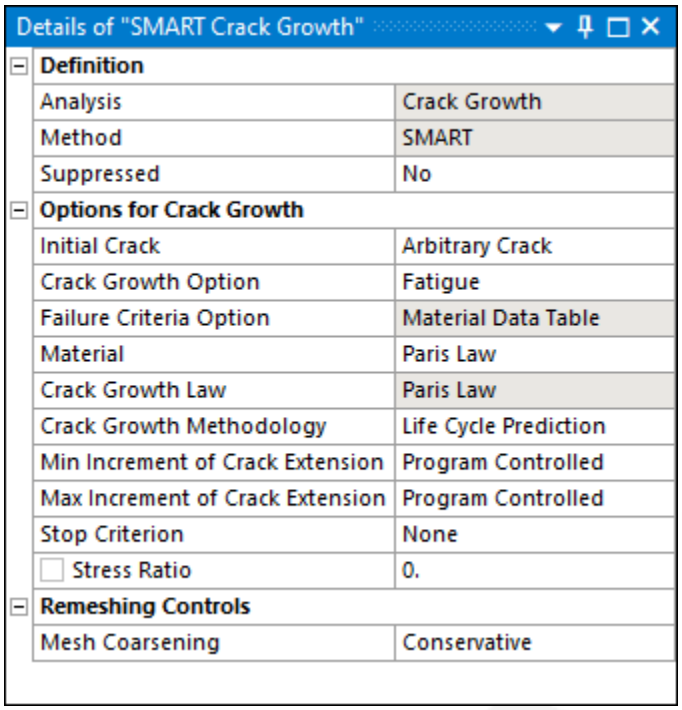
1. Insert a **SMART Crack Growth** object into the **Outline** by right-clicking on the **Fracture** object and selecting **Insert** > **SMART Crack Growth** from the context menu. Alternatively, you can select the **SMART Crack Growth** option on the Fracture Context Tab (p. 52) or right-click in the **Geometry** window and select **Insert** > **SMART Crack Growth**.

2. Select the new **SMART Crack Growth** object in the **Outline**. The **Initial Crack** and **Material** properties highlight. First, select the crack that you have already created for the **Initial Crack** property. An example is illustrated below using a **Pre-Meshed Crack**. Once selected, the application automatically selects the default **Material** of scoped crack body (specified by the **Initial Crack** property), in this case, Material1.

Details of "SMART Crack Growth"

Definition	
Analysis	Crack Growth
Method	SMART
Suppressed	No
Options for Crack Growth	
Initial Crack	
Crack Growth Option	Fatigue
Failure Criteria Option	Material Data Table
Material	
Crack Growth Law	Paris Law
Crack Growth Methodology	Life Cycle Prediction
Min Increment of Crack Extension	Program Controlled
Max Increment of Crack Extension	Program Controlled
Stop Criterion	None
Stress Ratio	0.
Remeshing Controls	
Mesh Coarsening	Conservative

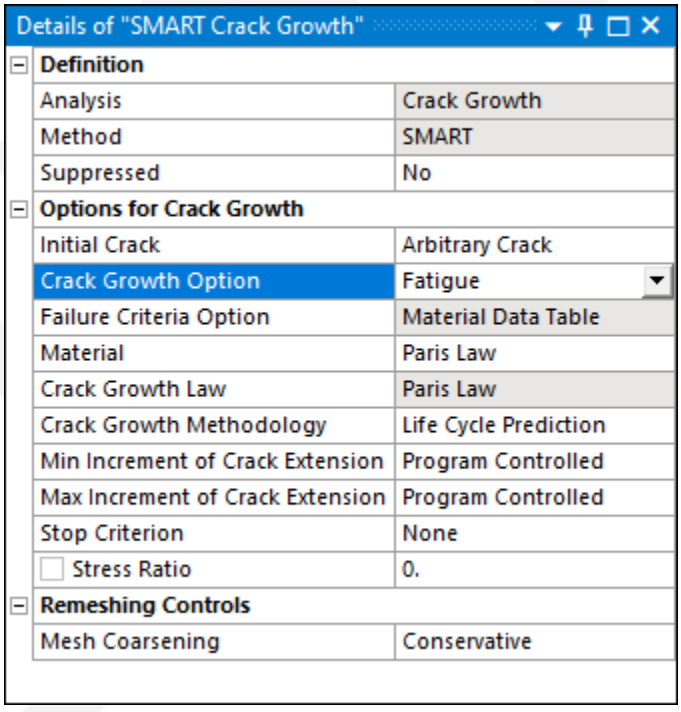
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



3. Specify the **Crack Growth Option** property. The setting of this property is based on the desired type of crack growth propagation. Select **Fatigue** (default) or **Static**.

Fatigue

If you set the **Crack Growth Option** property to **Fatigue**, your structure is subject to constant amplitude cyclic load.



The following other properties are available in the category:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Failure Criteria Option**: This is a read-only property that is set to **Material Data Table**.
- **Material**: The application automatically selects the default material that is assigned to the crack specified that is specified in the **Initial Crack** property. You can change the material using the property's fly-out menu. Any material that you select must include the material property Paris' Law.
- **Crack Growth Law**: This is a read-only property that displays the given Crack Growth Law: **Paris' Law**.
- **Crack Growth Methodology**: Fatigue crack growth can be modeled using either **Life Cycle Prediction** (default) or **Cycle By Cycle** methodologies. If you specify **Cycle By Cycle**, the property **Incremental Number of Cycles** displays. Use this property to specify the incremental number of cycles during a substep. The default setting is **10**.

  The following additional properties are also available:

  – **Min Increment of Crack Extension**: This property specifies the minimum crack extension increment value. The options include **Program Controlled** (default) and **Manual**. The **Program Controlled** option uses the default minimum increment value. If you set the property to **Manual**, The **Min Increment Value** property displays and enables you to specify a value. The default value is **0**.

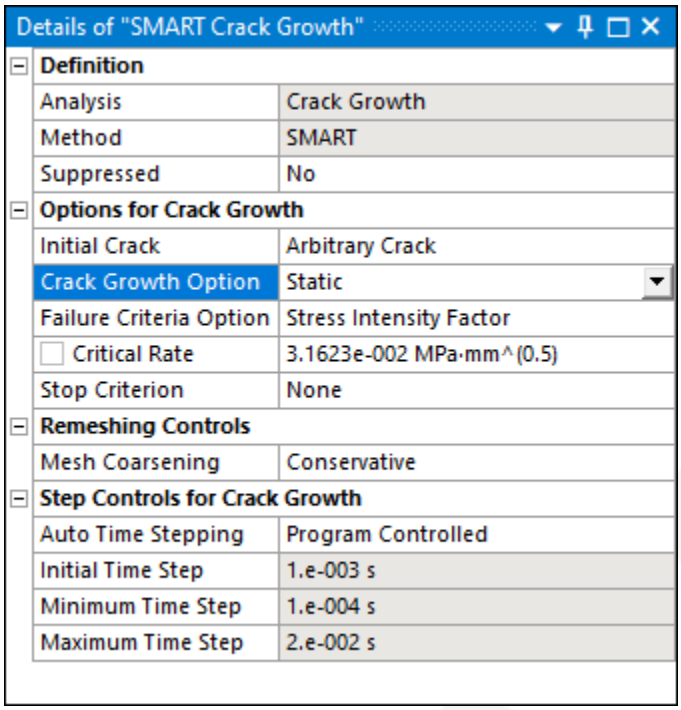
  – **Max Increment of Crack Extension**: This property specifies the maximum crack extension increment value. The options include **Program Controlled** (default) and **Manual**. The **Program Controlled** option uses the default maximum increment value. If you set the property to **Manual**, The **Max Increment Value** property displays and enables you to specify a value. The default value is **0**.

  – **Stress Ratio**: You use this property to specify the stress ratio. The default value is **0**. The entry range is less than **1**.

Static

If you set the **Crack Growth Option** property to **Static**, crack growth modeling is based on selected fracture parameters and criteria.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Using the **Failure Criteria Option** property, you can specify the failure criteria as either **Stress Intensity Factor** (default) or **J-Integral**. Each option requires you to specify a value in the dependent property **Critical Rate**. The default value for the Critical Rate property is **0** for either option. The unit system of the **Critical Rate** property varies based on your selection. The property can be parameterized.

Note:

Either the **Stress Intensity Factor** or **J-Integral** fracture parameter can be computed in one solution. Additionally, you can compute **Equivalent SIFS Range** fracture result and related time history results on any crack front node (Fracture Probes (p. 2127)).

Furthermore, when you set the **Crack Growth Option** property to **Static**, an additional category displays for the object: **Step Controls for Crack Growth**. The properties for this category include:

- **Auto Time Stepping**: Property options include **Program Controlled** (default) or **Manual**. Setting the property to Manual enables you to modify the following time step properties, otherwise they are read-only.
- **Initial Time Step**: Defines the initial time step to initiate crack growth.
- **Minimum Time Step**: Minimum time step for subsequent crack growth.
- **Maximum Time Step**: Maximum time step for subsequent crack growth.

4. As needed, specify the **Stop Criterion** property. Options include **None** (default), **Max Crack Extension**, **Free Boundary**, **Max Stress Intensity Factor**, and **Max Total Number of Cycles** (displayed when the **Crack Growth Option** property is set to **Fatigue**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When you select the **Max Crack Extension**, **Max Stress Intensity Factor**, or the **Max Total Number of Cycles**, the **--Stop Value** property displays. This property requires you to enter a value for the selected **Stop Criterion** option. Once the maximum stop criterion limit is reached, the application stops the solution process. In this instance, the solution is incomplete and the **Solution** folder will not be in solved state because the solution is not complete for all time points. If the maximum stop criterion limit is not reached during solution, then the solution process completes normally.

5. Specify the **Mesh Coarsening** property. You use this property to define a desired level of coarsening of the excessively fine mesh surrounding the crack front during the SMART crack growth remeshing processing. Options include:

   - **Conservative** (default): This option performs the least amount of mesh coarsening and creates a larger number of nodes and elements after a substantial amount of crack-growth. This options offers the greatest remeshing success rate.
   - **Moderate**: This option modestly reduces the number of nodes and elements and offers a satisfactory remeshing success rate.
   - **Aggressive**: This option quickly coarsens the mesh in the region behind crack front and offers the largest reduction in the number of nodes and elements following a substantial amount of crack-growth.

6. Repeat the steps above to define additional **SMART Crack Growth** objects when multiple cracks exist in the model.

SMART Crack-Growth Assumptions and Limitations

Go to a section topic:

- General Assumptions and Limitations (p. 473)
- Postprocessing Limitations (p. 475)
- Multiple SMART Crack Growth Objects (p. 475)

General Assumptions and Limitations

Review the following for the use of the **SMART Crack Growth** feature:

- Only supports Static Structural analyses.
- Supports 3-D crack growth only.
- Supports Mixed Mode Crack Growth for Mode I and II only. If using J-Integral as Crack Growth Criterion, then only straight (Mode I) crack growth is supported.
- Supports higher order tetrahedron mesh. To use it with a hex-dominant base mesh (for Arbitrary Crack and Semi-Elliptical Crack objects only) you need to set the Fracture object property **Re-mesh Hex-dominant to Tetrahedral** to **On**. This will re-mesh the bodies scoped to the **Arbitrary Crack** and **Semi-Elliptical Crack** objects to tetrahedrons when **Generate All Crack Meshes** (right-click) menu option is executed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Material behavior is assumed to be linear elastic isotropic.
- Fatigue crack growth is based on Paris' Law.
- Plasticity effects, nonlinear geometry effects, load-compression effects, and crack-tip-closure effects are not considered.
- Supports the Bonded, No-Separation, Frictionless, Rough, and Frictional contact Type (p. 1234) property options with CONTA174 and TARGE170 when they remain outside the remeshing zone during the simulation. SMART does not support any contact element inside the remeshing zone.
- Function based loads and tabular loads with time as independent variable are not supported for fatigue crack growth analysis.
- Node- and element-based components are not maintained after remeshing. Therefore, Ansys recommends that you use the **Tabular Data** option of the **Define By** property to define the load in a multi-step analysis.
- Does not currently support **Point Mass** or **Distributed Mass**.
- Only supports the following Imported Loads (p. 1736):
  - Imported Pressure
  - Imported Force
  - Imported Displacement
  - Imported Body Temperature
  - Imported Initial Stress
- Does not currently support Hydrostatic Pressure.
- Either SIFS or J-Integral fracture parameter can be computed in one solution.
- Restarting the analysis is currently not supported.

Note:

Activate beta options to make solution restarts available for **SMART Crack Growth**.

- When the crack grows to the point of breaking the structural component apart, all solution results are set to zero and no crack-front information is reported.
- **Graphics Limitation**: During your analysis, if your SMART crack grows from one body to another body, you need to scope the corresponding bodies to a Material Assignment object (p. 1049) and assign them with the same material using **Material Name** property. This in turn facilitates the proper display of the crack front contour result in the graphics window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Postprocessing Limitations

Note the following **SMART Crack Growth** postprocessing limitations:

- Probes scoped to the same body as a **SMART Crack Growth** object will **not** evaluate.
- The **Crack Extension** probe displays the sum of the crack extension increments from only those substeps in which crack extension increment information has been saved. That is, if crack results are not written for each specified Substep, as is the case when **Analysis Settings** > **Output Controls** property **Store Results At** is not set to **All Time Points** (or using the **OUTRES,CINT,Value** command snippet) in a Static Structural environment, the application does not display the entire crack extension for the **Crack Extension** probe. It is because these values are derived from the summation of results stored in the results file instead of the summation of results over all solved sub-steps. This same behavior is found with **Total Number of Cycles** probe result. Even if you issue additional **OUTRES** commands through the **Commands (APDL)** object, Ansys recommends that you issue **OUTRES,CINT,ALL** to specify all time points,

Multiple SMART Crack Growth Objects

Make sure of the following setting when you have specified multiple **SMART Crack Growth** objects:

- Each crack specified on the model must be associated with an unique **SMART Crack Growth** object (1:1 ratio).
- The **Crack Growth Option** property must be set to the same option (**Fatigue** or **Static**) for all **SMART Crack Growth** objects.
- The **Failure Criteria Option** property must be set to the same option (**SIFS** or **J-Integral**) when the **Crack Growth Option** property is set to **Static** for all **SMART Crack Growth** objects.
- The **Crack Growth Methodology** property must be set to the same option (**Life Cycle Prediction** or **Cycle By Cycle**) when the **Crack Growth Option** property is set to **Fatigue** for all **SMART Crack Growth** objects.

Note:

The **SMART Crack Growth** feature uses local re-meshing and adaptation techniques and therefore has restrictions for the crack extension size.

For example, the feature might modify your entries in the **Min Increment of Crack Extension** or **Max Increment of Crack Extension** properties for either **Crack Growth Methodology**, either **Life Cycle Prediction** or **Cycle By Cycle**.

When the **Crack Growth Methodology** property is set to **Life Cycle Prediction** and the **Max Increment of Crack Extension** manual entry is larger than 1.5 times of the element size at the crack front, the **Max Increment of Crack Extension** value is modified to 1.5 times of the element size. Similarly, if the manual entry for the **Min Increment of Crack Extension** is smaller than 0.25 times of the element size at the crack tip, the **Min Increment of Crack Extension** value is modified to 0.25 times of the element size.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

When the **Crack Growth Methodology** property is set to **Cycle By Cycle**, and you enter a number of cycles that is too large or too small, then the algorithm automatically re-defines the number of cycles according to the crack front element size. However, the **Min Increment of Crack Extension**, the **Max Increment of Crack Extension**, and the **Increment Number of Cycles** property values may not be satisfied during the solution to ensure a robust mesh change.

Interface Delamination and Contact Debonding

Adhesives are commonly used to bond structural components into assemblies or to bond layers of material into composite laminates. Simulations often assume the bonding layer to be of infinite strength, but you may want to model the progressive separation of the adhesive as it reaches some known criteria, such as a stress limit. Of the existing theories that define these failure criteria, Mechanical supports the Cohesive-Zone Model (CZM) method and the Virtual Crack Closure Technique (VCCT) method. (See the Cohesive Zone Material (CZM) Model in the *Theory Reference* and VCCT-Based Crack-Growth Simulation in the *Fracture Analysis Guide* for more information about these methods.) In either case, the separation occurs along a predefined interface and cannot propagate in an arbitrary direction

Mechanical supports the following features for modeling interface delamination and debonding:

- **Interface Delamination** – utilizes Mechanical APDL interface elements (INTER202 through INTER205) and supports the CZM and VCCT methods. Neither method supports interfaces with lower order triangle faces. Specifically, a prism with a triangle face on the interface or a tetrahedral element with a face on the interface. And, the VCCT does not support higher order elements.
- **Contact Debonding** utilizes Mechanical APDL contact elements (CONTA171 through CONTA177) and supports the CZM method.

For additional technical information about Interface Delamination, see Modeling Interface Delamination with Interface Elements in the *Fracture Analysis Guide*. For more information about Contact Debonding, see Modeling Interface Delamination with Contact Elements (Debonding) in the *Fracture Analysis Guide*.

See the Interface Delamination Application (p. 477) and Contact Debonding Application (p. 480) sections for the steps to specify and configure these features. In addition, if you are using the Ansys Composite PrepPost (ACP) application in combination with the Interface Delamination feature, see the steps in the Interface Delamination and Ansys Composite PrepPost (ACP) (p. 481) section.

Analysis Type Requirements

Interface Delamination is supported by Static Structural and Transient Structural analyses only.

Any analysis type may contain a **Contact Debonding** object, but only the Static Structural and Transient Structural analyses support the progressive separation of an interface. **Contact Debonding** also supports linear perturbation, which allows you to simulate the vibration (Pre-stressed Modal) or stability (Eigenvalue Buckling) characteristics of a partially delaminated structure. You can also use the modes extracted in the Pre-stressed model to perform Mode Superposition analyses such as Harmonic Response, Response Spectrum, and Random Vibration.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Interface Delamination Application

The **Interface Delamination** feature employs either the Virtual Crack Closure Technique (VCCT) method or the Cohesive-Zone Model (CZM) method for defining failure criteria. The VCCT method is a fracture mechanics based method and therefore requires an initial crack (in the form of a Pre-Meshed Crack) in the geometry. The CZM method uses relationships between the separations and tractions along the interface. Note that the CZM method is sensitive to mesh size and material parameters. The convergence of CZM models can generate issues, such as loading step size and stabilization.

Important:

The **Interface Delamination** feature is not supported with **Semi-Elliptical** or **Arbitrary** cracks.

To correctly insert the structural interface elements (INTER202 through INTER205) into the mesh, the Interface Delamination feature requires that the sides of the interface have identical element patterns.

Both the VCCT and CZM methods provide the option to use either the **Matched Meshing** or the **Node Matching** generation method. **Matched Meshing** requires that you create a Mesh **Match Control** at the delamination interface.

A **Match Control** requires that both faces referenced by the **Match Control** belong to the same part, so it is necessary that you create a multi-body part without shared topology. This can be accomplished in a CAD application, such as DesignModeler. **Matched Meshing** is the recommended **Generation Method** because it quickly obtains the matching node pairs from the mesh.

Caution:

The application will not respect mesh matching controls when one or more mesh Refinement controls exist. This may result in mismatched node pairs and element faces.

If using a **Match Control** is not an option and it is necessary to use the **Node Matching** method, you must ensure that node pairs and element faces match. Because it is necessary for Mechanical to search the scoped geometry for matching node pairs within the specified **Distance Tolerance**, this method can be slower and less robust than the **Matched Meshing** method.

Note:

The Interface Delamination feature does not support adaptive mesh refinement.

Also see the Interface Delamination Object Reference page for information about the properties of this feature.

Apply Interface Delamination

To specify **Interface Delamination**:

1. Insert a **Fracture** folder in the **Tree Outline**. The **Fracture** object becomes active by default.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

2. On the **Fracture** Context Tab (p. 52): click **Interface Delamination**. Or, right-click:

   - the **Fracture** tree object and select **Insert**>**Interface Delamination**.

     Or...

   - *in* the Geometry window and select **Insert**>**Interface Delamination**.

3. Select the desired **Method**: either **VCCT** (p. 478) (default) or **CZM** (p. 479). The properties vary based on your selection.

VCCT Method

1. Specify the **Failure Criteria Option** property: either **Energy-Release Rate** (default) or **Material Data Table**.

2. Based on the selected **Failure Criteria Option**:

   - If specified as **Energy-Release Rate**: enter a **Critical Rate** value. This value determines the energy release rate in one direction.

   - If specified as **Material Data Table**: specify a **Material**. This property defines the energy release rate in all three fracture modes. This property is defined in Engineering Data. See the Static Structural & Transient Structural section of the Engineering Data Help for additional information about the Cohesive Zone properties used by this feature.

3. Based on the **Generation Method** selected, either **Matched Meshing** (default) or **Node Matching**, perform one of the following:

   Matched Meshing

   If **Matched Meshing**, specify a **Match Control** by selecting a pre-defined **Match Control**. The **Match Control** that is referenced by the property requires that the delamination occurs between two independent parts that have the same element/node pattern.

   Node Matching

   If **Node Matching**, specify:

   a. **Scoping Method**

   b. **Source**

   c. **Target**

   Note:

   This option assumes that the existing mesh is already matched.

4. Define the **Initial Crack** by selecting a user-defined Pre-Meshed Crack.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. Specify the **Auto Time Stepping** property as either **Program Controlled** (default) or **Manual**. The following properties can be modified if **Manual** is selected, otherwise they are read-only.

   a. **Initial Time Step**

   b. **Minimum Time Step**

   c. **Maximum Time Step**

   Note:

   - The **Auto Time Stepping** property *must* be set to **On** in the **Step Controls** (p. 1418) category of the **Analysis Setting** object.
   - Time stepping values take effect when crack growth is detected.

6. If **Node Matching** is selected as the **Generation Type**, the **Node Matching Tolerance** category displays.

   Specify the **Tolerance Type** property as either **Program Controlled** (default) or **Manual**. The **Distance Tolerance** property can be modified if **Manual** is selected, otherwise it is read-only.

CZM Method

1. Specify a **Material**. This property is defined in Engineering Data. See the Static Structural & Transient Structural section of the Engineering Data Help for additional information about the Cohesive Zone properties used by this feature.
2. Define the **Generation Method** property as either **Matched Meshing** (default) or **Node Matching**.
3. Based on the **Generation Method** selected, either **Matched Meshing** or **Node Matching**, perform one of the following:

   Matched Meshing

   For the **Matched MeshingGeneration Method**, select a pre-defined **Match Control**. The **Match Control** that is referenced by the property requires that the delamination occurs between two independent parts that have the same element/node pattern.

   Node Matching

   If **Node Matching** is the **Generation Method**, then specify:

   a. **Scoping Method**

   b. **Source**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

c. **Target**

Note:

This option assumes that the existing mesh is already matched.

4. If **Node Matching** is selected as the **Generation Type**, the **Node Matching Tolerance** category displays.

   Specify the **Tolerance Type** property as either **Program Controlled** (default) or **Manual**. The **Distance Tolerance** property can be modified if **Manual** is selected, otherwise it is read-only.

Contact Debonding Application

Debonding simulations begin by defining contact regions along an interface that will separate. The properties for the contact elements require that the contact **Type** (p. 1234) be **Bonded** or **No Separation** contact and that the **Formulation** (p. 1241) is specified as the **Augmented Lagrange** method or the **Pure Penalty** method.

The **Contact Debonding** object specifies the pre-existing contact region (defined using the Connections (p. 1207) feature) that you intend to separate and it also references the material properties defined in Engineering Data. You must select the material properties from the **Cohesive Zone** category with type **Separation-Distance based Debonding** or **Fracture-Energies based Debonding**. See the Static Structural & Transient Structural section of the Engineering Data Help for additional information about the Cohesive Zone properties used by this feature.

Apply Contact Debonding

To specify **Contact Debonding**:

1. Insert a **Fracture** folder in the **Tree Outline**. The **Fracture** object becomes active by default.
2. On the **Fracture** Context Tab (p. 52): click **Contact Debonding**. Or, right-click:
   - the **Fracture** tree object and select **Insert**>**Contact Debonding**.

   Or...

   - *in* the Geometry window and select **Insert**>**Contact Debonding**.
3. Select a **Material**.
4. Select a **Contact Region**.

Tip:

To automatically generate a **Contact Debonding** object, select a **Contact Region** and drag and drop it onto the Fracture folder.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Also see the Contact Debonding Object Reference Help page for information about the properties of this feature.

Interface Delamination and Ansys Composite PrepPost (ACP)

Mechanical allows you to import interface layer(s) from the Ansys Composite PrepPost (ACP) application. You can define interface layers in ACP, import them into Mechanical, and use them to define **Interface Delamination** objects. You can automatically insert Interface Delamination objects into the **Fracture** folder when importing composite section data into Mechanical by setting the **Create Delamination Objects** property (see Specifying Options (p. 217)) to **Yes**. Alternatively, you can generate Interface Delamination objects automatically after you have imported Composite Section data by selecting the **Generate All Interface Delaminations** option in the context menu of the Fracture object.

Unexpected Penetration during Nonlinear Analysis

If you experience penetration at the interface layers during separation, you may wish to create a Contact condition (p. 1266) for the interface where the penetration is taking place. A Contact Region can be applied (p. 1227) to a **Pre-Generated Interface** provided by ACP. Although all contact Type (p. 1234) settings are supported for **Pre-Generated Interfaces**, the **Frictionless** setting is recommended for this case when specifying the contact condition. Other contact properties can be set to the default, **Program Controlled**, settings.

Apply Interface Delamination via ACP

To specify **Interface Delamination** using the ACP application:

Note:

The following steps assume that you have properly defined your interface layer in the ACP application.

VCCT Method (Default)

1. From the Workbench Project page, link your Static Structural or Transient Structural analysis to the **ACP (Pre)** system and then launch Mechanical.

   A **Fracture** folder is automatically created and includes an **Interface Delamination** object.

2. Select the new **Interface Delamination** object.

3. Specify the **Failure Criteria Option** property: either **Energy-Release Rate** (default) or **Material Data Table**.

4. Based on the selected **Failure Criteria Option**:

   - If specified as **Energy-Release Rate**: enter a **Critical Rate** value. This value determines the energy release rate in one direction.

   - If specified as **Material Data Table**: specify a **Material**. This property defines the energy release rate in all three fracture modes. This property is defined in ACP.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

5. The automatic setting for the **Generation Method** property is **Pre-Generated Interface**. Accept this setting.
6. As necessary, select the appropriate Interface Layer from the **Interface** property drop-down menu.
7. Define the **Initial Crack** by selecting the Pre-Meshed Crack created by ACP.
8. Specify the **Auto Time Stepping** property as either **Program Controlled** (default) or **Manual**. The following properties can be modified if **Manual** is selected, otherwise they are read-only.
   a. **Initial Time Step**
   b. **Minimum Time Step**
   c. **Maximum Time Step**

Note:

- The **Auto Time Stepping** property *must* be set to **On** in the **Step Controls** (p. 1418) category of the **Analysis Setting** object.
- Time stepping values take effect when crack growth is detected.

CZM Method

1. From the Workbench Project page, link your Static Structural or Transient Structural analysis to the **ACP (Pre)** system and then launch Mechanical.

   A **Fracture** folder is automatically created and includes an **Interface Delamination** object.
2. Select the new **Interface Delamination** object.
3. Specify the **Material** property. This property provides a fly-out menu to make a material selection that was defined in the **ACP (Pre)** system.
4. The automatic setting for the **Generation Method** property is **Pre-Generated Interface**. Accept this setting.
5. As necessary, select the appropriate Interface Layer from the **Interface** property drop-down menu.

Multi-Point Constraint (MPC) Contact for Fracture

The internally generated crack mesh is created after an initial base mesh is generated. Since the crack mesh is defined based on the crack object, while the base mesh is created based on the geometry and mesh parameters, the two meshes may not perfectly match at the boundaries of the fracture

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

affected zone. For more information on the fracture affected zone, see the Fracture Analysis (p. 406) section in the Meshing User's Guide.

Note:

- The application does not create a contact pair when you set the **Mesh Method** to **Tetrahedrons** when meshing Semi-Elliptical Crack.
- The application does not create a contact pair for Arbitrary crack meshing.

When a solution is performed on an analysis which contains an internally generated crack mesh, a contact region using Multi-Point Constraint (MPC) formulation is automatically created between the crack mesh and the base mesh at the boundaries of the fracture-affected zone. This contact is applicable to static structural analysis, transient structural analysis, modal analysis, steady-state thermal analysis, and transient thermal analysis. For more information about the MPC contact formulation, see Contact Formulation Theory (p. 1222). This contact is only created for a **Semi-Elliptical Crack** object when the **Mesh Method** property is set to **Hex Dominant** and is not applicable to the **Pre-Meshed Crack** object.

The characteristics/settings of the MPC contact are shown below. For more information about the different contact settings, see Advanced Settings (p. 1240).

- Bonded surface-to-surface contact is defined between the crack mesh and the base mesh at the boundary of the fracture-affected zone. The contact element CONTA174 is created on the faces of the base mesh, and the target element TARGE170 is created on the faces of the crack mesh.
- The contact is asymmetric in nature. The contact can be made auto asymmetric by setting the `use auto symmetric` variable to 1 in the Variable Manager (p. 247).
- Nodal contact detection, normal from the contact surface, will be defined.
- The initial gap and penetration are ignored.
- For steady-state thermal and transient thermal analysis, the temperature degree of freedom is selected.

For more information about contact settings, refer to the CONTA174 documentation in the Element Reference. For more information about the MPC constraint, see Multipoint Constraints and Assemblies in the *Contact Technology Guide*.

Solving a Fracture Analysis

Once the crack mesh is generated, you can apply loads and constraints, then solve the analysis. Then, once the solution is done, you can analyze the stress and deformation pattern around the crack. For meshes defined by the **Semi-Elliptical Crack** object or the **Arbitrary Crack** object, you can apply the loads on the crack face top and bottom discontinuity plane using nodal named selections.

For the **Semi-Elliptical Crack** object, the application defines the internally generated crack mesh after the initial base mesh. The base mesh generation is based on a different set of requirements and constraints than the crack mesh. As a result, the crack mesh, generated using the Hex dominant mesh method, may not perfectly match the boundaries of the fracture affected zone. Because they may

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

not match perfectly, kinematic constraints are required to establish a connection between base mesh and crack mesh in the boundaries of the fracture affected zone, which is accomplished using the multi-point constraint (MPC) contact (p. 482). A contact pair is created at the interface of the crack and base meshes, with contact surface created at the interface on the buffer zone side of the base mesh and target surface created at the interface on the fracture affected zone side of the hex dominant mesh. When the solution is performed using internally-generated crack meshes, the MPC contact region is automatically created and sent to the solver.

Important:

For **Arbitrary Cracks** as well as analytical cracks (ring, corner, etc.), the application does not create a contact pair when the **Mesh Method** property is set to **Tetrahedrons**.

Note:

Static Structural and Transient Structural analyses are the only analyses supported for fracture mechanics calculations. However, the mesh with cracks is also supported with a static structural analysis linked to an upstream steady state thermal or transient thermal analysis.

Also, all loads and boundary conditions applicable to the static structural analysis are applicable with the existence of crack in the solution.

Although you can add **Fracture** and crack objects of any definition to a Modal analysis or a Mode Superposition (MSUP) Transient analysis, the application does not compute fracture parameters during the solution.

Computation of Fracture Parameters

The stress and deformation pattern around the crack is not sufficient to evaluate the catastrophic failure of the structure. The computation of fracture parameters and its comparison against fracture toughness is necessary for designing safe structures.

To compute fracture parameters for all cracks defined under the **Fracture** folder, the **Fracture** property in the **Fracture Controls** (p. 1445) of the Analysis Settings must be set to **On**. This entry is visible only if the **Fracture** folder exists in the model. By default, the application does not compute fracture parameters for Material Force and T-Stress. You need to set their properties under the **Fracture Controls** of the Analysis Settings to **Yes**.

The computations used for fracture analysis include Stress Intensity Factors (SIFS), J-Integral (JINT), Energy Release Rates, Material Force, T-Stress and C*-Integral. The Mode 1 Stress Intensity Factor (K1), Mode 2 Stress Intensity Factor (K2), Mode3 Stress Intensity Factor (K3), and T-Stress are computed along the crack front using the interaction integral method. The Mode 1 Energy Release Rate (G1)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

and Mode 2 Energy Release Rate (G2), Mode 3 Energy Release Rate (G3) and Total Energy Release Rate (GT) are computed using the Virtual Crack Closure Technique (VCCT) along the crack front.

Note:

The Energy Release Rate parameters, which are specific to the Pre-Meshed Crack object, are computed using the Virtual Crack Closure Technique (VCCT). When the VCCT technique is used, a specific mesh pattern composed of hexahedral shapes along the crack front is recommended for better accuracy. For more information, see Understanding Fracture Mechanics in the *Fracture Analysis Guide*.

The JINT result is a mixed mode result and is also computed along the crack front using the domain integral method. The fracture parameters, for all cracks defined under the fracture folder, are automatically computed and stored in the results file when the **Fracture** property in the **Fracture Controls** (p. 1445) category of Analysis Settings is set to **On**. The SIFS and JINT results are calculated for all cracks defined under the Fracture folder. The VCCT results are calculated only if the crack mesh generated is of lower order (dropped midside nodes). Material Force and T-Stress results are calculated only when their respective control is set to Yes in the **Fracture Controls** (p. 1445) category of Analysis Settings. You can direct the fracture parameter computation for all cracks to use symmetry by setting the `all cracks symmetric` variable to active with a value of 1 in the Variable Manager. For more information, see Setting Variables (p. 247). Fracture parameter calculation based on SIFS supports linear isotropic elastic material behavior. VCCT based fracture parameter calculation supports linear isotropic elastic, anisotropic elastic and orthotropic elastic material behavior. J-Integral based and T-stress based fracture parameter calculation supports isotropic elastic and isotropic plastic material behaviors. Material force based fracture parameter calculation supports linear isotropic elastic, isotropic hardening plasticity, kinematic hardening plasticity and isotropic hyperelastic material behaviors. C*-Integral based fracture parameter calculation supports secondary (steady-state) creep material behavior and it is computed along the crack front using the domain integral method. You can exclude computation of any fracture parameter (except VCCT) by setting its respective control in the **Fracture Controls** (p. 1445) category of **Analysis Settings** to **No**.

Note:

If you get the following message:

The fracture parameters computed during solution may be incorrect. Check the Solver Output on the Solution Information object (p. 1833) for possible causes.

Check for the following:

- A contact might have been created in the region of the crack contours.
- A load might have been applied in the region of the crack contours that is not supported in the fracture parameter computation. Try replacing it with a Direct FE (p. 1719) load. You can also replace the normal Pressure loads using the **Applied By** property option, **Direct**.

Extracting Fracture Results from a Result File

The Fracture Tool (p. 2066) provides the **Scoping Method** option, **Result File Item**, that enables you to read a result file (p. 1861) into the application prior to solution processing. For the associated fracture results and probes, included under the **Fracture Tool**, you specify a desired **Solver ID** from the drop-down menu to evaluate the result from the result file. Furthermore, by reading a results file, you can evaluate the fracture results of a Pre-Meshed Crack without needing to define the crack. For all other crack types, your simulation must include a defined Fracture folder, a matching mesh, as well as defined boundary conditions.

See the Extract Fracture Results from a Result File (p. 2072) topic in the Fracture Results (p. 2066) section for the specific steps to extract fracture results from a result file (`file.rst`).

Requirements

Note the following requirements for this feature:

- You must ensure that the mesh in the result file matches the mesh in Workbench. This includes the Workbench generated mesh from the geometry as well as any nodes or elements defined in the input file (such as for contact or remote boundary conditions). Failure to do so could result in incorrect results and unexpected behavior.
- Fracture probes can be evaluated only if the fracture analysis had cracks associated with a **SMART Crack Growth** object from which the result file is saved and read.
- Once you read a result file, if you do not see an expected **Solver ID** in the property's drop-down menu, this indicates that the result was not available in the results file. You must delete or suppress the result in order to continue with your analysis.

Linear Dynamics Analysis Types

Applying external forces gradually to a structure does not cause it to experience any pulse or motion. You can solve structural responses with a simple static equilibrium analysis. That is, the structural elasticity forces and the external forces equilibrate one another.

In reality, however, structures are subject to rapidly applied forces (or so-called dynamic forces), for example, high-rise buildings, airplane wings, and drilling platforms are subject to wind gusts, turbulences, and ocean waves, respectively. These structures are in a state of motion as a result of the dynamic forces. To simulate and solve for the structural responses in a logical manner, a dynamic equilibrium analysis, or a dynamic analysis, is desirable. In a dynamic analysis, in addition to structural elasticity force, structural inertia and dissipative forces (or damping) are also considered in the equation of motion to equilibrate the dynamic forces. Inertia forces are a product of structural mass and acceleration while dissipative forces are a product of a structural damping coefficient and velocity.

When performing a linear dynamic analysis, the application calculates structural responses based the assumption that a structure is linear.

The following sections discuss the steps and requirements to perform different linear dynamic simulations.

Eigenvalue Buckling Analysis

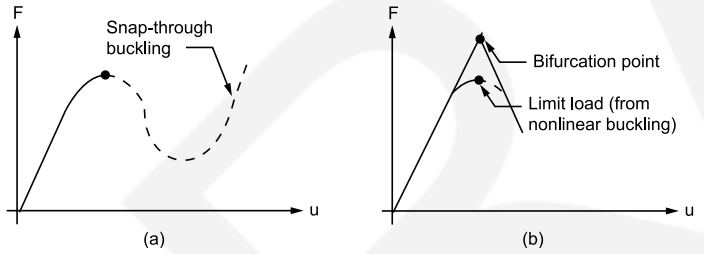
Background

An Eigenvalue Buckling analysis predicts the theoretical buckling strength of an ideal elastic structure. This method corresponds to the textbook approach to an elastic buckling analysis: for instance, an eigenvalue buckling analysis of a column matches the classical Euler solution. However, imperfections and nonlinearities prevent most real-world structures from achieving their theoretical elastic buckling strength. Therefore, an Eigenvalue Buckling analysis often yields quick but non-conservative results.

A more accurate approach to predicting instability is to perform a nonlinear buckling analysis. This involves a static structural analysis with large deflection effects turned on. A gradually increasing load is applied in this analysis to seek the load level at which your structure becomes unstable. Using the nonlinear technique, your model can include features such as initial imperfections, plastic behavior, gaps, and large-deflection response. In addition, using deflection-controlled loading, you can even track the post-buckled performance of your structure (which can be useful in cases where the structure buckles into a stable configuration, such as "snap-through" buckling of a shallow dome, as illustrated below).



(a) Nonlinear load-deflection curve, (b) Eigenvalue buckling curve.

Eigenvalue Buckling in Mechanical

In Mechanical, an Eigenvalue Buckling analysis is a linear analysis and therefore cannot account for nonlinearities. It employs the Linear Perturbation Analysis procedure of Mechanical APDL. This procedure requires a pre-loaded environment from which it draws solution data for use in the Eigenvalue Buckling analysis. Based on this requirement, an Eigenvalue Buckling analysis can consider nonlinearities that are present in the pre-stressed environment allowing you to attain a more accurate real-world solution as compared to a traditional linear preloaded state.

Note:

The application supports the use of the Samcef solver for this analysis type. However, the information presented below applies to the use of the Mechanical APDL Solver only.

Published: 2023-10-23

Points to Remember

- An Eigenvalue Buckling analysis must be linked to (proceeded by) a Static Structural Analysis (p. 652). This static analysis can be either linear or nonlinear and the linear perturbation procedure refers to it as the "base analysis" (as either linear or nonlinear).
- The nonlinearities present in the static analysis can be the result of nonlinear:
  - Geometry (the **Large Deformation** property is set to **Yes**)
  - Contact status (A contact condition with the **Type** property set to anything other than **Bonded** or **No Separation** is treated as a non-linearity for contact. In addition, when the **Small Sliding** property set to **Off**, the system is treated as non-linear contact.)
  - Material (such as the definition of nonlinear material properties in Engineering Data, hyperelasticity, plasticity, etc.)
  - Connection (such as nonlinear joints and nonlinear springs)
- A structure can have an infinite number of buckling load factors. Each load factor is associated with a different instability pattern. Typically the lowest load factor is of interest.
- Based upon how you apply loads to a structure, load factors can either be positive or negative. The application sorts load factors from the most negative values to the most positive values. The minimum buckling load factor may correspond to the smallest eigenvalue in absolute value.
- For **Pressure** boundary conditions in the Static Structural analysis: if you define the load with the **Normal To** option for faces (3D) or edges (2-D), you could experience an additional stiffness contribution called the "pressure load stiffness" effect. The **Normal To** option causes the pressure to act as a follower load, which means that it continues to act in a direction normal to the scoped entity even as the structure deforms. **Pressure** loads defined with the **Components** or **Vector** options act in a constant direction even as the structure deforms. For a given pressure value in the upstream static system, the **Normal To** option and the **Component**/**Vector** options can produce significantly different buckling load factors in the follow-on Eigenvalue Buckling analysis.
- Buckling mode shapes do not represent actual displacements but help you to visualize how a part or an assembly deforms when buckling.
- The procedure that the Mechanical APDL solver uses to evaluate buckling load factors is dependent upon whether the pre-stressed Eigenvalue Buckling analysis is linear-based (linear prestress analysis) or nonlinear-based (nonlinear prestress analysis), as described below.

Linear-based Eigenvalue Buckling Analysis

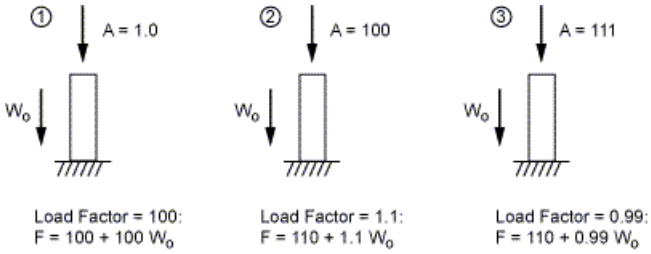
Note the following for an Eigenvalue Buckling analysis when the base analysis is linear:

- You can only define loading conditions in the upstream analysis.
- The results calculated by the Eigenvalue Buckling analysis are buckling load factors that scale **all** of the loads applied in the upstream Static Structural analysis. For example, if you applied a 10 N compressive load on a structure in the static analysis and if the Eigenvalue Buckling analysis calculates a load factor of 1500, then the predicted buckling load is 1500x10 = 15000 N. Because of this, it is typical to apply unit loads in the static analysis that precedes the buckling analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- The solver applies the buckling load factor to all the loads specified in the upstream static analysis.
- Note that the load factors represent scaling factors for all loads. If certain loads are constant (self-weight gravity loads) while other loads are variable (externally applied loads), you need to take special steps to ensure accurate results. For example, you can iterate on the Eigenvalue buckling solution, adjusting the variable loads until the load factor becomes 1.0 (or nearly 1.0, within some convergence tolerance). Consider the example below: a pole has a self-weight W_0 that supports an externally-applied load, A. To determine the limiting value of A in an Eigenvalue Buckling analysis, you could solve repetitively, using different values for A, until you find a load factor acceptably close to 1.0.



- If you receive all negative buckling load factor values for your Eigenvalue Buckling analysis and you wish to see them in the positive values, or vice versa, reverse the direction of all of the loads you applied in Static Structural analysis.
- You can apply a nonzero constraint in the Static Structural analysis. The load factors calculated in the buckling analysis should also be applied to these nonzero constraint values. However, the buckling mode shape associated with this load will show the constraint to have zero value.

Nonlinear-based Eigenvalue Buckling Analysis

Note the following for an Eigenvalue Buckling analysis when the base analysis is nonlinear:

- At least one form of nonlinearity must be defined in the upstream static analysis.
- You must define at least one load in the buckling analysis to proceed with the solution. To enable this, set the **Keep Pre-Stress Load-Pattern** property to **Yes** (default). This retains the loading pattern from the Static Structural Analysis in the Eigenvalue Buckling analysis. Setting the property to **No** requires you to define a new loading pattern for the Eigenvalue Buckling analysis. This new loading pattern can be completely different from that of the prestress analysis.
- In a nonlinear-based Eigenvalue Buckling analysis, load multipliers scale the loads applied in buckling analysis *ONLY*. When estimating the ultimate buckling load for the structure, you must account for the loading applied in both analyses. The equation to calculate the ultimate buckling load for the nonlinear-based Eigenvalue Buckling analysis is:

  $F_{BUCKLING} = F_{RESTART} + \lambda_i \cdot F_{PERTRUB}$

  where:

  – $F_{BUCKLING}$ = The ultimate buckling load for the structure.

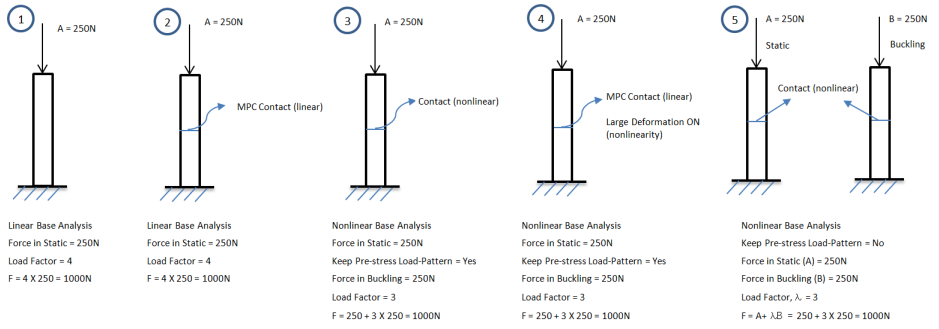
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- $F_{RESTART}$ = Total loads in Static Structural analysis at the specified restart load step.
- λ_i = Buckling load factor for the "i'th" mode.
- $F_{PERTRUB}$ = Perturbation loads applied in buckling analysis.

For example, if you applied a 100 N compressive force on a structure in the static analysis and a compressive force of 10 N in the Eigenvalue Buckling analysis and you get a load factor of 15, then the ultimate buckling load for the structure is 100 + (15 x 10) = 250 N.

You can verify the ultimate buckling load of the above equation using the buckling of a one dimensional column. However, calculating the ultimate buckling load for 2D and 3D problems with different combinations of loads applied in the Static Structural and Eigenvalue Buckling analyses may not be as straightforward as the 1D column example. This is because the $F_{RESTART}$ and $F_{PERTRUB}$ values are essentially the effective loading values in the static and buckling analyses, respectively.

For example, consider a cantilever beam that has a theoretical ultimate buckling strength of 1000N and that is subjected to a compressive force (A) of 250N. The procedure to calculate the ultimate buckling load (F), based on the load factors evaluated by Mechanical for linear-based and nonlinear-based Eigenvalue Buckling analyses is illustrated in the following schematic.



Note:

As illustrated, cases (3) and (5) are identical as the base analysis is nonlinear because of nonlinear contact definition. In Case (3), setting the **Keep Pre-Stress Load-Pattern** property to **Yes** automatically retains the loading from the pre-stress analysis. As a result, there is no need to define new loads for the buckling analysis in Case 3. For Case 5, the **Keep Pre-Stress Load-Pattern** property is set to **No**, enabling you to define a new load pattern in the buckling analysis that can be completely different from that of the Static Structural analysis.

- The buckling load factor evaluated in nonlinear-based Eigenvalue Buckling should be applied to all of the loads used in the buckling analysis.
- If you receive all negative buckling load factor values for your Eigenvalue Buckling analysis and you wish to see them in the positive values, or vice versa, reverse the direction of all of the loads you applied in the Static Structural analysis when the **Keep Pre-Stress Load-Pattern**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

property is set to **Yes**. If this property is set to **No**, reverse the direction of all of the loads that you applied in Eigenvalue Buckling analysis.

Preparing the Analysis

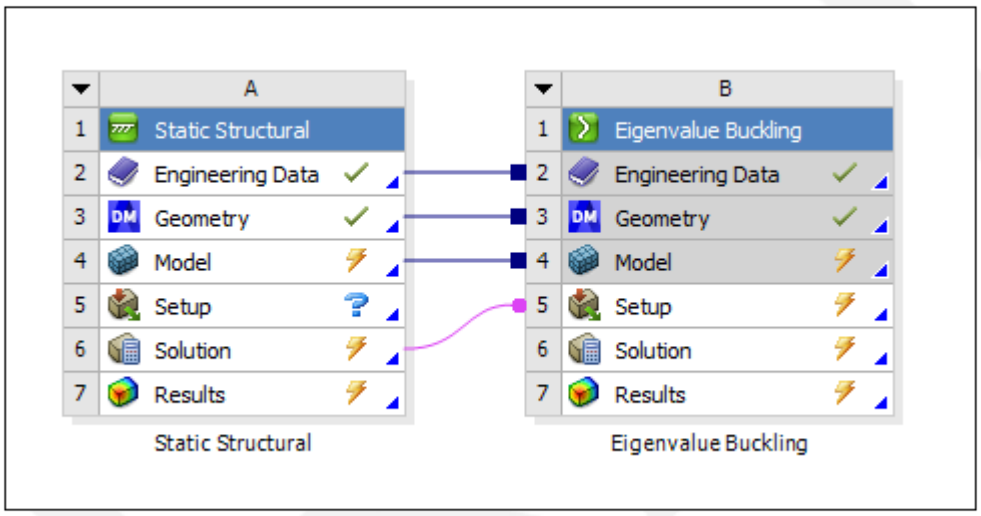
Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

Because this analysis is based on the Static Structural solution, a Static Structural analysis is a prerequisite. This linked setup allows the two analysis systems to share resources such as engineering data, geometry, and boundary condition type definitions.

From the **Toolbox**, drag a **Static Structural** template to the **Project Schematic**. Then, drag an **Eigenvalue Buckling** template directly onto the **Solution** cell of the **Static Structural** template. The proper linking is illustrated below.



Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

- Young's modulus (or stiffness in some form) must be defined.
- Material properties can be linear, nonlinear, isotropic or orthotropic, and constant or temperature-dependent.

Attach Geometry

There are no specific considerations for an Eigenvalue Buckling analysis.

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Linear-based Eigenvalue Buckling Analysis

The following contact settings are considered linear contact behaviors for Eigenvalue Buckling analyses. If any other contact settings are used, the analysis will be considered a Nonlinear-based Eigenvalue Buckling analysis.

- The **Formulation** property is set to **MPC** or **Beam**.

  Or...

- The **Type** property is set to **Bonded** or **No Separation** and **Small Sliding** is active.

Springs with linear stiffness definition are taken into account if they are present in the static analysis.

Only **Bushing** and **General** joints enable you to solve an analysis with nonlinear Joint Stiffness (p. 1331). Mechanical considers all other joint types to be linear. The application accounts for linear joints if they are present in the static analysis.

Nonlinear-based Eigenvalue Buckling Analysis

All nonlinear connections (including nonlinear springs and joints) are allowed. Any contact options other than the ones mentioned above would trigger a nonlinear-based Eigenvalue Buckling analysis.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no considerations specifically for an Eigenvalue Buckling analysis.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Specifics ***... for this analysis type:***

For an Eigenvalue Buckling analysis, the basic Analysis Settings (p. 1417) include:

Options (p. 1459)

- Use the **Max Modes to Find** property to specify the number of buckling load factors and corresponding buckling mode shapes of interest. Typically the first (lowest) buckling load factor is of interest. The default value for this field is **2**. You can change this default setting under the **Buckling** category of the **Frequency** (p. 224) options in the **Options** (p. 217) preference dialog.
- The **Keep Pre-Stress Load-Pattern** property is available for nonlinear-based Eigenvalue Buckling analyses. Use this property to specify whether you want to retain the pre-stress loading pattern to generate the perturbation loads in the Eigenvalue Buckling analysis. The default setting for this property is **Yes**, which automatically retains the structural loading pattern for the buckling analysis (refer to the **ALLKEEP***LoadControl* key setting for **PERTURB** command). Setting the property to **No** requires you to define a new loading pattern for the Eigenvalue Buckling analysis (refer to **PARKEEP***LoadControl* key setting for **PERTURB** command).

Important:

Because the **PARKEEP***LoadControl* key retains all displacements applied in Static Structural analysis for reuse in Eigenvalue Buckling analysis, any non-zero displacements applied in static analysis act as loads in Eigenvalue Buckling analysis. If you specifying different load types in the buckling analysis that are scoped to the same geometric entities and in the same direction, may be ignored. Define your new loading pattern carefully.

Solver Controls (p. 1428)

- **Solver Type**: The default option, **Program Controlled**, enables the application to select the appropriate solver type. Options include **Program Controlled**, **Direct**, and **Subspace**. By default, the **Program Controlled** option uses the **Direct** solver for linear-based Eigenvalue Buckling analyses and **Subspace** solver for nonlinear-based Eigenvalue Buckling analyses.

Note:

Both the **Direct** and **Subspace** solvers evaluate the buckling solutions for most engineering problems. If you experience a solution failure using one of the solvers because it cannot find the requested modes, it may help to switch the solvers. If both of the solvers fail to find the solution, then review your model carefully for possible stringent input specifications or loading conditions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Include Negative Load Multiplier**: The default option **Program Controlled** and the **Yes** option extract both the negative and positive eigenvalues (load multipliers). The **No** option only extracts positive eigenvalues (load multipliers).

Output Controls (p. 1473)

By default, only buckling load factors and corresponding buckling mode shapes are calculated. You can request **Stress** and **Strain** results to be calculated but note that "stress" results only show the relative distribution of stress in the structure and are not real stress values.

Note:

The **Output Controls** category is only exposed for the Mechanical APDL solver.

Analysis Data Management (p. 1484)

The properties of this category enable you to define whether or not to automatically save the Mechanical APDL database as well as automatically delete unneeded files.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

You must specify a Static Structural analysis that is using the same model in the initial condition environment, and:

- Because an Eigenvalue Buckling analysis must be preceded by a Static Structural analysis, you need to specify the same solver type for each, either Mechanical APDL or Samcef.
- The **Pre-Stress Environment** property in the **Pre-Stress (Static Structural)** initial condition object displays whether the pre-stress environment is considered linear or nonlinear for the Eigenvalue Buckling analysis.
- If the Static Structural analysis has multiple result sets, the value from any restart point available in the Static Structural analysis can be used as the basis for the Eigenvalue Buckling analysis. See the Restarts from Multiple Result Sets (p. 353) topic in the Applying Pre-Stress Effects (p. 352) Help section for more information.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

Loads are supported by Eigenvalue Buckling analysis only when the pre-stressed environment has nonlinearities defined.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The following loads are supported for a nonlinear-based Eigenvalue Buckling analysis:

- **Loads**: **Thermal Condition** (p. 1594)
- **Direct FE** (p. 1719) (node-based Named Selection scoping and constant loading only):
  - **Nodal Force** (p. 1721)
  - **Nodal Pressure** (p. 1724)
  - **Nodal Displacement** (p. 1728): At least one non-zero **Component** is required for the boundary condition to be fully defined.

Note:

- Choosing to keep the default setting (**Yes**) for the **Keep Pre-Stress Load-Pattern** property retains the pre-stress loading pattern for the buckling analysis and no additional load definition is necessary.
- For **Nodal Pressure**, the only definition option is **Normal To**. This results in the "pressure load stiffness" effect. To avoid the pressure stiffness effect, apply an equivalent **Nodal Force** load to the same surface and set the **Divide Load by Nodes** property to **Yes**. The equivalent force is equal to the value of the pressure multiplied by the area of the scoped surface.
- The node-based Named Selections used with the above **Direct FE Loads** (p. 1719) cannot contain nodes scoped to a rigid body.

No loading conditions can be created in a linear-based Eigenvalue Buckling analysis. The supports as well as the stress state from the linked Static Structural analysis are used in the linear-based Eigenvalue Buckling analysis. See the Apply Pre-Stress Effects for Implicit Analysis (p. 352) section for more information about using a pre-stressed environment.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

Solution Information (p. 1833) continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

You can view the buckling mode shape associated with a particular load factor by displaying a contour plot (p. 62) or by animating (p. 2260) the deformed mode shape. The contours represent relative displacement of the part.

Buckling mode shape displays are helpful in understanding how a part or an assembly deforms when buckling, but do not represent actual displacements.

"Stresses" from an Eigenvalue Buckling analysis do not represent actual stresses in the structure, but they give you an idea of the relative stress distributions for each mode. You can make **Stress** and **Strain** results available in the buckling analysis by setting the proper **Output Controls** (p. 1473) *before* the solution is processed.

Harmonic Response Analysis

Harmonic response analyses are used to determine the steady-state response of a linear structure to loads that vary sinusoidally (harmonically) with time, therefore enabling you to verify whether or not your designs will successfully overcome resonance, fatigue, and other harmful effects of forced vibrations.

Introduction

In a structural system, any sustained cyclic load will produce a sustained cyclic or harmonic response. Harmonic analysis results are used to determine the steady-state response of a linear structure to loads that vary sinusoidally (harmonically) with time, therefore enabling you to verify whether or not your designs will successfully overcome resonance, fatigue, and other harmful effects of forced vibrations.

This analysis technique calculates only the steady-state, forced vibrations of a structure. The transient vibrations, which occur at the beginning of the excitation, are not accounted for in a harmonic analysis.

In this analysis all loads as well as the structure's response vary sinusoidally at the same frequency. A typical harmonic analysis will calculate the response of the structure to cyclic loads over a frequency range (a sine sweep) and obtain a graph of some response quantity (usually displacements) versus frequency. "Peak" responses are then identified from graphs of response vs. frequency and stresses are then reviewed at those peak frequencies.

Points to Remember

A harmonic response analysis is a linear analysis. Some nonlinearities, such as plasticity will be ignored, even if they are defined. All loads and displacements vary sinusoidally at the same known frequency (although not necessarily in phase). If the **Reference Temperature** is set as **By Body** and that temperature does not match the environment temperature, a thermally induced harmonic load will result (from the thermal strain assuming a nonzero thermal expansion coefficient). This thermal harmonic loading is ignored for all harmonic analysis.

Mechanical offers the following solution methods for harmonic analyses:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Mode Superposition (Default)

For the **Mode Superposition** (also called "MSUP") option, the harmonic response to a given loading condition is obtained by performing the necessary linear combinations of the eigensolutions obtained from a Modal analysis.

For MSUP, it is advantageous for you to select an existing modal analysis directly (although Mechanical can automatically perform a modal analysis behind the scene) since calculating the eigenvectors is usually the most computationally expensive portion of the method. In this way, multiple harmonic analyses with different loading conditions could effectively reuse the eigenvectors. For more details, refer to Harmonic Response Analysis Using Linked Modal Analysis System (p. 509).

Acceleration (p. 1501) and/or Displacement (p. 1666) applied as a base excitation uses the Enforced Motion Method. See the Enforced Motion Method for Mode Superposition Transient and Harmonic Analyses section of the *Mechanical APDL Structural Analysis Guide* for additional information.

Full

Using the **Full** option, you obtain harmonic response through the direct solution of the simultaneous equations of motion. In addition, a Harmonic Response analysis can be linked to, and use the structural responses of, a Static-Structural analysis. See the Harmonic Analysis Using Pre-Stressed Structural System (p. 506) section of the Help for more information.

Include Residual Vector

This property is available when the **Solution Method** is set to **Mode Superposition**. You can turn the **Include Residual Vector** property **On** to execute the **RESVEC** command and calculate residual vectors.

Note:

The following boundary conditions do not support residual vector calculations:

- **Nodal Force**
- **Remote Force** scoped to a **Remote Point** (created via **Model** object)
- **Moment** scoped to a **Remote Point** (created via **Model** object)

Variational Technology

Using the **Variational Technology** option, the application evaluates the harmonic response for each excitation frequency based on one direct solution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Program Controlled

Using the **Program Controlled** option, the application selects the best solution method based on the model. Internally, the application chooses either the **Full** or **Variational Technology** solution method.

Note:

- For more technical information about Variational Technology, see the Harmonic Analysis Variational Technology Method section of the *Mechanical APDL Theory Reference*.
- Also see the **HROPT** command in the Mechanical APDL Command Reference for more information about harmonic analysis options.
- If a Command object is used with the MSUP method, object content is sent twice; one for the modal solution and another for the harmonic solution. For that reason, harmonic responses are double if a load command is defined in the object, for example, **F** command.

Preparing the Analysis

As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Define Engineering Data

Both Young's modulus (or stiffness in some form) and density (or mass in some form) must be defined. Material properties must be linear but can be isotropic or orthotropic, and constant or temperature-dependent. Nonlinear properties, if any, are ignored.

Define Connections

Any nonlinear contact such as **Frictional** contact (p. 1234) retains the initial status throughout the harmonic analysis. The stiffness contribution from the contact is based on the initial status and never changes.

The application accounts for spring stiffness as well as damping when using the **Program Controlled**, **Full**, and **Variational Technology** solution methods. For the **Mode Superposition** option, the application ignores damping from springs.

Establish Analysis Settings

For a Harmonic Response analysis, the basic Analysis Settings (p. 1417) include:

Step Controls

The **Step Controls** (p. 1426) category enables you to define step controls for an analysis that includes multiple load steps. You use the properties of this category to define the load steps and their options. When you select the **Analysis Settings** object, the content of the **Step Controls** category automatically displays in the **Worksheet**. You can modify certain properties in either the **Worksheet**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

or in the **Details** pane. For each load step, you can specify solution settings (Frequency Spacing, minimum frequencies, maximum frequencies, etc.). See the Step Controls for Harmonic Analysis Types (p. 1426) section for a description of the properties.

Options

The **Options** category (p. 1447) enables you to specify the frequency range and the number of solution points at which the harmonic analysis will be carried out as well as the solution method to use and the relevant controls.

The **Solution Method** property options for a harmonic response analysis, **Program Controlled**, **Mode Superposition**, Direct Integration (**Full**), and **Variational Technology**, are described below.

- **Program Controlled**: The application selects the best solution method based on the model. Internally, the application chooses either the **Full** or **Variational Technology** solution method.
- **Mode Superposition**: This is the default method and generally provides results faster than the other methods. Using this method, a modal analysis is first performed to compute the natural frequencies and mode shapes. Then the mode superposition solution is carried out where these mode shapes are combined to arrive at a solution. The **Mode Superposition** method cannot be used if you need to apply imposed (nonzero) displacements. When using this method, you can set the **Cluster Results** property to **Yes** to group the structure's natural frequencies. This results in a smoother, more accurate tracing of the response curve. The default method of equally spaced frequency points can result in missing the peak values. See the Options (p. 1447) section for more information about the cluster property.

  The method also includes the following additional properties:

  #### On Demand Expansion Option

  Options for this property include **Program Controlled** (default), **Yes**, and **No**. When set to **Program Controlled**, an additional read-only property, **On Demand Expansion**, displays. This property only displays for the **Program Controlled** option and the application determines the value for the property, either **Yes** or **No**.

  When the **On Demand Expansion Option** property is set to **Yes**, either manually or from the **Program Controlled** setting, the application creates the result file optimally. The application evaluates the results using the Modal solution data and calculates any other results "on demand." This improves solution performance and reduces file size. In addition, the application automatically removes mode shape data from the result file as determined by the **On Demand Mode Shape** preference.

  You can change the default setting for the **On Demand Expansion Option** property and the **On Demand Mode Shape** preference using the **Options (Modal, Harmonic and Transient Mode Superposition)** category of the Analysis Settings and Solution (p. 238) group in the **Options** dialog.

  #### Store Results At All Frequencies

  When you set the **Store Results At All Frequencies** (p. 1453) property to **No**, the application requests that only minimal data be retained. Only the harmonic results requested at the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

time of solution are calculated. The availability of the results is therefore not determined by the settings in the **Output Controls**.

Note:

With this option set to **No**, the addition of new frequency or phase responses to a solved environment requires a new solution. Adding a new contour result of any type (stress or strain) or a new probe result of any type (reaction force or reaction moment) for the first time on a solved environment requires you to solve, but adding additional contour results or probe results of the same type does *not* share this requirement; data from the closest available frequency is displayed (the reported frequency is noted on each result).

New and/or additional displacement contour results as well as bearing probe results do not share this requirement. These results types are basic data and are available by default.

The values of frequency, type of contour results (stress or strain) and type of probe results (reaction force, reaction moment, or bearing) at the moment of the solution determine the contents of the result file and the subsequent availability of data. Planning these choices can significantly reduce the need to re-solve an analysis.

Caution:

Use caution when adding result objects to a solved analysis. Adding a new result invalidates the solution and requires the system to be re-solved, even if you were to add and then delete a result object.

- **Full**: Calculates all displacements and stresses in a single pass. Its main disadvantages are:
  - It is more "expensive" in CPU time than the **Mode Superposition** method.
  - It does not allow clustered results, but rather requires the results to be evenly spaced within the specified frequency range.
- **Variational Technology**: Instead of using the full matrices to compute the results, the application computes the solution at the middle of the requested frequency range and then interpolates the system matrices and loading on the entire frequency range to approximate the results across the range.

Damping Controls (p. 1462)

These properties enable you to specify damping for the structure in the Harmonic Response analysis. Controls include: **Eqv. Damping Ratio From Modal** (MSUP method), **Damping Ratio** (MSUP method), **Constant Structural Damping Coefficient**, **Stiffness Coefficient** (beta damping), and a **Mass Coefficient** (alpha damping). They can also be applied as Material Damping (p. 1467) using the **Engineering Data** tab.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Element Damping: You can apply damping through spring-damper elements, however, this is not supported for the **Mode Superposition** solution method.

Note:

If multiple damping specifications are made the effect is cumulative.

Analysis Data Management (p. 1484)

These properties enable you to save solution files from the harmonic analysis. The default behavior is to only keep the files required for postprocessing. You can use these controls to keep all files created during solution or to create and save the Mechanical APDL application database (db file).

Define Initial Conditions

Currently, the initial conditions **Initial Displacement** and **Initial Velocity** are not supported for Harmonic analyses.

For a Pre-Stressed Full Harmonic analysis, the preloaded status of a structure is used as a starting point for the Harmonic analysis. That is, the static structural analysis serves as an Initial Condition for the Full Harmonic analysis. See the Applying Pre-Stress Effects (p. 352) section of the Help for more information.

Note:

- In the Pre-Stressed MSUP Harmonic Analysis, the pre-stress effects are applied using a Modal analysis.
- When you link your Harmonic (Full) analysis to a Structural analysis, all structural loading conditions, including Inertial (p. 1500) loads, such as Acceleration and Rotational Velocity, are deleted from the Full Harmonic Analysis portion of the simulation once the loads are applied as initial conditions (p. 349) (via the **Pre-Stress** object). Refer to the Mechanical APDL command **PERTURB**,**HARM**,,,**DZEROKEEP** for more details.
- If displacement loading is defined with **Displacement**, **Remote Displacement**, **Nodal Displacement**, or **Bolt Pretension** (specified as **Lock**, **Adjustment**, or **Increment**) loads in the Static Structural analysis, these loads become fixed boundary conditions for the Harmonic solution. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution.

Apply Loads and Supports

The Harmonic Response analysis supports the following boundary conditions:

Inertial

Acceleration (p. 1501) (**Phase Angle** is *not* supported.)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Loads

- Pressure (p. 1521)
- Pipe Pressure (p. 1532) (line bodies only) - *Not* supported for MSUP Solution Method.
- Force (p. 1543) (applied to a face, edge, or vertex)
- Moment (p. 1574)
- Remote Force (p. 1552)
- Bearing Load (p. 1561) (**Phase Angle** is *not* supported.)
- Line Pressure (p. 1585)
- Given a specified Displacement (p. 1666)

Supports

Any type of *Support* (p. 1663) can be used in harmonic analyses.

Note:

The **Compression Only** (p. 1685) support is nonlinear but should not be utilized even though it behaves linearly in harmonic analyses.

Conditions

Constraint Equation (p. 1702)

Direct FE (node-based Named Selection scoping and constant loading only)

- Nodal Orientation (p. 1719) (**Phase Angle** is *not* supported.)
- Nodal Force (p. 1721)
- Nodal Displacement (p. 1728)

Base Excitation (MSUP Only)

- Acceleration (p. 1501) as a base excitation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Displacement (p. 1666) as a base excitation.

Important:

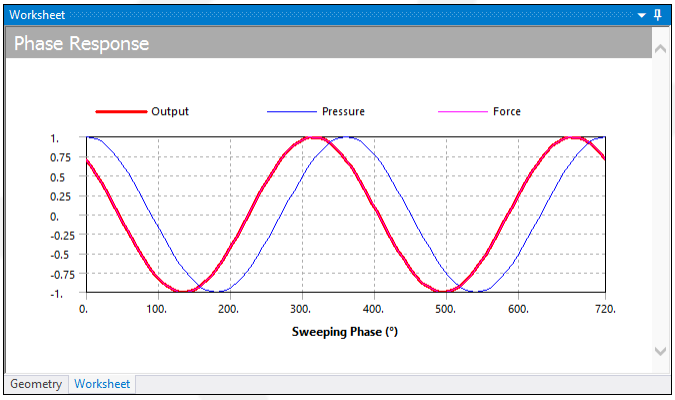
When duplicating an analysis within Mechanical that includes loads with the **Base Excitation** property set to **Yes** (Acceleration and/or Displacement), these loads will lose their scoping during the duplication process.

Note:

Support for boundary conditions varies for a Harmonic Response analysis that is linked to either a Static-Structural or Modal analysis. See the Harmonic Response Analysis Using Linked Modal Analysis System (p. 509) or the Harmonic Analysis Using Pre-Stressed Structural System (p. 506) sections of the Help for specific boundary condition support information.

In a Harmonic Response Analysis, boundary condition application has the following requirements:

- You can apply multiple boundary conditions to the same face.
- All boundary conditions must be sinusoidally time-varying.
- Transient effects are not calculated.
- All boundary conditions must have the same frequency.
- Boundary conditions supported with the **Phase Angle** property allow you to specify a phase shift that defines how the loads can be out of phase with one another. As illustrated in the example Phase Response below, the pressure and force are 45^{o} out of phase. You can specify the preferred unit for phase angle (in fact all angular inputs) to be degrees or radians using the **Units** option in the **Tools** (p. 45) group of the **Home** tab.



- An example of a **Bearing Load** (p. 1561) acting on a cylinder is illustrated below. The Bearing Load, acts on one side of the cylinder. In a harmonic analysis, the expected behavior is that the other side of the cylinder is loaded in reverse; however, that is not the case. The applied load simply reverses sign (becomes tension). As a result, Ansys recommends avoid the use of Bearing Loads in this analysis type.

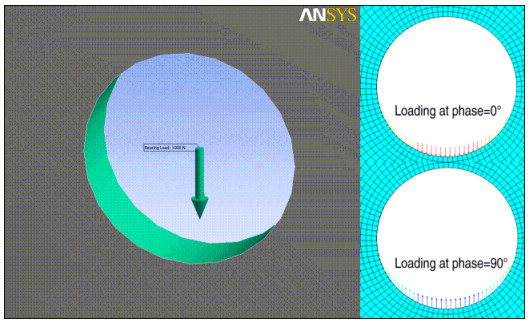
Published: 2023-10-23



Solve

Solution Information (p. 1833) continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis.

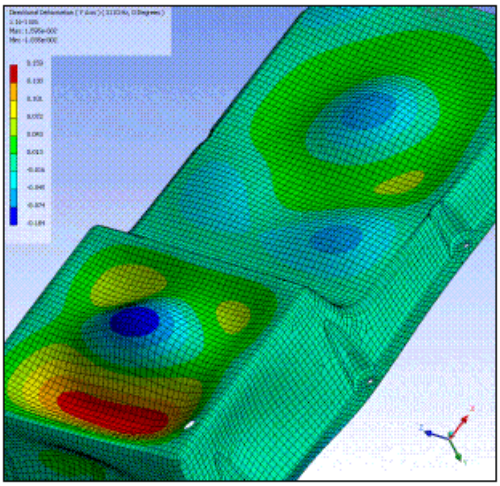
Review Results

Result specification for Harmonic Response analyses includes:

Contour Plots

Contour plots include stress (p. 2026), elastic strain (p. 2026), and deformation (p. 2018), and are basically the same as those for other analyses. If you wish to see the variation of contours over time for these results, you must specify an excitation frequency and a phase. The **Sweeping Phase** property in the details view for the result is the specified phase, in time domain, and it is equivalent to the product of the excitation frequency and time. Because **Frequency** is already specified in the Details view, the **Sweeping Phase** variation produces the contour results variation over time. The **Sweeping Phase** property defines the parameter used for animating the results over time. You can then see the total response of the structure at a given point in time, as shown below.

By setting the **Amplitude** property to **Yes**, you can see the amplitude contour plots at a specified frequency. For additional information about **Amplitude** calculation for derived results, see the Amplitude Calculation in Harmonic Analysis (p. 505) section of the Help.



Since each node may have different phase angles from one another, the complex response can also be animated to see the time-dependent motion.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Frequency Response and Phase Response

Frequency Response (p. 2046) and **Phase Response** (p. 2056) charts which give data at a particular location over an excitation frequency range and a phase period (the duration of the Phase Response results, respectively). Graphs can be either **Frequency Response** graphs that display how the response varies with frequency or **Phase Response** plots that show how much a response lags behind the applied loads over a phase period.

Note:

You can create a contour result from a **Frequency Response** result type in a Harmonic Analysis using the Create Contour Result (p. 2053) feature. This feature creates a new result object in the tree with the same **Type**, **Orientation**, and **Frequency** as the **Frequency Response** result type. However, the **Phase Angle** of the contour result has the same magnitude as the frequency result type but an opposite sign (negative or positive). The sign of the phase angle in the contour result is reversed so that the response amplitude of the frequency response plot for that frequency and phase angle matches with the contour results.

Fatigue Tool

You can use the Fatigue Tool to view fatigue results for the repeated loading of a particular Frequency and Phase Angle.

Waterfall Diagrams

If your analysis contains multiple RPM steps, you can use Waterfall Diagram (p. 2135) results. These result types are useful when analyzing the Noise Vibration Harshness (NVH) footprint of a device for the frequencies of all RPMs.

Amplitude Calculation in Harmonic Analysis

A Harmonic analysis result can be expressed using the following complex notation:

$$x = x_{real} + x_{imag} * i \tag{1}$$

The amplitude is calculated as:

$$|x| = \sqrt{(x_{real}2) + (x_{imag}2)} \tag{2}$$

You can verify Equation (2) for component results, such as a **Directional Deformation**, by solving the equation using the real and imaginary components of the given result.

Amplitude of a Derived Result

A derived result is computed from the component results. For example, **Total Deformation**, u_{total}, is a derived result because it is evaluated from the displacement components u_x, u_y, and u_z in X, Y, and Z directions, respectively, as shown in the following equation:

$$u_{total} = \sqrt{(u_x)^2 + (u_y)^2 + (u_z)^2} \tag{3}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

For derived results, the following procedure is employed to calculate **Amplitude**. Using the formula for a particular derived result, the real and the imaginary parts of the derived quantity are evaluated from the real and imaginary component results respectively. The **Amplitude** for the derived result is then calculated using Equation (2).

For example, the **Amplitude** of **Total Deformation** is calculated using the formula for **Total Deformation**, shown here:

$$(u_{total})_{real} = \sqrt{(u_x)^2_{real} + (u_y)^2_{real} + (u_z)^2_{real}} \quad (4)$$

$$(u_{total})_{imag} = \sqrt{(u_x)^2_{imag} + (u_y)^2_{imag} + (u_z)^2_{imag}} \quad (5)$$

The **Amplitude** of **Total Deformation**:

$$|u_{total}| = \sqrt{(u_{total})^2_{real} + (u_{total})^2_{imag}} \quad (6)$$

Caution:

Note that for the **Amplitude** results for Minimum, Middle, and Maximum Principal Stresses, the application sorts the three values from highest to lowest before it reports the results. To illustrate this, consider real and imaginary values for Minimum, Middle, and Maximum Principal Stresses, as S1, S2, and S3, at a certain node and frequency. You obtain the result values by setting the Sweeping Phase property to 0 and 90 degrees respectively. The table below shows application generated result values for this example. The amplitude values do not correspond, as applicable to Equation (2), for the real and imaginary components. This is because the application sorts the three amplitude values from highest to lowest, before reporting the result values.

Result	REAL (Phase = 0°)	COMPLEX (Phase = 90°)	AMPLITUDE
S1	3142.8	1.92E-13	3142.8
S2	-124.39	-7.62E-15	145.8
S3	-145.8	-8.93E-15	124.39

Harmonic Response (Full) Analysis Using Pre-Stressed Structural System

Preparing the Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

Because this analysis is linked to (and based on) structural responses, a **Static-Structural** analysis is a prerequisite. This setup allows the two analysis systems to share

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

resources, such as engineering data, geometry, and the boundary condition type definitions that are defined the in the structural analysis.

From the **Toolbox**, drag a **Static-Structural** template to the Project Schematic. Then, drag a **Harmonic Response** template directly onto the **Solution** cell of the Structural template.

Note:

You can create a pre-stress environment in a Harmonic Response system that is already open in Mechanical by:

1. Selecting the **Static Structural** option from the **Analysis** drop-down menu on the **Home** (p. 40) (or displayed) tab.
2. Setting the **Pre-Stress Environment** property (of the **Pre-Stress** object) to the Static Structural system.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For this analysis configuration, the basic Analysis Settings (p. 1417) include:

Step Controls

The **Step Controls** (p. 1426) category enables you to define step controls for an analysis that includes multiple load steps. You use the properties of this category to define the load steps and their options. When you select the **Analysis Settings** object, the content of the **Step Controls** category automatically displays in the **Worksheet**. You can modify certain properties in either the **Worksheet** or in the **Details** pane. For each load step, you can specify solution settings (Frequency Spacing, minimum frequencies, maximum frequencies, etc.). See the Step Controls for Harmonic Analysis Types (p. 1426) section for a description of the properties.

Options

See the Options for harmonic analyses (p. 1447) section for a complete listing of the properties. For a harmonic response analysis linked to an upstream static structural analysis, **Mode Superposition** is **not** an available selection.

Output Controls (p. 1473)

You can specify This category enables you to request **Stress**, **Strain**, **Nodal Force**, and **Reaction** results to be calculated.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Specifics ***... for this analysis type:***

The **Initial Conditions (Pre-Stress)** object of the Harmonic Response analysis must point to the linked Static Structural analysis.

Note:

- All structural loads, including Inertial (p. 1500) loads, such as Acceleration and Rotational Velocity, are deleted from the Harmonic Analysis portion of the simulation once the loads are applied as initial conditions (p. 349) (via the **Pre-Stress** object). Refer to the Mechanical APDL command **PERTURB**,**HARM**,,,**DZEROKEEP** for more details.
- For **Pressure** boundary conditions in the Static Structural analysis: if you define the load with the **Normal To** option for faces (3D) or edges (2-D), you could experience an additional stiffness contribution called the "pressure load stiffness" effect. The **Normal To** option causes the pressure acts as a follower load, which means that it continues to act in a direction normal to the scoped entity even as the structure deforms. **Pressure** loads defined with the **Components** or **Vector** options act in a constant direction even as the structure deforms. For a same magnitude, the "normal to" pressure and the component/vector pressure can result in significantly different results in the follow-on Full-Harmonic Analysis. See the Pressure Load Stiffness (p. 353) topic in the Applying Pre-Stress Effects for Implicit Analysis (p. 352) Help Section for more information about using a pre-stressed environment.
- If displacement loading is defined with **Displacement**, **Remote Displacement**, **Nodal Displacement**, or **Bolt Pretension** (specified as **Lock**, **Adjustment**, or **Increment**) loads in the Static Structural analysis, these loads become fixed boundary conditions for the Harmonic solution. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution. If you define a **Nodal Displacement** in the Harmonic analysis at the same location and in the same direction as in the Structural Static analysis, it overwrites the previous loading condition and/or boundary condition in the Harmonic solution.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are allowed for linked Harmonic Response (Full) analysis:

- Inertial: Acceleration (p. 1501) (**Phase Angle** is *not* supported.)
- **Direct FE** (node-based Named Selection scoping and constant loading only):
  - Nodal Force (p. 1721)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

– Nodal Pressure (p. 1724) (**Phase Angle** is *not* supported.)

– Nodal Displacement (p. 1728) - At least one non-zero Component is required for the boundary condition to be fully defined.

Note:

Any other boundary conditions must be defined in the prerequisite (parent) Structural Analysis, such as Support Type (p. 1663) boundary conditions.

Harmonic Response Analysis Using Linked Modal Analysis System

This section examines the workflow for a Harmonic Response analysis linked to an upstream Modal analysis. Topics include:

- Create Analysis System (p. 509)
- Establish Analysis Settings (p. 510)
- Define Initial Conditions (p. 512)
- Apply Loads and Supports (p. 512)
- Review Results (p. 514)
- File Management (p. 514)

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

Because this analysis is linked to (or based on) modal responses, a Modal analysis is a prerequisite. This setup allows the two analysis systems to share resources such as engineering data, geometry and boundary condition type definitions made in modal analysis.

Note:

- When you set the **Solution Method** property to **Mode Superposition** (MSUP), the harmonic analysis can be linked to a pre-stressed modal analysis.
- When solving a linked MSUP harmonic system database from a version prior to the most current version of Mechanical, it is possible to encounter incompatibility of the file *file.full* created by the modal system. This incompatibility can cause the harmonic system's solution to fail. In the event you experience this issue, use the **Clear Generated Data** feature and resolve the modal system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Refer to the Obtain the Mode Superposition Harmonic Solution section of the *MAPDL Structural Analysis Guide* for more information.

From the **Toolbox**, drag a **Modal** template to the **Project Schematic**. Then, drag a **Harmonic Response** template directly onto the **Solution** cell of the **Modal** template.

Note:

You can create a modal environment in a Harmonic Response system that is already open in Mechanical by:

1. Selecting the **Modal** option from the **Analysis** drop-down menu on the **Home** (p. 40) (or displayed) tab.
2. Setting the **Modal Environment** property (of the **Pre-Stress/Modal** object) to the Modal system.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For this analysis configuration, the basic Analysis Settings (p. 1417) include:

Step Controls (p. 1426)

This category enables you to define step controls for an analysis that includes rotational velocities in the form of revolutions per minute (RPMs). You use the properties of this category to define RPM steps and their options. Each RPM load is considered as a load step, such as frequency spacing, minimum frequencies, maximum frequencies, etc.

The **Step Controls** category (p. 1426) enables you to define step controls for an analysis that includes multiple load steps. You use the properties of this category to define the load steps and their options. When you select the **Analysis Settings** object, the content of the **Step Controls** category automatically displays in the **Worksheet**. You can modify certain properties in either the **Worksheet** or in the **Details** pane. For each load step, you can specify solution settings (Frequency Spacing, minimum frequencies, maximum frequencies, etc.). See the Step Controls for Harmonic Analysis Types (p. 1426) section for a description of the properties.

Options (p. 1459)

See the Harmonic Analysis Options Group (p. 1447) section for a complete listing of the Details properties for a Harmonic Response analysis. Note that for a Harmonic Analysis Using Linked Modal Analysis System, only the **Mode Superposition** option is applicable for the **Solution Method** property and it is therefore read-only.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

In addition, you can turn on the following properties:

- **Include Residual Vectors**. Set this property to **Yes** to execute the **RESVEC** command and calculate residual vectors.

- **Cluster Results**: Set this property to **Yes** to automatically cluster solution points near the structure's natural frequencies ensuring capture of behavior near the peak responses. This results in a smoother, more accurate, response curve.

- **On Demand Expansion Option**: Options for this property include **Program Controlled** (default), **Yes**, and **No**. When set to **Program Controlled**, an additional read-only property, **On Demand Expansion**, displays. This property only displays for the **Program Controlled** option and the application determines the value for the property, either **Yes** or **No**.

  When the **On Demand Expansion Option** property is set to **Yes**, either manually or from the **Program Controlled** setting, the application creates the result file optimally. The application evaluates the results using the Modal solution data and calculates any other results "on demand." This improves solution performance and reduces file size. In addition, the application automatically removes mode shape data from the result file as determined by the **On Demand Mode Shape** preference.

  You can change the default setting for the **On Demand Expansion Option** property and the **On Demand Mode Shape** preference using the **Options (Modal, Harmonic and Transient Mode Superposition)** category of the Analysis Settings and Solution (p. 238) group in the **Options** dialog.

- **Mode Selection Method**: This property enables you to select the modes for the mode expansion. Property options include:

  – **None** (default): This option expands all the extracted modes from the modal analysis. All the modes participate in the Mode Superposition harmonic analysis.

  – **Modal Effective Mass**: When you select this option, the **Significance Threshold** property also displays. For the **Significance Threshold** property value, the application selects the modes that have a ratio for the Modal Effective Mass to the Total Mass that is greater than this value, in all directions, for expansion. That is, only the selected modes participate in the Mode Superposition harmonic response analysis. The application default is **`0.001`**. This feature improves the performance of postprocessing the modal results and reduces the file size.

Also, **Mode Frequency Range** is not applicable because available modes are defined in the linked Modal system.

Note:

The following boundary conditions do not support residual vector calculations:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Nodal Force**
- **Remote Force** scoped to global a **Remote Point** (created via **Model** object)
- **Moment** scoped to global a **Remote Point** (created via **Model** object)

Output Controls (p. 1473)

This category enables you to request **Stress**, **Strain**, **Nodal Force**, and **Reaction** results to be calculated. For better performance, you can also choose to have these results expanded from Harmonic or Modal solutions. To expand reaction forces in the modal solution, set the **Nodal Force** property to **Yes** or **Constrained Nodes**.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

You must specify the desired upstream **Modal** analysis in the **Modal Environment** property of the **Initial Conditions** object for the **Harmonic Response** analysis. This object also indicates whether the upstream Modal analysis is pre-stressed. If it is a pre-stress analysis, the name of the pre-stress analysis system is displayed in the **Pre-Stress Environment** property, otherwise the field indicates **None**. The Modal analysis (p. 515) must extract enough modes to cover the frequency range. A conservative estimate is to extract enough modes to cover 1.5 times the maximum frequency in the excitation.

Note:

- Command objects can be inserted into **Initial Conditions** object to execute a restart of the solution process for the Modal Analysis.
- If displacement loading is defined with **Displacement**, **Remote Displacement**, or **Bolt Pretension** (specified as **Lock**, **Adjustment**, or **Increment**) loads in the Static Structural analysis, these loads become fixed boundary conditions for the Harmonic solution. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are allowed for the linked analysis:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Inertial

Acceleration (p. 1501) (**Phase Angle** is *not* supported.)

Loads

- Acceleration (p. 1501) as a base excitation
- Bearing Load (p. 1561) (**Phase Angle** is *not* supported.)
- Given a specified Displacement (p. 1666)
- Force (p. 1543) (applied to a face, edge, or vertex)
- Line Pressure (p. 1585)
- Moment (p. 1574)
- Pressure (p. 1521)
- Pipe Pressure (p. 1532) (line bodies only)
- Remote Force (p. 1552)

Direct FE

The **Direct FE** option **Nodal Force** (p. 1721) is supported for node-based Named Selection scoping and constant loading only.

Note:

- For the **Force** and **Pressure** loading conditions, the default setting for the **Applied By** property is **Direct**.
- When you have a supported topology (geometric or mesh entity) selected on your model, and you insert a **Remote Force** or a **Moment**, the application automatically creates (promotes) a corresponding **Remote Point** for the specified load and scopes the load to that **Remote Point**. This promotion feature is only available when none of the analyses in your project have been solved.

Loading and Support Limitations

Note the following load and support requirements and limitations:

- Remote Force is not supported for vertex scoping.
- Moment is not supported for vertex scoping on 3D solid bodies because a beam entity is created for the load application.
- During a linked MSUP Harmonic analysis, if a **Remote Force** or **Moment** scoped to an internal remote point is specified with the **Behavior** property set to **De-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

formable, the boundary conditions cannot be scoped to the edges of line bodies such that all of their nodes in combination are collinear.

- The **Force Reaction** and **Moment Reaction** probes are not supported for a either a Harmonic Response analysis or a Transient structural analysis using the **Mode Superposition** method Solution Method when 1) the **Damping Ratio** property is defined with a non-zero value and 2) if the Analysis Settings property **Expand Result From** is set to **Harmonic Solution** or **Transient Solution**.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Refer to the **Review Results** (p. 504) topic in the Harmonic Response Analysis (p. 496) section for more information regarding how to set up the harmonic results.

File Management Options

When solving a **Harmonic Response** analysis that includes an upstream linked **Modal** analysis, the application can reference the prerequisite files by specifying the full path of their location (refer to **RESUME** and **MODDIR** commands) instead of making copies. Referencing improves solution time and disk usage. The application will perform referencing once the following conditions and settings are performed:

- You must perform the solution locally (called "In Process (p. 1803)").
- The **On Demand Expansion Option** property of the Options (p. 1447) category of the **Analysis Settings** of the **Modal** analysis must be set to **Yes** manually or through the use of the **Program Controlled** option.

Important:

Make sure that **Modal** and the downstream **Harmonic Response** analysis request the same result data in the Output Controls (p. 1473). Otherwise, you may receive unexpected results.

Note:

If you specify material damping, the **Eqv. Damping Ratio From Modal** property (for the **Harmonic Response** analysis) must also be set to **Yes**.

Limitations

Also note the following limitations for referencing. The **Harmonic Response** analysis cannot include:

- Cyclic Symmetry
- Line Pressure

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Pressure or Force applied using the surface effect elements created on the top of the scoped geometry (**Applied By** property set to **Surface Effect**)
- Remote Force or Moment not scoped to global remote points
- Commands (APDL) object

Modal Analysis

Introduction

A modal analysis determines the vibration characteristics (natural frequencies and mode shapes) of a structure or a machine component. It can also serve as a starting point for another, more detailed, dynamic analysis, such as a transient dynamic analysis, a harmonic analysis, or a spectrum analysis. The natural frequencies and mode shapes are important parameters in the design of a structure for dynamic loading conditions. You can also perform a modal analysis on a pre-stressed structure, such as a spinning turbine blade.

If there is damping in the structure or machine component, the system becomes a damped modal analysis. For a damped modal system, the natural frequencies and mode shapes become complex.

For a rotating structure or machine component, the gyroscopic effects resulting from rotational velocities are introduced into the modal system. These effects change the system's damping. The damping can also be changed when a Bearing (p. 1413) is present, which is a common support used for rotating structure or machine component. The evolution of the natural frequencies with the rotational velocity can be studied with the aid of Campbell Diagram Chart Results.

A Modal analysis can be performed using the Ansys, Samcef, or ABAQUS solver. Any differences are noted in the sections below. Rotordynamic analysis is not available with the Samcef or ABAQUS solver.

Points to Remember

- The Rotational Velocity load is not available in Modal analysis when the analysis is linked to a Static Structural analysis.
- Pre-stressed Modal analysis requires performing a Static Structural analysis (p. 652) first. In the modal analysis you can use the **Initial Condition** object (p. 349) to point to the **Static Structural** analysis to include pre-stress effects.

Preparing the Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

From the **Toolbox**, drag a **Modal**, **Modal (Samcef)**, or **Modal (ABAQUS)** template to the **Project Schematic**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

Due to the nature of modal analyses any nonlinearities in material behavior are ignored. Optionally, orthotropic and temperature-dependent material properties may be used. The critical requirement is to define stiffness as well as mass in some form. Stiffness may be specified using isotropic and orthotropic elastic material models (for example, Young's modulus and Poisson's ratio), using hyperelastic material models (they are linearized to an equivalent combination of initial bulk and shear moduli), or using spring constants, for example. Mass may be derived from material density or from remote masses.

Note:

Hyperelastic materials are supported for pre-stress modal analyses. They are not supported for standalone modal analyses.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

When 2D geometry is used, Generalized Plane Strain is not supported for the Samcef or ABAQUS solver.

When performing a Rotordynamic Analysis, the rotors can be easily generated using the Import Shaft Geometry feature of Ansys DesignModeler. The feature uses a text file to generate a collection of line bodies with circular or circular tube cross sections.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

You can define a **Point Mass** (p. 901) for this analysis type.

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

- Joints are allowed in a modal analysis. They restrain degrees of freedom as defined by the joint definition.
- The stiffness of any spring is taken into account and if specified, damping is also considered.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For the Samcef and ABAQUS solvers, only contacts, springs, and beams are supported. Joints are not supported.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no special considerations for this analysis type.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a Modal analysis, the basic Analysis Settings (p. 1417) include:

Options (p. 1455)

Max Modes to Find

Using the **Max Modes to Find** property, specify the number of frequencies of interest. The default is to extract the first **6** natural frequencies. The number of frequencies can be specified in two ways:

1. The first N frequencies (N > 0), or...
2. The first N frequencies in a selected range of frequencies.

On Demand Expansion Option

You can change the setting of this property as needed to improve performance. Options for this property include **Program Controlled** (default), **Yes**, and **No**. When set to **Program Controlled**, an additional read-only property, **On Demand Expansion**, displays. This property only displays for the **Program Controlled** option and the application determines the value for the property, either **Yes** or **No**.

When the **On Demand Expansion Option** property is set to **Yes**, either manually or from the **Program Controlled** setting, the application creates the result file optimally. That is, the application evaluates the results using the Modal solution data and calculates any other results "on demand." This improves solution performance and reduces file size. And as applicable, the application changes parameters of the any linked downstream Harmonic Response and Transient analyses to also improve their performance. In addition, the application automatically removes mode shape data from the result file as determined by the **On Demand Mode Shape** preference (see note below).

If the application detects any of the following conditions, it automatically sets the **On Demand Expansion** property to **No**:

- The system is a standalone modal analysis (no downstream systems).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- You specify any Output Controls (p. 1473).
- A downstream system does not support an **On Demand Expansion Option** property setting of **Yes**.
- A downstream system has the On Demand Expansion Option set to either **No** or **Program Controlled** (**No**).
- Damping is present in the analysis.
- Symmetry present in the analysis.

You can change the default setting for the **On Demand Expansion Option** property and the **On Demand Mode Shape** preference using the **Options (Modal, Harmonic and Transient Mode Superposition)** category of the Analysis Settings and Solution (p. 238) group in the **Options** dialog.

Solver Controls (p. 1428)

The following two properties are available for this category:

- **Damped**: use this property to specify if the modal system is undamped or damped. Depending upon your selection, different solver options are provided. **Damped** by default, it is set **No** and assumes the modal system is an undamped system.
- **Solver Type** (p. 1429): it is generally recommended that you allow the program to select the type of solver appropriate for your model in both undamped and damped modal systems. When the Solver Type is set to **Reduced Damped**, the following additional properties become available:
  - **Store Complex Solution**: This property is only available when the **Solver Type** property is set to **Reduced Damped**. This property enables you to solve and store a damped modal system as an undamped modal system. By default, it is set to **Yes**.
  - **Mode Reuse**: This property allows the solver to compute complex eigensolutions efficiently during subsequent solve points by reusing the undamped eigensolution that is calculated at the first solve point. The default setting is **Program Controlled**. Set this property to **Yes** to enable it or **No** to disable it.

Note:

If you specify the **Solver Type** property as either **Unsymmetric**, **Full Damped**, or **Reduced Damped** , the modal system does not support a downstream Transient Structural, Harmonic Response, Random Vibration, or Response Spectrum system. However, for a MSUP Harmonic analysis or a MSUP Transient analysis, you can use the **Reduced Damped** setting when the **Store Complex Solution** property is set to **No**. Given these settings, the application also supports the use of the **Include Residual Vectors**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

property (set to **Yes**) as well as the use of **Base Excitation** loading in the downstream systems.

In this case, the mode shapes associated with undamped frequencies are calculated and used for Mode Superposition. However, both damped and undamped frequencies are reported in the **Tabular Data** pane of the Modal analysis. Even if you use the **Reduced Damped** solver with the **Store Complex Solution** property set to **No** in a damped analysis, it is not the equivalent to setting the **Solver Type** property **Undamped**.

If an undamped Modal analysis has a pre-stressed environment from a Static Structural Analysis with the **Newton-Raphson Option** set to **Unsymmetric**, the **Program Controlled** option selects **Unsymmetric** as the **Solver Type** setting (the Mechanical APDL command **MODOPT**,UNSYM is issued).

Cyclic Controls (p. 1446)

When running a cyclic symmetry (p. 1147) analysis, set the **Harmonic Index Range** to **Program Controlled** to solve for all harmonic indices, or to **Manual** to solve for a specific range of harmonic indices.

Output Controls (p. 1473)

By default, only mode shapes are calculated. You can request **Stress** and **Strain** results to be calculated but note that "stress" results only show the relative distribution of stress in the structure and are not real stress values. You can also choose whether or not to have these results stored for faster result calculations in linked systems.

Damping Controls (p. 1462)

The options of the **Stiffness Coefficient Defined By** property, **Direct Input** or **Damping vs. Frequency**, enable you to define the method used to define the **Stiffness Coefficient**. If you select **Damping vs. Frequency**, the **Frequency** and **Damping Ratio** properties appear requiring you to enter values to calculate the **Stiffness Coefficient**. Otherwise, you specify the **Stiffness Coefficient** manually. The **Mass Coefficient** property requires a manual entry.

Rotordynamics Controls (p. 1490)

Specify these properties as needed when setting up a Rotordynamic Analysis.

Analysis Data Management (p. 1484)

These properties enable you to save specific solution files from the Modal analysis for use in other analyses. You can set the **Future Analysis** field to **MSUP Analyses** if you intend to use the modal results in a subsequent Transient Structural, Harmonic Response, Random Vibration (PSD), or Response Spectrum (RS) analysis. If you link a Modal system to another analysis type in advance, the **Future Analysis** property defaults to the setting, **MSUP Analyses**. When a PSD analysis is linked

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

to a modal analysis, additional solver files must be saved to achieve the PSD solution. If the files were not saved, then the modal analysis has to be solved again and the files saved.

Note:

- **Solver Type**, **Damping Controls**, and **Rotordynamic Controls** are not available to the Samcef or ABAQUS solver.
- **Solver Type**, **Scratch Solver Files**, **Save Ansys db**, **Solver Units**, and **Solver Unit System** are only applicable to **Modal** systems.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

You can point to a **Static Structural** analysis in the **Initial Condition** environment field if you want to include pre-stress effects. A typical example is the large tensile stress induced in a turbine blade under centrifugal load that can be captured by a static structural analysis. This causes significant stiffening of the blade. Including this pre-stress effect will result in much higher, realistic natural frequencies in a modal analysis.

If the Modal analysis is linked to a Static Structural analysis for initial conditions and the parent static structural analysis has multiple result sets (multiple restart points at load steps/sub steps), you can start the Modal analysis from any restart point available in the Static Structural analysis. By default, the values from the last solve point are used as the basis for the modal analysis. See Restarts from Multiple Result Sets (p. 353) in the Applying Pre-Stress Effects for Implicit Analysis (p. 352) Help section for more information.

Note:

- When you perform a pre-stressed Modal analysis, the support conditions from the static analysis are used in the Modal analysis. You cannot apply any new supports in the Modal analysis portion of a pre-stressed modal analysis. When you link your Modal analysis to a Structural analysis, all structural loading conditions, including Inertial (p. 1500) loads, such as Acceleration and Rotational Velocity, are deleted from the Modal portion of the simulation once the loads are applied as initial conditions (p. 349) (via the **Pre-Stress** object). Refer to the Mechanical APDL command **PERTURB**,**HARM,,,DZEROKEEP** for more details.
- To account for the Coriolis Effect of rotational velocity applied in the Static analysis, you need to re-apply the rotational velocity in the Modal analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For **Pressure** boundary conditions in the Static Structural analysis: if you define the load with the **Normal To** option for faces (3D) or edges (2-D), you could experience an additional stiffness contribution called the "pressure load stiffness" effect. The **Normal To** option causes the pressure acts as a follower load, which means that it continues to act in a direction normal to the scoped entity even as the structure deforms. **Pressure** loads defined with the **Components** or **Vector** options act in a constant direction even as the structure deforms. For a same magnitude, the "normal to" pressure and the component/vector pressure can result in significantly different modal results in the follow-on Modal Analysis. See the Pressure Load Stiffness (p. 353) topic in the Applying Pre-Stress Effects for Implicit Analysis (p. 352) Help Section for more information about using a pre-stressed environment.
- If displacement loading is defined with **Displacement**, **Remote Displacement**, **Nodal Displacement** or **Bolt Pretension** (specified as **Lock**, **Adjustment**, or **Increment**) loads in the Static Structural analysis, these loads become fixed boundary conditions for the Modal solution. If the Modal solution is followed by a Harmonic solution, these displacement loads become fixed boundary conditions for the Harmonic solution as well. This prevents the displacement loads from becoming a sinusoidal load during the Harmonic solution.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

Only the Rotational Velocity (p. 1511) and Thermal Condition (p. 1594) boundary conditions are supported for a stand-alone modal analysis. All structural supports (p. 1663) can be applied except a non-zero **Displacement**, a **Remote Displacement**, and the **Velocity** support. Due to its nonlinear nature, a **Compression Only Support** is not recommended for a modal analysis. Use of compression only supports may result in extraneous or missed natural frequencies.

For the Samcef and ABAQUS solvers, the following supports are not available: Compression Only Support, Elastic Support. When using line bodies, the following Pipe Pressure and Pipe Temperature loads are not available to the Samcef solver. Additionally, the Pipe Idealization object is also unavailable for the Samcef or ABAQUS solver.

Note:

In a pre-stressed modal analysis:

- Any structural supports used in the static analysis persist. Therefore, you are not allowed to add new supports in the pre-stressed modal analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- When creating a Campbell diagram, the Rotational Velocity (p. 1511) in the Static Structural Analysis is used to create normal stress stiffening effects in the Modal Analysis. It is not used to create centrifugal force effects for generating the Campbell diagram.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

Solution Information (p. 1833) continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis.

Important:

If you specify the **Distribute Solution** setting (the default setting on the **Advanced Properties** dialog of the Solve Process Settings (p. 1804)), the files file.full, file.esav and file.emat may not be combined at the end of the Modal analysis solution. As a result, any downstream system, including a Response Spectrum, Mode Superposition Harmonic Respoonse, Mode Superposition Transient, or Random Vibration analysis, or a follow on Mechanical APDL (turn on the **Distributed** property in Project Schematic), must also use a **Distributed Solution** setting as opposed to a shared memory solution, when the setting is turned off.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Highlight the **Solution** object in the tree to view a bar chart of the frequencies obtained in the modal analysis. A tabular data grid is also displayed that shows the list of frequencies, stabilities, modal damping ratios and logarithm decrements of each mode.

Note:

In a Modal Analysis (and other eigenvalue-based analyses such as buckling), the solution consists of a deformed shape scaled by an arbitrary factor. The actual magnitudes of the deformations and any derived quantities, such as strains and stresses, are therefore meaningless. Only the relative values of such quantities throughout the model should be considered meaningful. The arbitrary scaling factor is numerically sensitive to slight perturbations in the analysis; choosing a different unit system, for example, can cause a significantly different scaling factor to be calculated.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

For an undamped modal analysis, only frequencies are available in the **Tabular Data** window. For a damped modal analysis, real and imaginary parts of the eigenvalues of each mode are listed as **Stability** and **Damped Frequency**, respectively, in the **Tabular Data** window. If the real/stability value is negative, the eigenmode is considered to be stable. For the damped modal analysis, **Modal Damping Ratio** and **Logarithmic Decrement** are also included in the **Tabular Data** window. Like the stability value, these values are an indicator of eigenmode stability commonly used in rotordynamics.

If you select the **Reduced Damped** solver and set the **Store Complex Solution** property to **No**, then the application solves and stores the damped modal system as an undamped modal system. In addition to the undamped **Frequency**, the **Damped Frequency**, **Stability**, **Modal Damping Ratio** and **Logarithmic Decrement** result values are available in the **Tabular Data** window.

Note:

For the **Reduced Damped** solver with the **Store Complex Solution** property set to **No**, the Mechanical APDL Solver only writes undamped frequencies into result file. The solver retrieves the **Damped Frequency**, **Stability**, **Modal Damping Ratio** and **Logarithmic Decrement** from the Ansys database on the fly during the solution process. Use extra caution when using the **/POST1** in a **Command** object and make sure that your command entries and syntax are correct (especially if using the ***GET** command). Incorrect command entries can cause zero values for the **Damped Frequency** and **Stability**. Check the **Solution Information** (p. 1833) and error/warning messages to troubleshooting issues.

If **Campbell Diagram** (p. 1490) is set to On, a Campbell diagram chart result is available for insert under Solution. A Campbell diagram chart result conveys information as to how damped frequencies and stabilities of a rotating structural component evolve/change in response to increased rotational velocities. More detailed information about the result can be found in Campbell Diagram Chart Results (p. 2132). The **Campbell Diagram** function is not available to the Samcef or ABAQUS solver.

Note:

The Campbell diagram result chart is only appropriate for a rotating structural component that is axis-symmetrical. It is supported for all body types: solid, shell, and line bodies, but limited to single spool systems. For a single spool system, all bodies in the modal system are subjected to one and only single rotational velocity.

The contour and probe results are post-processed using set number, instead of mode number. The total set number is equal to number of modes requested multiplied by number of rotational velocity solve points. You can use the **Set**, **Solve Point** and **Mode** columns in the table to navigate between the set number and mode, and rotational velocity solve point and mode.

The ABAQUS solver does not allow modal expansion when post-processing mode shapes.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

You can choose to review the mode shapes corresponding to any of these natural frequencies by selecting the frequency from the bar chart or tabular data and using the context sensitive menu (right-click) to choose **Create Mode Shape Results**. You can also view a range of mode shapes.

"Stresses" from a Modal analysis do not represent actual stresses in the structure, but they give you an idea of the relative stress distributions for each mode. Stress and Strain results are available only if requested before solution using **Output Controls**.

You can view the mode shape associated with a particular frequency as a contour plot (p. 62). You can also animate (p. 2260) the deformed shape including, for a damped analysis, the option to allow or ignore the time decay animation for complex modes. The contours represent relative displacement of the part as it vibrates.

For complex modes, the Phase Angle associated with a particular frequency represents the specified angle in time domain and is equivalent to the product of frequency and time. Since the frequency is already specified in the results details view for a specific mode, the phase angle variation produces the relative variation of contour results over time.

When running a cyclic symmetry (p. 1147) analysis, additional result object settings in the Details view are available, as well as enhanced animations and graph displays. See Cyclic Symmetry in a Modal Analysis (p. 1159) for more information.

Note:

The use of construction geometry is not supported for the postprocessing of cyclic symmetry results.

Random Vibration Analysis

Introduction

This analysis enables you to determine the response of structures to vibration loads that are random in nature. An example would be the response of a sensitive electronic component mounted in a car subjected to the vibration from the engine, pavement roughness, and acoustic pressure.

Loads such as the acceleration caused by the pavement roughness are not deterministic, that is, the time history of the load is unique every time the car runs over the same stretch of road. Hence it is not possible to predict precisely the value of the load at a point in its time history. Such load histories, however, can be characterized statistically (mean, root mean square, standard deviation). Also random loads are non-periodic and contain a multitude of frequencies. The frequency content of the time history (spectrum) is captured along with the statistics and used as the load in the random vibration analysis. This spectrum, for historical reasons, is called Power Spectral Density or PSD.

In a random vibration analysis since the input excitations are statistical in nature, so are the output responses such as displacements, stresses, and so on.

Typical applications include aerospace and electronic packaging components subject to engine vibration, turbulence and acoustic pressures, tall buildings under wind load, structures subject to earthquakes, and ocean wave loading on offshore structures.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Points to Remember

- The excitation is applied in the form of Power Spectral Density (PSD). The PSD is a table of spectral values vs. frequency that captures the frequency content. The PSD captures the frequency and mean square amplitude content of the load's time history.
- The square root of the area under a PSD curve represents the root mean square (rms) value of the excitation. The application computes this value using the linear trapezoidal rule. The unit of the spectral value of acceleration, for example, is G^2/Hertz.
- The input excitation is expected to be stationary (the average mean square value does not change with time) with a zero mean.
- This analysis is based on the Mode Superposition method. Hence a modal analysis (p. 515) that extracts the natural frequencies and mode shapes is a prerequisite.
- This feature covers one type of PSD excitation only- base excitation.
- The base excitation could be an acceleration PSD (either in acceleration^2 units or in G^2 units), velocity PSD or displacement PSD.
- The base excitation is applied in the specified direction to all entities that have a Fixed Support (p. 1663) boundary condition. Other support points in a structure such as **Frictionless Surface** are not excited by the PSD.
- Multiple uncorrelated PSDs can be applied. This is useful if different, simultaneous excitations occur in different directions.
- If stress/strain results are of interest from the random vibration analysis then you will need to request stress/strain calculations in the modal analysis itself. Only displacement results are available by default.
- Postprocessing:
  - The regular results output by the solver for the Random Vibration analysis, such as Directional Deformation (p. 2018), are by default one sigma values, or one standard deviation values (with zero mean value). These results follow a Gaussian distribution. The interpretation is that 68.3% of the time the response will be less than the standard deviation value. One sigma is indicated by the **Scale Factor** property. All other result are not one sigma values. If you create a User Defined Result (p. 2192) using the Solution Quantities and Result Summary Worksheet (p. 1961) that is not a one sigma value, you will receive informational message indicating the situation.

Note:

→ Currently, one sigma supports the following **Expressions** (p. 2197) for User Defined Results (p. 2192):

UX/UY/UZ

EPELX/EPELY/EPELZ

EPELXY/EPELYZ/EPELXZ

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

SX/SY/SZ

SXY/SYZ/SXZ

SEQV

SPSD

→ The use of the **Scale Factor** property is not supported for force-based results, such as FX/FY/FZ, even though these forces are considered one sigma in the Mechanical APDL application.

– You can scale the result by 2 times to get the 2 sigma values. The response will be less than the 2 sigma values 95.45% of the time and 3 sigma values 99.73% of the time.

– The **Coordinate System** setting for result objects is, by default, set to **Solution Coordinate System** and cannot be changed because the results only have meaning when viewed in the solution coordinate system.

– Since the directional results from the solver are statistical in nature they cannot be combined in the usual way. For example the X, Y, and Z displacements cannot be combined to get the magnitude of the total displacement. The same holds true for other derived quantities such as principal stresses.

– A special algorithm by Segalman-Fulcher is used to compute a meaningful value for equivalent stress.

Preparing the Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

Because a random vibration analysis is based on modal responses, a modal analysis is a required prerequisite. The requirement then is for two analysis systems, a modal analysis system and a random vibration analysis system that share resources, geometry, and model data.

From the **Toolbox**, drag a **Modal** template to the **Project Schematic**. Then, drag a **Random Vibration** template directly onto the **Modal** template.

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

Both Young's modulus (or stiffness in some form) and density (or mass in some form) must be defined in the modal analysis. Material properties must be linear but can be

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

isotropic or orthotropic, and constant or temperature-dependent. Nonlinear properties, if any, are ignored.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

There are no specific considerations for a random vibration analysis.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

You can define rigid bodies for this analysis type.

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Only linear behavior is valid in a random vibration analysis. Nonlinear elements, if any, are treated as linear. If you include contact elements, for example, their stiffnesses are calculated based on their initial status and are never changed.

Only the stiffness of springs is taken into account in a random vibration analysis.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no specific considerations for a random vibration analysis.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

A specific **Modal Environment** must be set as an initial condition/environment for the analysis to be solved.

Note:

The modal analysis (p. 515) must extract enough modes to cover the PSD frequency range. Ansys recommends that you extract enough modes to cover 1.5 times the maximum frequency in the PSD excitation.

In order to process the PSD solution, the application creates additional solver files from the upstream modal analysis. Therefore, to create these required files, you need to solve the upstream Modal analysis before you can solve the PSD analysis. See the Analysis Data Management (p. 1484) section for more information.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a Random Vibration analysis the basic **Analysis Settings** include:

Options for Analyses (p. 1447)

You use this category to specify the number of modes to use from the modal analysis. Ansys recommends that you include modes that cover 1.5 times the maximum frequency in the PSD excitation table. You can also exclude insignificant modes by setting the **Mode Significance Level** property to between 0 (all modes selected) and 1 (no modes selected).

Note:

If you set the **Mode Significance Level** property to **`0.0`**, the application considers all modes in mode superposition of random vibration responses. This can require significant computation time for large systems that use a large number of modes to obtain random vibration displacement responses.

In this case, a **Mode Significance Level** setting that excludes insignificant modes from superimposing random vibration displacement responses is recommended. However, this performance improvement reduces solution accuracy. As a result, you need to use caution and carefully check your solution. Set the **Mode Significance Level** to **`1e-4`** when you are concerned about solution processing time. During Random Vibration analyses, the velocity and acceleration responses are separate calculations, in addition to displacement responses.

To further improve your solution time, do not request velocity and acceleration responses unless needed. The velocity and acceleration responses require approximately the same computation time.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Output Controls (p. 1473)

By default, **Displacement** is the only response calculated. To include velocity (**Calculate Velocity** property) and/or acceleration (**Calculate Acceleration** property) responses, set their respective **Output Controls** to **Yes**. By default, modal results are removed from result file to reduce its size.

To keep modal results from an upstream system, set the **Keep Modal Results** property to **Yes**.

Note:

- If your **Random Vibration** system is linked to an upstream **Modal** analysis and you plan to send Modal data to a downstream **Sherlock (Post)** system, you need to set the **Keep Modal Results**, **Calculate Velocity**, **Calculate Acceleration** properties to **Yes**.
- You can change the default setting of these properties using the **Options** dialog. See the Specifying Application Defaults and Preferences (p. 217) section of the Help under the Analysis Settings and Solution (p. 238) category for the specific options.

Damping Controls (p. 1462)

Damping Controls enable you to specify damping for the structure in the Random Vibration analysis. Controls include: **Constant Damping**, **Damping Ratio**, **Stiffness Coefficient** (beta damping), and a **Mass Coefficient** (alpha damping). They can also be applied as Material Damping (p. 1467) using the **Engineering Data** tab. A non-zero damping is required. The **Damping Ratio** has a default setting of 0.01. This value can be modified by setting the **Damping** property to **Manual**.

Note:

For a Random Vibration system, if you choose the **Manual** setting for the **Constant Damping** property and **do not** define damping for one of the above controls, the solver uses a default damping value of **`0.01`**.

Analysis Data Management (p. 1484)

These settings enable you to save solution files from the **Random Vibration** analysis. The default behavior is to only keep the files required for postprocessing. You can use these controls to keep all files created during solution or to create and save a Mechanical APDL application database (db file).

Note:

The **Inertia Relief** option (under **Analysis Settings**) for an upstream Static Structural analysis is not supported in a Random Vibration analysis.

Apply Loads and Supports

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

- Any Support Type (p. 1663) boundary condition must be defined in the prerequisite Modal Analysis.
- The only applicable load is a **PSD Base Excitation** (p. 1589) of spectral value vs. frequency.
- Remote displacement cannot coexist with other boundary condition types (for example, fixed support or displacement) on the same location for excitation. The remote displacement will be ignored due to conflict with other boundary conditions.
- Four types of base excitation are supported: **PSD Acceleration**, **PSD G Acceleration**, **PSD Velocity**, and **PSD Displacement**.
- Each PSD base excitation should be given a direction in the nodal coordinate of the excitation points.
- Multiple PSD excitations (uncorrelated) can be applied. Typical usage is to apply 3 different PSDs in the X, Y, and Z directions. Correlation between PSD excitations is not supported.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

Solution Information (p. 1833) continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. In addition to solution progress you will also find the participation factors for each PSD excitation. The solver output also has a list of the relative importance of each mode in the modal covariance matrix listing.

Note:

When using a random vibration system database from a version prior to the most current version of Mechanical, it is possible to encounter incompatibility of the file(s) *file.mode*, *file.full*, and/or *file.esav*, created by the modal system. This incompatibility can cause the random vibration system's solution to fail. In the event you experience this issue, use the **Clear Generated Data** feature and resolve the modal system.

Refer to the Obtain the PSD Solution section of the *MAPDL Structural Analysis Guide* for more information.

Review Results

General *Basic general information about this topic (p. 356)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Specifics ***... for this analysis type:***

- If stress/strain results are of interest from the Random Vibration analysis then you will need to request stress/strain calculations in the modal analysis itself. You can use the **Output Controls** under **Analysis Settings** in the modal analysis for this purpose. Only displacement results are available by default.
- Linking a Random Vibration analysis system to a fully solved Modal analysis may result in zero equivalent stress. To evaluate correct equivalent stress in this situation, you need to re-solve the Modal analysis.
- Applicable results are Directional (X/Y/Z) Displacement/Velocity/Acceleration, normal and shear stresses/strains and equivalent stress. These results can be displayed as contour (p. 62) plots.
- For contour results, the **Information** category displays the properties described below. These properties are calculated *after* the associated result is evaluated and they refer to results contained in the results (`file.rst`) file. The following table describes property values and their result.

Example Details Pane Properties

Details of "Directional Acceleration"

Scope	
Definition	
Type	Directional Acceleration
Orientation	Y Axis
Reference	Absolute (including base motion)
Scale Factor	1 Sigma
Probability	68.269 %
Coordinate System	Solution Coordinate System
Identifier	
Suppressed	No
Results	
Options	
Acceleration in G	No
Information	
Load Step	5
Substep	1
Iteration Number	4

Property Output Descriptions

Load Step	Substep	Iteration Number	Result Description
3	1	2	1 Sigma Displacement solution.
4	1	3	1 Sigma Velocity solution (if the **Calculate Velocity** property in Output Controls (p. 1473) is set to **Yes**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Load Step	Substep	Iteration Number	Result Description
5	1	4	1 Sigma Acceleration solution (if the **Calculate Acceleration** property in Output Controls (p. 1473) is set to **Yes**).

See the Review the Results topic in the *Performing a Random Vibration (PSD) Analysis* section in the *Mechanical APDL Structural Analysis Guide* for additional information.

- The displacement results are relative to the base of the structure (the fixed supports).
- The velocity and acceleration results include base motion effects (absolute).
- Since the directional results from the solver are statistical in nature they cannot be combined in the usual way. For example the X, Y, and Z displacements cannot be combined to get the magnitude of the total displacement. The same holds true for other derived quantities such as principal stresses.
- For directional acceleration results, an option is provided to display the Transient Structural Analysis Using Linked in G (gravity) by selecting **Yes** in the **Acceleration in G** field.
- By default the 1 σ results are displayed. You can apply a scale factor to review any multiples of σ such as 2 σ or 3 σ. The Details view as well as the legend for contour results also reflects the percentage (using Gaussian distribution) of time the response is expected to be below the displayed values.
- Meaningful equivalent stress is computed using a special algorithm by Segalman-Fulcher. Note that the probability distribution for this equivalent stress is neither Gaussian nor is the mean value zero. However, the "3 σ" rule (multiplying the RMS value by 3) yields a conservative estimate on the upper bound of the equivalent stress.
- The Fatigue Tool enables you to perform a Spectral Fatigue analysis using the 1, 2, 3 σ stresses.
- For a **User Defined** result, if you want to request equivalent stress, you must specify **SPSD** for the **Expression** property (not SEQV). The SPSD Type uses the Segalman-Fulcher algorithm. SEQV uses a standard method to calculate equivalent stress, and in this instance, is incorrect for the desired 1 Sigma calculation.

  To ensure you properly select the SPSD expression, display results in the Solution Worksheet (p. 2192) and generate your result from the list of solution quantities. See the User Defined Results for the Mechanical APDL Solver (p. 2203) section for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Force Reaction** and **Moment Reaction** probes can be scoped to a **Remote Displacement**, **Fixed Support**, or **Displacement** boundary conditions to view Reactions Results.

  Note:

  – When you scope a **Moment Reaction** probe to a **Fixed Support** or a **Displacement**, the **Summation** property must be set to **Centroid**.

  – The results of **Force Reaction** and **Moment Reaction** probes scoped to a **Fixed Support** or **Displacement** are calculated using the **FSUM** Mechanical APDL solver command. This command reports the vector sum of the elemental nodal forces in the global coordinate system. See the **FSUM** command in the *Mechanical APDL Command Reference* for more information.

- The use of nodal averaging may not be appropriate in a random vibration analysis because the result values are not actual values but standard deviations. Moreover, the element coordinate system for the shell elements in a surface body may not all be aligned consistently when using the Default Coordinate System. Consider using unaveraged results for postprocessing instead.

File Management

When solving a Random Vibration analysis in an "In Process" solve mode, the pre-requisite files from the upstream Modal system are referenced by specifying the full path of their location (refer to **RESUME** and **MODDIR** commands) instead of making copies in order to improve solution time and disk usage. See the Solve Modes and Recommended Usage (p. 1803) section of the Help for more information about the different solve modes.

When you are solving in the "Out of Process" mode or when the **Keep Modal Results** property is set to **Yes**, the application copies the pre-requisite files from the Modal analysis to the Random Vibration Solver Files Directory. This may increase the required solution time for large models.

Using Command Objects within a Random Vibration Analysis

In an effort to minimize disk space usage, only the results from the Random Vibration analysis are kept in the result file. The results from the Modal analysis are removed during the solution.

If your command object contains commands which require this data, set the **Keep Modal Results** property in the **Output Controls** (p. 1473) to **Yes**.

Response Spectrum Analysis

Introduction

This analysis type is ideal for civil structure designs, such as high-rise buildings undergoing loads from wind as well as nuclear power plant designs experiencing seismic loads.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

A Response Spectrum analysis has similarities to the Random Vibration Analysis (p. 524). However, unlike a random vibration analysis, responses from a response spectrum analysis are deterministic maxima. For a given excitation, the maximum response is calculated based upon the input response spectrum and the method used to combine the modal responses. Combination methods include:

- Square Root of the Sum of the Squares (SRSS)
- Complete Quadratic Combination (CQC)
- Rosenblueth Double Sum Combination (ROSE)

Review the **Response Spectrum Options Category (p. 1458)** topic in the **Analysis Settings** > **Options for Analyses** section for more information about these methods.

Points to Remember

- The response spectrum is calculated based on modal responses. A modal analysis is therefore a prerequisite.
- If response strain/stress is of interest, then the modal strain and the modal stress need to be determined in the modal analysis.
- The excitation is applied in the form of a response spectrum. The response spectrum can have displacement, velocity, or acceleration units. For each spectrum value, there is one corresponding frequency.
- The excitation must be applied at fixed degrees of freedom.
- Because a new solve is required for each requested output (displacement, velocity, and acceleration), the content of a **Commands (APDL)** object is limited to solution (**SOLU**) commands.
- The results from the Mechanical APDL solver are displayed as the model's contour plot. The results are in terms of the maximum response.

Preparing the Analysis

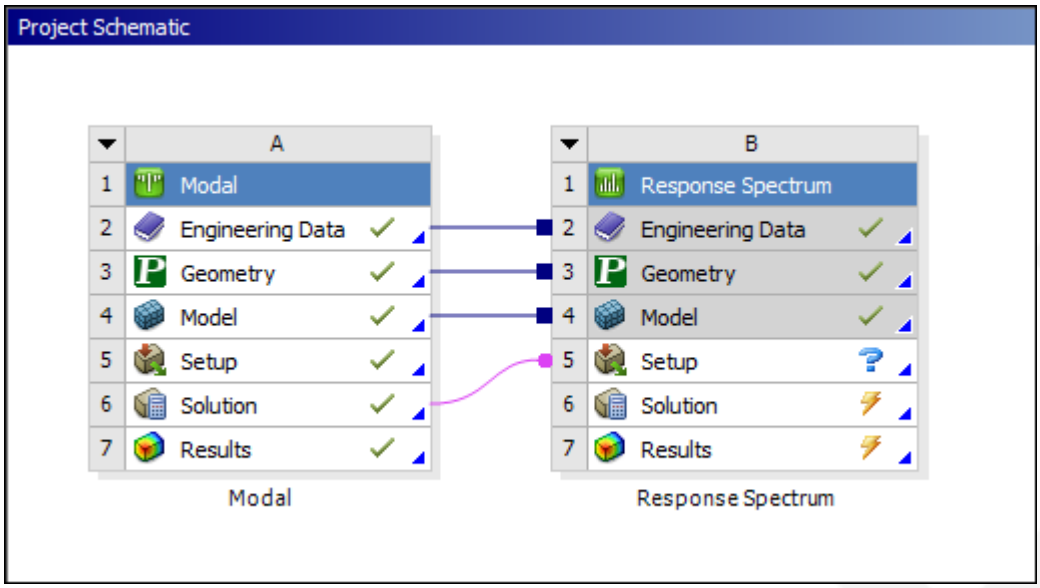
As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Create Analysis System

Because a response spectrum analysis is based on modal responses, a modal analysis is a required prerequisite. The modal analysis system and the response spectrum analysis system must share resources, geometry, and model data.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Define Engineering Data

Material properties must be defined in a modal analysis. Nonlinear material properties are not allowed.

Define Part Behavior

You can define rigid bodies for this analysis type.

Define Connections

Nonlinear element types are not supported. They will be treated as linear. For example, the contact stiffness is calculated using the initial status without convergence check.

Define Initial Conditions

A specific **Modal Environment** must be set as an initial condition/environment for response spectrum analysis to be solved.

Establish Analysis Settings

For a Response Spectrum analysis, the basic **Analysis Settings** include:

Options for Analyses - Response Spectrum Analyses (p. 1458)

Perform the following settings for a Response Spectrum analysis:

- Specify the **Number of Modes To Use** property for the response spectrum calculation. Ansys recommends that you include the modes whose frequencies span 1.5 times the maximum frequency defined in the input response spectrum.
- Specify the **Spectrum Type** to be used for response spectrum calculation as either **Single Point** or **Multiple Points**. If the input response spectrum is applied to all fixed degrees of freedom, use **Single Point**, otherwise use **Multiple Points**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Specify the **Modes Combination Type** to be used for response spectrum calculation. In general, the **SRSS** method is more conservative than the **CQC** and the **ROSE** methods.

Note:

The **Inertia Relief** option (under **Analysis Settings**) for an upstream static structural analysis is not supported in a response spectrum analysis.

Output Controls (p. 1473)

By default, only displacement responses are calculated. To include velocity and/or acceleration responses, set their respective **Output Controls** to **Yes**.

Damping Controls (p. 1462)

allow you to specify damping for the structure in the response spectrum analysis. Controls include: **Damping Ratio**, **Stiffness Coefficient** (beta damping), and a **Mass Coefficient** (alpha damping). They can also be applied as Material Damping (p. 1467) using the **Engineering Data** tab. For the CQC mode combination type, non-zero damping is required.

Note:

Damping is not applicable to the SRSS combination method. Damping Controls are not available when the **Modes Combination Type** property is set to **SRSS**.

Analysis Data Management (p. 1484)

These settings enable you to save solution files from the response spectrum analysis. An option to save the Mechanical APDL application database (db file) from the analysis is provided.

Apply Loads and Supports

Note the following for boundary condition use and processing:

- Supported boundary condition types include Fixed Support, Displacement, Remote Displacement and body-to-ground Spring. If one or more fixed supports are defined in the model, the input excitation response can be applied to all fixed supports.
- A Remote Displacement cannot coexist with other boundary condition types, such as a Fixed Support or a Displacement, at the same location (scoping) as the excitation. The Remote Displacement will be ignored due to conflict with other boundary conditions.
- Note that the All boundary condition types for **Single Point** Response Spectrum only includes those fixed degree of freedoms defined using Fixed Support, Displacement, Remote Displacement and Body-to-Ground Spring. To apply an RS load to All boundary condition types for **Single Point** Response Spectrum, at least one allowed boundary condition must be defined.
- For a **Single Point** spectrum type, input excitation spectrums are applied to all boundary condition types defined in the model. For **Multiple Points** however, each input excitation spectrum is associated to only one boundary condition type.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Three types of input excitation spectrum are supported: displacement input excitation (**RS Displacement**), velocity input excitation (**RS Velocity**) and acceleration input excitation (**RS Acceleration**). See RS Base Excitation (p. 1590) for further details.
- The input excitation spectrum direction is defined in the global coordinate system for Single Point spectrum analysis. For Multiple Points spectrum analysis, however, the input excitation is defined in the nodal coordinate systems (if any) attached to the constrained nodes.
- More than one input excitation, with any different combination of spectrum types, is allowed for the response spectrum analysis.
- Specify option to include or not include contribution of high frequency modes in the total response calculation by setting **Missing Mass Effect** (p. 1590) to **Yes** or **No**. The option for including the modes is normally required for nuclear power plant design.
- Specify option to include or not include rigid responses to the total response calculation by setting **Rigid Response Effect** (p. 1590) to **Yes** or **No**. The rigid responses normally occur in the frequency range that is lower than that of missing mass responses, but is higher than that of periodic responses.
- **Missing Mass Effect** is only applicable to **RS Acceleration** excitation. See the RS Base Excitation (p. 1590) section of the Help for more information.
- For a **Single Point** spectrum type, the entire table of input excitation spectrum can be scaled using the **Scale Factor** setting. The factor must be greater than 0.0. The default is 1.0.

Perform Solution

Ansys recommends that you review the **Solution Information** (p. 1833) page for any warnings or errors that might occur during the solution. You may receive some warning messages and still be able to solve the analysis.

Note:

When using a Response Spectrum system from a previous version of the application, it is possible you could encounter incompatibility of for the modal system file(s) *file.mode*, *file.full*, and/or *file.esav*. This incompatibility can cause the Response Spectrum system's solution to fail. In the event you experience this issue, use the **Clear Generated Data** feature and resolve the modal system.

Refer to the Obtain the Spectrum Solution section of the *MAPDL Structural Analysis Guide* for more information.

Review Results

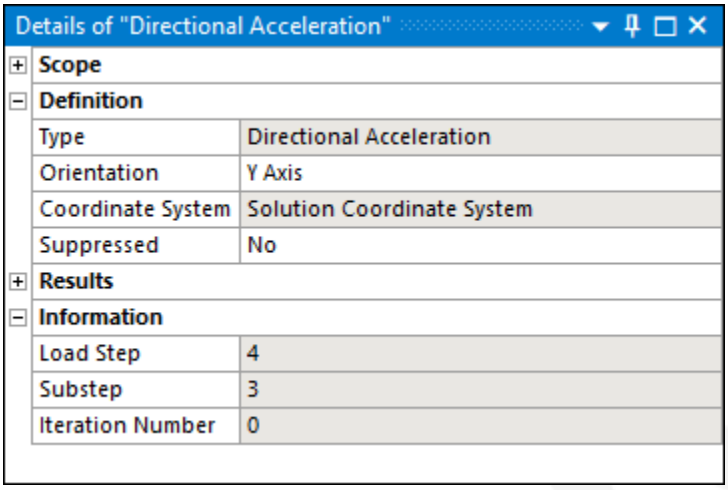
Note the following for result use and processing:

- To view strain/stress results, a selection must be made in **Output Controls** of the Modal analysis. By default, only **Deformation** drop-down menu results are available.
- Applicable **Deformation** results are **Total**, **Directional** (X/Y/Z), **Directional Velocity** and **Directional Acceleration**. If strain/stress are requested, applicable results are normal strain and stress, shear strain and stress, and equivalent stress.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Equivalent stress is a derived stress calculated using component stresses.
- Results are displayed as a contour plot on the model.
- For contour results, the **Information** category includes the following properties. These properties are calculated *after* the associated result is evaluated and they refer to results contained in the results (`file.rst`) file.

Example Details Properties



Property Output Descriptions

Load Step	Substep	Result Description
4	1	Displacement solution.
4	2	Velocity solution (if the **Calculate Velocity** property in Output Controls (p. 1473) is set to **Yes**).
4	3	Acceleration solution (if the **Calculate Acceleration** property in Output Controls (p. 1473) is set to **Yes**).

Note:

The value of the **Iteration Number** property varies based on analysis specifications. It is application defined, is information-based only, and has no impact on results.

You can also see the Review the Results topic in the *Performing a Random Vibration (PSD) Analysis* section in the *Mechanical APDL Structural Analysis Guide* for additional information.

- If you set the **Store Modal Result** property of the **Output Controls** to **No** in the upstream Modal analysis, the application creates additional auxiliary files in addition to standard files. The application automatically creates the `Displacement.mcom` file. And, if you set the **Calculate Velocity** and **Calculate Acceleration** properties (also **Output Controls**) of the downstream spectrum analysis

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

to **Yes**, then the application also creates the files `Velocity.mcom` and/or `Acceleration.mcom`. These files contain combination instructions as well as mode coefficients.

Note:

This configuration increases the computation time of spectrum analysis.

- **Force Reaction** and **Moment Reaction** probes can be scoped to a **Remote Displacement**, **Fixed Support**, or **Displacement** boundary conditions to view Reactions Results.

  Note:

  – When you scope a **Moment Reaction** probe to a **Fixed Support** or a **Displacement**, the **Summation** property must be set to **Centroid**.

  – The results of **Force Reaction** and **Moment Reaction** probes scoped to a **Fixed Support** or **Displacement** are calculated using the **FSUM** Mechanical APDL solver command. This command reports the vector sum of the elemental nodal forces in the global coordinate system. See the **FSUM** command in the *Mechanical APDL Command Reference* for more information.

- When the **Missing Mass Effect** property is set to **Yes**, the **Deformation** results that include the data from property in their result calculation are the **Directional** (Deformation/Displacement) and **Directional Acceleration** results. Note that the application supports the **Directional Velocity** result; however, it does not incorporate **Missing Mass Effect** conditions for its calculation.
- The **Directional** (Deformation/Displacement) result is a relative result whereas **Directional Velocity** and **Directional Acceleration** are absolute results.
- A **Directional Acceleration** result at or near fixed supports scoped to an **RS Acceleration** are correctly calculated by setting the **Missing Mass Effect** property and the **Rigid Response Effect** property to **Yes**. Corresponding properties display and require definition when these two properties are included.

File Management

When solving a Response Spectrum analysis with the "In Process" solve mode, the pre-requisite files from the upstream Modal system are referenced by specifying the full path of their location (refer to **RESUME** and **MODDIR** commands) instead of making copies in order to improve solution time and disk usage. See the Solve Modes and Recommended Usage (p. 1803) section of the Help for more information about the different solve modes.

When you are solving in the "Out of Process" mode, the application copies the pre-requisite files from the Modal analysis to the Response Spectrum **Solver Files Directory**. This may increase the required solution time for large models.

For additional technical information, refer to the Spectrum Analysis section of the *Mechanical APDL Structural Analysis Guide* as well as the **MMASS** command and the **RIGRESP** command in the *Mechanical APDL Command Reference*.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Substructure Generation Analysis

Introduction

The **Substructure Generation** analysis uses the component mode synthesis (CMS) to:

1. Condense all the finite elements of your model into one "superelement" that is represented as a matrix.
2. Create load vectors from the loading conditions and constraints that you apply. In addition, you can use an upstream Static Structural analysis to create pre-stress effects in the Substructure Generation analysis solution.

Once you have solved the analysis, you export this generated data as an Exported Condensed Part (`.cpa`) file for use in another appropriate simulation .

Note:

The load vectors extracted from the imported condensed part (`.cpa`) file are applied as loads in the use pass of the MSUP Harmonic Response analysis. No other analysis consumes these load vectors

---

Benefits

Substructuring reduces computer time and enables the solution of very large problems with limited computer resources. In a nonlinear analysis, you can substructure the linear portion of the model so that the element matrices for that portion do not need to be recalculated at every equilibrium iteration. In a structure with repeated patterns (such as the four legs of a table), you can generate one substructure to represent the pattern and simply make copies of it at different locations, thereby saving a significant amount of computer time.

Limitations

Note the following limitations for this analysis:

- This analysis type is supported for the Mechanical APDL solver only.
- This analysis supports External Model when Beta Options are active.
- The Master Degrees of Freedom Nodes (MDOFs) specified in the Mechanical application may be reduced by the solver during the solution of the analysis. This could be the result of a constraint defined on the MDOF nodes. The application reports this with a warning. For this case, there could be a discrepancy between Mechanical selected MDOFs and solver computed MDOFs as it might have been reduced due to over constraint. This is not recommended, and you should review the model before proceeding with use pass. A warning message will also display while eliminating the redundant degrees of freedom.
- The contact setting **Normal Lagrange** is not supported for the **Formulation** property.
- The only supported Joint types are **Fixed** and **Bushing** (with the **Formulation** property set to **Bushing**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Most element types can be used to generate a substructure. In general, the only restriction is that elements within the superelement are assumed to be linear and cannot use Lagrange multipliers. See the Generation Pass section of the *Mechanical APDL Substructuring Analysis Guide* for additional information.

Points to Remember

- All active bodies in the model will be condensed into one substructure (superelement).
- The substructure analysis can be linked to upstream Static Structure (p. 652) analysis in order to consider the prestressed effects of the structure. However, when you specify a pre-stress analysis, the **Substructure Generation** analysis only supports the following loading conditions:
  - Acceleration (p. 1501)
  - Standard Earth Gravity (p. 1509)
  - Nodal Force (p. 1721)
  - Nodal Pressure (p. 1724)
  - Nodal Orientation (p. 1719)
- This analysis supports Imported Pressure (p. 1752), including both real and imaginary values.

> **Note:**
>
> Imported Body Temperature (p. 1740) is also supported when Beta Options are active.

Preparing the Analysis

As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Establish Analysis Settings

The analysis includes the following Analysis Settings (p. 1417) categories:

- Options (p. 1458)

> **Note:**
>
> The maximum value for the **Number of Load Vectors** property is limited by the memory available on your computer.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Solver Controls (p. 1428): **Direct** is the only supported **Solver Type** property option.

  Note:

  The options **Supernode** and **Subspace** are available when Beta Options are active.

- Analysis Data Management (p. 1484)

Define Pre-Stress

If your analysis includes an upstream Static Structural (p. 652) system, specify the properties of the **Pre-Stress (Static Structural)** object. The analysis considers the pre-stressed inertial loads and boundary conditions during the generation pass. This is a result of the **Load Control** property of the **Pre-Stress** object being set (by default) to the **Keep Inertia and Displacement Constraints**. See the description of the **Load Control** property in the Pre-Stress object reference for more information.

Specify Interfaces

You specify interfaces on the **Substructure Definition** object using Named Selections (p. 1057) and Remote Points (p. 1089).

Tip:

To automatically create a **Named Selection** and a corresponding interface (in the **Worksheet**):

1. Select the **Substructure Definition** object.
2. From the **Geometry** window, select a supported geometric or mesh entity on the model.
3. Right-click and select **Create Selection and Add Interface**.

Define Substructure Definition Object

Specify the properties for the Substructure Definition object, including:

Category	Properties/Options/Descriptions
Geometry	**Geometry**: Read-only property that displays the number of bodies of the model.
Definition	**Physics Type**: Read-only property indicating the physics type (Structural). **Matrix Reduction Method**: Indicates the currently supported matrix reduction method - Component Mode Synthesis. **Interface Method**: Options include **Fixed** (default) or **Free**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Category	Properties/Options/Descriptions
	Lumped Mass Formulation: Specify the desired lumped mass matrix formulation. Options include **Program Controlled** (default), **Off**, and **On**. The **Off** setting uses the element-dependent default mass matrix formulation and the **On** setting uses a lumped mass approximation. **Generate Damping Matrix**: Specify whether to generate a damping matrix. Options include **Program Controlled** (default), **Yes**, and **No**.
Interfaces	**Number of Interfaces**: Read-only display of the number of interface entries detected by the application. **Number of Master Nodes**: Read-only display of the number of superelement master nodes resulting from interfaces.

Note:

The application treats added masses (from Point Masses (p. 901) and Distributed Masses (p. 902)) as internal to the superelement.

Apply Loads and Supports

Without considering the Limitations (p. 540), the analysis supports the following boundary conditions:

Inertial

- Acceleration (p. 1501)
- Standard Earth Gravity (p. 1509)

Loads

- Pressure (p. 1521)
- Force (p. 1543) (applied to a face, edge, or vertex)

Supports

The following *Supports* (p. 1663) can be used in this analysis:

- Fixed Support
- Displacement
- Remote Displacement
- Frictionless Support
- Compression Only Support
- Cylindrical Support
- Elastics Support

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Conditions

Constraint Equation (p. 1702)

Direct FE (node-based Named Selection scoping and constant loading only)

- Nodal Force (p. 1721)
- Nodal Pressure (p. 1724)
- Nodal Displacement (p. 1728)
- Nodal Orientation (p. 1719)

Imported Loads

Imported Pressure (p. 1752)

Note:

Imported Body Temperature (p. 1740) is also supported when Beta Options are active.

Note:

The application computes load vectors for each defined load. Once you export the solution (see below), you use these load vectors in another analysis through the **Imported Condensed Parts** (p. 790) object. Load vector information displays in the Worksheet when you select the **Imported Condensed Parts** object.

Specify Results

The only result supported by this analysis is Total Deformation (p. 2018).

Perform Solution

The **Solution Information** object presents continuous updates of any output from the solver and provides valuable information on the behavior of the structure during the analysis.

Select the **Solution** object to view the frequencies obtained from the solution process in the **Graph** and **Tabular Data** windows.

Exporting Substructure Solution

Once you have solved your analysis, you can export the generated superelement for use in a different session of the application. Right-click the **Solution** object, select **Export Substructure (.cpa)**, and then select one of the following options:

- **Use Pass Only**: Using this option, the application generates solution files required to perform a Use Pass analysis. No Expansion Pass can be performed when this option is selected.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Use Pass and On Demand Expansion**: Using this option, the application generates solution files required to perform a Use Pass analysis as well as **On Demand Expansion**.

A progress bar displays during the export operation and offers an option to stop (red square icon) the process.

Note:

If you set the **Future Analysis** property (**Analysis Settings**>Analysis Data Management (p. 1484)) to **Ansys Rigid Dynamics (Beta)**, the application automatically includes the additional files necessary to perform a downstream Rigid Dynamics (p. 550) analysis in the exported file.

Magnetostatic Analysis

Introduction

Magnetic fields may exist as a result of a current or a permanent magnet. In the Mechanical application you can perform 3D static magnetic field analysis. You can model various physical regions including iron, air, permanent magnets, and conductors.

Typical uses for a magnetostatic analysis are as follows:

- Electric machines
- Transformers
- Induction heating
- Solenoid actuators
- High-field magnets
- Nondestructive testing
- Magnetic stirring
- Electrolyzing cells
- Particle accelerators
- Medical and geophysical instruments.

Points to Remember

- This analysis is applicable only to 3D geometry.
- The geometry must consist of a single solid multibody part (p. 847).
- A magnetic field simulation requires that air surrounding the physical geometry be modeled as part of the overall geometry. The air domain can be easily modeled in DesignModeler using the Enclosure feature. Ensure that the resulting model is a single multibody part which includes the physical geometry and the air.
- In many cases, only a symmetric portion of a magnetic device is required for simulation. The geometry can either be modeled in full symmetry in the CAD system, or in partial symmetry. DesignModeler has a Symmetry feature that can slice a full symmetry model, or identify planes of symmetry for a partial symmetry model. This information is passed to the Mechanical application for convenient application of symmetry plane boundary conditions.
- A Magnetostatic analysis supports a multi-step solution.

From the **Toolbox**, drag the **Magnetostatic** template to the **Project Schematic**.

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

- Magnetic field simulation supports 4 categories of material properties:

  1. Linear "soft" magnetic materials - typically used in low saturation cases. A **Relative Permeability** is required. This may be constant, or orthotropic with respect to the coordinate system of the body (See Details view). Orthotropic properties are often used to simulate laminate materials.

  2. Linear "hard" magnetic materials - used to model permanent magnets. The demagnetization curve of the magnet is assumed to be linear. **Residual Induction** and **Coercive Force** are required.

  3. Nonlinear "soft" magnetic material - used to model devices which undergo magnetic saturation. A B-H curve is required. For orthotropic materials, you can assign the B-H curve in any of the orthotropic directions, while specifying a constant **Relative Permeability** in the other directions. (Specifying a value of "0" for **Relative Permeability** will make use of the B-H curve in that direction.)

  4. Nonlinear "hard" magnetic material - used to model nonlinear permanent magnets. A B-H curve modeling the material demagnetization curve is required.

- When using an Ansys license that includes the Emag license feature, only the following material properties are allowed: Isotropic Resistivity, Orthotropic Resistivity, Relative Permeability, Relative Permeability (Orthotropic), Coercive Force & Residual Induction, B-H Curve, B-H Curve (Orthotropic), Demagnetization B-H Curve. You may have to turn the filter off in the **Engineering Data** tab to suppress or delete those material properties/models that are not supported for the license.

- Conductor bodies require a **Resistivity** material property. Solid source conductor bodies can be constant or orthotropic with respect to the coordinate system of the body. Stranded source conductor bodies can only be modeled as isotropic materials.

- For convenience, a library of common B-H curves for soft magnetic material is supplied with the product. Use the **Import** tool in Engineering Data to review and retrieve curves for use.

Note:

In a magnetostatic analysis, you can orient a polarization axis for a Linear or Nonlinear Hard material in either the positive or negative x direction with respect to a local or global coordinate system (p. 1191). Use the **Material Po-**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

larization setting in the Details view for each body to establish this direction. The **Material Polarization** setting appears only if a hard material property is defined for the body. For a cylindrical coordinate system, a positive x polarization is in the positive radial direction, and a negative x polarization is in the negative radial direction.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

There are no specific considerations for a magnetostatic analysis.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

Mechanical does not support Rigid Bodies in Magnetostatic analyses. For more information, see the *Stiffness Behavior* documentation for Rigid Bodies (p. 852).

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Connections are not supported in a magnetostatic analysis.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

- Although your body is automatically meshed at solve time, it is recommended that you select the **Electromagnetic Physics Preference** in the Details view of the Mesh object folder.
- Solution accuracy is dependent on mesh density. Accurate force or torque calculations require a fine mesh in the air regions surrounding the bodies of interest.
- The use of pyramid elements in critical regions should be minimized. Pyramid elements are used to transition from hexagonal to tetrahedral elements. You can eliminate pyramid elements from the model by specifying **Tetrahedrons** using a **Method** mesh control tool.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Specifics ***... for this analysis type:***

For a Magnetostatic Analysis, the basic **Analysis Settings** include:

Step Controls for Static and Transient Analyses (p. 1418)

Step Controls are used to specify the end time of a step in a single or multiple step analysis.

Multiple steps are needed if you want to change load values, the solution settings, or the solution output frequency over specific steps. Typically you do not need to change the default values.

Solver Controls (p. 1428)

Solver Controls enable you to select either a direct or iterative solver. By default the program will use the direct solver. Convergence is guaranteed with the direct solver. Use the Iterative solver only in cases where machine memory is an issue. The solution is not guaranteed to converge for the iterative solver.

Nonlinear Controls (p. 1468)

Nonlinear Controls enable you to modify convergence criteria and other specialized solution controls. These controls are used when your solution is nonlinear such as with the use of nonlinear material properties (B-H curve). Typically you will not need to change the default values for this control. CSG convergence is the criteria used to converge the magnetic field. CSG represents magnetic flux. AMPS convergence is only used for temperature-dependent electric current conduction for solid conductor bodies. AMPS represents current.

Output Controls (p. 1473)

Output Controls enable you to specify the time points at which results should be available for postprocessing. A multi-step analysis involves calculating solutions at several time points in the load history. However you may not be interested in all of the possible results items and writing all the results can make the result file size unwieldy. You can restrict the amount of output by requesting results only at certain time points or limit the results that go onto the results file at each time point.

Analysis Data Management (p. 1484)

The **Analysis Data Management** settings enable you to save solution files from the magnetostatic analysis. The default behavior is to only keep the files required for postprocessing. You can use these controls to keep all files created during solution or to create and save the Mechanical APDL application database (db file).

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

There is no initial condition specification for a magnetostatic analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

- You can apply electromagnetic boundary conditions and excitations in the Mechanical application. See Electromagnetic Boundary Conditions and Excitations (p. 1635) for details.
- Boundary conditions may also be applied on symmetry planes via a **Symmetry** (p. 1127). A **Symmetry** folder allows support for Electromagnetic Symmetry (p. 1130), Electromagnetic Anti-Symmetry (p. 1131), and Electromagnetic Periodicity (p. 1131) conditions.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

The **Solution Information** (p. 1833) object provides some tools to monitor solution progress in the case of a nonlinear magnetostatic analysis.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

Adaptive mesh refinement (p. 1853) is available for magnetostatic analyses.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

A magnetostatic analysis offers several results (p. 2157) for viewing. Results may be scoped to bodies and, by default, all bodies will compute results for display. For **Inductance** or **Flux Linkage**, define these objects prior to solution. If you define these after a solution, you will need to re-solve.

Rigid Dynamics Analysis

Introduction

You can perform a Rigid Dynamics analysis in the Mechanical application using the Ansys Rigid Dynamics solver. This type of analysis is used to determine the dynamic response of an assembly of rigid bodies linked by joints and springs. You can use this type of analysis to study the kinematics of a robot arm or a crankshaft system for example.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Points to Remember

- Inputs and outputs are joint forces, moments, displacements, velocities and accelerations.
- On rigid parts, there are no stresses and strain results produced, only forces, moments, displacements, velocities and accelerations.
- The solver is tuned to automatically adjust the time step. Doing it manually is often inefficient and results in longer run times.

This section contains the following topics:

Preparing a Rigid Dynamics Analysis
Command Reference for Rigid Dynamics Systems
Using the Variable Load Add-on
Using the Motion Load Transfer Add-on
Multibody Dynamics Theory Guide

Preparing a Rigid Dynamics Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

From the **Toolbox**, drag a **Rigid Dynamics** template to the **Project Schematic**.

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

Density is the only material property utilized by rigid bodies. Models that use zero or nearly zero density fail to solve with the Ansys Rigid Dynamics solver.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

Sheet, solid, and line bodies are supported by the Ansys Rigid Dynamics solver, but line bodies can only be flexible and included in a condensed part (p. 781). Plane bodies cannot be used.

Rigid line bodies are not supported in RBD because the mass moment of inertia is not available.

Define Part Behavior

Published: 2023-10-23

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

You can define a **Point Mass** (p. 901) for this analysis type.

Stiffness behavior can be rigid or flexible.

Note:

If the part behavior is flexible, it must be included in a condensed part.

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Applicable connections are joints (p. 1292), springs (p. 1395), and contacts (p. 1235).

When an assembly is imported from a CAD system, joints or constraints are not imported, but joints may be created automatically after the model is imported. You can also choose to create the joints manually.

Each joint is defined by its coordinate system of reference. The orientation of this coordinate system is essential as the free and fixed degrees of freedom are defined in this coordinate system.

Automatic contact generation is also available after the model is imported.

For information on contact specifically oriented for Rigid Dynamics, see Contact in Rigid Dynamics (p. 1275) and Best Practices for Contact in Rigid Body Analyses (p. 1278).

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Mesh controls apply to surfaces where contact is defined as well as to deformable parts.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For Rigid Dynamics analyses the basic controls are:

Step Controls (p. 1418) enable you to create multiple steps. Multiple steps (p. 1418) are useful if new loads are introduced or removed at different times in the load history.

Published: 2023-10-23

A Rigid Dynamics analysis can use an explicit time integration scheme, especially if the model is made only of rigid parts. Unlike the implicit time integration, there are no iterations to converge in an explicit time integration scheme. The solution at the end of the time step is a function of the derivatives during the time step. As a consequence, the time step required to get accurate results is usually smaller than is necessary for an implicit time integration scheme. Another consequence is that the time step is governed by the highest frequency of the system. A very smooth and slow model that has a very stiff spring will require the time step needed for the stiff spring itself, which generates the high frequencies that will govern the required time step. Stiff models can be more efficiently solved using the Implicit Generalized-α, Implicit Stabilized Generalized-α, or MJ Time Stepping time integration schemes.

Because it is not easy to determine the frequency content of the system, an automatic time stepping algorithm is available, and should be used for the vast majority of models. This automatic time stepping algorithm is governed by **Initial Time Step**, **Minimum Time Step**, and **Maximum Time Step** under **Step Controls**; and **Energy Accuracy Tolerance** under **Nonlinear Controls**.

- **Initial Time Step**: If the initial time step chosen is vastly too large, the solution will typically fail, and produce an error message that the accelerations are too high. If the initial time step is only slightly too large, the solver will realize that the first time steps are inaccurate, automatically decrement the time step and start the transient solution over. Conversely, if the chosen initial time step is excessively small, and the simulation can be accurately performed with higher time steps, the automatic time stepping algorithm will, after a few gradual increases, find the appropriate time step value. Choosing a good initial time step is a way to reduce the cost of having the solver figure out what time step size is optimal to minimize run time. While important, choosing the correct initial time step typically does not have a large influence on the total solution time due to the efficiency of the automatic time stepping algorithm.

- **Minimum Time Step**: During the automatic adjustment of the time step, if the time step that is required for stability and accuracy is smaller than the specified minimum time step, the solution will not proceed. This value does not influence solution time or its accuracy, but it is there to prevent the solver from running forever with an extremely small time step. When the solution is aborting due to hitting this lower time step threshold, that usually means that the system is over constrained, or in a lock position. Check your model, and if you believe that the model and the loads are valid, you can decrease this value by one or two orders of magnitude and run again. That can, however generate a very large number of total time steps, and it is recommended that you use the **Output Controls** settings to store only some of the generated results.

- **Maximum Time Step**: Sometimes the time step that the automatic time stepping settles on produces too few results outputs for precise postprocessing needs. To avoid these postprocessing resolution issues, you can force the solution to use time steps that are no bigger than this parameter value.

Solver Controls (p. 1428): For this analysis type, enables you to select a time integration algorithm (Program Controlled, Runge-Kutta order 4, Implicit Generalized-α, Stabilized Generalized-α, MJ Time Stepping) and select whether to use constraint stabilization. The default time integration option, **Program Controlled**, provides the appropriate

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

accuracy for most applications. The default, **Program Controlled** is valid for most applications, however; you may wish to set this option to **User Defined** and manually enter customized settings for weak spring and damping effects. The default is **Off**.

Nonlinear Controls (p. 1468) enable you to modify convergence criteria and other specialized solution controls. Typically you will not need to change the default values for this control.

- **Energy Accuracy Tolerance**: This is the main driver to the automatic time stepping. The automatic time stepping algorithm measures the portion of potential and kinetic energy that is contained in the highest order terms of the time integration scheme, and computes the ratio of the energy to the energy variations over the previous time steps. Comparing the ratio to the **Energy Accuracy Tolerance**, Workbench will decide to increase or decrease the time step. Energy accuracy tolerance is program controlled by default. It is enabled with the Explicit Runge-Kutta method and disabled by default with Implicit Generalized-α, Implicit Stabilized Generalized-α, and MJ Time Stepping.

  Note:

  For systems that have very heavy slow moving parts, and also have small fast moving parts, the portion of the energy contained in the small parts is not dominant and therefore will not control the time step. It is recommended that you use a smaller value of integration accuracy for the motion of the small parts.

  Spherical (p. 1302), slot (p. 1301) and general (p. 1310) joints with three rotation degrees of freedom usually require a small time step, as the energy is varying in a very nonlinear manner with the rotation degrees of freedom.

- **Force Residual Relative Tolerance:** (Only available with Implicit Generalized-α or Stabilized Generalized-α time integration or MJ Time Stepping integration) This option controls the threshold used in Newton-Raphson for force residual convergence. The default value is 1.e-7. A smaller value will lead to a smaller residual, but it will require more iterations. The convergence of force residual can be monitored in **Solution Information** using Force Convergence.

- **Constraint Equation Residual Relative Tolerance:** (Only available with Implicit Generalized-α or Stabilized Generalized-α time integration or MJ Time-Stepping integration) This option controls the threshold used in Newtom-Raphson to check convergence of constraint equations violations. The default value is 1.e-8. The convergence of this criterion can be checked in **Solution Information** using Displacement Convergence

Output Controls (p. 1473) enable you to specify the time points at which results should be available for postprocessing. In a transient nonlinear analysis it may be necessary to perform many solutions at intermediate time values. However i) you may not be interested in reviewing all of the intermediate results and ii) writing all the results can make the results file size unwieldy. This group can be modified on a per step basis.

Define Initial Conditions

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

Before solving, you can configure the joints and/or set a joint load to define initial conditions.

1. Define a **Joint Load** (p. 1592) during a short initial load step to set initial conditions on the free degrees of freedom of a joint.

   For the Ansys Mechanical APDL solver to converge, it is recommended that you ramp the angles and positions from zero to the real initial condition over one step. The Ansys Rigid Dynamics solver does not need these to be ramped. For example, you can directly create a joint load for a revolute (p. 1299) joint of 30 degrees, over a short step to define the initial conditions of the simulation. If you decide to ramp it, you have to keep in mind that ramping the angle over 1 second, for example, means that you will have a non-zero angular velocity at the end of this step. If you want to ramp the angle and start at rest, use an extra step maintaining this angle constant for a reasonable period of time or, preferably, having the angular velocity set to zero. Another way to specify the initial conditions in terms of positions and angles is to use the Configure tool (p. 1380), which eliminates the time steps needed to apply the initial conditions.

   To fully define the initial conditions, you must define position and velocities. Unless specified by joint loads, if your system is initially assembled, the initial configuration will be unchanged. If the system is not initially assembled, the initial configuration will be the "closest" configuration to the unassembled configuration that satisfies the assembly tolerance (p. 219) and the joint loads.

   Unless specified otherwise, *relative* joint velocity is, if possible, set to zero. For example, if you define a double pendulum and specify the angular velocity of the grounded revolute joint, by default the second pendulum will not be at rest, but will move rigidly with the first one.

2. Configure a joint (p. 1380) to graphically put the joint in its initial position.

See Joint Initial Conditions (p. 1296) for further details.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads and supports can be used in a Rigid Dynamics analysis:

- **Acceleration** (p. 1501)
- **Standard Earth Gravity** (p. 1509)
- **Joint Load** (p. 1592)
- **Remote Displacement** (p. 1674)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Remote Force** (p. 1552)
- **Constraint Equation** (p. 1702)

Joint Load

Magnitude

For a **Joint Load**, the joint condition's magnitude could be a constant value, could vary with time as defined in a table or via a function, or could depend on other values measured on the model during the solution. See Using the Variable Load Add-on (p. 611) to define such a load variation. Details of how to apply a tabular or function load are described in Defining Boundary Condition Magnitude (p. 1771). Details on the **Joint Load** are included below.

In addition, see the Apply Loads and Supports (p. 354) section for more information about time stepping and ramped loads.

Interpolation/Derivation

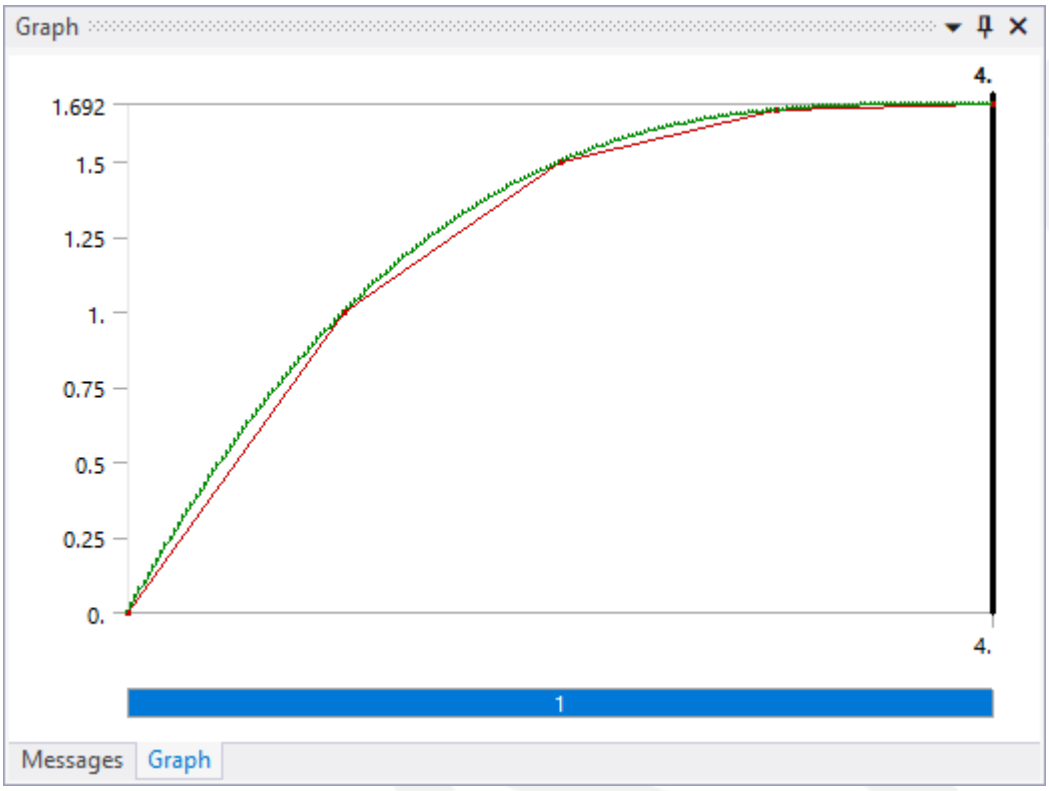
For joint loads applied through tabular data values, the number of points input will most likely be less than the number of time steps required to solve the system. As such, an interpolation is performed. When a joint load requires fitting, the result of the fitting is displayed in the joint load chart along with the user-specified values. The number of segments used to display the curve is driven by the **Number Of Segments** property.

The underlying fitting method used for interpolation can be configured using the **Fitting Method** field (specific to Rigid Dynamics analysis). Options include:

- **Program Controlled (default):** Depending on the **Joint Load** type, the solver chooses the appropriate interpolation method. Accelerations and Force joint loads use a piecewise linear. Displacement/Rotation/Velocity/Rotational Velocity joint loads use either a linear fitting when only two points are given per load step, or a cubic spline fitting when there are more than two points as shown on the following graph:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



A large difference between the interpolated curve and the linear interpolation may prevent the solution from completing. If this is the case and you intend to use the linear interpolation, you can simply use multiple time steps, as the interpolation is done in one time step.

- **Fast Fourier Transform:** Fast Fourier Transform is performed to fit tabular data. Unlike cubic spline fitting, no verification on the fitting quality is performed. The additional cutoff frequency parameter specifies the threshold (expressed in Hz) used to filter high frequencies. Higher cutoff frequency results in a better fitting, but leads to smaller time steps. The following graphs show the effect of cutoff frequency on FFT fitting on a triangular signal using 5 Hz and 10 Hz, respectively.

Note:

The Fourier Fitting implicitly expects cyclic data. Lack of continuity between end time and start time values may lead to oscillations known as Gibbs phenomenon. Similarly, the lack of continuity for the derivatives may also lead to unwanted oscillations around jumps. For instance, an imposed displacement requires the continuity of the first and second derivatives. The Rigid Dynamics solver implements several dedicated treatments to prevent Gibbs phenomenon. However, results of Fourier Fitting must be carefully reviewed to check there are no artificial oscillations.

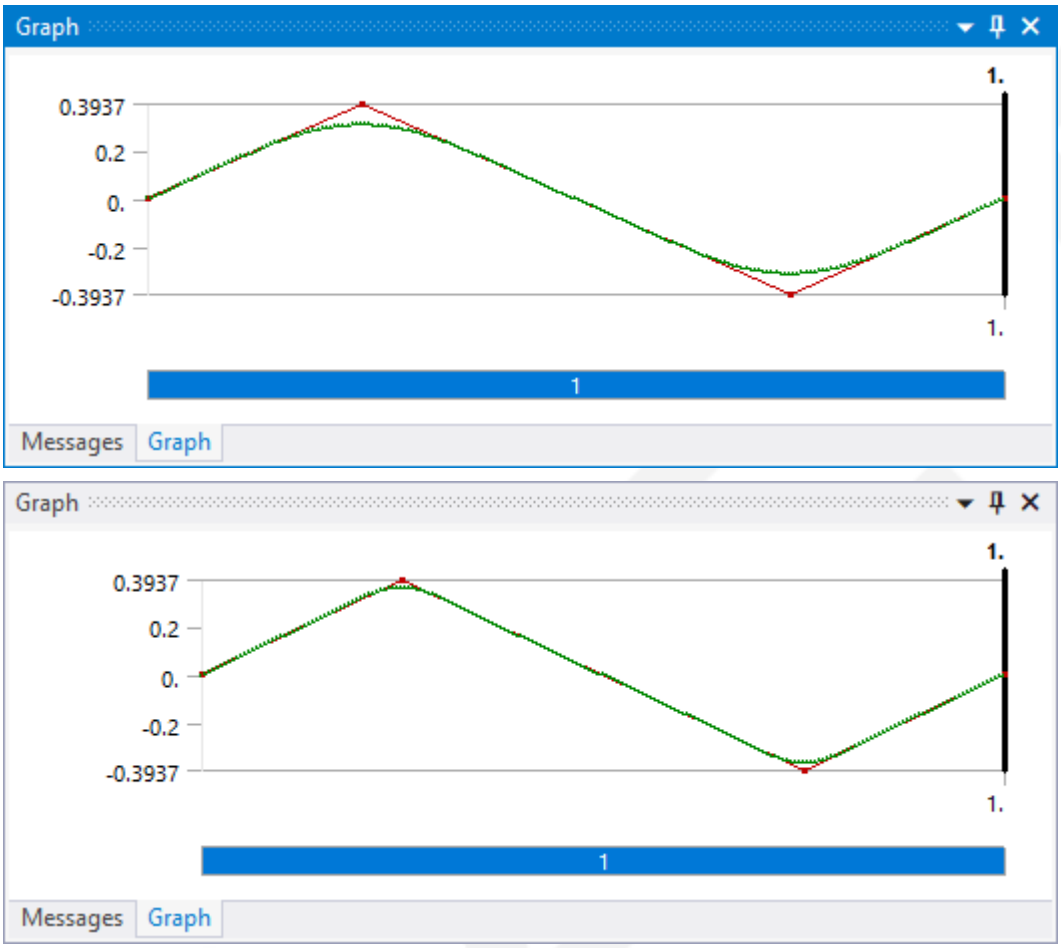
Published: 2023-10-23

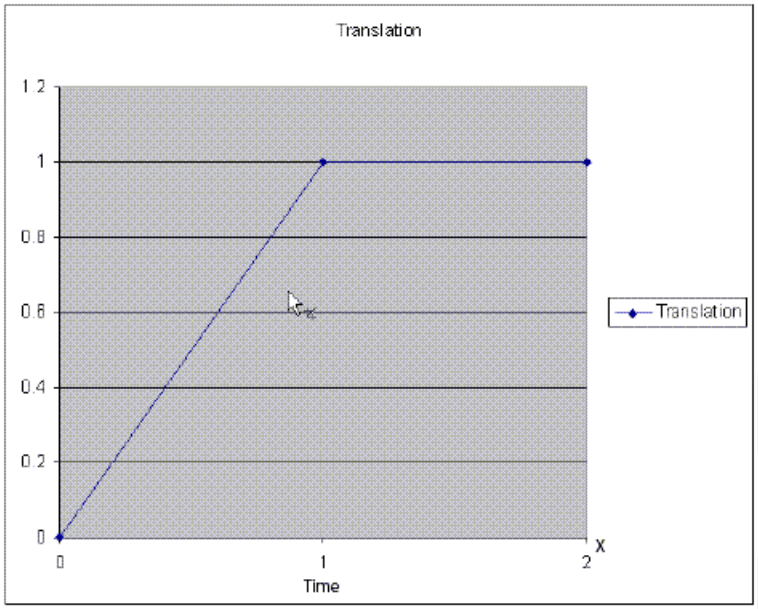


Discontinuities

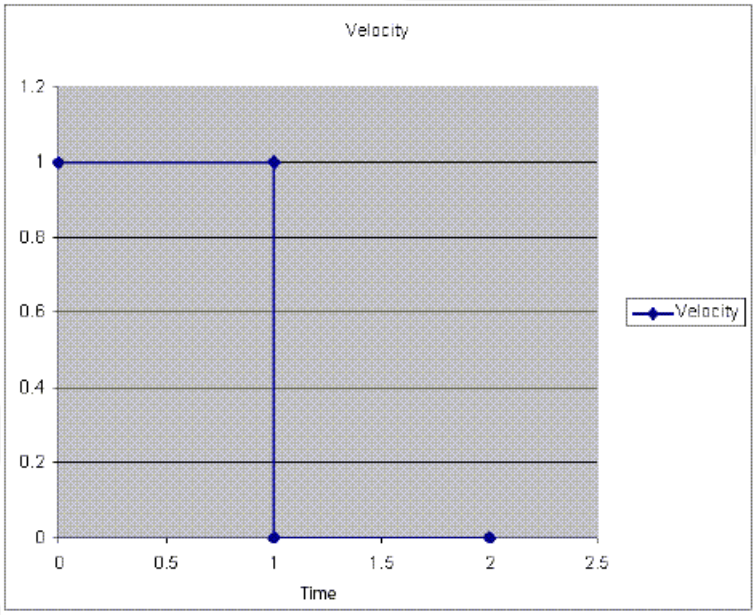
When defining a joint load for a position and an angle, the corresponding velocities and accelerations are computed internally. When defining a joint load for a translational and angular velocity, corresponding accelerations are also computed internally. By activating and deactivating joint loads, you can generate some forces/accelerations/velocities, as well as position discontinuities. Always consider what the implications of these discontinuities are for velocities and accelerations. Force and acceleration discontinuities are perfectly valid physical situations. No special attention is required to define these velocity discontinuities. Discontinuities can be obtained by changing the slope of a relative displacement joint load on a translational joint, as shown on the following graphs using two time steps:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



The corresponding velocity profile is shown here.



This discontinuity of velocity is physically equivalent to a shock, and implies infinite acceleration if the change of slope is over a zero time duration. The Ansys Rigid Dynamics solver will very often handle these discontinuities, and redistribute velocities after the discontinuity according to all active joint loads. This process of redistribution of velocities usually provides accurate results; however, no shock solution is performed, and this process is not guaranteed to produce a physically acceptable energy redistribution. A closer look at the total energy probe will tell you if the solution is valid. In case the redistribution is not done properly, use one step instead of two to use an interpolated, smooth position variation with respect to time.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Discontinuities of positions and angles are not a physically acceptable situation. Results obtained in this case may not be physically sensible. Workbench cannot detect this situation up front. If you proceed with position discontinuities, the solution may abort or produce false results.

Rotations

For fixed axis rotations, it is possible to count a number of turns. For 3D general rotations, it is not possible to count turns. In a single axis case, although it is possible to prescribe angles higher than 2π, it is not recommended because Workbench can lose count of the number of turns based on the way you ramp the angle. You should avoid prescribing angular displacements with angles greater than Pi when loading bushing joints, because the angle-moment relationship could differ from the stiffness definition if the number of turns is inaccurate, or in case of Euler angles singularity. It is highly recommended that you use an angular velocity joint load instead of an angle value to ramp a rotation, whenever possible.

For example, replace a rotation joint load designed to create a joint rotation from an angle from 0 to 720 degrees over 2 seconds by an angular velocity of 360 degrees/second. The second solution will always provide the right result, while the behavior of the first case can sometimes lead to the problems mentioned above.

For 3D rotations on a general joint for example, no angle over 2π can be handled. Use an angular velocity joint load instead.

Multiple Joint Loads On The Same Joint

When prescribing a position or an angle on a joint, velocities and acceleration are also prescribed. The use of multiple joint loads on the same joint motion can cause for joint loads to be determined inaccurately.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

Only synchronous (p. 1803) solves are supported for Rigid Dynamics analyses.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Use a **Solution Information** object to track, monitor, or diagnose problems that arise during solution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Applicable results are Deformation (p. 2018) and Probe (p. 1946) results.

Note:

If you highlight **Deformation** results in the tree that are scoped to rigid bodies, the corresponding rigid bodies in the **Geometry** window are not highlighted.

To plot different results against time on the same graph or plot one result quantity against a load or another results item, use the Chart and Table (p. 1929) feature.

If you duplicate (p. 40) a Rigid Dynamics analysis, the results of the duplicated branch are also cleared (p. 1981).

Joint Conditions and Expressions

When a rotation, position, velocity or angular velocity uses an expression that user the power (^) operator, such as (x)^(y), the table will not be calculated properly if the value x is equal to zero. This is because its time derivative uses log(x), which is not defined for x = 0. An easy workaround is to use x*x*x... (y times), which assumes that y is an integer number and thus can be derived w.r.t time without using the log operator.

Remote Force

Remote Force (p. 1552) direction can be configured in Rigid Dynamics analyses using the **Follower Load** option. Remote direction can be either constant (**Follower Load**=**No**, Default), or it can follow the underlying body/part (**Follower Load**=**Yes**).

Command Reference for Rigid Dynamics Systems

The Rigid Dynamics solver uses an object-based approach that uses Python-based commands that follow Python syntax. This section explains this approach and the role of Python in rigid body commands. It also provides a library of commands for Rigid Dynamics analyses (arranged by parent object) and examples of command usage. Topics available in this section include:

An ACT extension is provided to facilitate the creation of complex joint and body loads that would otherwise require using Python command snippets. You can find information about how to load and use the extension in Using the Variable Load Add-on (p. 611).

IronPython References

Rigid Dynamics uses an object-based approach, so it is useful to have experience with object oriented programming and the Python language when writing commands for the solver. Ansys Workbench scripting is based on IronPython, which is well integrated with the rest of the .NET Framework (on Windows) and Mono CLR (on Linux). This makes all related libraries easily available to Python programmers while maintaining compatibility with the Python language. For more information on IronPython, see http://ironpython.net.

IronPython is compatible with existing Python scripts, but not all C-based Python library modules are available under IronPython. Refer to the IronPython website for more information. For more information on Python, including a standard language reference, see http://www.python.org/.

The Rigid Dynamics Object Model

In the Rigid Dynamics object-based approach, the **Environment** is the top level object that allows access to all other underlying objects. The environment is associated with an environment object in the **Mechanical** tree. Many environments can exist on the same model. The model is called the **System** in the **Rigid Dynamics Object** model. The system contains the physical representation of the model, and the environment contains the representation of a given simulation done on the model. This means that **Bodies** and **Joints** belong to the systems, and **Joint Conditions** or **Loads** are available on the environment.

You can access an object using its unique ID, which is the same ID used by Mechanical. Global object tables help you to access an object for which you have an ID.

For example, a **Joint** with the ID **`_jid`** can be accessed using the following call:

```
Joint= CS_Joint.Find(_jid)
```

`CS_xxx` is the table of all **`xxx`** type objects.

If the ID of an object is not known, or if only one occurrence of the object exists in the object model, query the object table to find the first occurrence of a given object type. This is explained in the following example:

```
Environment = CS_Environment.FindFirstNonNull()
```

`GetId()`

This call returns the object ID.

`GetName()`

This call returns the object name.

`SetName(name)`

This call sets or changes the object name.

Some objects have to be created by calling the object constructor. For example, to create a constant variable:

```
Var = CS_ConstantVariable()
```

Rigid Dynamics Command Objects Library

The following Rigid Dynamics command objects are available:

Actuator (p. 563)
Basis (p. 564)
Body (p. 565)
Body Coordinate System (p. 566)
Body Load (p. 567)
CMSBody (p. 568)
Condition (p. 569)
Contact (p. 570)
ContactDebugMask (p. 570)
ContactOptions (p. 571)
Driver (p. 572)
Environment (p. 572)
Flexible Body (p. 574)
GILTable (p. 576)
Joint (p. 578)
JointDOFLoad (p. 582)
Load (p. 583)
Measure (p. 583)
MSolverDB (p. 587)
PointsTable (p. 588)
PolynomialTable (p. 588)
Relation (p. 589)
Spring (p. 592)
SolverOptions (p. 590)
System (p. 592)
Table (p. 593)
UserTable (p. 594)
Variable (p. 594)

Actuator

The actuator is the base class for all Loads (p. 583), Body Loads (p. 567), and Drivers (p. 572).

ID table: **`CS_Actuator`**

DRAFT

Members:

`Condition`

All actuators can be conditional. See Condition (p. 569) to create this condition.

`AppliedValue`

Measure that stores the evaluation of the actuator variable. Can be useful when the applied value depends on a measure other than time.

`EnergyMeasure`

Measure that stores the energy generated by the actuator.

Member Functions:

There are two ways to define the value of the load: using a variable, or by defining a table of input measures (in which case a variable is defined automatically).

`SetVariable(variable)`

`variable` is a list of input measures in table form.

`SetInputMeasure(measure)`

`measure` is typically the time measure object, but other measures can be used as well. When using an expression to define a load variation, the measure must have only one component (it cannot be a vector measure). The variation can be defined by a constant, an expression, or a table.

`SetConstantValues(value)`

`value` is a Python float constant. See Relation (p. 589) object for defining a constant.

`SetTable(table)`

`table` is a **`CS_Table`** .

`SetFunc(string, is_degree)`

`string` is similar to the expression used in the user interface to define a joint condition by a function. Note that the literal variable is always called **`time`**, even if you are using another measure as input.

`is_degree` is a boolean argument. If the expression uses trigonometric function, it specifies that the input variable should be expressed in degrees.

Basis

A basis is a material frame moving with a body. Each coordinate system has a basis, but multiple coordinate systems can share the same basis.

ID table: **`CS_Basis`**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Constructors:

CS_Basis()

CS_Basis(Angle1, Angle2, Angle3)

Members:

double [,]Matrix

Sets or gets function of the transformation matrix

Body

A body corresponds to a **Part** in the geometry node of the Mechanical tree, or can be created by a command snippet. The preset **_bid** variable can be used to find a corresponding body.

ID table: **CS_Body**

Example:

```
MyBody = CS_Body.Find(_bid)
print MyBody.Name
```

Constructors:

CS_Body()

CS_Body(Id)

Members:

Name

Name of the body.

Origin

Origin Coordinate System of the body. This Coordinate System is the moving coordinate system of one of the joints connected to the body. The choice of this joint, called parent joint, is the result of an optimization that minimizes the number of degrees of freedom of the system.

InertiaBodyCoordinateSystem

Inertia body coordinate system of the body.

BodyType

Type of body, values in **E_UnknownType**, **E_Ground**, **E_Rigid**, **E_CMS**, **E_General**, **E_Fictitious**, **E_RigidLeaf**, **E_RigidSubModel**, **E_PointMass**, **E_Beam**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Member Functions:

`SetMassAndInertia(double mass, double Ixx, double Iyy, double Izz, double Ixy, double Iyz, double Ixz)`

Overwrites the mass and inertia values of a body.

`SetCenterOfMassAndOrientationAngles(double Xg, double Yg, double Zg, double XYAngle, double YZAngle, double XZAngle)` and `SetCenterOfMassAndOrientationMatrix(double Xg, double Yg, double Zg, double mxx, double mxy, double mxz, double myx, double myy, double myz, double mzx, double mzy, double mzz)`

Overwrites the position of the center of mass and the orientation of the inertia coordinate system.

`SetVariableMassAndPrincipalInertia(CS_Variable mass, CS_Variable Ixx, CS_Variable Iyy, CS_Variable Izz)`

Overwrites the constant mass and principal inertia properties by variable properties. During the solution process, the mass and inertia variation rate needs to be evaluated. Therefore, only Point Table, Polynomial and Function can be used to define the variation. Python user tables cannot be used to define kinetic properties variations. You can make some of the properties (mass, Ixx, Iyy and Izz) constants by using constant variables.

Note:

The principal axis needs to be defined when the principal inertia is being assigned. If the body is created by a command, **`SetCenterOfMassAndOrientationAngles`** or **`SetCenterOfMassAndOrientationMatrix`** must be called before calling **`SetVariableMassAndPrincipalInertia`**.

This function only applies to rigid bodies.

Note:

All quantities used in the solver must use a consistent unit system, which sometimes differs from the user interface unit system. For example if the user interface unit system is "mm,kg,N,s", the solver unit system will be “mm,t,N,s". When using `SetMassAndInertia` or `SetVariableMassAndPrincipalInertia`, the values of mass and inertia have to be entered using the solver unit system.

Derived Classes:

`CS_FlexibleBody`

Body Coordinate System

The body coordinate system is used to connect a body to joints, hold the center of mass, or define a load. See Joint (p. 578) or Body (p. 565) to access existing coordinate systems. Coordinate systems can also be created.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

ID table: **CS_BodyCoordinateSystem**

Constructors:

CS_BodyCoordinateSystem(body, type, xyz, basis)

Members:

Basis (p. 564)

Member Functions:

RotateArrayThroughTimeToLocal(MeasureValues)

Rotates the transient values of a measure to a coordinate system. **MeasureValues** is a python two-dimensional array, such as that coming out of **FillValuesThroughTime** or **FillDerivativesThroughTime**. This function works for 3D vectors such as relative translation between two coordinate systems or 6-D vectors such as forces/moments.

RotateArrayThroughTimeToGlobal(MeasureValues)

Rotates the transient values of a measure from a coordinate system to the global coordinate system.

Type

Type of coordinate system, values in **E_Unknown**, **E_Ground**, **E_Part**, **E_Joint**, **E_Inertia**, **E_BodyTransform**, **E_Contact**, **E_SplitJoint**.

Derived Classes:

None

Example:

```
forceInGlobal=joint.GetForce()

valuesInGlobal=forceInGlobal.FillValuesThroughTime()

for i in range(0,valuesInGlobal.GetLength(0)):
    print '{0:e} {1:e} {2:e} {3:e}'.format(valuesInGlobal[i,0],
 valuesInGlobal[i,1],valuesInGlobal[i,2],valuesInGlobal[i,3])

mobileCS=joint.MobileCoordinateSystem

valuesInLocal=valuesInGlobal.Clone()

mobileCS.RotateArrayThroughTimeToLocal(valuesInLocal)

for i in range(0,valuesInGlobal.GetLength(0)):
    print '{0:e} {1:e} {2:e} {3:e}'.format(valuesInLocal[i,0],
    valuesInLocal[i,1],valuesInLocal[i,2],valuesInLocal[i,3])
```

Body Load

A body load is a load that is applied to all bodies in the system. Gravity or global acceleration are body loads.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The body load must implement a **`GetAccelerationVector`** method. This vector is applied to the center of mass of each body. In order to maintain the energy balance of the system, the body load must also implement a **`ComputeEnergy`** method.

Example: Acceleration varying with time

```
HalfTime = 1.0
HalfAmplitude = 10.0

Env=CS_Environment.GetDefault()
Sys=Env.System
(ret,found,time) = Sys.FindOrCreateInternalMeasure(CS_Measure.E_MeasureType.E_Time)

class MyBodyLoad(CS_UserBodyLoad):
    def __init__(self):
        CS_UserBodyLoad.__init__(self)
        self.value = 0.0

    def GetAccelerationVector(self,Mass,xyz,vel,bodyLoadForce):
        values = time.Values
        print 'MyBodyLoad::GetAccelerationVector'
        bodyLoadForce[0] = 0.0
        bodyLoadForce[1] = 0.0
        bodyLoadForce[2] = Mass*HalfAmplitude*math.sin(values[0]*3.14/(2.*HalfTime))

    def ComputeEnergy(self,Mass,xyz,vel):
        print 'MBodyLoad::ComputeEnergy'
        return 0.0

load=MyBodyLoad()
load.value = 10.0

Env=CS_Environment.GetDefault()

Env.BodyLoads.Add(load)
```

CMSBody

A CMSBody represents a condensed part in the Mechanical tree.

Constructors:

None.

Members:

`CondensedPartId (read only)`

The ID of the condensed part in the Mechanical tree.

`PartIds (read only)`

The vector of the IDs of the Mechanical parts that are used in the condensed part.

Member Functions:

None.

Derived Classes:

None.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Condition

Condition causes a load or a joint condition to be active only under defined circumstances. A condition is expressed in one of the following forms:

1. **`MeasureComponent`** operator **`threshold`**
2. **`LeftThreshold`** < **`MeasureComponent`** < **`RightThreshold`**
3. **`LeftCondition`** operator **`RightCondition`**

For case 1:

- **`MeasureComponent`** is a scalar Measure (p. 583).
- **`Operator`** is one of the following math operators:

  `E_GreaterThan`
  `E_LessThan`
  `E_DoubleEqual`
  `E_ExactlyEqual`

- **`Threshold`** is the threshold value.

Note:

A condition cannot be shared between various actuators. For example, if two joint conditions must be deactivated at the same time, two conditions must be created.

Example:

```
DispCond = CS_Condition(CS_Condition.E_ConditionType.E_GreaterThan,DispX,0.1)
```

For case 2:

- **`MeasureComponent`** is a scalar Measure (p. 583).
- **`LeftThreshold`** and **`RightThreshold`** are the bounds within which the condition will be true.

Example:

```
RangeCond = CS_Condition(DispX,0.0,0.1)
```

For case 3:

- **`LeftThreshold`** and **`RightThreshold`** are two conditions (case 1, 2 or 3).
- **`Operator`** is one of the following boolean operators:

  `E_Or`
  `E_And`

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Example:

```
BoolCond = CS_Condition(CS_Condition.E_ConditionType.E_Or, RangeCond, DispCond)
```

Contact

A Contact corresponds to a contact pair between two bodies.

Corresponding ID table: **`CS_Contact`**

Note:

If multiple contact objects have been defined between the same two bodies (with different surfaces), the solver merges them into one single pair. In that case, only one of the contact pairs exists and the call to **`CS_Contact.Find(_cid)`** will fail for all contact objects other than the one that was used to handle the pair of bodies.

Constants:

None

Members:

None

Member Functions:

`GetOutputContactForce()`

Retrieves a measure that contains the total contact force between the two linked bodies.

ContactDebugMask

The ContactDebugMask object allows you to activate and customize the output of contact points. It can also be used to modify the default behaviour of contact. ContactDebugMask uses a set of switches that can be toggled on or off.

ID table: **`CS_ContactDebugMask`**

Constants:

```
      E_DEBUG_Flag.E_None,
 (*)E_DEBUG_Flag.E_Point1: point on the side 1 (contact)
   E_DEBUG_Flag.E_Point2: point on the side 2 (target)
   E_DEBUG_Flag.E_Normal: contact normal
   E_DEBUG_Flag.E_Normal1: normal on side 1 (Reference)
   E_DEBUG_Flag.E_Normal2: normal on side 2 (Target)
   E_DEBUG_Flag.E_Violation: contact violation (rd.n = P1P2.n)
   E_DEBUG_Flag.E_MaterialVelocity: material normal velocity (V2-V1).n
(*)E_DEBUG_Flag.E_TotalVelocity: total normal velocity (material velocity + sliding velocity)
   E_DEBUG_Flag.E_EntityId1: geometric entity Id on side 1 (contact)
   E_DEBUG_Flag.E_EntityId2: geometric entity Id on side 2 (target)
   E_DEBUG_Flag.E_SurfaceId1: surface Id on side 1 (contact)
   E_DEBUG_Flag.E_SurfaceId2: surface Id on side 2 (target)
(*)E_DEBUG_Flag.E_EntityType: type of geometric entities (vertex/edge/surface)
(*)E_DEBUG_Flag.E_GeometricStatus: status of the contact position and velocity (touching,separated,.
   E_DEBUG_Flag.E_Accepted: points that are finally kept
   E_DEBUG_Flag.E_InconsistentPoint: points not consistent with rank analysis
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
    E_DEBUG_Flag.E_ReceivedPoint: all points send by the contact
    E_DEBUG_Flag.E_DeletedPoint: points deleted during Geometric Filtering
    E_DEBUG_Flag.E_TrackedPoint: points successfully tracked
    E_DEBUG_Flag.E_TrackedPointFailure: points that failed for tracking
    E_DEBUG_Flag.E_NormalAngle: angle between normal (in degrees)
    E_DEBUG_Flag.E_SlidingVelocity1: sliding velocity on side 1 (contact) in global coordinates
    E_DEBUG_Flag.E_SlidingVelocity2: sliding velocity on side 2 (target) in global coordinates
    E_DEBUG_Flag.E_FailSafeFilteringMode: adjust contact radius to accept at least one point
    E_DEBUG_Flag.E_CheckIntegration: check consistency of integration between solver and contact
    E_DEBUG_Flag.E_RankAnalysis: result from rank analysis
    E_DEBUG_Flag.E_Transition: result from edge transitions analysis
  (*)E_DEBUG_Flag.E_NewTimeStep: at beginning of time step
    E_DEBUG_Flag.E_BeforeCorrection: before external loop of correction
    E_DEBUG_Flag.E_BeforeCorrectionPlus: before geometric correction
    E_DEBUG_Flag.E_All
```

Members:

None

Member Functions:

`SetOn(E_DEBUG_Flag flag)`

Enable output of contact points information specified by flag.

`SetOff(E_DEBUG_Flag flag)`

Disable output of contact points information specified by flag.

Example:

```
CS_ContactDebugMask.SetOn(E_DEBUG_Flag.E_Accepted)
```

ContactOptions

The ContactOptions object allows you to customize the behaviour of a contact server. ContactOptions uses a set of numerical values (real or integer) that can be get or set. When used as a switch, 0 means off and 1 is on.

Constants:

None

Members:

TimeOut

Time in second (=30.0 by default)

Verbose

Enable verbose mode in contact.out file (=0, disabled by default)

NumberOfThreads

Number of parallel threads used for contact detection (=2 by default)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Member Functions:

None

Example:

```
cOpts=CS_ContactOptions()
cOpts.Verbose=1
```

Driver

A driver is a position, velocity or acceleration, or translational or rotational joint condition. Drivers derive from the Actuator class.

Corresponding ID table: **`CS_Actuator`**

Constants:

`E_Acceleration`, **`E_Position`**, **`E_Velocity`**

Members:

None

Member Functions:

`CS_Driver(CS_Joint joint, int[] components, E_MotionType driverMotionType)`

Creation of a joint driver, on joint **`joint`**, degree of freedom **`components`**, and with motion type **`driverMotionType`**. Note that the same driver can prescribe more than one joint motion at the same time. This is useful if you want to add the same condition to all components of a prescribed motion for example. Components must be ordered, are zero based, and refer to the actual free degrees of freedom of the joint.

Environment

This is the top level of the Rigid Dynamics model.

ID table: **`CS_Environment`**

Members:

System:

Corresponding system.

Example:

```
Env=CS_Environment.FindFirstNonNull()
Sys = Env.System
```

Ground:

Ground body.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Example:

```
Env = CS_Environment.FindFirstNonNull()
Ground = Env.Ground
```

Loads:

The vector of existing loads. This includes **Springs** that are considered by the solver as loads, as well as force and torque joint conditions.

Example:

```
Xdof = 0
Friction=CS_JointDOFLoad(PlanarJoint,Xdof)
Env.Loads.Add(Friction)
```

BodyLoads:

The vector of **Body Loads**.

Example:

```
MyBodyLoad = CS_BodyLoad()
…
Env.BodyLoads.Add(MyBodyLoad)
```

Relations:

The vector of external constraint equations.

Example:

```
rel3=CS_Relation()
rel3.MotionType=CS_Relation.E_MotionType.E_Velocity

var30=CS_ConstantVariable()
var30.SetConstantValues(System.Array[float]([0.]))

var31=CS_ConstantVariable()
var31.SetConstantValues(System.Array[float]([23.]))

var32=CS_ConstantVariable()
var32.SetConstantValues(System.Array[float]([37.]))

var33=CS_ConstantVariable()
var33.SetConstantValues(System.Array[float]([-60.+37.]))

rel3.SetVariable(var30)
rel3.AddTerm(jp,0,var31)
rel3.AddTerm(js3,0,var32)
rel3.AddTerm(jps,0,var33)

Env.Relations.Add(rel3)
```

Drivers:

The vector of **Displacements**, **Velocity** and **Acceleration** joint conditions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

InitialConditions:

The vector of **Displacements**, **Velocity**, and **Acceleration** joint conditions to be used only at **time**=**0**.

PotentialEnergy:

Gets the Potential Energy Measure.

KineticEnergy:

Gets the Kinetic Energy Measure.

TotalEnergy:

Gets the Total Energy Measure.

ActuatorEnergy:

Gets the Actuator Energy Measure.

RestartTime

Specifies the starting time in a restart analysis

Member Functions:

`FindFirstNonNull()`:

Returns the first environment in the global list. The table usually contains only one environment, thus it is a common way to access the current environment.

Example:

```
Env=CS_Environment.FindFirstNonNull()
```

`AlterSimulationEndTime(endTime)`

Overwrites the end time of the simulation.

`Solve()`

Solves the current analysis.

Derived Classes:

None

FlexibleBody

A Flexible Body is used by RBD for bodies that have flexible behavior, for instance a CMS-Body (p. 568).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Constructors:

None.

Members:

AlphaDamping

Uses a variable to define the amount of alpha Rayleigh damping (proportional to the mass matrix) to be considered for the flexible body. The variable can be either dependent or constant.

Example:

```
aFlexibleBody.AlphaDamping=100
```

Or equivalently:

```
var=CS_Variable()
var.SetConstantValues(System.Array[float]([100.]))
aFlexibleBody.AlphaDamping=var
```

BetaDamping

Uses a variable to define the amount of beta Rayleigh damping (proportional to the mass matrix) to be considered for the flexible body. The variable can be either dependent or constant.

Example:

```
Env=CS_Environment.GetDefault()
Sys=Env.System

array=System.Array.CreateInstance(float,4,2)
array[0,0]=0.0
array[0,1]=5.e-6
array[1,0]=0.05
array[1,1]=5.e-6
array[2,0]=0.051
array[2,1]=1.e-4
array[3,0]=0.1
array[3,1]=1.e-4

table=CS_PointsTable(array)

(err,found,time)=Sys.FindOrCreateInternalMeasure(CS_Measure.E_MeasureType.E_Time)

var=CS_Variable()
var.AddInputMeasure(time)
var.SetTable(table)

aFlexibleBody.BetaDamping = var
```

CMatrixScaleFactor

Define a factor to be used to multiply the default damping matrix. For instance, with a CMSBody (p. 568), this matrix can be created during the generation pass. When the damping matrix is generated for a Condensed Part (CMSBody (p. 568)), it will be automatically taken into account in the RBD use pass with a factor equal to 1.0.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Member Functions:

`SetModalDamping(iDof, variable)`

Define the amount of damping used for the degree of freedom specified by **`iDof`** (index starts at 0). The variable can be either dependent or constant.

`GetModalDamping(iDof)`

Retrieve the damping variable defined for the degree of freedom **`iDof`** (index starts at 0).

`SetLoadVectorScaleFactor(iLV, variable)`

Define a scale factor applied to the flexible body internal load specified by **`iLV`** (index starts at 0). By default, the first load vector uses a constant scale factor equal to 1.0.

`GetLoadVectorScaleFactor(iLV, variable)`

Retrieve the variable associated to the factor specified by **`iLV`** (index starts at 0).

Derived Classes:

`CS_CMSBody`

GILTable

A general multi-input interpolated table based on an unstructured cloud of points.

Corresponding ID table: **`CS_GILTable`**

Member Functions:

`CS_GILTable(sizeIn,sizeOut)`

Creates a GIL table with **`sizeIn`** inputs and **`sizeOut`** outputs

`CS_GILTable(sizeIn, sizeOut, filename, scale, separator, noHeader)`

Creates a GIL table from a text file; **`filename`** is the name of the file containing the points (typically a `.CSV` file). This file must be in ASCII format, with one data point per row. Each row must contain **`sizeIn`** + **`sizeOut`** columns. The columns must be separated by a character specified by the argument **`separator`**. The default value of **`separator`** is **`,`**. **`scale`** is an optional argument that scales all the output values. The default value, used if the optional argument is not specified, is 1.0. **`noHeader`** is a boolean, optional argument that should be **`true`** if there is no first row with labels.

Example file:

```
Velocity, Deflection, Force
0.,0.,10.0
100.,0.,200.0
...
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

AddInterpolationPoint(values)

Adds an interpolation point to the General Interpolation Table. **values** is a one dimensional array of size **sizeIn**+**sizeOut**. The first **sizeIn** values in array **values** corresponds to the values of the input variables. The following **sizeOut** values in array **values** correspond to the output values.

Example 1: Creation of a Nonlinear Stiffness Value That Depends on Spin Velocity (Omega) and on Deflection (dY)

```
VarForceY = CS_Variable();
#
# Variable 0: spin
VarForceY.AddInputMeasure(SpinMeasure )
#
# Variable 1: Y displacement
VarForceY.AddInputMeasure( TransY )
#
# Create table with 2 input and 1 output
EvalY = CS_GILTable(2,1)

Omega = -1.0
dY = -1e-4
stiff = -9.0

values=System.Array.CreateInstance(float,3)

values[0] = Omega
values[1] = dY
values[2] = stiff
EvalY.AddInterpolationPoint( values )

Omega = 11.0
dY = -1e-4
stiff = -21.0
values[0] = Omega
values[1] = dY
values[2] = stiff
EvalY.AddInterpolationPoint( values )
…
```

AddInterpolationPointArray(values)

Adds a set of points to the General Interpolation Table. **values** is a two dimensional array of size (**numberOfPoints**, **sizeIn**+**sizeOut**). On each row of the array, first **sizeIn** values in array **values** corresponds to the values of the input variables. The following **sizeOut** values in array **values** correspond to the output values. Each row contains a single interpolation point in the cloud of points.

Example 2: Creation of a Nonlinear Force Value (F) That Depends on Deflection (dX)

```
ForceVariable = CS_Variable()
ForceVariable.AddInputMeasure( TransX )
Evaluator = CS_GILTable( 1,1 )
values = System.Array.CreateInstance( float, 6, 2 )
dX = 0.0
F = 0.0
values[0,0] = dX
values[0,1] = F

dX = 10.0
F = 1.0
values[1,0] = dX
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
values[1,1] = F

F = 2.0
values[2,0] = dX
values[2,1] = F

dX = 60.0
F = 3.0
values[3,0] = dX
values[3,1] = F

dX = 90.0
F = 4.0
values[4,0] = dX
values[4,1] = F

dX = 130.0
F = 5.0
values[5,0] = dX
values[5,1] = F
Evaluator.AddInterpolationPointArray( values )
```

`SetVerbosity(bVerbose)`

If **`bVerbose`** is set to true, the GILTable will print the output value every time it is evaluated. This can be used for debugging purposes, but it will affect the performance if used on a table in a long simulation.

Limitations:

These tables can only be used to apply forces and moments, not for other joint conditions or remote displacements.

Joint

ID table: **`CS_Joint`**

Constants: For the joint type (**`E_JointType`**):

`E_2DSlotJoint`, **`E_BushingJoint`**, **`E_CylindricalJoint`**, **`E_GeneralJoint`**, **`E_FixedJoint`**, **`E_FreeJoint`**, **`E_PlanarJoint`**, **`E_PointOnCurveJoint`**, **`E_RevoluteJoint`**, **`E_ScrewJoint`**, **`E_SingleRotationGeneralJoint`**, **`E_SlotJoint`**, **`E_SphericalJoint`**, **`E_TranslationalJoint`**, **`E_TwoRotationGeneralJoint`**, **`E_UniversalJoint`**,

Members:

`Name`

Name of the joint

`ReferenceCoordinateSystem`

Joint reference coordinate system

Example:

```
J1 = CS_Joint.Find(_jid)
CSR = J1.ReferenceCoordinateSystem
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

MovingCoordinateSystem

Joint moving coordinate system

Example:

```
J1 = CS_Joint.Find(_jid)
CSM = J1. MovingCoordinateSystem
```

Type

Joint type

IsRevert

The internal representation of the joint can use flipped reference and mobile coordinate systems. In that case, all the joint results (for example, forces, moments, rotation, velocities and acceleration) must be multiplied by -1 to go from their internal representation to the user representation. As transient values of joint measures are giving the internal representation, use this **IsRevert** information to know if results should be negated.

AccelerationFromVelocitiesDerivatives

When extracting joint degrees of freedom on joints that return true, accelerations should be done using the time derivatives of the joint velocity measure. On joints that return false, joint DOF derivatives should be extracted using the joint acceleration measure. It is important to check this flag first. Use of the wrong method to query joint acceleration can result in failure or incorrect results.

Example:

```
if Universal.AccelerationFromVelocitiesDerivatives:
 UniversalAccelerationValues=UniversalVelocityM.FillDerivativesThroughTime()
else:
 UniversalAcceleration = Universal.GetAcceleration()
 UniversalAccelerationValues=UniversalAcceleration.FillValuesThroughTime()
```

Stops

Returns the list of the stops defined on the joint.

Member Functions:

GetVelocity()

Returns the joint velocity measure. The size of this measure is the number of degrees of freedom of the joint. The derivatives of this measure give access to the joint accelerations.

GetRotation()

Returns the joint rotation measure. The type of measure depends on the joint number of rotational degrees of freedom (**E_1DRotationMeasure**, **E_3DRotationMeasure**, **E_UniversalAngles**). These rotations components are relative to the reference coordinate system of the joint.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

GetTranslation()

Returns the joint translation measure. The length of this measure is the number of translational degrees of freedom of the joint. The translation components are expressed in the reference coordinate system of the joint.

GetForce()

Returns the joint force measure. The length of this measure is always 6 (3 forces components, 3 torque component). This force measure is the total force/moment, including constraint forces/moment, external forces/moment applied to the joint, and joint internal forces/moment, such as elastic moment in a revolute joint that has a stiffness on the Z rotation axis. The force measure components are expressed in the global coordinate system. Note that the sign convention is different from the sign convention used in the Joint Probes in Mechanical.

GetAcceleration()

Returns the joint acceleration measures on the joints that are constraint equations based. See the **AccelerationFromVelocitiesDerivatives** member to see when this function should be used.

Example:

```
J1 = CS_Joint.Find(_jid)
jointRotation = J1.GetRotation()
jointVelocity = J1.GetVelocity()
jointAcceleration = J1.GetAcceleration()
jointForce = J1.GetForce()
```

SetFrictionVariable(var)

Replaces the constant value already given to the friction coefficient with the expression given by **var**.

Example:

```
Joint = CS_Joint.Find(_jid)
Var = CS_Variable()
u0 = 0.1
u1 = 0.2
alpha = 0.5
Var.SetFunc('u0+u1exp(-alpha*time)',0)
Var.AddInputMeasure(Joint.GetVelocity())
Joint.SetFrictionVariable(Var)
```

The command has no effect if no value for the friction coefficient has been provided in the UI. For more information, see Joint Friction (p. 1335)

SetFrictionTolerance(tol)

Sets the friction tolerance.

Example:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

```
Joint = CS_Joint.Find(_jid)
Joint = Joint.SetFrictionTolerance(1e-4)
```

Derived Classes:

On **SphericalJoint, SlotJoint, BushingJoint, FreeJoint, General-Joint**.

Member Function

AddStop(angle_max, restitution_factor)

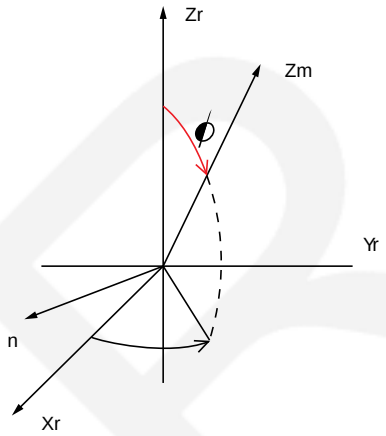
Adds a spherical stop to a joint that has three rotations. A spherical stop constrains the motion of the X and Y rotational degrees of freedom, to give to the joint the behavior of a loose revolute joint, with a rotational gap. This will allow easier handling of over-constrained systems and building higher fidelity models without having to use contact.

angle_max

The angle between the reference coordinate system **Zr** axis and the moving coordinate system **Zm**. **Zr** is the natural **revolute** axis.

restitution_factor

The restitution factor, similar to other joint stops (p. 1360).



On CylindricalJoint:

ReplaceByScrew(pitch)

Creates a relation between the translational and the rotational degrees of freedom of a cylindrical joint.

Note:

- The pitch is in the current length unit. Any stop and/or lock defined on the original cylindrical joint is not transferred to the screw joint.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Similarly, any constraint equation defined on the original cylindrical joint is not converted and so will prevent a proper solution.

- The ReplaceByScrew command is deprecated. It is replaced by the Screw Joint (p. 1307) provided in the Mechanical UI.

On Bushing Joint:

`GetBushingAngles()`

Returns the measure of the joint angles. This measure is used to compute the forces and torques developed in the joint. Note that this is only available for post-processing operations, as the measure does not exist before the solve has been performed.

Creating New Joints:

The following joint can be created by commands:

```
CS_GeneralJoint(from, to, FreeX, FreeY, FreeZ, FreeRX,
FreeRY, FreeRZ)
```

Where **`from`** and **`to`** are of type **`CS_BodyCoordinateSystem`** and **`Free*`** are integers where 0 is no available motion and nonzero is available motion. Selecting two free rotations is not allowed.

JointDOFLoad

JointDOFLoads are loads applied on a given degree of freedom of a joint. The load is applied in the joint reference coordinate system.

JointDOFLoad derives from Load (p. 583).

Constructor:

`CS_JointDOFLoad(joint,dof)`

`joint`

A joint object

`dof`

An integer that defines the joint degree of freedom to be included in the term. The ordering of the degrees of freedom sets the translation degrees of freedom first. The degrees of freedom numbering is zero based. For example, in a slot joint, the translational degree of freedom is 0, while the third rotational degree of freedom is 3.

Measure:

Most useful measures are pre-existing in the Rigid Dynamics model, and can be accessed using other object "get" functions. Additional measures can be created before solving for use in custom post-processing or as input values for joint conditions. For example, measures can be created to express conditions. In this case, the measure must be added to the system to be computed at each time step (see component measure example below).

ID table: **CS_Measure**

Constants: For the measure type (**E_MeasureType**):

E_1DRotationJoint, **E_3DRotationBody**, **E_3DRotationJoint**, **E_Acceleration**, **E_ActuatorStatus**, **E_ActuatorEnergy**, **E_AnsysJointForceAndTorque**, **E_AXPY**, **E_BodyAcceleration**, **E_BodyIntertialBCSQuaternion**, **E_BodyRotation**, **E_BodyTranslation**, **E_CenterOfGravity**, **E_Component**, **E_Constant**, **E_Contact**, **E_ContactForce**, **E_ContactVelocity**, **E_Counter**, **E_Displacement**, **E_Distance**, **E_DistanceDot**, **E_Divides**, **E_EigenValue**, **E_DOFSensitivity**, **E_Dot**, **E_ElasticEnergy**, **E_Energy**, **E_EulerAngles**, **E_ForceMagnitude**, **E_Forces**, **E_IntegratedOmega**, **E_JointAcceleration**, **E_JointDOFFrictionCone**, **E_JointDriverForce**, **E_JointForce**, **E_JointMBDVelocity**, **E_JointNormalForce**, **E_JointTranslation**, **E_JointRotation**, **E_JointVelocity**, **E_KineticEnergy**, **E_MassMomentsOfInertia**, **E_MeasureDotInDirectionOfLoad**, **E_Minus**, **E_Modulus**, **E_Multiplies**, **E_Norm**, **E_Omega**, **E_OmegaDot**, **E_OutputContactForce**, **E_Plus**, **E_PointOnCurveGeometryMeasure**, **E_PointOnCurveJointSigmaMeasure**, **E_PointToPointRotation**, **E_PointToPointRotationDot**, **E_Position**, **E_PotentialEnergy**, **E_RadialGap**, **E_ReferenceEnergy**, **E_RelativeAcceleration**, **E_RelativePosition**, **E_RelativeVelocity**, **E_RotationalRelativeDOF**, **E_RotationMatrix**, **E_SphericalStop**, **E_StopVelocity**, **E_StopStatus**, **E_Time**, **E_TimeStep**, **E_TranslationalJoint**, **E_UniversalAngles**, **E_UnknownType**, **E_User**, **E_Velocity**, **E_Violation**, **E_XYZAnsysRotationAngles**, **E_ZYXRotationAngles**,

```

Type:

Measure type

Calculation Method:

A measure can use direct calculation or be time integrated. On a measure that uses direct calculation, it is possible to retrieve the measure value through time. On a measure that is time-integrated, both values and time derivatives can be retrieved.

Name:

Measure Name

Member Functions:

`FillValuesThroughTime()`

Returns a two dimensional array. This function is to be called after the solution has been performed. The first dimension of the returned array is the number of time values in the transient. The second dimension is the size of the measure plus one. The first column contains the time values, while the subsequent columns contain the corresponding measure values.

Example:

```
jointRotation = J1.GetRotation()
jointVelocity = J1.GetVelocity()
jointAcceleration = J1.GetAcceleration()
jointForce = J1.GetForce()

jointRotationValues =jointRotation.FillValuesThroughTime()
jointVelocityValues =jointVelocity.FillValuesThroughTime()
jointAccelerationValues =jointAcceleration.FillValuesThroughTime()
jointForceValues =jointForce.FillValuesThroughTime()

nbValues = jointRotationValues.GetLength(0)

print jointRotation.Id

print '  Time     Rotation Velocity Acceleration'
for i in range(0,nbValues):
    print jointRotationValues[i,0],jointRotationValues[i,1],jointVelocityValues[i,1],jointAccelerat

fich.close()
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

`FillDerivativesThroughTime()`

Returns a two dimensional array. This function is to be called after the solution has been performed. The first dimension of the returned array is the number of time values in the transient. The second dimension is the size of the measure plus one: the first column contains the time values, while the subsequent columns contain the corresponding measure derivatives. These derivatives are available on measures that are time integrated. To know if a measure is time integrated, use the **`CalculationMethod`** member.

Derived Classes:

`CS_JointVelocityMeasure`

Both translational and rotational joint velocities are expressed in the joint reference coordinate system. The number of components is the number of translational degrees of freedom plus the number of rotational degrees of freedom. For example, the size of the joint velocity measure for a revolute joint is 1. It contains the relative joint rotation velocity along the z axis of the joint reference coordinate system. The size of the measure for a slot joint is 4: one component for the relative translational velocity, and the 3 components of the relative rotational velocity. The joint velocity measure can be obtained from the joint using the **`GetVelocity`** function. Rotational velocities are expressed in radians/second.

`CS_JointAccelerationMeasure`

Both translational and rotational joint accelerations are expressed in the joint reference coordinate system. The number of components is the number of translational degrees of freedom plus the number of rotational degrees of freedom. The joint acceleration measure can be obtained from the joint using the **`GetAcceleration`** function.

`CS_JointRotationMeasure`

- For revolute joints, cylindrical joints, or single rotation general joints, this measure has only one component: the relative angle between the reference and the moving coordinate system of the joint. Rotations are expressed in radians.
- For slots, spherical joints, bushing joints, and 3 rotation vectors, this measure contains values that are not directly usable.
- For universal joints, this measure contains the two joint axis rotational velocities. (The first one along the X axis of the reference coordinate system and the second along the Z axis of the moving coordinate system.) These angles are expressed in radians.

`CS_JointTranslationMeasure`

This measure contains only the joint relative translations, expressed in the joint reference coordinate system. The joint translation measure can be obtained from the joint using the **`GetTranslation`**function.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

CS_JointForceMeasure

This measure contains the total forces and moment that develop in the joint. This includes constraint forces, elastic forces, and external forces. The joint velocity measure can be obtained from the joint using the **GetForce**function.

CS_PositionMeasure

This measure allows for tracking of the position of a Body Coordinate System over time.

Example:

```
CoMBCS = OneBody.InertiaBodyCoordinateSystem
Pos = CS_PositionMeasure(CoMBCS)
Env=CS_Environment.FindFirstNonNull()
Sys = Env.System
Sys.AddMeasure(Pos)
```

CS_ComponentMeasure

This measure allows the extraction of one component of an existing measure. This component can be expressed in a non default coordinate system. A component of -2 will compute the norm 2 of the vector of values of the measure.

Example:

```
Planar = CS_Joint.Find(_jid)
Vel = Planar.GetVelocity()
Xglobaldirection = 0
VelX = CS_ComponentMeasure(Vel,Xglobaldirection)
Sys.AddMeasure(VelX)
```

CS_AXPYMeasure

This measure allows a linear transformation from another measure with a scaling factor and an offset. This can be useful to transform an internal rotation measure that is expressed in radians to a measure in degrees used as an input to a load calculation, for example.

Example:

```
Revolute = CS_Joint.Find(_jid)
Rot = Revolute.GetRotation()
RotInDegrees = CS_AXPYMeasure( Rot, 180.0/math.pi, 0. )
Sys.AddMeasure(RotInDegrees)
```

CS_ModulusMeasure

This measure allows you to compute the floating point remainder of value/modulus.

Example:

```
Revolute = CS_Joint.Find(_jid)
Rot = Revolute.GetRotation()
Rot02pi = CS_ModulusMeasure( Rot, 2.0*math.pi )
Sys.AddMeasure(Rot02pi)
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

`CS_OutputContactForceMeasure`

This measure contains four 3D vectors:

- Values 0 to 2 are the total contact force components between the two bodies, including the normal and tangential contributions.
- Values 3 to 5 are the coordinates of the point where the interaction between the two bodies is reduced to a force; in other words, the total torque is zero.
- Values 6 to 8 are the frictional force between the two bodies.
- Values 9 to 11 are frictional moment components at the reduction point.

MSolverDB

Solver database. The database is both the input and the results file to the solver. It can be used to solve outside the Mechanical session (for example, for co-simulation purposes) or to restart from a previous run.

Members:

`SetFileName(FileName)`

Set the database file name.

`SetDirectoryName(DirectoryName)`

Set the database directory.

`ReadDatabase()`

Read the content of the database.

`WriteDatabase()`

Write the current database to a file.

`DeleteDatabase()`

Delete the database.

`CloseDatabase()`

Close the database file.

`OpenDatabase()`

Open the database file and reads the database content table.

`Dispose()`

Clear the content of the database and free memory used by the database.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

PointsTable

Corresponding ID table: **`CS_PointsTable`**

Members Functions:

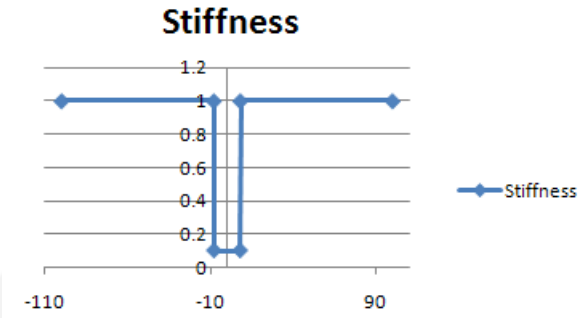
`CS_PointsTable( tab )`

`tab` is a two dimensional array where the first column contains the input values and the second column contains the corresponding output values.

Example:

```
tab = System.Array.CreateInstance(float,6,2)
tab[0,0]=-100.
tab[1,0]=-8.
tab[2,0]=-7.9
tab[3,0]= 7.9
tab[4,0]= 8.
tab[5,0]= 100.

tab[0,1]=1.0
tab[1,1]=1.0
tab[2,1]=0.1
tab[3,1]=0.1
tab[4,1]=1.0
tab[5,1]=1.0
Table = CS_PointsTable(tab);
```



Here, the output (shown as Stiffness in the chart above) varies in a linear, piece-wise manner. For values of input less than -8.0 or greater than 8.0, the output is equal to 1.0. For values between -7.9 and +7.9, the output is 0.1. The transition is linear between -8.0 and -7.9, and as well between +7.9 and +8.0.

PolynomialTable

Corresponding ID: **CS_PolynomialTable**

Create a polynomial relation between **`sizeIn`** inputs and **`sizeOut`** outputs using the following function:

$$y_j = c_j^0 + \sum_k c_j^k x_1^{\alpha_1^k} \cdots x_i^{\alpha_i^k} \cdots x_{sizeIn}^{\alpha_{sizeIn}^k}$$

Where i denotes the index of input and goes from 1 to n (**`sizeIn`**), j denotes the index of output (from 1 to **`sizeOut`**).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Member Functions:

`CS_PolynomialTable()`

Creates an empty polynomial table.

`Initialize(constant)`

Specialized for 1x1 table. Initializes the table to be a 1 input, 1 output table, and sets the constant term (constant is a float value).

`Initialize(sizeIn,sizeOut,constantValues)`

(generic version) Initializes the table with **`sizeIn`** inputs and **`sizeOut`** outputs and sets the constant terms. **`sizeIn`** and **`sizeOut`** are two integer values, and **`constantValues`** is an array of **`sizeOut`** float values.

`AddTerm(coefficient,order)`

Specialized for 1x1 table. Adds one monomial term to the table. The coefficient is a float value and order is an integer value giving the power of the input.

`AddTerm(coefficients,orders)`

(generic version) Adds one monomial term to the table. The coefficients are given by a **`sizeOut`** float array and the power for each input by an array of **`sizeIn`** integers.

Relation

The relation object enables you to write constraint equations between degrees of freedom of the model. For example, two independent lines of shaft can be coupled using a relation between their rotational velocities.

If you have a gear coupling between two shafts where the second shaft rotates twice as fast as the first one, you can write the following equation:

$2.0 \times \Omega 1 + \Omega 2 = 0$

where $\Omega 1$ and $\Omega 2$ are joint rotational velocities.

This relation contains two terms and a constant right hand side equal to zero.

The first term ($2 \times \Omega 1$) can be described using the following information:

- A joint selection
- A joint degree of freedom selection
- The nature of motion that is used in the equation (joint velocities, which is the most common case). For convenience, the nature of motion upon which the constraint equation is formulated is considered as being shared by all the terms in the relation.

This information defines $\Omega 1$

- The factor 2.0 in the equation can be described by a constant variable, whose value is 2.0

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

ID table: **CS_Actuator**

The coefficients of the relation can be constant or variable; however, the use of non-constant coefficients is limited to relations between velocities and relations between accelerations. If non-constant coefficients are used for relations between positions, the solution will not proceed.

Constants:

E_Acceleration, **E_Position**, **E_Velocity**

Members:

None

Member Functions:

SetRelationType(type)

Type of relation, with type selected in the previous enumeration.

AddTerm(joint, dof, variable)

Adds a term to the equation.

joint

A joint object

dof

An integer that defines the joint degree of freedom to be included in the term. The ordering of the degrees of freedom sets the translation degrees of freedom first, and that the degrees of freedom numbering is zero based. For example the translational degrees of freedom in a slot joint is **0**, while the third rotational degree of freedom is **3**.

variable

A variable object

SetVariable(variable)

Sets the right hand side of the relation. "variable" is a variable object.

SolverOptions

The SolverOptions object allows you to customize the behaviour of the RBD solver. The option uses a group of numerical values (real or integer) that can be get or set. When used as a switch, 0 means off and 1 is on.

Corresponding ID table: **CS_SolverOptions**

Constants:

None

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Member Functions:

`VelocityToleranceFactor`

Multiplicative factor used to determine zero velocity tolerance (=100.0 by default);

`ContactRadiusFactor`

Contact radius factor used in contact failsafe mode (=2.0 by default);

`MaximumNumberOfCorrectionAttempts`

Number of external loops for geometric correction (=2 by default));

`FrictionForShock`

Enable friction for shock solve (=0, disabled by default);

`MaximumNumberOfDiagnostics`

Number of diagnostics messages given in Mechanical UI (=10 by default);

`InactiveTouchingInDynamics`

Prevent inactive contact pair from being violated (=1, enabled by default);

`DisablePolygonEvent`

Disable polygon event for contact (=0, active by default);

`PrintDynamicSystem`

Print the dynamics system (=0 by default);

`PurgeGST`

Purge GST file every n steps (=0, never by default);

`PrintErrorEstimation`

Force output of error estimation (=0, disabled by default);

`ExportXLSFileForCMS`

Export generalized coordinates for CMS bodies in a CSV file (=0, disabled by default)

`HandlePOCTransitionsWithEnergyMinimization`

When point on curve joints are used, different solutions (depending on the topology) may be found when crossing curve connections. Furthermore, these solutions do not guarantee the conservation of the kinetic energy at the transition. To remedy this issue, this option makes the transitions using a method that minimizes the kinetic energy in a way similar to the assembly process using the inertia matrix (p. 644). This solution works well for explicit time integration schemes, but it is not guaranteed for implicit ones. (=0, disabled by default)

```
sOpts=CS_SolverOptions()
sOpts.ExportXLSFileForCMS=1
```

Spring

Corresponding ID table: **`CS_Actuator`**

Members:

None

Member Functions:

`ToggleCompressionOnly()`

Calling this function on a translational spring will make the spring develop elastic forces only if its length is less than the spring free length. The free length has to be defined in the regular spring properties.

`ToggleTensionOnly()`

Calling this function on a translational spring will make the spring develop elastic forces only if its length is greater than the free length of spring. The free length has to be defined in the regular spring properties.

`SetLinearSpringProperties(system, stiffness, freeLength)`

Enables you to overwrite the stiffness and free length of a translational spring. This can be useful to parameterize these properties. For example, system is the system object, stiffness and free length are the double precision values of stiffness and free length.

`SetNonLinearSpringProperties(table_id)`

Enables you to replace the constant stiffness of a spring with a table of ID **`table_id`** that gives the force as a function of the elongation of the spring. The table gives the relation between the force and the relative position of the two ends.

`GetDamper()`

The user interface has stiffness and damping properties of the spring. Internally, the **Spring** is made of two objects; a spring and a damper. This function enables you to access the internal damper using the **Spring** object in the GUI.

Derived Classes:

None

System

Members:

`Bodies`

Gets the list of bodies.

`Joints`

Gets the list of joints.

Member Functions:

`AddBody(body)`

Adds a body to the system.

`AddJoint(joint)`

Adds a joint to the system.

`PrintTopology()`

Prints the topology of the systems (parent/child relation).

`AddMeasure(measure)`

Adds a measure to the system, to be calculated during the simulation. This function must be called prior to solving so that the measure values through time can be retrieved.

`(istat,found,measure)=FindOrCreateInternalMeasure( MeasureType)`

Extracts an existing global measure on the system. Supported measure types are: E_Energy, E_PotentialEnergy, E_ElasticEnergy, E_KineticEnergy, and E_Time.

Derived Classes:

None

Table

A table is the base class for Points Tables, Polynomial Tables, User Tables, and GIL Tables.

ID table: **`CS_Table`**

Members:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Member Functions:

`Evaluate(In, Out)`

Allows evaluating a table in Python. In and Out are arrays of float, with sizes corresponding to the table input and output sizes. This function can be called from a user table for example.

`Dispose()`

Explicit destruction of the table. This explicit destructor should be used only when the table hasn't been assigned to an actuator. When the table is assigned to an actuator, the actuator is calling this destructor. Omitting to call this destructor can cause the evaluation of the results to fail.

UserTable

A user table is a function with *i* input values and *o* output values, with an evaluator that is defined in IronPython, allowing complex variation, or even evaluation performed outside the solver.

Example:

```
LeftVarCoefX = CS_Variable();

# input 0,1,2 of the variable
LeftVarCoefX.AddInputMeasure( LeftRelTrans )

# input 3 to 8 of the variable
LeftVarCoefX.AddInputMeasure( LeftRelVelo )

class XForceTable(CS_UserTable):
    def __init__(self,sizeIn,sizeOut):
        CS_UserTable.__init__(self,sizeIn,sizeOut)

    def Evaluate(self,In,Out):
        TX = In[0]
        VX = In[3]

        Force = 1000.0*TX
        Out[0] = Force
        print 'ForceX = {0:e}'.format(Out[0])
        return 0

LeftForceTableX = XForceTable( 9, 1 )
LeftVarCoefX.SetTable( LeftForceTableX )
```

Variable

A variable is an n-dimensional vector quantity that varies over time. It is used to define the variation of a load or a joint condition, or to express the coefficients in a relation between degrees of freedom. For convenience, the solver allows the creation of constant variables, where only the value of the constant has to be provided. More complex variables can be built using a function variable. A function variable is a function of input, where input is given by a measure (p. 583) and function is described by a table. In some cases, you are able to replace the table or the measure of an internal variable as used in a joint condition.

ID table: **`CS_Variable`**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Members:

None

Member Functions:

`SetConstantValues(value)`

`value` is an array, whose size is equal to the size of the table. To create a constant scalar variable, the value can be defined as shown in the following example:

```
value = System.Array[float]([1.0])
```

`System`, **`Array`**, and **`float`** are part of the **Python** language. The result of this is an array of size one, containing the value 1.0.

`AddInputMeasure(measure)`

`measure` is a measure object. The same variable can have more than one measure. The input variable of the variable is formed by the values of the input measure in the order that they have been added to the list of input measures.

`SetTable(table)`

`table` is a CS_PointsTable.

`SetFunc(string, is_degree)`

`string` is similar to the expression used in the user interface to define a joint condition by a function. Note that the literal variable is always called "time", even if you are using another measure as input. "is_degree" is a boolean argument. If the expression uses a trigonometric function, it specifies that the input variable should be expressed in degrees.

Note:

Variables cannot be shared by different actuators.

Derived Classes:

ConstantVariable

Command Use Examples

The following command use examples are included in this section:

Constraint Equation

Joint Condition: Initial Velocity

Joint Condition: Control Using Linear Feedback

Non-Linear Spring Damper

Spherical Stop

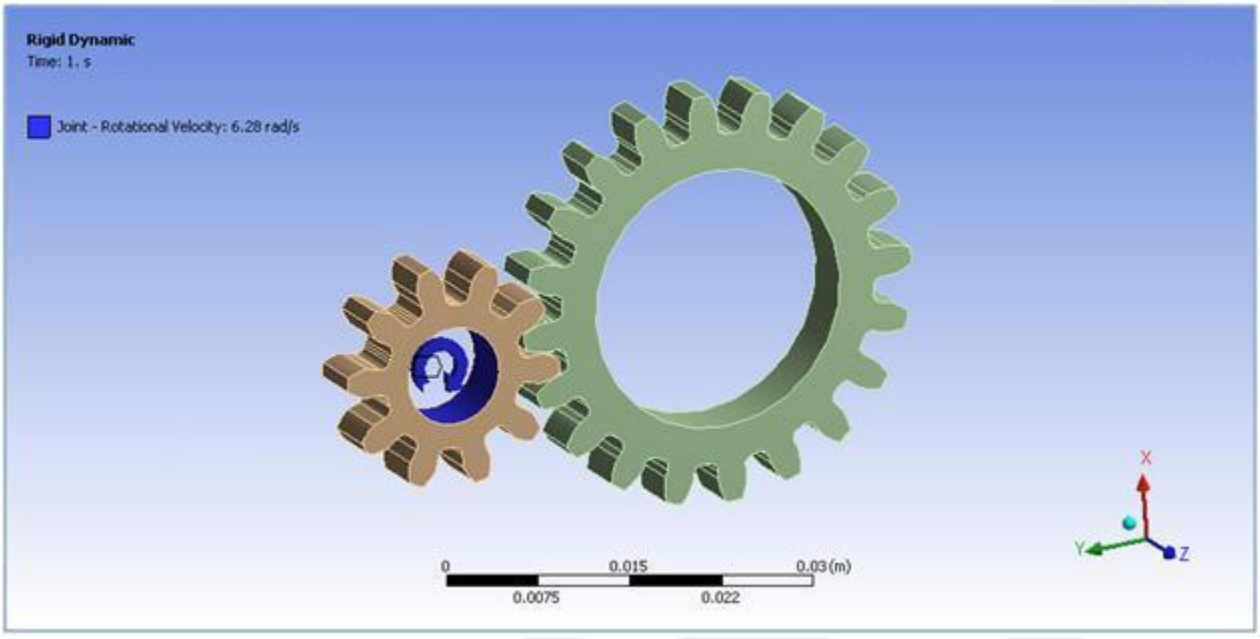
Export of Joint Forces

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Breakable Joint

Constraint Equation

This example considers the gear mechanism shown below.



A relation is created between two revolute joints to simulate a gear with a ratio 2 M. Commands are used to enforce the ratio of velocities between the two wheels, and create a linear relation between rotational velocities, defined by:

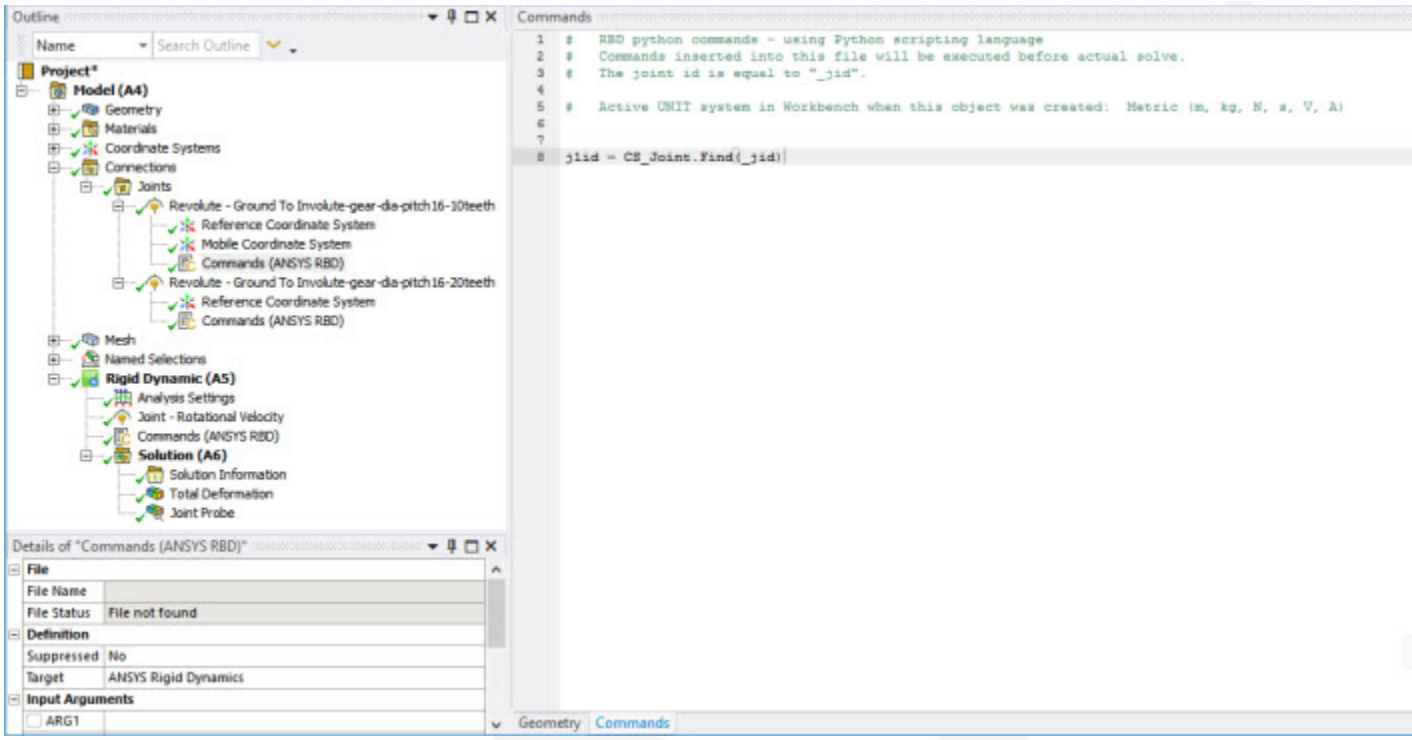
$(1)*\omega_1 + (-2)*\omega_2 = 0$

First, the joint objects are retrieved using their IDs:

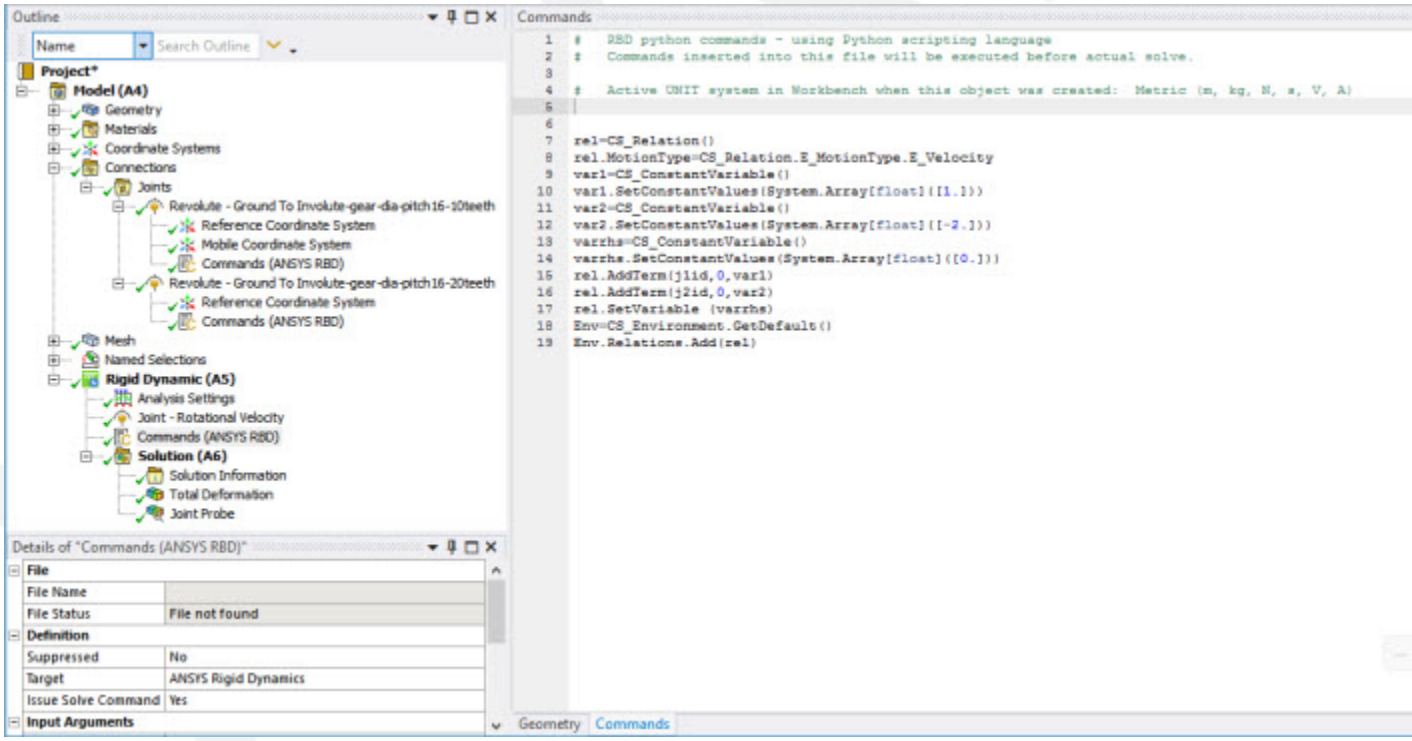
```
j1id = CS_Joint.Find(_jid)
j2id = CS_Joint.Find(_jid)
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Next, the relationship between the two wheels is defined. The complete list of commands is shown below. A description of these commands follows.



1. A relation object is created and specified as a relation between velocities:

```
rel=CS_Relation()
rel.MotionType=CS_Relation.E_MotionType.E_Velocity
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

2. The constant coefficients that appear in the relation are created. The first constant term is created by:

```
var1=CS_ConstantVariable()
var1.SetConstantValues(System.Array[float]([1.]))
```

3. The second coefficient and constant right hand side are created by:

```
var2=CS_ConstantVariable()
var2.SetConstantValues(System.Array[float]([-2.]))
varrhs=CS_ConstantVariable()
varrhs.SetConstantValues(System.Array[float]([0.]))
```

4. The first term of relation (1) X ω_1 is added to the relation object:

```
rel.AddTerm(j1id,0,var1)
```

   The first argument is the joint object. The second argument defines the DOF (degrees of freedom) of the joint that are involved in the relation. Here, **0** represents the rotation, which is the joint's first and only DOF is the rotation.

5. The second term and right hand side are introduced in the same manner:

```
rel.AddTerm(j2id,0,var2)
rel.SetVariable (varrhs)
```

6. The relation is added to the list of relations:

```
Env=CS_Environment.GetDefault()
Env.Relations.Add(rel)
```

Joint Condition: Initial Velocity

This example shows how to impose an initial velocity to a joint. A velocity driver (joint condition) is created using commands and added to the list of initial conditions. During the transient solve, initial conditions are applied only at t=0.

The complete list of commands and their explanation follows.

```
Joint=CS_Joint.Find(_jid)
driver=CS_Driver(Joint,System.Array[int]([0]),CS_Driver.E_MotionType.E_Velocity)
Env=CS_Environment.GetDefault()
Sys=Env.System
(ret,found,time) = Sys.FindOrCreateInternalMeasure(CS_Measure.E_MeasureType.E_Time)
driver.SetInputMeasure(time)
driver.SetConstantValues(System.Array[float]([-4.9033]))
Env.InitialConditions.Add(driver)
```

1. The joint is retrieved using its ID(_jid):

```
Joint=CS_Joint.Find(_jid)
```

2. A velocity driver (imposed velocity) is created on this joint:

```
driver=CS_Driver(Joint,System.Array[int]([0]),CS_Driver.E_MotionType.E_Velocity)
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The driver constructor takes the joint instance as the first argument. The second argument is an array of integer that defines which DOFs are active. The physical meaning of these integers is dependent of the joint. For instance, if the underlying joint is a translation joint, **0** is the translation along x. But if the joint is revolute, **0** now is the rotation along z axis. Similarly, for a cylindrical joint, **0** is is the translation along z, and **1** is the rotation. The last argument gives the type of driver here velocity. Drivers can be one of three types: position, velocity, or acceleration:

3. The default environment and corresponding system are retrieved

```
Env=CS_Environment.GetDefault()
Sys=Env.System
```

4. This command returns an instance on an internal measure. It is often used to obtain the instance of the time measure:

```
(ret,found,time) = Sys.FindOrCreateInternalMeasure(CS_Measure.E_MeasureType.E_Time)
```

5. The time measure is specified as the input measure for the driver and a constant value is given to the driver. As the driver may be applied to several components of the joint, the values are given as an array of float:

```
driver.SetInputMeasure(time)
driver.SetConstantValues(System.Array[float]([-4.9033]))
```

6. The driver is added to the list of initial conditions. Consequently, it will be active only at t=0 and will give an initial velocity to the joint:

```
Env.InitialConditions.Add(driver)
```

Joint Condition: Control Using Linear Feedback

In this example, an existing load is modified to apply a torque proportional to the joint velocity. Two Methods are discussed:

Method 1

Obtain the velocity measure from the joint:

```
joint = CS_Joint.Find(_jid)
vel=joint.GetVelocity()
```

Next, modify an existing moment in order to use the velocity measure as its input measure:

```
Env=CS_Environment.FindFirstNonNull()

ids=Env.DSToInternalIds[_jcid]

load=CS_Actuator.Find(ids[0])
load.SetInputMeasure(vel)
```

Method 2

Using this method, the load is created entirely using commands. These commands are shown below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

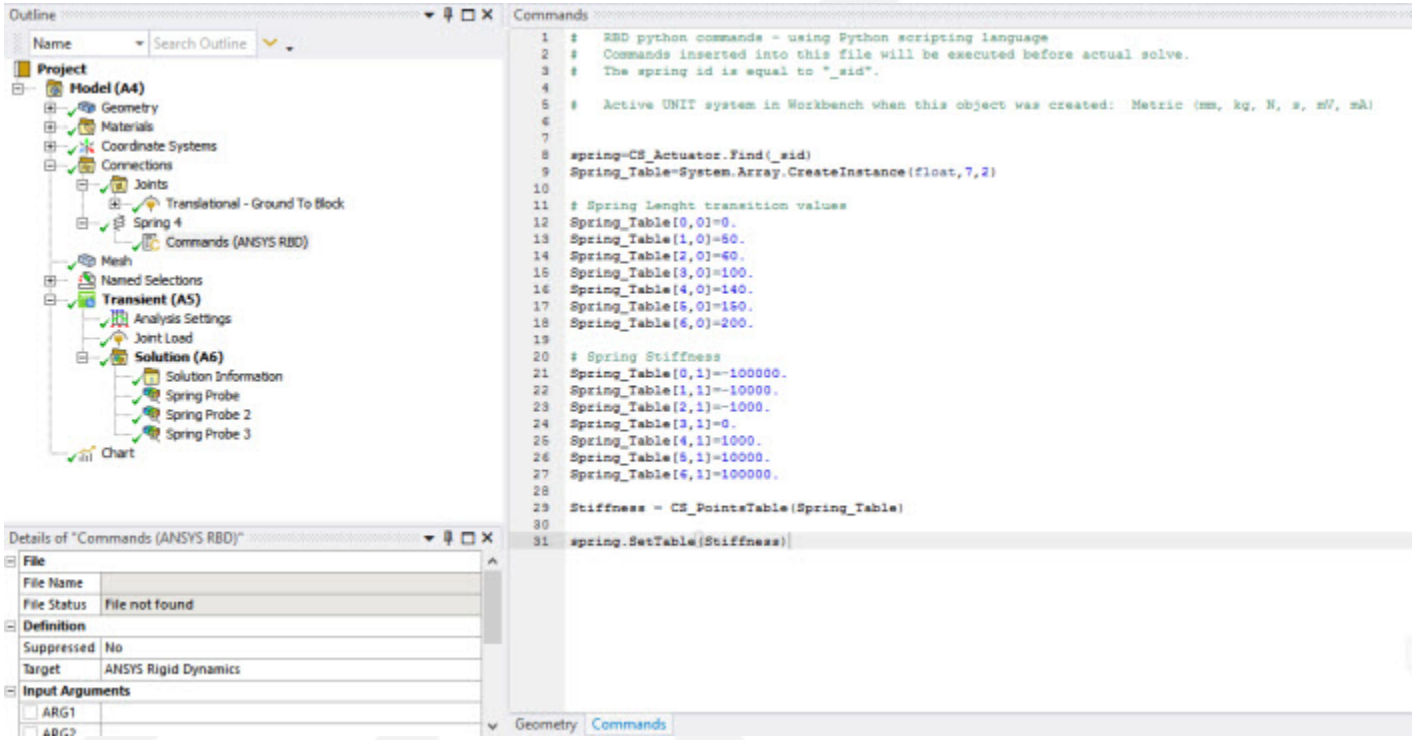
```
Env=CS_Environment.FindFirstNonNull()

load=CS_JointDOFLoad(joint,0)
load.SetInputMeasure(vel)
load.SetFunc('0.1*(-2*acos(-1)-time)',0)

Env.Loads.Add(load)
```

Non-Linear Spring Damper

This example shows how the behavior of a spring can be altered to introduce a non-linear force-displacement relationship. The complete list of commands is shown below. A description of these commands follows.



1. Retrieve the spring object using its ID:

   ```
   Spring=CS_Actuator.Find(_sid)
   ```

2. Create an array of real values and fill it with the pairs of values (elongation, force):

   ```
   Spring_table=System.Array.CreateInstance(float,7,2)

   #
   # LENGTH transition values
   spring_table[0,0]=0.
   spring_table[1,0]=50.
   spring_table[2,0]=60.
   spring_table[3,0]=100.
   spring_table[4,0]=140.
   spring_table[5,0]=150.
   spring_table[6,0]=200.

   #
   # Spring Stiffness
   spring_table[0,1]=-100000.
   spring_table[1,1]=-10000.
   spring_table[2,1]=-1000.
   ```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

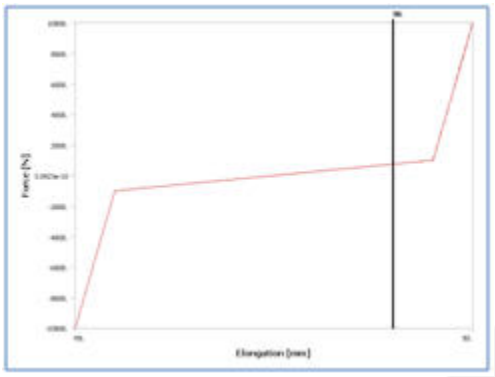
Published: 2023-10-23

```
spring_table[3,1]=0.
spring_table[4,1]=1000.
spring_table[5,1]=10000.
spring_table[6,1]=100000.

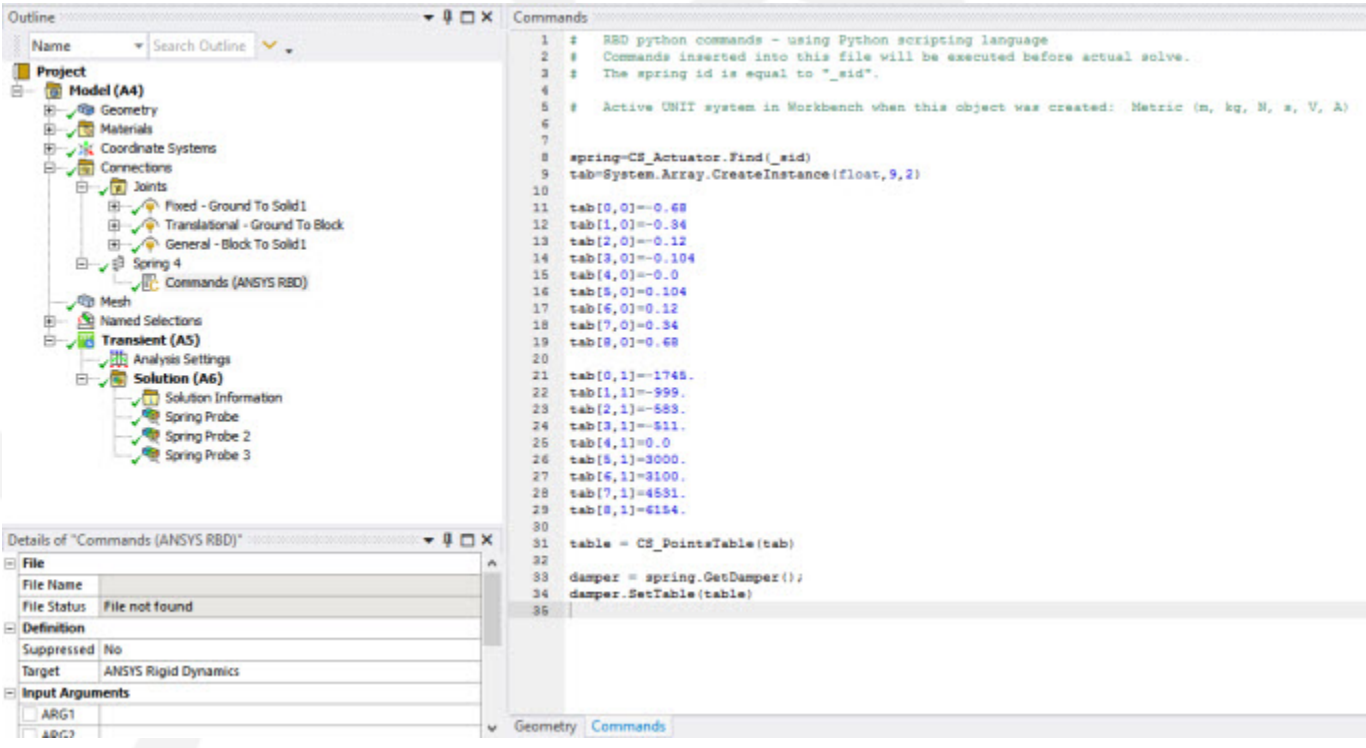
stiffness = CS_PointsTable(spring_table)

spring.SetTable(stiffness)
```

In this command, **7** represents the number of rows and **2** for the number of columns. The first column gives elongation and the second, the corresponding force value. This command generates a PointsTable assigned to the spring, as shown below.



Each spring object in the Mechanical GUI is actually a combination of a spring and a damper. The **`GetDamper`** method enables you to retrieve the damper object on a given spring, as shown below.



3. Introduce a table is to define a non-linear force velocity relation:

```
Damper=spring.GetDamper()
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Spherical Stop

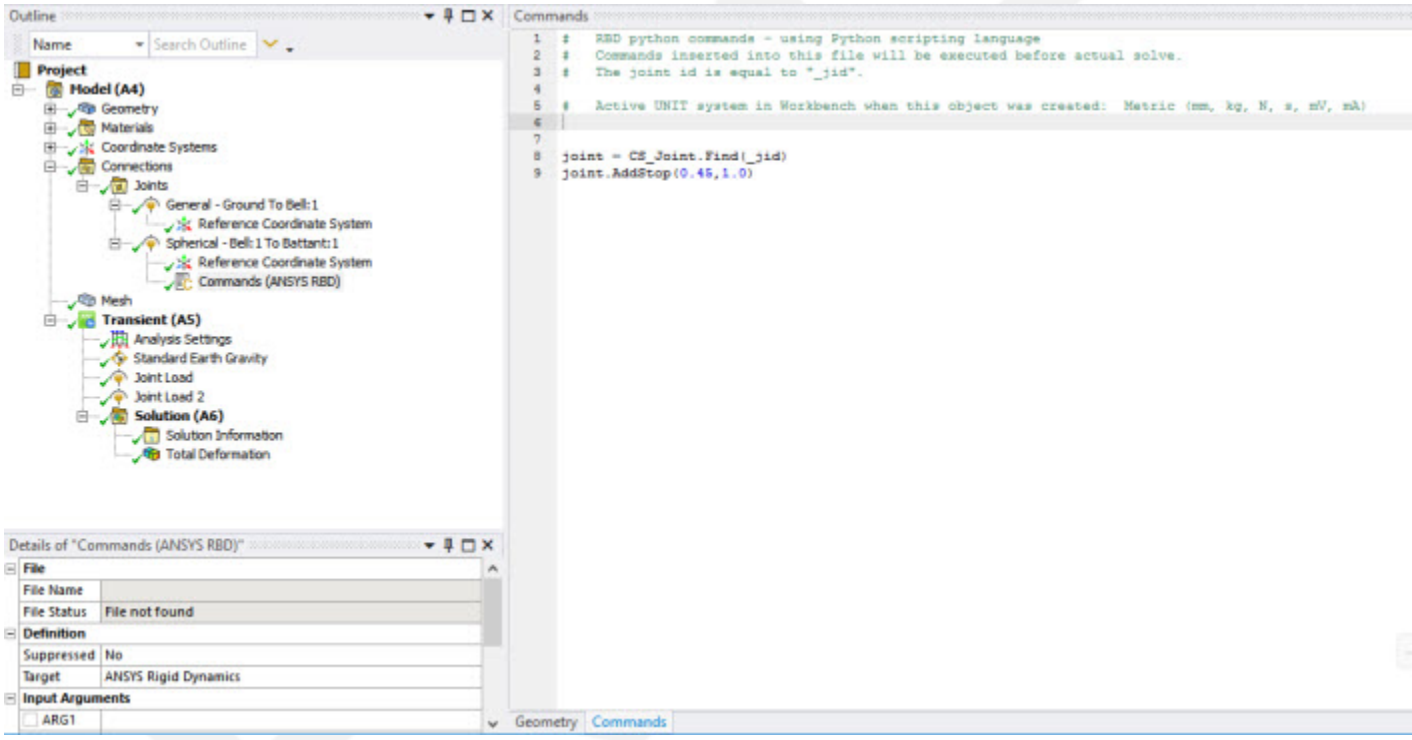
This example describes the implementation of a spherical stop. A spherical stop is a joint that has 3 rotations (joints include spherical, slot, bushing, free and general joints). This specific type of stop creates a limit to the angle between the z-axis of the reference frame and the z-axis of the moving frame. This functionality is available using the following command:

```
AddStop(angle_max, restitution_factor)
```

For example, to add a spherical stop for an angle value equal to 0.45 radians and a restitution factor equal to 1.0, the following command would be issued:

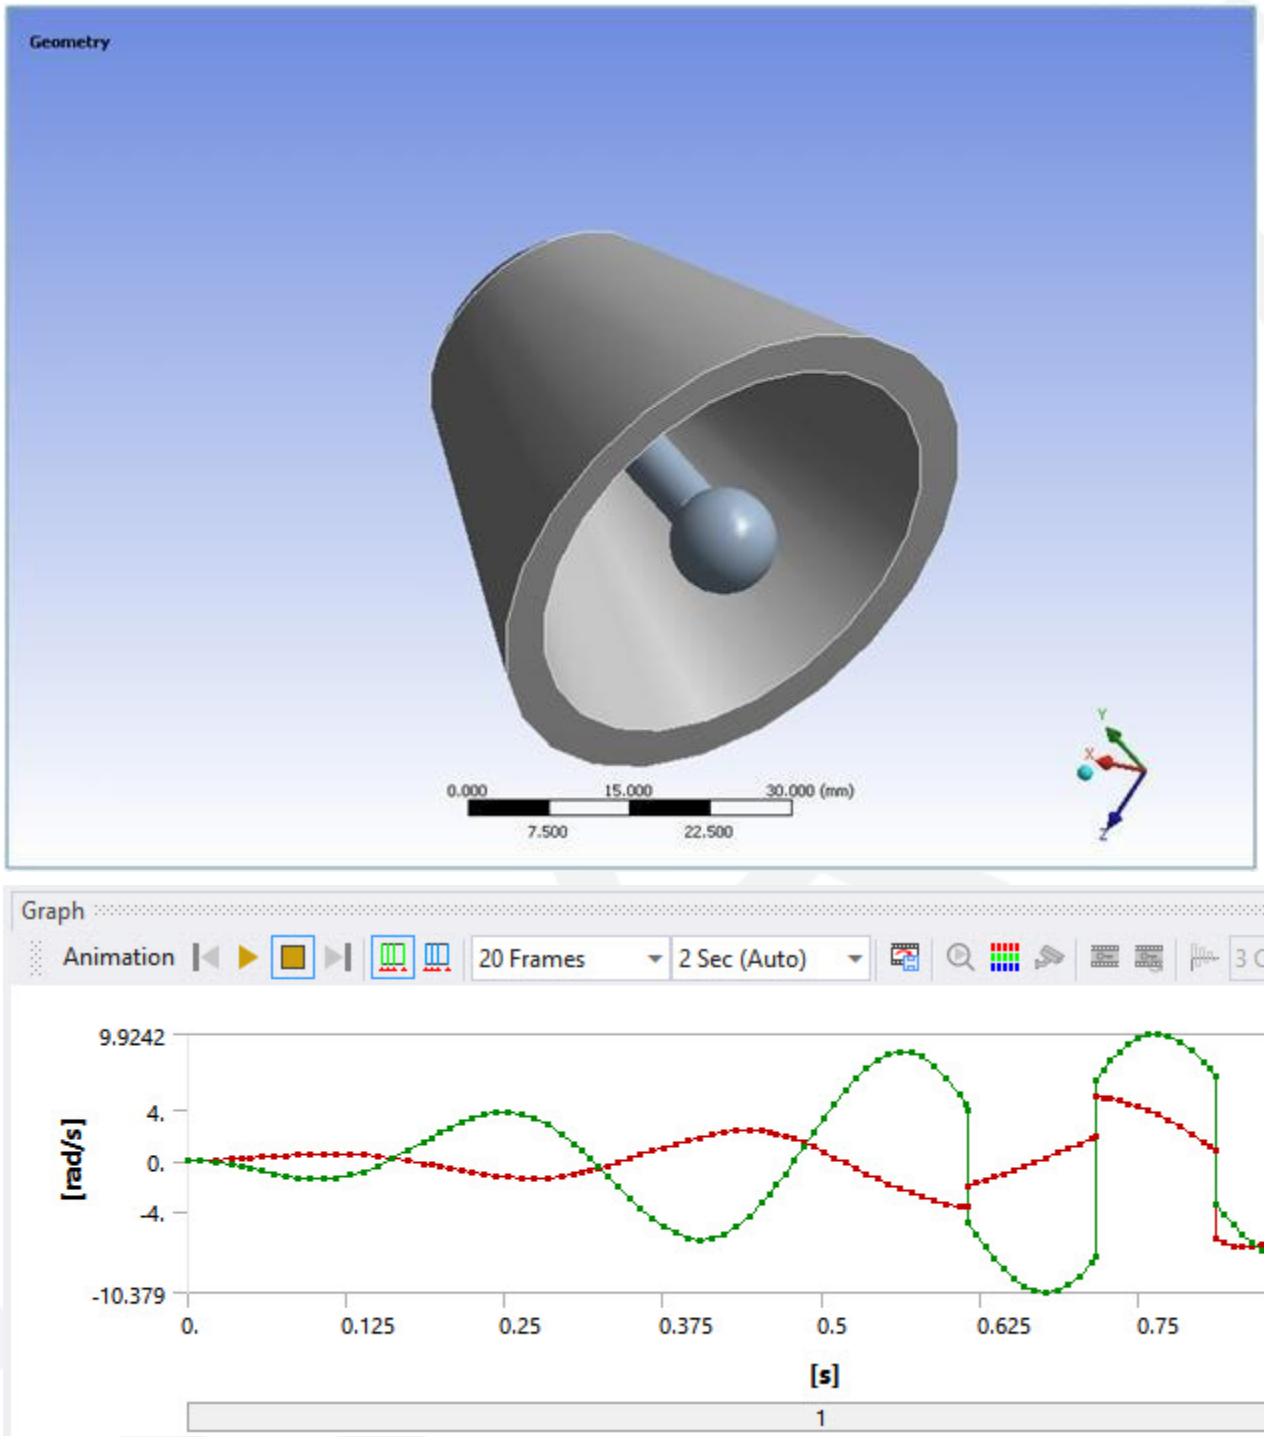
```
Joint.AddStop(0.45,1.0)
```

An example of the model and the results of this command are shown below.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Export of Joint Forces

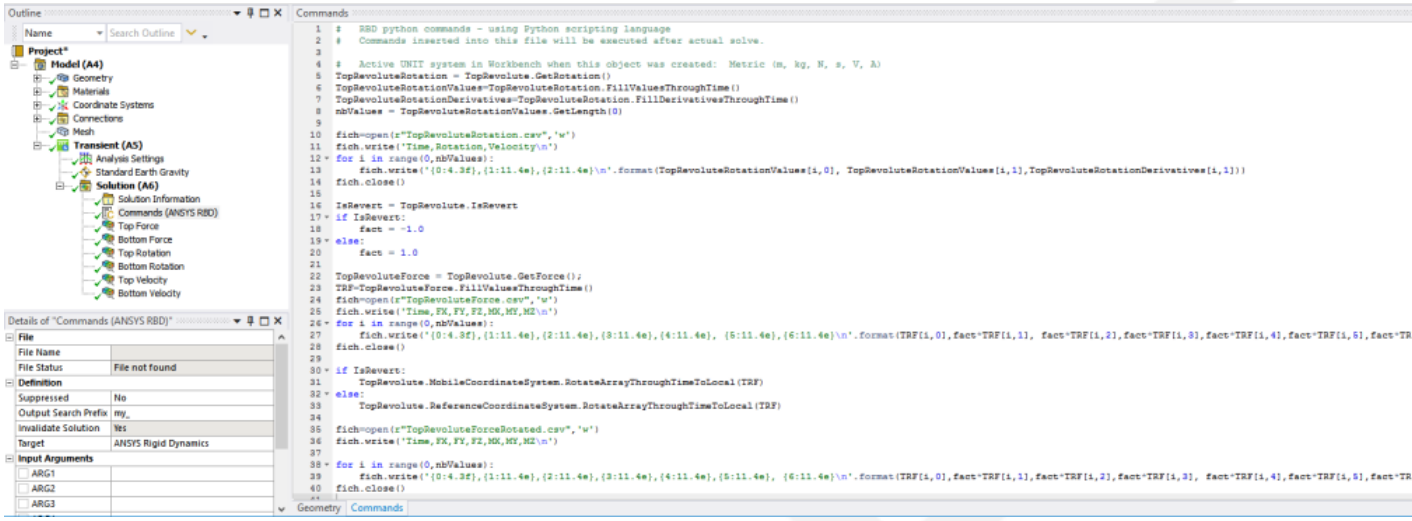
In this example joint forces are extracted in the local coordinate system, rotated into the global coordinate system, and written into an ASCII File

First, the joint is retrieved by inserting the following command on the corresponding joint in the tree:

```
TopRevolute = CS_Joint.Find(_jid)
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Next, the commands object shown below is inserted in the result node. An explanation of these commands follows.



1. Get measures from the joint:

```
TopRevoluteRotation = TopRevolute.GetRotation()
```

2. Extract transient values for this measure:

```
TopRevoluteRotationValues=TopRevoluteRotation.FillValuesThroughTime()
```

3. Get angle derivatives by extracting the time derivatives of the measure:

```
TopRevoluteRotationDerivatives=TopRevoluteRotation.FillDerivativesThroughTime()
```

4. Count the number of components of this array:

```
nbValues = TopRevoluteRotationValues.GetLength(0)
```

5. Open the ASCII output file:

```
fich=open(r"TopRevoluteRotation.csv",'w')
fich.write('Time,Rotation,Velocity\n')
```

6. Loop over all time values, and write values:

```
for i in range(0,nbValues):
 fich.write('{0:4.3f},{1:11.4e},{2:11.4e}\n'.format(TopRevoluteRotationValues[i,0],
 TopRevoluteRotationValues[i,1],TopRevoluteRotationDerivatives[i,1]))
fich.close()
```

7. Check if joint is « revert » or not:

```
IsRevert = TopRevolute.IsRevert
if IsRevert:
 fact = -1.0
else:
 fact = 1.0
```

8. Extract Force Measure and write them into the file:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

```
TopRevoluteForce = TopRevolute.GetForce();
TRF=TopRevoluteForce.FillValuesThroughTime()
fich=open(r"TopRevoluteForce.csv",'w')
fich.write('Time,FX,FY,FZ,MX,MY,MZ\n')
for i in range(0,nbValues):
 fich.write('{0:4.3f},{1:11.4e},{2:11.4e},{3:11.4e},{4:11.4e},
{5:11.4e},{6:11.4e}\n'.format(TRF[i,0],fact*TRF[i,1],
fact*TRF[i,2],fact*TRF[i,3],fact*TRF[i,4],fact*TRF[i,5],fact*TRF[i,6]))

fich.close()
```

9. Get the joint reference coordinate system, and rotate the forces from the global coordinate system to the joint coordinate system:

```
if IsRevert:
    TopRevolute.MobileCoordinateSystem.RotateArrayThroughTimeToLocal(TRF)
else:
    TopRevolute.ReferenceCoordinateSystem.RotateArrayThroughTimeToLocal(TRF)

fich=open(r"TopRevoluteForceRotated.csv",'w')
fich.write('Time,FX,FY,FZ,MX,MY,MZ\n')

for i in range(0,nbValues):
 fich.write('{0:4.3f},{1:11.4e},{2:11.4e},{3:11.4e},{4:11.4e},{5:11.4e},
{6:11.4e}\n'.format(TRF[i,0],fact*TRF[i,1],fact*TRF[i,2],fact*TRF[i,3],
fact*TRF[i,4],fact*TRF[i,5],fact*TRF[i,6]))
fich.close()
```

Breakable Joint

This example considers a breakable joint. A breakable joint is a joint that cannot withstand an internal force higher than a given value. To create a breakable joint:

1. Get the joint by inserting a command on a planar joint:

```
joint=CS_Joint.Find(_jid)
```

2. Create a joint condition to prescribe zero velocity on the two translational degrees of freedom:

```
driver=CS_Driver(Joint,System.Array[int]([0,1]),CS_Driver.E_MotionType.E_Velocity)
```

3. Define the value of the velocity, then retrieve the time measure:

```
Env=CS_Environment.GetDefault()
Sys=Env.System
(ret,found,time)=Sys.FindOrCreateInternalMeasure(CS_Measure.E_MeasureType.E_Time)
```

4. Define the time as variable, and use constant values for the two components:

```
driver.SetInputMeasure(time)
driver.SetConstantValues(System.Array[float]([0.,0.]))
```

   Next, make the driver only active if the force in the joint is less than a maximum threshold of 3N. To do that, create a Condition based on the joint force measure norm.

5. Retrieve the force on the joint:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
force=joint.GetForce()
```

6. Create a component measure, that is the norm 2 of the force. To be computed at each time step, this measure has to be added to the system.

```
norm=CS_ComponentMeasure(force,-2)
Sys.AddMeasure(norm)
```

7. Now, create the condition and assign it to the driver:

```
cond=CS_Condition(CS_Condition.E_ConditionType.E_LessThan,norm,3.0)
driver.Condition=cond
```

8. Finally, add the driver to the environment:

```
Env.Drivers.Add(driver)
```

Debugging RBD Commands with Visual Studio

You can debug RBD command snippets Using Microsoft Visual Studio. This allows you to execute commands line by line and review variable values.

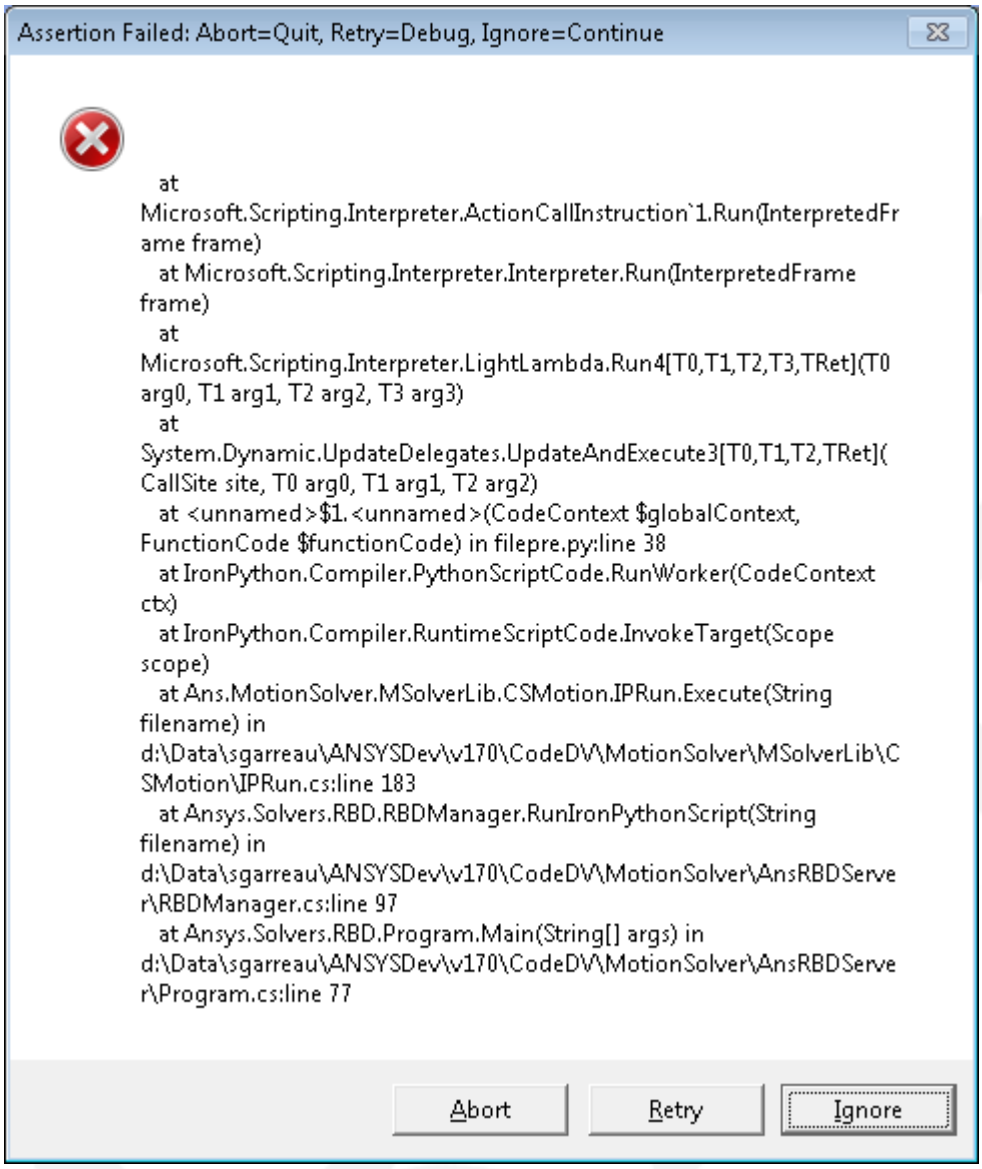
1. To begin, insert the following lines before the commands snippet you want to debug. (Note that if there are several commands snippet, they are executed in the order they appear in the Mechanical tree.)

```
from System import Diagnostics
Diagnostics.Debug.Assert(0)
```

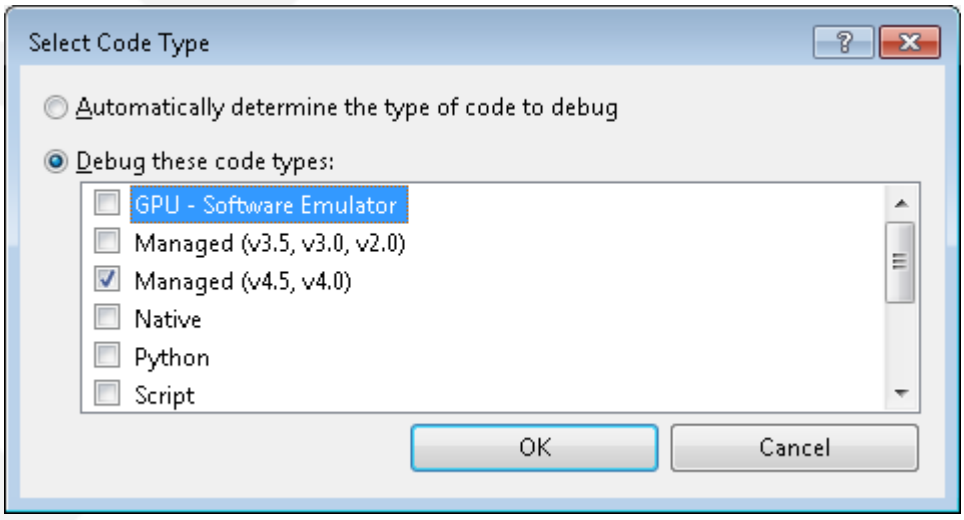
2. Begin the solve. When the solution begins, the following warning dialog appears. Do not close this dialog. The dialog will pause the solver and allow you to attach the Visual Studio debugger and set breakpoints.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

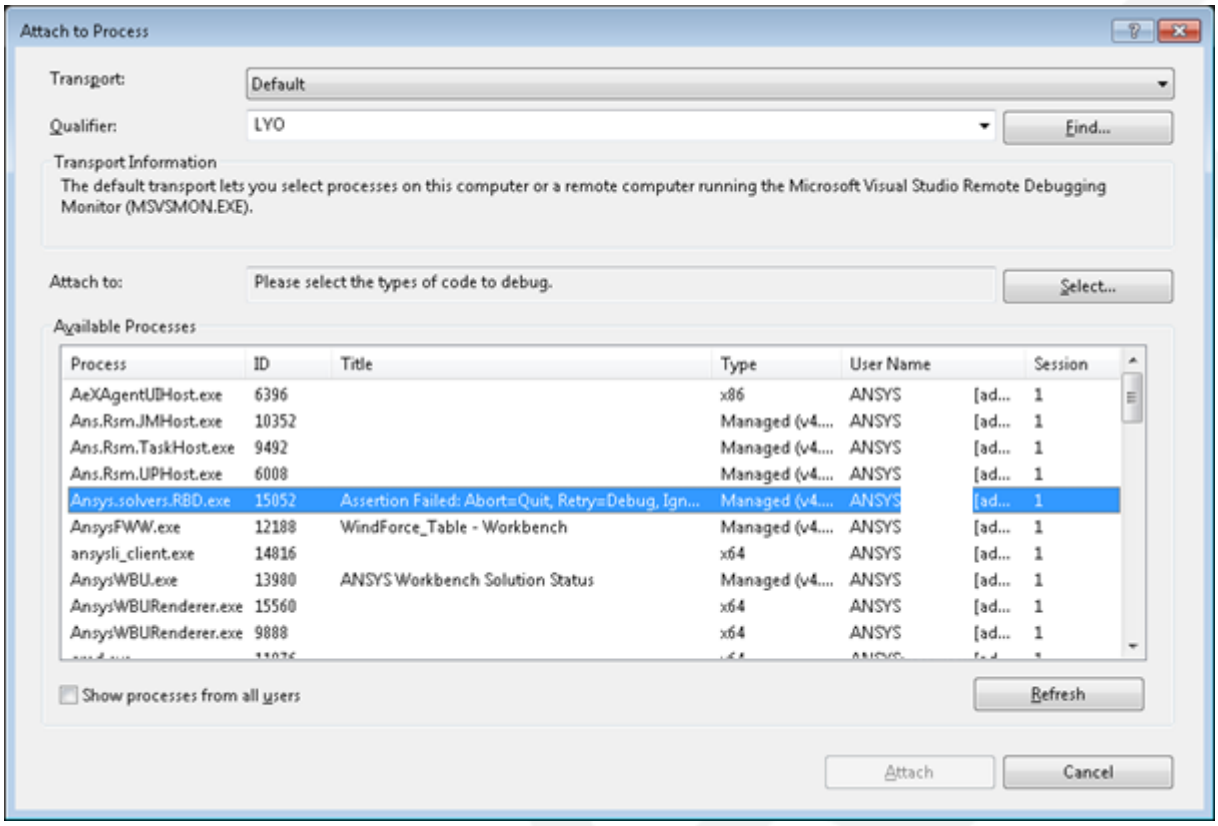
Published: 2023-10-23



3. In Visual Studio, select **Attach To Process...** from the **DEBUG** menu. In the **Select Code Type** dialog, select **Managed**, then click **OK**.



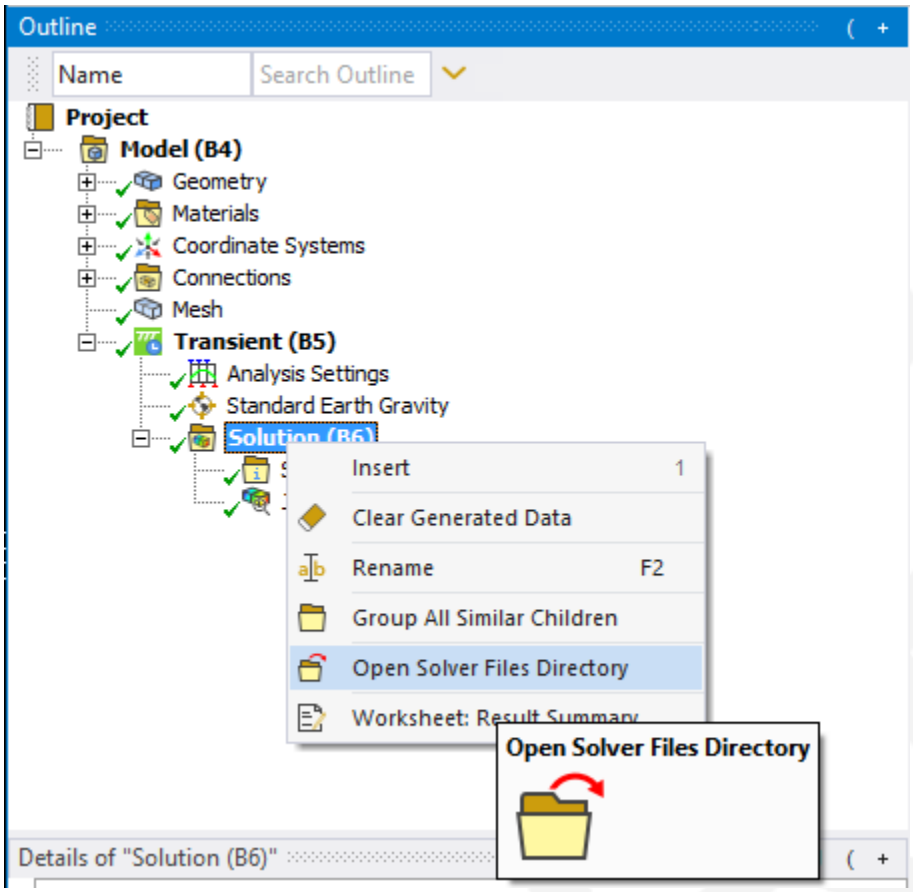
4. In the **Attach to Process** dialog, select the RBD solver process (**Ansys.solvers.RBD.exe**), then click **Attach**.



5. Once Visual Studio is attached to the RBD solver, open the script file in Visual Studio. To locate script files, in Mechanical, right-click the **Solution** object and select **Open Solver Files Directory**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



6. In the solver files directory, commands are written to two python files: `filepre.py` and `filepost.py`. `filepre.py` contains the commands that are executed before solve (all command snippets except those at solution level). `filepost.py` is executed after the solve (only command snippets at solution level).

   Open the desired file in Visual Studio. You can insert breakpoints as desired and click **Ignore** on the warning dialog to resume the solve.

Using RBD Commands with Excel

It is possible to call Microsoft Office Excel from an RBD command to read and write data to and from Excel. If Excel is available, RBD will automatically detect and load the Excel interopt. If Excel is detected, the solver output will contain the following lines at the beginning.

```
Processing Python commands
import base modules and macros
Microsoft.Office.Interop.Excel is loaded
Ans.Customize.Misc interop is not available
ready to process commands
```

The Excel application is initiated using:

```
excel=Microsoft.Office.Interop.Excel.ApplicationClass()
excel.Visible=True
excel.DisplayAlerts=False
```

Use the following line to open an Excel file:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
workbook=excel.Workbooks.Open(r"E:\RBD\MODELS\COMMANDES\EXCEL\Excel_v160_files\Velocity.xlsx")
ws=workbook.Worksheets[1]
```

To read data from the current worksheet, use the following:

```
xlrange = ws.Range["A2", "B66"]
values=xlrange.Value2
```

Before using the values in an RBD script, it may be necessary to convert them to real values:

```
realValues=System.Array.CreateInstance(float,2,values.GetLength(0))
for i in range(0,values.GetLength(0)):
    print '{0:e} {1:e}'.format(values[i,0],values[i,1])
    realValues[0,i]=values[i,0].real
    realValues[1,i]=values[i,1].real
```

Similarly, it is possible to write values to the current worksheet. The following sequence of commands shows how to create a new worksheet and write the joint force in the new worksheet:

```
# retrieve joint force measure
force=joint.GetForce()

# obtain time values for this measure
values=force.FillValuesThroughTime()

# create a new worksheet
ws2=workbook.Worksheets.Add()
ws2.Name='Reaction forces'

len=values.GetLength(0)

cell=ws2.Range["A1"]
cell.Value2='Time'
cell=ws2.Range["B1"]
cell.Value2='Fx'
cell=ws2.Range["C1"]
cell.Value2='Fy'
cell=ws2.Range["D1"]
cell.Value2='Fz'
cell=ws2.Range["E1"]
cell.Value2='Mx'
cell=ws2.Range["F1"]
cell.Value2='My'
cell=ws2.Range["G1"]
cell.Value2='Mz'

# put values into the new worksheet
end="G"+str(1+len)
cells=ws2.Range("A2",end)
cells.Value2=values
```

Using RBD Commands from the IronPython Console

It is possible to use any rigid body dynamics commands you would use during a simulation from the IronPython console, outside of the simulation environment. The following command snippets and instructions provide a demonstration of this capability:

You can access the IronPython console by clicking the **File** > **Scripting** > **Open Command Window** menu item.

The following code snippets load the RBD Command module into IronPython:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

```
import clr
import os
import Ansys
import sys

clr.AddReference('Ans.Utilities')
ver=Ansys.Utilities.ApplicationConfiguration.DefaultConfiguration.VersionInfo.VersionString

awp_root=os.getenv('AWP_ROOT'+ver)
sys.path.Add(awp_root+r'\aisol\bin\winx64')
clr.AddReference('Ans.MotionSolver.MSolverLib.CSMotion')

from Ans.MotionSolver.MSolverLib.CSMotion import *
```

You can read an already-solved rigid body dynamics model using the following code:

```
dbIn=CS_MSolverDB()
dbIn.SetFileName(GetProjectDirectory()+'/TestRestart_files/dp0/SYS/MECH/file.mbd')
dbIn.OpenDataBase(0)
dbIn.ReadDB()
dbIn.Dispose()
```

The environment and system objects are accessed in the following way:

```
environment=CS_Environment.GetDefault()
system=environment.System
```

It is now possible to alter properties of the simulation. For example, you could modify the end time and restart from 0.5 s:

```
environment.AlterSimulationEndTime(2.0)
environment.RestartTime=0.5
environment.Solve()
```

Once you have made your changes, make use the following code snippet to save the modified database:

```
dbOut=CS_MSolverDB()
dbOut.SetFileName(GetProjectDirectory()+'/TestRestart_files/dp0/SYS/MECH/file.mbd')
dbOut.OpenDataBase(1)
dbOut.WriteDB()
dbOut.Dispose()
```

Note:

You cannot restart a Rigid Dynamics analysis using this procedure if the model has contact or a Point On Curve joint, or if there are multiple load steps.

Using the Variable Load Add-on

The Variable Load Add-on greatly simplifies the definition of complex loading for Rigid Dynamics systems. It allows you to create loads that depend on the state of the model, and to make these loads conditionally applied.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Without the add-on, such complex loads can only be defined using command objects. The Variable Load Add-on will similarly write commands to define these loads.

Note:

The add-on is only available on Windows platforms.

The following topics explain the use of the Variable Load Add-on:

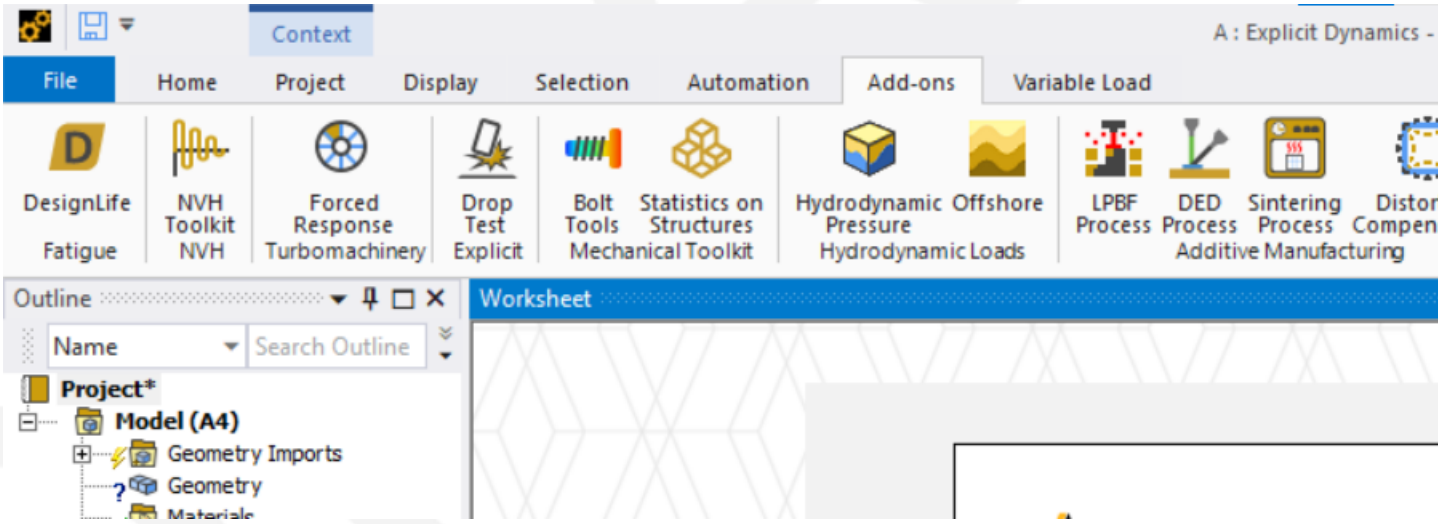
How to Load the Add-on
Creating Measures
Defining Joint Loads Dependent on one or more Measures
Defining Force Loads Dependent on one or more Measures
Known Issues and Limitations

How to Load the Add-on

The Variable Load Add-on is included in the Ansys product installation but must be loaded into Workbench.

To make the capabilities of the Variable Load Add-on available, click the **Variable Load** Icon in the **Add-ons** Ribbon. The icon will be highlighted in blue, indicating that the add-on is loaded.

Figure 1: Variable Load Add-on Showing Loaded Status



Once the add-on is loaded, the **Variable Load** Toolbar will appear in the Mechanical Ribbon.

Creating Measures

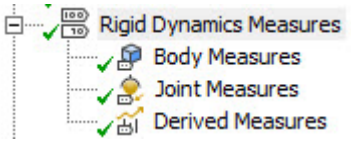
Measures can be thought of as sensors used to instrument the models. The workflow consists of instrumenting the model with measures that capture the state of the model, and then using these measure values to compute the value of the applied loads, or to activate and deactivate them.

Joints and Bodies can be instrumented with Measures. For these base measures, derived measures that transform the base measures can be introduced.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

To create the Rigid Dynamics Measures folder in the Project tree, click the Insert Measures icon .

The corresponding folder appears in the tree.

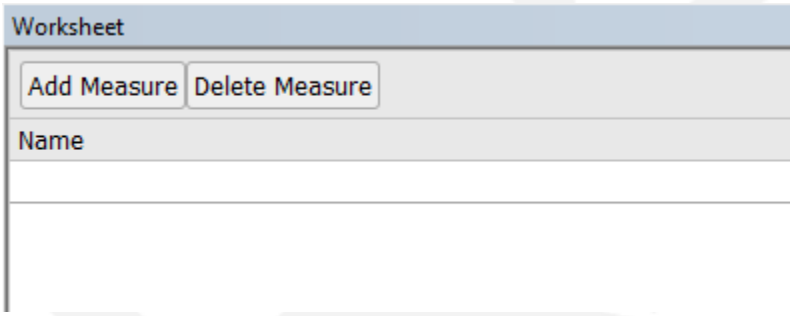


Note:

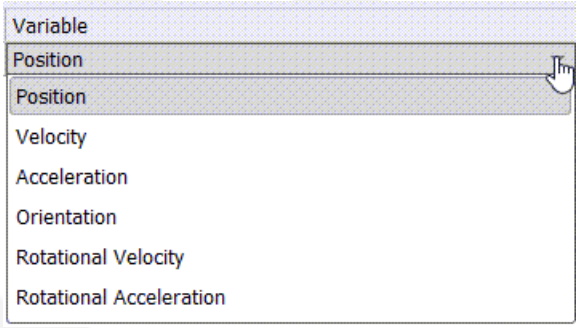
- All measures are computed and consumed during the solution. The solver uses the consistent unit system that is associated with the user unit system. Therefore, you should define operations done on derived measures, or the tables that consume the measure values, with the consistent unit system in mind.
- All rotations are in radians and all rotations velocities are in rad/s.

Body Measures

1. Select **Body Measure** in the tree. The Body Measure worksheet appears.
2. To add a new measure, click **Add Measure**.



3. Give a **Name** to this measure. You should use unique names, as the name of the measure will be used in selections later on.
4. Select the body that you want to instrument in the **Selection** column.
5. Select the quantity that you want to measure from the **Variable** dropdown list.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

6. Select the coordinate system that defines the position of the point where position, velocity and acceleration are reported.

7. If you need to delete a measure that you previously created, select its row in the worksheet and click **Delete Measure**.

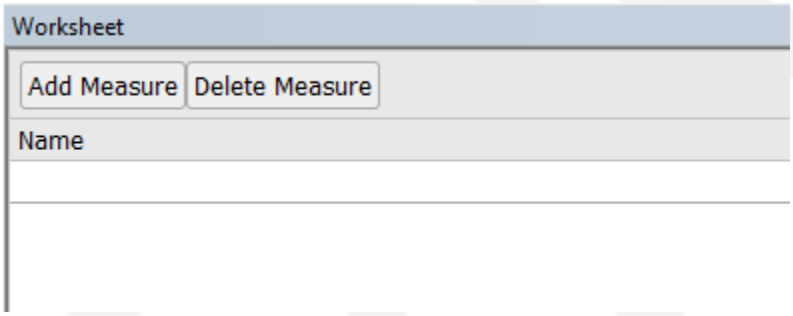
Note:

- Position, Velocity, Acceleration, Rotational Velocity and Rotational Accelerations are 3D vectors, with X, Y and Z components.
- For Orientation, Rotational Velocity and Rotational Acceleration, the coordinate system is not used.
- The coordinate system just gives the position. X, Y and Z components of Position, Velocity, and Acceleration are global coordinates.

Joint Measures

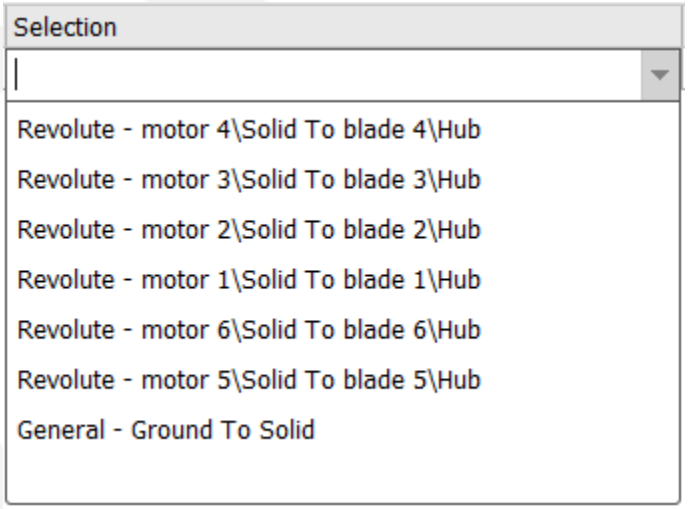
1. Select **Joint Measure** in the tree. The Joint Measure worksheet appears.

2. To add a new measure, click **Add Measure**.



3. Give a **Name** to this measure. You should use unique names, as the name of the measure will be used in selections later on.

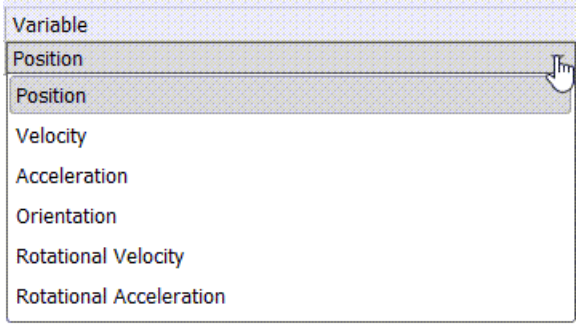
4. Select the joint that you want to instrument from the dropdown in the **Selection** column.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. Select the quantity that you want to measure from the **Variable** dropdown list.



6. If you need to delete a measure that you previously created, select its row in the worksheet and click **Delete Measure**.

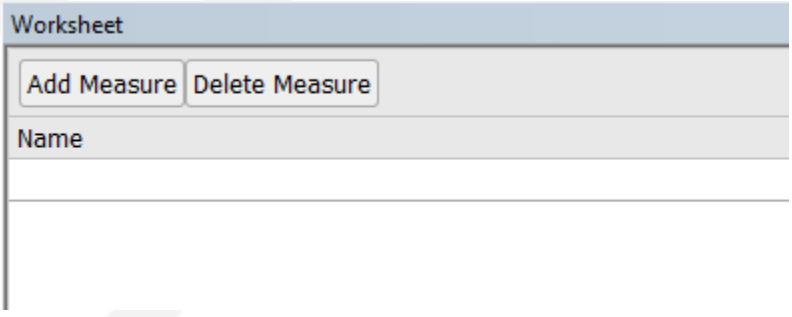
Note:

- The quantities available will depend on the type of joint that is selected. Select the joint first so that the Variable drop-down menu updates the list with relevant quantities.
- The number of components of the position, rotation, velocity and acceleration measure depends on the joint type.
- During the solution, the solver sometimes flips the reference and mobile coordinate system of the joint. If the joint is reverted, force load must be negated. See the model topology tool from the connection menu to see which joints are reverted. See the IsRevert property in the CS_joint class of the scripting manual.

Derived Measures

Based on how the loads consuming the measures are defined, one-dimensional measures might be needed. Measures also sometimes need to be transformed by some math operators. Derived measures are made for these operations.

1. Select **Derived Measure** in the tree. The Derived Measure worksheet appears.
2. To add a new measure, click **Add Measure**.



3. Give a **Name** to this measure. You should use unique names, as the name of the measure will be used in selections later on.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

4. Select the **Base Measure** the operator applies to.
5. Select select a transformation **Type**, Component or Operator.
   - When using Component, select the component from among the components available. The list of component depends on the base measure type.

   - When using Operator, choose from Modulo or Scale Factor.
     – Modulo corresponds to a modulus operation. It can for example be used to remove the number of turns from the rotation angle of a revolute joint. The modulus is defined by the **Operator Value** property.
     – Scale Factor scales the value of the input measure by a constant defined by the **Operator Value** property.
6. If you need to delete a measure that you previously created, select its row in the worksheet and click **Delete Measure**.

Note:

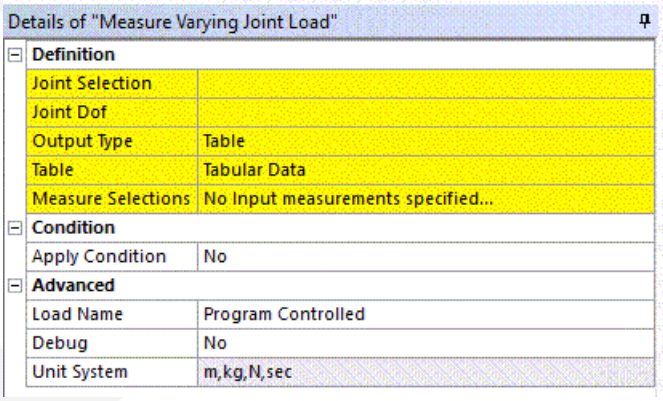
The base measure of a derived measure can be a derived measure.

Defining Joint Loads Dependent on one or more Measures

To define a joint load that depends on one or more measures:

1. Click the Insert Measure Varying Joint Load icon .

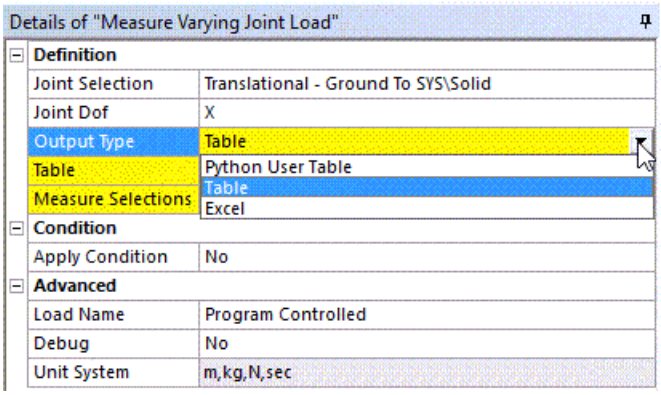
   The properties of this load can then be edited in the **Details** panel.



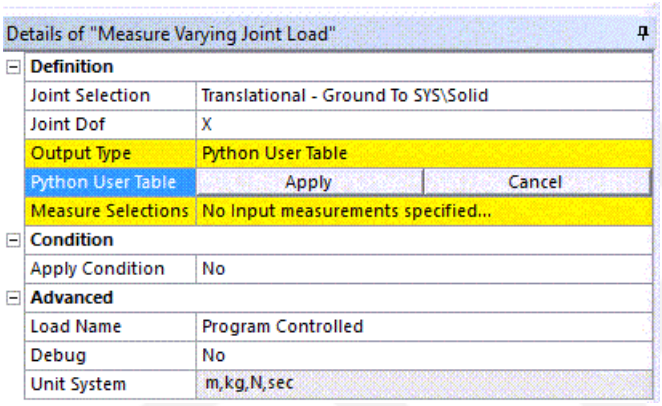
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

2. Select the joint on which to apply the load in the **Joint Selection** field.
3. Select the joint degree of freedom on which the load is applied in the **Joint Dof** field.
4. Define the **Output Type** from the dropdown list.



- *Python User Table*



When you select Python User Table, a text editor will open, allowing you to define the evolution of the joint load with respect to the input variable defined in the **Measure Selections** field.

The text editor will contain a pre-defined IronPython function.

```
class UserTable_33(CS_UserTable):
   def __init__(self, sizeIn, sizeOut):
       CS_UserTable.__init__(self, sizeIn, sizeOut)

   def Evaluate(self, In, Out):
       ## define Out[] as a function of In[] here
       Stiffness = 43.0
       Damping = 0.1
       Preload = 100.0
       Displacement = In[0]
       Velocity = In[1]
       Out[0] = -Stiffness*Displacement -Damping*Velocity + Preload

       return 0

#define input size and output size here
SizeIn=1
SizeOut=1
table_33 = UserTable_33(SizeIn,SizeOut)
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
print "    *** CS_UserTable UserTable_33 created ***"
```

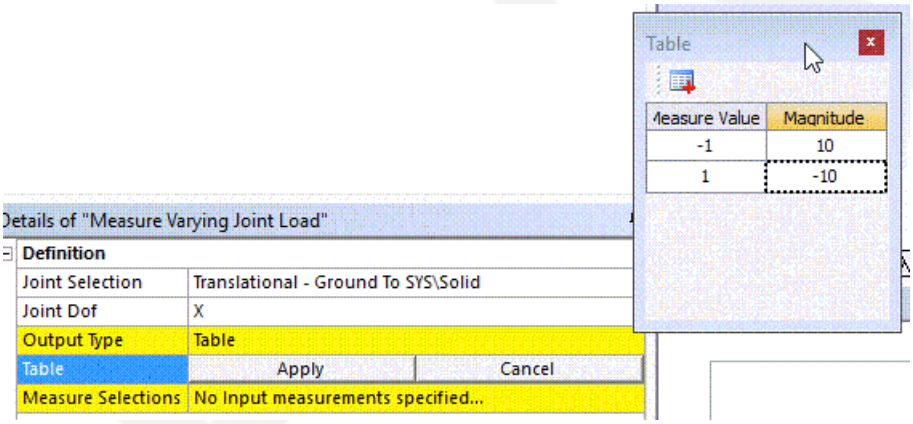
Note:

- The string _33 is given here as example. Actual value will vary.
- The text editor that will be used is that associated with the `.txt` add-on in your user preferences.
- This feature relies on the CS_UserTable class of the scripting manual.

In general, you would only modify the Evaluate function. Its role is to compute *Out[0]*. The input measures come into this function in the *In[]* array. In the example above, the load has two input measures: one is the joint displacement and the other is the joint velocity, for a joint that has only one degree of freedom. The force is computed as if a preloaded spring and damper were acting together.

- *Table*

  This option will allow you to define tabular data defining output as a function of input. This option requires that you have only one input variable. The table will have two columns, the first one corresponding to the input values and the second one corresponding to the output values.



- *Excel*

  You can also use Excel to define tabular output, and the data will be read from an Excel comma separated value file (`.csv`). Click the field next to **Excel** to browse to your Excel file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Details of "Measure Varying Joint Load"	
Definition	
Joint Selection	Translational - Ground To SYS\Solid
Joint Dof	X
Output Type	Excel
Excel	
Skip Header	Yes
Output Scale Factor	1
Column Separator	,
Measure Selections	No Input measurements specified...
Condition	
Apply Condition	No
Advanced	
Load Name	Program Controlled
Debug	No
Unit System	m,kg,N,sec

The Excel table must have two columns, the first one corresponding to the input values and the second one corresponding to the output values.

– By default, the first row of the table is assumed to contain labels that describe the columns.

	A	B
1	Displacement	Force
2	0	-3.55E-15
3	0.01	1.00E+00
4	0.03	3.00E+00
5	0.07	7.00E+00
6	0.12	2.00E+00
7	0.17	7.00E+00
8	0.22	2.00E+00
9	0.27	7.00E+00
10	0.32	2.00E+00
11	0.37	7.00E+00
12	0.42	2.00E+00
13	0.47	7.00E+00
14	0.52	2.00E+00
15	0.57	7.00E+00
16	0.6	1.00E+01
17		

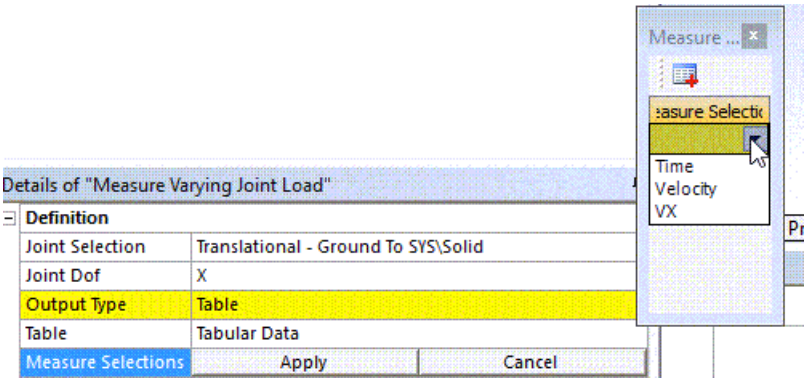
If this first row contains data (it is not a header), you should set the **Skip Header** option to No.

– Values from the spreadsheet can be scaled by the **Output Scale Factor**. This can be useful, for example, if the `.csv` file hasn't been created in the same unit system as the solution.

– By default, the Comma Separated Values file format uses "," as a separator. However, depending on the language of your operating system, or of the machine that has generated the `.csv` file, Excel can use a different character to delimit the fields. You can specify this character using the **Column Separator** field.

5. Define one or more Input Measures using the **Measure Selection** field.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



If **Output Type** is set to Table only one measure can be defined. If **Output Type** is Excel or Table, the Input Measure(s) must be scalar. Use a derived measure to extract one particular component of a multi-dimensional base measure.

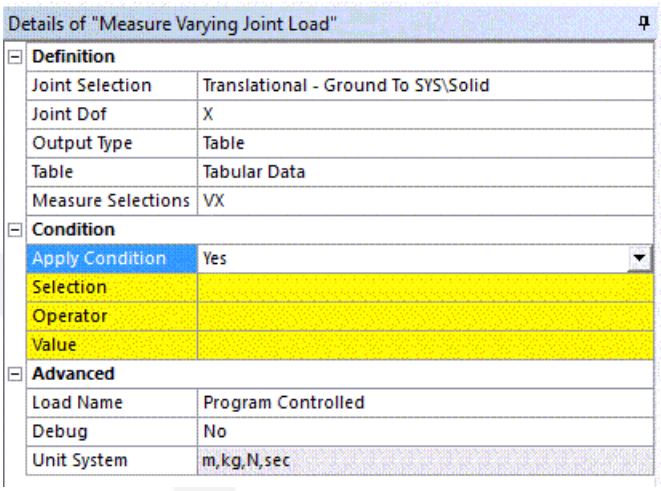
The measure Time is always available. While time-varying loads can be defined on all transient Mechanical loads, the use of IronPython can be very powerful for complex loads.

Note:

- You cannot specify a Force measure or a measure derived from a Force measure as an input used to compute loads.
- You should not use accelerations as inputs because it could lead to very small time steps or lack of convergence. If the intent is to link the accelerations of two joints, it is more efficient to use a constraint equation that links the two accelerations.

---

6. Joint loads can be applied conditionally, based on the value of any derived measure.



- Use **Selection** to define the scalar measure that the condition is based on.
- Select the **Operator** from the list.
- Select the right-hand side of the condition in the **Value** field.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

You can, for example, define a "breakable" spring that will act only if the joint displacement is less than a maximum displacement.

7. The load has a default name. This name can be overwritten using the **Load Name** field in order to increase the readability of the created script.

8. Use the **Debug** option to print the value of the input values and calculated output values of the table. This option should be used only for short simulations as it will slow down the evaluation of the load.

Important:

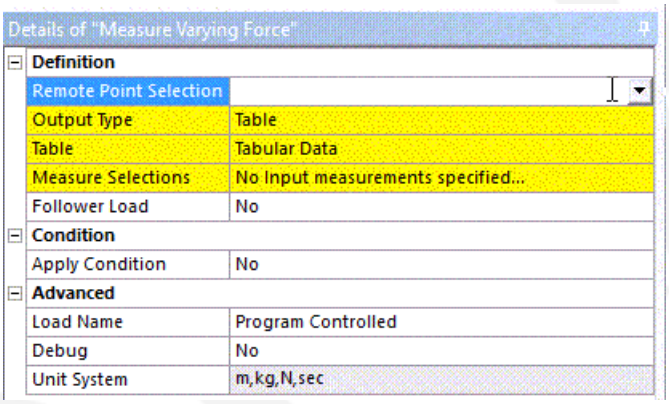
The read-only property **Unit System** is shown for information, as the **Measure Varying Joint Load** object does not change if you change the unit system in the Mechanical Application. It is strongly recommended that you use one single unit system to define all the measure varying loads and to solve using this same unit system.

Defining Force Loads Dependent on one or more Measures

To define a force load that depends on one or more measures:

1. Click the Insert Measure Varying Force icon .

2. The properties of this load can then be edited in the **Details** panel.



- Select the **Remote Point** on which the load will be applied.

Note:

The Remote Point must be connected to a geometric entity or a named selection. It cannot be a freestanding remote point. The corresponding body must be a rigid body.

- Refer to Defining Joint Loads Dependent on one or more Measures (p. 616) step 2 to 8 to define the load. The only difference is that the resulting forces has 3 components (3-dimensional vector) rather than a single value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Use the **Follower Load** property if the load's application and orientation varies with the rigid body it is applied to.

Known Issues and Limitations

Using **Clear Generated Data** at the project level after a first solve may prevent further solutions. There is no workaround to this problem, and it may require that all of the variable loads be recreated.

Using the Motion Load Transfer Add-on

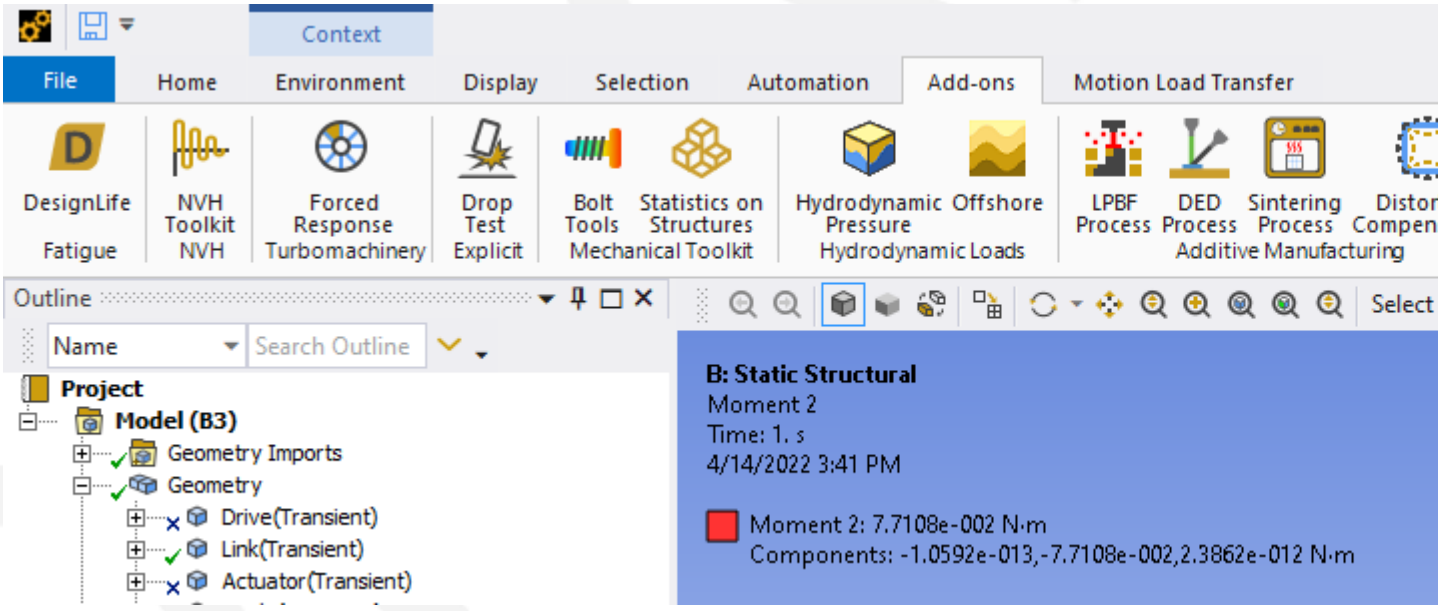
The Motion Load Transfer Add-on allows you to apply the loads created in a Rigid Dynamics analysis on the flexible bodies in a Static Structural analysis. For more information about exporting geometry from deformation results, see Geometry From Rigid Dynamics Results (p. 1027).

How to Load the Add-on

The Motion Load Transfer Add-on is included in the Ansys product installation but must be loaded into Workbench.

To make its capabilities available, click the **Motion Load Transfer** icon in the **Add-ons** Ribbon. The icon will be highlighted in blue, indicating that the add-on is loaded.

Figure 2: Motion Load Transfer Add-on Showing Loaded Status



Once the add-on is loaded, the **Motion Load Transfer** toolbar appears in the Mechanical Ribbon. Next, navigate to the Project window and add a Rigid Dynamics analysis system to the project. The system will have the Motion Loads features available.

Setting up the Motion Loads Transfer

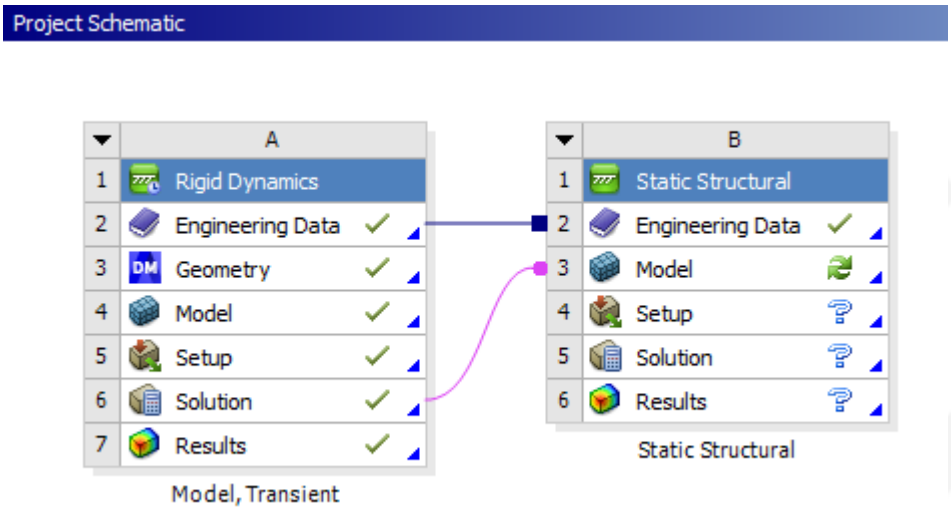
Follow these steps to set up the Motion Loads transfer:

1. Perform a Rigid Dynamics simulation.

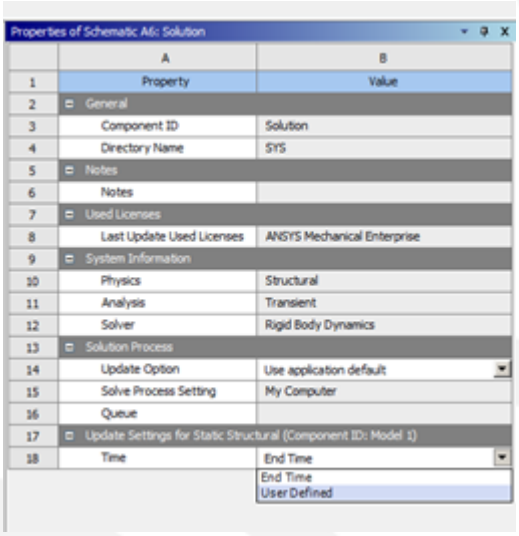
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

2. On the Project Schematic, add a Static Structural system and link the Rigid Dynamics system Engineering Data cell to the Static Structural Engineering Data cell, and the Solution cell to the Model cell.



3. Right-click the **Solution** cell of the Rigid Dynamics system and choose Properties. Under **Update Settings for Static Structural (Component)** set **Time** to User Defined, then enter the time at which you want to transfer the loads to the system.



4. Update the Rigid Dynamics system, then update the Model cell of the Static Structural system.

Note:

After a Save and Resume of a Rigid Dynamics analysis containing a motion load transfer, the motion load transfer won't work unless you delete the connection between the Rigid Dynamics Solution cell and the downstream system and recreate it using the steps in this section.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Transferring the Motion Loads

Open the Static Structural system and follow these steps:

1. Select a body in the model by picking it in the Graphics view.

2. Click the Motion Loads icon in the Motion Loads tab.

   This automatically:

   - Creates Remote Points where Forces and Moments issued from the Rigid Dynamic Solution are applied.
   - Creates Rotational Velocity and Rotational Acceleration corresponding to the Angular Velocity and Angular Acceleration issued from the Rigid Dynamic Solution.
   - Changes the behavior of the selected body to flexible.
   - Suppresses all the other bodies.

3. While the loads applied by remote forces and moments are balanced by the inertia forces, the part is nevertheless not "supported" and the analysis needs to be adapted to be stable. This can be achieved, in general, by adding weak springs (p. 1433) and/or with inertia relief (p. 1435). In some instances, for example when the part has a fixed joint to ground, it can be preferable to replace the force and torque corresponding to this joint to ground by a fixed support. When accurate contact representation between bodies is important to properly capture stresses, you could choose to keep more than one body in the analysis. In that case, use separate static systems for each part and assemble them together.

4. Now solve the Static Structural system.

To Perform the same operation on another body, unsuppress all bodies and repeat steps 1 through 4.

Note:

The modification of the Rigid Dynamics system or the export time requires the Motion Loads to be re-imported.

Multibody Dynamics Theory Guide

Multibody dynamics is the study of the motion of assemblies of bodies, rigid or flexible, that undergo large motion in the 3D space. The free motion of bodies is restrained by joints. Every joint links two bodies in two points. These joints are idealizations of the contact between the two bodies. Joints are characterized by the motion that they allow between the two bodies that they connect. For example, a revolute joint allows one relative rotation between two bodies, constrains all three relative translations, and blocks the two other relative rotations.

The primary unknowns of a multibody dynamics solution are the translation and rotation of each body and the motion in the joints themselves. The output quantities on rigid bodies are the forces that develop in the joints and flow through the rigid bodies, as opposed to a structural analysis where

Published: 2023-10-23

the output quantities are strains or stresses. Flexible bodies can be included in a multibody analysis. These flexible bodies will have both joint forces and stress and strain results.

The following topics are discussed in this section:

Rigid Degrees of Freedom

This section discusses the options available when selecting degrees of freedom (DOFs) in a rigid body assembly and their effect on simulation time.

The double pendulum model shown below is considered in this section. The first body in this model (in blue) has center of gravity G1. This body is linked to the ground through revolute joint R1, and linked to a second body through revolute joint R2. The second body (in red) has center of gravity G2, and is linked to the first body through revolute joint R2.

Figure 3: Double Pendulum Model

Published: 2023-10-23

The two bodies in this model are rigid, meaning that the deformations of these bodies are neglected. The distance between any two points on a single rigid body is constant regardless of the forces applied to it. All the points on the body can move together, and the body can translate and rotate in every direction.

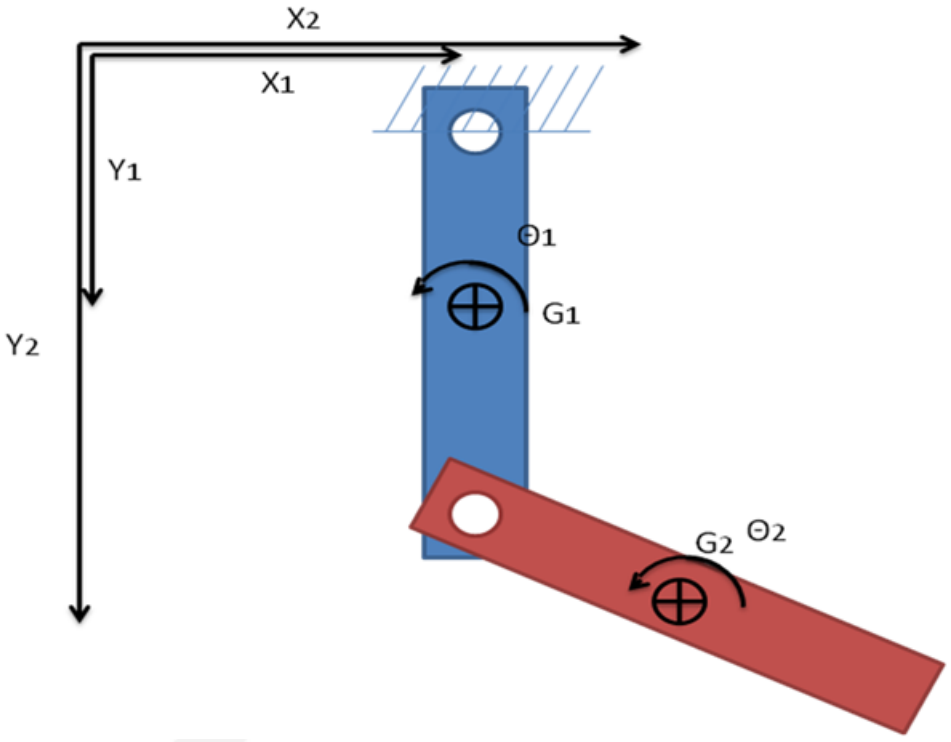
Many parameters are available to describe the body position and orientation, but the parameter usually chosen for the translation is the position of the center of mass with respect to a ground coordinate system. It is extremely difficult to represent 3D rotations for the orientation in a universal way. A sequence of angles is often used to describe the orientation, but some configurations are singular. An option frequently used to describe the orientation in computer graphics is the use of quaternion (also known as Euler-Rodrigues parameters); however, this option uses four parameters instead of three, and does not have a simple interpretation.

A natural choice of parameters to describe the position and orientation of the double pendulum model, is to use the position and orientation of the two individual bodies. In other words, use three translational and rotational degrees of freedom for each body, and introduce the joints using constraint equations.

The constraint equations used state that the two points belonging to the two bodies linked by the revolute joint are always coincident, and that the rotation axis of the joint remains perpendicular to the other body. This requires five constraint equations for each revolute joint.

The selected degrees of freedom (six DOFs per body and certain joints based on constraint equations) are considered "absolute" parameters.

Figure 4: Absolute Degrees of Freedom



The model shown in Figure 4: Absolute Degrees of Freedom (p. 626) depicts global parameters in 2-D for the double pendulum. Body 1 and 2 are respectively parameterized by X and Y translation

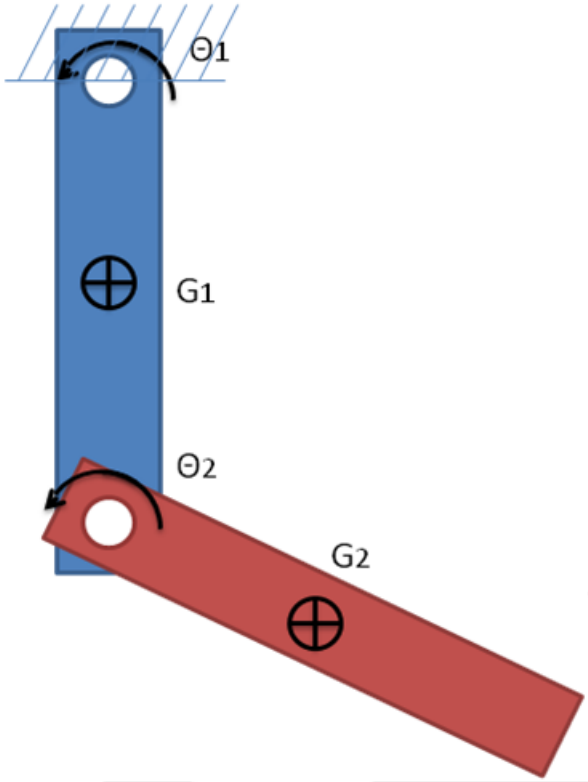
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

and theta rotation. Because the model has only two degrees of freedom, it does not require any additional constraint equations.

Global parameters for the body are chosen independently of the joints that exist between those bodies. When these joints are known, parameters for the joints can be chosen that reduce the number of parameters and constraint equations needed. For this example, the first degree of freedom is defined as the relative orientation of the first body with respect to the ground. The second degree of freedom is defined as the relative orientation of the second body with respect to the first body. Relative degrees of freedom are shown in the figure below:

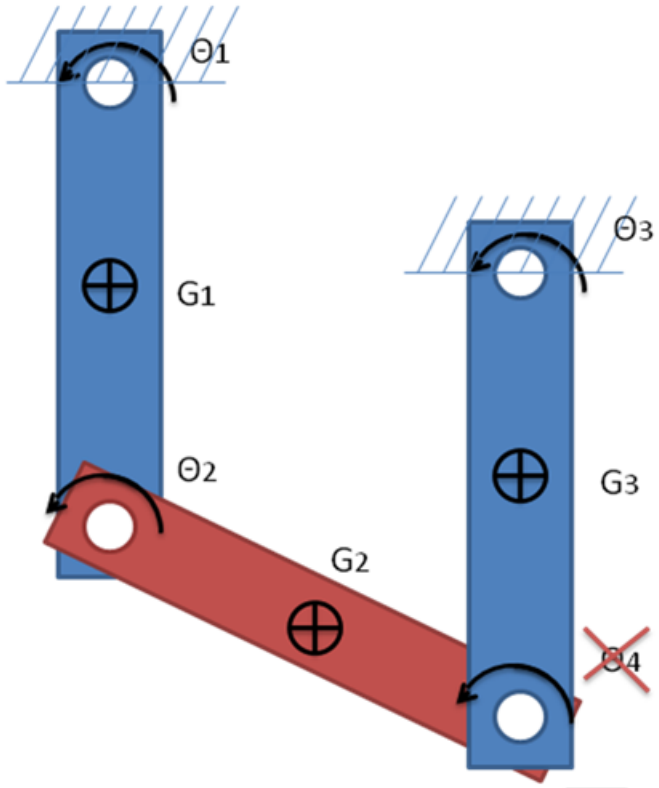
Figure 5: Relative Degrees of Freedom



Next, a third body is added to the model that is grounded on one side and linked to the second body with another revolute joint, as shown below:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Figure 6: Closed Loop Model



The closed loop model shown above has three bodies (plus the ground) and four revolute joints. The degrees of freedom can be chosen for the example as follows:

- Θ1 - The relative rotation of body 1 with respect to ground
- Θ2 - The relative rotation of body 2 with respect to body 1
- Θ3 - The relative rotation of body 3 with respect to ground

The fourth revolute joint cannot be based on degrees of freedom because both the motions of Body 2 and Body 3 are already defined by existing degrees of freedom. For this joint, constraint equations are added to the relative degree of freedom parameters.

Θ1, Θ2, and Θ3 will be the degrees of freedom, and the corresponding joints will be topological joints. The fourth joint will be based on a constraint equation. Constraint equation-based joints are also known as kinematic joints. Kinematic joints are needed when the model has closed loops, that is, when there is more than one way to reach the ground from a given body in the system.

To determine which joints will be topological joints and which will be kinematic joints, a graph is constructed to show connections where the bodies are vertices and the joints are arcs. This graph is decomposed into a tree, and the joints corresponding to arcs that are not used in the tree are transformed into kinematic joints.

The Model Topology (p. 1369) view displays whether joints are based on degrees of freedom or constraint equations.

Kinematic Variables vs. Geometry Variables

Euler's theorem on rotations states that an arbitrary rotation can be parameterized using three independent parameters. The choice of these three parameters is not unique, and many choices are possible. For example:

- A sequence of three rotations, as introduced by Euler (the first rotation around X, the second rotation around the rotated Y' axis, and the third rotation around the updated Z'' axis). Many other sequences of rotations exist, among them the Bryant angles.
- The 3 components of the rotation vector
- Etc…

Unfortunately, these minimal sets of parameters are not perfect. Sequences of angles usually have some singular configurations, and the composition of rotations using these angles is simple. This composition of rotation is intensively used in transient simulation. For example, it can be used to prevent the use of the rotation vector.

Another option is to use the 3x3 rotation matrix. Composition of rotations is easy with this option, as it corresponds to matrix multiplication; however, this matrix is an orthogonal matrix, and time integration must be done carefully to maintain the matrix properties.

A good compromise is to use quaternion, which have 4 parameters and a normalization equation.

Once rotation parameters have been selected, the time derivatives of these parameters have to be established:

$$\{\dot{g}\} = f(g, \vec{\Omega}) \tag{7}$$

where $\vec{\Omega}$ is the angular velocity vector.

Two sets of variables exist:

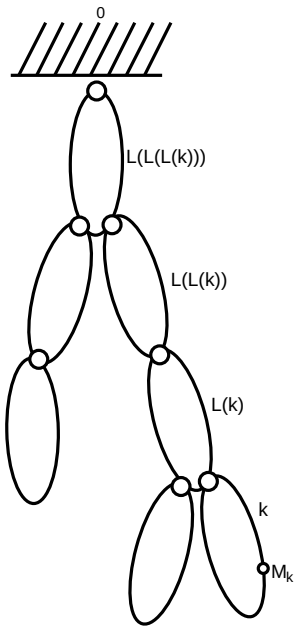
- Kinematic variables, expressed as $\{q\}$: $\vec{\Omega}$ as long as the translational velocities.
- Geometric variables, expressed as $\{g\}$, as well as the position variables for the translations. The geometric variables are obtained by time-integration of the kinematic variables.

Rigid Shape Functions

Shape functions, also called generalized velocities, are the projections of the velocity of material point M_k attached to body k on the kinematic variables of the model. Generalized velocities of a material point are depicted in the figure below:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

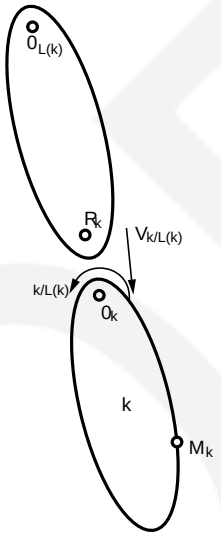
Figure 7: Generalized Velocities of a Material Point



Because of the choice of relative degrees of freedom, the velocity of M_k is a function of kinematic variables of the joint located between body *k* and its parent body *L(k)*, as well as those of the joint between *L(k)* and *L(L(k))*, continuing until the ground is reached.

To understand how these generalized velocities are formed, it helps to first focus on the contribution of the first joint of the chain (pictured below). This joint is located between body *k* and its parent, *L(k)*.

Figure 8: Contribution of the Parent Joint to the Generalized Velocities



Because body *k* is rigid, the velocity of point M_k with respect to the ground 0 can be expressed from the velocity of point O_k. Point O_k is the material point on the mobile coordinate system of the joint between body *k* and its parent, *L(k)*. This is expressed as follows:

$$\vec{V}_{Mk/0} = \vec{V}_{Ok/0} + \vec{\Omega}_{k/0} \wedge \overrightarrow{O_k M_k} \tag{8}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The angular velocity of body *k* with respect to the ground $\vec{\Omega}_{k/0}$ can be expressed as the angular velocity of its parent, plus the contribution of the joints linking body *k* and its parent, *L(k)*. This is expressed as follows:

$$\vec{\Omega}_{k/0}=\vec{\Omega}_{L(k)/0}+\vec{\Omega}_{k/L(k)} \tag{9}$$

Similarly, $\vec{V}_{Ok/0}$ can be expressed using point R_k , which is the reference coordinate system of the joint between body *k* and its parent, *L(k)*. Note that R_k is a material point on body *L(k)*. This is expressed as follows:

$$\vec{V}_{Ok/0}=\vec{V}_{Rk/0}+\vec{\Omega}_{L(k)/0}\wedge\overrightarrow{R_kO_k}+\vec{V}_{k/L(k)} \tag{10}$$

where $\vec{V}_{k/L(k)}$ is the joint relative velocity, i.e. the translational velocity between body *k* and its parent, *L(k)*.

It is important to realize that the vector $\overrightarrow{R_kO_k}$ has an angular velocity of $\vec{\Omega}_{L(k)/0}$. Joints can have translational degrees of freedom, and rotational degrees of freedom. The translation is expressed in the reference coordinate system, while the rotation center is the moving coordinate system. In other words, the joint translation is applied first, and the rotation is applied after the coordinate system is updated with the results of the joint translation. The decomposition of the Model Topology graph into a tree results in an oriented parent-child relationship. When the joint has both translational and rotational degrees of freedom and its reference coordinate system is on the child side, the joint must be split into a rotational joint linked to the parent side, and a translational joint linked to the child side, with a fictitious mass-less body between these two joints. While this is an internal representation of that "reverted" joint (that is, a joint that has both translational and rotational degrees of freedom and a link to the ground on the mobile coordinate system side), results are reported on the original user-defined joint.

Because R_k is a material point of body *L(k)*, the same methodology can be used to decompose the velocity into the contribution of the parent joint located between *L(k)* and *L(L(k))* and the contribution of the parent.

Two important quantities have been introduced in this process:

- $\vec{\Omega}_{k/L(k)}$ is the joint contribution to the angular velocity of body *k*.
- $\vec{V}_{k/L(k)}$ is the joint contribution to the translational velocity of point M_k

The concept of recursive calculation of the generalized velocities has also been introduced. The generalized velocities on body *k* can be computed by adding the contribution of the parent joint to the generalized velocities of body *L(k)*.

The contribution of each joint in the chain between body *k* and the ground can be found and expressed as:

$$\vec{V}_{Mk/0}=\sum_i \vec{V}_i q_i \tag{11}$$

$$\vec{\Omega}_{k/0}=\sum_i \vec{\Omega}_i q_i \tag{12}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Vector $\vec{V}_i$, which is associated with the kinematic variable q_i, is the "partial velocity" of the variable expressed at point M_k. It is configuration dependent, that is, it varies with the geometric variables of the joints located between body *k* and the ground.

The translational and accelerations can similarly be derived to obtain:

$$\vec{\Gamma}_{Mk/0}=\sum_i\left(\vec{V}_{Ok\,i}\dot{q}_i+\dot{\vec{V}}_{Ok\,i}q_i\right) \tag{13}$$

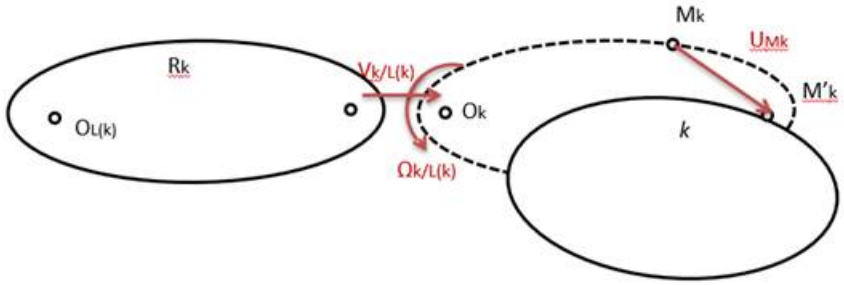
$$\dot{\vec{\Omega}}_{k/0}=\sum_i\left(\vec{\Omega}_i\dot{q}_i+\dot{\vec{\Omega}}_i q_i\right) \tag{14}$$

Flexible Shape Functions

We assume here that the body is not rigid anymore, but undergoes small elastic deflections.

To define the position of a point of body k, we use a floating reference rigid body and define a small displacement vector between the point and its reference position on the floating reference body.

Figure 9: Flexible Bodies Kinematics



With the assumption of small deflections and elastic behavior, sub-structuring can be used to reduce the flexible body to a small set of DOFs. We will define a set of generalized coordinates q_i such that:

$$\{u_M\}=\sum_1^n\{N_{i\,M}\}y_i=[N]u$$

The global position of M' becomes:

$$\overrightarrow{OM'}=\overrightarrow{OO_k}+\overrightarrow{O_kM}+\overrightarrow{MM'}=\overrightarrow{OO_k}+\overrightarrow{O_kM}+[N]u \tag{15}$$

The global velocity of M' is expressed by:

$$\vec{V}_{M_{k/0}}=\vec{V}_{O_{k/0}}+\vec{\Omega}_{k/0}\wedge\overrightarrow{O_kM}+\vec{\Omega}_{k/0}\wedge[N]u+[N]\dot{u} \tag{16}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Compared to the rigid case, the translational shape functions are modified to be expressed at the flexible point location, and the flexible generalized coordinates now contribute to the shape functions.

The basis of vectors [*N*] is obtained using a Component Mode Synthesis analysis with Fixed Interfaces (see Component Mode Synthesis (CMS) in the *Theory Reference* for more details). Master nodes are created for each joint connected to the condensed part. The internal modes and attachment modes Φ are orthogonalized to form the N basis.

The point O_k can be any point in the condensed part. However, in practice, it can be either on a joint or on the center of gravity of the condensed part.

Note:

Before simulating a model that contains a condensed part, the Rigid Dynamics solver first runs a sanity check. An eigenvalue decomposition called free-free modal analysis in the log is calculated with free master nodes based on the reduced mass and stiffness matrices provided by the MAPDL solver.

The purpose of this decomposition is to check that the condensed part contains exactly six rigid modes, which are near zero frequency. The first flexible frequency is used to estimate the time step required by the Rigid Dynamics analysis, which must be smaller than the inverse of that frequency.

Equations of Motion

Equations of Motion for Rigid Bodies

Many methods are available to derive the equations of motion, such as Newton Euler equations, Gibbs-Appell equations, and Lagrange equations.

The combination of Gibbs-Appell equations with generalized velocities is often referred to as Kane's equations [KAN61 (p. 652)]. Kane's equations are used for this example.

Open Loop Equations of Motion

The positional variation of a point M_k on body *k* is written as a reduction point using the origin of the body O_k :

$$\delta\vec{M}_k=\delta\vec{O}_k+\delta\vec{\Omega}_{k/0}\wedge\overrightarrow{O_kM_k} \tag{17}$$

Similarly, the translational acceleration of point M_k can be expressed using reduction point O_k :

$$\vec{\Gamma}_{Mk/0}=\sum_i\left(\vec{V}_{Oki}\dot{q}_i+\dot{\vec{V}}_{Oki}q_i\right)+\sum_i\left(\vec{\Omega}_i\dot{q}_i+\vec{\Omega}_iq_i\right)\wedge\overrightarrow{O_kM_k}+\vec{\Omega}_iq_i\wedge(\vec{\Omega}_iq_i\wedge\overrightarrow{O_kM_k}) \tag{18}$$

The virtual work of the acceleration can be formed and integrated over body *k*, and summed over the bodies as follows:

$$\sum_k\int_k\vec{\Gamma}_{Mk/0}.\delta\vec{M}_kdm \tag{19}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The integration over the body leads to integrating quantities as follows:

$$\int_k \overrightarrow{O_k M_k}\ dm \tag{20}$$

These terms can be easily pre-calculated as follows:

$$\int_k \overrightarrow{O_k M_k}\ dm = m_k \overrightarrow{O_k G_k} \tag{21}$$

In this equation, M_k stands for the mass of body *k*, and G_k stands for the center of gravity of that body. Other terms lead to:

$$\int_k \overrightarrow{O_k M_k}\ \hat{}\ v\ \hat{}\ \overrightarrow{O_k M_k}\ dm \tag{22}$$

where v is a constant vector. Those terms can be expressed as a function of the inertia tensor of body *k*.

Similarly, the virtual work of external distributed forces is computed as follows:

$$\int \vec{F}_{ext} . \delta \vec{M}_k \tag{23}$$

Finally, the open loop equations of motion lead to the following algebraic system:

$$M\{\dot{q}\} = F \tag{24}$$

Both the mass matrix *M* and the force vector *F* are dependent on the geometric variables and time *t*. The force vector is also a function of the generalized velocities.

$$M(g,t)\{\dot{q}\} = F(g,q,t) \tag{25}$$

When the mass and inertia properties of a rigid body are not constant, the force vector includes some additional terms dependent on the mass matrix time derivatives $\dot{M}$.

Equations of Motion with Flexible Bodies

Assuming that body k is flexible, the variation of the position of a point M'_k on body k is written, using the origin of the body O_k as a reduction point:

$$\vec{\delta}_{M'} = \vec{V}_m \delta q_m + \vec{\Omega}_m \delta q_m \wedge \left(\overrightarrow{O_k M} + [N]u \right) + \vec{N}_j \delta u_j \tag{26}$$

Similarly, the translational acceleration of point M'_k can be expressed using a reduction point O_k

$$\overrightarrow{\Gamma_{M'/O}} = \vec{V}_l \ddot{q}_l + \vec{V}_l \dot{q}_l + \left(\vec{\Omega}_l \ddot{q}_l + \vec{\Omega}_l \dot{q}_l \right) \wedge \left(\overrightarrow{O_k M} + [N]u \right) + \vec{\Omega}_l \dot{q}_l \wedge \left(\vec{\Omega}_l \dot{q}_l \wedge \overrightarrow{O_k M'} \right) + 2.* \vec{\Omega}_l \dot{q}_l \wedge \vec{N}_i \dot{u}_i + \vec{N}_i \ddot{u}_i \tag{27}$$

As in the case of rigid bodies, the virtual work of the acceleration can be formed and integrated over body k, and summed over the bodies:

$$\sum_k \int_k \vec{\Gamma}_{M'_{k/0}} . \overrightarrow{\delta M'}_k dm \tag{28}$$

In presence of flexible bodies, the equations of motion are modified by 2 sets of terms:

- Terms that involve only the set of flexible degrees of freedom only,

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Coupling terms, involving flexible degrees of freedom and rigid degrees of freedom.

Please refer to [SHA13 (p. 652)] for more detailed information about the equations of motion.

Because the equilibrium is written on the current (deformed) configuration, the mass matrix and right hand side depend on the flexible degrees of freedom. To avoid having to go back to the finite element model to compute these integrals, these terms are decomposed over a basis of invariant terms, which are computed only once in the generation pass.

These invariants are expressed below. These terms are approximated using a lumped mass approach.

$$I_1 = \int \vec{N}_i dm \approx \sum_{i=0}^{n} M_{i,i} \cdot \Phi(i) \tag{29}$$

$$I_2 = \int \overrightarrow{OM} \wedge \vec{N}_i dm \approx \sum_{i=0}^{n} M_{i,i} \cdot \left(\vec{P}_i \wedge \overrightarrow{\Phi(i)} \right) \tag{30}$$

$$I_3 = \int \overrightarrow{OM} \cdot \vec{N}_i dm \approx \sum_{i=0}^{n} M_{i,i} \cdot \left(\vec{P}_i \cdot \overrightarrow{\Phi(i)} \right) \tag{31}$$

$$I_4 = \int \left(\vec{N}_i \right)_x \cdot \overrightarrow{OM} dm \approx \sum_{i=0}^{n} M_{i,i} \cdot \left(\Phi_i x \vec{P} \right) \qquad resp.\ y,z \tag{32}$$

$$I_5 = \int \overrightarrow{N_i N_j} dm \approx \sum_{i=0}^{n} \sum_{j=0}^{m} M_{i,i} \cdot \Phi_i \cdot \Phi_j \tag{33}$$

$$I_6 = \int \vec{N}_i \wedge \vec{N}_j dm \approx \sum_{i=0}^{n} \sum_{j=0}^{m} M_{i,i} \cdot \Phi_i \wedge \Phi_j \tag{34}$$

Where the *Φ(i)* are the Component Mode Synthesis base vectors.

Closed Loop Equations of Motion

When the model has some closed loops, not all joints can be treated as topological joints, thus requiring constraint equations to be added to the system. These constraint equations are usually written in terms of velocities as follows:

$$B(g)\{q\} = H(g,t) \tag{35}$$

Each kinematic joint generates up to six of these equations, depending on the motion direction that the joint fixes.

To be introduced in the equations of motion, a time derivative of these equations must be written as follows:

$$B(g)\{\dot{q}\} = \dot{H}(g,t) = G(g,t) \tag{36}$$

The equations of motion for the closed loop system become:

$$M(g,t)\{\dot{q}\} = F(g,q,t) \tag{37}$$

Subject to:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

$$B(g)\{\dot{q}\}=\dot{H}(g,t)=G(g,t) \tag{38}$$

An additional scalar variable λ (called a Lagrange Multiplier) is introduced for each constraint equation. These constraint equations are introduced in the algebraic system, which then becomes:

$$\begin{pmatrix} M & B^T \\ B & 0 \end{pmatrix}\begin{Bmatrix} \dot{q} \\ \lambda \end{Bmatrix}=\begin{Bmatrix} F \\ G \end{Bmatrix} \tag{39}$$

M, B, F, and G can be formed from a set of known geometric variables and kinematic variable values. The above system can be resolved, providing both accelerations $\dot{q}$ and Lagrange multipliers λ.

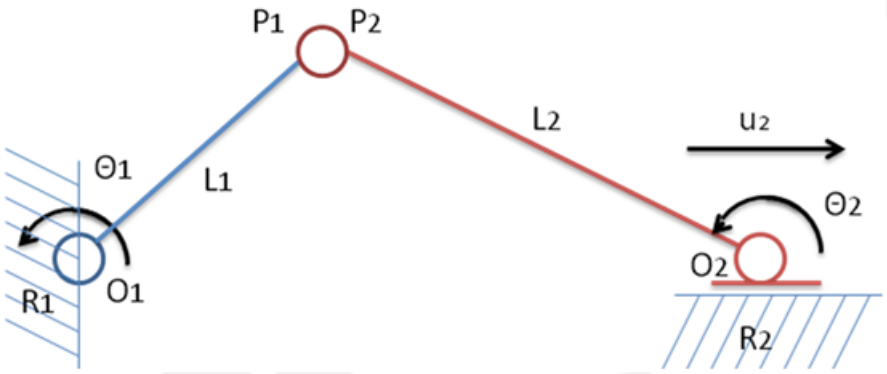
These Lagrange multipliers can be interpreted as constraint forces, equivalent to the amount of force needed to prevent motion in the direction of the constraint equations.

Redundant Constraint Equations

The system matrix shown in Equation 39 (p. 636) has size n+m where n is the number of degrees of freedom, and m is the number of constraint equations in *B*. The mass matrix *M* is usually positive-definite, but the full matrix including the constraint equation will retain that property only if there are no redundant constraint equations in *B*.

The constraint equations are applied to the piston/crankshaft system shown below to demonstrate how the *B* matrix can contain redundant constraint equations.

Figure 10: Crankshaft Mechanism



The revolute joint between point P1 on body 1 and point P2 on body 2 generates five constraint equations. For the sake of simplicity, these equations are written below in the global coordinate system, even if it is not always possible in general cases. The equations are:

1. $\left(\vec{v}_{P_2}-\vec{v}_{P_1}\right).\vec{x}=0$
2. $\left(\vec{v}_{P_2}-\vec{v}_{P_1}\right).\vec{y}=0$
3. $\left(\vec{v}_{P_2}-\vec{v}_{P_1}\right).\vec{z}=0$
4. $\left(\vec{\Omega}_2-\vec{\Omega}_1\right).\vec{x}=0$
5. $\left(\vec{\Omega}_2-\vec{\Omega}_1\right).\vec{y}=0$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

These equations must be projected on the degrees of freedom. This is achieved in the code by writing the shape functions on each body on points P1 and P2:

$$\vec{v}_{P_2} = \dot{u}_2\vec{x} + \dot{\Theta}_2\vec{z} \wedge \overrightarrow{O_2P_2} \tag{40}$$

$$\vec{\Omega}_2 = \dot{\Theta}_2\vec{z} \tag{41}$$

and:

$$\vec{v}_{P_1} = \dot{\Theta}_1\vec{z} \wedge \overrightarrow{O_1P_1} \tag{42}$$

$$\vec{\Omega}_1 = \dot{\Theta}_1\vec{z} \tag{43}$$

Replacing the velocities in the five constraint equations leads to:

1. $\dot{u}_2 + \dot{\Theta}_2 L_2 sin\Theta_2 = \dot{\Theta}_1 L_1 sin\Theta_1$
2. $\dot{\Theta}_2 L_2 cos\Theta_2 = \dot{\Theta}_1 L_1 cos\Theta_1$
3. $0 = 0$
4. $0 = 0$
5. $0 = 0$

The five equations above only generate two nontrivial constraints. The third equation indicates that the mechanism cannot shift along the z axis. It also indicates that the mechanism cannot be assembled if the z-coordinate of O_2 and O_2 are not the same. Similarly, the fourth and fifth equations indicate that the orientation of the axis of the revolute joint in P1/P2 is already entirely dependent on the axis of the two other revolute joints. A manufacturing error in the parallelism of the axis would result in a model that cannot be assembled. As such, this system is redundant.

Because introducing the five equations into Equation 39 (p. 636) would make the system matrix singular, some processing must be done on the full set of equations to find a consistent set of equations. Equations that are trivial need to be removed, as well as equations that are colinear. An orthogonalization technique is used to form a new set of equations that keep the matrix invertible. The matrix is decomposed into two orthogonal matrices, B_f and R:

$$[B] = [B_f][R] \tag{44}$$

where the $[B_f]$ matrix has a full rank and $[R]$ is a projection matrix. This matrix can then used in Equation 39 (p. 636):

$$\begin{pmatrix} M & B_f{}^T \\ B_f & 0 \end{pmatrix} \begin{Bmatrix} \dot{q} \\ \lambda_f \end{Bmatrix} = \begin{Bmatrix} F \\ G \end{Bmatrix} \tag{45}$$

Joint Forces Calculation

A benefit of using Kane's equations and relative parameters is that joint forces in topological joints are eliminated from the algebraic system. Joint forces can be calculated explicitly by writing the dynamic equilibrium of each body recursively, starting from the leaves of the tree associated with the connection graph, with the unknown being the body parent joint's forces and torque.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

When the system has redundancies, that is, the [*B*] matrix does not have a full rank, some forces cannot be calculated. In the crankshaft example, no information is available in the forces developing in the revolute joint in P1/P2 in the z direction, and the moments cannot be calculated in this joint. These values will be reported as zero, but it is recommended that you avoid such situations by releasing some of the degrees of freedom in the system.

Time Integration with Explicit Runge-Kutta

Equation 25 (p. 634) (open loop) and Equation 39 (p. 636) (closed loop) provide a relation between generalized accelerations $\{\dot{q}\}$ and generalized velocities {q}.

Equation 7 (p. 629) provides a relation between generalized velocities $\{q\}$ and the time derivatives of the geometry variables $\{\dot{g}\}$

These two sets of equations form a system of first order explicit ordinary differential equations (ODE).

$$\dot{y}=f\left(y,t\right) \tag{46}$$

This system is integrated using the explicit Runge-Kutta method RK4.

RK4 Method

The fourth order method is based on four estimations. Given an initial value *y* at time value *t*, and a time step value *dt*, the following four estimations are formed:

$$\dot{y}_1=f\left(y,t\right) \tag{47}$$

$$\dot{y}_2=f\left(y+\frac{dt}{2}\dot{y}_1,t+\frac{dt}{2}\right) \tag{48}$$

$$\dot{y}_3=f\left(y+\frac{dt}{2}\dot{y}_2,t+\frac{dt}{2}\right) \tag{49}$$

$$\dot{y}_4=f\left(y+dt\dot{y}_3,t+dt\right) \tag{50}$$

A fourth order approximation of *y(t+dt)* is given by:

$$y\left(t+dt\right)\simeq y+\frac{dt}{6}\left(\dot{y}_1+2\dot{y}_2+2\dot{y}_3+\dot{y}_4\right) \tag{51}$$

Adaptive Time Stepping (for explicit time integration)

Time step *dt* must be chosen carefully for the integration of the ODEs to ensure that it is stable (that is, not becoming exponentially large), and accurate (that is, the difference between the approximation of the solution and the exact solution is controlled).

RK4 is conditionally stable, meaning that stability can be guaranteed if the time step is small enough. While the algorithm is accurate when it is stable, the time step chosen must be large enough to maintain computational efficiency.

For both integration schemes, quantifying the amount of kinetic energy contained in the highest order term of the polynomial approximation can give a good indication of whether the time step should be reduced or increased.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

If the energy in the high order term is too large, it is likely that the approximation is inaccurate, and the time step should smaller.

If this energy is significant and controlled, the time step can be accepted, but the time step used will be smaller.

If the energy is low, then the next time step can be increased.

Rigid body systems usually have relatively slow motion, but the following factors can lead to smaller time steps:

- Existence of stiff springs and bushing in the model
- Three-dimensional rotations
- Proximity to geometrically singular configurations, such as the top, dead center position of a piston/crankshaft mechanism

These factors imply that the optimal time step varies with the system velocities and configuration, and thus cannot be determined before running the solution. As a consequence, automatic time stepping generally should not be turned off.

When automatic time stepping is used, the energy balance of the system is maintained within the tolerance that is requested. Note that impacts and shock can be non-conservative, and will affect the energy balance. This loss during impact is detailed in Contact and Stops (p. 645).

Implicit Generalized-α Method

Implicit Generalized-α Method

This family of methods was initially developed by Chung and Hilbert for the resolution of dynamics in the context of computational mechanics of solids. Cardona and Géradin adapted the method to compute the dynamics of multibody systems. Many extensions have been developed in the past, such as the extension developed by O. Brüls and M. Arnold for dynamics equations formulated as an index-3 DAE. The dynamics is written at time t_{n+1} as:

$$\begin{cases} M\ddot{q}_{n+1} = F(q_{n+1}, \dot{q}_{n+1}, t_{n+1}) + G^T(q_{n+1})\lambda_{n+1} \\ g(q_{n+1}) = 0 \end{cases} \tag{52}$$

The acceleration-like variable a_n is defined by the recurrence relation as:

$$(1-\alpha_m)a_{n+1} + \alpha_m a_n = (1-\alpha_f)\ddot{q}_{n+1} + \alpha_f \ddot{q}_n \tag{53}$$

At the beginning of the simulation, this variable is initialized as $a_0 = \ddot{q}_0$. The following difference equations relate q_{n+1}, $\dot{q}_{n+1}$, and a_n, a_{n+1}:

$$\begin{cases} q_{n+1} = q_n + h\dot{q}_n + h^2\left(\frac{1}{2} - \beta\right)a_n + h2\beta a_{n+1} \\ \dot{q}_{n+1} = \dot{q}_n + h(1-\gamma)a_n + h\gamma a_{n+1} \\ g(q_{n+1}) = 0 \end{cases} \tag{54}$$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

where the constants of α_f, α_m, β, and γ are suitably chosen so that the scheme is stable. The algorithm is unconditionally stable if the coefficients are chosen such that for $\rho_\infty<1$,

$$\begin{cases} \alpha_m=\frac{2\rho_\infty-1}{\rho_\infty+1}<\frac{1}{2} \\ \alpha_f=\frac{\rho_\infty}{\rho_\infty+1}<\frac{1}{2} \\ \gamma=\frac{1}{2}+\alpha_f-\alpha_m>\frac{1}{2} \\ \beta=\frac{1}{4}\left(\gamma+\frac{1}{2}\right)^2 \end{cases} \tag{55}$$

The scheme is based on a prediction step and a correction step where some Newton iterations are performed in order to solve the dynamical and the constraint residuals R_q and R_λ, defined by:

$$\begin{cases} R_q(q_{n+1}^k,\dot{q}_{n+1}^k,t_{n+1})=M(q_{n+1},t_{n+1})\ddot{q}_{n+1}-F(q_{n+1},\dot{q}_{n+1},t_{n+1})-G^T(q_{n+1})\lambda_{n+1}=0 \\ R_\lambda(q_{n+1})=g(q_{n+1})=0 \end{cases} \tag{56}$$

The Newton iterations solve the following linear system:

$$\begin{pmatrix} \beta' M(q_{n+1}^k,t_{n+1})+\gamma' C_t\left(q_{n+1},\dot{q}_{n+1}^k,t_{n+1}\right)+K_t\left(q_{n+1}^k,\dot{q}_{n+1}^k,t_{n+1}\right) & -G^T\left(q_{n+1}^k\right) \\ G\left(q_{n+1}^k\right) & 0 \end{pmatrix}\begin{pmatrix}\Delta q \\ \Delta\lambda\end{pmatrix}=-\begin{pmatrix} R_q\left(q_{n+1}^k,\dot{q}_{n+1}^k,t_{n+1}\right) \\ R_\lambda\left(q_{n+1}^k\right)\end{pmatrix} \tag{57}$$

where $\beta'=\frac{1-\alpha_m}{h^2\beta(1-\alpha_f)}$, $\gamma'=\frac{\gamma}{h\beta}$, M is the inertia matrix, $K_t=\frac{\partial\left(M\ddot{q}-F+G^T\lambda\right)}{\partial q}$ is the stiffness matrix, and $C_t=-\frac{\partial F}{\partial\dot{q}}$ is the damping matrix, and *k* denotes the number of the Newton iterations. Note that this algorithm maintains the constraints at the position level, but it can also be reformulated to write the constraints at the velocity level or the acceleration level.

When considering the constraints at the velocity level, the problem is formulated as an index-2 DAE, whose discretization is given by the first two equations of Equation 54 (p. 639), as well as:

$$G\left(q_{n+1}\right)v_{n+1}=0 \tag{58}$$

In this case, the correction step is performed using Newton iterations to solve the following linear system:

$$\begin{pmatrix} \beta' M(q_{n+1},t_{n+1})+\gamma' C_t\left(q_{n+1},\dot{q}_{n+1},t_{n+1}\right)+K_t\left(q_{n+1},\dot{q}_{n+1},t_{n+1}\right) & -G^T\left(q_{n+1}\right) \\ G\left(q_{n+1}\right) & 0 \end{pmatrix}\begin{pmatrix}\Delta\dot{q} \\ \Delta\lambda\end{pmatrix}=-\begin{pmatrix} R_q\left(q_{n+1}^k,\dot{q}_{n+1}^k,t_{n+1}\right) \\ G\left(q_{n+1}\right)v_{n+1}\end{pmatrix} \tag{59}$$

where:

$$\beta'=\frac{1-\alpha_m}{h\beta(1-\alpha_f)}$$

$$\gamma'=\frac{h\beta}{\gamma}$$

The integration error is estimated using the methodology proposed by Géradin and Cardona for the **HHT** schemes family. The exact value of the positions vector can be approximated using a truncated Taylor series development around t_n as follows:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

$$q_e(t_n+h)=q_n+h\dot{q}_n+\frac{h^2}{2}\ddot{q}_n+\frac{h^3}{6}\dddot{q}_n+O(h^4) \tag{60}$$

The integration error is computed as:

$$err=q_{n+1}-q_e(t_n+h) \tag{61}$$

By substituting the expression q_{n+1} from Equation 54 (p. 639) into Equation 61 (p. 641), we obtain:

$$err=h^2\left(\frac{1}{2}-\beta\right)a_n+h^2\beta a_{n+1}-\frac{h^2}{2}\ddot{q}_n-\frac{h^3}{6}\dddot{q}_n+O(h^4) \tag{62}$$

The third derivative $\dddot{q}_n$ of the position can be approximated by:

$$\dddot{q}_n=\frac{\ddot{q}_{n+1}-\ddot{q}_n}{h}+O(h) \tag{63}$$

By substituting a_{n+1} and $\dddot{q}_n$ into Equation 62 (p. 641), and by using the relations in Equation 54 (p. 639), we obtain:

$$err=q_{n+1}-q_n-\frac{1}{h}\dot{q}_n-\frac{h^2}{3}\ddot{q}_n-\frac{h^2}{6}\ddot{q}_{n+1}+O(h^4) \tag{64}$$

Adaptive Time Stepping (for implicit time integration)

Much like RK4, the Implicit Generalized-α method also implements an adaptive time stepping strategy based on the energy conservation. However, the order of the Implicit Generalized-α method is lower than RK4. Consequently, the Implicit Generalized-α method may require smaller time steps than explicit method to achieve the same accuracy.

Unlike RK4, the Implicit Generalized-α method is unconditionally stable. This method remains stable even for large time steps, regardless the accuracy. As such, it is particularly suitable to address situations where the explicit RK4 method requires small time steps. The energy tolerance control can be relaxed in these situations, and the time step is driven only by the Newton-Raphson convergence. If a large number of iterations was required for the last time step, the time step decreases. Conversely, if fewer iterations were required for convergence of the previous time step, the time step increases.

Stabilized Implicit Generalized-α Method

At the end of each time step, violated constraints equations are corrected as explained in Geometric Correction (p. 643). However, this correction perturbs the dynamics of the system and may introduce artificial energy to the system, which leads to vibrations when flexible bodies are involved. These artificial vibrations cause the time integration method to use tight time steps and more iterations which leads to long simulation times. The Stabilized Generalized-α method remedies this issue.

The equations of the dynamics are discretized as in Equation 59 (p. 640). A new Lagrange multiplier is introduced which satisfies the position-level constraints equations:

$$M(q_n)U_n-G^T(q_n)\mu_n=\vartheta(h^2) \tag{65}$$

Where U_n represents the position gap needed to vanish the violation $g(q_n)$. The correction of this position drift is achieved using:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

$$\begin{pmatrix} M(q_n) & -G^T(q_n) \\ G(q_n) & 0 \end{pmatrix} \begin{pmatrix} U_n \\ \mu_n \end{pmatrix} = - \begin{pmatrix} 0 \\ g(q_n) \end{pmatrix} \tag{66}$$

This correction is followed by another dynamics solve using Equation 59 (p. 640). In this way, both the dynamics and the applied constraints are satisfied, which leads to more stable numerical systems.

Compared to the Generalized-α method, the Stabilized Generalized-α method uses larger average time steps and needs less iterations to converge.

Moreau-Jean Method

In time-stepping schemes, the formulation of the dynamics equations enables the scheme to simultaneously handle the smooth dynamics and non-smooth dynamics. The idea behind these schemes is to consider the dynamics equations as a measure differential inclusion. On the velocity level, they are expressed as:

$$\begin{cases} \dot{q} = v \\ M(q)\frac{dv}{dt} = F(q,v,t) + di \\ -di \in N_{T_C(q)}(v^+) \end{cases} \tag{67}$$

where di is the reaction measure.

In the case $C = \mathbb{R}^+$:

$$0 \le \lambda \perp g \ge 0 \Leftrightarrow -\lambda \in N_{\mathbb{R}^+}(g) \supseteq N_{T_{\mathbb{R}^+}(g)}(\dot{g}^+) \tag{68}$$

therefore:

$$\begin{cases} g > 0 \Rightarrow \dot{g}^+ \in T_{\mathbb{R}^+}(g) = \mathbb{R} \text{ and } N_{\mathbb{R}^+}(g) = \{0\} \\ g = 0 \Rightarrow \dot{g}^+ \in T_{\mathbb{R}^+}(g) = \mathbb{R}^+ \text{ and } N_{\mathbb{R}^+}(g) = \mathbb{R}^- \end{cases} \tag{69}$$

In the Moreau-Jean time stepping method (MJ Time Stepping (p. 1436)), unilateral contact is modeled with a Signorini condition at the velocity level, that is a complementarity between the contact impulse and the relative velocity, which ensures impenetrability. In order to handle multiple contacts with potentially changing status, an implicit algorithm is used to integrate the dynamics. As a simplified example, consider $F_{\text{int}}(q,v) = -C\dot{q} - Kq$ and $M(q) = M$. The discrete form of the equations of motion is:

$$\begin{cases} q(t_{i+1}) = q(t_i) + \int_{]t_i,t_{i+1}]} v^+ \, dt \\ M(v^+(t_{i+1}) - v^+(t_i)) = \int_{t_i}^{t_{i+1}} ((-Cv(t) - Kq(t)) + F_{ext}) \, dt + \int_{]t_i,t_{i+1}} di \end{cases} \tag{70}$$

The smooth terms may be discretized using a θ-method as:

$$\begin{cases} q_{i+1} = q_i + h[\theta v_{i+1} + (1-\theta) v_i] \\ \int_{t_i}^{t_{i+1}} (Cv^+ + Kq) \, dt = h(\theta(Cv_{i+1} + Kq_{i+1}) + (1-\theta)(Cv_i + Kq_i)) \\ \int_{t_i}^{t_{i+1}} F_{ext} \, dt = h(\theta(F_{ext})_{i+1} + (1-\theta)(F_{ext})_i \end{cases} \tag{71}$$

then:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

$$\begin{cases} q_{i+1}=q_i+h(\theta v_{i+1}+(1-\theta)v_i) \\ v_{i+1}=v_{\text{free}}+\hat{M}^{-1}p_{i+1} \\ \widehat{M}=M+h\theta C+h^2\theta^2 K \\ v_{\text{free}}=v_i+\hat{M}^{-1}(-hCv_i-hKq_i-h^2\theta K v_i+h[\theta(F_{ext})_{i+1}+(1-\theta)(F_{ext})_i]) \end{cases} \tag{72}$$

where $p_{i+1}\approx\int_{]t_i,t_{i+1}]}di$ is the approximation of the impulse over the time step. Note that the acceleration of the system is never explicitly computed because it becomes infinite for impulsive forces. The kinematic equations are discretized as follows for contact α:

$$\begin{cases} \dot{g}^{\alpha}_{n+1}=G^{\alpha}(q_{n+1})v_{n+1} \\ P^{\alpha}_{n+1}\approx\int_{]t_n,t_{n+1}}d\lambda^{\alpha} \\ p^{\alpha}_{n+1}=G^{\alpha T}P^{\alpha}_{n+1} \\ g^{\alpha}_{n+1}=g^{\alpha}_{n+1}+h(\theta\dot{g}^{\alpha}_{n+1}+(1-\theta)\dot{g}^{\alpha}_{n}) \\ \tilde{q}_{n+1}=q_n+\frac{h}{2}v_n \\ \text{if } g^{\alpha}(\tilde{q}_{n+1})\le 0 \text{ then } 0\le g^{\alpha}_{n+1}\perp P^{\alpha}_{n+1}\ge 0 \end{cases} \tag{73}$$

Finally, Newton's law is implicitly formulated as:

$$\begin{cases} \text{if } g^{\alpha}(\tilde{q}_{ni+1})\le 0 \text{ then } 0\le U^{\alpha}_{n+1}+eU^{\alpha}_{n}\perp P^{\alpha}_{n+1}\ge 0 \\ \text{if } g^{\alpha}(\tilde{q}_{ni+1})>0 \text{ then } P^{\alpha}_{n+1}=0 \\ U^{\alpha}_{n}=\dot{g}^{\alpha}_{n} \\ U^{\alpha}_{n+1}=\dot{g}^{\alpha}_{n+1} \end{cases} \tag{74}$$

Because the Moreau-Jean time stepping method is formulated in terms of non-smooth velocities, it better handles the acceleration discontinuities that can happen when the geometry is non-smooth. Consequentially, it is well-suited to work with mesh-based contact (p. 648).

Geometric Correction

Using relative parameters, the majority of joints are introduced in the system using their natural degrees of freedom. As a consequence, no matter how big the variation of the degrees of freedom is over the time step, these joints only allow motions that are consistent with the joint kinematics. For example, a revolute joint that has one single rotational degree of freedom can have an increment with a rotation of 3600 degrees in one time step, and it will still not generate out of plane motion, nor will the two points linked by the joint separate. Conversely, some joints are constraint equation based (all the graph closed-loop joints) and need special attention to satisfying proper joint kinematics.

The time integration schemes that are used provide a piecewise polynomial approximation of the solution. These schemes realize a polynomial approximation of the solution. The constraint equations such as those developed in the crankshaft example shown in Figure 10: Crankshaft Mechanism (p. 636) are not polynomial expressions of the geometric variables. Similarly the relation between kinematic variables and geometric variables, expressed as $\{\dot{g}\}=f(g,\vec{\Omega})$, is usually not polynomial. As a con-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

sequence, using for example the RK4 time integration, the constraint equations that are exactly satisfied in terms of accelerations at each of the Runge-Kutta estimations might not be satisfied in terms of velocities and positions at the end of the time step. After a number of time steps, closed loops will not be closed anymore, and points P1 and P2 in the crankshaft example will slowly drift away from each other.

To avoid these violations of constraint equations, various strategies can be used.

The drift of the violated constraints equations is corrected by a projection of the numerical solution. Two methods are available to perform it:

Pure Kinematic Method

As proposed by Dehombreux [DEH95 (p. 652)], this method is performed by projecting back the solution of the constraint equation.

Both positions and velocities can be projected back using this correction.

By projecting the solution, an increment of the geometry variables can be found iteratively:

$$B(g)\{\delta q\} = h_p \tag{75}$$

$$\delta g = f(g, \delta q) \tag{76}$$

$$g := g + \delta g \tag{77}$$

Note that the relation between the kinematic variables and the geometric variables is reused in an incremental form.

Because of the dependency of the constraint equations on the geometric variables, this solution is nonlinear, and must be performed until the increment δg is small enough.

Once the position has been corrected, another step can be done to correct velocities:

$$B(g)\{\Delta q\} = h_v \tag{78}$$

$$q := q + \Delta q \tag{79}$$

As these equations are not velocity dependent, there is no need to iterate on this system.

Inertia Matrix Method

In this method, geometry variables are calculated iteratively by solving:

$$\begin{pmatrix} M & B^T \\ B & 0 \end{pmatrix} \begin{pmatrix} \Delta q \\ \lambda \end{pmatrix} = - \begin{pmatrix} 0 \\ g \end{pmatrix} \tag{80}$$

Once convergence is reached, the velocity increments are obtained using

$$\begin{pmatrix} M & B^T \\ B & 0 \end{pmatrix} \begin{pmatrix} \Delta v \\ \lambda \end{pmatrix} = - \begin{pmatrix} 0 \\ \frac{dg}{dt} \end{pmatrix} \tag{81}$$

This method results from the minimization of kinetic energy. Using the inertia matrix for correction of violated constraints leads to more consistent results than when using the pure kinematic method. Furthermore, scaling with the inertia matrix M enables you to perform a resolution which is consistent with the metrics of the problem.

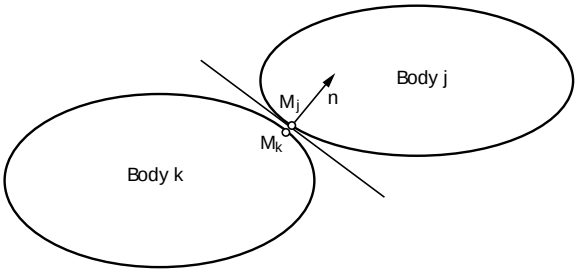
Contact and Stops

So far, the only interaction between bodies that has been considered was permanent joints; however, impacts and contacts will also play a significant role.

Contact Kinematics

The figure below depicts the contact between convex bodies *j* and *k*.

Figure 11: Contact Between Two Convex Bodies



The non-penetration equation below describes the contact between these bodies, and is written along the shared normal at the contact point:

$$\left(\frac{d\overrightarrow{OM_j}}{dt}-\frac{d\overrightarrow{OM_k}}{dt}\right).\vec{n}=0 \tag{82}$$

In this equation, the two points M_j and M_k are the points that minimize the distance between the two bodies, and thus are not material points, that is, their location varies over the bodies with time.

For more information on the definition of the contact point, refer to Pfeiffer [PFE96 (p. 652)] in References (p. 652).

Special Cases

Some special cases are worth mentioning. For instance, when contact occurs in a joint between two bodies linked by that joint, the contact points become material points, and Equation 82 (p. 645) can become dependent on one single degree of freedom. Figure 12: Stops on a Translational Joint (p. 646) shows an example of stop on a translational joint. Both left and right vertical surfaces can impact the red body, but this translates very easily into a simple double inequality:

$$u_m \leq u \leq u_M \tag{83}$$

where subscript $_m$ stands for the minimum bound, and M stands for the maximum bound. The normal here is replaced by the projection on the joint degree of freedom.

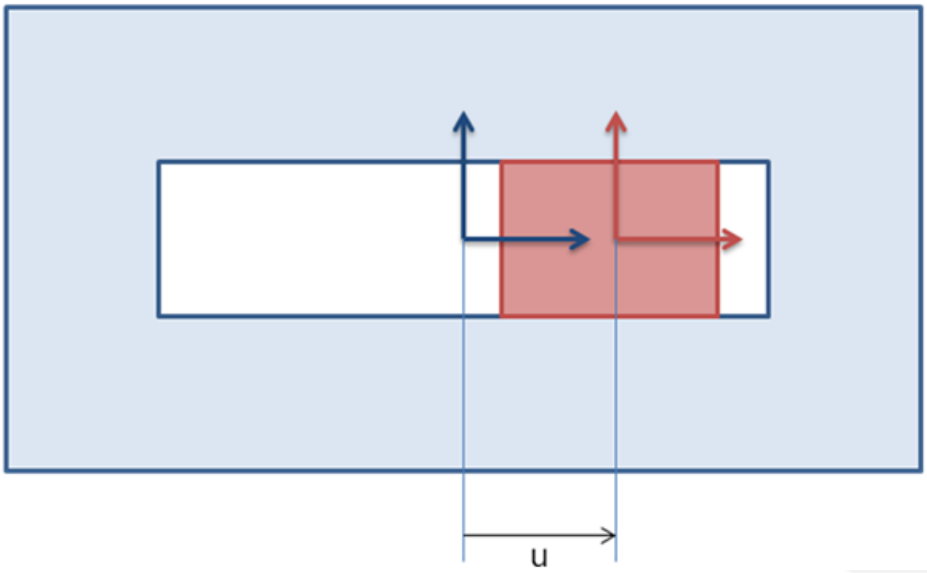
Published: 2023-10-23

Figure 12: Stops on a Translational Joint

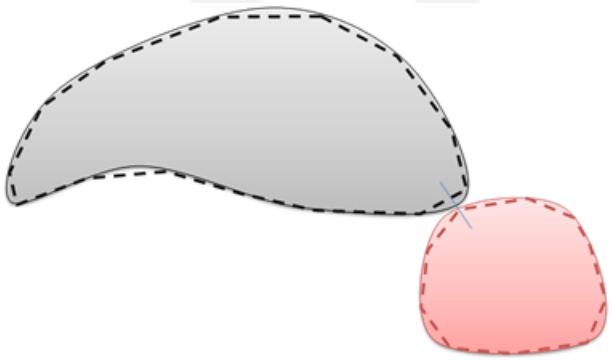


Another case of specialized contact geometry is the radial gap where contact points can be computed explicitly. In the general case of complex geometries, the strategy for computing the contact points and the impact times is more complex.

General Cases

In general cases, geometries that are potentially in contact are neither simple nor convex. It is however required to find the accurate position of the contact points between two bodies. Sometimes the contact point is unique, as shown in the figure below.

Figure 13: One Contact Point

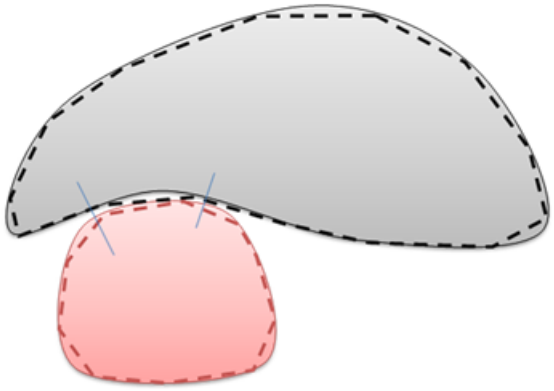


But for the same pair, the contact can occur in more than one point, as shown in the figure below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

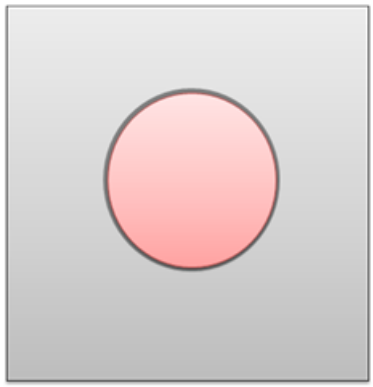
Published: 2023-10-23

Figure 14: Two Contact Points



Finally, the contact can exist along a full line for some geometries, or even on an entire surface, as shown in the figure below. In this case, there is an infinite number of contact points.

Figure 15: Cylinder/Cylinder Contact



Contact Formulation

Two bodies will impact when their distance is equal to zero. Once the distance is equal to zero and the bodies are touching, forces can develop in the contact. When the contact distance is greater than zero, there is no interaction between the bodies. Introducing interaction in the equations of motion results in the addition of inequalities to the system:

$$B_u(g)\{q\} \geq G_u(g,t) \tag{84}$$

where the subscript $_u$ stands for unilateral.

In the Rigid Dynamics solver, contact and stops always use a pure Lagrange formulation. Unlike the penalty based approaches, pure Lagrange prevents any penetration.

Note:

Although a pure Lagrange formulation prevents penetration, a small penetration (linear with the time step) may be visible when using the MJ Time Stepping time integration due to the lack of exact collision detection.

Rigid Contact Detection

To control the density of contact points that will need to be adjusted, a surface mesh is used on the bodies that has contact defined. Mesh based contact points are first computed.

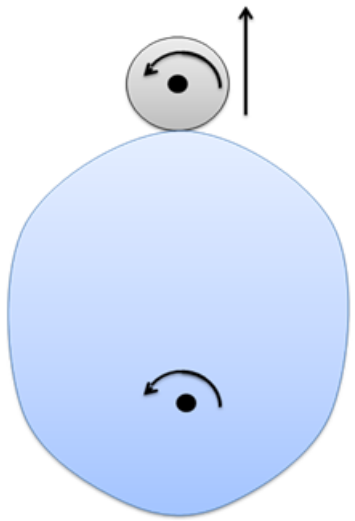
When the contact is geometry-based, these discrete points are then adjusted on the actual geometrical surfaces.

Based on whether the contact is geometry-based or mesh-based, the requirements in terms of mesh are different:

Geometry-Based Contact

It is important to understand that contact will create constraints between the two bodies. The relative motion between these two bodies varies in a 6-dimensional space, so 6 contact points at most will be used to constrain the relative motion of two bodies. These constraints will be added to already existing constraint, so contact can create additional redundancies. For example, two cams with parallel axis will contact along a line (as shown in the figure below). However, if the two axes are maintained parallel by existing joints in the model, one single point through the thickness of the cam is necessary to properly represent the kinematics of the assembly. To avoid useless calculation, the mesh through the thickness can be coarse.

Figure 16: Contact Requiring One Single Point



If the mesh is very refined, many points through thickness can satisfy the contact equations. An automatic filtering of the contact points will also be performed, but the position of the points through thickness might vary from one step to the next. This can cause some unexpected changes in the moment developed in the contact. To avoid this situation, it can be useful to modify the joints or the geometry itself, and include a draft angle in the cam profile extrusion for force the contact along a line.

Mesh-Based Contact

Similar to geometry-based contact, the mesh defines the density of contact points defined between the bodies. Because the points are on the mesh and not on the geometry, the contact

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

happens between faceted geometries. To avoid spikes in the forces, it is recommended that you refine the mesh further when contact is mesh-based.

Caution:

When the mesh-based contact detection method is used, the behavior of the contact is not symmetric. Results may change when the contact is flipped.

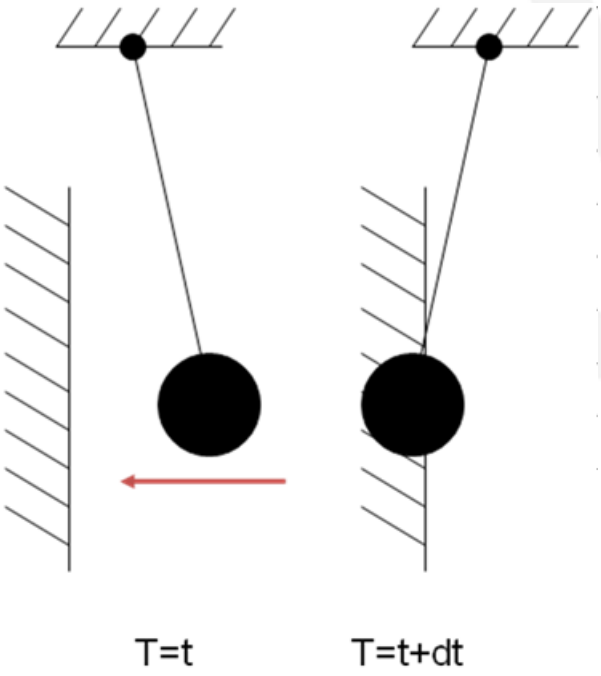
Using mesh-based contact with Runge-Kutta (p. 638) may lead to computationally expensive simulations. Mesh-based contact is recommended for use with the Moreau-Jean method (p. 642).

Time Integration and Contact

In the Rigid Dynamics solver, two alternate methods are available. The first method is suited for situations where contact is mostly intermittent, the second method is suited where contact is mostly established, for example the contact involved in a pair of gears.

Method 1: Event Capturing Contact Formulation

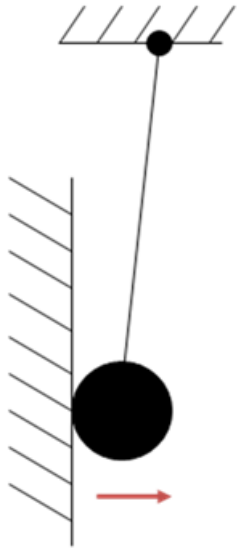
A second method of contact formulation is to detect the transition between the separated space of a given pair of bodies and the configuration where they are overlapping. The image below depicts a point mass approaching a separate wall, and the overlapping configuration following impact.



Determining the time of the transition using this point mass model involves advancing in time without introducing non-penetration constraint equations, and realizing at the end of the time step that the penetration is not acceptable. By using the polynomial interpolation that the time integration scheme provides over the time step, the moment where the penetration reaches zero can be found fairly accurately. This time value can be expressed as a fraction of the time

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

step. To determine this time value, find α such that $p(t+\alpha\Delta t)=0$ where p is the penetration distance.



$T=t0+\alpha dt$

Advancing in time up to $\alpha\Delta t$ will position the system exactly at the impact time and position, where an impact occurs between the bodies. This impact is assumed to have a very short duration, orders of magnitude smaller than the simulation time. During the impact, the interaction forces between the bodies are first increasing in a compression phase, and then decreasing in the expansion phase until they vanish entirely. This impact will lead to a certain amount of energy loss determined by the material of the bodies interacting.

Newton's impact laws are idealized in this impact process. They relate the relative velocity before the impact to the "bouncing" velocity after the impact using a restitution factor. This restitution factor varies from zero to one. A restitution factor of one indicates that the normal velocity after the impact is equal to the velocity before the impact.

$$v^{+}=-v^{-} \tag{85}$$

Where the superscript $^{+}$ represents quantities after the impact, and the superscript $^{-}$ represents quantities before the impact.

A restitution of zero leads to:

$$v^{+}=0 \tag{86}$$

And the general formula will be:

$$v^{+}-v^{-}=-(1+r)v^{-} \tag{87}$$

where r is the restitution factor.

This equation is written as a scalar equation at the impact point. Combined with the conservation of momentum it leads to the following system:

$M(g,t)\{\Delta q\}=\{0\}$

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

$B(q)\{\Delta q\}=0$ for all permanent equations and active contacts, and $B(q)\{\Delta q\}=-(1+r)v^{-}$ for the impacting contact.

Each impact with a restitution factor less than one will introduce an energy loss in the system. In a model with multiple imperfect impacts over time, the total energy will be constant piecewise with a drop at each impact.

Runge-Kutta 4, Generalized-α, and Stabilized Generalized-α integration methods are event capturing schemes (see the table below).

Method 2: Event Absorbing Contact Formulation

When the density of events increases (small bounces, with phases where the contact is sliding, such as the contact in a pair of gears) the event detection method starts to lose efficiency and robustness, for two reasons:

- It requires accurate detection of the transition time, thus forcing the reduction of the time step to avoid missing changes. If events are changed, inconsistencies between the state of the contact (whether the contact is touching, separated, or in-between) and the actual relative position of the bodies.
- Each event processing phase has a computational cost.

To work around these difficulties, it is possible to reformulate what happens during the time step in terms of variation of velocities. These variations come from both smooth dynamics (the variation due to finite accelerations) and from non-smooth dynamics (the variation due to infinite accelerations over a zero duration, which corresponds to a shock). For specific theory information, see Moreau-Jean Method (p. 642).

MJ Time Stepping is an event absorbing scheme.

Summary of Time Integration Methods

The following table summarizes the characteristics of the Time Integration Types available for the Rigid Dynamics solver and the corresponding recommended setting for the Contact Detection.

Time Integration type		RK4, Generalized-α, Stabilized Generalized-α	MJ Time Stepping
Event treatment		Event capturing	Event absorbing
RBD Contact Detection	Geometry based	Best choice	Not recommended
	Mesh based	Not recommended	Best choice

Note:

When the Time Integration Type is set to Program Controlled, the Rigid Dynamics solver chooses the time integration type based only on the use of flexible parts, regardless of the contact definition. If the contact uses only rigid bodies, the solver will use RK4. If there are any Condensed Parts, it will use Stabilized Generalized-α. The contact definition has no influence on this logic.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The use of mesh-based contact detection with explicit time integration (RK4) is likely to lead to solver problems and is not recommended.

Static Structural Analysis

Introduction

A static structural analysis determines the displacements, stresses, strains, and forces in structures or components caused by loads that do not induce significant inertia and damping effects. Steady loading and response conditions are assumed; that is, the loads and the structure's response are assumed to vary slowly with respect to time. A static structural load can be performed using the Ansys, Samcef, or ABAQUS solver. The types of loading that can be applied in a static analysis include:

- Externally applied forces and pressures
- Steady-state inertial forces (such as gravity or rotational velocity)
- Imposed (nonzero) displacements
- Temperatures (for thermal strain)

Point to Remember

Note the following for this analysis type:

- A static structural analysis can be either linear or nonlinear. All types of nonlinearities are allowed - large deformations, plasticity, stress stiffening, contact (gap) elements, hyperelasticity and so on. This chapter focuses on linear static analyses, with brief references to nonlinearities. Details of how to handle nonlinearities are described in Nonlinear Controls (p. 1468).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- When 2D geometry is used, Generalized Plane Strain is not supported for the Samcef or ABAQUS solver.
- Note that available nonlinearities can differ from one solver to another.
- As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Define Engineering Data

Material properties can be linear or nonlinear, isotropic or orthotropic, and constant or temperature-dependent. You must define stiffness in some form (for example, Young's modulus, hyperelastic coefficients, and so on). For inertial loads (such as **Standard Earth Gravity** (p. 1509)), you must define the data required for mass calculations, such as density.

Define Part Behavior

You can define a **Point Mass** (p. 901) for this analysis type.

A "rigid" part is essentially a point mass connected to the rest of the structure via joints. Hence in a static structural analysis the only applicable loads on a rigid part are acceleration and rotational velocity loads. You can also apply loads to a rigid part via joint loads. The output from a rigid part is the overall motion of the part plus any force transferred via that part to the rest of the structure. Rigid behavior cannot be used with the Samcef or ABAQUS solver.

If your model includes nonlinearities such as large deflection or hyperelasticity, the solution time can be significant due to the iterative solution procedure. Hence you may want to simplify your model if possible. For example you may be able to represent your 3D structure as a 2-D plane stress, plane strain, or axisymmetric model or you may be able to reduce your model size through the use of symmetry or antisymmetry surfaces. Similarly if you can omit nonlinear behavior in one or more parts of your assembly without affecting results in critical regions it will be advantageous to do so.

Define Connections

This analysis supports:

- Contact, joints, springs, beams, mesh connections, and end releases.
- (Samcef and ABAQUS solvers only), contacts, springs, and beams are supported. Joints are **not** supported.

Apply Mesh Controls/Preview Mesh

Provide an adequate mesh density on contact surfaces to allow contact stresses to be distributed in a smooth fashion. Likewise, provide a mesh density adequate for resolving stresses; areas where stresses or strains are of interest require a relatively fine mesh compared to that needed for displacement or nonlinearity resolution. If you want to include nonlinearities, the mesh should be able to capture the effects of the nonlinearities. For example, plasticity requires a reasonable integration point density (and therefore a fine element mesh) in areas with high plastic deformation gradients.

Published: 2023-10-23

Establish Analysis Settings

For simple linear static analyses you typically do not need to change these settings. For more complex analyses the basic **Analysis Settings** include:

Large Deflection (p. 1435)

Large Deflection is typically needed for slender structures. Use large deflection if the transverse displacements in a slender structure are more than 10% of the thickness.

Small deflection and small strain analyses assume that displacements are small enough that the resulting stiffness changes are insignificant. Setting **Large Deflection** to **On** will take into account stiffness changes resulting from changes in element shape and orientation due to large deflection, large rotation, and large strain. Therefore the results will be more accurate. However this effect requires an iterative solution. In addition it may also need the load to be applied in small increments. Therefore, the solution may take longer to solve.

You also need to turn on large deflection if you suspect instability (buckling) in the system. Use of hyperelastic materials also requires large deflection to be turned on.

Step Controls for Static and Transient Analyses (p. 1418)

Step Controls are used to i) control the time step size and other solution controls and ii) create multiple steps when needed. Typically analyses that include nonlinearities such as large deflection or plasticity require control over time step sizes as outlined in the Automatic Time Stepping (p. 1493) section. Multiple steps are required for activation/deactivation of displacement loads or pretension bolt loads. This group can be modified on a per step basis.

Note:

Time Stepping is available for any solver.

Rotordynamics Controls (p. 1490)

Specify these properties as needed when setting up a Rotordynamic analysis.

Output Controls (p. 1473)

Output Controls allow you to specify the time points at which results should be available for postprocessing. In a nonlinear analysis it may be necessary to perform many solutions at intermediate load values. However i) you may not be interested in all the intermediate results and ii) writing all the results can make the results file size unwieldy. This group can be modified on a per step basis except for **Stress** and **Strain**.

Nonlinear Controls (p. 1468)

Nonlinear Controls allow you to modify convergence criteria and other specialized solution controls. Typically you will not need to change the default values for this control. This group can be modified on a per step basis. If you are performing a *nonlinear* Static Structural analysis, the **Newton-Raphson Type** property becomes available. This property only affects nonlinear analyses. Your selections execute the Mechanical APDL **NROPT** command. The default option, **Program Controlled**, allows

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

the application to select the appropriate **NROPT** option or you can make a manual selection and choose **Full**, **Modified**, or **Unsymmetric**.

See the Help section for the **NROPT** command in the *Mechanical APDL Command Reference* for additional information about the operation of the **Newton-Raphson Type** property.

Analysis Data Management (p. 1484)

Settings enable you to save specific solution files from the **Static Structural** analysis for use in other analyses. You can set the **Future Analysis** field to **Pre-Stressed Analysis** if you intend to use the static structural results in a subsequent **Harmonic Response**, **Modal**, or **Eigenvalue Buckling** (**Eigenvalue Buckling** is applicable to **Static Structural** systems only) analysis. If you link a structural system to another analysis type in advance, the **Future Analysis** field defaults to **Pre-Stressed Analysis**. A typical example is the large tensile stress induced in a turbine blade under centrifugal load. This causes significant stiffening of the blade resulting in much higher, realistic natural frequencies in a modal analysis. More details are available in the section Define Initial Conditions (p. 349).

Note:

Scratch Solver Files, **Save Ansys db**, **Solver Units**, and **Solver Unit System** are applicable to **Static Structural** systems only.

Define Initial Conditions

Initial condition is not applicable for **Static Structural** analyses.

Apply Loads and Supports

For a Static Structural analysis applicable loads include:

- Inertial (p. 1500)
- Structural (p. 1520)
- Interaction (p. 1521)
- Imported (p. 1736)

Applicable structural Supports (p. 1663), certain Conditions Type Boundary Conditions (p. 1697), as well as supported Direct FE Type Boundary Conditions (p. 1719) are also available.

For the Samcef and ABAQUS solvers, the following loads and supports are not available: Hydrostatic Pressure, Bearing Load, Bolt Pretension, Joint Load, Interface, Motion Loads, Compression Only Support, Elastic Support.

Loads and supports vary as a function of time even in a static analysis as explained in the Role of Time in Tracking (p. 1491). In a static analysis, the load's magnitude could be a constant value or could vary with time as defined in a table or via a function. Details of how to apply a tabular or function load are

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

described in Defining Boundary Condition Magnitude (p. 1771). In addition, see the Apply Loads and Supports (p. 354) section for more information about time stepping and ramped loads.

Note:

A static analysis can be followed by a "pre-stressed" analysis such as modal or linear (eigenvalue) buckling analysis. In this subsequent analysis the effect of stress on stiffness of the structure (stress-stiffness effect) is taken into account. If the static analysis has a pressure or force load applied on faces (3D) or edges (2D) this could result in an additional stiffness contribution called "pressure load stiffness" effect. This effect plays a significant role in linear (eigenvalue) buckling analyses. This additional effect is computed during the Eigenvalue Buckling analysis using the pressure or force value calculated at the time in the static analysis from which the perturbation occurs. See the Applying Pre-Stress Effects (p. 352) section for more information on this topic.

When using the Samcef or ABAQUS solver, **Direct FE** boundary conditions are not available.

Solve

When performing a nonlinear analysis you may encounter convergence difficulties due to a number of reasons. Some examples may be initially open contact surfaces causing rigid body motion, large load increments causing non-convergence, material instabilities, or large deformations causing mesh distortion that result in element shape errors. To identify possible problem areas some tools are available under **Solution Information** (p. 1833) object Details view.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

You can display contour plots of **Newton-Raphson Residuals** in a nonlinear static analysis. Such a capability can be useful when you experience convergence difficulties in the middle of a step, where the model has a large number of contact surfaces and other nonlinearities. When the solution diverges identifying regions of high Newton-Raphson residual forces can provide insight into possible problems.

Result Tracker (p. 1844) (applicable to **Static Structural** systems only) is another useful tool that enables you to monitor displacement and energy results as the solution progresses. This is especially useful in case of structures that possibly go through convergence difficulties due to buckling instability. **Result Tracker** is not available to the Samcef or ABAQUS solver.

Review Results

All structural result types (p. 2017) except frequencies are available as a result of a static structural analysis. You can use a **Solution Information** (p. 1833) object to track, monitor, or diagnose problems that arise during a solution.

Once a solution is available you can contour the results (p. 62) or animate the results (p. 2260) to review the response of the structure.

As a result of a nonlinear static analysis you may have a solution at several time points. You can use probes (p. 1946) to display the variation of a result item as the load increases. An example might be large deformation analyses that result in buckling of the structure. In these cases it is also of interest to plot

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

one result quantity (for example, displacement at a vertex) against another results item (for example, applied load). You can use the Charts (p. 1929) feature to develop such charts.

Steady-State Thermal Analysis

Introduction

You can use a steady-state thermal analysis to determine temperatures, thermal gradients, heat flow rates, and heat fluxes in an object that are caused by thermal loads that do not vary over time. A steady-state thermal analysis calculates the effects of steady thermal loads on a system or component. Engineers often perform a steady-state analysis before performing a transient thermal analysis, to help establish initial conditions. A steady-state analysis also can be the last step of a transient thermal analysis, performed after all transient effects have diminished. A steady-state thermal analysis can be performed using the Mechanical APDL, Samcef, or ABAQUS solver.

Important:

By default, the application does not write thermal gradient results to the result file. To have these results written to the results file, use a Command object (p. 2303) and insert the command **OUTRES**,**ERASE**.

Point to Remember

A steady-state thermal analysis may be either linear, with constant material properties; or nonlinear, with material properties that depend on temperature. The thermal properties of most material do vary with temperature, so the analysis usually is nonlinear. Including radiation effects or temperature dependent convection coefficient also makes the analysis nonlinear.

Preparing the Analysis

Create Analysis System

There are no specific considerations for a steady-state thermal analysis.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

Mechanical does not support Rigid Bodies in thermal analyses. For more information, see the *Stiffness Behavior* documentation for Rigid Bodies (p. 852).

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

In a thermal analysis only contact is valid. Any joints or springs are ignored.

With contact the initial status is maintained throughout the thermal analysis, that is, any closed contact faces will remain closed and any open contact faces will remain open for the duration of the thermal analysis. Heat conduction across a closed contact face is set to a sufficiently high enough value (based on the thermal conductivities and the model size) to model perfect contact with minimal thermal resistance. If needed, you can model imperfect contact by manually inputting a **Thermal Conductance** (p. 1253) value.

By default, Contact Results (p. 2043) (accessible through User Defined Results (p. 2192) via CONTSTAT or CONTFLUX – see the User Defined Results for the Mechanical APDL Solver (p. 2203) section.) are not written to the result file in a thermal analysis.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no specific considerations for steady-state thermal analysis itself. However if the temperatures from this analysis are to be used in a subsequent structural analysis the mesh must be identical. Therefore in this case you may want to make sure the mesh is fine enough for structural analysis.

Establish Analysis Settings

For a steady-state thermal analyses you typically do not need to change these settings. The basic Analysis Settings include:

Step Controls for Static and Transient Analyses (p. 1418)

Step Controls enable you to control the rate of loading which could be important in a steady-state thermal analysis if the material properties vary rapidly with temperature. When such nonlinearities are present it may be necessary to apply the loads in small increments and perform solutions at these intermediate loads to achieve convergence. You may wish to use multiple steps if you a) want to analyze several different loading scenarios within the same analysis or b) if you want to change the analysis settings such as the time step size or the solution output frequency over specific time ranges.

Output Controls (p. 1473)

Output Controls enable you to specify the time points at which results should be available for postprocessing. In a nonlinear analysis it may be necessary to perform many solutions at intermediate load values. However i) you may not be interested in all the intermediate results and ii) writing all the results can make the results file size unwieldy. In this case you can restrict the amount of output by requesting results only at certain time points.

Nonlinear Controls (p. 1468)

Nonlinear Controls enable you to modify convergence criteria and other specialized solution controls. Typically you will not need to change the default values for this control.

Nonlinear Controls are exposed for the Mechanical APDL solver only.

Analysis Data Management (p. 1484)

Analysis Data Management settings enable you to save specific solution files from the steady-state thermal analysis for use in other analyses.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a steady-state thermal analysis you can specify an initial temperature value. This uniform temperature is used during the first iteration of a solution as follows:

- To evaluate temperature-dependent material properties.
- As the starting temperature value for constant temperature loads.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Specifics ***... for this analysis type:***

The following loads are supported in a steady-state thermal analysis:

- Temperature (p. 1598)
- Convection (p. 1602)
- Radiation (p. 1609)
- Heat Flow (p. 1614)
- Perfectly Insulated (p. 1614)
- Heat Flux (p. 1617)
- Internal Heat Generation (p. 1620)
- Imported Temperature (p. 1756)
- Imported Convection Coefficient (p. 1744)
- Fluid Solid Interface (p. 1648)
- System Coupling Region (p. 1651)

Loads and supports vary as a function of time even in a static analysis as explained in the Role of Time in Role of Time in Tracking (p. 1491). In a static analysis, the load's magnitude could be a constant value or could vary with time as defined in a table or via a function. Details of how to apply a tabular or function load are described in Defining Boundary Condition Magnitude (p. 1771). In addition, see the Apply Loads and Supports (p. 354) section for more information about time stepping and ramped loads.

Fluid Solid Interface (p. 1648) is not available for the Samcef or ABAQUS solver.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

The **Solution Information** (p. 1833) object provides some tools to monitor solution progress.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

You can also insert a **Result Tracker** (p. 1844) object under **Solution Information**. This tool enables you to monitor temperature at a vertex as the solution progresses. **Result Tracker** is not available to the Samcef or ABAQUS solver.

Review Results

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Applicable results are all thermal result types (p. 2153).

Once a solution is available you can contour the results (p. 62) or animate the results (p. 2260) to review the response of the structure.

As a result of a nonlinear analysis you may have a solution at several time points. You can use probes (p. 1946) to display the variation of a result item over the load history. Also of interest is the ability to plot one result quantity (for example, maximum temperature on a face) against another results item (for example, applied heat generation rate). You can use the Charts (p. 1929) feature to develop such charts.

Note that Charts (p. 1929) are also useful to compare results between two analyses of the same model.

Thermal-Electric Analysis

Introduction

A Steady-State Thermal-Electric Conduction analysis allows for a simultaneous solution of thermal and electric fields. This coupled-field capability models joule heating for resistive materials and contact electric conductance as well as Seebeck, Peltier, and Thomson effects for thermoelectricity, as described below.

- **Joule heating** - Heating occurs in a resistive conductor carrying an electric current. Joule heating is proportional to the square of the current, and is independent of the current direction. Joule heating is also present and accounted for at the contact interface between bodies in inverse proportion to the contact electric conductance properties. (Note however that the **Joule Heat** results object will not display contact joule heating values. Only solid body joule heating is represented).
- **Seebeck effect** - A voltage (Seebeck EMF) is produced in a thermoelectric material by a temperature difference. The induced voltage is proportional to the temperature difference. The proportionality coefficient is known as the **Seebeck Coefficient** (α).
- **Peltier effect** - Cooling or heating occurs at a junction of two dissimilar thermoelectric materials when an electric current flows through that junction. Peltier heat is proportional to the current, and changes sign if the current direction is reversed.
- **Thomson effect** - Heat is absorbed or released in a non-uniformly heated thermoelectric material when electric current flows through it. Thomson heat is proportional to the current, and changes sign if the current direction is reversed.

Points to Remember

Electric loads may be applied to parts with electric properties and thermal loads may be applied to bodies with thermal properties. Parts with both physics properties can support both thermal and electric loads. See the Steady-State Thermal Analysis (p. 657) section and the Electric Analysis (p. 403) section of the help for more information about applicable loads, boundary conditions, and results types.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

In addition to calculating the effects of steady thermal and electric loads on a system or component, a Steady-State Thermal-Electric analysis supports a multi-step solution.

Preparing the Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

From the **Toolbox**, drag the **Thermal-Electric** template to the **Project Schematic**.

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

To have Thermal and/or Electrical effects properly applied to the parts of your model, you need to define the appropriate material properties. For a steady-state analysis, the electrical property **Resistivity** is required for Joule Heating effects and **Thermal Conductivity** for thermal conduction effects. Seebeck/Peltier/Thomson effects require you to define the **Seebeck Coefficient** material property.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

Note that 3D shell bodies and line bodies are not supported in a thermal-electric analysis.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

Mechanical does not support Rigid Bodies in thermal-electric analyses. For more information, see the *Stiffness Behavior* documentation for Rigid Bodies (p. 852).

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Contact across parts during a thermal-electric analysis consider thermal and/or electric effects based on the material properties of adjacent parts. That is, if both parts have thermal properties, thermal contact is applied and if both parts have electric properties, electric contact is applied.

Published: 2023-10-23

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no specific considerations regarding meshing for a thermal-electric analysis.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a Thermal-Electric analysis, the basic **Analysis Settings** include:

Step Controls for Static and Transient Analyses (p. 1418)

: used to specify the end time of a step in a single or multiple step analysis. Multiple steps are needed if you want to change load values, the solution settings, or the solution output frequency over specific steps. Typically you do not need to change the default values.

Nonlinear Controls (p. 1468)

Typical thermal-electric problems contain temperature dependent material properties and are therefore nonlinear. Nonlinear Controls (p. 1468) for both thermal and electrical effects are available and include Heat and Temperature convergence for thermal effects and Voltage and Current convergence for electric effects.

Output Controls (p. 1473)

Output Controls enable you to specify the time points at which results should be available for postprocessing. A multi-step analysis involves calculating solutions at several time points in the load history. However you may not be interested in all of the possible results items and writing all the results can make the result file size unwieldy. You can restrict the amount of output by requesting results only at certain time points or limit the results that go onto the results file at each time point.

Analysis Data Management (p. 1484)

Review these settings as needed.

Solver Controls (p. 1428)

The default Solver Controls (p. 1428) setting for thermal-electric analysis is the **Direct** (Sparse) solver. The Iterative (PCG) solver may be selected as an alternative solver. If Seebeck effects are included, the solver is automatically set to Direct.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Specifics ***... for this analysis type:***

There is no initial condition specification for a thermal-electric analysis.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are supported in a **Thermal-Electric** analysis:

- Voltage (p. 1627)
- Current (p. 1630)
- Coupling Condition (p. 1698)
- Temperature (p. 1598)
- Convection (p. 1602)
- Radiation (p. 1609)
- Heat Flow (p. 1614)
- Perfectly Insulated (p. 1614)
- Heat Flux (p. 1617)
- Internal Heat Generation (p. 1620)
- System Coupling Region (p. 1651)

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

The **Solution Information** (p. 1833) object provides some tools to monitor solution progress.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the model during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Applicable results include all thermal and electric results (p. 1927).

Once a solution is available, you can contour the results (p. 62) or animate the results (p. 2260) to review the responses of the model.

For the results of a multi-step analysis that has a solution at several time points, you can use probes (p. 1946) to display variations of a result item over the steps.

You may also wish to use the Charts (p. 1929) feature to plot multiple result quantities against time (steps). For example, you could compare current and joule heating. Charts can also be useful when comparing the results between two analysis branches of the same model.

Transient Structural Analysis

A transient analysis, by definition, involves loads that are a function of time. In the Mechanical application, you can perform a transient analysis on either a flexible structure or a rigid assembly. For a flexible structure, the Mechanical application can use the Ansys Mechanical APDL, Samcef, or ABAQUS solver to solve a Transient Structural analysis.

You can perform a transient structural analysis (also called time-history analysis) in the Mechanical application using the transient structural analysis that specifically uses the Ansys Mechanical APDL solver. This type of analysis is used to determine the dynamic response of a structure under the action of any general time-dependent loads. You can use it to determine the time-varying displacements, strains, stresses, and forces in a structure as it responds to any transient loads. The time scale of the loading is such that the inertia or damping effects are considered to be important. If the inertia and damping effects are not important, you might be able to use a static analysis instead.

Points to Remember

A transient structural analysis can be either linear or nonlinear. All types of nonlinearities are allowed - large deformations, plasticity, contact, hyperelasticity, and so on. Ansys Workbench offers an additional solution method of Mode-Superposition to perform linear transient structural analysis. In the Mode-Superposition method, the transient response to a given loading condition is obtained by calculating the necessary linear combinations of the eigenvectors obtained in a modal analysis. For more details, refer to Transient Structural Analysis Using Linked Modal Analysis System (p. 674) section. The Mode Superposition method is not available to the Samcef or ABAQUS solver.

A transient dynamic analysis is more involved than a static analysis because it generally requires more computer resources and more of your resources, in terms of the "engineering" time involved. You can save a significant amount of these resources by doing some preliminary work to understand the physics of the problem. For example, you can:

1. Try to understand how nonlinearities (if you are including them) affect the structure's response by doing a static analysis first. In some cases, nonlinearities need not be included in the dynamic analysis. Including nonlinear effects can be expensive in terms of solution time.

2. Understand the dynamics of the problem. By doing a modal analysis, which calculates the natural frequencies and mode shapes, you can learn how the structure responds when those modes are excited. The natural frequencies are also useful for calculating the correct integration time step.

3. Analyze a simpler model first. A model of beams, masses, springs, and dampers can provide good insight into the problem at minimal cost. This simpler model may be all you need to determine the dynamic response of the structure.

Note:

Refer to the following sections of the Mechanical APDL application documentation for a more thorough treatment of dynamic analysis capabilities:

- The *Transient Dynamic Analysis* chapter of the *Structural Analysis Guide* - for a technical overview of nonlinear transient dynamics.

- The *Multibody Analysis Guide* - for a reference that is particular to multibody motion problems. In this context, "multibody" refers to multiple rigid or flexible parts interacting in a dynamic fashion.

Although not all dynamic analysis features discussed in these manuals are directly applicable to Mechanical features, the manuals provide an excellent background on general theoretical topics.

Preparing the Analysis

As needed throughout the analysis, refer to the Steps for Using the Application (p. 323) section for an overview the general analysis workflow.

Published: 2023-10-23

Define Engineering Data

Material properties can be linear or nonlinear, isotropic or orthotropic, and constant or temperature-dependent. Both Young's modulus (and stiffness in some form) and density (or mass in some form) must be defined.

Define Part Behavior

You can define a **Point Mass** (p. 901) for this analysis type.

In a transient structural analysis, rigid parts are often used to model mechanisms that have gross motion and transfer loads between parts, but detailed stress distribution is not of interest. The output from a rigid part is the overall motion of the part plus any force transferred via that part to the rest of the structure. A "rigid" part is essentially a point mass connected to the rest of the structure via joints. Hence in a transient structural analysis the only applicable loads on a rigid part are acceleration and rotational velocity loads. You can also apply loads to a rigid part via joint loads. Rigid behavior cannot be used with the Samcef or ABAQUS solver.

If your model includes nonlinearities such as large deflection or hyperelasticity, the solution time can be significant due to the iterative solution procedure. Hence, you may want to simplify your model if possible. For example, you may be able to represent your 3D structure as a 2-D plane stress, plane strain, or axisymmetric model, or you may be able to reduce your model size through the use of symmetry or antisymmetry surfaces. Similarly, if you can omit nonlinear behavior in one or more parts of your assembly without affecting results in critical regions, it will be advantageous to do so.

Define Connections

This analysis supports Contact (p. 1207), Joints (p. 1292), and Springs (p. 1395).

Note:

You can specify a damping coefficient property in longitudinal springs that will generate a damping force proportional to velocity.

Samcef and ABAQUS Solvers

Only contacts, springs, and beams are supported. Joints are not supported.

Apply Mesh Controls/Preview Mesh

Provide an adequate mesh density on contact surfaces to allow contact stresses to be distributed in a smooth fashion. Likewise, provide a mesh density adequate for resolving stresses; areas where stresses or strains are of interest require a relatively fine mesh compared to that needed for displacement or nonlinearity resolution. If you want to include nonlinearities, the mesh should be able to capture the effects of the nonlinearities. For example, plasticity requires a reasonable integration point density (and therefore a fine element mesh) in areas with high plastic deformation gradients.

In a dynamic analysis, the mesh should be fine enough to be able to represent the highest mode shape of interest.

Published: 2023-10-23

Establish Analysis Settings

For a Transient Structural analysis, the basic **Analysis Settings** include:

Large Deflection (p. 1435)

Large Deflection is typically needed for slender structures. It is typical to use large deflection if the transverse displacements in a slender structure are more than 10% of the thickness.

Small deflection and small strain analyses assume that displacements are small enough that the resulting stiffness changes are insignificant. Setting **Large Deflection** to **On** will take into account stiffness changes resulting from change in element shape and orientation due to large deflection, large rotation, and large strain. Therefore the results will be more accurate. However this effect requires an iterative solution. In addition it may also need the load to be applied in small increments. Therefore the solution may take longer to solve.

You also need to turn on large deflection if you suspect instability (buckling) in the system. Use of hyperelastic materials also requires large deflection to be turned on.

Step Controls for Static and Transient Analyses (p. 1418)

Step Controls enable you to control the time step size in a transient analysis. Refer to the Guidelines for Integration Step Size (p. 1493) section for further information. In addition this control also enables you to create multiple steps. Multiple steps (p. 1418) are useful if new loads are introduced or removed at different times in the load history, or if you want to change the analysis settings such as the time step size at some points in the time history. When the applied load has high frequency content or if nonlinearities are present, it may be necessary to use a small time step size (that is, small load increments) and perform solutions at these intermediate time points to arrive at good quality results. This group can be modified on a per step basis.

Output Controls (p. 1473)

Output Controls enable you to specify the time points at which results should be available for postprocessing. In a transient nonlinear analysis it may be necessary to perform many solutions at intermediate time values. However, i) you may not be interested in all the intermediate results, and ii) writing all the results can make the results file size unwieldy. This group can be modified on a per step basis except for **Stress** and **Strain**.

Nonlinear Controls (p. 1468)

Nonlinear Controls enable you to modify convergence criteria and other specialized solution controls. Typically you will not need to change the default values for this control. This group can be modified on a per step basis. If you are performing a *nonlinear* Full Transient Structural analysis, the **Newton-Raphson Type** property becomes available. This property only affects nonlinear analyses. Your selections execute the Mechanical APDL **NROPT** command. The default option, **Program Controlled**, allows the application to select the appropriate **NROPT** option or you can make a manual selection and choose **Full**, **Modified**, or **Unsymmetric**.

See the Help section for the **NROPT** command in the *Mechanical APDL Command Reference* for additional information about the operation of the **Newton-Raphson Type** property.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Damping Controls (p. 1462)

Damping Controls enable you to specify damping for the structure in the Transient analysis. Controls include: **Stiffness Coefficient** (Beta Damping) and **Mass Coefficient** (Alpha Damping). They can also be applied as Material Damping (p. 1467) using the **Engineering Data** tab. In addition, **Numerical Damping** is also available for handling result accuracy. Damping controls are not available to the Samcef or ABAQUS solver.

Analysis Data Management (p. 1484)

Analysis Data Management settings enable you to save specific solution files from the transient structural analysis for use in other analyses. The default behavior is to only keep the files required for postprocessing. You can use these controls to keep all files created during solution or to create and save the Mechanical APDL application database (db file).

Define Initial Conditions

The structure of a transient analysis is, by default, "at rest." That is, both initial displacement and initial velocity are zero. Using the Initial Conditions object, you can specify a **Velocity** at time = zero, as a **Vector** or axially, using **Components**.

In many analyses one or more parts will have an initial known velocity such as in a drop test, metal forming analysis, or kinematic analysis. In these analyses, you can specify a constant Velocity initial condition if needed. The constant velocity could be scoped to one or more parts of the structure. The remaining parts of the structure which are not part of the scoping will retain the "at rest" initial condition.

Note:

When you are using the Mechanical APDL solver, you can also specify initial conditions using step controls, that is, by specifying multiple steps in a transient analysis and controlling the time integration effects along with activation/deactivation (p. 1423) of loads. This is useful when different parts of your model have different initial velocities or more complex initial conditions.

The following are common initial condition scenarios:

1. **Initial Displacement = 0, Initial Velocity ≠ 0 for some parts:** The nonzero velocity is established by applying small displacements over a small time interval on the part of the structure where velocity is to be specified.

   a. Specify two steps in your analysis. The first step will be used to establish initial velocity on one or more parts.

   b. Choose a small end time (compared to the total span of the transient analysis) for the first step. The second step will cover the total time span.

   c. Specify displacement(s) on one or more faces of the part(s) that will give you the required initial velocity. This requires that you do not have any other boundary condition on the part that will interfere with rigid body motion of that part. Make sure that these displacements are ramped from a value of 0.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

d. Deactivate or release the specified displacement load in the second step so that the part is free to move with the specified initial velocity.

For example, if you want to specify an initial Y velocity of 5 inch/second on a part, and your first step end time is 0.001 second, then specify the following loads. Make sure that the load is ramped from a value of 0 at time = 0 so that you will get the required velocity.

Tabular Data

	Steps	Time [s]	Y [in]
1	1	0.	0.
2	1	1.e-003	5.e-003
3	2	30.	= 5.e-003
*			

In this case the end time of the actual transient analysis is 30 seconds. Note that the Y displacement in the second step is deactivated.

e. In the **Analysis Settings** Details view, set the following for first step:

Details of "Analysis Settings"

Step Controls	
Number Of Steps	2.
Current Step Number	1.
Step End Time	1.e-003 s
Auto Time Stepping	Off
Define By	Substeps
Number Of Substeps	1.
Time Integration	Off

f. You can choose appropriate time step sizes for the second step (the actual transient). Make sure that time integration effects are turned on for the second step.

In the first step, inertia effects will not be included but velocity will be computed based on the displacement applied. In the second step, this displacement is released by deactivation and the time integration effects are turned on.

2. **Initial Displacement ≠ 0, Initial Velocity ≠ 0:** This is similar to case a. above except that the imposed displacements are the actual values instead of "small" values. For example if the initial displacement is 1 inch and the initial velocity is 2.5 inch/sec then you would apply a displacement of 1 inch over 0.4 seconds.

a. Specify two steps in your analysis. The first step will be used to establish initial displacement and velocity on one or more parts.

b. Choose a small end time (compared to the total span of the transient analysis) for the first step. The second step will cover the total time span.

c. Specify the initial displacement(s) on one or more faces of the part(s) as needed. This requires that you do not have any other boundary condition on the part that will interfere with rigid body motion of that part. Make sure that these displacements are ramped from a value of 0.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

d. Deactivate or release the specified displacement load in the second step so that the part is free to move with the specified initial velocity.

For example if you want to specify an initial Z velocity on a part of 0.5 inch/sec and have an initial displacement of 0.1 inch, then your first step end time = (0.1/0.5) = 0.2 second. Make sure that the displacement is ramped from a value of 0 at time = 0 so that you will get the required velocity.

Tabular Data

	Steps	Time [s]	Z [in]
1	1	0.	0.
2	1	0.2	0.1
3	2	2.	= 0.1
*			

In this case the end time of the actual transient analysis is 5 seconds. Note that the Z displacement in the second step is deactivated.

e. In the **Analysis Settings** Details view, set the following for first step:

Details of "Analysis Settings"

Step Controls	
Number Of Steps	2.
Current Step Number	1.
Step End Time	0.2 s
Auto Time Stepping	Off
Define By	Substeps
Number Of Substeps	4.
Time Integration	Off

f. You can choose appropriate time step sizes for the second step (the actual transient). Make sure that time integration effects are turned on for the second step.

In the first step, inertia effects will not be included but velocity will be computed based on the displacement applied. In the second step, this displacement is released by deactivation and the time integration effects are turned on.

3. **Initial Displacement ≠ 0, Initial Velocity = 0:** This requires the use of two steps also. The main difference between b. above and this scenario is that the displacement load in the first step is not ramped from zero. Instead it is step applied as shown below with 2 or more substeps to ensure that the velocity is zero at the end of step 1.

a. Specify two steps in your analysis. The first step will be used to establish initial displacement on one or more parts.

b. Choose an end time for the first step that together with the initial displacement values will create the necessary initial velocity.

c. Specify the initial displacement(s) on one or more faces of the part(s) as needed. This requires that you do not have any other boundary condition on the part that will interfere with rigid

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

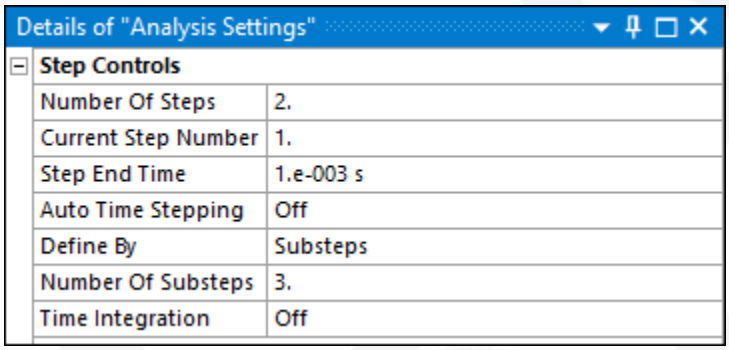
body motion of that part. Make sure that this load is step applied, that is, apply the full value of displacements at time = 0 itself and maintain it throughout the first step.

d. Deactivate or release the specified displacement load in the second step so that the part is free to move with the initial displacement values.

   For example if you want to specify an initial Z displacement of 0.1 inch and the end time for the first step is 0.001 seconds, then the load history displays as shown below. Note the step application of the displacement.

   In this case the end time of the actual transient analysis is 5 seconds. Note that the Z displacement in the second step is deactivated.

e. In the **Analysis Settings** Details view, set the following for first step. Note that the number of substeps must be at least 2 to set the initial velocity to zero.



f. You can choose appropriate time step sizes for the second step (the actual transient). Make sure that time integration effects are turned on for the second step.

In the first step, inertia effects will not be included but velocity will be computed based on the displacement applied. But since the displacement value is held constant, the velocity will evaluate to zero after the first substep. In the second step, this displacement is released by deactivation and the time integration effects are turned on.

Apply Loads and Supports

For this analysis type, loading is always step-applied (regardless of the setting of the **Time Integration** property). The Environment (p. 61) Context tab provides the various groups of loads, supports, and conditions (p. 1500).

In this analysis, the load's magnitude can be constant or vary with time as defined in **Tabular Data** or as a **Function**. Details of how to apply a tabular or function load are described in Defining Boundary

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Condition Magnitude (p. 1771). In addition, see the Apply Loads and Supports (p. 354) section for more information about time stepping and ramped loads.

Note:

- You can use a Joint Load (p. 1592) to kinematically drive a joint. See For the solver to converge, it is recommended that you ramp joint load angles and positions from zero to the real initial condition over one step.
- Joint loads are not supported for the Samcef or ABAQUS solver.
- Acceleration (p. 1501) and/or Displacement (p. 1666) can be defined as a base excitation only in a Transient Structural Analysis Using Linked Modal Analysis System.

Solve

When performing a nonlinear analysis, you may encounter convergence difficulties due to a number of reasons. Some examples may be initially open contact surfaces causing rigid body motion, large load increments causing non-convergence, material instabilities, or large deformations causing mesh distortion that result in element shape errors. To identify possible problem areas some tools are available under **Solution Information** (p. 1833) object Details view.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

You can display contour plots of **Newton-Raphson Residuals** in a nonlinear static analysis. Such a capability can be useful when you experience convergence difficulties in the middle of a step, where the model has a large number of contact surfaces and other nonlinearities. When the solution diverges, identifying regions of high Newton-Raphson residual forces can provide insight into possible problems.

Result Tracker (p. 1844) is another useful tool that enables you to monitor displacement and energy results as the solution progresses. This is especially useful in the case of structures that may go through convergence difficulties due to buckling instability. **Result Tracker** is not available to the Samcef or ABAQUS solver.

Review Results

All structural result types (p. 2017) except frequencies are available as a result of a transient structural analysis. You can use a **Solution Information** (p. 1833) object to track, monitor, or diagnose problems that arise during a solution.

Once a solution is available you can contour the results (p. 62) or animate the results (p. 2260) to review the response of the structure.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

As a result of a nonlinear static analysis, you may have a solution at several time points. You can use probes (p. 1946) to display the variation of a result item as the load increases.

Note:

Fixed body-to-body joints between two rigid bodies will not produce a joint force or moment in a transient structural analysis.

Also of interest is the ability to plot one result quantity (for example, displacement at a vertex) against another result item (for example, applied load). You can use the Charts (p. 1929) feature to develop such charts. Charts (p. 1929) are also useful to compare results between two analyses of the same model. For example, you can compare the displacement response at a vertex from two transient structural analyses with different damping characteristics.

Transient Structural Analysis Using Linked Modal Analysis System

This section examines the workflow for a Transient Structural analysis linked to an upstream Modal analysis. Topics include:

- Create Analysis System (p. 674)
- Establish Analysis Settings (p. 675)
- Define Initial Conditions (p. 677)
- Apply Loads and Supports (p. 677)
- Support Limitations (p. 678)
- Analysis Notes (p. 679)
- File Management (p. 679)

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

Because this analysis is linked to (or based on) modal responses, a Modal analysis is a prerequisite. This linked setup allows the transient system to share resources such as engineering data, geometry, and boundary condition type definitions made in the Modal analysis.

Linking the Modal Solution cell to the Transient Setup cell configures the Transient analysis so that the application selects, by default, the **Mode-Superposition** (MSUP) Solution Method.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The Samcef and ABAQUS solvers do not support a linked Modal/Transient Structural analysis. For additional support requirements and notes regarding this analysis configuration, see the references at the bottom of this section.

Note:

- For a Mode Superposition Transient Structural analysis, the Modal analysis can be pre-stressed (p. 352) by a Static Structural analysis.
- When solving a linked MSUP transient system database from a version prior to the most current version of Mechanical, it is possible to encounter incompatibility of the file *file.full* created by the modal system. This incompatibility can cause the transient system's solution to fail. In the event you experience this issue, use the **Clear Generated Data** feature and resolve the modal system.

  Refer to the Obtain the Mode-Superposition Transient Solution section of the *MAPDL Structural Analysis Guide* for more information.

From the **Toolbox**, drag a **Modal** template to the **Project Schematic**. Then, drag a **Transient Structural** template directly onto the **Solution** cell of **Modal** template.

Note:

You can create a modal environment in **Transient Structural** system that is already open in Mechanical by:

1. Selecting the **Modal** option from the **Analysis** drop-down menu on the Home (p. 40) tab (or displayed tab).
2. Setting the **Modal Environment** property of the **Modal (None)** object to the Modal system. The **Modal** object is included under the **Initial Conditions** object.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a Transient Structural system linked to a Modal system, the basic Analysis Settings (p. 1417) include:

Step Controls (p. 1418)

This analysis is only compatible with constant time stepping. So, auto time stepping is turned off and will always be in read only mode. The user specified substep or time step value is applicable to all the load steps. All of the **Step Controls** settings applied to this analysis are not step aware. The time integration is turned on by

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

default and will always be in read-only mode. A Time Step value that results in an integral number of sub steps over the load step must be selected.

Options (p. 1459)

You can turn on the following properties:

- **Include Residual Vectors**. Set this property to **Yes** to execute the **RESVEC** command and calculate residual vectors.
- **On Demand Expansion Option**: If you set this property to **Yes** manually or through the **Program Controlled** setting, the application does not create a result file. Your results are evaluated using the Modal solution data and otherwise calculated "on demand." This property supports specific result types. See the property's description in the **Options** (p. 1459) section for a listing.
- **Mode Selection Method**: This property enables you to select the modes for the mode expansion. Property options include:
  - **None** (default): This option expands all the extracted modes from the modal analysis. All the modes participate in the mode-superposition transient dynamic analysis.
  - **Modal Effective Mass**: When you select this option, the **Significance Threshold** property also displays. For the **Significance Threshold** property value, the application selects the modes that have a ratio for the Modal Effective Mass to the Total Mass that is greater than this value, in all directions, for expansion. That is, only the selected modes participate in the mode-superposition transient dynamic analysis. The application default is **`0.001`**. This feature improves the performance of postprocessing the modal results and reduces the file size.

Note:

The following loads do not support residual vector calculations:

- **Nodal Force**
- **Remote Force** scoped to a **Remote Point** (created via **Model** object)
- **Moment** scoped to a **Remote Point** (created via **Model** object)

Output Controls (p. 1473)

These controls enable you to request **Stress**, **Strain**, **Nodal Force**, **Reaction**, **Velocity and Acceleration** results to be calculated. To expand reaction forces in the modal solution, set the **Nodal Force** property to **Yes** or **Constrained Nodes**. The **General Miscellaneous** property needs to be set to **Yes** in order to apply a Beam Tool (p. 2087) and/or to calculate Beam Results (p. 2089). In addition, this setting is required to correctly produce twisted beam shapes. For better performance, you can also choose

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

to have these results expanded from transient or modal solutions. The **Contact Miscellaneous** option is not available.

Note:

Solver Controls (p. 1428), Restart Controls (p. 1438), Nonlinear Controls (p. 1468) and Creep Controls (p. 1445) are not applicable to the current analysis.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

The Transient Structural analysis must point to a Modal analysis in the **Modal** (Initial Conditions) object. This object also indicates whether the upstream Modal analysis is pre-stressed. If it is a pre-stress analysis, the name of the pre-stress analysis system is displayed in the **Pre-Stress Environment** field, otherwise the field indicates **None**. The Modal Analysis (p. 515) must extract all modes that may contribute to the dynamic response.

Note:

Command (ADPL) objects can be inserted into **Initial Conditions** object to execute a restart of the solution process for the Modal Analysis.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are allowed for the linked analysis:

- Acceleration (p. 1501)
- Acceleration (p. 1501) as a base excitation
- Pressure (p. 1521)
- Pipe Pressure (p. 1532)
- Force (p. 1543) (applied to a face, edge, or vertex)
- Line Pressure (p. 1585)
- Moment (p. 1574)
- Remote Force (p. 1552)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Standard Earth Gravity (p. 1509)

Direct FE

The **Direct FE** option **Nodal Force** (p. 1721) is supported for node-based Named Selection scoping.

Note:

- For the **Force** and **Pressure** loading conditions, the default setting for the **Applied By** property is **Direct**.
- When you have a supported topology (geometric or mesh entity) selected on your model, and you insert a **Remote Force** or a **Moment**, the application automatically creates (promotes) a corresponding **Remote Point** for the specified load and scopes the load to that **Remote Point**. This promotion feature is only available when none of the analyses in your project have been solved.

Support Limitations

Note the following limitations:

- If the **Reference Temperature** is set as **By Body** and that temperature does not match the environment temperature, a thermally induced transient load will result (from the thermal strain assuming a nonzero thermal expansion coefficient). This thermal transient loading is ignored for Transient Structural Analysis using Linked Modal Analysis System.
- **Remote Force** is not supported for vertex scoping.
- During a linked MSUP Transient analysis, if a **Remote Force** or **Moment** scoped to an internal remote point is specified with the **Behavior** property set to **Deformable**, the boundary conditions cannot be scoped to the edges of line bodies such that all of their nodes in combination are collinear.
- **Remote Force** and **Moment** applied to a rigid body is not supported.
- **Moment** is not supported for vertex scoping on 3D solid bodies because a beam entity is created for the load application. The beam entity changes the stiffness of the structural component shared and solved by the preceding modal analysis.
- Joint probes (p. 2118), **Energy** Probe, and Strain Energy (p. 2037) results are not supported when expanded from a Modal solution.
- The **Force Reaction** and **Moment Reaction** probes are not supported for a either a Harmonic Response analysis or a Transient structural analysis using the **Mode Superposition** method Solution Method when 1) the **Damping Ratio** property is defined with a non-zero value and 2) if the Analysis Settings property **Expand Result From** is set to **Harmonic Solution** or **Transient Solution**.
- Cyclic symmetry (p. 1134) models are not supported for a Transient Structural Analysis that is using a linked Modal Analysis System.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Spring probe (p. 2123) only supports Elastic force result when expanded from modal solution where as it supports both Elastic force and Elongation results when expanded from transient solution. The Elastic force results include the spring damping effect if the Reduced method is selected from Modal Solver controls (p. 1428), and Store Complex Solution is set to **No**.
- **Standard Earth Gravity** is not allowed in conjunction with the **Acceleration** load.
- Elemental Triads (p. 1936) results are not available on solid bodies.
- When the **Step Controls** are defined by **Substeps**, the time step value sent to the solver is based on the settings for the first load step. For the load **steps** greater than one, you may notice an inconsistent value of the number of sub-steps in the Details View or the Worksheet View.
- For the Samcef and ABAQUS solvers, Hydrostatic Pressure and Pipe Pressure are not supported.

Analysis Notes

- Remote Force and Moment loading combined with the Rigid contact behavior is allowed when the loading is scoped through a Remote Point Application (p. 1090).
- To obtain the most accurate results, it is recommended that you specify **Bonded** as the contact **Type** and set the contact **Formulation** to **MPC** in the **Details** for the Contact Region. See the Contact Definition (p. 1234) and Contact Advanced Category (p. 1240) for more detailed information about these settings.
- When the result is expanded from Modal Solution or when **Reaction Object** is scoped to a Contact Region, the Reaction Object requires both **Nodal Forces** and **Calculate Reactions** Output Controls settings to be turned **On**. If they are not set, the error message "A result is invalid with current output control settings" displays. For other cases, the **Reaction Object** requires only the **Calculate Reactions** Output Controls setting to be turned **On**.
- The default value of Numerical Damping is different for full and mode-superposition transient structural analyses. So, the results comparison of a model must be done by matching the Numerical Damping value settings in the Damping Controls (p. 1462) section.

File Management Options

When solving a **Transient** Structural analysis that includes an upstream linked **Modal** analysis, the application can reference the prerequisite files by specifying the full path of their location (refer to **RESUME** and **MODDIR** commands) instead of making copies. Referencing improves solution time and disk usage. The application will perform referencing once the following conditions and settings are performed:

- You must perform the solution locally (called "In Process (p. 1803)").

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- The **On Demand Expansion Option** property of the Options (p. 1447) category of the **Analysis Settings** of the **Modal** analysis must be set to **Yes** manually or through the **Program Controlled** setting.

Important:

Make sure that **Modal** and the downstream **Transient** analysis request the same result data in the Output Controls (p. 1473). Otherwise, you may receive unexpected results.

Note:

If you specify material damping, the **Eqv. Damping Ratio From Modal** property (for the **Transient** Structural analysis) must also be set to **Yes**.

Limitations

Also note the following limitations for referencing. The **Transient** structural analysis cannot include:

- Cyclic Symmetry
- Line Pressure
- Pressure or Force applied using the surface effect elements created on the top of the scoped geometry (**Applied By** property set to **Surface Effect**)
- Remote Force or Moment not scoped to global remote points
- Commands (APDL) object

Transient Thermal Analysis

Introduction

Transient thermal analyses determine temperatures and other thermal quantities that vary over time. The variation of temperature distribution over time is of interest in many applications such as with cooling of electronic packages or a quenching analysis for heat treatment. Also of interest are the temperature distribution results in thermal stresses that can cause failure. In such cases the temperatures from a transient thermal analysis are used as inputs to a structural analysis for thermal stress evaluations. Transient thermal analyses can be performed using the Mechanical APDL, Samcef, ABAQUS, or LS-DYNA solvers.

Many heat transfer applications such as heat treatment problems, electronic package design, nozzles, engine blocks, pressure vessels, fluid-structure interaction problems, and so on involve transient thermal analyses.

Point to Remember

A transient thermal analysis can be either linear or nonlinear. Temperature dependent material properties (thermal conductivity, specific heat or density), or temperature dependent convection coefficients or

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

radiation effects can result in nonlinear analyses that require an iterative procedure to achieve accurate solutions. The thermal properties of most materials do vary with temperature, so the analysis usually is nonlinear.

Preparing the Analysis

Create Analysis System

General *Basic general information about this topic (p. 323)*

Specifics ***... for this analysis type:***

From the **Toolbox**, drag the **Transient Thermal**, **Transient Thermal (Samcef)**, **Transient Thermal (ABAQUS)**, or LS-DYNA template to the **Project Schematic**.

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

Thermal Conductivity, Density, and Specific Heat must be defined for a transient thermal analysis. Thermal Conductivity can be isotropic or orthotropic. All properties can be constant or temperature-dependent.

Attach Geometry

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

There are no special considerations for a transient thermal analysis.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

Mechanical does not support Rigid Bodies in thermal analyses. For more information, see the *Stiffness Behavior* documentation for Rigid Bodies (p. 852).

You can define a **Thermal Point Mass** (p. 905) for this analysis type.

Define Connections

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

In a thermal analysis only contact is valid. Any joints or springs are ignored.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

With contact the initial status is maintained throughout the thermal analysis, that is, any closed contact faces will remain closed and any open contact faces will remain open for the duration of the thermal analysis. Heat conduction across a closed contact face is set to a sufficiently high enough value (based on the thermal conductivities and the model size) to model perfect contact with minimal thermal resistance. If needed, you can model imperfect contact by manually inputting a **Thermal Conductance** (p. 1253) value.

By default, Contact Results (p. 2043) (accessible through User Defined Results (p. 2192) via CONTSTAT or CONTFLUX – see the User Defined Results for the Mechanical APDL Solver (p. 2203) section.) are not written to the result file in a thermal analysis.

Apply Mesh Controls/Preview Mesh

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

There are no specific considerations for transient thermal analysis itself. However if the temperatures from this analysis are to be used in a subsequent structural analysis the mesh must be identical. Therefore in this case you may want to make sure the mesh is fine enough for a structural analysis.

Establish Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

For a Transient Thermal analysis, the basic **Analysis Settings** controls include:

Step Controls for Static and Transient Analyses (p. 1418)

Step Controls are used to: i) specify the end time of the transient analysis, ii) control the time step size, and iii) create multiple steps when needed.

The rate of loading could be important in a transient thermal analysis if the material properties vary rapidly with temperature. When such nonlinearities are present it may be necessary to apply the loads in small increments and perform solutions at these intermediate loads to achieve convergence. Multiple steps are needed if you want to change the solution settings, for example, the time step size or the solution output frequency over specific time spans in the transient analysis.

Output Controls (p. 1473)

Solver Controls enable you to specify the time points at which results should be available for postprocessing. A transient analysis involves calculating solutions at several time points in the load history. However: i) you may not be interested in all the intermediate results and ii) writing all the results can make the results file size unwieldy. In this case you can restrict the amount of output by requesting results only at certain time points.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Nonlinear Controls (p. 1468)

Nonlinear Controls enable you to modify convergence criteria and other specialized solution controls. Typically you will not need to change the default values for this control.

Analysis Data Management (p. 1484)

Analysis Data Management settings enable you to save specific solution files from the transient thermal analysis for use in other analyses.

Define Initial Conditions

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

A transient thermal analysis involves loads that are functions of time. The first step in applying transient thermal loads is to establish initial temperature distribution at Time = 0.

The default initial condition for a transient thermal analysis is a uniform temperature of 22°C or 71.6°F. You can change this to an appropriate value for your analysis. An example might be modeling the cooling of an object taken out of a furnace and plunged into water.

You can also use the temperature results from a steady-state analysis of the same model for the initial temperature distribution. A casting solidification study might start with different initial temperatures for the mold and the metal. In this case a steady-state analysis of the hot molten metal inside the mold can serve as the starting point for the solidification analysis.

In the first iteration of a transient thermal analysis, this initial temperature is used as the starting temperature value for the model except where temperatures are explicitly specified. In addition this temperature is also used to evaluate temperature-dependent material property values for the first iteration.

If the **Initial Temperature** field is set to **Non-Uniform Temperature**, a **Time** field is displayed where you can specify a time at which the temperature result of the steady-state thermal analysis (selected in **Initial Condition Environment** field) will be used as the initial temperature in the transient analysis. A zero value will be translated as the end time (of the steady-state thermal analysis) and this value can not be greater than the end time.

Apply Loads and Supports

General *Basic general information about this topic (p. 354)*

Specifics ***... for this analysis type:***

The following loads are supported in a transient thermal analysis:

- Temperature (p. 1598)
- Internal Heat Generation (p. 1620)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Convection (p. 1602)
- Radiation (p. 1609)
- Heat Flow (p. 1614)
- Perfectly Insulated (p. 1614)
- Heat Flux (p. 1617)
- Imported Heat Generation (p. 1748)
- Imported Temperature (p. 1756)
- Imported Convection Coefficient (p. 1744)
- System Coupling Region (p. 1651)

In this analysis, the load's magnitude could be a constant value or could vary with time as defined in a table or via a function. Details of how to apply a tabular or function load are described in Defining Boundary Condition Magnitude (p. 1771). In addition, see the Apply Loads and Supports (p. 354) section for more information about time stepping and ramped loads.

Solve

General *Basic general information about this topic (p. 355)*

Specifics ***... for this analysis type:***

The **Solution Information** (p. 1833) object provides some tools to monitor solution progress.

Solution Output continuously updates any listing output from the solver and provides valuable information on the behavior of the structure during the analysis. Any convergence data output in this printout can be graphically displayed as explained in the **Solution Information** (p. 1833) section.

You can also insert a **Result Tracker** (p. 1844) object under **Solution Information**. This tool enables you to monitor temperature at a vertex as the solution progresses. **Result Tracker** is not available to the Samcef or ABAQUS solver.

Review Results

General *Basic general information about this topic (p. 356)*

Specifics ***... for this analysis type:***

Applicable results are all thermal result types (p. 2153).

Once a solution is available you can contour the results (p. 62) or animate the results (p. 2260) to review the response of the structure.

As a result of a nonlinear analysis you may have a solution at several time points. You can use probes (p. 1946) to display the variation of a result item over the load history. Also of interest is the ability to plot one result quantity (for example, maximum temperature on a face) against another results item (for example, applied heat generation rate). You can use the Charts (p. 1929) feature to develop such charts.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Note that Charts (p. 1929) are also useful to compare results between two analyses of the same model.

Special Analysis Topics

This section includes special topics available the Mechanical application for particular applications. The following topics are included:

Additive Manufacturing Process Simulation
Composite Analysis
ECAD Analysis using Trace Mapping
Electromagnetics (EM) - Mechanical Data Transfer
External Data
External Study Import
Fluid-Structure Interaction (FSI)
Icepak to Mechanical Data Transfer
Inverse Solving for Nonlinear Static Structural Analyses
Mechanical-Electronics Interaction (Mechatronics) Data Transfer
Polyflow to Mechanical Data Transfer
Reinforcement Specification Using Mesh-Independent Method
Rotordynamics Analysis
Substructure Analysis
Static Analysis From Rigid Dynamics Analysis
Submodeling
System Coupling
Thermal-Stress Analysis
Transferring Hydrodynamic Loads to a Structural System
Twin Builder/Rigid Dynamics Co-Simulation

Additive Manufacturing Process Simulation

An additive manufacturing process constructs 3D objects by building one layer at a time until the object is complete. Of the various 3D print processes available in additive manufacturing, Ansys Mechanical simulates the Laser Powder Bed Fusion (LPBF) and Directed Energy Deposition (DED) processes for metals. These processes use a laser to melt and fuse each individual layer of metal powder to the layers below it to create a part.

For detailed, step-by-step instructions and background information on simulating these additive manufacturing methods, consult the LPBF Simulation Guide and the DED Simulation Guide.

Composite Analysis

Layered Composites: You can create a layered composite model using the Ansys Composite PrepPost (ACP) application. You can then import the model into Mechanical and perform a composite analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Often, you employ the Composite Failure Tool (p. 2072) to perform post-processing on your composite structures that you modeled using ACP. To better understand how to perform the steps for this analysis, see the Workbench Workflow Examples in the *ACP User's Guide*.

Short Fiber Reinforced Composites: You can simulate short fiber reinforced composites by importing injection molding simulation results in Mechanical through the **Injection Molding Data** system. This process involves importing and mapping fiber orientation tensor data from other software tools onto the mesh defined in Mechanical. When combined with a homogenized material computed with Material Designer, this workflow allows you to perform a Mechanical analysis of parts made of short fiber reinforced composites. To better understand how to perform the steps for this analysis, see the Short Fiber Composites Guide.

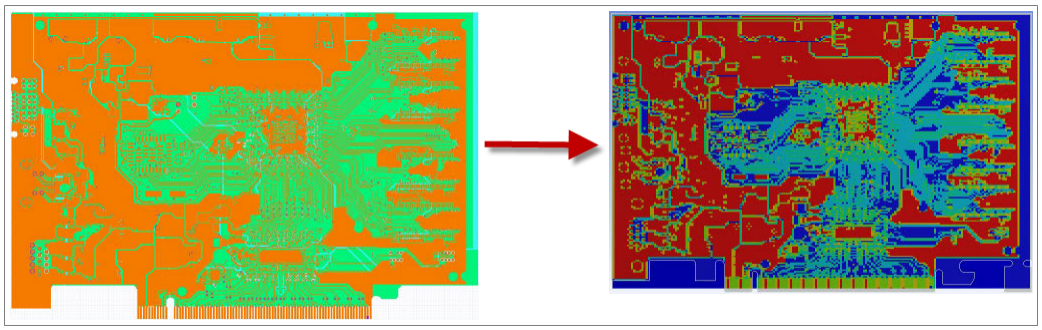
ECAD Analysis using Trace Mapping

Mechanical's trace mapping feature provides a fast and efficient method to model Printed Circuit Boards (PCBs) and packages that would otherwise require an inordinate amount of time to process a geometry and mesh. Typically, the geometry that you produce in your electronic computer-aided design (ECAD) system contains a large number of bodies and therefore large amounts of data. Given the complexity of the system, producing a mesh can be very difficult. The trace mapping feature simplifies your model by modeling the geometry as dielectric layers and includes the effect of traces by mapping the metal fraction onto the dielectric layers.

Mapping takes place in two stages. As illustrated below, during the first stage, a representation of the layout is built upon a rectangular grid using the data from a specified ECAD layout. The cell size of the grid is governed by the smallest features in the layout that have to be resolved. This size can be controlled by the user and should be specified based on the resolution required. A metal fraction value is assigned to each cell depending on the contribution of metal to that cell. The metal fraction value ranges from 0 to 1, where the 0 value represents a pure dielectric material and 1 a pure metal material.

The conduction paths that connect the metal traces between the different layers, that is, the vias, can be specified as either hollow or solid (default).

Building a Representation Upon a Rectangular Grid



During the second stage, the metal fraction values are mapped from the source grid to the target mesh. Once the mesh is created, Mechanical then generates the mapped metal fractions. The sequence of this construction is illustrated below.

Mapping Metal Fractions

General Workflow from Workbench

The following workflow describes the general steps to perform an analysis of a Printed Circuit Board that includes trace mapping.

1. Import supported ECAD files into External Data and update your project.
2. Add the supported Mechanical system to the project.
3. Add appropriate materials using Engineering Data.
4. You can open an ECAD layout geometry in an analysis system in Workbench once you have the proper file format. You can use SpaceClaim or SCDM.

   Note:

   You can open Ansys EDB, ODB++, and IPC2581 files in Mechanical using the **Geometry** cell of the analysis system. An External Data system is not required until you import the trace mapping. See the ECAD Import (p. 703) section for more information.

5. Connect the **Setup** cell of the External Data system to the analysis system's **Model** cell.
6. Launch Mechanical. See the next section Trace Mapping in Mechanical (p. 693) for the specifics of setting up the Imported Trace object.
7. Specify vias as required.
8. Assign (p. 345) Dielectric material to the bodies. As needed, modify additional **Geometry** object properties.

   Note:

   Reference temperatures specified on bodies are included in the solution calculation for any trace material contained in an element on the associated body.

9. Assign appropriate ECAD File to **Imported Trace** object.
10. Verify that the trace layout source is properly aligned (p. 698) with geometry.
11. Assign Metal material (p. 696) to imported trace layers.
12. Define and generate mesh.
13. Set discretization (p. 695).
14. Generate the trace mapping.
15. Define boundary conditions (p. 1500).

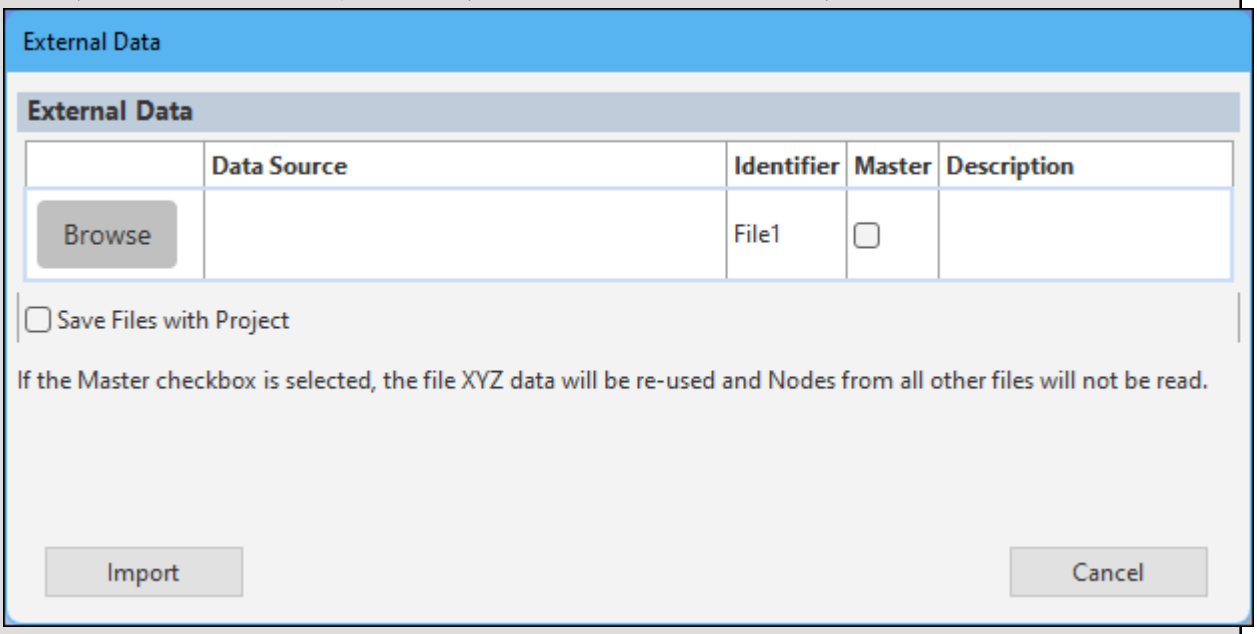
General Workflow from Mechanical

The following workflow describes the general steps to perform an analysis of a Printed Circuit Board that includes trace mapping.

1. Open the application from the **Start Menu** option **Ansys 2024 R1** and select **Mechanical 2024 R1**.
2. Insert an analysis system.
3. From the Materials object, select the **Imported Trace** option. The application automatically inserts the Imported Trace object into the tree and the External Data (p. 736) dialog displays. You use this dialog to specify the desired external file(s) you wish to import.

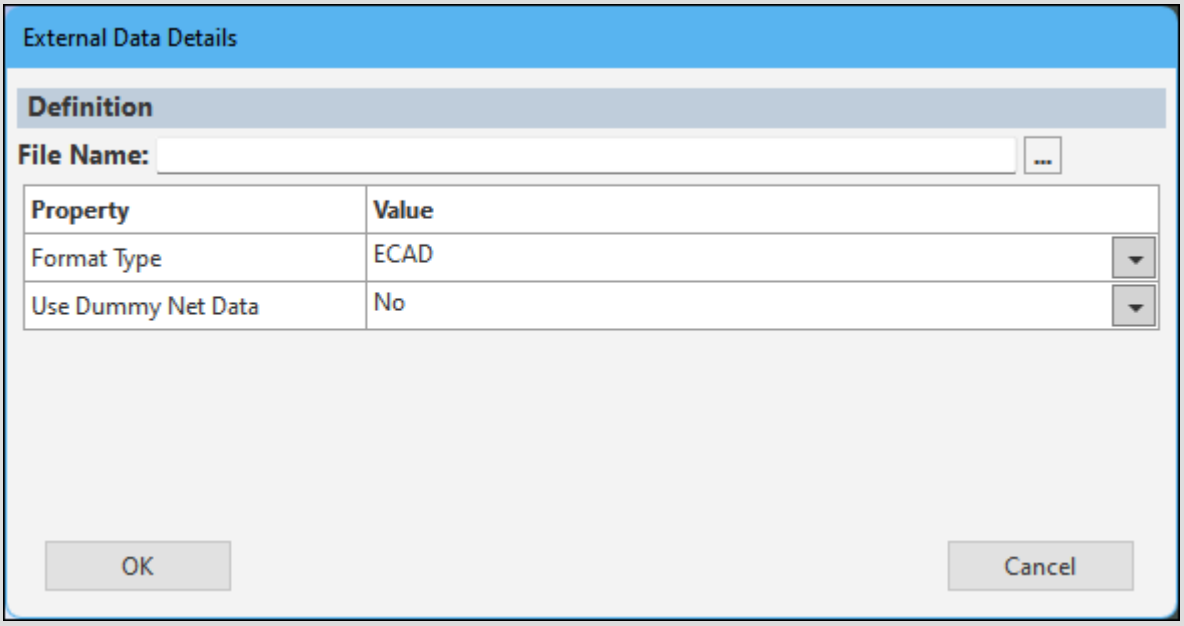


> **Note:**
>
> If you have already selected a file and displayed the dialog, there are two additional context (right-click) menu options: **Edit** and **Reload**. The **Edit** option re-opens the External Data dialog enabling you to modify the imported object's details and the **Reload** option reloads data from the source file(s).

4. Select the **Browse** button. The following dialog displays.
5. Select a desired file using the **File Name** option.
6. Specify a desired **File Format** and associated properties. Options include:
   - **ECAD**: Supported data files include ANSOFT ANF, ODB++ TGZ, IPC-2581 XML, or EDB DEF. The Use Dummy Net Data property specifies whether to import trace data belonging to the dummy net of the file.
   - **ICEPAK**: This format type supports ICEPAK BOOL or ICEPAK COND data.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



7. Select the **OK** button and then the Import button. The data file is now associated with the object.

   See the next section Trace Mapping in Mechanical (p. 693) for the specifics of setting up the Imported Trace object.

8. Specify vias as required.

9. Assign (p. 345) Dielectric material to the bodies. As needed, modify additional **Geometry** object properties.

   Note:

   Reference temperatures specified on bodies are included in the solution calculation for any trace material contained in an element on the associated body.

10. Assign appropriate ECAD File to **Imported Trace** object.

11. Verify that the trace layout source is properly aligned (p. 698) with geometry.

12. Assign Metal material (p. 696) to imported trace layers.

13. Define and generate mesh.

14. Set discretization (p. 695).

15. Generate the trace mapping.

16. Define boundary conditions (p. 1500).

17. Solve the analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

18. Define and evaluate results (p. 1927).

Requirements

This workflow requires the following components or systems:

- Engineering Data: This component enables you to define materials required for the analysis. The materials defined the in the Engineering Data component will be available in the corresponding Mechanical model. For your convenience two materials (FR-4 and Copper Alloy) which commonly represent dielectric and metal in a PCB are available in the General Materials sample library.
- **Geometry**: This component enables you to create or import the geometry representing the board or the package layout. The SpaceClaim geometry editor enables you to directly import the supported ECAD formats (see below) and automatically create a (trace layout) **Geometry**. See the ECAD section in *Importing and exporting* in the SpaceClaim documentation for details.
- External Data: This component enables you to specify the ECAD file for import in Mechanical. The following ECAD File formats are supported for Trace Analysis (p. 693):

  In Mechanical

  - Ansys EDB
  - ODB++
  - IPC2581

  In External Data

  - Ansoft ANF (External Data)
  - ODB++ TGZ
  - Icepak BOOL+INFO

    Note:

    For this file type, when you are using the Linux platform, the metal fraction calculation is not supported when you start Workbench using remote access software.

  - Icepak COND+INFO

  Once an ECAD file is specified in **External Data**, additional **Rigid Transformation** controls are available in the component to align the trace data with the geometry.
- **Mechanical Systems**: The supported Mechanical systems enable you to import Trace Data, setup the analysis and solve. The following analysis are supported:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Supported Structural Analysis Systems

- Harmonic Response
- LS-DYNA
- LS-DYNA Restart
- Modal
- Static Structural
- Transient Structural

Supported Thermal Analysis Systems (Solid Bodies Only)

- Steady-State Thermal
- Transient Thermal

See Trace Mapping in Mechanical (p. 693) for the specifics of setting up an analysis.

Trace Mapping in Mechanical

This section examines the following trace mapping topics:

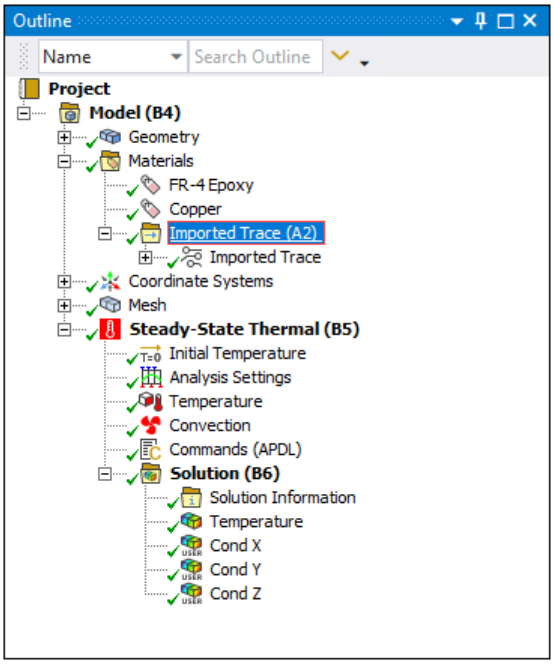
- Import Trace Mapping (p. 693)
- Specify External File (p. 694)
- Specify Properties and Settings (p. 695)
- Import Trace Layout Data (p. 699)
- Visualize Source Data (p. 701)
- Apply Boundary Conditions (p. 702)
- Solve the Analysis (p. 702)
- Evaluate Results (p. 703)

Import Trace Mapping

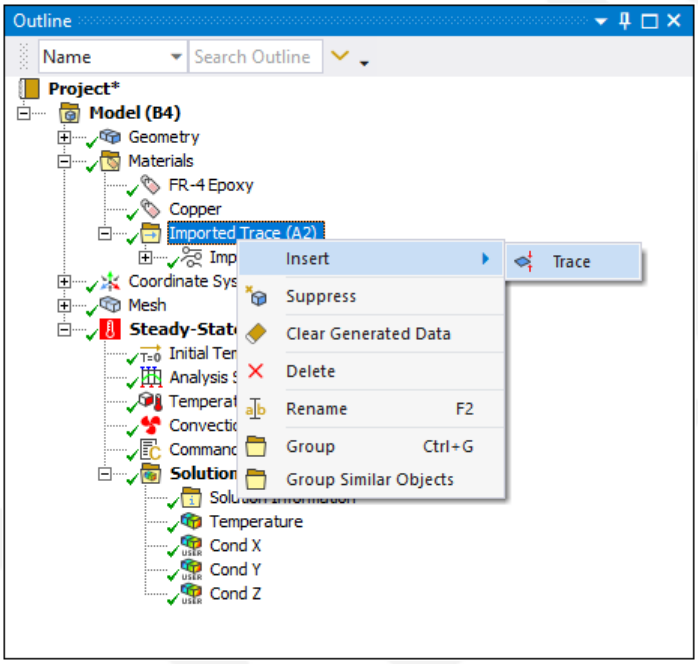
This step applies to the workflow for importing data from Workbench. In Mechanical, the application automatically inserts an Imported Trace folder and an Imported Trace object under the **Material** object.

DRAFT

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Using the context menu (right-click) option **Insert** > **Trace** enables you to insert additional **Imported Trace** objects into the tree as needed.



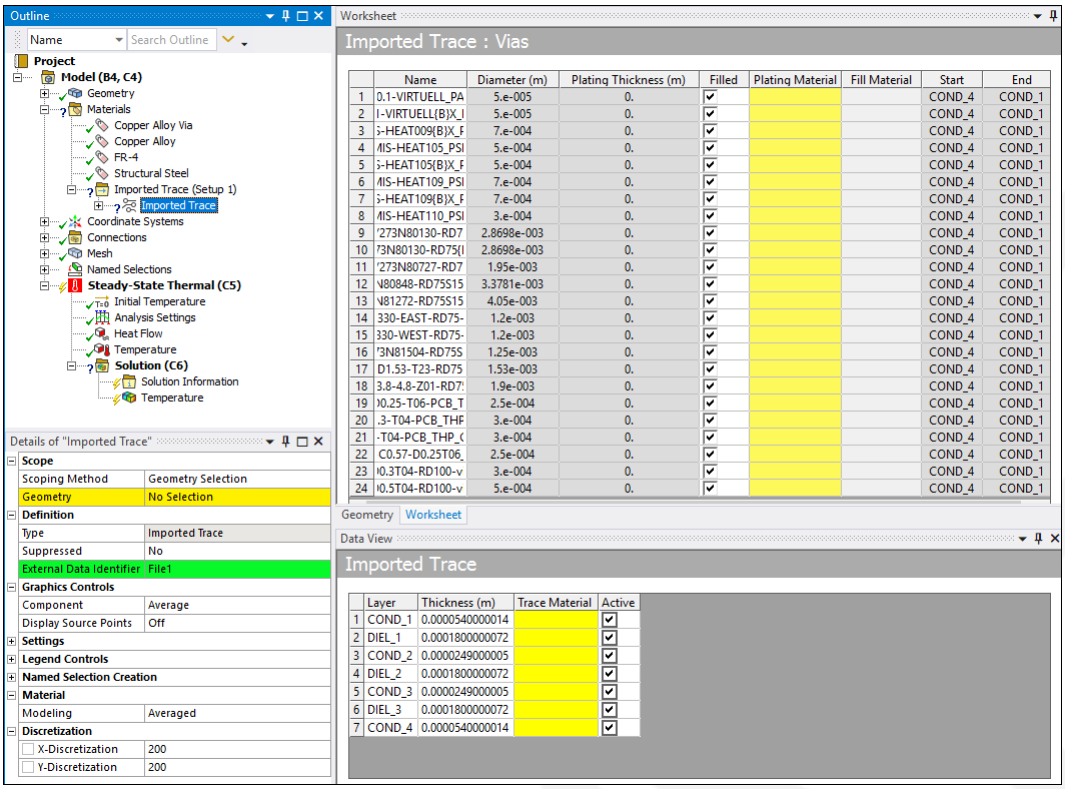
Specify External File

Once inserted, the **Imported Trace: Vias** Worksheet and the **Data View** window display. Once you specify the **External Data Identifier** property, source system data populates various application fields.

You can use the context (right-click) option on the **Worksheet** and **Data View** table to specify materials for the vias and imported traces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Specify Properties and Settings

The **Details** view and the **Data View** for the **Imported Trace** object enable you to control the specification of the imported trace file in Mechanical.

The following options are available in the Details pane to control the **Imported Trace** specification.

- **Scope**: The **Geometry** or the **Named Selection** properties, as specified by the **Scoping Method** property, support scoping to the bodies representing the layer geometry for the PCB or to elements contained on the layers of geometry.

  You can model the geometry of a PCB as a shell or solid. When modeled as solid, you should model each layer as a separate body. When modeling shells, the application models all of the layers as a single shell geometry. Mechanical uses layered shell elements to model the layers of a PCB.

  Note:

  Using the meshing Sweep Method Control, you can mesh a solid body with the Solid-Shell element (SOLSH190). This option is available from the **Element Option** property of the **Sweep Method**.

- **External Data Identifier**: This property provides a drop-down list of available ECAD files from the list of files specified in the **External Data** system.

- **X-/Y-Discretization**: Mechanical performs a two stage mapping to calculate metal fractions on the target mesh. First it computes a metal fraction distribution of the board from the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

source ECAD file to a regular grid, and then from the regular grid to the target mesh. The **X-/Y-Discretization** properties enable you to specify the size of the regular grid. The grid density count is **200** x **200** by default. Depending on the trace resolution and the computational costs desired, you can change the values for the rows and columns to receive optimum results. For accurate results, it is recommended that the X and Y discretization be specified such that the grid cell length be less than or equal to the minimum trace width. The Mechanical mesh size is recommended to be less than 4 times the grid cell length.

These fields are read-only when the ECAD File specified in **External Data Identifier** is of Icepak **COND+INFO** format and displays the discretization of the **COND** file.

Numerous additional properties are available in the Details. See the Data Transfer Mesh Mapping (p. 2389) section for more information about these various properties.

The **Data View** of the **Imported Trace** object enables you to see and/or control/override the following properties of the layers in the trace layout:

- **Layer**: The name of the **Layer**.
- **Thickness**: The thickness of the layers.
- **Trace Material**: This property specifies the material for the metal traces on each layer. This material is created in the Engineering Data workspace for the Mechanical system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Dielectric Material** (shell geometry only): This property specifies the dielectric material for each layer.

  This option is only available for traces scoped to shells. For imported traces scoped to solids, the base (dielectric) material is specified on the **Material Assignment** property of the selected bodies (under the Geometry object).

- **Active**: This option enables you to activate or deactivate one or more layers. This option is not available for shell geometries. All layers are sent to the solver for traces imported on shells.

- **Mechanical Layer No.**: Only available for traces scoped to shells. This read-only field displays the layer number by which this layer is identified. For example, if you want to post process results on the *L1* layer show below, you will need to specify *Layer 7* in the Details view of the result object.

Geometry | Worksheet

Column Heading	Column Description
Name	This field displays the name of the layer as defined in the source file.
Diameter	This read-only field displays the outer diameter value of the via.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Column Heading	Column Description
Plating Thickness	This field displays the thickness of the interior wall of the via that is not filled. Only applicable when via is hollow (not filled).
Filled	Check and/or uncheck this fill to indicate whether the vias is filled or hollow.
Plating Material	When active, this field displays the metal material of the via. It provides a drop-down menu that enables you to specify different materials for the via.
Fill Material	This field provides a drop-down menu when the corresponding **Fill** option is inactive, i.e. via is hollow (not filled). It enables you to specify a material for the hollow region of the via. You can assign Air (defined in Engineering Data) if the hollow region is empty.
Start/End	These read-only fields display the layer associated with where the via starts and ends.

In addition to these basic controls, the Details view of the **Imported Trace** object provides additional properties that enable you to control/visualize the source data in Mechanical:

- **Display Source Points**/**Interior Points**: These properties enable you to visualize the source points from the trace layout files. These settings can be used to verify the alignment of the source points with the target geometry. If misaligned, use the **Rigid Transformation** controls in the **External Data** system to align the source mesh with the target.
- **Mapping Control**: This property controls mapping settings for the import. Options include **Program Controlled** (default) and **Manual**. The **Program Controlled** option enables the application to determine the appropriate algorithm and settings based on the source and target mesh data, as well as the data type being transferred. See the Program Controlled Mapping (p. 2408) topic in the *Data Transfer Mesh Mapping* section for additional information.
- **Interpolation**: Options include **Nondirectional** (default) and **Directional**. The **Nondirectional** option calculates effective conductivity by averaging the trace data in each element. Using the **Directional** option, the application calculates the effective orthotropic conductivity for each element using the position and values of the trace data within each element.

  Directional Trace Mapping

  This interpolation calculates orthotropic thermal conductivities for each element. The calculation is done by modeling the trace data in each element as a thermal resistance network. The examples illustrated below describe the calculated conductivity values based on the corresponding scenarios on the left. The dielectric in this example has a conductivity of 0.294 W/mK and the metal has a conductivity of 400 W/mK. Each element is 51% metal and 49% dielectric (Metal Fraction of 0.51).

	Metal Fraction	Kx (W/mK)	Kx (W/mK)	Kz (W/mK)

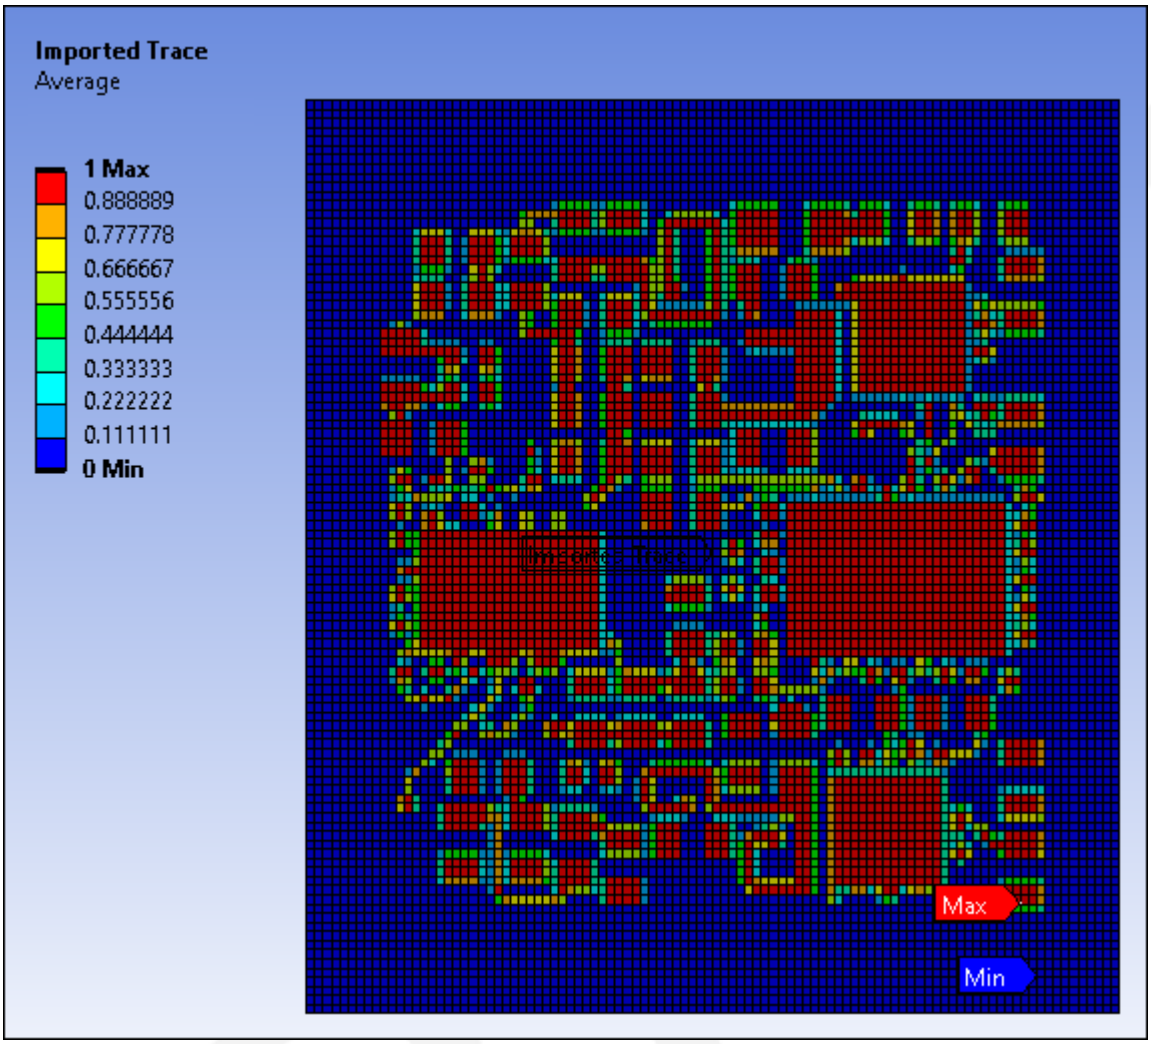
Import Trace Layout Data

Once you have fully defined the object, right-click the **Imported Trace** object and select **Import Trace** to import the trace layout data onto the specified bodies. As illustrated below, the object displays the variable data, per element, of how much of the trace data is dielectric (metal) material. One (1) is 100% metal and zero (0) is 0% metal.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



When you import trace layout data, the application generates the Imported Data Transfer Summary object. This object presents a summary, in the Comment pane, of the mapped source data as compared to target data. More specifically, it presents an average metal fraction for target elements, including both averaged modeling and black/white modeling. This enables you to validate your target metal fractions against the external application, such as Ansys Sherlock, you use to provide this metal fraction. However, unless the source data aligns perfectly to the target mesh, Ansys does not recommended that you compare the source and target average metal fractions.

In addition, the following properties in the **Graphics** category help to visualize the mapped data:

- **Component**: X, Y, or Z component or the average of the imported metal fraction data.
- **Layer**: Layer to display the data for (only applicable when scoped to shells)

Visualize Source Data

The source data can be visualized using the Validation object. To visualize the source data, use the context menu option **Insert**>**Validation** on the **Imported Trace** object to insert a **Validation** object in the tree. Once inserted, set the appropriate properties and use context menu option **Analyze**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

on the validation object. See Mapping Validation (p. 2412) in the *Ansys Mechanical User's Guide* for details.

Apply Boundary Conditions

You can freely apply any supported boundary condition (p. 1500) on solid bodies scoped to Imported Traces. Certain restrictions apply for boundary conditions on shell bodies scoped to Imported Traces. For example boundary conditions like Thermal Condition (p. 1594) and Imported Body Temperature (p. 1740) can only be applied to both the shell faces.

Solve the Analysis

The effects of **Imported Trace** data are included during the solution phase by computing the material properties of the materials assigned to the bodies based on the metal fraction. The **Modeling** property in the **Material** group controls how material properties are calculated based on computed metal fraction values. Two options are available:

- **Black/White**: Assign trace material to regions with average metal fraction greater than or equal to 0.5, and dielectric to the rest.
- **Averaged**: Calculate material properties based on calculated metal fraction. The supported material properties based on metal fraction are listed in the tables below:

  Thermal Analysis

  The supported thermal material properties include:

  – Thermal Conductivity (Kx/Ky/Kz)

  – Specific Heat

  Structural Analysis

  The supported structural material properties include:

  – Young's Modulus (Ex/Ey/Ez)

  – Poisson's Ratio (PRxy/PRyz/PRxz)

  – Coefficient of Thermal Expansion

  – Density

  Note:

  – Non-linear materials are not supported when **Material Modeling** is set to **Averaged**. If the application detects non-linear materials assigned either as trace or dielectric material when the material modeling is set to **Average**, then the **Imported Trace** object becomes invalid and the solution cannot proceed unless the conditions are made valid.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- If any linear material properties other than the ones listed in the above table are present on either the trace or dielectric material, they are not sent to the solver.
- When using LS-DYNA trace mapping, thermal analysis is not supported, and the coefficient of thermal expansion is not a supported material property.

Material Property Calculation for Temperature Dependent Material Properties

For temperature dependent material properties, averaging takes place over two stages. First the material properties are calculated at the union of all the temperatures, and then the average metal properties are calculated based on the above table for each temperature point. For example, the Metal material has property **P** specified at temperatures **T1**, **T2** and **T3**, whereas the Dielectric material has property **P** specified at **T2** and **T4**, then the material property is first calculated for both Metal and Dielectric materials at temperatures **T1**, **T2**, **T3**, and **T4**, and then the effective material properties are calculated at **T1**, **T2**, **T3**, and **T4** using the table specified above.

Offsets (Only applicable for shells)

When scoped to shells, the **Shell Offset** property allows user to specify the shell offset for the scoped bodies. Available options are **Top/Middle/Bottom** and **User Defined**. The **User Defined, Membrane Offset** property allows you to specify the offset value.

Evaluate Results

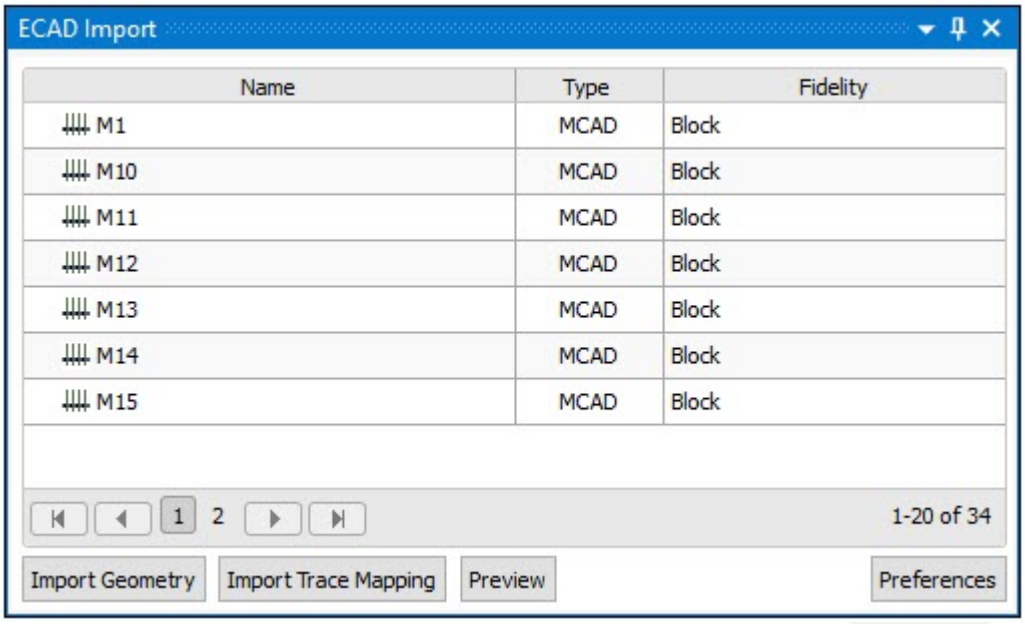
Once the solution is complete, user can insert appropriate results and evaluate them. Since the effect of metal and dielectric within an element is captured through material property averaging, stress results may deviate from full fidelity analysis. However it provides a qualitative description of stress distribution. User may perform a subsequent Submodeling analysis to get accurate stress distribution.

ECAD Import Pane (Windows Only)

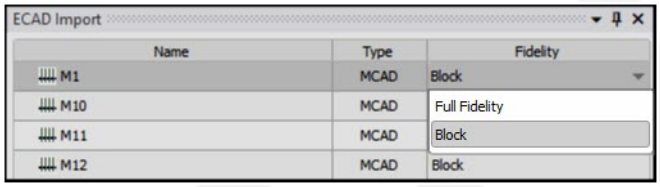
On the Windows platform, you can open Ansys EDB, ODB++, and IPC2851 ECAD files directly in Mechanical using the **Geometry** cell of the analysis system.

When you import ECAD files into Mechanical, the **ECAD Import** pane, illustrated below, displays automatically. Because printed circuit boards contain many detailed components, this feature enables you to either limit or expand the degree of detail for displaying a component and its bodies. Specifically, you can greatly simplify the display of complicated components that are not pertinent to your analysis and as a result speed up processes such as mesh and solution.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The first two columns of the pane list each part of your model by **Name** and **Type**. Parts can include PCBs, MCAD components (3D geometries representing board components like USB ports, power connectors), BGAs, etc. The **Fidelity** column enables you to specify whether to present a component as a **Block** (default) or to includes the detailed parts or bodies of the component using the **Full Fidelity** option.



ECAD Import Pane Features

The **ECAD Import** pane provides the following options for your analysis:

Import Geometry

This option imports your geometry into Mechanical. You can make fidelity changes before and after importing the geometry. You must select the **Import Geometry** button again in order changes to take effect.

Import Trace Mapping

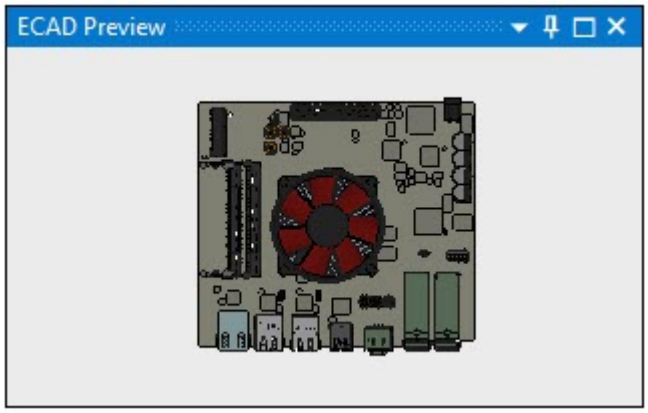
This option automatically links an upstream **External Data** system to the **Model** cell of your analysis on the Workbench project page and imports Trace Mapping data. An **Imported Trace (Group)** folder and its child object, Imported Trace, are automatically inserted under the Materials folder in the **Outline**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

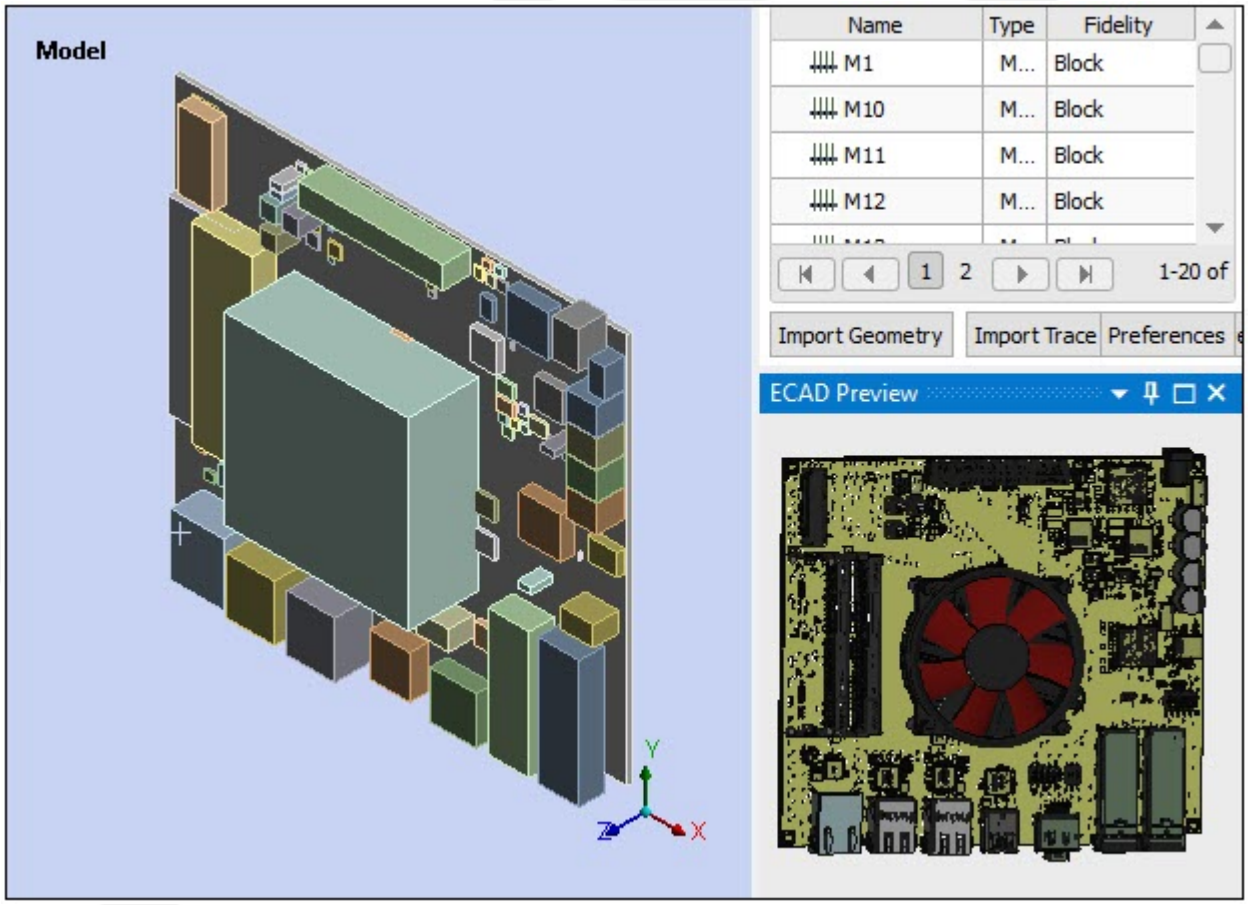
Published: 2023-10-23

Preview

The **Preview** option displays a rendering of your model. By default, before you import your geometry into Mechanical, the **ECAD Preview** pane renders it with all components in **Full Fidelity**.



Once you select the **Import Geometry** button, the model renders in the **Geometry** window based on the settings of the **ECAD Import** pane. An example is illustrated here with all components using **Block** fidelity.



You can change the fidelity settings as desired and update the model rendering in the **Geometry** window using the **Import Geometry** button. Note that this action can invalidate scoping.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Preferences

The **Preferences** button displays the dialog shown below. The options of the dialog are active by default. These options automatically take general import actions.

Dialog	Preference	Description
	**Group Components**	Automatically g under the **Geor**
	Import Materials	Automatically ir the materials fr to complete the
	Import Package Detail	Automatically ir

Defining Fidelity following Import

In addition to the drop-down menu of each row in the **ECAD Import** pane, you can change the **Fidelity** using any of the following methods. Once a fidelity change is made to a component, you must select the **Import Geometry** button in order for it to take effect. Also note that re-importing the model can affect the scoping of associated components.

- Select multiple rows simultaneously using the **[Shift]** key.
- Select multiple rows individually using the **[Ctrl]** key.
- Right-click on parts of the model in the **Geometry** window and select **Set Fidelity** > **Block** or **High Fidelity**. This action also automatically displays the ECAD Import pane if it is not already displayed.

Electromagnetics (EM) - Mechanical Data Transfer

You can import data generated by the HFSS, Maxwell, or Q3D Extractor applications and perform an analysis in Mechanical by applying the imported loads. In the case of loads originating from HFSS and Maxwell, you can also export the temperature or deformation results obtained from the Mechanical analysis so that they can be imported back into HFSS or Maxwell. Furthermore, you can import:

- Thermal loss data generated by the HFSS, Maxwell, or Q3D Extractor applications and use the imported load to perform a thermal analysis. The resulting temperature results then can be exported and applied during the subsequent solution of the upstream Maxwell analysis.
- Force densities generated by the Maxwell application and use the data to perform a static or transient structural analysis. The resulting deformation results can then be exported and applied during the subsequent solution of the upstream Maxwell analysis.
- Forces and Moments or Surface Force Densities generated by the Maxwell application to use as loading conditions in a Harmonic Response analysis using the load. If you perform a Maxwell Parametric Study, the application automatically transfers all Maxwell loads for all RPMs.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Overall Workflow for an EM - Mechanical Analysis

1. Create and solve the electromagnetic application using HFSS, Maxwell, or Q3D Extractor.
2. Drag and drop a steady-state thermal, transient thermal, static structural, transient structural, or harmonic (Maxwell *only*) template on top of the HFSS, Maxwell, or Q3D Extractor systems solution cell to enable the data transfer.
3. Attach geometry to the Mechanical application, and then double-click **Setup** to open the Mechanical window. An **Imported Load** or an **Imported Remote Load** folder is added under the **Environment** folder, by default.

   Note:

   Note that a Maxwell system is not required for a Coupled Field Harmonic, Harmonic Acoustics, and Harmonic Response analysis to import Remote Force and Remote Moment boundary conditions. These boundary conditions can be imported directly from an external Maxwell file. See the Importing Forces and Moments (p. 711) section for more information.

4. As required, you can add or generate imported loads and set their options.
5. Perform all steps to set up a Steady-State Thermal (p. 657), Transient Thermal (p. 680), Static Structural (p. 652), Transient Structural (p. 665), Coupled Field Harmonic (p. 380), Harmonic Acoustics, or Harmonic Response (p. 496) analysis. Specify mesh controls, boundary conditions, and solution settings as you normally would.
6. Solve the Ansys analysis.
7. If applicable, export your results to make them available for import by the upstream applications.

See the following sections for more detailed procedures to import and/or export loads during Thermal, Structural, and Harmonic analyses.

- Importing Data into Thermal or Structural (Static or Transient) Analyses (p. 707)
- Importing Data into Harmonic Analyses (p. 710)
- Exporting Results from Thermal or Structural Analyses (p. 718)
- Electric Machines NVH Analyses (with Waterfall Diagram) (p. 720)

For additional information, refer to the **Maxwell Coupling** section in the **Maxwell Online Help**, available through the *Ansys customer site*.

Importing Data into Thermal or Structural (Static or Transient) Analyses

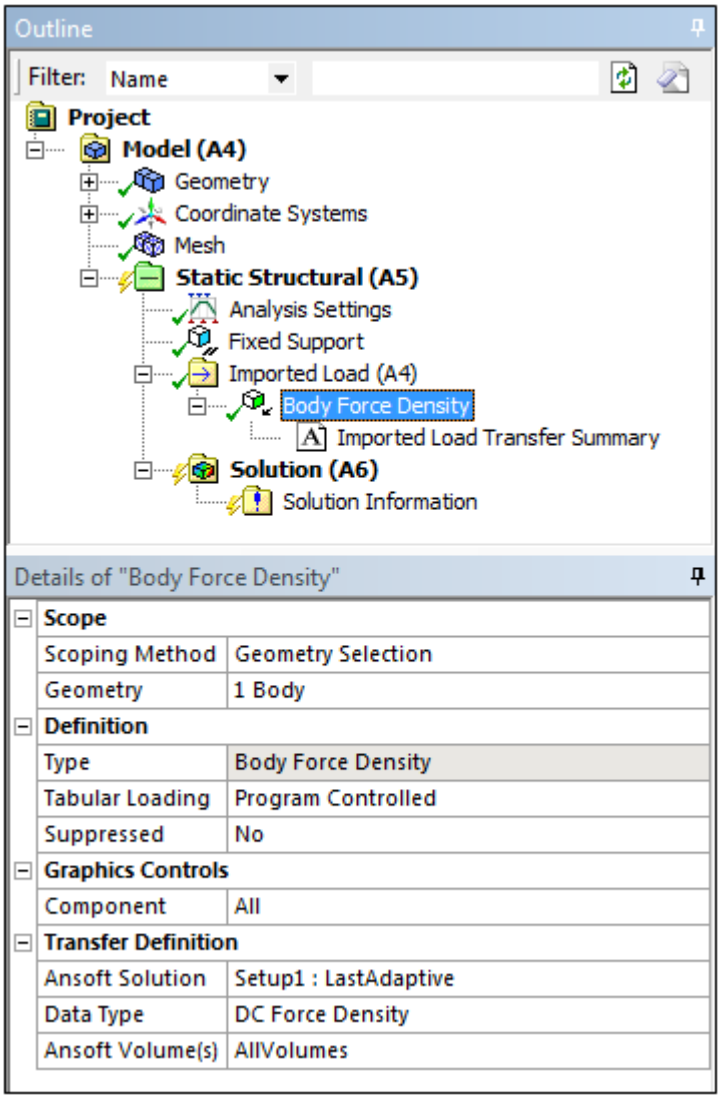
This feature enables you to perform a one-way Electromagnetics (EM) - Mechanical interaction problem by solving the electromagnetic analysis of the geometry in the HFSS, Maxwell, or Q3D Extractor applications, importing the thermal or structural results into the Ansys Mechanical applic-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

ation where the defined load is applied to a thermal or structural analysis which is then solved and post processed.

For a thermal analysis, you can import Imported Heat Generation (p. 1748) and Imported Heat Flux (p. 1748) load types.

For a structural analysis you can import Imported Body Force Density (p. 1739) (illustrated below) and Imported Surface Force Density (p. 1755) load types.



Add the Imported Load

Follow these steps to add an imported load and associate it with parts of the geometry.

1. Double-click the **Model** cell in your analysis system to open the Mechanical application.
2. Click the **Imported Load** group object. In the Details view, set the following field as needed:
   - If you want to suppress all of the loads under this **Imported Load** group, set the **Suppressed** field to **Yes**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

3. For the **Body Force Density** and the **Surface Force Density** loading types, you can choose to import the **Max Force Density** or the **DC Force Density**, if the source provides the data, using the **Data Type** property. By default, the application imports the **DC Force Density** values. The application combines AC and DC values to calculate the **Max Force Density** value. Because the AC force is a complex vector, the peak vector among all phases of the AC force is taken and added to the DC force to obtain the **Max Force Density**.

4. There are several ways to select an imported load and associate it with a part of your model.

   - Select an **Imported Load** group object in the tree, select a part of the model, then right-click **Imported Loads** and from the **Insert** menu, select the desired load type. The load will be applied to the object you selected on the model.

   - Click an **Imported Load** group object in the tree, then select the **Imported Loads** drop-down menu on the Context tab and select the desired load type from the allowed imported load types. In the Details view, click the **Geometry** field. Select the objects in the model to which you want to apply the load and click the **Apply** button in the Geometry field.

   - Right-click the **Imported Loads** group object and select **Insert** and the desired load type from the allowed imported load types. In the Details view, click the **Geometry** field. Select the objects in the model to which you want to apply the load and click the **Apply** button in the Geometry field.

   Note:

   Heat generation loads scoped to a surface body use the constant thickness value specified in the details view of the surface body object when data is imported. Surface body thickness defined using the thickness object is not accounted for when data is imported.

Set the Imported Load Options

1. Click the imported load object that you've added to the tree.

2. Select the desired Ansoft solution you would like to import the load from. Some of the properties in the Details view and **Data View** tab are filtered based on this selection.

3. Change any of the fields in the Details View as needed:

   - **Scoping Method**: Select the method of choosing objects to which the load is applied: Geometry Selection or Named Selection.

   - **Geometry or Named Selection**: Use these fields to choose the objects to which the load is applied, as appropriate from your Scoping Method choice.

   - **Suppressed**: Select **Yes** to suppress this load.

   - **Ansoft Surface(s)**: Select the Ansoft Surface(s) for a Heat Flux or Surface Force Density load.

     or

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Ansoft Volume(s): Select the Ansoft Volume(s) for a Heat Generation or Body Force Density load.

Set the Imported Load Analysis Options

You can specify when the imported data should be applied and also modify the imported data, either by adding an offset or by using a scale factor.

To see the analysis setting for a load, click the object that you've added to the tree. The analysis options appear in the **Data View** tab of the window below the model. Make any changes to the load's analysis options as indicated below.

Change any of the columns in the **Data View** tab as needed:

- **Source Frequency** - Select from the drop-down list one of the frequencies supplied from the transfer file. The load values associated with this frequency will be imported.
- **Source Time** - Select from the drop-down list one of the Source Times supplied from the transfer file. The load values associated with this time will be imported.
- For thermal loads from Maxwell transient solutions, you must select from the drop-down list the desired **Source Start Time** and **Source Stop Time** to define the interval for integrating the power loss density distribution.
- **Analysis Time** - Choose the analysis time at which the load will be applied. This must coincide with the end time of a step defined in the Analysis Settings object in the tree.
- **Scale** - The amount by which the imported load values are scaled before applying them.
- **Offset** - An offset that is added to the imported load values before applying them.

You must re-solve after making any changes to the analysis options of a load.

You can define multiple rows in the **Data View** tab to import additional data from the selected Ansoft solution and apply the rows at different analysis times. If multiple rows are defined in the **Data View** tab, you can display imported values at different time steps by changing the **Active Row** option in the Details pane.

Right-click the **Imported Load** object and click **Import Load** to import the load. When the load has been imported successfully, a contour plot of the temperatures will be displayed in the Geometry window and a summary of the transfer is displayed as a comment in the particular load branch.

Importing Data into Harmonic Analyses

Mechanical enables you to import either object-based (**Imported Remote Loads** (p. 1736) - Forces and Moments) or element-based (**Surface Force Density** (p. 1755) or **Body Force Density** (p. 1739)) data from an upstream analysis. If there is a frequency sweep setup in Maxwell, the element-based data can be imported at any frequency specified in the upstream sweep. If a Parametric Setup is defined in Maxwell, loads are imported for all RPMs. Object-based data are always imported at the nominal frequency. Select a link below for additional information for each import type:

- Importing Forces and Moments (p. 711): Supported by Maxwell Transient and Eddy Current Solvers.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Importing Surface Force Density (p. 716): Supported by Maxwell Eddy Current Solver and Transient Solvers.
- Importing Body Force Density (p. 1739): Supported by Maxwell Eddy Current Solver and Transient Solvers.

For additional information, refer to the **Maxwell Coupling** section in the **Maxwell Online Help**, available through the *Ansys customer site*.

Importing Forces and Moments

The following procedure assumes that you have properly defined and solved your Maxwell system.

Go to a section topic

- Import Remote Loads (p. 711)
- Define Imported Remote Loads (p. 711)

Import Remote Loads

To import data into Mechanical, either:

- Link your Maxwell system with a Harmonic Response analysis in the Workbench Project Schematic to automatically import the remote forces and moments or you can export your data from Maxwell and import it directly into a Harmonic Response system in Mechanical. For this configuration, the application only supports a Harmonic Response system.
- Open a Coupled Field Harmonic, Harmonic Acoustics, or Harmonic Response analysis and use the **Imported Remote Loads** option available in the **Loads** drop-down menu of the Environment tab, to manually insert an object of the same name that provides the **Transfer File** property. This property enables you to import Remote Force and Moment boundary conditions directly from an external Maxwell file.

Note:

When importing Maxwell files, note that there is an **Options** > Import (p. 222) category preference, **Improve Reading Performance**, that is active by default and that significantly improves the import process.

Define Imported Remote Loads

1. Select the **Imported Remote Loads** object in the **Outline**. In the Details pane, define the following properties, if necessary:

   Scoping Method

   This property defines the geometry on which the imported data is applied. Face/edge/vertex selections are supported for 3D analyses and edges/vertices for 2D analyses. Options include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Geometry Selection**: default setting, indicating that the load is applied to a geometry or geometries.

  When the **Scoping Method** is set to **Geometry Selection**, the **Geometry** property becomes visible. Use this property to specify your desired geometry selections. Once specified, the field displays the type of geometry (Face or Edge) and the number of geometric entities (1 Face, 2 Edges) to which the load has been applied using the selection tools.

- **Named Selection**: indicates that the geometry selection is defined by a **Named Selection**.

  When the **Scoping Method** is set to **Named Selection** a **Named Selection** property becomes visible. This property provides a drop-down list of available user-defined **Named Selections**.

Transfer File

This property displays when you have manually inserted a **Imported Remote Loads** object from the **Loads** drop-down menu. You use this property to specify the external Maxwell file from which you want to import data. This property is not visible if you have an upstream Maxwell system linked to the analysis. Linking a Maxwell system in the Project Schematic automatically places an **Imported Remote Loads** object in the Outline.

Solution

Select the desired Maxwell solution you would like to import the load from.

Grouping

This property specifies that the loads are grouped by scoping location. That is, one load per location for all RPMs instead of one load per location and RPM. Options for this property include **No** (default) and **By Location**.

If you group remote loads, use the **RPM Selection** property of the individual loads to view the imported load data for each RPM step, presented in the **Tabular Data** window.

Data Type

This property enables you to select which remote loads to import. Options for this property include **Forces and Moments**, **Forces Only**, and **Moments Only**.

Remote Points

Select the appropriate option to generate **Internal** or **Globally Available** remote points. If you select the **Globally Available** option, the application automatically creates the Remote Points/Remote Point objects in the Outline. If you switch from the from the **Globally Available** setting to **Internal**, you need to select the **Generate Remote Loads** context menu option to remove the **Remote Points** objects from the tree.

On Data Refresh

This option is available when the **Remote Points** options is set to **Globally Available**. The **Regenerate** option deletes the remote points that were created during the previous

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

import and adds new remote points when data is imported. The **Reuse Remote Points** option reuses the previously added remote points and only updates the scoping and location, if necessary.

Number of Frequencies To Consider

With this property, you can specify the number of Maxwell frequencies to use in the analysis. The application automatically includes the first frequency, by default, and up to the value you specify. The default setting is **20**.

Import Status

This read-only property displays the status of the import. One of the following status conditions will exist:

- **Data Unavailable**: no data is available to perform the import.
- **Obsolete**: data is available to be imported, but no data has been imported or the data is obsolete and should be re-imported.
- **Uptodate**: all data has been imported.
- **Import Failed**: an error occurred during the import process and no data was imported
- **Number Of Frequencies To Consider**: The default value is **25**. Select the frequency row number used to synchronize the **Analysis Settings**. For each RPM, the application uses the **RPM Frequency Range Maximum** and **RPM Solution Intervals** of the selected **Number Of Frequency To Consider**.

Suppressed

If you want to suppress all of the loads under this **Imported Remote Loads** object, set this property to **Yes**.

Note:

Object-based data are always imported at the nominal frequency.

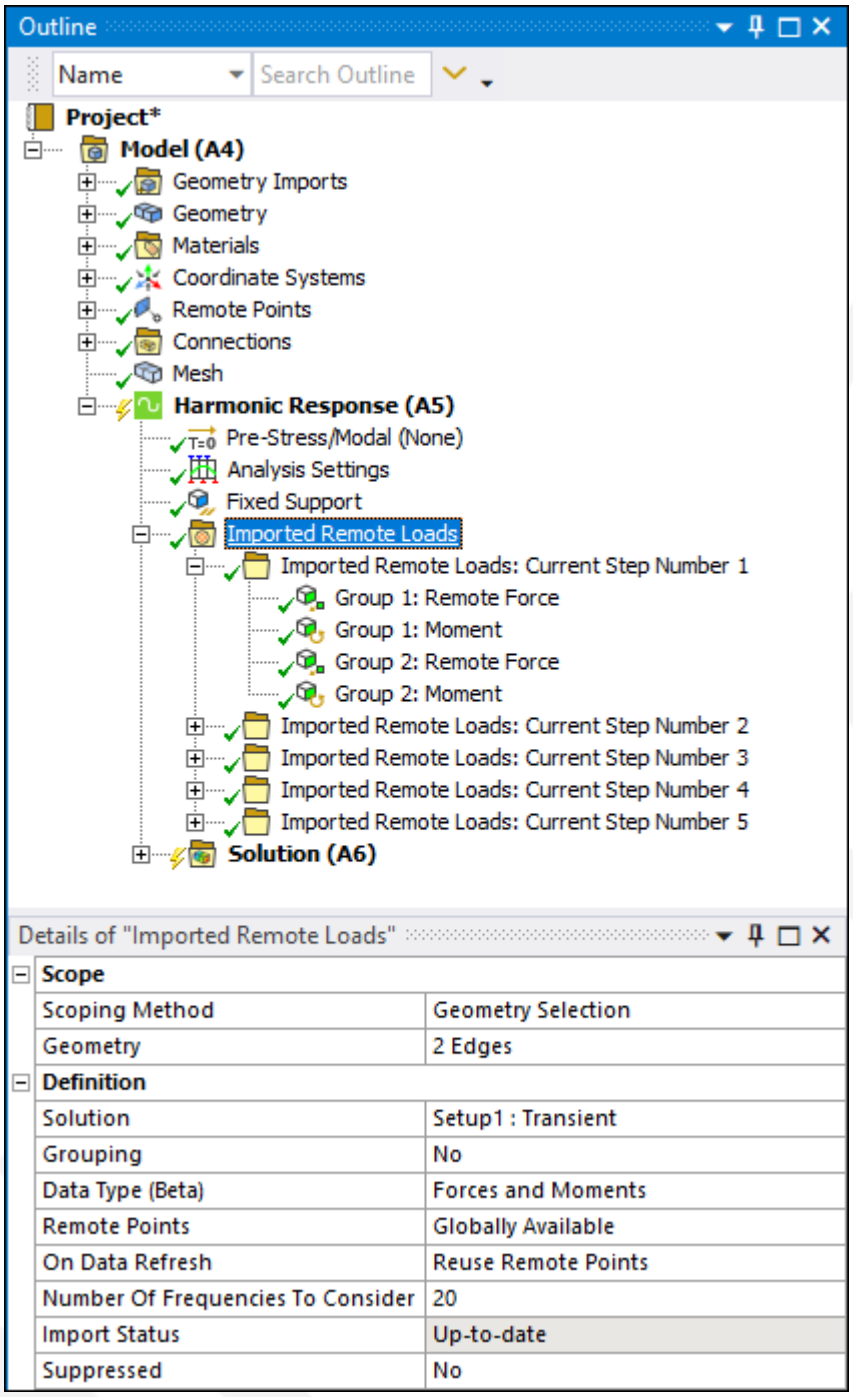
---

2. Once you have defined the necessary import options, right-click the **Imported Remote Loads** object and select **Generate Remote Loads**. This action imports the source data and associates it with the selected target geometry. Once executed, Mechanical adds objects to the tree based on the source data.

   The following items will be added into the tree based on the source data. For each location that Maxwell reports the calculated forces, Mechanical:

   - Adds a **Remote Force** object and a **Moment** object with the imported data. Each set of two loads are named with a Group ID number, as illustrated in the following example.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



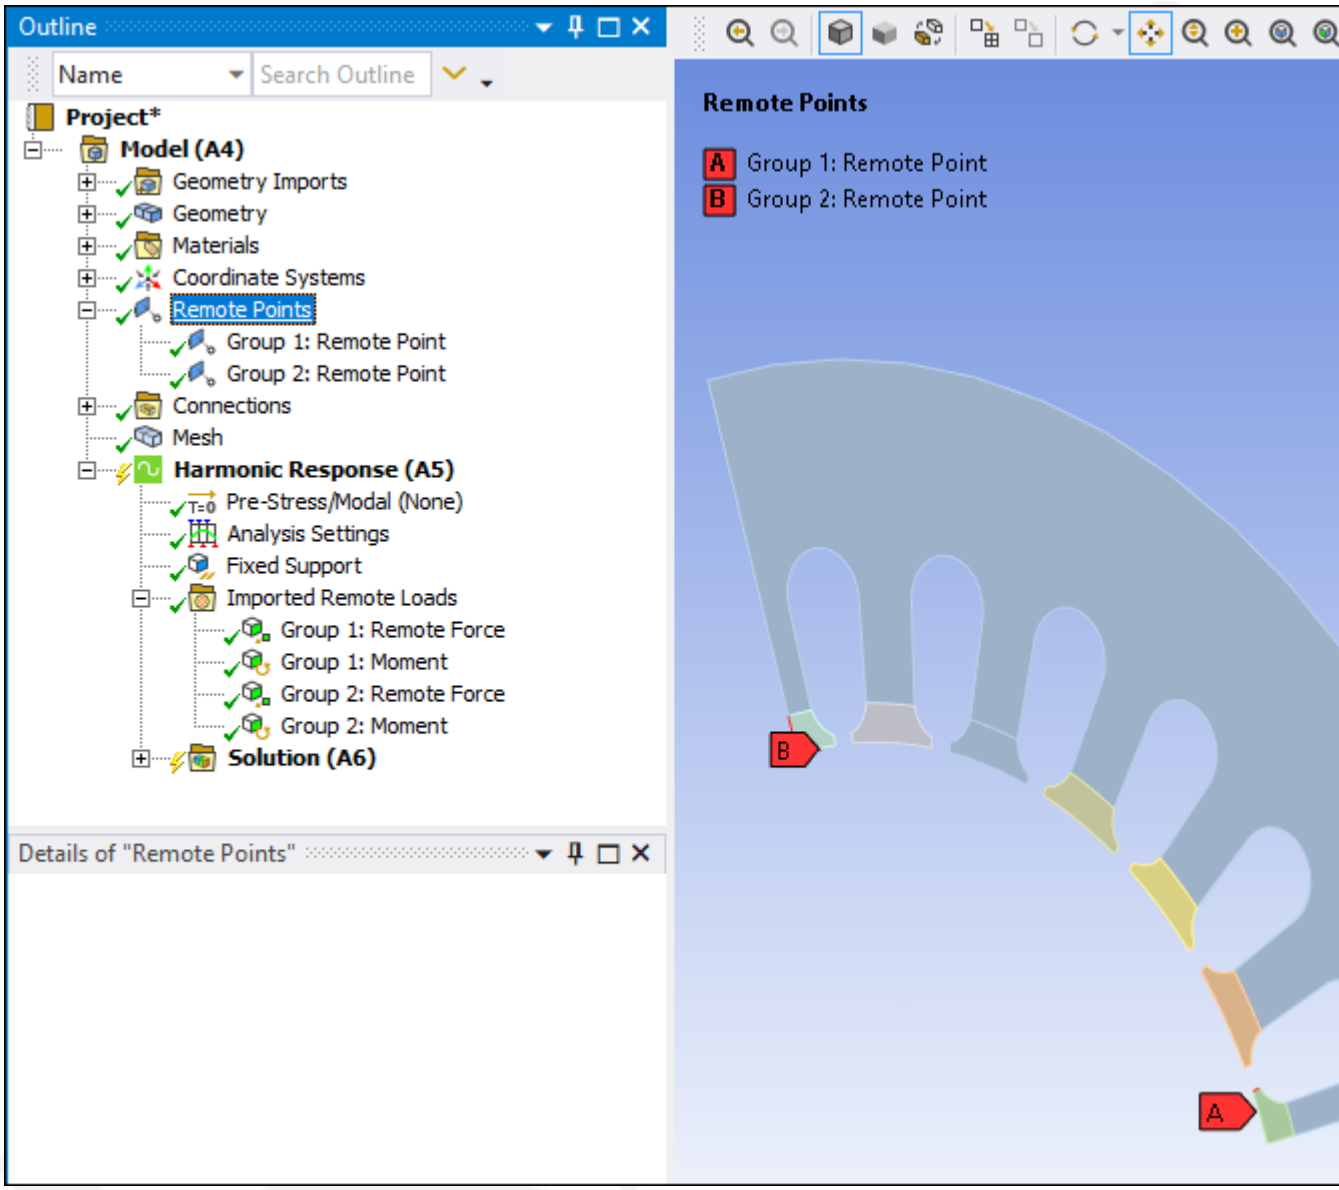
- Creates a **Remote Point** at that location and associates it with the group of two loads. The **Remote Point** is named with the same Group ID number as the load group, as illustrated below.

Note:

When using internal remote points, if you change the scoping or behavior of a load, all loads of the group automatically update because they share the same remote point.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



For each scoped reference (face or edge), applied using the **Scoping Method** property on the **Imported Remote Load** object, Mechanical finds the closest **Remote Point** and assigns the reference as scoping for that Remote Point.

Maxwell Parametric Setup

If your Maxwell analysis contains a Parametric Setup, remotes forces are created for each RPM and grouped into folders. In addition, RPM-varying Step Controls (p. 1426) (Analysis Settings) are automatically defined.

Note:

For a Mode Superposition Harmonic Response analysis, the application applies Remote Forces and Moments using **Tabular Data**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Specify mesh controls, boundary conditions, and solution settings.

4. Solve the analysis.

Importing Surface Force Density

The following procedure assumes that you have properly defined your model in Maxwell and that the source and target systems are connected on the Workbench Project Schematic. Given that, follow these steps to import data and associate it with parts of the geometry.

1. Double-click the **Model** cell of your harmonic analysis system to open the Mechanical application.

2. Open the **Imported Load** object to display the **Surface Force Density** object(s).

   If your Maxwell solution contains a Parametric Setup, you can use the context (right-click) menu option **Create Surface Force Densities and Sync Analysis Settings** to automatically create RPM varying analysis settings properties (Number of RPMs, RPM Value).

   Note:

   During a Mode Superposition Harmonic Response Analysis

   - For improved solution processing, set the **Load Application Type** property to either **Program Controlled** (default) or **Nodal Force**. The application uses the **Nodal Force** setting when the property is set to **Program Controlled**.
   - If you select **Element Pressure** optioin for **Load Application Type** property:
     - It is recommended that you expand the results from the Modal solution to improve performance.
     - If the **Surface Force Densities** loads are the only loads generating load vectors, the application issues the **MODCONT,ON,,,ON** command in the Modal restart phase to reduce the solution time.

3. Select the **Surface Force Density** object and change the default settings as necessary. The options are described below.

Category	Properties/Descriptions
Scope	**Scoping Method**: Options include Geometry Selection and Named Selection. Based on your selection, you need to specify the desired geometry or Named Selection using the associated property.
Definition	**Type**: This read-only property indicates the imported load type - **Surface Force Density**. **Tabular Loading**: This property provides the following options. • **Program Controlled** (default) • **Ramped**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Category	Properties/Descriptions
	• **Stepped** • **Off** **Suppressed**: You use this property to include (**No**) or exclude (**Yes**) the load in your analysis. **Load Application Type**: This property is available for Mode Superposition Harmonic Response analyses Options for this property include: • **Program Controlled** (default) • **Element Pressure** • **Nodal Force** (used when **Programmed Controlled** is selected)
Graphics Controls	**Complex Component**: The options for this property include **Imaginary** (default) and **Real**. **Component**: This property provides the following options. • **All** • **Total** • **X Component** (default) • **Y Component** • **Z Component**
Transfer Definition	**Ansoft Solution** **Solution**: This property provides a drop-down menu of available upstream systems. **Variation** (Maxwell Parametric Setup only): This property provides a drop-down menu that includes RPM values for the selected **Solution**. **Data Type**: This is a read-only property. **AC Force Density** is the only supported loading type. **Ansoft Surface(s)**: Select the Ansoft surface(s) for the **Surface Force Density** load. The default setting is **All Surfaces**.

4. You can specify when the imported data should be applied and also modify the imported data, either by adding an offset or by using a scale factor. Change any of the columns in the **Data View** tab as needed:

   • **Source Frequency**: Select from the drop-down list one of the frequencies supplied from the transfer file. The load values associated with this frequency will be imported.

   • **Analysis Frequency**: Select the frequency at which the load will be applied.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Scale**: The amount by which the imported load values are scaled before applying them.
- **Offset**: An offset that is added to the imported load values before applying them.

Note:

- You can define multiple rows in the **Data View** tab to import additional data from the selected Ansoft solution and apply the load at different analysis frequencies. If multiple rows are defined in the **Data View** tab, you can display imported values at different frequency steps by changing the **Active Row** option in the Details pane.
- You need to re-solve the analysis if you make changes to the **Data View** options.

5. Solve the analysis.

Exporting Results from Thermal or Structural Analyses

If you have solved an analysis containing loads imported from Maxwell or HFSS, you can choose to export temperature or deformation results and apply them during the subsequent solve of the upstream analysis, if this option was previously set in the upstream analysis.

- Temperature results can be exported back to HFSS or Maxwell from a thermal analysis
- Deformation, Stress, and Strain results can be exported to Maxwell from a structural analysis.

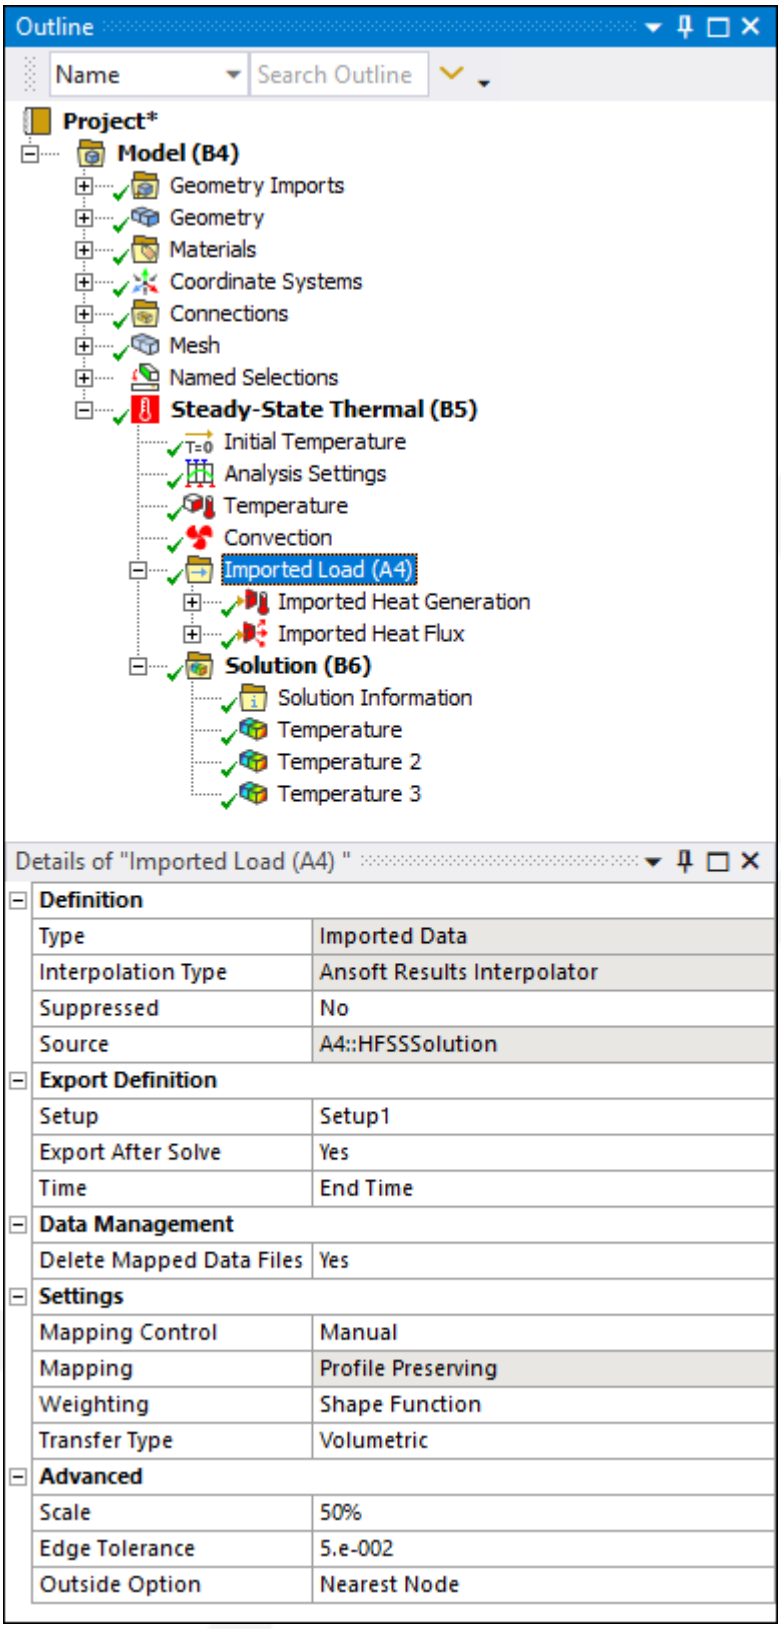
Note:

Mechanical only supports exporting results when the geometry is three-dimensional (3D) in both Mechanical as well as in Maxwell/HFSS.

Select the **Imported Load Group** object in the tree to view the **Details** pane. If the export option is set, you will see the **Export Definition** category. The **Setup** field enables you to specify the Ansoft Setup for which the exported results will be written. The **All** option for the **Setup** property exports results to all the setups requesting feedback.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



In the Details pane, you can also set:

- The **Export After Solve** property. Using this property, you can export the results automatically at the end of the analysis. Option include **Yes** and **No**. Setting the property to **Yes** writes

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

the results when the solution has finished. Setting the option to **No** exports the file after the solution.

- The **Time** property. This property specifies the analysis time at which results are exported. The default setting is **End Time**, which you select by entering 0. You must enter a value between 0 and the end time of the analysis.
- Properties of the Settings category. See the Data Transfer Mesh Mapping (p. 2389) section for more information about these properties.
- The **Delete Mapped Data Files** property of the **Data Management** category. This property enables you to delete the files generated by the application during the mapping process. Options include **Yes** and **No** (default).

Note:

- Refer to the Ansoft application documentation for more details on settings required to support the export from the Mechanical application to the Ansoft application.
- Results can only be exported to setups that have contributed to the current solution.
- This feature does not support the mapping of stress and strain results from shell bodies. Shell bodies and their corresponding results are not included in during the mapping process.

Electric Machines NVH Analyses (with Waterfall Diagram)

When you analyze electric machines and the effects of electromagnetic forces, noise and vibration is a primary consideration.

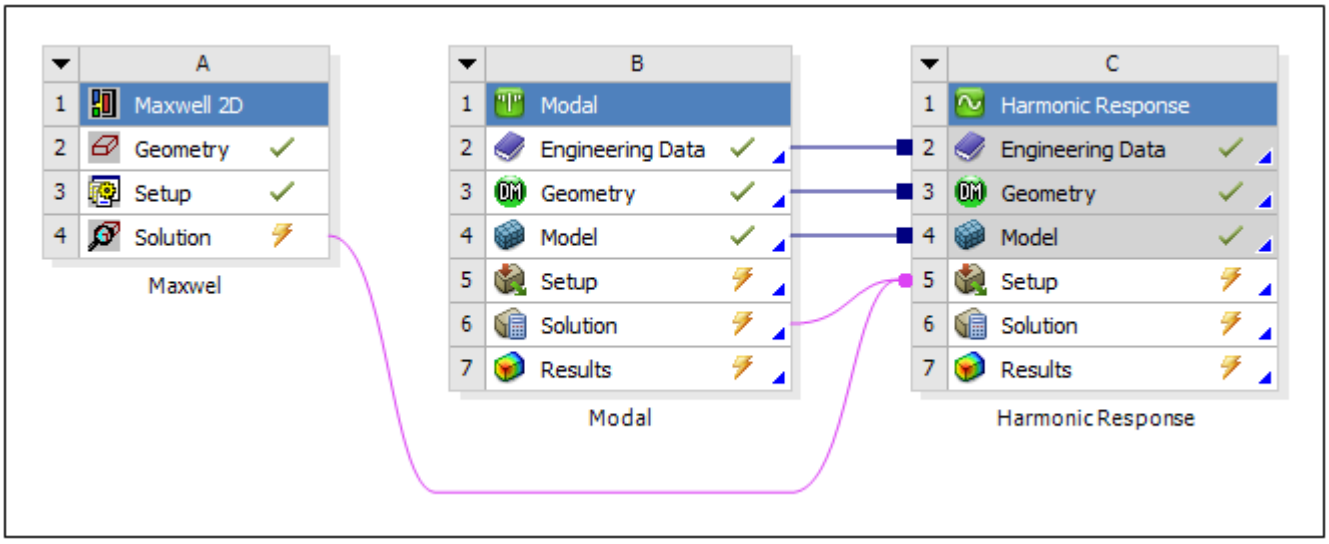
Ansys Workbench enables you to evaluate Equivalent Radiated Power (ERP) Waterfall diagrams. ERP diagrams provide efficient results that you can use to analyze structure vibration for a range of rotating conditions and frequencies.

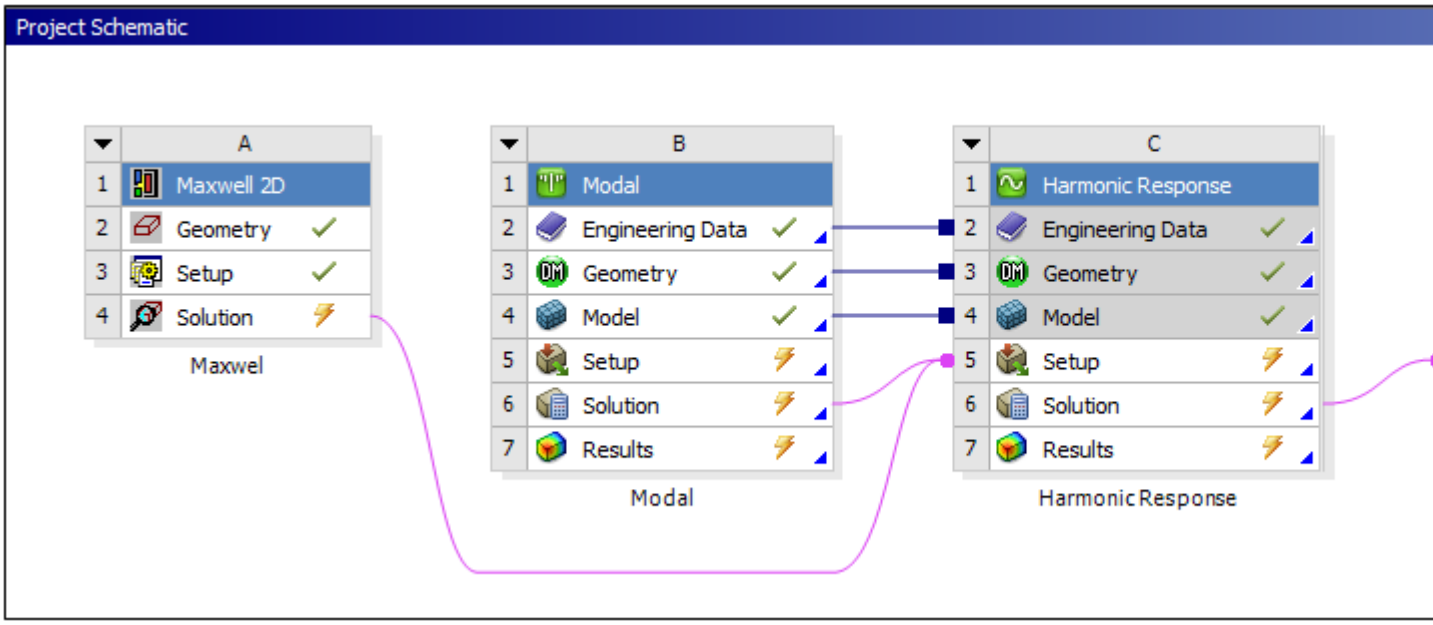
For a more in-depth acoustic analysis, you can generate waterfall diagrams for Far-field Sound Power Level and Far-field Sound Pressure Level Microphone results. See the Adding an Acoustics Analysis (p. 732) topic at the end of the section for the steps to incorporate this analysis type.

This section examines the workflows to simulate electromagnetic forces for rotational velocities as well as the steps to transfer the data to a downstream Ansys Mechanical (frequency domain) Harmonic Response and Harmonic Acoustics systems. Example system configurations are show below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



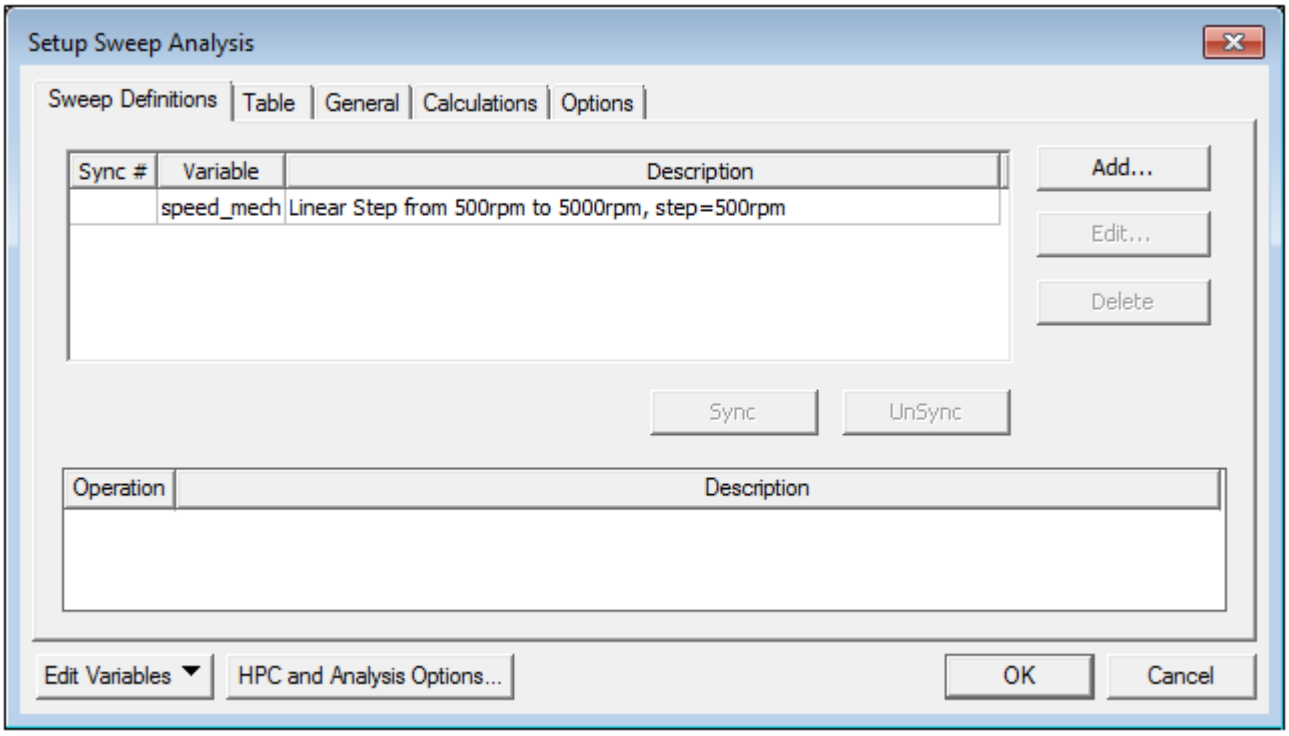


Also note that you can use the operating conditions from your Harmonic Response analysis for Acoustics analyses. This can include all or selected (more critical) operating conditions.

Maxwell Parametric Study

You can use a Maxwell analysis (2D or 3D) that includes several rotational velocities to analyze the overall operating conditions of a Mechanical system. You can use Maxwell to calculate the electro-magnetic forces for each of the RPM (Rotations Per Minute). As depicted in the following dialog, you can create a DesignXplorer setup in Maxwell using the rotational velocity as a variable for the Sweep Definitions. See the Maxwell Help for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Import Loading

Based on the option **Type** (Object Based or Mesh Based) selected in **Enable Harmonic Force Calculation** dialog in Maxwell, you send either integrated force per object or spatially varying data are to Mechanical:

- **Object Based**: This type calculates remote forces (p. 1552) and moments (p. 1574) on each selected object and imports frequency varying Remote Forces and Moments (p. 711) to Mechanical.
- **Mesh Based (Surface)**: This type calculates forces on mesh entities for the selected objects, converted to frequency domain, and imports spatially varying Surface Force Density (p. 716) loads to Mechanical.
- **Mesh Based (Volume)**: It type calculates forces on mesh entities for the selected objects, converted to frequency domain, and imports spatially varying Body Force Density (p. 1739) loads to Mechanical.

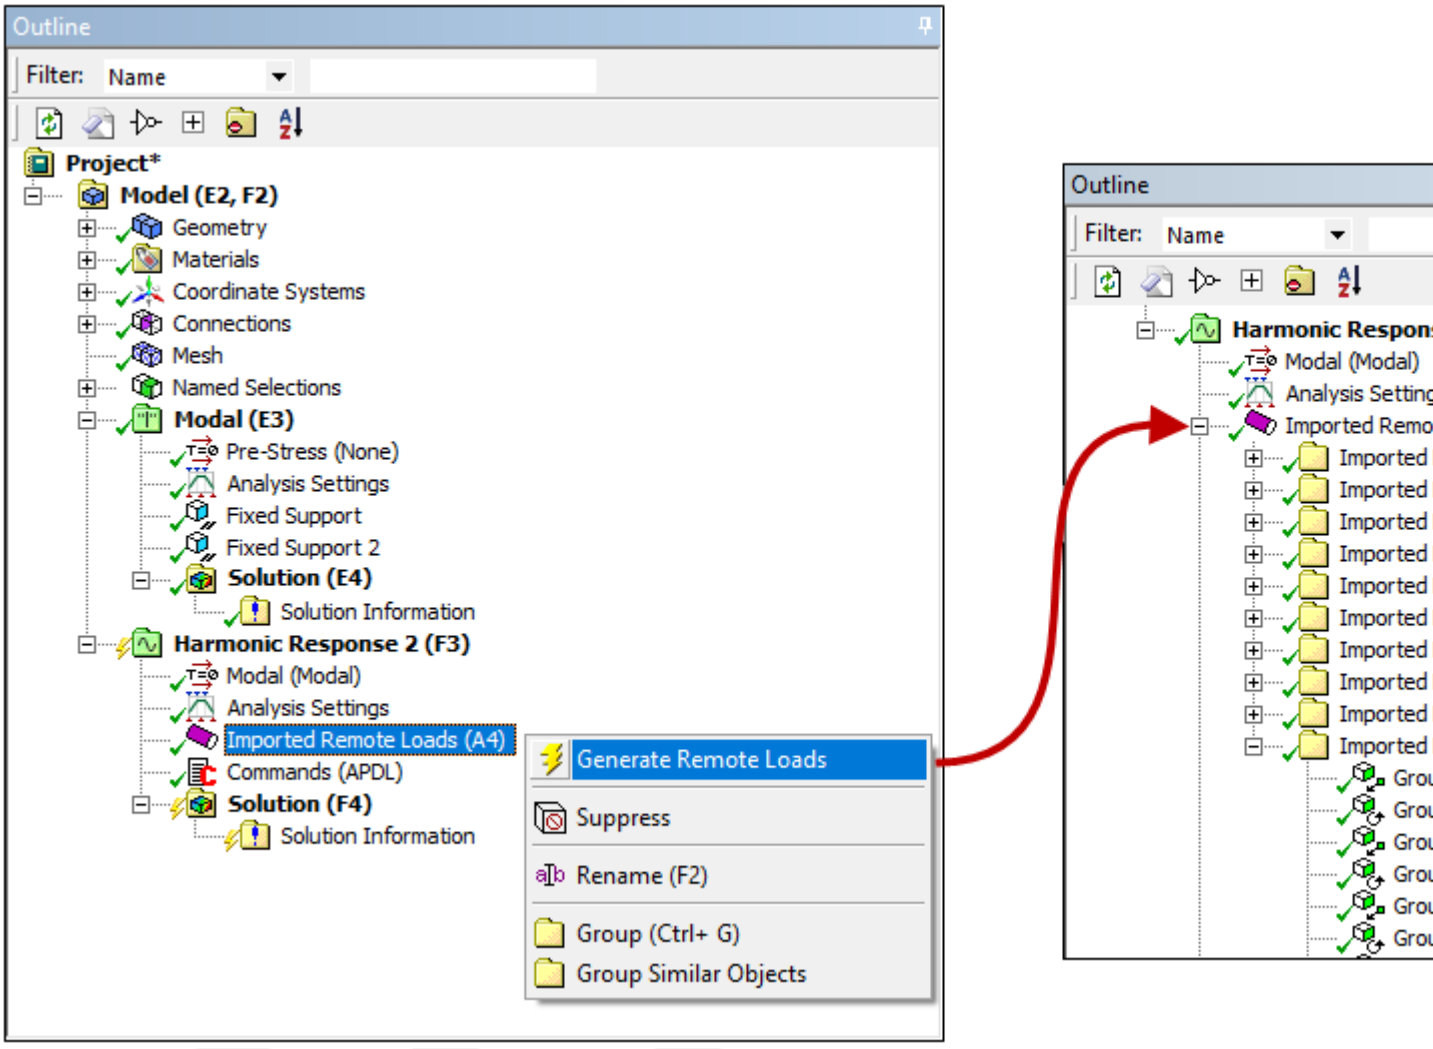
Object Based - Remote Force and Moment

For the **Object Based** option when you import your Maxwell analysis into Mechanical, the application automatically creates an **Imported Remote Loads** object. The context (right-click) menu for this object provides the option **Generate Remote Loads**. When you execute this option, the application automatically imports the remote forces (p. 1552) and moments (p. 1574) from Maxwell and maps the loads to the geometric entities on the model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



For each RPM variation solved in Maxwell, Mechanical creates a folder containing the forces associated with the rotational velocity. Here are the Details properties for a selected (imported) Remote Force (p. 1552). You can see the load is specified as a varying load (**RPM Varying** property) and it includes a load value (**RPM Selection** property).

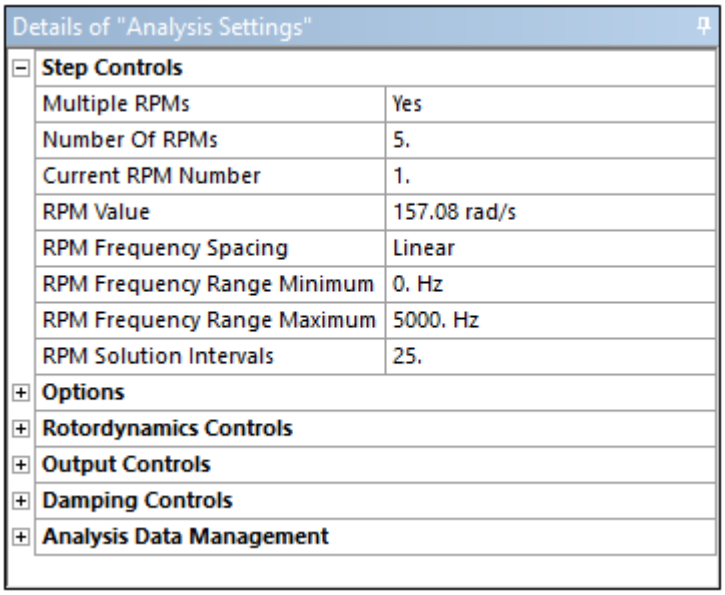
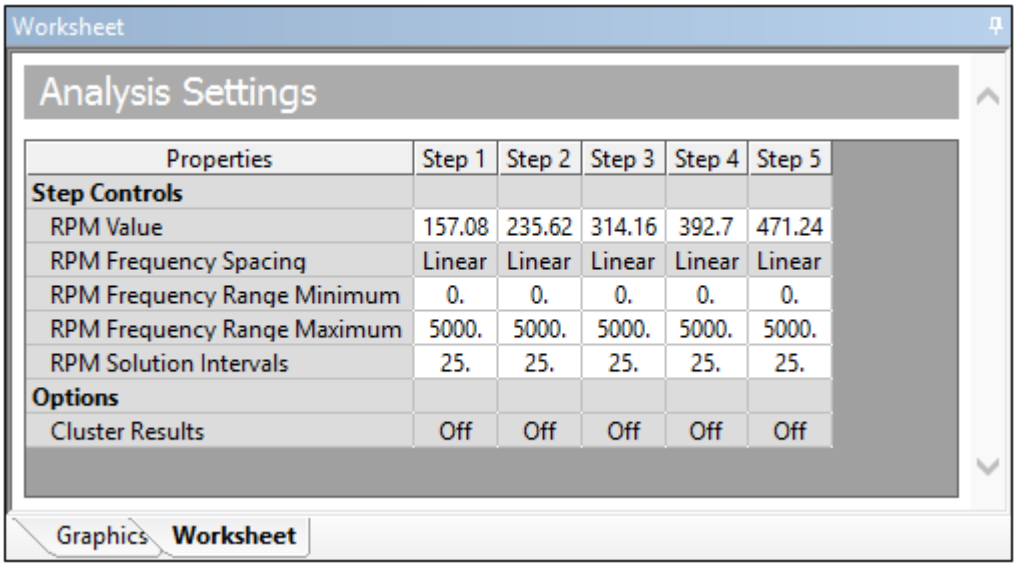
Define Analysis Settings

When your Maxwell load data includes multiple RPM conditions, the application automatically reflects the RPM conditions as load steps in the **Step Controls** (p. 1426) category of the **Analysis Settings** of your downstream, Harmonic Response analysis. You can modify these RPMs (individually) using the **Step Controls** category.



You can also modify the RPM **Step Controls** using the **Worksheet**.



Harmonic Solution Method

The application supports the Maxwell import scenarios both the **Full** and **Mode Superposition** Solution Method in your Harmonic Response analysis. Each of these methods supports constant loading conditions that you may apply (on each step) in addition to the imported RPM varying loads, that the application applies on a per step basis. For example, you want to add loads in addition

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

to the imported electromagnetic forces. You may wish to add loading conditions to consider other noise sources, such as those generated by bearings or aerodynamic forces.

For the **Mode Superposition** method, by default, the application defines the remote forces (p. 1552) using the **Table** option for the **Loading Application** property to improve solution performance.

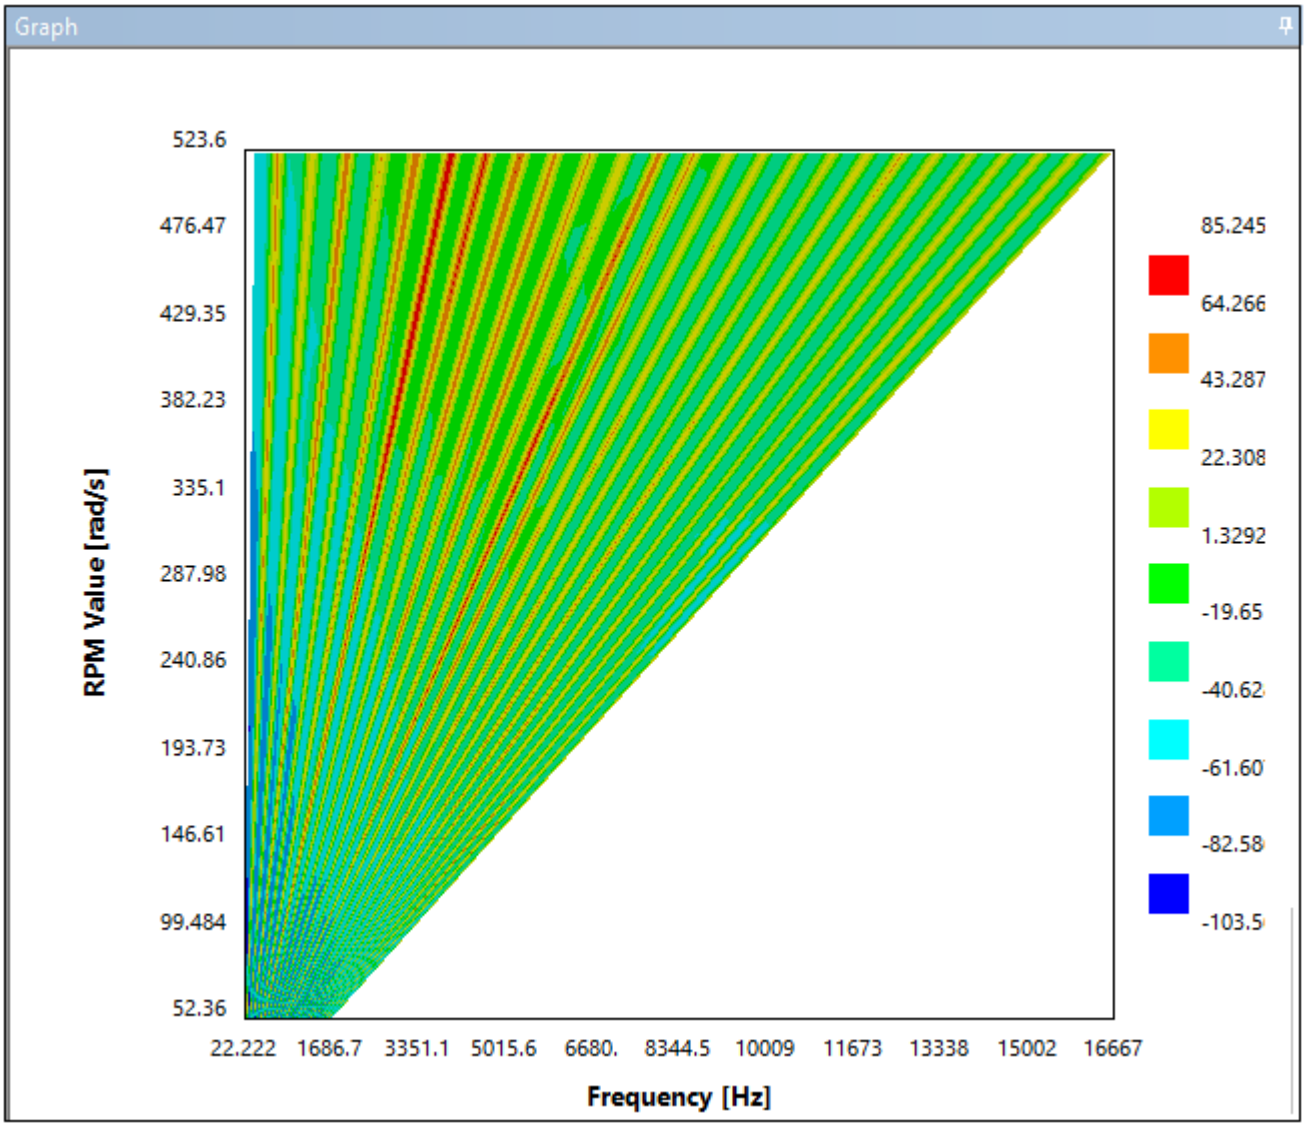
Details of "Group 1: Remote Force"	
Scope	
Scoping Method	Geometry Selection
Geometry	1 Face
Coordinate System	Global Coordinate System
X Coordinate	2.6437e-003 m
Y Coordinate	8.0756e-002 m
Z Coordinate	0. m
Location	Click to Change
Definition	
ID (Beta)	8067
Type	Remote Force
Define By	Components : Real – Imaginary
X Component - Real	Tabular Data
X Component - Imag	Tabular Data
Y Component - Real	Tabular Data
Y Component - Imag	Tabular Data
Z Component - Real	Tabular Data
Z Component - Imag	Tabular Data
Suppressed	No
Behavior	Deformable
Step Controls	
RPM Varying	Yes
RPM Selection	500. RPM
Advanced	
Pinball Region	All
Loading Application	Table

Also note that when you import **Surface Force Densities**, you can improve solution performance by initiating the **Expand Results From** (p. 1477) property (**Output Controls** (p. 1473)) by setting either the **Stress**, **Strain**, or **Calculate Reactions** properties to Yes.

ERP Waterfall Diagram

The Equivalent Radiated Power (ERP) (p. 2047) waterfall diagram results provide a global acoustic signature based on the selected radiating faces. The application displays this result in two forms: (1) using polylines for each RPM case or (2) on a 2D color map, as illustrated here. This result enables you to detect the most critical operational conditions (RPM and Frequency) analyzed with additional detail in a downstream Harmonic Acoustics analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

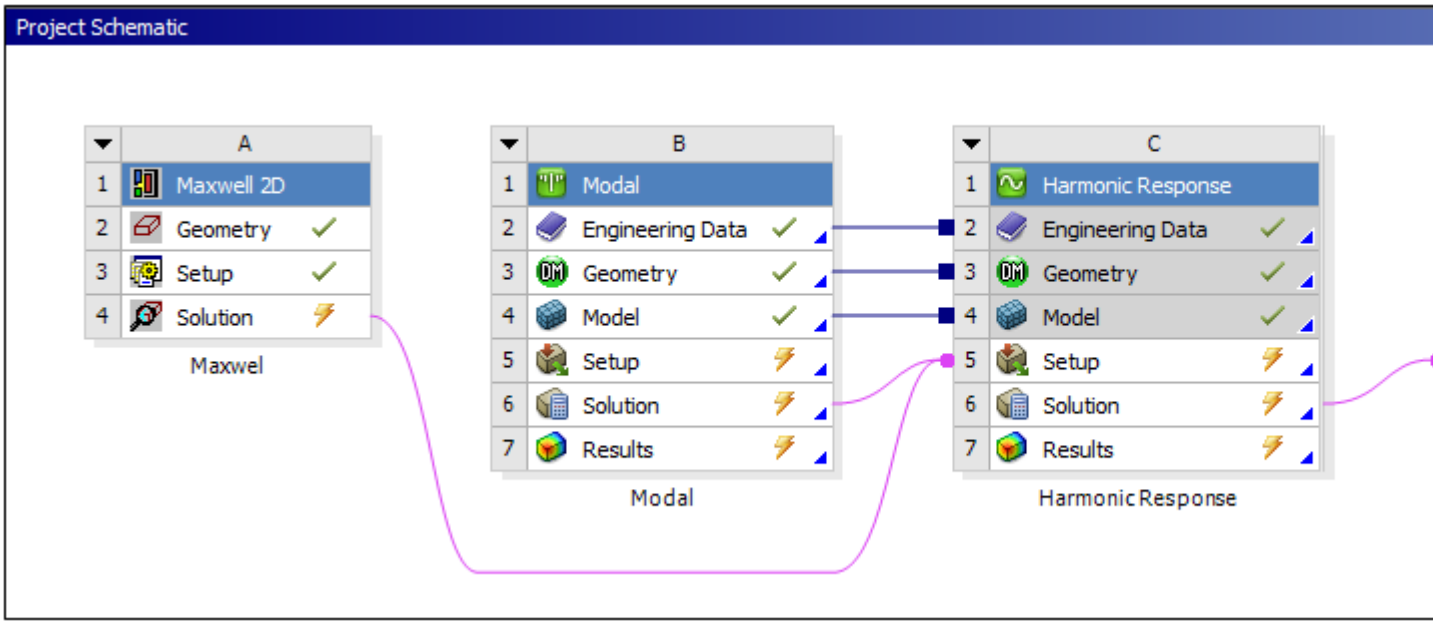


Adding an Acoustics Analysis

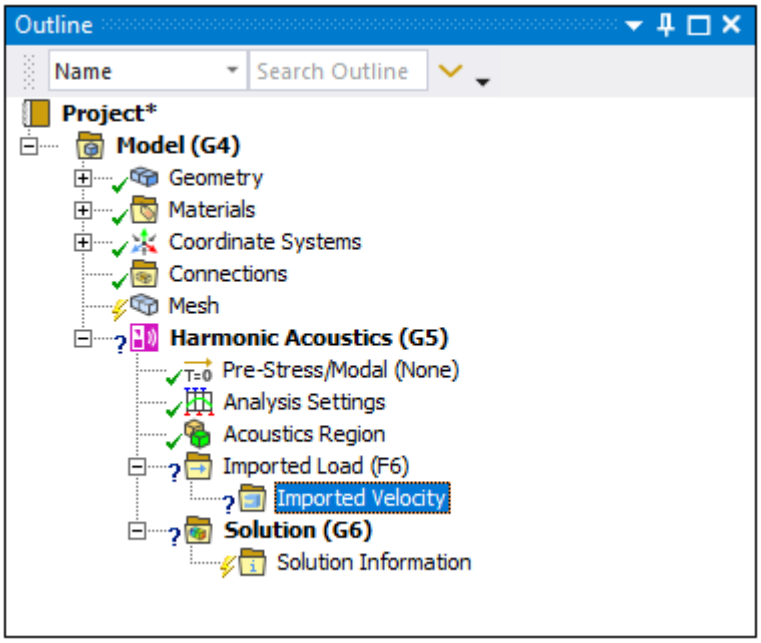
You can examine the acoustics of your structural vibrations by adding a Harmonic Acoustics analysis to your NVH simulation. As illustrated, you insert a Harmonic Acoustics into the project as a downstream system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

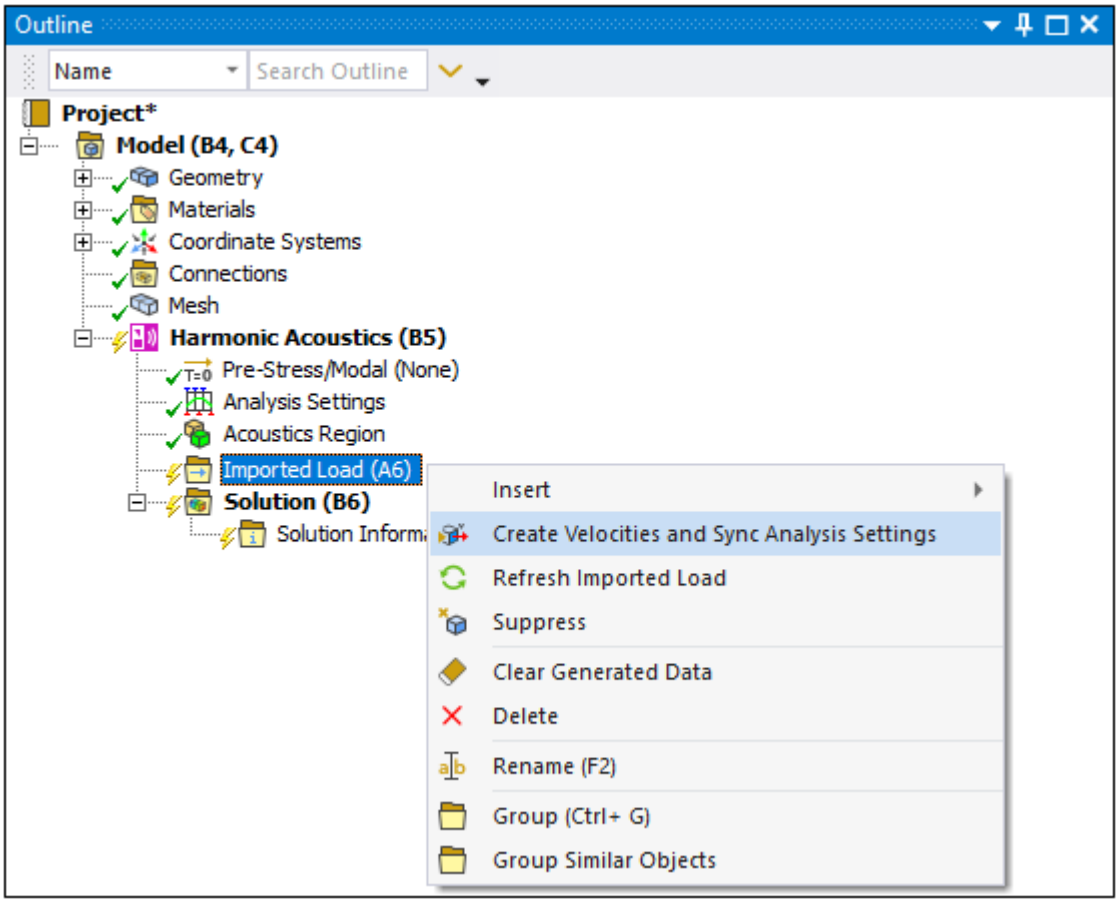


Once opened in Mechanical, the application automatically creates an **Imported Load** object. By default, the application inserts a **Imported Velocity** object.

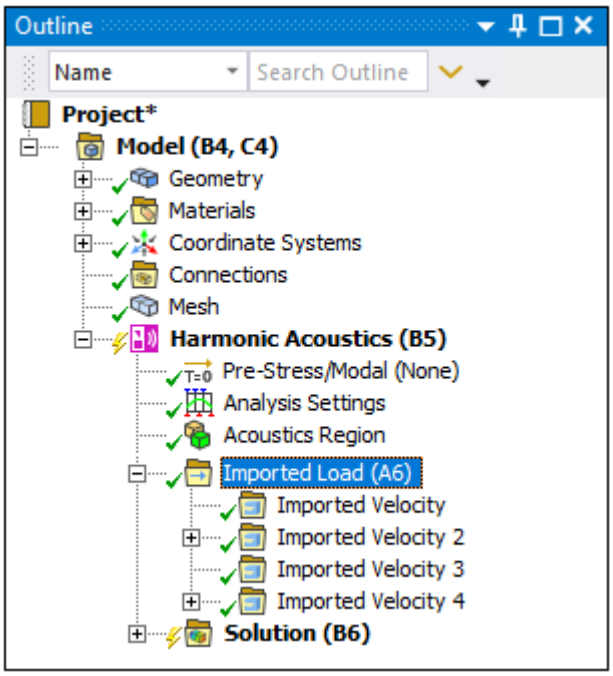


You can add **Imported Velocity** objects by right-clicking on the **Imported Load** folder and selecting **Insert** > **Velocity** or you can select the option **Create Velocities and Sync Analysis Settings** to import and map all of the velocity loads available in the upstream system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The application creates an **Imported Velocity** object for each RPM imported from the upstream Harmonic Response analysis.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Details of "Imported Velocity"

Scope	
Scoping Method	Geometry Selection
Geometry	1 Face
Definition	
Type	Imported Velocity
Tabular Loading	Program Controlled
Suppressed	No
Source Bodies	All
RPM Selection	20.94 rad/s
Source Frequency	All
Graphics Controls	
Settings	
Rigid Transformation	
Legend Controls	
Named Selection Creation	

When you import multiple RPMs, the application automatically reflects the RPM conditions as load steps in the **Step Controls** category (that automatically displays in the **Worksheet**) of the **Analysis Settings** of your downstream Harmonic Acoustics analysis. This behavior is similar to the **Step Controls** of a Harmonic Response system. See the Step Controls for Harmonic Analysis Types (p. 1426) section for more information.

Worksheet

Analysis Settings

Properties	Step 1	Step 2	Step 3	Step 4
Step Controls				
RPM Value	20.944	41.888	62.832	83.776
RPM Frequency Spacing	Linear	Linear	Linear	Linear
RPM Frequency Range Minimum	0.	0.	0.	0.
RPM Frequency Range Maximum	15000	25000	35000	45000
RPM Solution Intervals	3.	3.	3.	3.

Result Diagrams

Once you complete your analysis, the result options Far-field Sound Power Level Waterfall Diagram and Far-field SPL Mic Waterfall Diagram enable you to analyze the acoustic behavior for the entire range of RPMs and frequencies so that you can detect the most critical situations. An example is illustrated below. See the Acoustic Waterfall Diagrams for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

External Data

Use **External Data** to import data from one or more text files and apply it in a Mechanical analysis. Supported analysis types include:

- Coupled Field Static (p. 391)
- Coupled Field Transient (p. 395): Supports Imported Body Temperature (p. 1740) (Thermal Condition) and Imported Temperature (p. 1756).
- Explicit Dynamics: Currently, the Explicit Dynamics system and the LS-DYNA ACT extension provide limited support for the Workbench **External Data** system.
- Modal (p. 515): Supports Imported Body Temperature (p. 1740).
- Static Structural (p. 652)/Transient Structural (p. 665): These analysis types do not support the use of the Rigid Dynamics solver for External Data import.
- Steady-State Thermal (p. 657)/Transient Thermal (p. 680)/Thermal-Electric (p. 661).

Note:

The surface pressures and line loads calculated in a Hydrodynamic Diffraction analysis or a time domain Hydrodynamic Response analysis can be transferred to panel and beam elements in a Static Structural analysis using the Hydrodynamic Pressure Mapping ACT extension, through a link on the Workbench Project Schematic page. See The Hydrodynamic Pressure Add-on for more information.

Go to a subsection topic based on how you want to use **External Data**:

Importing Data from Workbench
Importing Data from Mechanical
Importing Thickness
Importing Loads
Exporting Data

Importing Data from Workbench

To import a supported file using the Workbench External Data system:

1. Insert an **External Data** system into the **Project Schematic** from the **Component Systems** group of the Toolbox.
2. Right-click the **Setup** cell and select **Edit**. This automatically opens the **External Data** tab
3. Browse to the location of the file to add.

   Note:

   Importing files from design point folders within the same project directory (with the exception of the Current design point) is not supported.

4. In the **Location** column of the **Outline of Schematic** pane, select the ellipsis button ( ), and select your data source files. The selected file name, location, and identifier are automatically displayed in the **Data Source** column. The identifier is a string that can be used to identify the file in the downstream Mechanical application.

   - When multiple files are added to the same system, each file is given a unique identifier (that is, File1, File2, and so on). These identifiers are used in conjunction with the data identifiers (Pressure1, Thickness1, and so on) to identify and apply the dataset(s) within Mechanical.
   - If your files contain data for the same nodal coordinates, or if only one of your files contains the nodal information, you can choose the **primary** option in the **External Data** system to designate a primary file. This option notifies the mapping utility that the group of files, defined in the **External Data** system, share the same nodal information. The nodal information is therefore processed and stored only from the primary file. This greatly reduces the memory usage by only allocating space for the nodes once, not once per file. It can also result in much faster import times as only one mapping operation will be required.
   - Mechanical APDL `.cdb` files can be added as a primary mesh in the **External Data** system; for details, see Importing a CDB File as Input in the *Workbench User's Guide*.

5. Return to the **Project** tab. Display the properties for the **Setup** cell of the **External Data** system by right-clicking on the cell and selecting **Properties**.
6. Specify the **Files Import Type** property as needed. Options include **By Copy** (default) and **By Reference**. The **By Reference** option instructs the application to directly reference the External

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Data file instead of transferring the file to the project folder. For large size files, this action can drastically reduce disk storage requirements and improve performance.

Note:

When you specify the **By Reference** option and wish to archive your project using the option **Imported files external to project directory** of the **Archive Options** dialog, the application automatically copies the External Data files to the archived project.

Important:

The **By Reference** option cannot be used with the **System Coupling** feature.

7. Specify additional Workbench properties as needed:

   - To transfer shell thickness data to Mechanical, either:

     – Drag the **Setup** cell of the **External Data** and drop it onto the **Model** cell of a Mechanical system to create the link.

     – Right-click the **Setup** cell of the **External Data** system and select **Transfer Data to New** > **[Mechanical_system]**. This creates a link to the **Model** cell of a new **Static Structural** system *and* a connection to the **Setup** cell. Remove the unwanted connection to the **Setup** cell.

   - To transfer load data to Mechanical, drag the **Setup** cell of the **External Data** system and drop it onto the **Setup** cell of an applicable Mechanical system.

     Alternatively, you can right-click the **Setup** cell of the **External Data** system and select **Transfer Data to New** > **[Mechanical_system]**. This creates a link to the **Setup** cell of a new **Static Structural** system *and* a connection to the **Model** cell. Remove the unwanted connection to the **Model** cell.

   - When an **External Data** system is connected to a system using the Samcef or ABAQUS solver, the following quantities cannot be used: Body Force Density, Stress, Strain, Heat Flux, and the Emag Condition.

   - When an **External Data** system is connected to a system using the ABAQUS solver, the ABAQUS system does not support the import of Forces.

8. Attach the geometry to the analysis system and open Mechanical. Right-click the **Setup** cell of the analysis system and select **Edit**. You can also double-click the **Setup** cell to open the application.

Importing Data from Mechanical

Mechanical enables you to import load data, thickness data, or element orientation coordinate data from external source files directly into the application. Go to a section topic:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Import Options (p. 739)
- External Data Dialog (p. 739)
- Definition and Preview Tabs (p. 742)

Import Options

Imported Loads

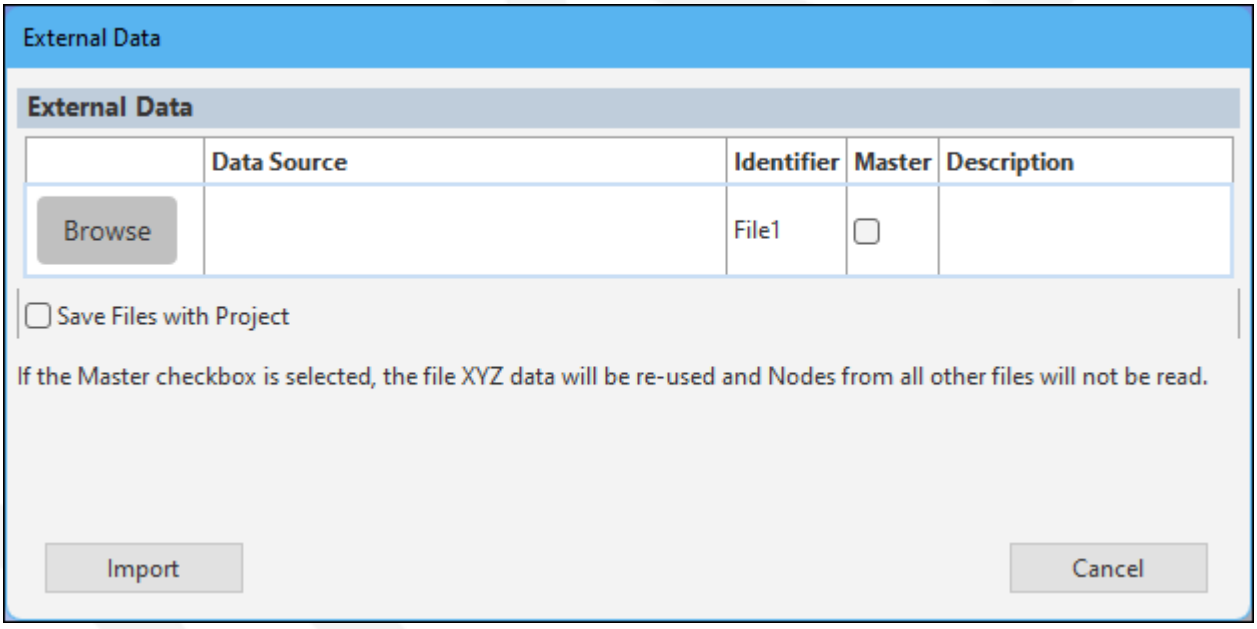
The **Imported Loads** menu of the **Environment** object context ribbon includes an **External Data** option to import load data. This option opens the **External Data** dialog.

Imported Thickness and Element Orientations

The **Imported Thickness** and **Imported Element Orientations** options of the **Geometry** object context ribbon enable you to import element orientation data or shell thickness data from an external file. Both of these options open the **External Data** dialog.

External Data Dialogs

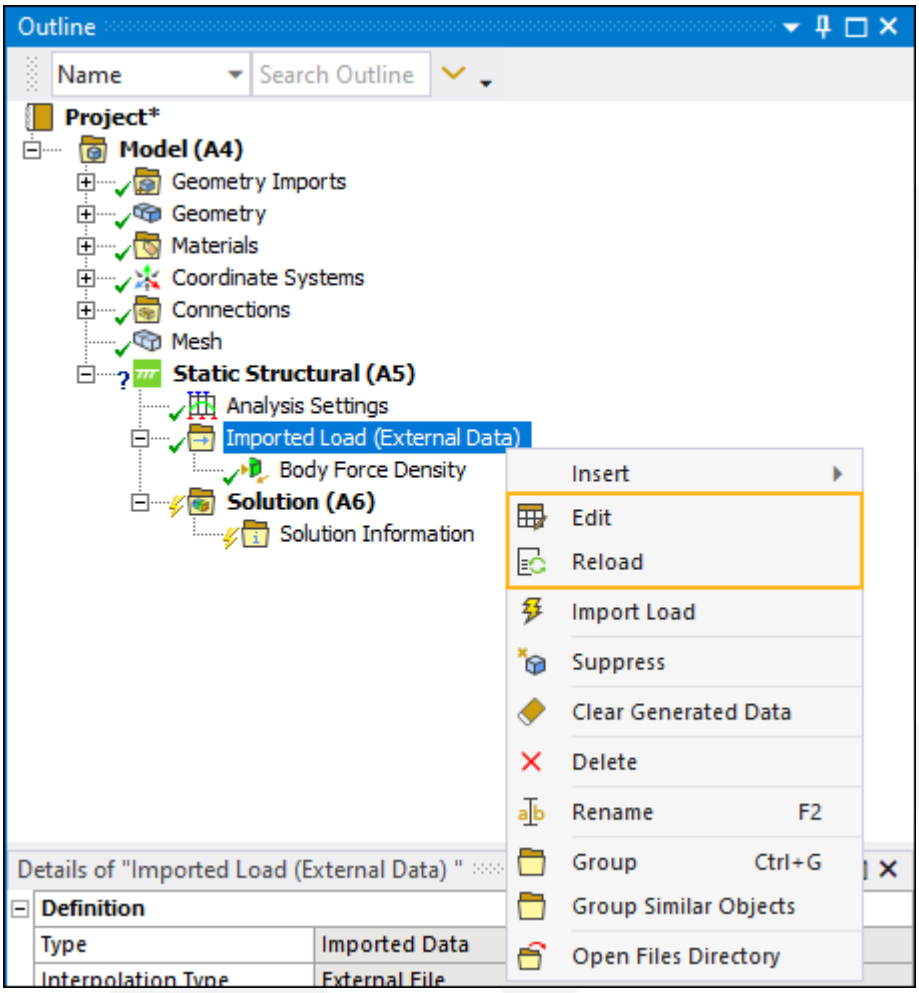
1. From the appropriate object, select the desired option. The application automatically inserts the corresponding object into the tree and the **External Data** dialog displays. You use this dialog to specify the desired external file(s) you wish to import.



Note:

- If you have already selected a file and displayed the dialog, there are two additional context (right-click) menu options: **Edit** and **Reload**. The **Edit** option re-opens the External Data dialog enabling you to modify the imported object's details and the **Reload** option reloads data from the source file(s).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



- Although similar to using an **External Data** system in Workbench, there are some differences. You should review the External Data section of the *Workbench User's Guide* as well as the External Data System (p. 736) section in the *Mechanical User's Guide* for a description of the feature and its requirements.

Additional dialog options include:

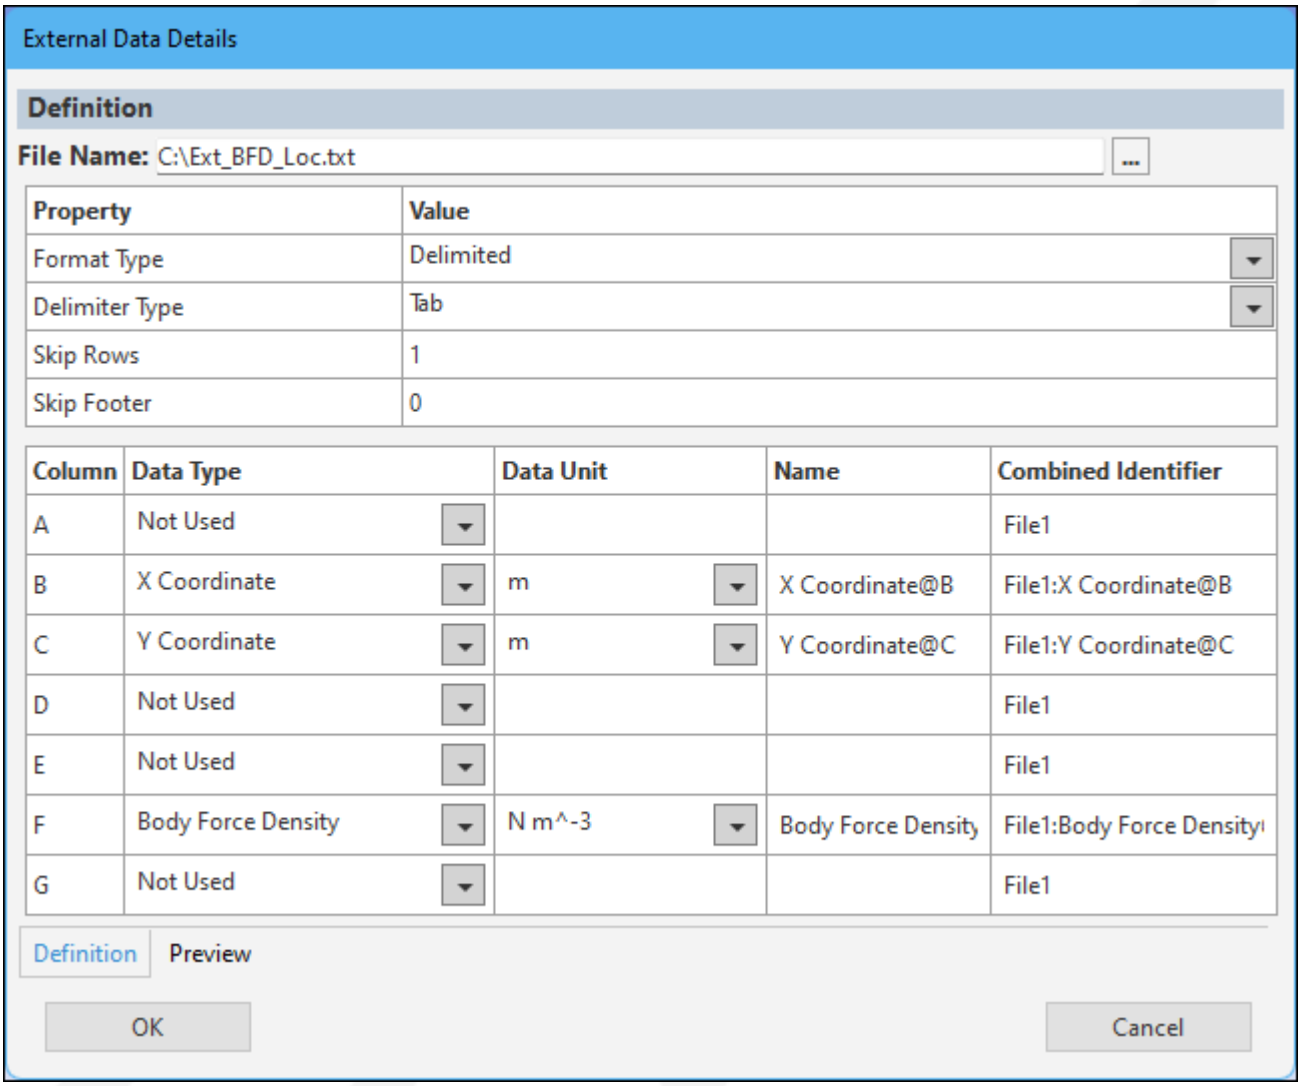
- **Save Files with Project**: Copy the external data files to the project directory. If left unchecked, the application references the source files directly using the File Path without making a copy. The default is unchecked.
- **Identifier**: The identifier is a string that can be used to identify the file in the downstream Mechanical application.
- **Master**: Specify the file as the master external data file. The nodal coordinate data for the selected master file is processed by the mapping utility. The application skips this nodal coordinate data in all other files. Only one file can be set as the master file. Mechanical APDL format type files should always be marked as the master file.

2. Select the **Browse** button. The **External Data Details** dialog displays. It includes two tabs: **Definition** and **Preview**. See the Definition and Preview Tabs topic below for a description of these dialogs and their options.

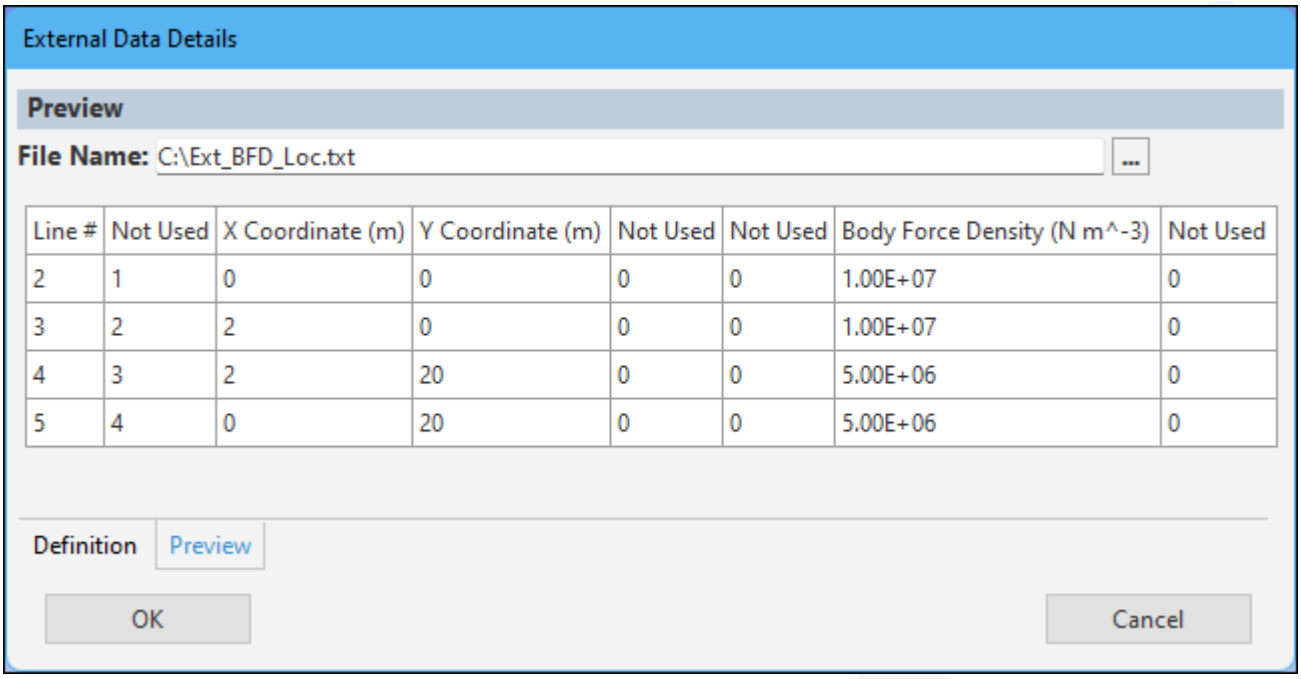
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

3. Select the **File Name** option to navigate to and select your file. Specify dialog properties as needed and select **OK**.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



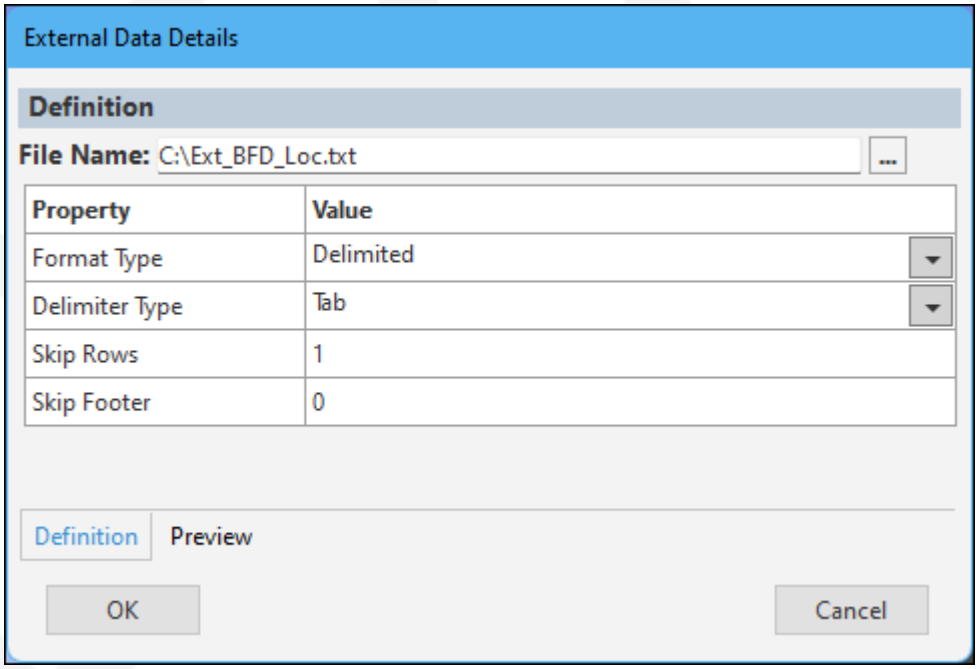
4. Select the **Import** button. The data file is now associated with the object.

Definition and Preview Tabs

Descriptions of the properties of the **Definition** and **Preview** tabs for **External Data Details** dialog are shown below.

Definition Tab

The **Definition** tab specifies the details of the external data file.



Properties for the **Definition** dialog include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Property	Description/Value
Format Type	This property sets the corresponding format for the selected file. Different format type results in different properties. Options for this property include: • Delimited (default): This format type represents a file containing data with each column delimited by a specific character. When selected, the Delimiter Type property also displays. This property specifies the delimiter used to separate the columns in data file. Options include **Comma**, **Semicolon**, **Space**, **Tab**, and **User Defined Separator**. If you select **User Defined Separator**, the additional property User Defined Separator displays. You use this property to specify any character as the data delimiter. • **Fixed Width**[a]: This format type represents a file that contains data in columns that have a fixed width. Based on the width, the column specifies a string using Fortran-like fixed-format specifications. This is equivalent to the User-Defined option of the Format Type property as described in the External Data section of the Workbench User's Guide. Review the description in that section for the supported format specifiers, such as Decimal floating point, Scientific notation, etc. • **MAPDL**: This format type represents a Mechanical APDL CDB data file. When selected, the following additional properties display: – **Dimension**: Specifies the source data dimension. Options include **2D** and **3D** (default). – **Unit Lengths**: Specifies the length unit used for source point locations. The default value is Meters. **Note:** If you have multiple external data files that include the MAPDL import format, the property **Average Corner Nodes To Midside Nodes** displays under the **Delimited** or **Fixed Width** file definition. If you set this property to **Yes**, the application calculates data at the midside nodes as an average of the values contained at the corner nodes.
Skip Rows	Specifies the number of rows to skip at the start of the data source. The default is **0**.
Skip Footer	Specifies the number of rows to skip at the end of the data source. The default is **0**.

[a] **Fixed Width Example**

In the following example, the line has one integer followed by four exponential data types:

385 8.333333333E-003 9.375000000E-003 3.375000000E-001 0.000000000E+000

The corresponding format is 1i3,4e17.9.

Where:

– The first entry is the number of occurrences.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

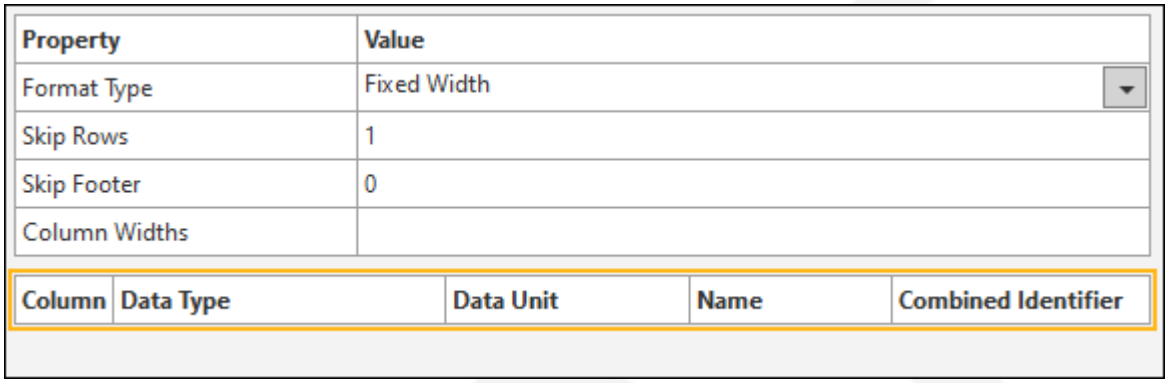
– The second entry is the format specifier.

– The third entry is the number of characters of data in the definition (including numeric values (0-9), the letter "e" (for instances of scientific notation), and any white space and + or - signs).

– The fourth entry is the number of digits after the decimal point.

Column Definition

When you select the **Delimited** or **Fixed Width** format types, the following table displays in the dialog.



Column: Index field.

Data Type: Select a desired data type from the drop-down menu.

Name: String used to identify a specific column.

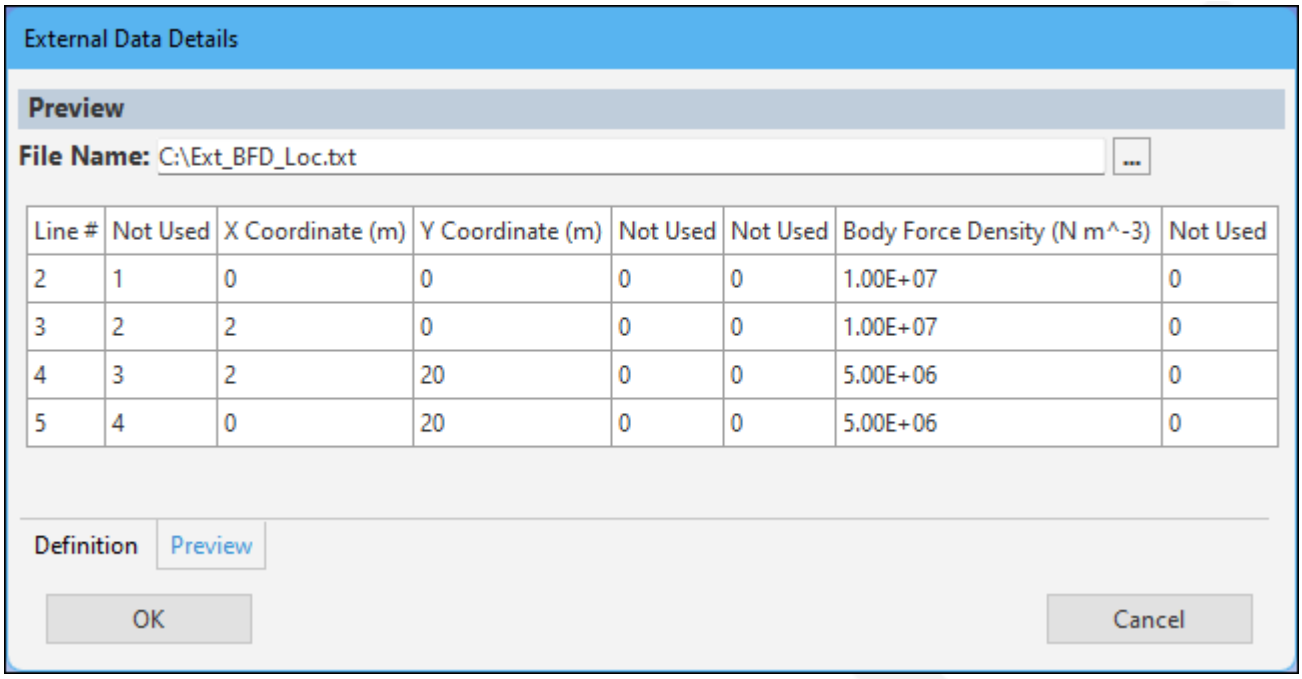
Combined Identifier: String that combines the **File Identifier** and **Column** name, it can be used to identify the column in the child imported load object.

Preview Tab

The **Preview** tab displays a preview of the imported lines from the file.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Note:

- The application only displays the first 10 rows of data for preview.
- The **Line #** column refers to the line number in the source data file.

Importing Thickness

If your simulation has a shell thickness defined from **External Data**, an **Imported Thickness** folder is automatically added under the **Geometry** folder.

Application

To specify imported thickness:

1. Select appropriate geometry or mesh entity.
2. Specify properties as needed. You can modify the mapping settings to achieve the desired mapping accuracy.

   You can specify a thickness value for the unmapped target nodes using the **Unmapped Data Value** property. By default, a zero thickness value is assigned to the unmapped nodes.

Important:

For the Mechanical APDL solver, the thickness value at each node must be greater than zero.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Right-click the **Imported Thickness**, and then click **Import Thickness** to import the thickness. When the thickness has been imported successfully, a contour plot will be displayed in the **Geometry** window and any mesh display will be based upon the mapped thickness of the elements.

Importing Loads

If your simulation has load data defined from **External Data**, an **Imported Load** folder is added under the **Environment** folder.

1. To add an imported load, select the **Imported Load** folder and select a desired load from the **Imported Loads** drop-down menu on the **Environment** Context tab or right-click the **Imported Load** folder and select the appropriate load from the **Insert** context menu.

2. Select appropriate geometry or mesh entity.

3. In a 3D structural analysis, if the Imported Body Temperature load is scoped to one or more surface bodies, the **Shell Face** option in the Details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.

4. When mapping data to surface bodies, you can control the effective offset and thickness value at each target node, and consequently the location used during mapping, by using the **Shell Thickness Factor** property. By default, the thickness value at each target node is ignored when data is mapped.

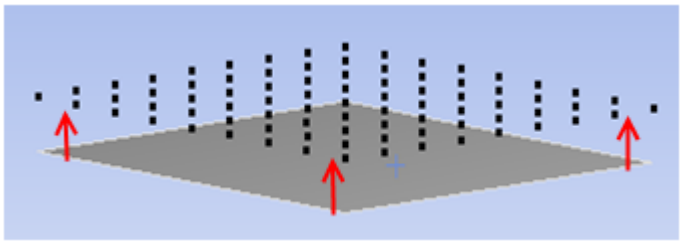
   You can choose to enter a positive or negative value for the **Shell Thickness Factor**. This value is multiplied by each target node's physical thickness and is used along with the node's offset to determine the top and bottom location of each target node. A positive value for the **Shell Thickness Factor** uses the top location of each node during mapping, while a negative value uses the bottom location of each node. For example:

   - A value of 0.0 means that the physical thickness and offset of the surface body nodes will be ignored; all target nodes are mapped at default surface body locations.

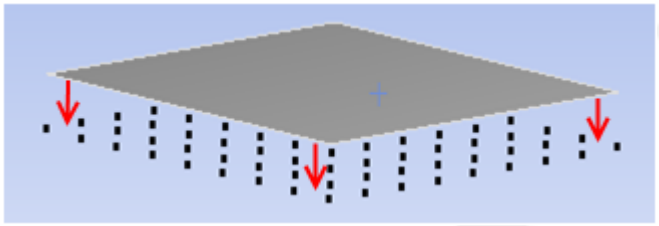
     
   - A value of 1.0 means that the thickness used for a target node will be equal to the physical thickness value specified for that node. The top location of the node will be used during the mapping process. The image below depicts a change to the position of the nodes, but this is not a reflection of what you will see in the application.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

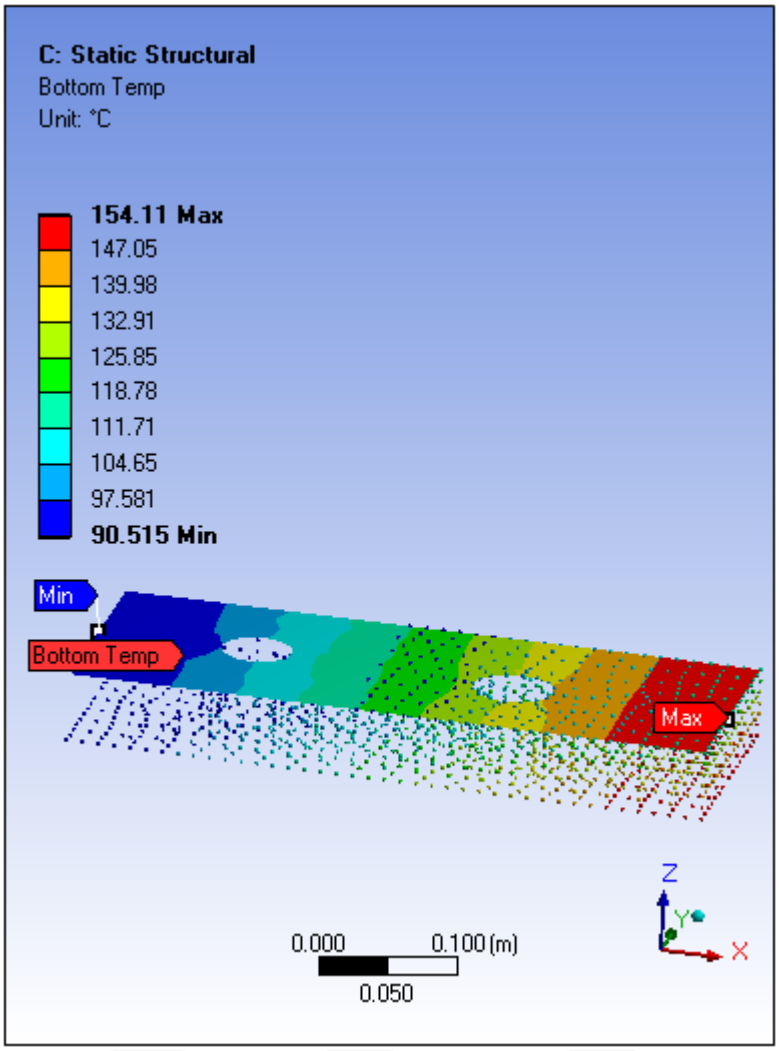


- A value of -2.0 means that the thickness used for a target node will be equal to twice the physical thickness value specified for that node. The bottom location of the node will be used during the mapping process. The image below depicts a change to the position of the nodes, but this is not a reflection of what you will see in the application.



The view will look similar to the following for a value of –1.0. The colored dots represent the location and corresponding values of the source nodes. In this case, each target node will be projected using its physical thickness value to its bottom location and then mapped.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



5. Select appropriate options in the **Details** view. You can modify the Settings (p. 2389) category properties to achieve the desired mapping accuracy. And, mapping can be validated by using mapping Validation (p. 2412) for an object.

   - For pressure loads, you can apply the load in the direction normal to the face or by specifying a direction. Setting **Define By** to **Components** enables you to define the direction by specifying the x, y, and z magnitude components of the load. The z component is not applicable for 2-D analyses. For pressure loads in Harmonic Response, you can apply both real and imaginary components of the loads.

   - In a 3D analysis, if the **Triangulation** mapping algorithm is used, the **Transfer Type** mapping option defaults to **Surface** when an Imported Temperature or Imported Body Temperature load scoping is only on shell bodies. If the scoping is on shell bodies and other geometry types, the **Transfer Type** mapping option will default to **Volumetric**. In such cases, to obtain a more accurate mapping, you should create a separate imported load for geometry selections on shell bodies, and use the **Surface** option for **Transfer Type**. See **Transfer Type** under Mapping Settings (p. 2389) for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For Imported Pressure loads, you can apply the load onto centroids or corner nodes using the **Applied to** property in the **Details** view. See Imported Pressure (p. 1752) for additional information.
- For imported force loads, both conservative and profile preserving algorithms are available using the **Mapping** property. See Imported Force (p. 1747) and Mapping Settings (p. 2389) for additional information.

6. For each load step, if an **Imported Displacement** and other support/displacement constraints are applied on common geometry selections, you can choose to override the specified constraints by using the **Override Constraints** option in the details of the Imported Displacement object. By default, the specified constraints are respected and imported displacements are applied only to the free degrees of freedom of a node.

7. For **Vector**[1]and **Tensor**[2]loads, the **Coordinate System** property can be used to associate the component identifiers, defined in the worksheet, to a particular coordinate system. This option is useful when the source data is defined, or needs to be defined, with respect to a coordinate system that is not aligned with the Global coordinate system. If a cylindrical coordinate system is chosen, the data is interpreted to be in the radial, tangential, and axial directions. By default, the Source coordinate system is used.

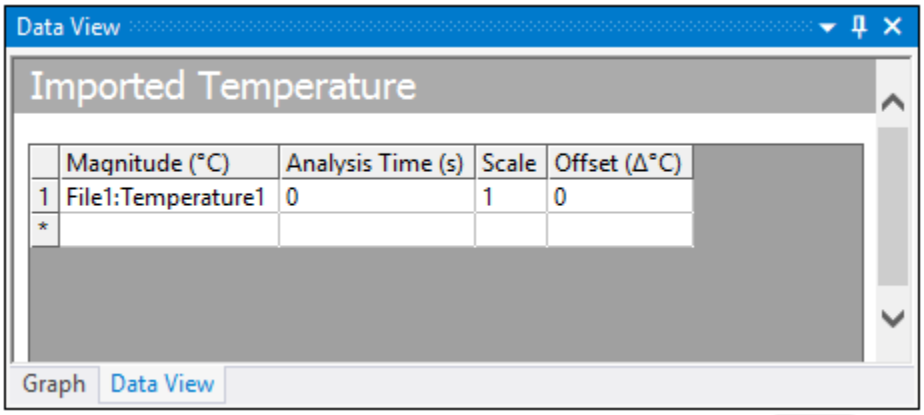
   Note:

   The **Source Coordinate System** option of the **Coordinate System** property is an internal coordinate system that is not visible in the Outline. This coordinate system represents source points transformed first by Rigid Transformation process in the upstream External Data system and then by the Rigid Transformation process in the Mechanical application. If there are no rigid transformations from the upstream **External Data** system or in Mechanical, then the **Source Coordinate System** is the same as the **Global Coordinate System**.

8. Under **Data View**, select the desired **data Identifier**, for the imported load. The data identifier (File Identifier: Data Identifier) strings are specified in **External Data**. You can also change the **Analysis Time/Frequency** and specify **Scale** and **Offset** values for the imported loads.

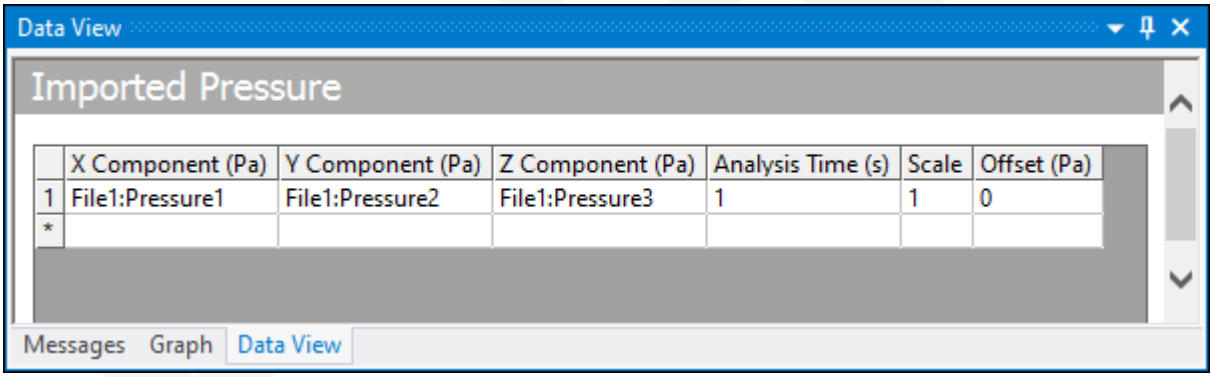
[1] Supported loads include Imported Displacement, Imported Force, Imported Pressure, and Imported Velocity.
[2] Supported loads include Imported Stress and Imported Strain.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

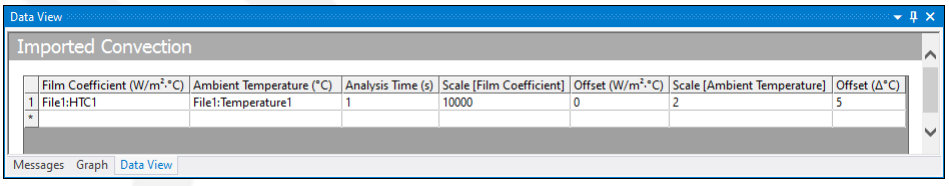


- For **Vector**[1] and **Tensor**[2] loads, if the **Define By** property is set to **Components** you should select data identifiers that represent the x/radial, y/tangential, and z/axial magnitude components of the load. For **Vector**[1] and **Tensor**[2], the components are applied in the **Coordinate System** specified in the **Details** view. The z component is not applicable for 2-D analyses. For **Imported Displacement** load, you can choose to keep a component free, or fixed *(displacement = 0.0)* by selecting the **Free** or **Fixed** option from the list of data identifiers. For all other loads, you can choose to ignore a component if you do not have data for that direction by selecting the **Ignore** identifier from the drop-down list.

  – For **Imported Body Force Density**/**Imported Pressure**/**Imported Velocity** in Harmonic Response analyses, you should select data identifiers for both real and imaginary components. You can also specify **Scale** and **Offset** for both real and imaginary components.



- For **Imported Convections**, you should select data identifiers for film coefficient and ambient temperature. You can also specify **Scale** and **Offset** values for both film coefficient and ambient temperature.



9. Right-click in the **Data View** and select **Add row** to specify additional data for a different analysis time/frequency.

10. Change any of the columns in the **Data View** tab as needed:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Magnitude/Film Coefficient/Ambient Temperature**

  Select the appropriate data identifier that represents the load values to be applied from the drop-down list.

- **X Component**

  Select the appropriate data identifier that represents the x component of the load values to be applied from the drop-down list.

- **Y Component**

  Select the appropriate data identifier that represents the y component of the load values to be applied from the drop-down list.

- **Z Component**

  Select the appropriate data identifier that represents the z component of the load values to be applied from the drop-down list.

Note:

If you do not have data for a direction you can choose to ignore that component by selecting **Ignore** from the appropriate drop-down box. Select the **Fixed** option from the drop-down list to make the component constant with a value of zero or the **Free** option for the component to be without any constraints.

If multiple files have been used in External Data, the data identifiers for component-based vector or convection loads must come from the same file or from files that have a primary file association. For example, you can select File1:PressureX, File1:PressureY, and File1:PressureZ, but you cannot select File1:PressureX, File2:PressureY, File3.PressureZ (assuming that File1, File2, and File3 do not have a primary file association).

- **XX**, **YY**, **ZZ**, **XY**, **YZ**, and **ZXComponent**

  Select the appropriate data identifiers to represent the components of the symmetric tensor to be applied from the drop-down list.

- **Analysis Time/Frequency**

  Choose the analysis time at which the load will be applied.

- **Scale**

  The amount by which the imported load values are scaled before applying them.

- **Offset**

  An offset that is added to the imported load values before applying them.

11. In the Outline, right-click the **Imported Load**, and then click **Import Load** to import the load.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12. When the load has been imported successfully, a contour or vector plot will be displayed in the **Geometry** window.

    - For **Vector**[1] loads, contours plots of the magnitude (**Total**) or X/Y/Z component can be viewed by changing the **Data** option in the details pane. Defaults to a vector plot (**All**).
    - For **Tensor**[2] (p. ?) loads, contours plots of the **Equivalent (von-Mises)** or XX, YY, ZZ, XY, YZ and ZX components can be viewed by changing the **Data** option in the details pane. Defaults to a Vector Principal plot.
    - For **Imported Convections** loads, contours plots of film coefficient or ambient temperature can be viewed by changing the **Data** option in the details pane.
    - For complex load types, such as Pressure/Velocity in Harmonic Response, the real/imaginary component of the data can be viewed by changing the **Complex Data Component** option in the details pane.

    Note:

    - Many imported loads as well as Element Orientations support Vector Display (p. 74) options.
    - The range of data displayed in the graphics window can be controlled using the **Legend controls** options. See Imported Boundary Conditions (p. 1736) for additional information.

13. If multiple rows are defined in the **Data View**, imported values at different time steps can be displayed by changing the **Active Row** option in the details pane.
14. To activate or deactivate the load at a step, highlight the specific step in the **Graph** or **Tabular Data** window, and choose **Activate/Deactivate***at this step!* See Activating and Deactivating Loads (p. 1423) for additional rules when multiple load objects of the same type exist on common geometry selections.

Important:

- For **Vector**[1] and **Tensor**[2] loads, when the **Define By** property is set to **Components**:
  - Any transformations specified in **External Data** and/or in Mechanical, are applied to the mapped data if the **Coordinate System** property is set to **Source Coordinate System**. If another Coordinate System is specified, then the components are applied in that Coordinate System.
  - Rotations produced by a cylindrical projection coordinate system, for 2D to 3D mapping, are also applied to the mapped data. Rotations resulting from analytical transformations specified in **External Data**, do not get applied to the mapped data.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For **Imported Displacements**, selecting the **Free** identifier for a source component will result in the corresponding target component being left unconstrained and free to deform in that direction, whereas **Fixed** identifier results in a value of zero being applied. For other load types, a value of zero is applied on selecting the **Ignore** component.

Exporting Data

You can export results data to one or more text files and use them in External Data in order to apply the data as boundary conditions.

To export result data, right-click a result and select Export (p. 249) > **Export Text File**. Be sure to include the Node Locations which are off by default as described in the External Data section.

For thermal analyses, you can export temperatures and heat flows on any surface with a **Fluid Solid Interface** boundary condition. See Fluid Solid Interface (p. 1648) for more information.

External Study Import

The **External Study Importer** is an **ACT App**. It assists the designer-to-analyst workflow by enabling you to import files from simulation applications such as Discovery, Autodesk Fusion 360, and PTC Creo Ansys Simulation into Mechanical for further analysis. Imported files can include a full definition of geometry, materials, loads, and constraints from the source simulation.

Note:

The **External Study Importer** is not supported on Linux operating systems.

This section examines how to:

- Create a/an:
  - Discovery Simulation Data File (p. 753)
  - Autodesk Fusion 360 Simulation Data File (p. 754)
- Enable the External Study Importer (p. 754)
- Import the following simulations into Mechanical:
  - Discovery (p. 754)
  - Autodesk Fusion 360 (p. 755)
  - PTC Creo Ansys Simulation (p. 755)

Create a Discovery Simulation Data File

To transfer a Discovery file to another application, you need to transfer the Discovery file using the following steps:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

1. From the **Transfer** menu in the ribbon of the **Simulation** tab, choose a product from the list.

2. In the **Save Discovery Document** dialog box, type a name for the Discovery file in the **File name** field and click **Save**.

Create an Autodesk Fusion 360 Simulation Data File

Perform these steps from within Autodesk Fusion 360 to create a Fusion 360 Simulation file:

1. Open the Simulation workspace for a Generative Design outcome.

2. Select **Send Study to Ansys** from the Solve group in the ribbon.

   - If Mechanical 2020 R1 is installed, this will automatically populate a Workbench project with the study and launch Mechanical.

   - If Mechanical 2020 R1 is not installed, you can save a Fusion 360 Simulation (`.sdz`) file, which you can later import via the External Study Importer.

Enable the External Study Importer

The External Study Importer is provided as an ACT App that is installed by default with Workbench.

To load the External Study Importer:

1. From the **Project** tab in Workbench, click **ACT Start Page** to open the ACT Home page.

2. Click **Manage Extensions**.

3. On the Extension Manager page, click **ExternalStudyImporter** and select **Load extension** from the context menu.

   If you want the External Study Importer to be loaded automatically for future Workbench sessions, click **ExternalStudyImporter** and select **Load as default** from the context menu.

4. Return to the ACT Home page and click **Launch Wizards**.

5. On the Wizards page, click **Execute wizard** to launch the External Study Importer.

Import a Discovery Simulation into Mechanical

After creating a Discovery Simulation Data file, you can import it into Mechanical. You can import it into a new project or an existing project.

To import a Discovery simulation into a new project in Mechanical: in Windows File Explorer, double-click a `.dscodat` file to launch Workbench and import the simulation into a new project.

To import a Discovery simulation into an existing project in Mechanical:

1. On the Wizards page (which you can access as described above), click **Execute wizard** to launch the External Study Importer Wizard.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Ensure **Study Type** is set to **Discovery Simulation**.
3. In **File To Import**, browse to the Discovery Simulation Data file you want to add to the project and click **Open**.
4. In the External Study Importer Wizard, click **Import**.
5. The import process creates a fully-populated Simulation System on the Workbench **Project Schematic** page, which you can subsequently open in Mechanical.
6. In the External Study Importer Wizard, click **Finish**.

Note:

Because of the way that Discovery manages the scoping of the Default Convection load in certain instances, you could see differences between your model in Discovery compared to Mechanical when the load is transferred between the results of the two applications.

Import an Autodesk Fusion 360 Simulation into Mechanical

You can import an Autodesk Fusion 360 Generative Design simulation into Mechanical via a Fusion 360 Simulation file (`.sdz`). In release 2020 R1, the External Study Importer supports Autodesk Fusion 360 Simulation files that have been created from Fusion 360 Generative Design outcomes. You can import the .sdz file into a new project or an existing project.

To import an Autodesk Fusion 360 Generative Design simulation into a new project in Mechanical: in Windows File Explorer, double-click a `.sdz` file to launch Workbench and import the simulation into a new project.

To import an Autodesk Fusion 360 simulation into an existing project in Mechanical:

1. On the Wizards page (which you can access as described above), click **Execute wizard** to launch the External Study Importer Wizard.
2. Ensure **Study Type** is set to **Fusion 360 Simulation**.
3. In **File To Import**, browse to the Fusion 360 Simulation Data file you want to add to the project and click **Open**.
4. In the External Study Importer Wizard, click **Import**.

   The import process creates a fully-populated Simulation System for each load case in the Fusion 360 simulation, which you can subsequently open in Mechanical.
5. In the External Study Importer Wizard, click **Finish**.

Import a PTC Creo Ansys Simulation into Mechanical

As described below, you can open a PTC Creo Ansys Simulation Data (`.casdat`) file as a new Mechanical system or you can open it in an active Mechanical system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Create a New System

Navigate to the file folder that contains the file and double-click the file. This 1) opens Workbench and places a new system in the **Project Schematic** and 2) opens the system Mechanical.

Import File into Existing System

1. As described above, open the **ACT Start Page**, select the **Launch Wizards** option, and select the **External Study** option to launch the **External Study Importer** wizard.
2. Set the **Study Type** field to **PTC Creo Ansys Simulation**.
3. Use the **Browse** option to specify your file in **File To Import** field.
4. Select the **Import** button. The import process creates a fully-populated simulation system in the Workbench Project Schematic.
5. Select the **Finish** option.
6. Open the new system in Mechanical.

Fluid-Structure Interaction (FSI)

Fluid-Structure Interaction (FSI) analysis is an example of a multiphysics problem where the interaction between two different physics phenomena, done in separate analyses, is taken into account. From the perspective of Mechanical, an FSI analysis consists of performing a structural or thermal analysis in the application, with some of the loads (forces or temperatures, for example) coming from a corresponding fluid analysis or previous CFD analysis. In turn, the results of the Mechanical analysis may be used as loads in a fluids analysis. The interaction between the two analyses typically takes place at the boundaries that the Mechanical model shares with the fluids model. These boundaries of interaction are collectively called the *fluid-structure* interface. It is at this interface where the results of one analysis are passed to the other analysis as loads.

A general way of tying two otherwise independent analyses together is described in System Coupling (p. 820). The specific use of System Coupling as one way to perform certain FSI analyses is mentioned where applicable in the following sections.

For one specific multiphysics problem, the structural thermal-stress analysis, an FSI analysis is not always required. If the thermal capabilities of the Mechanical application are sufficient to determine a proper thermal solution, an FSI approach (using separate applications for separate analyses) is not required and the thermal-stress analysis can be done entirely within Mechanical. In the case where the thermal solution requires the specialized capabilities of a CFD analysis, the structural thermal-stress analysis is done using the FSI approach. The CFD analysis is done first, then the calculated temperatures at the fluid-structure interface are applied as loads in the subsequent Mechanical analysis.

Typical applications of FSI include:

- Biomedical: drug delivery pumps, intravenous catheters, elastic artery modeling for stent design.
- Aerospace: airfoil flutter and turbine engines.
- Automotive: under-the-hood cooling, HVAC heating/cooling, and heat exchangers.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Fluid handling: valves, fuel injection components, and pressure regulators.
- Civil engineering: wind and fluid loading of structures.
- Electronics: component cooling.

The Mechanical application supports two types of Fluid-Structure Interaction: one-way transfer (p. 757) and two-way transfer (p. 757). In one-way FSI, CFD results are applied as loads in the Mechanical analysis, but the results of the Mechanical analysis are not passed back to a fluids analysis. In two-way FSI, the results of the Mechanical analysis *are* passed back as loads to the fluids model. Two-way FSI is important when the Mechanical analysis could produce results that, when applied as loads in the fluids analysis, would significantly affect the fluids analysis.

One-Way Transfer FSI

In a one-way transfer FSI analysis, the CFD analysis results (forces, pressures, temperatures, convection loads, or heat flows) at the fluid-structure interface are transferred to the Mechanical model and applied as loads. The subsequently calculated displacements or temperatures at the interface are not transferred back to the CFD analysis. One-way transfer is appropriate when displacements and temperatures differentials calculated in the Mechanical application are not large enough to have a significant effect on the fluid analysis.

There are four supported applications of a one-way FSI analysis:

1. Based on the setting of the **Interpolation Type** property:
   - **Mechanical-Based Mapping** (default): Pressure results from a CFD analysis are input as normal pressure in a structural analysis at the fluid-structure interface.
   - **CFD Results Interpolator**: Pressure results from a CFD analysis are input as applied forces in a structural analysis at the fluid-structure interface.
2. Temperature results from a heat transfer CFD analysis are input as body loads in a structural or LS-DYNA analyses to determine the thermally induced displacement and stresses (thermal-stress analysis).
3. Convections from a heat transfer CFD analysis are input as convection boundary conditions (film coefficients and bulk temperatures) in a thermal analysis at the fluid-structure interface.
4. Temperatures or heat flows from a heat transfer CFD analysis are input as temperature or heat flow boundary conditions in a thermal analysis at the fluid-structure interface.

There are two methods available for performing a one-way FSI analysis: importing loads and System Coupling. See Using Imported Loads for One-Way FSI (p. 758) and One-Way FSI Transfers Using System Coupling in Workbench (p. 828), respectively.

Two-Way Transfer FSI

In a two-way transfer FSI analysis, the CFD analysis results (forces, temperatures, heat flows, or heat transfer coefficients and near wall temperatures) at the fluid-structure interface are transferred to the Mechanical model and applied as loads. Within the same analysis, the subsequently calculated displacements, temperatures, or heat flows at the fluid-structure interface are transferred back to

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

the CFD analysis. Two-way transfer is appropriate when displacements and temperature differentials calculated in Mechanical are large enough to have a significant effect on the fluid analysis.

Because of the two-way interaction between the two analyses, the analyses are looped through repeatedly until overall equilibrium is reached between the Mechanical application solution and CFD solution. Two-way FSI is supported between Mechanical and Fluent and Mechanical and CFX. In either case, you set up the static or transient structural portion of the analysis in the Mechanical application, including defining one or more fluid-structure interface boundary conditions. You continue the analysis in Fluent or CFX, and view the structural results in the Mechanical application.

For general information on two-way FSI, see System Coupling (p. 820). For more information on two-way FSI using Mechanical and Fluent, see Performing System Coupling Simulations Using Fluent in the *Fluent User's Guide*. For more information on two-way FSI using Mechanical and CFX, see Coupling CFX to an External Solver: System Coupling Simulations in the *CFX-Solver Modeling Guide*.

Note:

In a System Coupling setup, if you apply an external force or external heat flow on the same region as a Fluid-Structure Interaction load, this external variable will not be acknowledged by the Mechanical APDL solver.

Using Imported Loads for One-Way FSI

This feature enables you to import fluid forces, pressures, temperatures, and convections from a steady-state or transient CFD analysis to a Mechanical application analysis.

This one-way transfer of face forces (tractions) or pressures at a fluid-structure interface enables you to investigate the effects of fluid flow in a static or transient structural analysis. Similarly, the one-way transfer of temperatures or convection information from a CFD analysis can be used in determining the temperature distribution on a structure in a steady-state or transient thermal analysis or to determine the induced stresses in a structural or LS-DYNA analysis.

To import loads from a CFD analysis:

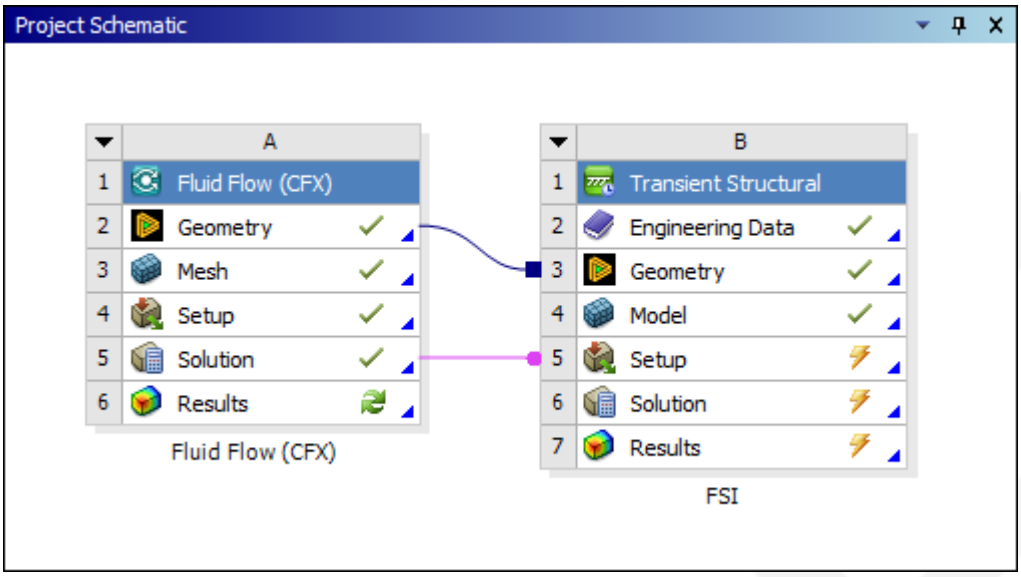
1. Complete your CFD analysis. From the **Project Schematic**, add an appropriate Mechanical analysis and create links between:

   a. The **Solution** cell of your CFD analysis and the **Setup** cell of the newly added Mechanical or LS-DYNA analysis.

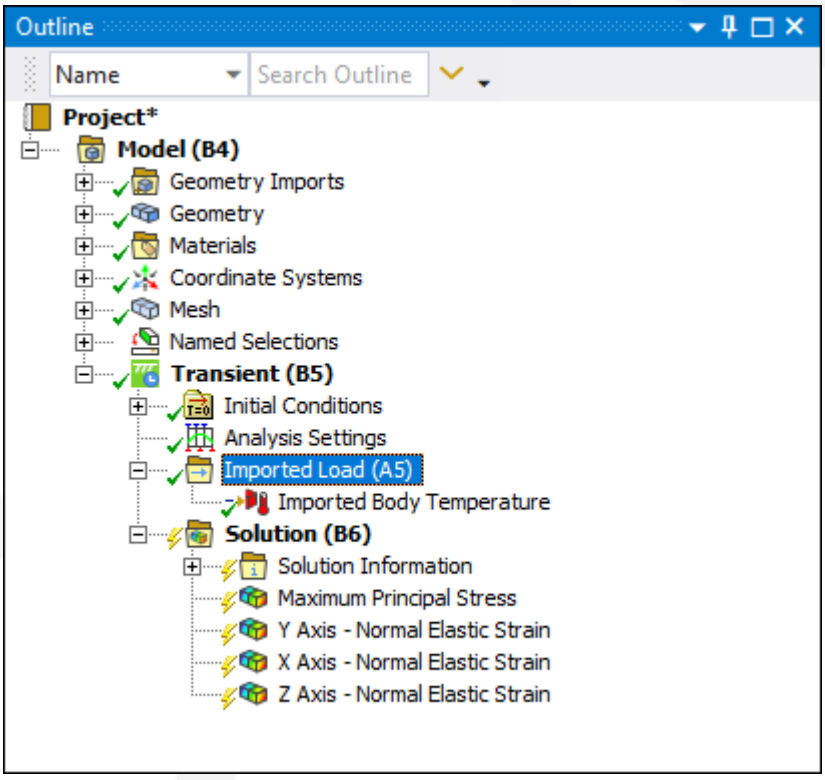
   Your system should appear as illustrated here.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



2. Double-click **Setup** cell to open Mechanical. By default, an **Imported Load** folder is added under the **Environment** folder. Alternatively, select the Fluids Results File option of the **Imported Loads** drop-down menu on the **Environment** ribbon to manually insert an **Imported Load (Fluids Results File)** object to select an existing fluids results file from the disk.



3. Select the **Imported Load (Group)** object and:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

a. Specify the **Interpolation Type** property as either: **CFD Results Interpolator** or **Mechanical-Based Mapping** (default).

Note:

The **Mechanical-Based Mapping** option is not available for LS-DYNA analyses.

b. Right-click, select **Insert**, and then select the desired load type you wish to add. Loads can also be added via the **Environment** Context Tab **Imported Loads** drop-down menu.

4. For your newly inserted load object, you can modify the following properties in the **Definition** category:

- **Tabular Loading**: This property controls the creation and content of the **Data View** table. **Data View** values are applied at each load step. The options for this property include **Program Controlled** (default), **Ramped**, **Stepped**, **Off**.
- **Source Time**: This property enables you to manage how the data from your source analysis is imported into the **Data View** table. The options for this property include **Worksheet** (default), **All**, and **Range**. Based on your selection, the time-based data contained in the **Data View** table displays accordingly.

Note:

– While defining source times and time step data, at any time you can right-click the imported load object and select the option **Sync Analysis Times**. This option synchronizes the data of the **Data View** table with your **Step Controls** (p. 1418) in the **Analysis Settings** object.

– As needed, you can also change the values of the **Source Time** column entries in the **Data View** table. To do so, select a **Source Time** cell for the imported load in **Data View** table and specify a different value. Press **Enter**. The **Source Time Step** value changes based on the source time you select. If the selected source time corresponds to more than one source time step, you will also need to select the desired time step value. You can also change the **Analysis Time** and specify **Scale** and **Offset** values for the imported loads.

– **Source Time** is not available for LS-DYNA analyses.

Note:

For the **Mechanical-Based Mapping** setting, the **Source Time** field does not support non-zero values that are less than or equal to 1e-9s.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. For your newly inserted load object, you can modify the following properties in the **Transfer Definition** category based on the setting of the **Interpolation Type** property. Note the following when making your specifications:

   - If you specify the **Interpolation Type** property as **Mechanical-Based Mapping** (default), refer to the Data Transfer Mesh Mapping (p. 2389) section for detailed descriptions of the properties contained in the **Settings**, **Graphics Controls**, and **Legend Controls** categories.

   - Under the **Transfer Definition** category:

     – For surface transfer, open the drop-down menu for the **CFD Surface** property and select the corresponding CFD surface. If you have specified the **Interpolation Type** property as **Mechanical-Based Mapping**, you can use the **Ctrl** key to select multiple options from this menu.

     – For volumetric transfer, open the drop-down menu for the **CFD Domain** property and select the corresponding CFD Domain. If you have specified the **Interpolation Type** property as **Mechanical-Based Mapping**, you can use the **Ctrl** key to select multiple options from this menu.

   - For **CFD Convection** loads only: select the appropriate **Ambient Temperature Type**.

     Note:

     – **CFD Near-Wall Ambient (bulk) Temperature** (default): This option uses the fluid temperature in the near-wall region as the ambient temperature for the film coefficient calculation. This value will vary along the face. When you specify **Mechanical-Based Mapping** as the **Interpolation Type**, Mechanical calculates the **Wall Adjacent Heat Transfer Coefficient** as the film coefficient. If you wish to use the Fluent derived heat transfer coefficients, export the solution data from Fluent and import it via External Data (p. 736) import.

     – **Constant Ambient Temperature**: This constant value applies to the entire scoped face(s). The film coefficient will be computed based on this constant ambient temperature value. Use of a constant ambient temperature value in rare cases may produce a negative film coefficient if the ambient temperature is less than the local face temperature. If this is the case, you can define a Supplemental Film Coefficient. This value will be used in place of the negative computed film coefficient and the ambient temperature adjusted to maintain the proper heat flow.

   - In a structural analysis, if the **Imported Body Temperature** load is scoped to one or more surface bodies, the **Shell Face** option in the details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

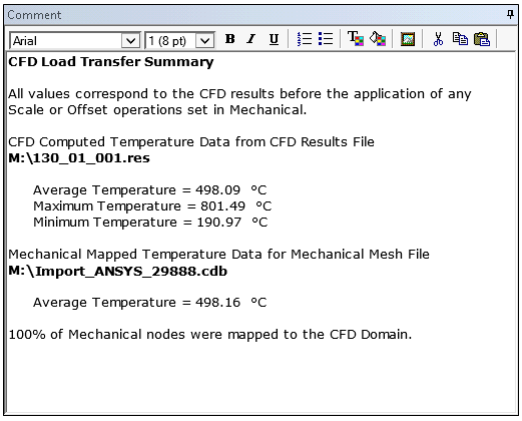
6. In the Project **Outline**, right-click the imported load object and then select the **Import Load** option to import the load. When the load has been imported successfully, a contour plot will be displayed in the **Geometry** window.

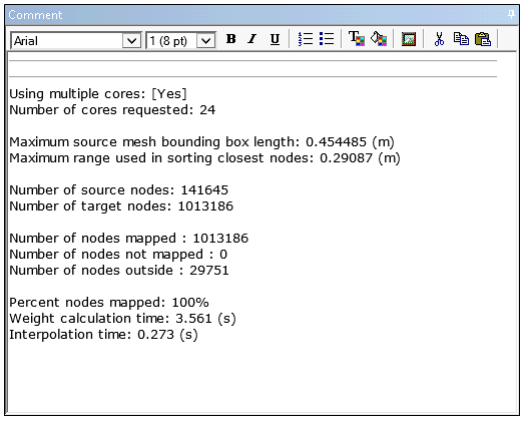
Once the solution is complete for the **Interpolation Type** property set to **CFD Results Interpolator**, a CFD Load Transfer Summary is displayed as a Comment in the particular CFD load branch. The summary contains the following information:

- For a CFD Pressure load: the net force, due to shear stress and normal pressure, on the face computed in CFD and the net force transferred to the Mechanical application faces. Note that Mechanical-Based Mapping only imports normal pressure.
- For a CFD Temperature load: For surface transfers - the average computed temperature on the CFD boundary and the corresponding average mapped temperature on the Mechanical application faces.

  For volumetric transfers – the average, maximum, and minimum temperature of the CFD domain and the corresponding Mechanical Application body selection(s).
- For a CFD Convection load: the total heat flow across the face, and the average film coefficient and ambient temperature on the face.

The computed and mapped face data may be compared in order to get a qualitative assessment of the accuracy of the mapped data. Examples of the **Imported Load Transfer Summary** for the Interpolation Types are illustrated below.

CFD Results Interpolator	Mechanical-Based Mapping
	




The following additional topics are covered in subsequent sections:

Face Forces at Fluid-Structure Interface

Face Temperatures and Convections at Fluid-Structure Interface

Volumetric Temperature Transfer

CFD Results Mapping

Face Forces at Fluid-Structure Interface

You can use results at a fluid-structure interface from a CFD analysis as face forces (from the vector sum of the normal pressures and shear stresses) on corresponding faces in the Mechanical

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

application. The import process involves interpolating a CFD solution onto the Mechanical application face mesh. This requires that the following conditions are met:

- The fluid-structure interface must be a defined *boundary* in CFD.
- The location of the CFD boundary (with respect to the global Cartesian coordinate system) must be the same as the corresponding face(s) in the Mechanical application model.

Refer to the Imported Boundary Conditions (p. 1736) section for more information.

Face Temperatures and Convections at Fluid-Structure Interface

This feature allows the transfer of either of the following thermal solutions from a CFD solution boundary to a corresponding face in the Mechanical application model:

- Temperatures at the fluid-structure interface.
- Film coefficients and bulk temperature values at the fluid-structure interface.

The import process involves interpolating a CFD solution onto the Mechanical application face mesh. This requires that the following conditions are met:

- The fluid-structure interface must be a defined *boundary* in CFD.
- The location of the CFD boundary (with respect to the global Cartesian coordinate system) must be the same as the corresponding face(s) in the Mechanical application model.

Refer to the Imported Loads (p. 1736) section for more information.

Volumetric Temperature Transfer

You can transfer temperature results from a CFD analysis and apply them as body loads in the Mechanical application. The import process involves interpolating a CFD solution onto the mesh for the bodies selected in the Mechanical application. This requires that the following condition is met:

- The location of the bodies in the Mechanical application model (with respect to the global Cartesian coordinate system) must be the same as the corresponding CFD domains.

CFD Results Mapping

When mapping CFD results onto the Mechanical application face(s) the Mechanical nodes are projected on to the CFD face. All the Mechanical application face nodes will map to the CFD face according to the following rules:

a. Project normal to the CFD mesh faces.

b. If rule a fails, project to the closest edge.

c. If rule b. fails, project to the closest node on the CFD face.

Rule c. will always work, so in the end every node will get some kind of mapping. However the most accurate load mapping occurs for nodes projected normal to the mesh face. The percentage of the Mechanical application nodes that mapped successfully using rule a. above is reported in

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

the diagnostics. When the Mechanical application mesh is very coarse, there can be some misses near the edges of the CFD boundary. However all nodes become mapped eventually. The accuracy of force transfer improves as the Mechanical application mesh is refined.

When mapping CFD domain results onto the corresponding Mechanical Application body selection(s), all the Mechanical Application nodes that cannot be mapped to the CFD domain will be set to the average temperature.

Icepak to Mechanical Data Transfer

The Mechanical application enables you to transfer temperature data from Icepak into Mechanical. This process involves the import of temperature data from the solid objects defined in Icepak onto the geometry defined in Mechanical. As the meshes used in Icepak and Mechanical could be quite different, mapping the temperatures involves an interpolation method between the two. Once the mapping is completed, it is possible to view the temperatures and utilize them to perform a Mechanical analysis. The workflow is outlined below.

Workflow for Icepak Data Transfer

1. In Icepak, perform all steps for an Icepak analysis by creating the Icepak model, meshing and solving the model. After the solution has finished, Icepak writes out the temperature data for each of the solid objects to a file with the extension loads. In addition, a summary file with the extension load summary is written out.

   Note:

   The **CFD Post/Mechanical data** option must be enabled in the **Solve** panel to transfer data to CFD-Post/Mechanical. If this option was not enabled prior to solving, you also have the option of exporting data using the **Post** > **Workflow data** menu in Ansys Icepak.

2. Drag and drop a Mechanical cell, which could be one of Static Structural, Steady-State Thermal, Transient Structural, Transient Thermal, or Thermal-Electric analysis on top of the Icepak Solution cell.

3. Import the geometry or transfer the geometry into the Mechanical application. Double click the Setup cell to display the Mechanical application.

4. In the Details section of **Imported Temperature** or **Imported Body Temperature** under **Imported Loads**, you will first select the Scoping method. Select **Geometry Selection** as the Scoping method unless you have created a **Named Selection**. See Scoping Analysis Objects to Named Selections (p. 1083) for a detailed description.

5. If **Geometry Selection** is selected as the **Scoping method**, pick the geometry using **Single select** or **Box select** and click **Apply** or select a **Named Selection** object in the drop-down list.

6. In a structural analysis, if the Imported Body Temperature load is scoped to one or more surface bodies, the Shell Face option in the details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

7. To suppress this load, select **Yes**. Otherwise, retain the default setting.

8. In the drop-down field next to **Icepak Body**, select one body at a time, **All** or a **Named Selection**. If selecting an individual body, make sure your selection corresponds to the volume selected in step 5. If **All** bodies were selected, select **All**.

9. The Icepak Data Solution Source field displays the Icepak temperature source data file.

10. You can modify the Mapper Settings (p. 2389) to achieve the desired mapping accuracy.

11. Click the imported load object, then right-click and select **Import Load**. This process first generates a mesh, if one doesn't already exist, and then interpolates the temperatures from the Icepak mesh onto the Mechanical mesh. This process might take long if the mesh size or the number of bodies is large. Improving the quality of the mesh will improve the interpolation results but the computation time may be higher.

    Note:

    If the import is successful, you can see the temperature plot in the graphics display window.

    If multiple time steps refer to the same time, an error will be displayed in the Mechanical message window.

12. You can apply other boundary conditions and click **Solve** to solve the analysis.

How to Set up a Transient Problem

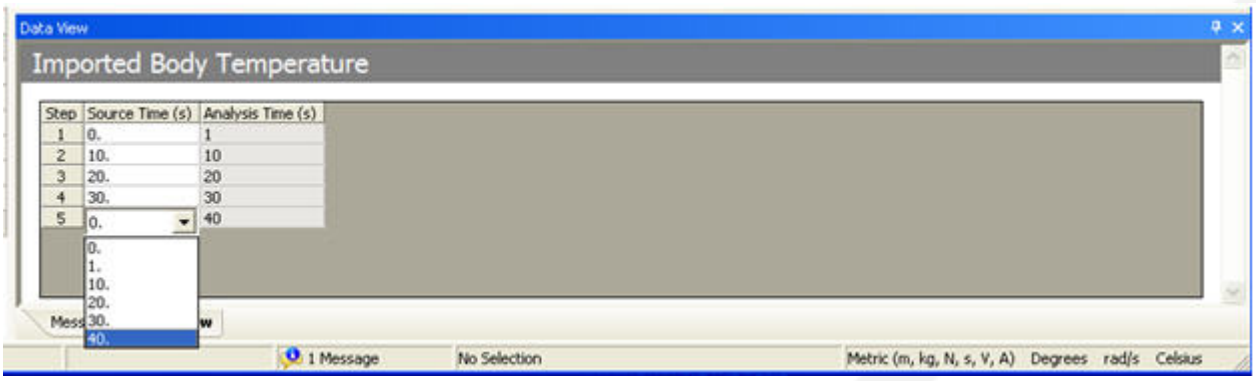
1. In Icepak, perform all steps for a transient Icepak analysis and solve the model.

2. Perform steps 2 – 9 as described above.

3. Click the **Analysis Settings** object in the tree. Begin adding each step's **End Time** values for the various steps to the tabular data window. You can enter the data in any order but the step end time points will be sorted into ascending order. The time span between the consecutive step end times will form a step. You can also select a row(s) corresponding to a step end time, click the right mouse button and choose **Delete Rows** from the context menu to delete the corresponding steps. See Establish Analysis Settings (p. 349) for further information. Whenever a new row is added or deleted, the imported body temperature data view will be updated to match the number of rows in the **Analysis Settings**.

4. Click the imported load object and the Data View tab with updated **Analysis Times** is displayed. If the **Analysis Time** is different, the **Source Time** will display the original time, matching to the closest available **Source Time** coming from Icepak. If the match is not satisfactory, you can select a **Source Time(s)** from the drop-down list and Mechanical will calculate the source node and temperature values at that particular time. This combo box will display the union of source time and analysis time values. The values displayed in the combo box will always be between the upper and lower bound values of the source time. If the user modifies the source time value, the selection will be preserved until the user modifies the value even if the step's end time gets changed on the analysis settings object. If a new end time value is added/deleted, Source Time will get the value closest to the newly added Analysis time value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



5. Click the imported load object, then right-click and select **Import Load**. This will interpolate the value at all the selected time steps.

6. User can display interpolated temperature values at different time steps by changing the **Active Row** option in the detail pane.

7. Apply required boundary conditions, continue with any further analysis and solve.

Inverse Solving for Nonlinear Static Structural Analyses

Introduction

The basic difference between a traditional (forward) analysis and the use of the Inverse Option, is the state of the initial geometry. For a forward solution process, the initial geometry is deformed under loading conditions and results are evaluated on the deformed geometry. While using the Inverse Option for your solution, you begin with a known input geometry that is already deformed under a set of loads that produced the deformation. Therefore, the solution output generated by the solver is the geometry (also referred to as solution geometry or reference geometry) that would have existed without the application of the loads. However, the result values are always calculated on the input geometry during the inverse stage of the solution.

For both solution processes, the basic concepts, solution approaches, and steps are the same.

Important:

Inverse solving is only supported for Static Structural (p. 652) nonlinear analyses with the **Large Deflection** property set to **On**, that is, when the deformations may be large enough to affect the solutions results.

Application

To perform inverse solving, simply set the **Inverse Option** property to **Yes** in the **Advanced** category (p. 1461) of the Analysis Settings. Setting the property to **Yes** also displays the **End Step** property. The **End Step** property specifies the step number in the analysis when the inverse solving routine ends. The default value of **End Step** is **1** and is read-only (unless Beta Options options are enabled). The steps in the analysis until the **End Step** of Inverse Option are referred to as inverse steps. The steps in the analysis that occur after the **End Step** of the Inverse Option are referred as forward steps.

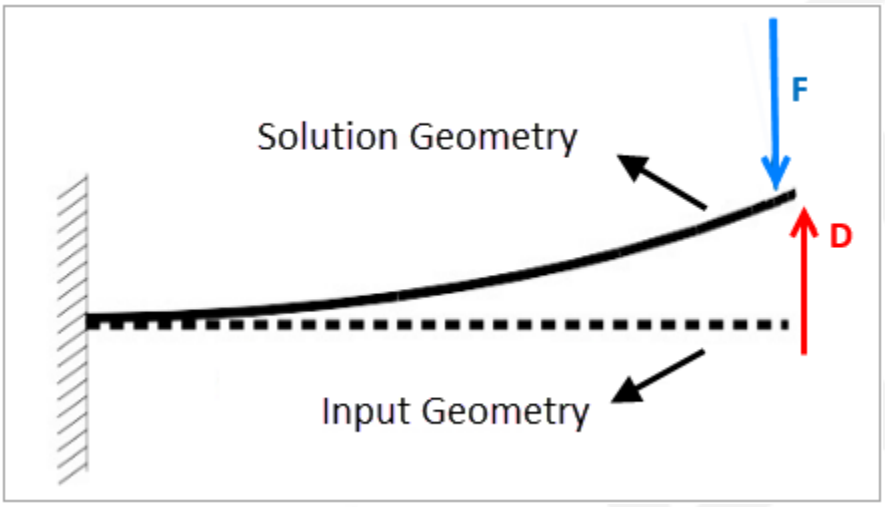
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When set to **Yes**, the **Inverse Option** will always perform an inverse solving on at least the first load step. This assumes that the input geometry for the analysis is a geometry that is already deformed under the specified loading during the inverse steps.

Proper specification of the **End Step** and **Number of Steps** properties enables you to perform:

- Inverse solving with the intent to obtain the solution/reference geometry only. You can perform purely inverse solving by setting the same value for **End Step** and the **Number of Steps** properties. The direction of force-based loading, such as Pressure, Force, etc., should be considered such that it brings the Solution Geometry to the Input Geometry. However, for displacement-based loads, such as Displacement, Remote Displacement, etc., the prescribed displacement should be defined such that it brings the Input Geometry to the Solution Geometry.



- Inverse solving followed by a forward solving. This is useful when you need to examine the structural response under additional loading. You perform this type of analysis by setting the **End Step** property to a value that is less than the value provided for the **Number of Steps** property. The analysis begins with an input geometry that is already deformed under the specified loading conditions during the inverse steps. During the start of the forward solution step, the solver resets the displacements to zero and start from the Input geometry. As a result, you may see a sudden jump in displacement from the end of inverse step to the beginning of the forward step because of this reset.

- Loop test to verify the modelling details used with **Inverse Option**. To perform a loop test, 1) enter an **End Step** property value that is less than the setting of the **Number of Steps** property, 2) make sure the applied loads remain the same between the inverse and forward steps. Because the applied load is same for the Inverse and forward step, the same Input geometry, which exists at time = 0, will be recovered at the end of the forward step.

Note:

To perform a loop test, it is recommended that you export the solution geometry (**Export** > **STL**) following the inverse step in order to have a separate analysis and apply the same loads that were applied for the inverse steps.

Be sure to review the Requirements and Limitations (p. 768) outlined below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Requirements and Limitations

Review the categorized requirements and limitations listed below. In order to the inverse capability, you must make sure these requisites are met.

Analysis Settings

When defining Analysis Settings, the **Inverse** option requires the:

- **Large Deflection** property to be set to **On**.
- The **Inverse Option** requires the Unsymmetric solver. If the **Inverse Option** property is set to **Yes**, the application automatically selects this solver.

Elements

The Inverse Option only supports a mesh with higher order elements.

Contact

The **Inverse** option only supports the **MPC** setting for the **Formulation** property for contact conditions and does not support Bearings, Springs, Joints, Beams, and Spot Welds connection types.

Loading and Boundary Conditions

Supported Load and Boundary Conditions include:

- Inertial (p. 1500): Acceleration, Standard Earth Gravity, Rotation Velocity, and Rotational Acceleration.
- Loads (p. 1520): Pressure (direct and normal pressures only), Remote Force, and Moment.
- Supports (p. 1663): Fixed Support, Displacement, Remote Displacement, Frictionless Support, and Cylindrical Support.
- Conditions (p. 1697): Coupling and Constraint Equation.
- Direct FE (p. 1719): Nodal Force, Nodal Pressure, Nodal Displacement, and Nodal Orientation.

Important:

Because displacement type loads like Displacement and Remote Displacement brings the displacement from Input Geometry to Solution Geometry, it is important to reverse the direction of these prescribed displacements during the forward step if you wish to perform the loop test or continue with additional loads/displacements in the forward step.

Important:

The following loading conditions are **not supported**:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Remote loads (Remote Forces/Remote Displacements/Moments) specified using beam behavior.
- Loads that rely on the internal generation of elements (surface effect elements, beam elements, pretension elements, etc.).

Materials

The **Inverse** option supports the following materials:

- Linear Elastic
- Hyperelastic with a material incompressibility factor $d \neq 0$.

Any nonlinear material effects, such as plasticity and creep, are not supported.

Linked Environments

If you use an inversely solved Static Structural analysis as a prestress environment for a downstream Modal or Harmonic Response analysis:

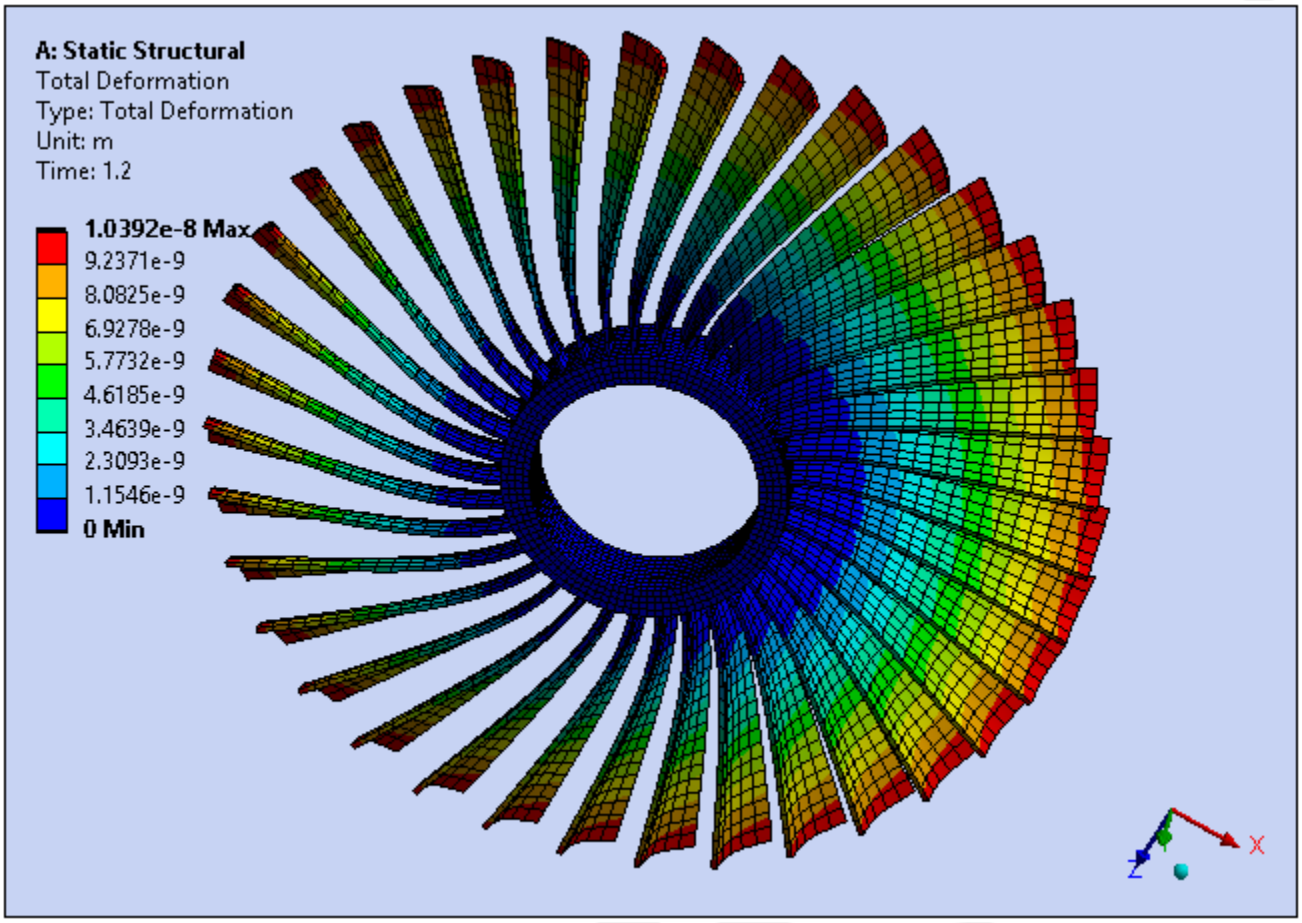
- Only forward solved steps can be selected as prestress steps for linked Modal/Harmonic Response analyses.
- For undamped Modal analyses, the application uses the **Unsymmetric** setting for the **Solver Type** property (via the **Program Controlled** setting). The other solver types (Direct, Iterative, Subspace, and Supernode) are not supported for an undamped Modal environment.

Post-Processing of Results

For result entities plotted at **Time** or **Result Set** corresponding to an inverse step, please note the following:

- Deformation results retrieved for inverse step, represent the deformation of the model with respect to the input geometry. Deformation results are plotted on the solution geometry.

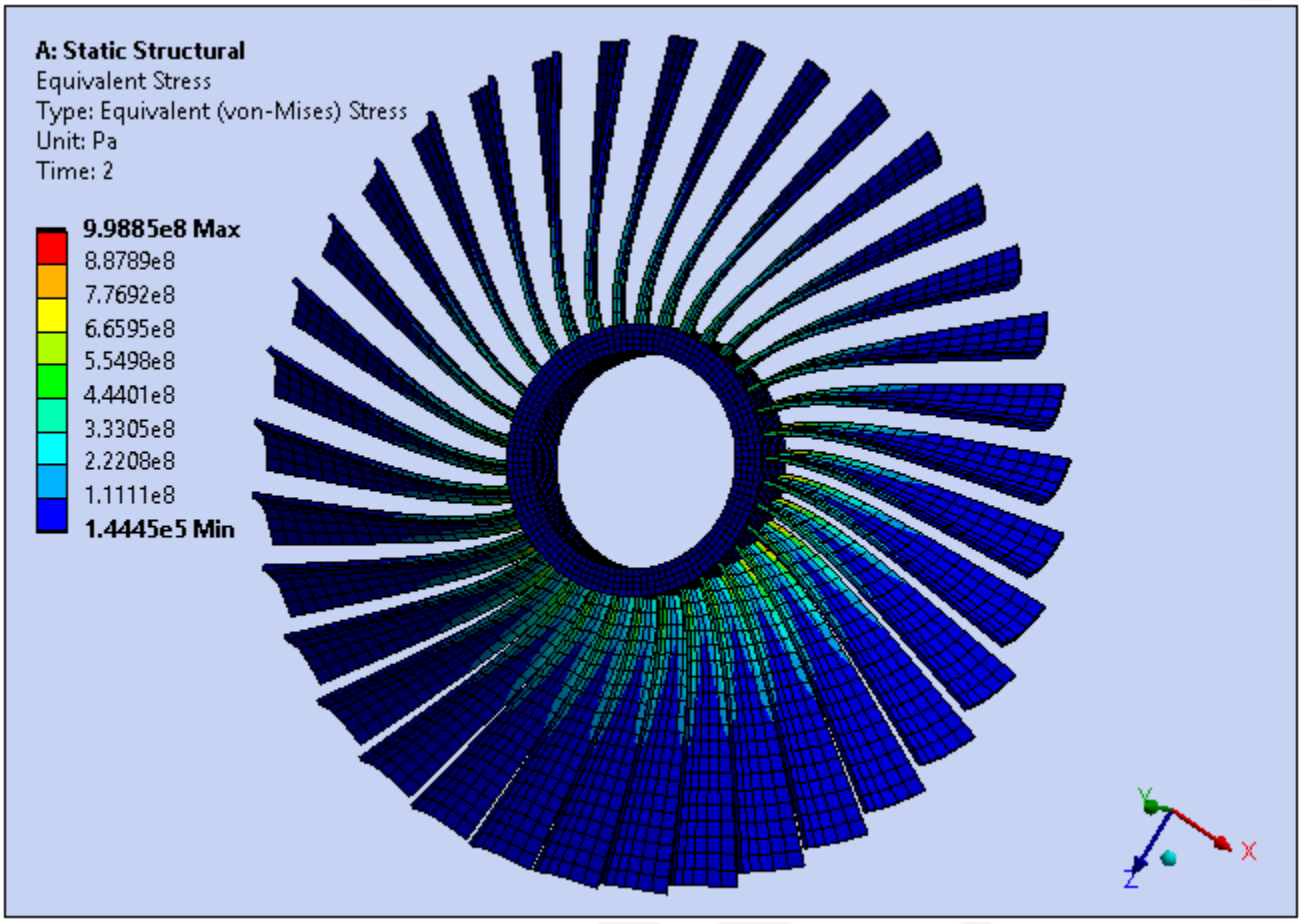
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



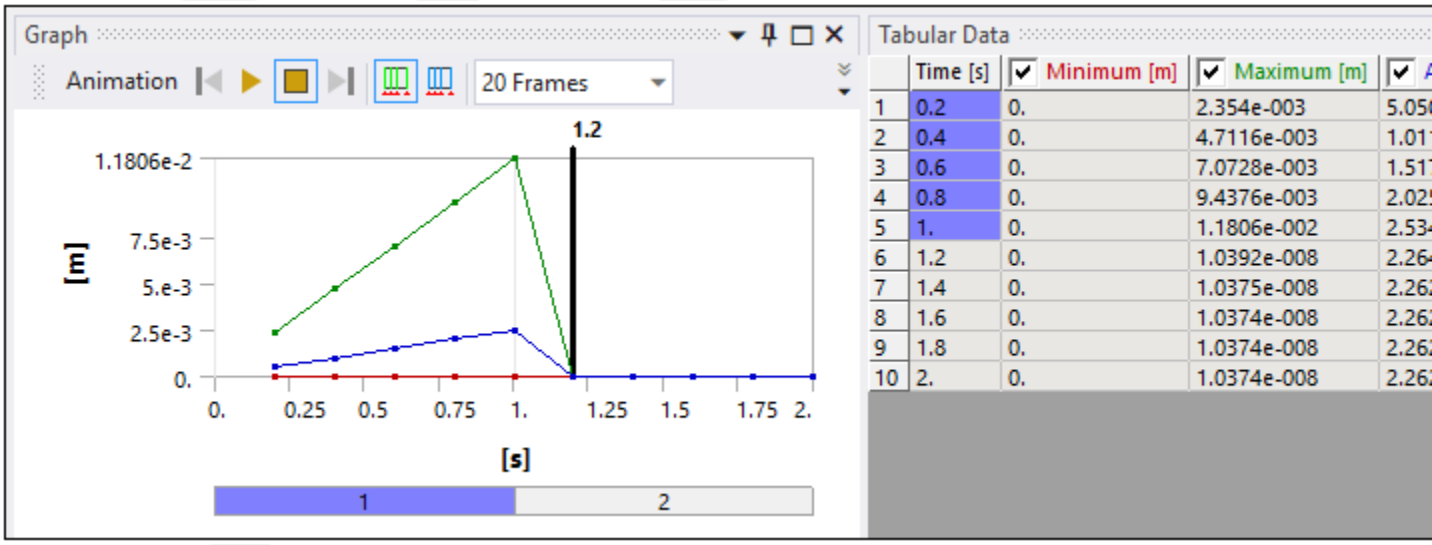
- All other result items (e.g. stress, strains, probes etc.) are plotted on the input geometry of the analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



- Results produced during the Inverse solution are shown with a colored highlight in the **Graph** and **Tabular Data** window.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- You can save the solution/reference geometry using the context (right-click) menu option **Insert** > **Export** > **STL** on a deformation result created for the **Display Time**/**Load Step** corresponding to the **End Step** of the inverse solution.

Note:

Be sure to use the Zoom to Fit Animation (p. 2263) option in the **Graph** window to properly animate your Inverse results. When the option is active, Mechanical loops through all the time steps to compute a scale factor that accommodates a full range of time steps and makes sure that the animation fits properly within the **Geometry** window.

MAPDL Reference

For an additional information, review the Nonlinear Static Analysis with Inverse Solving section of the Mechanical APDL Structural Analysis Guide.

Mechanical-Electronics Interaction (Mechatronics) Data Transfer

You can export a reduced model that can be imported into Twin Builder.

Overall Workflow for Mechatronics Analysis

1. Create a modal analysis system.
2. Define the inputs using **Remote Points** and/or **Named Selections**. The names of the entities created must include the prefix `input_` and the degree of freedom in the trailing suffix, signified by an underbar (e.g. "`input_MyName_ux`").

   Note:

   The **Named Selection** can only be scoped to a vertex.

   ---

3. Define the outputs using **Named Selection**. The names of the entities created must include the prefix `output_` and the degree of freedom in the suffix (e.g. "`output_MyName2_rotx`").

   Note:

   The **Named Selection** can only be scoped to a vertex.

   ---

4. Specify the modal damping in a Commands Object under an Environment, for example:

```
dmprat,.02          ! 2% damping on all modes
mdamp,1,.05         ! 5% damping on mode 1
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. At Solution level, add a Commands Object and import the macro `ExportStateSpaceMatrices.mac` to export the reduced model. It is located at the installation folder under: `ANSYS Inc\v241\aisol\DesignSpace\DSPages\macros`

   Note:

   The macro is based on the Mechanical APDL command **SPMWRITE**.

6. Solve the Modal Analysis.

7. The reduced model file (`file.spm`) and the graphics file (`file_spm.png`) will exist in the solver files directory and can then be imported into Twin Builder. (See Saving and Managing Project Files in *Workbench User's Guide* for more information on solver files directories.)

Set up the Mechanical Application for Export to Twin Builder

To set up the Mechanical application to retrieve the inputs and outputs defined so they can be used in the reduced model exported to Twin Builder:

1. From the **File** tab, select the **Variable Manager** option.

2. In the **Variable Manager** window, add/activate the variable **ExportToTwinBuilder** and set it to 1.

Polyflow to Mechanical Data Transfer

This feature enables you to import data from a Polyflow system and apply it in a Mechanical application analysis. Temperature data can be imported into a static structural, transient structural[3] steady-state thermal, transient thermal or thermal-electric analysis.

To import data from a **Polyflow** system:

- In the **Project Schematic**, right-click the **Solution** cell of the **Polyflow** system and select **Transfer Data to New**><*Mechanical system*>, a link is created to the **Model** cell of the selected Mechanical system. If you select **Transfer Data to New** > ***<Mechanical system>***, this operation automatically creates a link to the **Model** cell of the Mechanical system. Alternatively, you can drag the **Solution** cell of the **Polyflow** system and drop it onto the **Model** cell of a Mechanical system to create the link.
- To transfer temperature data to Mechanical, drag the **Solution** cell of the **Polyflow** system and drop it onto the **Setup** cell of an applicable Mechanical system.
- To transfer thickness data to Mechanical, drag the **Solution** cell of the **Polyflow** system and drop it onto the **Model** cell of an applicable Mechanical system.

If your simulation has thickness defined from a Polyflow system, an **Imported Thickness** folder is added under the **Geometry** folder.

[3] The rigid dynamics solver is not supported.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

1. Select appropriate geometry in the **Details** view, and then click **Apply**.
2. Select appropriate options in the **Details** view. You can modify the mapping settings to achieve the desired mapping accuracy.
3. You can specify a thickness value for the unmapped target nodes using the **Unmapped Data Value** property. By default, a zero thickness value is assigned to the unmapped nodes.

   Important:

   For the Mechanical APDL solver, the thickness value at each node must be greater than zero.

4. Right-click the **Imported Thickness** object, and then click **Import Thickness** to import the thickness. When the thickness has been imported successfully, a contour plot will be displayed in the **Geometry** window and any mesh display will be based upon the mapped thickness of the elements.

If your simulation has temperature data defined from a Polyflow system, an Imported Load folder is added under the Environment folder.

1. Select an imported temperature load to add from the **Imported Loads** drop-down menu on the **Environment** Context tab or right-click the **Imported Load** folder and select the appropriate load from the **Insert** context menu.
2. Select appropriate geometry in the **Details** view, and then click **Apply**.
3. In a 3D structural analysis, if the Imported Body Temperature load is scoped to one or more surface bodies, the **Shell Face** option in the details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.
4. Select appropriate options in the **Details** view. You can modify the mapper settings (p. 2389) to achieve the desired mapping accuracy.

   - In a 3D analysis, if the **Triangulation** mapping algorithm is used, the **Transfer Type** mapping option defaults to **Surface** when an Imported Temperature or Imported Body Temperature load scoping is only on shell bodies. If the scoping is on shell bodies and other geometry types, the **Transfer Type** mapping option will default to **Volumetric**. In such cases, to obtain a more accurate mapping, you should create a separate imported load for geometry selections on shell bodies, and use the **Surface** option for **Transfer Type**.

5. Under **Data View**, select the desired **data Identifier**, for the imported load. The data identifier (File Identifier: Data Identifier) strings are specified by the upstream **Polyflow** system. You can also change the **Analysis Time** and specify **Scale** and **Offset** values for the imported loads.
6. Right-click in the **Data View** and select **Add row** to specify additional data for a different analysis time.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

7. In the project tree, right-click the **Imported Load** object, and then click **Import Load** to import the load. When the load has been imported successfully, a contour plot will be displayed in the **Geometry** window.

8. If multiple rows are defined in the **Data View**, imported values at different time steps can be displayed by changing the **Active Row** option in the details pane.

9. Change any of the columns in the **Data View** tab as needed:

   - **Magnitude**

     Select the appropriate data identifier that represents the load values to be applied from the drop-down list.

   - **Analysis Time**

     Choose the analysis time at which the load will be applied. For the Mechanical APDL solver, this must coincide with the end time of a step defined in the **Analysis Settings** object in the tree.

   - **Scale**

     The amount by which the imported load values are scaled before applying them.

   - **Offset**

     An offset that is added to the imported load values before applying them.

10. To activate or deactivate the load at a step, highlight the specific step in the **Graph** or **Tabular Data** window, and choose **Activate/Deactivate***at this step!* See Activating and Deactivating Loads (p. 1423) for additional rules when multiple load objects of the same type exist on common geometry selections.

Reinforcement Specification Using Mesh-Independent Method

Introduction

For an appropriately modeled geometry, Mechanical provides options to specify reinforcements within a structure. Mechanical can model these reinforcing geometries with specialized reinforcing elements. These reinforcing elements provide extra reinforcing by interacting with the standard structural or thermal elements, referred to as base elements, via the shared nodes.

This section examines:

- Feature Overview (p. 776)
- Application (p. 777)
- Loading Condition Specification (p. 779)
- Post Processing (p. 779)
- Requirements and Limitations (p. 779)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Feature Overview

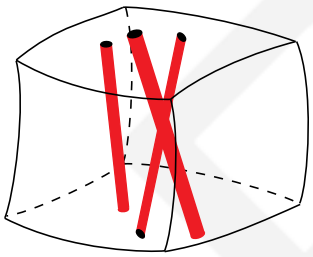
Reinforcement is supported for the following three-dimensional analysis types:

- Static Structural
- Steady-State Thermal
- Thermal-Stress (Steady-State Thermal linked to Static Structural)
- Modal (Standalone and Pre-Stressed)
- Harmonic Analysis (Standalone, Pre-Stressed, and MSUP)
- Random Vibration
- Response Spectrum

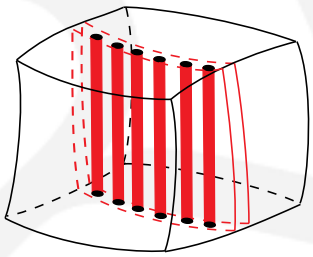
These analyses require that your imported model already include the line or surface bodies you wish to specify as reinforcements as well as an appropriate material to assign to these reinforcement bodies.

As illustrated, Mechanical provides reinforcement specification for line bodies (discrete reinforcing) and surface bodies (smeared reinforcing). Each line body specified as reinforcement basically represents a reinforcing fiber arbitrarily oriented in space. Each surface body specified as reinforcement basically represents a reinforcing layer. This reinforcing layer can be either a homogeneous reinforcing layer (membrane) or reinforcing layer with evenly spaced fibers.

Discrete (Line Bodies Only)



Smeared (Surface Bodies Only)



Mechanical uses the Mechanical APDL-based Mesh-Independent Method for Defining Reinforcing to create reinforcing elements. The mesh-independent method uses MESH200 elements to represent the reinforcing member locations inside the generated reinforcing elements.

When the solution is initiated, the application temporarily defines the reinforcement locations using MESH200 elements along with the base elements. During the solution process, the application internally creates the element REINF264 for line bodies or the element REINF265 for surface bodies based on the intersection of corresponding MESH200 and base elements.

Important:

- The line and surface bodies defined as reinforcements are *reinforcement representations*, not actual reinforcing elements or members created by the MAPDL solver.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Different solver units might affect the number of reinforcing elements or members generated during the solve due to tolerances. This could lead to small differences in the result values.

Application

The steps to specify line or surface bodies as reinforcements include:

Line Bodies

For the Line Body object:

1. Select the **Reinforcement** option for the **Model Type** property.
2. As needed, assign a material to the Line Body reinforcement.
3. Verify that the desired cross section is specified in the **Cross Section** property. The area value of this cross section is sent to the solver (**Area** property of the corresponding cross section object).

   Note:

   - The solver does not consider the shape of the cross section. The area of the cross section is the only required value. See the *Reinforcing* topic in the **SECDATA** command section of the *Mechanical APDL Command Reference* for more information.
   - During the solution process, by default, the application 1) turns on Tension and Compression and 2) removes the base material from the space occupied by the reinforcing fibers.

4. Repeat the above steps for all line bodies to be used as a reinforcement.

Surface Bodies

For Surface Body objects, the default setting for the **Model Type** property is **Shell**. The **Shell** setting treats the body as a surface body - there is no reinforcement treatment.

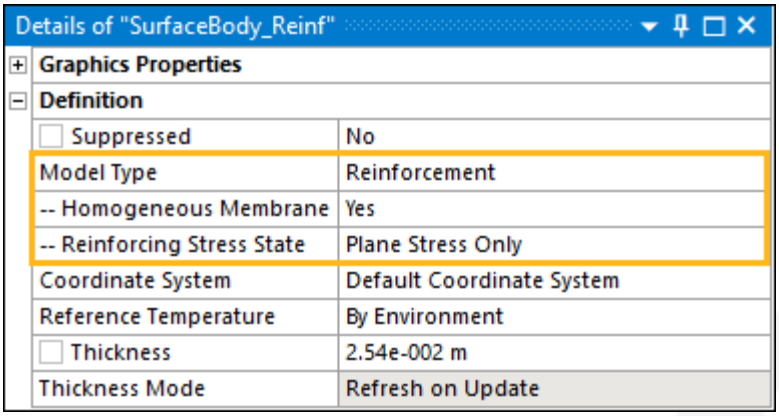
To specify the Surface Body as a reinforcement:

1. Select the **Reinforcement** option for the **Model Type** property.
2. As needed, assign a material to the Surface Body reinforcement.
3. When you select the **Reinforcement** option, an additional property, **Homogeneous Membrane**, displays.

   If the **Homogeneous Membrane** property is set to **Yes** (default), then the Surface body is treated as a homogeneous reinforcing layer (membrane) in a plane-stress state. Verify

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

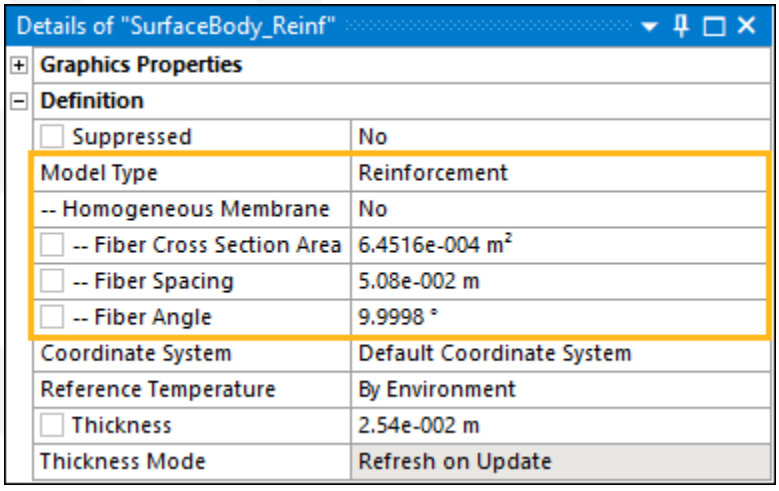
the value in the **Thickness** property since this value is used for defining the cross section area of the reinforcing membrane inside the reinforcing element.



For 3D Structural analyses, when the **Homogeneous Membrane** property is set to **Yes**, the additional property **Reinforcing Stress State** displays. This property enables you to specify the reinforcing stress state and stiffness behavior of the homogeneous reinforcing layer (membrane). Options include **Plane Stress Only** (default), **Plane Stress with Transverse Shear**, and **Plane Stress with Transverse Shear and Bending**. See the Reinforcing topic in the **SECCONTROL** section of the *Mechanical APDL Command Reference* for more information.

If **Homogeneous Membrane** property is set to **No**, then the Surface Body is treated as a reinforcing layer with a cluster of parallel and equidistant fibers having the same cross section. This means that the layer has a uniaxial-stress state in the direction of the fibers. The value in the **Thickness** property is ignored. The following additional properties display and require specification:

- **Fiber Cross Section Area**: Cross section area of the fiber.
- **Fiber Spacing**: Distance between fibers.
- **Fiber Angle**: Orientation of the associated fibers in the specified coordinate system.



In addition, select the appropriate Coordinate System to define the specific orientation of the fibers. See **Element Coordinate System** description in the MESH200 element section for more information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

4. Repeat the above steps for all surface bodies to be used as a reinforcement.

Note:

During the solution process, by default, the application 1) turns on Tension and Compression when the Homogeneous Membrane property is set to No (uni-axial stress state) and 2) removes the base material from the space occupied by the reinforcing layer.

Loading Condition Specification

Only an Internal Heat Generation (p. 1620) load or an Imported Heat Generation (p. 1748) load can be applied to the bodies specified as Reinforcements.

Post Processing

You can create results for reinforcement bodies through **Geometry Selection** or using **Named Selections**. You can select specific reinforcement bodies or use the default setting of **All Bodies** and hide appropriate base bodies to view the results on the reinforcements.

Because the solver generates reinforcing elements, only body-based results are available on the reinforcement bodies. Mechanical does not allow Face/Edge/Vertex/Node/Element/Element Face based results on Reinforcement bodies.

Also, if you mix reinforcement body selections with non-reinforcement body selections for your result scoping, the application displays results for the bodies that are not specified as Reinforcements and excludes the evaluation of results on the Reinforcement bodies.

Note:

If you set the **Scoping Method** property to **Result File Item**, the **Global ID** property displays for results on a specified set of reinforcing members. This corresponds to the global identifier (**EGID**) in Mechanical APDL.

Requirements and Limitations

Note the following when performing this analysis type:

- Reinforcement is supported for 3D Static Structural and Steady-State Thermal analyses.
- If you are using **Material Assignment** (p. 1049) objects, Ansys recommends that you use separate **Material Assignment** objects or Line bodies and Surface bodies modeled as Reinforcements as well as for any non-reinforcement bodies. This helps ensure the application properly plots result data.
- If you have assigned a material to the base body that does not support a 1D stress state, such as Drucker Prager, the application does not remove the base material in the space occupied by reinforcing members that have uniaxial stress state.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- If you have a result object selected, certain mesh-based features are not available for the reinforcement elements of the geometry, including mesh selection filters (nodes (p. 269), elements, and element faces (p. 276)), as well as the ability to display a Node ID in the probe label (p. 206), and Selecting Nodes and Elements by ID (p. 279).
- Reinforcements do not support bending for nonhomogeneous membranes.
- Thermal analyses do not support surface and line bodies as base bodies for creating reinforcing elements.
- Reinforcement bodies do not support Remote Points (p. 1089), Symmetry (p. 1127), Fracture (p. 406), or Connections (p. 1207). These features are ignored when scoped to reinforcement bodies.
- Condensed Parts are not supported when a model contains reinforcements. If present, you can suppress the Condensed Part(s) or Reinforcement bodies in order to proceed with the solution.
- Only Body-based results are supported for Reinforcement Bodies. (See the Post Processing (p. 779) topic above)
- Reinforcements do not support **Elemental Triads** and **Elemental Euler Angle** results.
- For nodal results, such as nodal Reactions (p. 2107), that are scoped to reinforcement elements, the application displays values that are extrapolated, via shape functions, to element intersection points (II, JJ, etc.). This is also the case if you export result values. Exported result values may contain node numbers, but the result values are the interpolated intersection values. In addition, the summation of Mechanical nodal reaction results may not match those of the Mechanical APDL application.
- For element nodal Reactions (p. 2107) force results on reinforcement elements, the application only displays a subset of nodes on the result as compared to Mechanical APDL. For example, MAPDL lists 20 nodes for a smeared reinforcement element whereas Mechanical only lists four nodes. This also applies to exported result values.

Rotordynamics Analysis

Rotordynamics is a specialized branch of applied mechanics that studies the behaviors of rotating structures. This rotating structure, or "rotor system," is typically composed of rotors, stators, and bearings. For a simple rotor system, the rotor component rotates about an axis that is stabilized by a bearing that is supported by a stator. This structure can be as simple as computer disk or as complicated as a jet engine.

The Mechanical Rotordynamics Analysis helps to direct you when selecting properties such as rotor stiffness and geometry, bearing stiffness, damping, and stator properties for a rotor system based on a given rotating speed. For example, to effectively study a system's vibratory characteristics, you can use a Campbell diagram. A Campbell diagram enables you to determine critical speeds (for different rotating modes), such as the rate at which the rotating structure experiences resonance (peak response) to avoid possible catastrophic failure. Or, a Rotordynamic Analysis can be used to determine safe operational ranges for a rotor system.

In the Mechanical documentation, see the Rotordynamics Controls (p. 1490) section for more information, and in the Mechanical APDL documentation, the *Rotordynamic Analysis Guide*.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Refer to the following areas of the documentation for additional and associated information for Rotordynamics:

- Import Shaft Geometry
- Bearings (p. 1413)
- Campbell Diagram Chart Results (p. 2132)

Substructure Analysis

Substructuring is a procedure that condenses a group of finite elements into one element represented as a matrix. The single-matrix element is called a superelement. You can use a superelement in an analysis as you would any other element type. By summarizing the mechanical behavior of the bodies, they can be assembled to synthesize the response of a more complex structure, or to model flexible bodies in the Rigid Dynamics solver.

Mechanical provides the options to generate superelements. You use the Condensed Parts object to create superelements on a sub assembly or the Substructure Generation (p. 540) analysis to create a superelement of an entire assembly. When you use the **Substructure Generation** analysis, you can specify constraints and pre-stress effects and generate load vectors and use the elements in an analysis. When you use the Condensed Parts you can expand their solutions using the Expansion Settings object.

Supported Analysis Types

Substructuring currently supports the following analysis types:

- Harmonic Response (p. 496) (MSUP only)
- Modal (p. 515)
- Random Vibration (p. 524)
- Response Spectrum (p. 533)
- Rigid Dynamics (p. 550)
- Motion

Substructuring Types

Mechanical enables you to perform:

- **Top-down Substructuring**: Using top-down substructuring, the application generates superelements on parts that you specify using Condensed Part objects. Each **Condensed Part** object enables you to treat a set of bodies as a single superelement consisting of matrices and load vectors with far fewer degrees of freedom than the full finite element mesh. The use pass (described below) is then performed and includes all generated superelements. Using Expansion Settings, the solution expands the superelements for the specified parts. See the Top-Down

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Substructuring section in the *Mechanical APDL Substructuring Analysis Guide* for additional technical information.

Important:

You can use the Substructure Generation (p. 540) analysis to automatically generate superelements that include load vectors from the loading conditions and constraints that you apply. In addition, you can use an upstream Static Structural analysis to create pre-stress effects in the Substructure Generation analysis solution.

Or…

- **Bottom-up Substructuring**: Using bottom-up substructuring, you import superelements using the Imported Condensed Part (p. 790) object that were created in a different Mechanical session. These imported superelements represent subassemblies of the model on which the generation pass is already performed during a different Mechanical session and in the current Mechanical session these superelements are then combined with the rest of the model to perform the use pass on the entire model.

Important:

Bottom-up Substructuring does not support the Expansion pass.

Condensed Parts Introduction

Condensed Parts are defined by three key pieces of information:

- A group of bodies whose elements are to be reduced to a superelement.
- A set of interfaces defining the primary nodes that should be retained in the generated superelement.
- A list of solution settings that control the reduction process.

Substructuring Process

The top-down substructuring of condensed geometry involves the following operations:

1. **Generation**: The preliminary computation, the "Generation Pass," reduces the Condensed Part bodies into a single superelement and its primary nodes, located on the defined interfaces. The remaining interior nodes become hidden from the analyses that use the Condensed Part. For top-down substructuring, the generation pass is done in the same mechanical session as the use pass. For bottom-up substructuring, the generation pass is done in a different mechanical session and superelements are imported in the current session on which no generation pass is required.
2. **Use**: Once your Condensed Parts are properly defined and generated and Imported Condensed parts are imported into the Mechanical session, they can be used in the solution (the "Use Pass"). By hiding the interior nodes, flexible bodies can be included in a Rigid Dynamics

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

analysis when they are included in a Condensed Part. They can also be assembled together in Modal analyses to compose the overall vibration properties of a more complex structure.

3. **Expansion** (Top-down substructuring only): Following the Use Pass, you can obtain results on elements inside the Condensed Geometry using an "Expansion Pass."

Rigid Dynamics Only

For a Rigid Dynamics analysis, additional results can be produced by the Generation Pass to allow a faster expansion, which does not need to go back to the finite element model to compute stresses and deformation on a condensed part (see Expansion Pass (p. 800)).

Note:

Material and System Damping

- The solver ignores any Material Dependent Damping (**Damping Ratio** and **Constant Structural Damping Coefficient** material properties) specified in the material assigned to the bodies included in Condensed Part(s). Material dependent damping is defined in Engineering Data.
- If you specify the property **Constant Structural Damping Coefficient** (p. 1465) as global system damping using the Damping Controls (p. 1462) of the Analysis Settings, the solver ignores this value during a Modal that includes Condensed Parts or Imported Condensed Parts.

Importing Condensed Parts (Bottom Up Substructuring)

Ansys refers to the substructuring procedure described above as “top-down” substructuring. There is also a procedure to perform “bottom-up” substructuring. This procedure imports superelements that are created separately, in different Mechanical sessions. All superelements are then assembled during the use pass.

Bottom-up substructuring is performed using the Imported Condensed Part object. This object enables you to import previously generated superelements that you can then use for the Use Pass in the current system. Supported file types include:

- **Exported Condensed Part (.cpa)** (default): This file format is for superelements generated in Mechanical using the Condensed Part feature.
- **Generation Pass Output (.sub)**: This file format is for superelements generated in Mechanical APDL.
- **Super Element Matrix (.dmig)**: This file format is for superelements generated in NASTRAN.

Note:

No load vectors are imported in to Mechanical for the **Imported Condensed Part** and therefore cannot be applied to Use pass.

Published: 2023-10-23

See the Imported Condensed Part (p. 790) section for the steps to use this option.

Substructure Generation Analysis

Note that you can employ the Substructure Generation (p. 540) analysis to perform a generation pass on your model that condenses all the finite elements into one superelement and creates load vectors for all loading conditions. In addition, the analysis supports the use of an upstream Static Structural system to incorporate pre-stress effects in the simulation.

Analysis File Management

To improve solution processing times and memory usage when solving the Use Pass and Expansion Pass, the Mechanical APDL Solver (required) refers to the prerequisite files generated by the upstream condensed parts using the entire path to their location. See the **SEOPT** and **MODDIR** commands in the *Mechanical APDL Command Reference* for more information.

Feature Description and Application

See the following sections that describe the use of the substructuring/Condensed Part features.

Condensed Part Overview
Condensed Part Application

Imported Condensed Parts
Expansion Pass
Limitations
Best Practices

Condensed Part Overview

You insert a Condensed Geometry object via the **Model** object in the **Outline** and then insert and define Condensed Part objects. To properly define a **Condensed Part**, you need to configure the following:

- A group of bodies
- A set of interfaces
- Solution settings

Condensed Part Bodies and Interconnections

You create a Condensed Part from one or more interconnected bodies.

Important:

Because the resulting superelement is linear, any nonlinearities in the Condensed Part elements, materials, and interior connections are ignored.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When defining a **Condensed Part** using multiple bodies, the following connections may be included:

- Beam Connections
- Bonded (p. 1234) Contact
- Distributed Mass
- Fixed Joint
- Point Mass
- Spring
- Shared topology

General Restrictions for Part Bodies and Interior Connections

- Cyclic Symmetry is not supported.
- Rigid bodies may be used, but it is best for at least one body to be flexible.
- Elements cannot use Lagrange multipliers. For example, interior contact regions cannot use the **Normal Lagrange** Formulation (p. 1241).

Part Bodies and Interconnection Solver Restrictions (Ansys Rigid Dynamics Solver)

- Multi-body parts must be fully contained in a single **Condensed Part**, that is, partial selections are invalid. You may however use several multi-body parts in a single **Condensed Part**.
- The single connected component must produce six rigid modes. An insufficient number of modes will cause the Use Pass not to converge. An excess of modes can usually be remedied by breaking the **Condensed Part** into smaller rigidly connected components.

Interfaces

An interface defines the primary nodes for the resulting superelement and therefore suggests how a Condensed Part could connect to the rest of the model. In Mechanical, an interface table lists each of these connections, detailing their Type, Side, and Name. Supported interface types are based on:

- **Geometry**: Geometry interfaces directly expose all nodes on a particular topology, for example, on a vertex, face or edge. These primary nodes are therefore suitable for the application of boundary conditions such as contacts and supports.
- **Remote Points**. These entries expose remote points as primary nodes, while hiding interior nodes on the underlying topology that attach to them. Common examples include the Mobile or Reference side of Joints and Springs and the scoping of Point Masses and Remote Points. This is the only type of interface supported for the Ansys Rigid Dynamics Solver.
- **Named Selections**: Named Selections can be used to expose any node as a primary node, with the help of criterion-based Named Selection. For example, selected internal nodes

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

within a condensed part volume could be relegated to the interface in order to produce a higher resolution of the structure's inertial or flexibility behavior

- **Connections**: Contact Region, Joint, etc.

  Note:

  For a **Contact Region** interface of a **Condensed Part**, when the **Trim Contact** (p. 1237) property is set to **On**, the generation of the **Condensed Part** trims the contact nodes on the interface and uses the trimmed nodes as the Master Degrees of Freedom for the generation pass. The reduction of the number of nodes can significantly improve the performance of the generation pass. When you select the Condensed Part object after the generation pass, the application displays the trimmed nodes in the **Geometry** window for the **Contact Region** Interface instead of the actual **Contact Region** scoping.

- **Loads and Supports**: Fixed Supports, Displacements, etc.
- **Point Masses**

General interfaces each contribute the number of nodes on their topology and remote interfaces each contribute a single node.

Important:

When a Condensed Part Interface includes faces, edges, vertices, or nodes that overlap with other interfaces where constraint equations are applied, such as remote points, boundary conditions scoped to remote points, MPC-based contact (p. 1243), etc.), the solver may remove some master node DOFs in the generation pass. This may interfere with the use pass solve as well as postprocessing.

Note:

When duplicate DOFs are disqualified and eliminated during the Generation Pass, the Rigid Dynamics solver issues an error and aborts the Use Pass.

Interface Solver Restrictions (Ansys Rigid Dynamics and Motion Solvers)

Only interfaces that are based on Remote Points are presently recognized by the Rigid Dynamics and Motion solvers (Joints, Springs, Point Masses, and Remote Points). In addition, a Remote Point must have all six DOFs with an interface treatment of either **Rigid** or **Deformable**.

Condensed Part Application

This section describes the steps to define Condensed Geometry objects. You should review all associated documentation so that you understand the application-driven actions that take place as well as the inherent limitations of the feature.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The operation of condensing parts in Mechanical is largely automated. For example, Mechanical provides facilities that analyze the connectivity of the bodies in the model and group them into Condensed Parts. Connections are classified as interior or exterior (interfaces).

Application

To create a **Condensed Part**:

1. From the Workbench **Project Schematic**, create a supported analysis system.
2. Select a geometry and open Mechanical
3. Create and define the applicable boundary conditions and connections, that is Joints, Springs, Point Mass, Remote Points, Supports and/or Contacts.

   For Rigid Dynamics analyses, expand the **Geometry** folder and specify the desired connected parts as **Flexible**. These parts will be converted to Condensed Parts following the completion of the steps below.
4. Select the **Model** object and insert a **Condensed Geometry** object.

   Note:

   The application automatically inserts the **Expansion Settings** object under the **Solution** folder when a **Condensed Geometry** object is created.
5. From the **Condensed Geometry** object, you can create your condensed parts using the context (right-click) menu option **Create Automatic Condensed Parts** or you can insert individual **Condensed Part** objects in to the tree.

   The application provides two automatic methods for defining interfaces for a **Condensed Part** using the context menu options:

   - **Create Automatic Condensed Part**: This option selects the bodies and detects the interfaces and automatically creates new **Condensed Part** objects. For example, in Rigid Dynamics analyses, flexible bodies may be grouped into condensed parts and linked to other bodies through joints at the interfaces.
   - **Detect Condensed Part Interface**: This option automatically suggests interfaces. This is especially useful if you would like to manually select bodies.

   Note:

   - The **Condensed Part** object displays the number of superelement master nodes resulting from interfaces in the **Details** view.
   - The application does not consider objects imported from External Model systems for the automatic interface detection. For the imported objects that are associated with condensed parts, use the promote feature in the worksheet of the imported objects in order to be able to perform interface detection.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See the object reference pages for the Condensed Geometry and Condensed Part objects for descriptions of all associated **Details** view properties.

6. Insert desired results. This feature supports Deformation, Stress, and Strain results.
7. Solve the analysis.
8. As desired, you can obtain results in the original elements within the **Condensed Part** by selecting the **Expansion Settings** object and displaying the Worksheet. From there, select the desired result for your Condensed Part(s).

   It is possible to add or remove interfaces directly on the Interfaces **Worksheet** using its context menus. This is especially useful for specifying new remote interfaces not already automatically detected. Mechanical attempts to verify all interface selections during the Generation and Use Passes and issues a warning should any be missing. Mechanical also tracks operations that remove and suppress upstream objects affecting the interface and reacts accordingly.

Note:

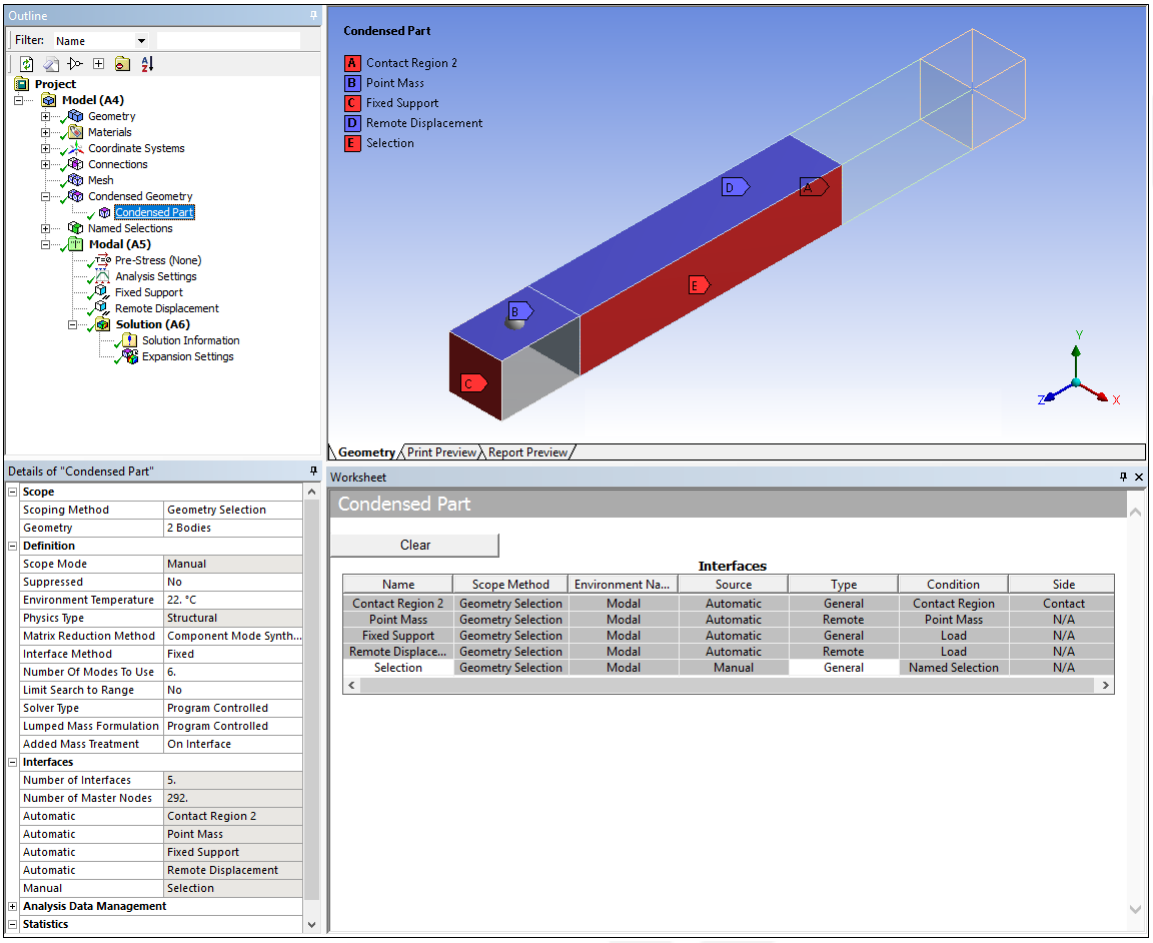
To delete a **Condensed Geometry** object, it is necessary to clean and remove any generated Condensed Parts. Similarly, to delete an **Expansion Settings** object, it is necessary to clean any generated data.

Condensed Part Worksheet

The **Worksheet** for the **Condensed Part** object is illustrated below. The **Worksheet** populates when you generate interfaces.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

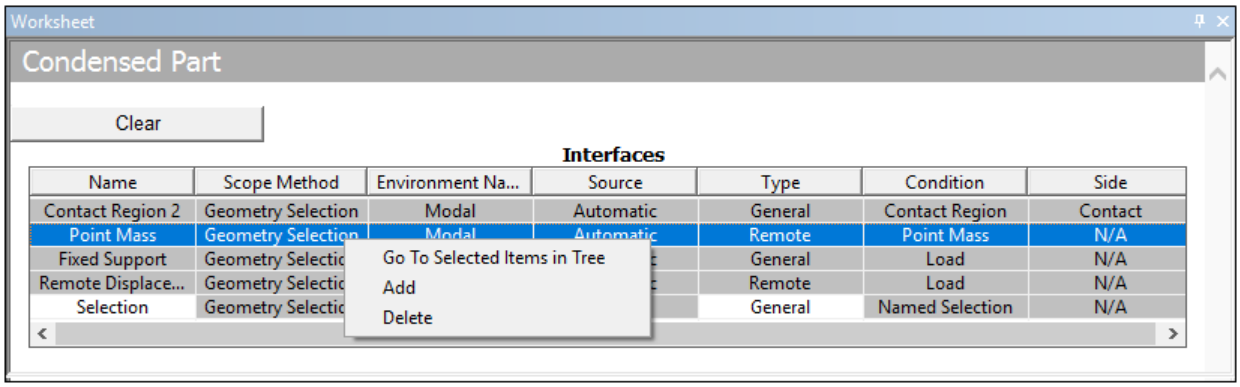
Published: 2023-10-23



Column	Description
Name	This column displays the Name of the tree object.
Scope Method	This column displays the scoping method used for the interface: Geometry Selection, **Named Selection** (geometry- or node-based), **Worksheet**, **Remote Point**, and **Free Standing**.
Environment Name	This column displays analysis system associated with the interface.
Source	This column displays how the interface is added. The field is set to **Automatic** when the interface is inserted using the **Condensed Part** object option, **Detect Condensed Part Interface** or when you manually enter an interface using the **Add** option.
Type	This column identifies the interface as either a **General** interface or a **Remote** interface. The **Remote** option is assigned for remote boundary conditions (p. 1735). In addition, the **Remote** option is the only option available for the Ansys Rigid Dynamics Solver.
Condition	This column displays the contact condition for the interface. Whether it is a **Contact Region** or a loading condition, Named Selection, **Point Mass**, etc.
Side	This column displays the topology with which the interface connects with. As such, the options include **Contact**, **Target**, **Reference**, **Mobile**, **Source Geometry**, or **Target Geometry**. See the Connections folder section for more information.

Once populated, the **Worksheet** provides the context (right-click) menu options illustrated below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



These common **Worksheet** options include:

- **Go To Selected items**: This option automatically selects and displays the corresponding object in the tree **Outline** based on the Name of the selected row in the table. You can select multiple rows using either the **Ctrl** or **Shift** keys to select and display multiple objects in the tree. Selected **Outline** objects are also highlighted in the **Geometry** window by annotations, if you switch to that view.
- **Add**: This option adds a row to the **Worksheet** that you can then manually define.
- **Delete**: This option deletes the selected row. You can select multiple rows for deletion using either the **Ctrl** or **Shift** keys. The **Delete** key can also be used to delete table rows.

Exporting Condensed Parts

The ability to export an existing solved Condensed Part enable you to use the exported file in a different simulation as an Imported Condensed Part (p. 790).

To export a Condensed Part:

1. Right-click a solved **Condensed Part** object and select **Export Condensed Part**. A progress bar displays during the export operation and offers an option to stop (red square icon) the process. The Mechanical file format for generated superelements is **Exported Condensed Part (.cpa)**.
2. Specify a file name in the **Save As** dialog and click **Save**

Note:

You can also export the solution of a Substructure Generation (p. 540) analysis as a **Exported Condensed Part (.cpa)** file.

Imported Condensed Parts

This section describes how to use the **Imported Condensed Part** object. Go to a section topic:

- Overview (p. 791)
- Application (p. 791)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Worksheet Examples (p. 793)

Overview

Using an **Imported Condensed Part** object, you can import superelements from another system into your current system. This enables you to use the superelements in the current solution ("Use Pass"). **Imported Condensed Part** objects are defined by the following information:

- A set of master nodes that represents the reduced superelement being imported.
- A set of interfaces defining the master nodes that are retained when the application generates the superelement.
- A list of controls that define the location and node numbering for the imported superelement.

Application

The following steps assume that you have already created a **Condensed Geometry** object and that you are prepared to import a supported file type.

To specify an **Imported Condensed Part** object:

1. Right-click the **Condensed Geometry** object and select **Insert** > **Imported Condensed Part**. You can also select the **Imported Condensed Part** option from the **Condensed Geometry** Context tab. Once inserted, the **Worksheet** automatically displays.
2. Select the desired file type from the drop-down list of the **Import File Format** property. Supported file formats include:
   - **Exported Condensed Part (.cpa)** (default): You create this file by either exporting Condensed Parts (p. 790) or exporting a Substructure Generation (p. 540) solution.
   - **Generation Pass Output (.sub)**
   - **Super Element Matrix (.dmig)**
3. Using the **Condensed Part File** property, define the path to the import file.
4. Right-click the new object and select **Import Condensed Part**. A progress bar displays during the import operation and offers an option to stop (red square icon) the process. Once imported, the **View Transformed Data** option/display activates. If you need to make manual **Worksheet** entries, see the steps provided in the Worksheet Options and Actions (p. 792) topic below.
5. As needed, modify the following properties:
   - **Unit System**
   - **Locating System**: Specify a desired Coordinate System to orient the imported super element. The default setting is **Global Coordinate System**.
   - **Node Offset**: Specify an offset number to be used on the imported nodes. This property has a default setting of **Program Controlled** that equates to the value zero. Using this

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

setting the application automatically offsets the node number based on the Mesh. Any value that is greater than zero offsets the Node Ids by that value.

Note:

- Remote Points need to be connected to the interfaces of the Imported Condensed parts. To avoid rigid body modes, set the **Behavior** property of the **Remote Point** to **Coupled**.
- The outline of the **Imported Condensed Part** is only displayed on the part if the information is available in the selected source file.

Worksheet Options and Actions

There may be times that you need to import or copy and paste data into the **Worksheet** using the available interface options. The **Worksheet** presents interface options and interface data based upon file format.

Exported Condensed Part

For the **Exported Condensed Part (.cpa)** format, interface data includes **ID**, **Name**, **Node Connectivity**, and **Number of Nodes**. Only the **Clear** option is available for this file format.

Note:

If a Master node of the interface is reduced during the Generation Pass, the Worksheet displays a column listing the **Reduced Number of Nodes**.

Generation Pass Output and Super Element Matrix

For the **Generation Pass Output (.sub)** and **Super Element Matrix (.dmig)** formats, interface data includes **Node ID**, **Location** and **Rotation** data. In addition, the following radio buttons display and enable you to display either the original or transformed state of the interface data.

Important:

For the **Super Element Matrix (.dmig)** file format, Mechanical reads the file's matrices in the order shown below. Make sure that the source file uses this order because the application only processes the first three matrices.

1st: Stiffness Matrix

2nd: Mass Matrix

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

3rd: Damping Matrix

Tip:

If you have multiple **Super Element Matrix (.dmig)** files for each matrix, use the following API method on **Project** object to generate a single file that uses the required order of matrices.

```
CombineTextFiles(primaryFilePath, secondaryFilePath)
```

Worksheet Option	Description
View Original Data	Radio button that displays imported data when you use the **Read Interface Data** option. It displays **Original Interface Data**.
View Transformed Data	Radio button that activates automatically once the import process is complete. It displays **Transformed Interface Data**.
Read Interface Data	This option is available when the **View Original Data** option is selected, and no data has been imported. When selected, the application reads file data and populates the table with read-only Node ID and Location data from the selected file. This enables you to validate the file data. If the file contains no location data, the Location fields in the table will contain zeros (0). To complete the import process once you have read a file, right-click the object and select **Import Condensed Part**.
Edit	Select this option to enter data manually. Manual data entry can be done using copy and paste. This includes copying data from a spreadsheet. Properly select all location data from your spreadsheet and highlight the first data cell, Location X, and then paste all data. See the Worksheet Examples (p. 793) topic below for more information about manually entering data.
Save Changes	Save table data.
Clear	Clear all table data.

Worksheet Examples

The following examples describe the scenarios when importing data. Go to a topic:

- Overview (p. 794)
- Load Vectors (p. 795)
- View Original Data (p. 796)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

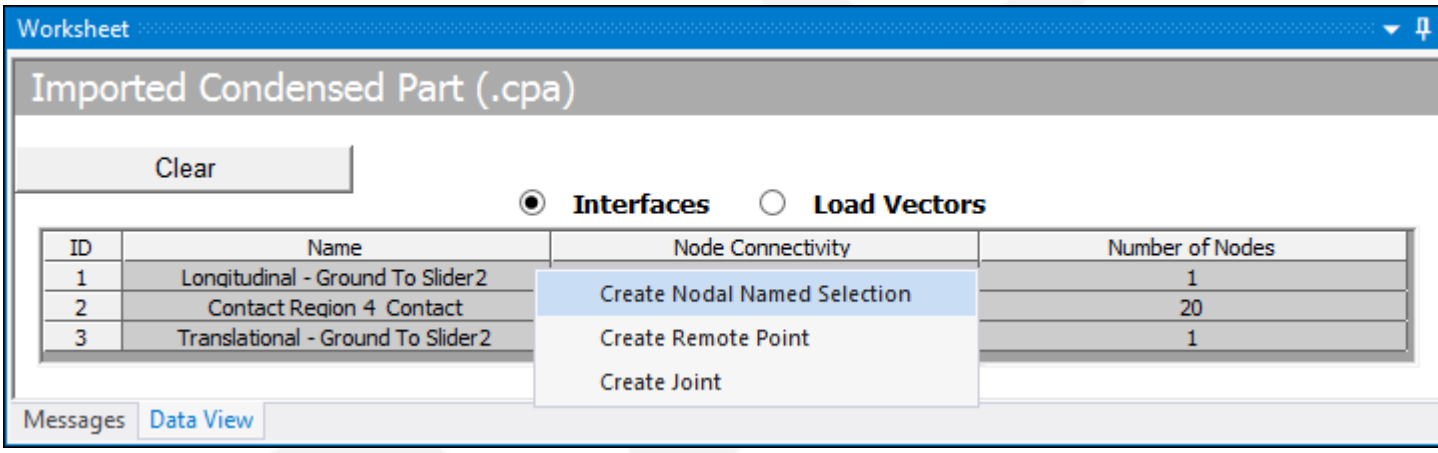
- View Transformed Data (p. 797)
- Manually Importing Spreadsheet Data (p. 798)

Overview

A successful import for an **Exported Condensed Part (.cpa)** file is shown here. The worksheet for this file type has two display options: **Interfaces** and **Load Vectors**, as described below.

Interfaces

Whether user-defined or system generated, the condensed part interfaces are listed in the worksheet by default. As illustrated, you can right-click the data presented in the **Worksheet** to create Nodal Named Selections, Remote Points, and Joints for each interface that can then be used to define connections and/or boundary conditions.



Note:

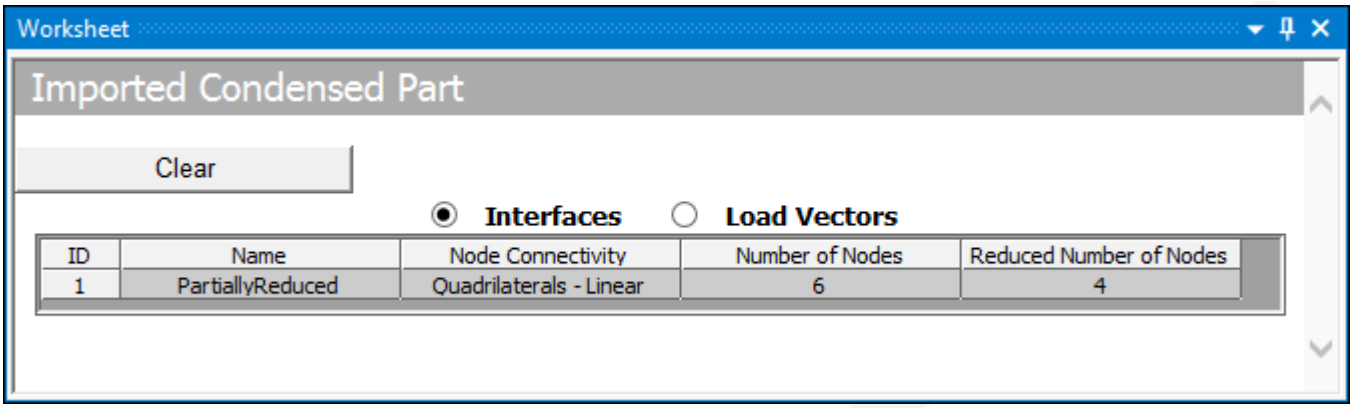
If you select the **Clear Generated Data** option on the **Imported condensed Part**:

- Named Selections or Remote Points you created will lose their scoping. When you re-import the Imported Condensed Part, the Named Selections or Remote Points get reassociated with their original scoping.
- Contact Region scoped to a Named Selection which is created from the Interfaces of the **Imported Condensed Part** remains properly defined.

During the solution Generation Pass, the application could reduce the Master degree of freedom (MDOF) as a result of an internal constraint equation. This could result in the reduction of the Master node (see **M** Command). For example, if you have an interface with six nodes and due to an application generated internal constraint equation, the solver ignores two Master nodes. This results in an interface of only four Master nodes. If the application reduces a Master node, the **Worksheet** displays an additional column, as illustrated below, that shows the exact number of nodes on that interface. This node value is supported by the options to create Nodal Named Selections, Remote Points, and Joints.

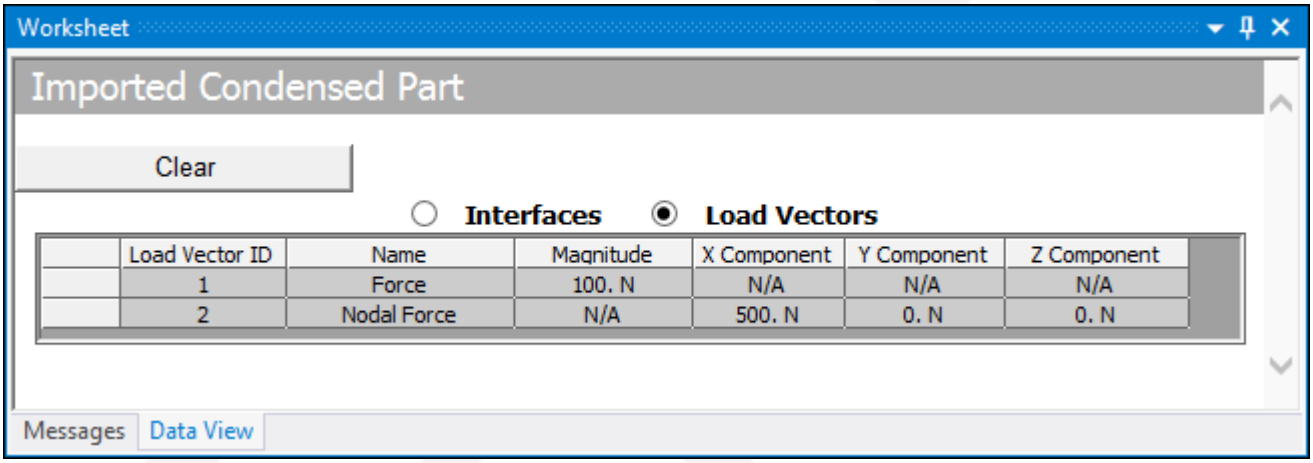
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

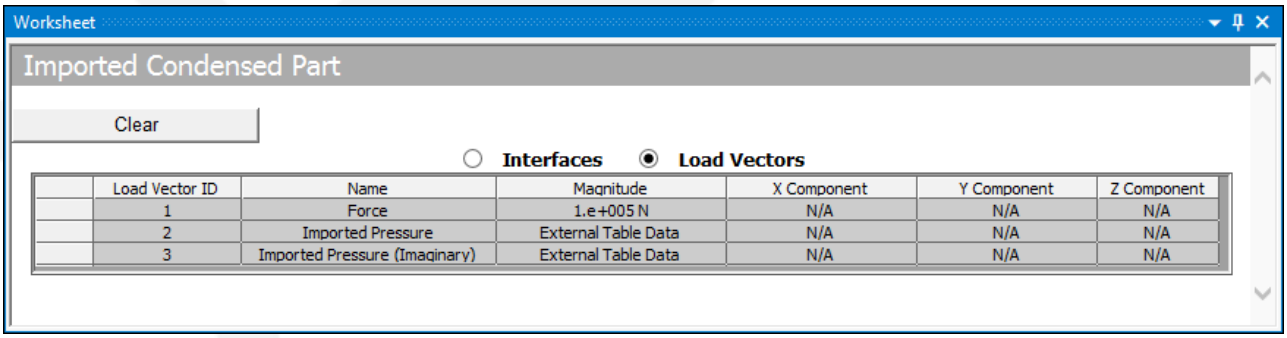


Load Vectors

Load Vectors, as well as prestressed load vector values, are exported from a solved Substructure Generation (p. 540) analysis as a `.cpa` file, and imported and displayed in the worksheet, as shown in the example below. If no load vectors are available, the table is blank.

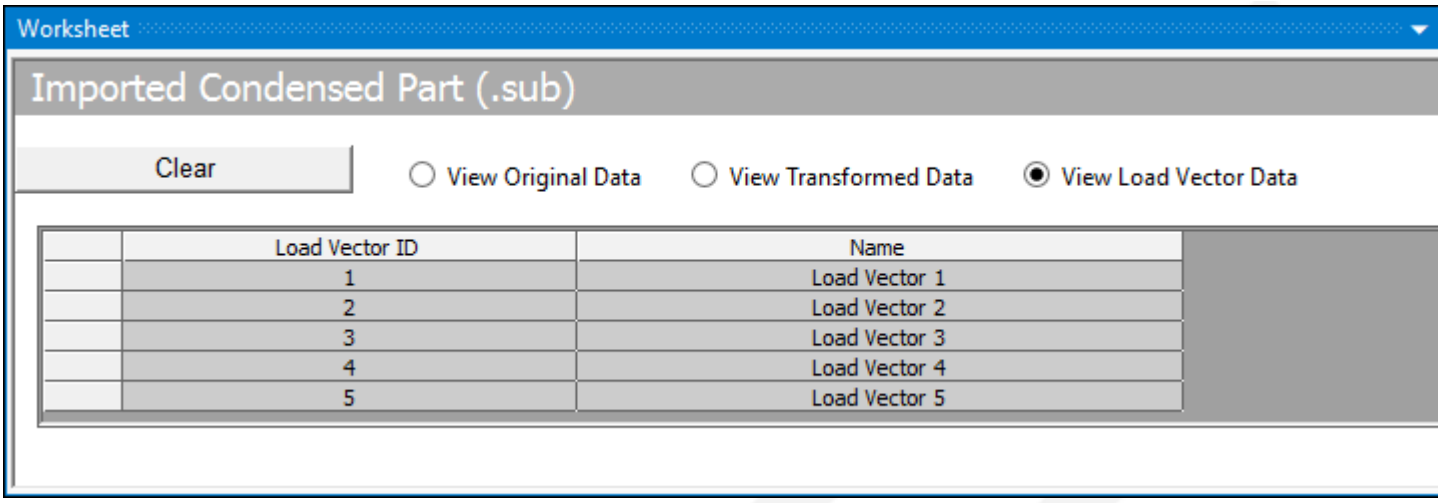


Load vectors are also generated for imported loading conditions.



Load vectors can also be imported from a **Generation Pass Output (.sub)** file that was created in the Mechanical APDL application, as illustrated here.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



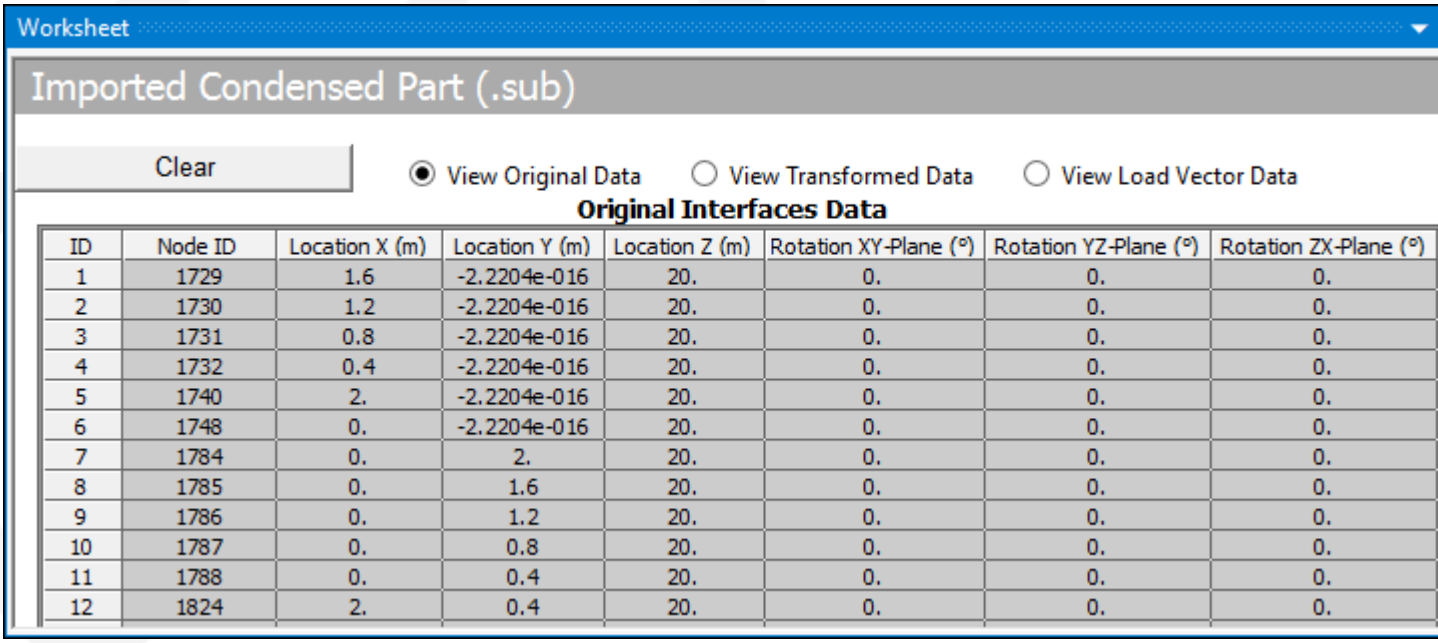
Note:

Depending upon the specified loading, the following analysis types automatically create load vectors during the solution process. If you include an **Imported Condensed Parts** object in either analysis, all of the load vectors will be contained in the solution output file.

- Harmonic Response Analysis (Mode Superposition) (p. 496)
- Harmonic Response Analysis using Linked Modal Analysis (p. 509)

View Original Data

Here is an example of the **View Original Data** option for the data read from a **Generation Pass Output (.sub)** file.

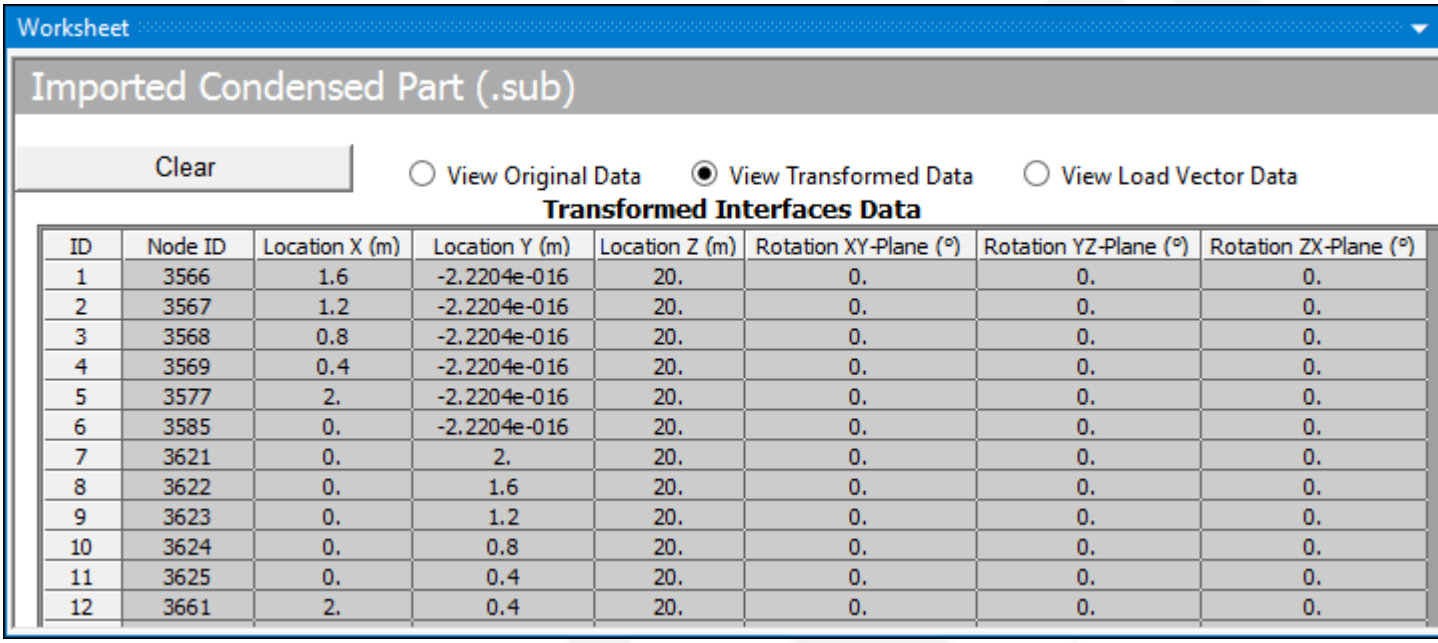


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

View Transformed Data

Once imported, the **View Transformed Data** option automatically displays. Here you can see transformed data. Note the Node ID values for this example versus the above example. These values are based on the **Actual Node Offset** value which for this example is 3261.



ID	Node ID	Location X (m)	Location Y (m)	Location Z (m)	Rotation XY-Plane (°)	Rotation YZ-Plane (°)	Rotation ZX-Plane (°)
1	3566	1.6	-2.2204e-016	20.	0.	0.	0.
2	3567	1.2	-2.2204e-016	20.	0.	0.	0.

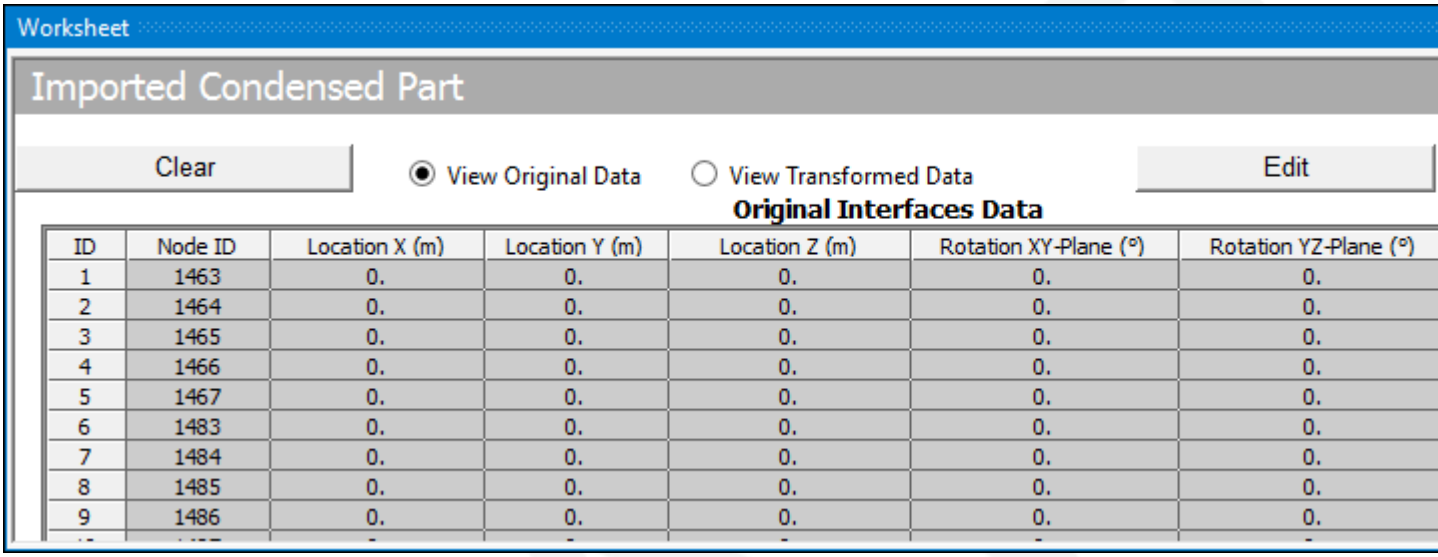
Manually Importing Spreadsheet Data

For the **Super Element Matrix (.dmig)** file format, there may be times that you need to manually copy data into the worksheet table. For the **Worksheet** example shown here, no location data was found in the file. To make manual entries, select the **Edit** button.



ID	Node ID	Location X (m)	Location Y (m)	Location Z (m)	Rotation XY-Plane (°)	Rotation YZ-Plane (°)
1	1463	0.	0.	0.	0.	0.
2	1464	0.	0.	0.	0.	0.
3	1465	0.	0.	0.	0.	0.
4	1466	0.	0.	0.	0.	0.
5	1467	0.	0.	0.	0.	0.
6	1483	0.	0.	0.	0.	0.
7	1484	0.	0.	0.	0.	0.
8	1485	0.	0.	0.	0.	0.
9	1486	0.	0.	0.	0.	0.

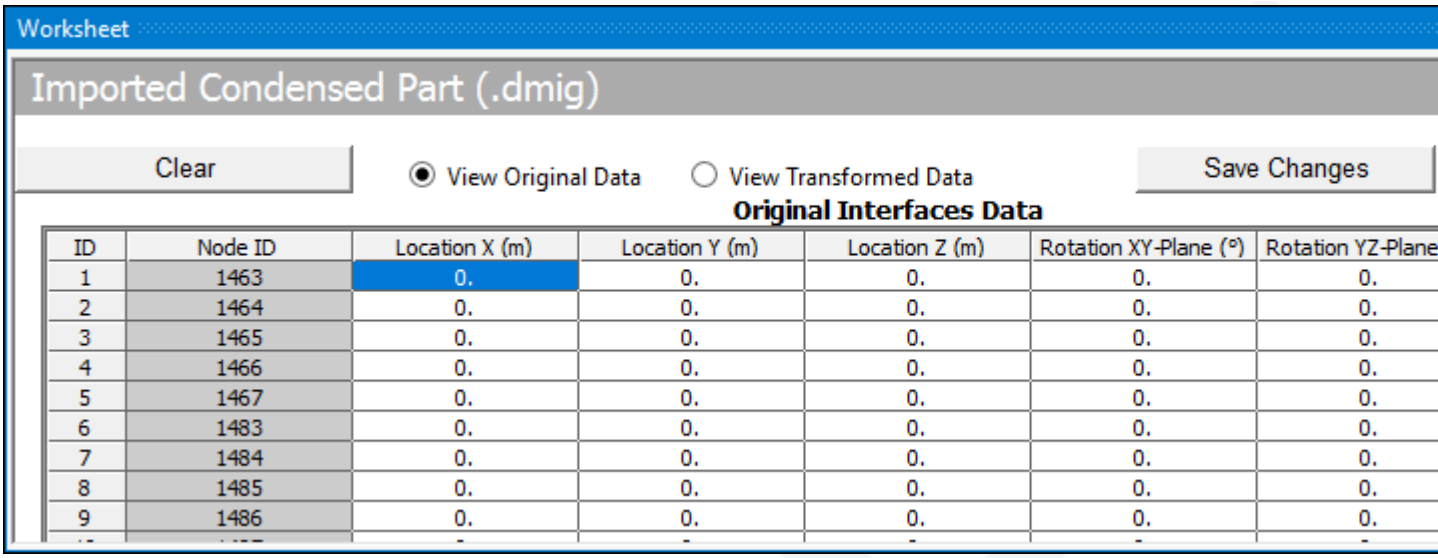
Properly select all location data (only) from your spreadsheet.

C	D	E	F
Node ID	Loc X	Loc Y	Loc Z
1463	1.67E-02	0.165	3.00E-02
1464	3.33E-02	0.165	3.00E-02
1465	5.00E-02	0.165	3.00E-02
1466	6.67E-02	0.165	3.00E-02
1467	8.33E-02	0.165	3.00E-02
1483	0.1	0.165	3.00E-02
1484	0.1	0.165	0.33
1485	8.33E-02	0.165	0.33

Highlight the **Location X** field as illustrated below. This ensures that the data will be properly distributed throughout the table when you paste.

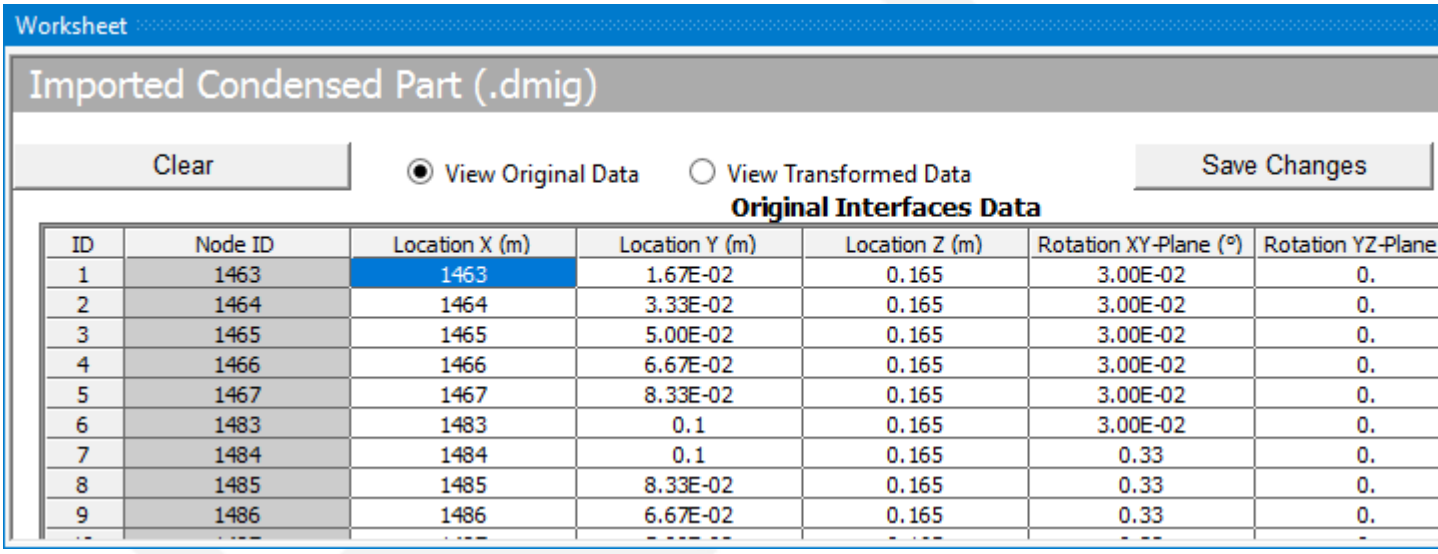
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



ID	Node ID	Location X (m)	Location Y (m)	Location Z (m)	Rotation XY-Plane (°)	Rotation YZ-Plane
1	1463	0.	0.	0.	0.	0.
2	1464	0.	0.	0.	0.	0.
3	1465	0.	0.	0.	0.	0.
4	1466	0.	0.	0.	0.	0.
5	1467	0.	0.	0.	0.	0.
6	1483	0.	0.	0.	0.	0.
7	1484	0.	0.	0.	0.	0.
8	1485	0.	0.	0.	0.	0.
9	1486	0.	0.	0.	0.	0.

Review the pasted data and then select the **Save Changes** button.



ID	Node ID	Location X (m)	Location Y (m)	Location Z (m)	Rotation XY-Plane (°)	Rotation YZ-Plane
1	1463	1463	1.67E-02	0.165	3.00E-02	0.
2	1464	1464	3.33E-02	0.165	3.00E-02	0.
3	1465	1465	5.00E-02	0.165	3.00E-02	0.
4	1466	1466	6.67E-02	0.165	3.00E-02	0.
5	1467	1467	8.33E-02	0.165	3.00E-02	0.
6	1483	1483	0.1	0.165	3.00E-02	0.
7	1484	1484	0.1	0.165	0.33	0.
8	1485	1485	8.33E-02	0.165	0.33	0.
9	1486	1486	6.67E-02	0.165	0.33	0.

Once saved, right-click the object and select **Import Condensed Part**. This action imports the data, and automatically displays **Transformed Interface Data** that you can use to options to create Nodal Named Selections, Remote Points, or Joints for the selected interface.

Note:

- When you create a Nodal Named Selections or a Remote Point, the application automatically scopes to the object for the selected interface nodes. For a generated Remote Point, the **Behavior** property is automatically set to **Coupled**.
- When you create a Joint, the application creates a Joint whose **Reference Side** is automatically scoped to the selected interface nodes with the **Direct Attachment** option specified.

7	3733	0.1	0.165	0.33	0.	0.
8	3734	8.3333e-002	0.165	0.33	0.	0.
9	3735	6.6667e-002	0.165	0.33	0.	0.

Expansion Pass

The solution of an analysis containing a **Condensed Part** immediately produces the results at the Condensed Part interface, that is, at the master nodes. In order to obtain results on the original bodies in the **Condensed Part** an optional calculation called an "Expansion Pass" is necessary. Mechanical furnishes an Expansion Settings object for this purpose.

Important:

To perform an Expansion Pass, you must set the **Keep Files For** property to **MAPDL Expansion** for the **Condensed Part** object.

When you expand results on selected **Condensed Parts** in the **Expansion Settings Worksheet**, the application uses the settings of the **Distribute Solution** and the **Max number of utilized cores** options defined in the **Advanced Settings** of the Solve Process Settings (p. 1804) dialog.

Note:

- You cannot currently run expansions for Random Vibration (p. 524) and Response Spectrum (p. 533) analyses.
- For a Rigid Dynamics analysis, additional results can be produced by the Generation Pass to allow a faster expansion. To enable this faster expansion, set the **Condensed Part Expansion** field in the **Details** pane of the **Expansion Settings** object to On Demand. Then insert Stress or Displacement results under the **Solution** object and evaluate them.

Using the **Worksheet** on the **Expansion Settings** object you can request that results be expanded within each **Condensed Part** separately and incrementally. Keep in mind that any unexpanded Condensed Parts will not display in results or animations. Once an expansion is requested, it will be automatically performed upon evaluating an affected result. It is possible to run expansions by themselves, which will obsolete any affected results. It is possible to run expansions separately using

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Run Expansions Only, and to clean their generated data, both of which will obsolete any affected results.

Note:

Do not use the **Worksheet** if you set the **Condensed Part Expansion** field in the details panel of the **Expansion Settings** object to **On Demand** in a Rigid Dynamics analysis. Making any selections in the Worksheet will cancel the on demand expansion.

The **Expansion Settings** object is automatically inserted when the **Condensed Geometry** object is inserted into the **Outline**.

Note:

- Unless you do an expansion, you may not detect the minimum or maximum results since they may reside within the condensed part. Review results carefully.
- Commands object Snippets targeting the Mechanical APDL solver are not supported.
- Velocity and Acceleration results are not presently supported for flexible bodies.
- Motion analyses do not require an Expansion Pass, therefore Expansion Settings are not created for a Motion system.

Limitations

General

Note the following general limitations associated with the definition of Condensed Parts:

- The Master Degrees of Freedom Nodes (MDOFs) may be reduced by the solver during the:
  - Generation of a Condensed Part.
  - Solution of a Substructure Generation (p. 540) analysis

  This could be the result of a constraint defined on the MDOF nodes. The application reports this with a warning. In addition, in this case, there could be a discrepancy between Mechanical MDOFs and solver MDOFs. A warning message will also display while eliminating the redundant degrees of freedom.
- The application does not write Named Selections scoped to the interface nodes of a Condensed Part to Use Pass input file unless the Named Selection is used in the scoping of a nodal boundary conditions (Nodal Force, Nodal Pressure, Nodal Displacement and Nodal Orientation) in the Use Pass.
- For **Imported Condensed Parts**:
  - Do not support Rigid Dynamics or Motion analyses.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

  - The application does not import load vectors from **Super Element Matrix** (`.dmig`) files. As a result, they cannot be applied to the Use pass.

  - When you import superelements from another system into your current system using an Imported Condensed Part object, and you change the Unit System of the Imported Condensed Part, the application does not automatically resize Interface Mesh nodes. They can be resized using **Rescale** option from **Annotation** (p. 79) group of **Display** tab.

  - Note the following when you are working with Model Assembly (p. 991):

    → If the **assembled system** includes imported condensed parts and you change the transfer property, **Number of Copies**, and update, the application may not import the exact copies of the geometry and/or source mesh.

    → The application does not currently support importing condensed parts that are included in the **source system**.

  - If you use the **Clear Generated Data** option on the mesh or an **Imported Condensed Part** object, the application also clears the scoping for joints created using the Imported Condensed Part interface. You must recreate the joints in this case.

  - The application only shows the outline of the superelement when the active object is an **Imported Condensed Part** or **Condensed Geometry**.

- If your analysis includes only Imported Condensed Parts and no geometry file, parameters and design points are not supported. However, you can import a model and suppress the bodies to use the Parameter (p. 2337) options..

- Reinforcements using the **Mesh Independent Method** are not supported with **Condensed Parts** and **Imported Condensed Parts**.

- **Remote Solve Manager (RSM)**

  You can employ RSM for the Generation and Use passes only. Solution processing for the Expansion Pass using the RSM is not supported. The application always performs the Expansion Pass process on your local machine.

  The Generation Pass uses the default queue selected in the Solve Process Settings (p. 1804) dialog. And, the application always performs the Generation Pass in synchronous mode regardless of the settings of the Advanced properties in the Solve Process Settings.

- You cannot scope result Probes to objects which are fully contained inside any **Condensed Part**. For example, a spring can be fully contained inside a **Condensed Part** if the topologies of both the reference and the mobile scoping are on bodies that belong to the **Geometry Selection** scoping of the same **Condensed Part**.

- When you have 1) active Expansion Settings in the Worksheet **and** 2) you set the **Scoping Method** property for a result to **Result File Item** (p. 2002), the only supported option for the **Item Type** property is **Component Name**.

  Also for this specification, **Material IDs** and **Element Name IDs** are not available for the **Material and Element Type Information** selection on the **Solution Quantities and Result Summary** (p. 1961) page of the Worksheet.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For Harmonic Response analysis or a Transient analysis linked to an upstream Modal analysis, the **On Demand Expansion Options** property is available (see Options for Analyses (p. 1447)). If you set this property to **Yes**, either manually or from the **Program Controlled** setting, the condensed part results are always expanded. As a result, **Expansion Settings** specifications become redundant.
- Stress and strain cannot be evaluated on **Condensed Parts**.
- Contact and Target contact may get flipped internally to meet Condensed Part requirements.
- The edge-edge contact between a shell body and beam body is not supported when the **Target** side of the contact pair is on the shell body that belongs to a Condensed Part.
- Elements cannot use Lagrange multipliers, such as interior contact regions cannot using the Normal Lagrange Formulation.
- The following are not supported:
  - Force Reaction and Moment Reaction probes (Expansion Pass only)
  - Pipe Idealization
  - Spot Weld connections
  - Symmetry Region scoped to a Condensed Part
  - Cyclic Symmetry
  - Linear Periodic Symmetry
  - The **Detect Condensed Part Interface** option does not detect imported loads or connections, however, they can be added manually. For the imported objects that are associated with condensed parts, use the promote feature in the worksheet of the imported objects in order to be able to perform interface detection.
- For Joints internal to a Condensed Part, the application only supports Fixed (p. 1298) joints and Bushing (p. 1303) joints (with **Formulation** property set to **Bushing**).
- The Rotational Velocity and Thermal Condition loads are only supported on a non-condensed part.
- Once you have scoped and generated Condensed Parts, any mesh modifications made to the parts of the model that **do not** belong to the generated Condensed Parts, do not require you to regenerate the Condensed Parts. That is, Condensed Parts maintain an up-to-date status following mesh changes to other model parts. However, there are a few exceptions. If you have imported your model using external systems, **External Model** and/or **Mechanical Model** systems, any geometry modifications to geometries not specified as a Condensed Part, do cause the Condensed Parts to become obsolete and require regeneration. In addition, the use of features such as **Mesh Edit**, **Element Orientation**, or **Mesh Numbering** objects cause up-to-date Condensed Parts to become obsolete and require regeneration.
- Condensed Parts require regeneration if you make any geometry modifications in the CAD application. This applies even if you have the **Smart CAD Update** option (SpaceClaim only) of the **Advanced Geometry Options** in **Geometry** cell properties of the Project Schematic.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

See the Geometry Preferences section in the CAD Integration documentation for more information.

- When importing `.mechdat` files, the **Solution** object displays with an unsolved state.
- The application does not display finite element connection lines (p. 1840) for any object scoped to the bodies included in the definition of a **Condensed Part**.

Note:

For additional restriction information, see the MATRIX50 Element Description in the *Mechanical APDL Element Reference* as well as the Assumptions and Restrictions (within Superelement) topic in the *Substructuring Analysis* section of the *Mechanical APDL Theory Reference*.

Rigid Dynamics Analyses

Note the following specific limitations for Rigid Dynamics analyses:

- You can apply loading conditions only to the interfaces of Condensed Parts. Remote Displacements and Remote Forces applied to the Condensed Parts using geometry selection, must match the scoping of an interface of the Condensed Part, or be applied directly via Remote Point selection. Inertial loads are automatically applied on all Condensed Parts by the Rigid Dynamics Solver.
- Contact cannot be used to connect Condensed Parts with the rest of the model.
- For On Demand Expansion, the supported results are Total Deformation, Directional Deformation, and all Stress and Strain results **except** the vector Principal. The limitations on these supported results are:
  - Only global CS evaluation is supported.
  - For the stress and strain results, only the averaged results display is supported.

Modal Analyses

Note the following specific limitations for Modal analyses:

- Pre-stress analysis is not supported with Condensed Parts.
- Rigid bodies are supported but it is best that at least one body be Flexible.
- **Rotational Velocity** and **Thermal Condition** loads cannot be scoped to a Condensed Part.
- Fracture Analysis is not supported when Condensed Parts are defined in the model.

Random Vibration and Response Spectrum Analyses

You cannot currently run expansions for Random Vibration and Response Spectrum analyses.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Best Practices

General

1. When a Condensed Part Interface includes faces, edges, vertices, or nodes that overlap with other interfaces where constraint equations are applied, such as remote points, boundary conditions scoped to remote points, MPC-based contact (p. 1243), etc.), the solver may remove some master node DOFs in the generation pass. This may interfere with the use pass solve as well as postprocessing.

2. If you define a joint between a rigid body and flexible body, you need to specify the Condensed Part on the Reference side in order to get accurate results.

Importing Condensed Parts

Use the right-click options of the Worksheet to automatically create node-based Named selections for use in the analysis to scope features such as Contact, Remote Points, Joints, etc.

Remote Points need to be connected to the interfaces of the Imported Condensed parts. To avoid rigid body modes, set the **Behavior** property of the **Remote Point** to **Coupled**. This applies to other connection types, such as a Joint that is also connected through remote points.

It is also recommended to use Imported Condensed part interface on the Reference/Source side while connecting the superelements to the rest of the model.

Rigid Dynamics Analyses

Review the following recommendations when you are defining Condensed Parts.

Analysis Settings

For the **Solver Controls** (p. 1428) property **Time Integration Type** of the Analysis Settings, the default option is Program Controlled. This option automatically uses the Implicit Stabilized Generalized Alpha setting. Ansys recommends the use of generalized implicit time integration. The Runge-Kutta explicit time integration option may lead to small time steps and consequently significant computation effort during the Use Pass. Older models (prior to R17.0) may be specified to use a Runge-Kutta option by default. If so, the processing requirements will be significant during the Use Pass. It is also recommended to set **Energy Accuracy Tolerance** property to **Program Controlled** for better performance during implicit time integration.

Note:

For additional information, see the **Analysis Settings** Help for the Nonlinear Controls for Rigid Dynamics Analyses (p. 1472).

The number of stored results points has a direct effect on the computational efforts required by Expansion Pass. It is therefore recommended that you specify the **Store Results At** property of the **Output Controls** (p. 1473), in the Analysis Settings, as **Equally Spaced Points** and set the **Value** property accordingly to limit the number of result time points and to reduce the processing requirements of the expansion.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Analyses Using the Mechanical APDL Solver

You should use the same setting for the number of cores for the generation process for all condensed parts as well as your solution and expansion(s) as defined by the **Distribute Solution** option in the **Advanced Settings** of the Solve Process Settings (p. 1804) dialog.

Static Analysis From Rigid Dynamics Analysis

You can perform a Rigid Dynamics Analysis (p. 550) and then change it to or link it to a downstream Static Structural Analysis (p. 652) analysis for the purpose of determining deformation, stresses, and strains (which are not available in the Rigid Dynamics analysis).

Note:

The Motion Loads (p. 622) ACT extension allows you to more easily apply the loads created in a Rigid Dynamics analysis on the flexible bodies in a Static Structural analysis especially when the model contains joints with translational joint degrees of freedom.

Creating an Analysis System

1. From the toolbox, drag and drop a **Rigid Dynamics** template onto the project schematic. Follow the procedure for creating a Rigid Dynamics Analysis (p. 550) analysis. Apply forces and/or drivers, and insert any valid solution result object(s).
2. Specify the time of interest in the tabular data table or in the Graph window.
3. Select a solution result object and click the right mouse to display the popup menu. Select **Export Motion Loads** and specify a load file name.
4. In the project schematic, duplicate the **Rigid Dynamics** analysis system. Replace the duplicated analysis system with a **Static Structural** analysis system.

   Note:

   If you do not need to keep the original **Rigid Dynamics** analysis, you can replace it with the **Static Structural** analysis system.

   ---

5. Edit the **Static Structural** analysis (using **Model**, **Edit**) by suppressing all parts except the desired part for the **Static Structural** analysis.
6. Change the **Stiffness Behavior** of the part to be analyzed from **Rigid** to **Flexible**.
7. Change mesh solver preference to be Ansys Mechanical instead of Ansys Rigid Dynamics.
8. Delete or suppress all loads used in the **Rigid Dynamics** analysis.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

9. Import the motion loads that were exported from the **Rigid Dynamics** analysis. Highlight the **Static Structural** branch and then right mouse click, **Insert**> **Motion Loads...**.

   Note:

   Moments and forces created for the static structural analysis can be in an invalid state if all three components of the force/moment are almost equal to zero.

10. Delete the result objects and add new ones.

11. Solve the single part model with the static structural analysis and evaluate the results.

Point to Remember

It is important that you create the **Static Structural** analysis after the **Rigid Dynamics** analysis is finished and the export load is done.

Submodeling

The Submodeling feature in Mechanical enables you to import the solution output of an upstream (source) analysis and apply that output as boundary conditions in the downstream (target) system in order to more closely analyze a region of interest. The application uses the results for your entire model as the imported data. The application interpolates the data for the geometry region you specify as the submodel.

In order to use this feature, you need to prepare your submodel in the appropriate modeling application and understand where on the geometry the loading will be applied.

Note:

For nonlinear, load-history-dependent problems (for example, when plastic materials exist), you must cut boundary conditions from the coarse model at multiple substeps to simulate the load history dependency in the fine-mesh model analysis. The more boundary cutting you do, the more accurate are the results of the fine-mesh model analysis.

During the data transfer process, the application creates a Submodeling object in Mechanical. This object is essentially the same as an Imported Load (Group).

Note:

If you want to import results from an upstream system, Ansys recommends that you instead import data using the **Imported Load (Group)** object.

Mechanical allows submodeling for structural (stress) and thermal analyses. In a thermal analysis, the temperatures calculated on the cut boundary of the coarse model are specified as boundary conditions for the submodel.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Take the time to review the *Submodeling* section of the *Advanced Analysis Guide* for a more detailed technical description of the feature and the principles in use. Also see the Shell-to-Solid Submodels (p. 818) section for the specific requirements for submodeling shells.

Restrictions

The following restrictions apply to submodeling:

- Supported for the Mechanical APDL solver only.
- The principle behind submodeling assumes that the cut boundaries are far enough away from the stress concentration region. You must verify that this assumption is adequately satisfied.

Benefits

Aside from the obvious benefit of yielding more accurate results in a region of your model, the submodeling technique has other advantages:

- It reduces, or even eliminates, the need for complicated transition regions in solid finite element models.
- It enables you to experiment with different designs for the region of interest (different fillet radii, for example).
- It helps you in demonstrating the adequacy of mesh refinements.

Application

See the following topics for additional information and the steps to perform submodeling in structural and thermal analyses:

- Structural Submodeling Workflow (p. 808)
  - Beam-to-Solid/Shell Submodels (p. 813)
- Thermal Submodeling Workflow (p. 816)
- Shell-to-Solid Submodels (p. 818)

Structural Submodeling Workflow

Use the workflow below to perform a submodeling analysis using linked structural systems. You should review the Data Transfer Mesh Mapping content in Appendix B: Data Transfer Mapping and Validation (p. 2389) of the Help. This section describes the various Details view properties associated with the loading types for the submodeling feature. Refer to this section as needed during your analysis.

Note:

You can add a template for the linked structural systems by creating your own template.

Published: 2023-10-23

Supported Boundary Conditions

A structural analysis supports the following imported load options:

Body Temperature

This option inserts an **Imported Body Temperature** (p. 1740) object when you transfer temperatures from the coarse analysis.

Cut Boundary Constraint

This option inserts an **Imported Cut Boundary Constraint** (p. 1745) object when you transfer displacements for Solid- or Shell-Solid submodeling and displacements and rotations for Shell-Solid submodeling. Also see the **Imported Displacement** (p. 1746) section.

Cut Boundary Remote Force (Beam to Shell or Solid Only)

This option inserts an **Imported Cut Boundary Remote Force** (p. 1746) object in order to map forces and moments from beam-based coarse models to shell or solid submodels. These loading conditions are generated from the results defined on the nearest beam node of coarse model.

Important:

In order to add beam forces to the results file and make them available for your submodel, you need to set the **Nodal Forces** property (Analysis Settings>Output Controls (p. 1473)) to **On** in the coarse model.

Cut Boundary Remote Constraint (Beam to Shell or Solid Only)

This option inserts an **Imported Cut Boundary Remote Constraint** (p. 1744) object in order to map remote displacements and rotational forces from beam-based coarse models to shell or solid submodels. These loading conditions are generated from the results defined on the nearest beam node of coarse model.

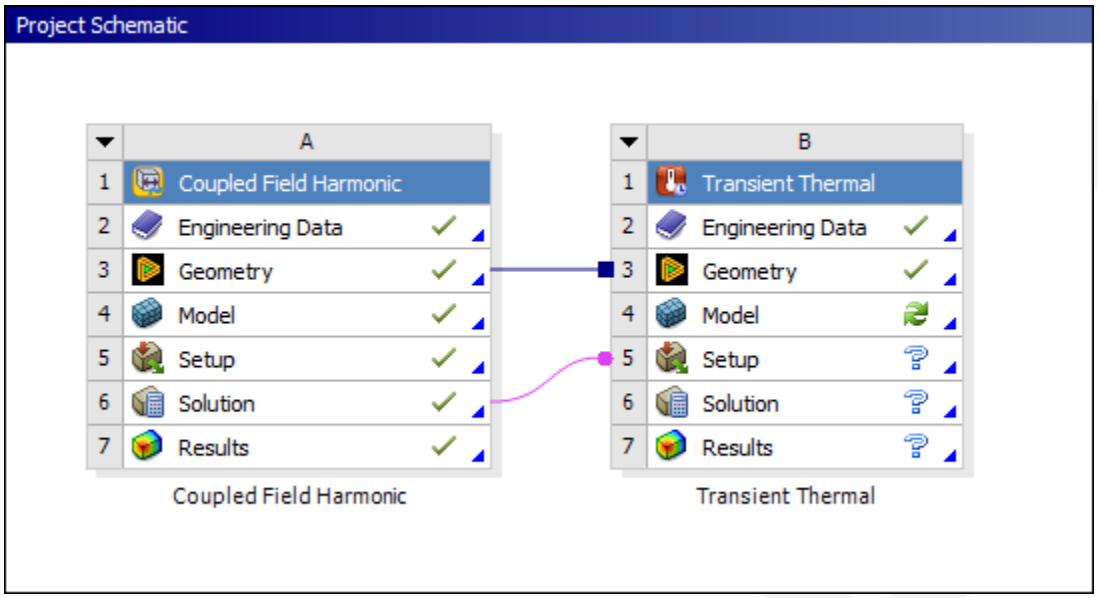
Structural Analysis Submodeling Workflow

1. On the Workbench **Project** page, create and complete (solve) a static or transient structural analysis. Perform all of the steps to set up and analyze the model. Specify mesh controls, boundary conditions, and solution settings as you normally would and solve the analysis.

   To easily identify this initial model, this example uses the name "Coarse" to identity the upstream system. This does not mean that the mesh refinement is coarse, only that it is relatively coarse compared to the "Submodel."

2. Create a new **Static Structural** or **Transient Structural** analysis on the **Project** page. Link the **Solution** cell of the upstream onto the **Setup** cell of the downstream system. As required, you can also link the **Engineering Data** and **Geometry** cells.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



3. Double-click the downstream system's **Setup** cell to open Mechanical. The application automatically adds a **Submodeling** object to the system's tree. This object references the upstream analysis' **Solution** object in parenthesis, for example, **Submodeling "(A6)"**.

4. Select the **Submodeling** object and add the desired imported conditions by:

   - Selecting the appropriate load from the **Imported Loads** drop-down menu on the **Environment** Context tab.

     Or...

   - Right-clicking on the **Submodeling** object and selecting **Insert** and then selecting the appropriate load from the context menu.

5. Now, you need to select the appropriate cut-boundaries from the geometry using either the **Geometry** or the **Named Selection** scoping option. The scoping options for the imported boundary conditions are described below.

Load Type	**3D Solid Analyses**	**2D Shell Analyses**
Imported Cut Boundary Constraint	Face, Edge, or Nodes	Face, Edge, or Node
Imported Cut Remote Force	Face or Edge	Edge
Imported Boundary Remote Constraint	Face or Edge	Edge

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Thermal Condition	Body or Nodes	Body or Nodes

Note:

- You cannot mix the scoping of surface bodies with other geometry types.
- Node-based Named Selections are not valid for transferring temperatures for Shell-Shell submodeling.

6. The application automatically populates the **Transfer Key** property. Options include:

Shell-Shell

The application selects this option for a shell-based geometry in the upstream system.

Note the following for **Shell-Shell** submodeling:

- You have the option to import **Displacements**, **Rotations**, or **Both** using the **Sub Type** property.
- You have the option to import temperatures from the **Top/Bottom** face or the **Middle** shell plane using the **Shell Face** option. The **Top/Bottom** option uses the temperature on both the top and bottom shell face to calculate the temperature on a target node, whereas the **Middle** option only uses the temperature at the middle shell plan.

Solid-Solid

The application selects this option for a solid body geometry in the upstream system.

Shell-Solid

You may select this **Transfer Key** option for Shell-to-Solid (p. 818) submodels.

For **Shell-Solid** submodeling, you have the option to import temperatures on **Top/Bottom** face or the **Middle** shell plane using the **Shell Face** option. The **Top/Bottom** option calculates and applies the temperatures on the top and bottom face independently, whereas the **Middle** option calculates the temperature at the middle shell plane and applies it across the thickness of the shell.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Beam-Shell/Solid

The application selects this option for a beam-based geometry in the upstream system.

Important:

If your submodel includes only forces and moments and has no other constraints, you must set the **Weak Springs** (p. 1433) property (Analysis Settings>Solver Settings (p. 1428)) to **On**.

Note:

- When you set the **Transfer Key** property to **Shell-Shell** or **Shell-Solid**, only shell bodies are selected from the upstream analysis.
- When the **Transfer Key** is set to **Beam-Shell/Solid**, only beam bodies are selected from the upstream analysis.
- When you set the **Transfer Key** property to **Solid-Solid**, the values on the middle shell plane of shell bodies are used for mapping.
- Mapping Validation is not supported when the **Transfer Key** property is set to **Shell-Solid** or **Beam-Shell/Solid**.

---

7. As needed, modify **Details** view properties. See Appendix B: Data Transfer Mapping and Validation (p. 2389) for additional information.
8. Select your defined imported load, right-click the object, and click **Import Load**. When the load successfully imports, a plot of the mapped values displays in the **Geometry** window.

   For displacement loads, the following data is available for viewing:

   - Displacement
   - Rotations (**Transfer Key** setting of **Shell-Shell** only)

   Note:

   - When multiple data types are available for viewing, the appropriate data type can be chosen in the **Data** field the **Graphics Controls** category.
   - Contours plots of the magnitude (**Total**) or X/Y/Z component can be viewed by changing the **Vector Component** option in the details pane. Defaults to a vector plot (**All**).
   - The range of data displayed in the **Geometry** window can be controlled using the properties of the **Legend Controls** category. See Imported Boundary Conditions (p. 1736) for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- For temperature loads on bodies when the **Transfer Key** property is set to **Shell-Shell**, the **Shell Face** option becomes available under **Graphics Controls**. This property enables you to view the data on top, middle or the bottom face of the shell.
- The data displayed on the middle face is calculated by averaging the interpolated data on the top and bottom face.

9. To activate or deactivate the load at a step, highlight the specific step in the **Graph** or **Tabular Data** window, and select **Activate/Deactivate**.

   See Activating and Deactivating Loads (p. 1423) for additional rules when multiple load objects of the same type exist on common geometry selections.

10. Define any other loads and boundary conditions, specify load step options, and obtain the submodel solution.

11. The final step is to verify that the cut boundaries of the submodel are far enough away from the concentration. You can do this by comparing results (stresses and so on) along the cut boundaries with those along the corresponding locations of the coarse model. If the results are in good agreement, it indicates that proper cut boundaries have been chosen; otherwise, you will need to recreate and reanalyze the submodel with different cut boundaries further away from the region of interest.

Note:

If the upstream (coarse) system is modified and re-solved after importing the load, a refresh operation on the Submodel system's Setup cell is required to notify Mechanical that source data has changed and re-import is required. Alternatively, the source data can be refreshed using the right-click operation on the Submodeling folder and choosing the **Refresh Imported Load** option.

Beam-to-Solid/Shell Submodels

For the Beam-to-Shell or -Solid submodeling technique, the coarse model is a beam model, and the submodel is either a 3D solid model or 3D shell model.

During the process of beam submodeling:

- The application determines the beam node that is nearest to each cut face (for beam-solid) or edge (for beam-shell) on the submodel. Then, depending upon the desired submodeling method, the application calculates either forces and moments or displacements and rotations from the coarse analysis's beam solution. If the scoped cut boundaries include connected faces or edges, the application uses the result from the nearest common beam node for each group of connected boundaries.
- The application applies the extracted forces and moments or displacements and rotations, from the beam nodes to the submodel by generating remote loads. The application posi-

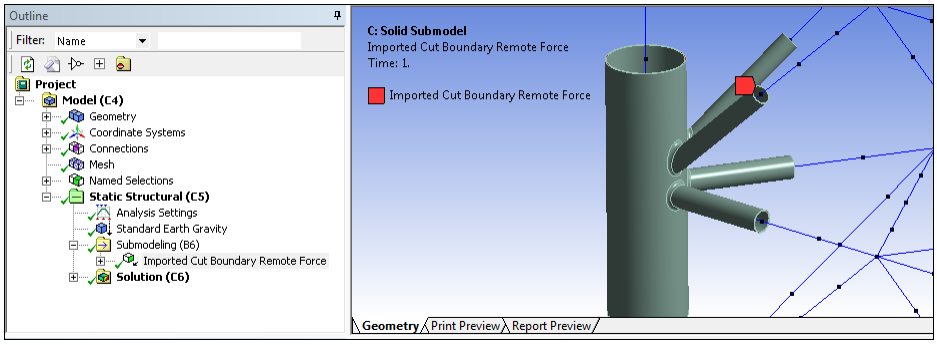
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tions these remote loads at the nearest beam node, but scoped to the appropriate cut face or edge on the submodel.

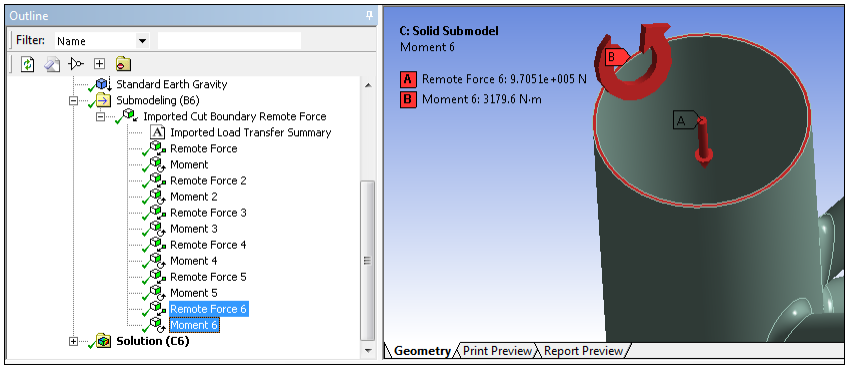
- Beam to shell or solid submodeling transfers can transfer the following from a beam model:
  - Forces and moments using the Cut Boundary Remote Force option. Using this method, each remote force and moment pair share a remote point that is by default, deformable. See examples below.
  - Displacements and rotations using the Cut Boundary Remote Constraint option. Using this method, the application applies displacements and rotations using remote displacement objects that by default, are rigid. See examples below.
- The generated remote loads are by default, read-only, however, you can change this setting using the Read Only property for generated load.

Loading Condition Examples

Here is an example of imported forces and moments using the **Cut Boundary Remote Force** import option. Note the beam nodes at the cut face locations (as well as all beam node locations). The remote points are located at the nearest beam node.



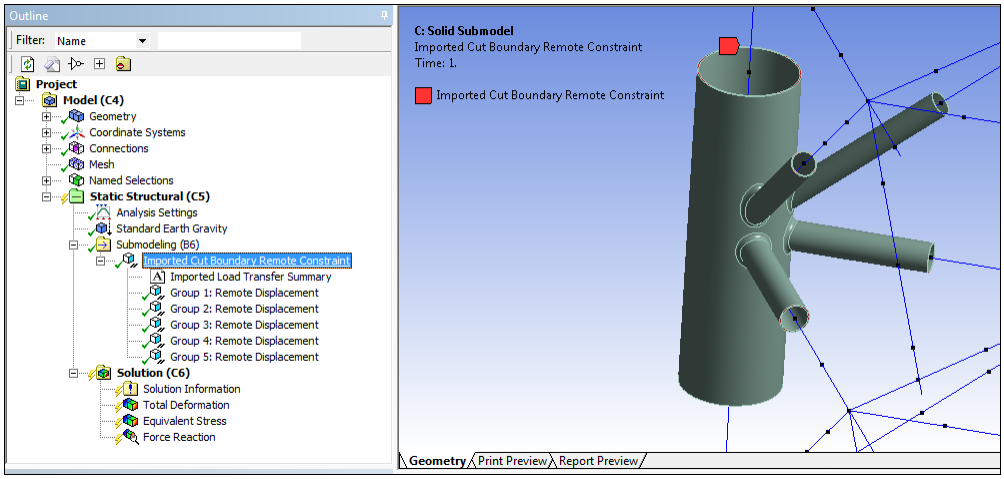
This example illustrates the force and moment loads for a specific cut face.



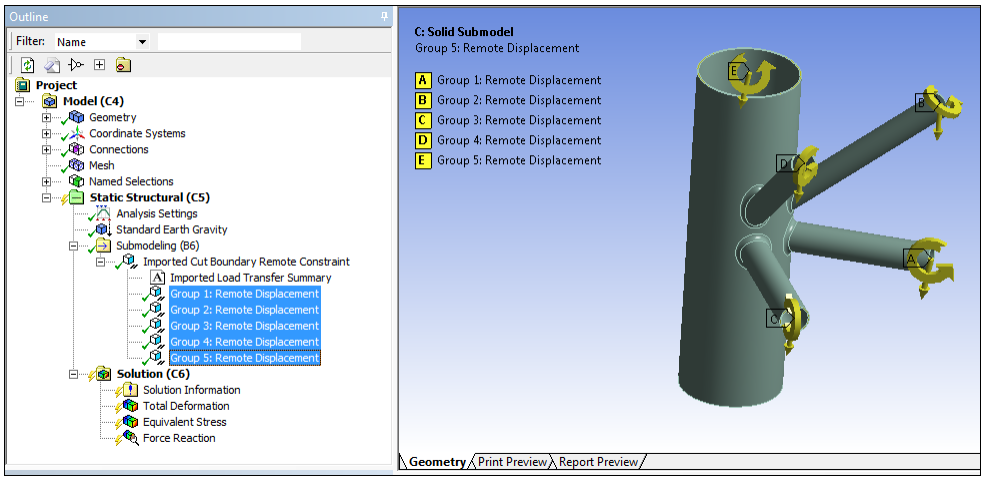
This example illustrates the **Cut Boundary Remote Constraint** import option.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Here you can see the remote displacements for the imported loading for the specific cut faces.



In addition, note the information provided by the **Imported Load Transfer Summary** object. This important tabular information enables validation of the data transfer. In particular, the nodes used to map the imported loads as well as the target coordinates.

Thermal Submodeling Workflow

Use the workflow below to perform a submodeling analysis using linked thermal systems. You should review the *Data Transfer Mesh Mapping* content in Appendix C (p. 2389) of the Help. This section describes the various Details view properties associated with the loading types for the submodeling feature. Refer to this section as needed during your analysis.

Supported Boundary Conditions

Thermal submodeling analyses support the Imported Temperature (p. 1756) only.

Thermal Analysis Submodeling Workflow

1. On the Workbench **Project** page, create and complete (solve) a steady-state thermal or transient thermal analysis. Perform all of the steps to set up and analyze the model. Specify mesh controls, boundary conditions, and solution settings as you normally would and solve the analysis.

   To easily identify this initial model, this example uses the name "Coarse" to identity the upstream system. This does not mean that the mesh refinement is coarse, only that it is relatively coarse compared to the "Submodel."

2. Create a new **Steady-State Thermal** or **Transient Thermal** analysis on the **Project** page. Link the **Solution** cell of the upstream onto the **Setup** cell of the downstream system. As required, you can also link the **Engineering Data** and **Geometry** cells.

Note:

- You can add a template for the linked thermal systems by creating your own template.
- Data can be transferred from a 2D coarse model to a 3D submodel. The settings for 2D projection of target mesh nodes can be specified in Appendix B: Data Transfer Mapping and Validation (p. 2389).

3. Double-click the downstream system's **Setup** cell to open Mechanical. The application automatically adds a **Submodeling** object to the system's tree. This object references the upstream analysis' **Solution** object in parenthesis, for example, **Submodeling "(A6)"**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

An imported temperature object is automatically inserted under the **Submodeling** folder to represent the transfer. To add additional Imported Temperature objects, right-click the **Submodeling** folder and select the appropriate load from the **Insert** context menu.

4. Now, you need to select the appropriate cut-boundaries from the geometry using either the **Geometry** or the **Named Selection** scoping option.

   The Imported Temperature (p. 1756) boundary condition supports Face, Edge, and Node selections for 3D solids and Edge and Node selections for 2D shells.

   Note:

   You cannot mix the scoping of surface bodies with other geometry types.

5. The application automatically populates the **Transfer Key** property. Options include:

   Shell-Shell

   The application selects this option for a shell-based geometry in the upstream system.

   Solid-Solid

   The application selects this option for a solid body geometry in the upstream system.

   Shell-Solid

   You may select this **Transfer Key** option for Shell-to-Solid (p. 818) submodels.

   Beam-Shell/Solid

   The application selects this option for a beam-based geometry in the upstream system.

   Note:

   - When you set the **Transfer Key** property to **Shell-Shell** or **Shell-Solid**, only shell bodies are selected from the upstream analysis.
   - When the **Transfer Key** is set to **Beam-Shell/Solid**, only beam bodies are selected from the upstream analysis.
   - Mapping Validation is not supported when the **Transfer Key** property is set to **Shell-Solid** or **Beam-Shell/Solid**.
   - If you are using the Material Assignment (p. 1049) feature on source bodies that are different (shell and beam), you could experience mapping errors. The application may skip a source body during the mapping process. To address this issue, use the feature on the bodies individually – do not mix body types.
   - The application only considers beam and shell section type elements from the source data. It ignores all other section types.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- The range of data displayed in the graphics window can be controlled using the **Legend controls** options. See Imported Boundary Conditions (p. 1736) for additional information.

6. As needed, modify **Details** view properties. See Appendix C (p. 2389) for additional information.
7. Right-click the **Imported Load** object and click Import Load to import the load. When the load has been imported successfully, a plot of the mapped values will be displayed in the Geometry window.
8. To activate or deactivate the load at a step, highlight the specific step in the **Graph** or **Tabular Data** window, and choose **Activate/Deactivate***at this step*!

   See Activating and Deactivating Loads (p. 1423) for additional rules when multiple load objects of the same type exist on common geometry selections.
9. Define any other loads and boundary conditions, specify load step options, and obtain the submodel solution.
10. The final step is to verify that the cut boundaries of the submodel are far enough away from the concentration. You can do this by comparing results (stresses and so on) along the cut boundaries with those along the corresponding locations of the coarse model. If the results are in good agreement, it indicates that proper cut boundaries have been chosen; otherwise, you will need to recreate and reanalyze the submodel with different cut boundaries further away from the region of interest.

Note:

If the upstream (Coarse) system is modified and re-solved after importing the load, a refresh operation on the Submodel system's Setup cell is required to notify Mechanical that source data has changed and re-import is required. Alternatively, the source data can be refreshed using the right-click operation on the Submodeling folder and choosing the **Refresh Imported Load** option.

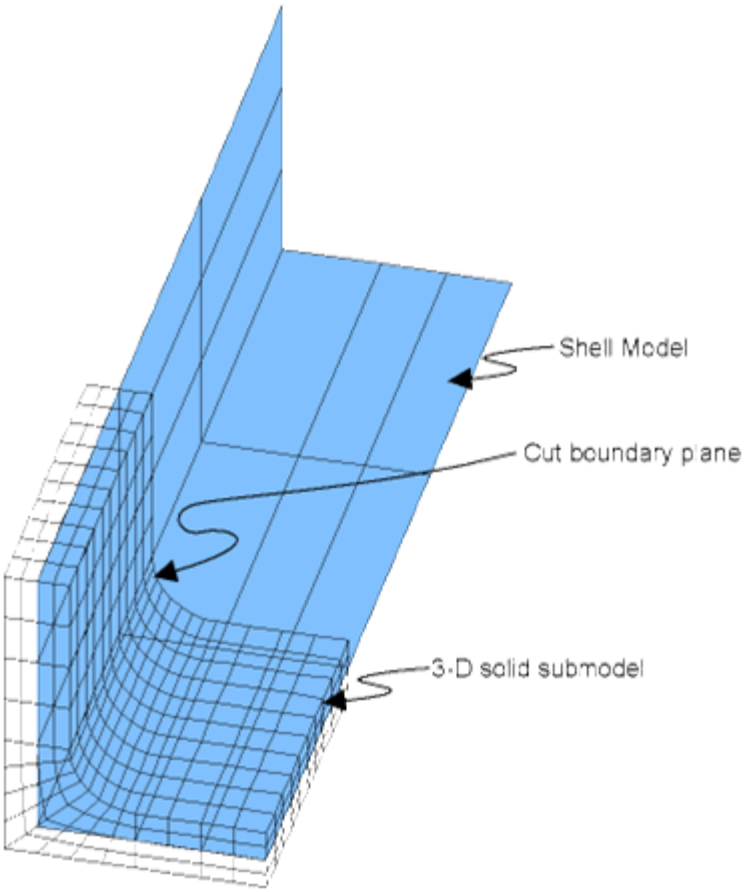
Shell-to-Solid Submodels

In the shell-to-solid submodeling technique, the coarse model is a shell model, and the submodel is a 3D solid model, as shown in this example:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Figure 17: 3D Solid Submodel Superimposed on Coarse Shell Model



The procedure for shell-to-solid submodeling is essentially the same as that for solid-to-solid submodeling, with these exceptions:

- Shell-to-solid submodeling is activated by setting the **Transfer Key** to Shell-Solid in the Imported Load details view.
- Cut boundaries on the submodel are the end planes that are normal to the shell plane (see Figure 18: Node rotations (a) before mapping command, (b) after mapping command (p. 820)).
- To determine the degree-of-freedom values at a cut-boundary node, the program first projects the node onto the nearest element in the shell plane. The degree-of-freedom values of this projected point are then calculated by interpolation and assigned to the corresponding node.
- In a structural analysis, only translational displacements are calculated for the cut-boundary nodes, but their values are based on both the translations and rotations of the projected point. Also, the node is rotated such that the nodal UY direction is always perpendicular to the shell plane, as shown in Figure 18: Node rotations (a) before mapping command, (b) after mapping command (p. 820). A UY constraint is calculated only for nodes that are within 10 percent of the average shell element thickness from the shell plane, preventing overconstraint of the submodel in the transverse direction.

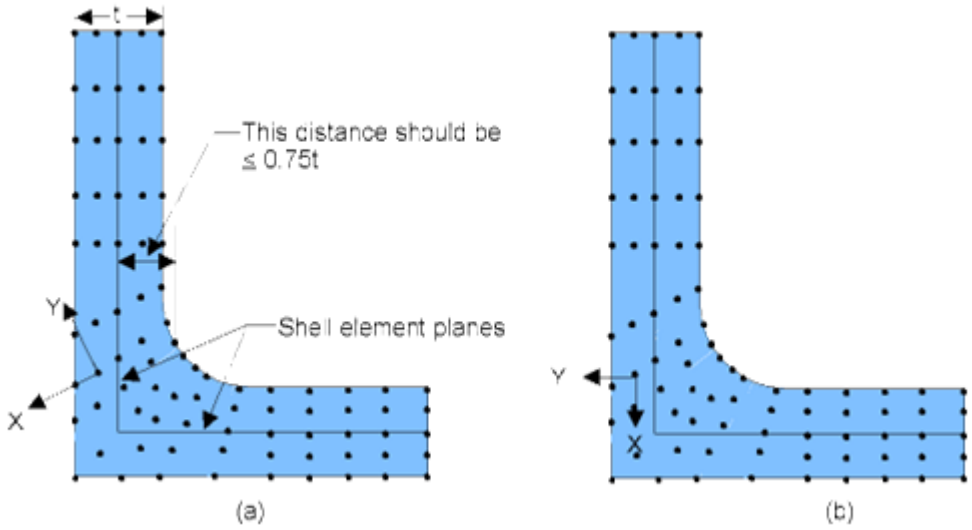
Published: 2023-10-23

Figure 18: Node rotations (a) before mapping command, (b) after mapping command



Note:

- If you are using the Material Assignment (p. 1049) feature on source bodies that are different (shell and beam), you could experience mapping errors. The application may skip a source body during the mapping process. To address this issue, use the feature on the bodies individually – do not mix body types.
- The application only considers beam and shell section type elements from the source data. It ignores all other section types.

System Coupling

You can use System Coupling to perform coupled simulations between multiple physics solvers, coupling active co-simulation participants and/or importing static data from a external data source. For example, you can run Mechanical and CFX in a coupled analysis or import data from an output file into a Fluent analysis. Once the physics and coupling setups are complete, the coupled analysis is executed and managed by System Coupling.

System Coupling can be used in the following contexts:

System Coupling's User Interfaces:

System Coupling is run from its graphical user interface (GUI) or its command-line interface (CLI). System Coupling's interfaces provide enhanced control over coupled simulation processes, including automatic starts and restarts for participants, the ability to manipulate System Coupling's data model, and an interactive solution workflow.

In these contexts, you still set up participant physics in the participant's user interface, but you'll perform the coupled analysis — starting System Coupling, loading participants, specifying values for coupling-related analysis settings, and automatically starting participants —

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

using System Coupling's GUI or CLI. Alternatively, if a coupled analysis setup was exported from Workbench, you can open it and execute it in the GUI or CLI.

A list of supported coupling participants is given in Supported Coupling Participants in the *System Coupling User's Guide*.

For more information, see Using System Coupling's User Interfaces in the *System Coupling User's Guide*.

System Coupling in Workbench:

System Coupling is run from the Workbench interface.

In this context, you'll connect the **Setup** cell from a Workbench analysis system to the **Setup** cell for the System Coupling component system, signaling that the Mechanical solver will act as a co-simulation participant in a coupled analysis. Most of the coupling-related analysis settings are made using the System Coupling system's **Setup** cell.

Once the physics and coupling setups are completed in Workbench, you can either execute the coupled analysis in Workbench, or export the setup for execution in one of System Coupling's user interfaces.

A list of supported coupling participants is given in Supported Coupling Participants for System Coupling in Workbench.

For more information, see Using System Coupling in Workbench in the *System Coupling User's Guide*.

The few coupling-related settings that are required in the setup are described below in System Coupling Related Settings in Mechanical (p. 825).

Once the physics and coupling setups are complete, the coupled analysis is executed and managed by System Coupling.

Supported Capabilities and Limitations

Mechanical supports the following capabilities when used in a System Coupling analysis:

- Data exchange across **System Coupling Region** (p. 1651) interfaces defined on regions in the Mechanical model. This boundary condition defines the interface between the fluid in the coupled participant system (for example, Fluent) and the solid in the Mechanical system.
- Data transfer regions are the regions upon which the **System Coupling Region** (p. 1651) condition is applied. In a coupled analysis, at each data transfer region, the following variables can be sent and received:
  - In a **coupled structural analysis**, Force and Displacement can be transferred at data transfer regions.
    - → Both Force and Force Density transfers are available. They are very similar, except that the Force Density variable uses follower effects within the Mechanical solution: as the structural geometry deforms within a time step, the Force rotates along with it. This can lead to a more robust solution, especially for soft materials such as hyperelastic solids.
    - → When the solver receiving the motion (such as Fluent) solves before or simultaneously with the solver sending the motion (such as Mechanical), then the Incremental Displacement transferred during the first coupling iteration of each coupling step is identically zero.
  - In a **coupled thermal analysis**, Heat Transfer Coefficients and Near Wall Temperatures, Temperatures, and Heat Flows can be transferred at data transfer regions.
    - → Heat Transfer Coefficient is also known as "convection coefficient."
    - → Near Wall Temperature is also known as "bulk temperature," or "ambient temperature."
  - In a **coupled thermal-structural analysis**, Mechanical can send Displacements along with only one Temperature or Heat Flow condition, and can in turn receive a Force load and either one Temperature or Heat Flow, or a combined Heat Transfer Coefficient and Reference Temperature.
  - In a **coupled thermal-structural-fluid analysis** (performed using a coupled field system (p. 830)), both Displacement and thermal data can be transferred on data transfer regions.

  For a listing of Mechanical's data transfer variables, see Variables Available for System Coupling (p. 824).
- Surface and volume meshes that include higher-order elements.
- Shared memory parallel mode. Note that convergence and therefore results will change between repeated runs of Mechanical in shared memory parallel mode. These changes will occur even if no setup changes were applied. The changes in the coupled analysis' convergence and results are due to the segregated solution algorithm used and the inherent sensitivity of the coupled physics problems being solved.
- Distributed parallel mode. Note that to run Mechanical in distributed parallel mode from within the Workbench interface, the working directory must be a shared network directory with the same path for all computer servers. Alternatively, the analysis can run in different working direct-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

ories on all servers if Mechanical is run as a coupling participant from one of System Coupling's user interfaces. For more information, see Running Mechanical as a Coupling Participant in System Coupling's GUI or CLI (p. 835).

- **SOLID** and **SHELL** elements. For a complete list of elements, see Load-Transfer Coupled Analysis -- Workbench: System Coupling in the *Coupled-Field Analysis Guide*.

- Structural convergence information and Result Tracker information are provided to System Coupling for display in the charts generated by System Coupling in Workbench.

  When using the Result Tracker in a System Coupling in Workbench analysis, note that **Kinetic Energy** and **Stiffness Energy** values are only computed at the end of a coupling step, and values of zero are reported for the intermediate coupling iterations. The **Kinetic Energy** and **Stiffness Energy** values reported in System Coupling are lagged, so the value reported at the start of a coupling step is actually the value corresponding to the end of the previous coupling step. The value corresponding to the last coupling step will not be reported in System Coupling.

- Custom restart files are available when using System Coupling's GUI or CLI. These files allow for the insertion of pre-solve command snippets into Mechanical's restart file. Mechanical APDL commands that are supported for coupled analysis restarts (such as **TIMINT**) may be used.

Note the following limitations when using Mechanical in a System Coupling analysis:

- System Coupling requires participants to use 3D meshes, with data transfer regions consisting of element faces within the 3D mesh. Data transfer regions cannot exist in 2D meshes (where the data transfer would be a line/curve). Line elements such as **BEAM** elements in Mechanical cannot form data transfer regions but may be included elsewhere in the Mechanical model.

- In a System Coupling setup, if you apply an external force or external heat flow on the same region as a **System Coupling Region** interface, this external variable will be ignored by the Mechanical APDL solver.

- Transfers of Force Density are not supported for:

  – Cases where Mechanical uses shell elements and Force Density is transferred to both sides of any shell.

  – Execution using System Coupling in Workbench. To make the FDNS input variable available in a coupled analysis created in Workbench, export the coupling setup so the analysis can be executed in System Coupling's GUI or CLI. For details, see Exporting a System Coupling Setup and Running an Exported System Coupling Setup in the *System Coupling User's Guide*.

- When Mechanical participates in a System Coupling analysis, only one load step can be defined in Mechanical. Loads can still vary as a function of time within this load step. Other operations that would normally require multiple load steps will require a System Coupling restart to be performed. For example, a pre-stressed analysis can be performed by executing a System Coupling simulation using the pre-stressing load conditions in Mechanical, then continuing the analysis by restarting System Coupling after making the necessary changes in Mechanical.

- Mechanical restarts are not supported for the transfer of thermal variables.

- Note that the internally computed contact damping is a function of the total number of substeps. The internal damping is reduced in subsequent substeps within a load step, and very little

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

damping is applied in the last substep. Therefore, the solution convergence pattern is different when solving a contact analysis that has only one substep (or a few substeps) per load step compared to an analysis having multiple substeps per load step. In some cases, the solution may fail to converge if a small number of substeps is used per load step. You can specify absolute damping coefficients to overwrite internal damping values by inserting a Command object (p. 2303) under the **Contact Region** and setting appropriate values for the real constants, FDMN and FDMT.

- If you are using a System Coupling in Workbench component system in combination with your Mechanical analysis, the **Save Project Before Solution** and **Save Project After Solution** properties of the Project object are not supported.
- When transferring data to or from a wall boundary in a sliding mesh zone, you must make sure that Mechanical does not rotate the mesh. You can accomplish this by using a Rotational Velocity (p. 1511). For information about sliding meshes in Ansys Fluent, see the Using Sliding Meshes documentation in the *Fluent User's Guide*.

Variables Available for System Coupling

The following variables are available on all data transfer regions.

Table 1: Variables On Boundary Wall Regions

Display Name / Internal Name	**Transfer Direction**	**Tensor Type**	**Extensive/Intensive**	**Quantity Type**
Force / FORC	Input	Vector	Extensive	Force
Force Density / FDNS[1]	Input	Vector	Intensive	Force
Displacement / INCD	Output	Vector	Intensive	Length
Heat Flow / HFLW	Input and Output	Scalar	Intensive	Heat Rate
Heat Transfer Coefficient / HCOE	Input	Scalar	Intensive	Heat Transfer Coefficient
Temperature / TEMP	Input and Output	Scalar	Extensive	Temperature
Near Wall Temperature / TBULK	Input	Scalar	Intensive	Temperature
1: FDNS is not supported for System Coupling in Workbench or for cases where Mechanical uses shell elements and Force Density is applied to both sides of any shell.				

Table 2: Variables On Body System Coupling Regions

Display Name / Internal Name	**Transfer Direction**	**Tensor Type**	**Extensive/Intensive**	**Quantity Type**
Heat Rate Density / HGEN	Input	Scalar	Intensive	Heat Rate

Published: 2023-10-23

Display Name / Internal Name	Transfer Direction	Tensor Type	Extensive/Intensive	Quantity Type
Temperature / TEMP	Output	Scalar	Intensive	Temperature
Temperature / TPLD	Input	Scalar	Intensive	Temperature

Note:

When using System Coupling in Workbench, the data plotted in System Coupling's chart monitors are provided by the coupling participants. For non-linear analyses, the structural convergence quantities from Mechanical are plotted in terms of the activated degrees of freedom in the structural solver. For linear analyses, the structural convergence quantities from Mechanical are plotted only for thermal analyses with the temperature degrees of freedom.

System Coupling Related Settings in Mechanical

End Time Specification

For transient analyses, Mechanical requires the end time specified in the setup to be respected. When coupling participants require their end time to be respected, the maximum allowable end time for the coupled analysis is the minimum of the end time specified by such participants.

Other participant systems, such as Fluent, can run past the end time specified in the setup. These participant systems have no effect on the allowable end time of the coupled analysis.

Ramping of Data-Transfer Loads

Mechanical has two types of ramping that can modify the loads obtained through data transfers in a coupled analysis. The two types of ramping are ramping over substeps, and ramping over coupling steps. The ramping on your load will be determined by the interaction of ramping settings you have set between Mechanical as well as System Coupling. Both Mechanical ramping behaviors are controlled by the Solution Command Object **KBC**, which can be set to **1** or **0**. In a steady-state analysis, the default setting is **KBC = 0** (ramping on). In a transient analysis, the default setting is **KBC = 1** (ramping off).

In System Coupling, substeps are unique to Mechanical, and are steps within a coupling iteration. Loads can be ramped over these substeps. The ramping factor applied to these loads is based on the number of substeps, N_{SS}. At the i^{th} substep, the ramping factor of i/N_{SS} is applied. This ramping is based on the initial value of the load at the end of the last step. When KBC = 0 and $N_{SS}>1$, ramping over substeps occurs. If KBC = 1 or $N_{SS}=1$, ramping over substeps does not occur.

In System Coupling, Mechanical has a second ramping option which ramps loads over the coupling steps. Regardless of what other ramping settings are on, System Coupling always transfers the full load at the end of the coupling step, and then Mechanical applies a ramping factor to this full value at each coupling step. The ramping factor applied to the full load at the coupling step is based on the number of coupling steps, N_{CS}. At the i^{th} coupling step, the ramping factor of i/N_{CS} is applied. When **KBC = 0** and $N_{CS}>1$, ramping over coupling steps occurs. If **KBC = 1** or $N_{CS}=1$, ramping over

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

coupling steps does not occur. Note that if you set ramping over coupling steps to occur in a transient analysis, loads received from System Coupling will be ramped over all coupling steps, and so the full load will only be applied at the last coupling step. This situation is not physical, but may still be useful when using a Transient Structural system to get steady-state results, for example when pre-stressing the structure for a further transient analysis.

Ramping of Loads Within Mechanical

Loads within the Mechanical system (that is, loads that are not transferred to Mechanical through the coupled analysis) are ramped linearly using the **Step End Time** specified in Mechanical. In a steady-state coupled analysis, ramping of these loads is controlled by the relationship between the **Step End Time** specified in Mechanical, and the number of coupling steps specified in System Coupling. For a steady-state analysis, each coupling step in System Coupling corresponds to 1 s of time in Mechanical.

- When the number of seconds set for the **Step End Time** in Mechanical equals the number of coupling steps set in System Coupling, the load is ramped linearly across all steps in the coupled analysis.
- When the number of seconds set for the **Step End Time** in Mechanical is less than the number of coupling steps set in System Coupling, the load is ramped linearly to the coupling step that matches the end time, and then the full load is applied for the remaining steps.
- When the number of seconds set for the **Step End Time** in Mechanical is more than the number of coupling steps set in System Coupling, the load is ramped linearly, but it will not reach its full value. The final value applied will be the ramped value that corresponds to the last coupling step, which may cause inaccuracies in your simulation.
- If Mechanical's **Step End Time** is set to 1s, this ramping will not occur.

Note that Mechanical's computational end time and its load-based end time are independent. The computational end time is equal to the number of coupling steps. The load-based end time controls the ramping behavior, and is set by the **Step End Time** option in the Mechanical interface.

Output Controls

When Mechanical is connected to System Coupling, behavior of the **Output Controls** is changed. For a normal Mechanical run, the **Store Results At** settings are applied per step and **Specified Recurrence Rate** is defined as the output frequency within a step at some substep frequency. When the Mechanical application is connected to System Coupling, these settings are applied across all steps, not within one step. This means that you cannot output results within a step. System Coupling simulations may run many steps, so these settings should be used to reduce the results frequency as needed.

For more information about how to use Mechanical for FSI analyses, see Fluid-Structure Interaction (FSI) (p. 756).

Using Higher-Order Meshes for Coupled Analyses

System Coupling supports both surface and volume meshes with mid-side nodes, providing improved interpolation for Mechanical cases with quadratic element meshes. Previously, Mechanical participants dropped mid-side mesh nodes and sent only corner nodes to System Coupling. Beginning in the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

2020 R2 release, Mechanical sends mid-side nodes to System Coupling by default for the following types of cases:

- New coupled analyses created with the 2020 R2 or later release
- Unsolved existing coupled analyses created with a pre-2020 R2 release

For instructions on other scenarios, see:

- Applying Mid-Side Nodes to Existing Solved Cases (p. 827)
- Reverting to the Use of Corner Nodes (p. 827)

Applying Mid-Side Nodes to Existing Solved Cases

To apply the new feature to existing cases that were created with an earlier release and that have already been solved using only the corner nodes, perform the following steps:

1. Clear coupled analysis solution data.
2. Save the Mechanical project.
3. Regenerate Mechanical's solver file.
4. Re-solve the coupled analysis.

Reverting to the Use of Corner Nodes

To revert to Mechanical's previous behavior of sending only corner nodes to System Coupling, perform the following steps:

1. Load the case into Mechanical.

   Note:

   If the case has already been solved using the new functionality, perform the steps described in above topic, Applying Mid-Side Nodes to Existing Solved Cases (p. 827).

2. Open the Commands (APDL) object, using either of the following methods:

   a. On the **Home** tab, **Insert** group, select **Commands**.

   b. In the **Outline**, right-click the **A5** analysis environment object and select **Insert** > **Commands**.

   The **Commands (APDL)** object is added to the **Outline** tree and the corresponding Worksheet opens. The text displayed indicates that the command will be placed in the /SOLU section of the .dat file, so will be executed just prior to the **SOLVE** command.

3. In the **Worksheet**, enter the following command snippet:

```
SCOPT,,NO
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

4. From the **File** tab, select **Save Project**.

When the solution is run, Mechanical will run the command snippet and revert to sending only linear meshes and data to System Coupling, even when it is using quadratic meshes in its own solution.

One-Way FSI Transfers Using System Coupling in Workbench

One-way data transfers using System Coupling in Workbench are particularly useful as a first step in a sequence of coupled analyses that may advance to co-simulation involving two-way transfers. In some cases, one-way coupled analyses may also be an alternative to transferring data using imported loads.

Coupled analyses may be used to transfer force into, structural data out of, or thermal data into or out of the Mechanical analyses. Either co-simulation data from a coupling participant system or static data from an External Data system may be transferred through System Coupling. (Transferring data from an External Data system may be useful when users with different licenses are working on the same project.)

For all cases (whether Mechanical is the source or target participant, and whether co-simulation or static data are being transferred):

- Start by defining a System Coupling Region (p. 1651) boundary condition at the location corresponding to the fluid-structure interface.
- Connections between coupling participant systems and a System Coupling system are made by linking their **Setup** cells.

For more information, see:

- Transferring Data Into a Mechanical Analysis (p. 828)
- Transferring Data Out of a Mechanical Analysis (p. 829)

Transferring Data Into Mechanical Analyses

In a one-way coupled analysis with Mechanical as the target participant, a System Coupling system can transfer steady-state or transient thermal data (temperature, heat flow, or heat transfer coefficient and near wall temperature), or force (from CFD pressures and viscous forces) to a Mechanical system. Either co-simulation data or static data may be transferred into Mechanical.

Transfer co-simulation data into Mechanical:

When a co-simulation coupling participant, such as a Fluent system, is connected to a Mechanical system via System Coupling, Mechanical is given access to data directly from the other participant.

1. Connect a Mechanical system to a System Coupling system.
2. Connect another co-simulation participant system to the System Coupling system.
3. Edit the System Coupling system to define data transfers from the other co-simulation participant system to the Mechanical system.

Transfer static data into Mechanical:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When the External Data system is connected to a Mechanical system via System Coupling, Mechanical is given access to static data from Ansys External Data (.axdt) files.

1. Connect a Mechanical system to a System Coupling system.
2. Connect an External Data system to the System Coupling system.
3. Edit the External Data system to select one or more .axdt files.
4. Edit the System Coupling system to define data transfers from the External Data system to the Mechanical system.

The Ansys External Data text-formatted files can be generated by the CFD-Post component system from another participant's (such as Fluent's) analysis results.

Transferring Data Out of Mechanical Analyses

In a one-way coupled analysis with Mechanical as the source participant, a System Coupling system can transfer displacement or thermal data (temperature or heat flow) from Mechanical to other coupling participants. Either co-simulation or static data may be transferred out of Mechanical.

Transfer co-simulation data out of Mechanical:

When a Mechanical system is connected via System Coupling to another co-simulation coupling participant, such as a Fluent system, the other participant is given access to data directly from Mechanical.

1. Connect a Mechanical system to a System Coupling system.
2. Connect another co-simulation participant system to the System Coupling system.
3. Edit the System Coupling system to define data transfers from the Mechanical system to the other co-simulation participant system.

Transfer static data out of Mechanical:

To transfer static data out of Mechanical, export Ansys External Data files (`.axdt`) from Mechanical and use the files to transfer the data into an External Data system.

1. In Mechanical's **System Coupling Region**, set the **Export Results** property to **Yes**.
2. It you are running Mechanical from the command line for a thermal coupled analysis, add the macro `dumpFSIHeats.mac` to your **Mechanical APDL** directory before running Mechanical.

   The macro is available in the **C:\Program Files\ANSYS Inc\v241\aisol\DesignSpace\DSPages\macros** directory.
3. Add an External Data system to the **Project Schematic**.
4. Edit the External Data system to select one or more `.axdt` files.

   When the coupled analysis is run, Mechanical writes one `.axdt` file per **System Coupling Region** to its solver files directory. Each file may contain temperatures and heat flows, with

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

only corner node values recorded. (The mid-side node values for heat flows, if present, are summed to the corresponding corner nodes.) Heat flow data includes the sum of heat flows through surfaces with applied temperatures, convection, and radiation.

5. Connect the External Data system to the System Coupling system.

6. Edit the System Coupling system to define data transfers from the External Data system to the other co-simulation participant system.

Coupled Field Co-Simulation Using System Coupling

System Coupling supports static and transient coupled field co-simulations involving thermal-fluid-structural couplings between Mechanical and another coupling participant (such as Fluent). The co-simulation may be run using either System Coupling in Workbench or one of System Coupling's user interfaces (GUI or CLI). Setup of Mechanical's coupled field system is the same in all scenarios.

To set up and run a coupled field co-simulation, perform the following steps:

1. Set up the coupled field system in Mechanical.

   a. Add a **Coupled Field Static** or **Coupled Field Transient** analysis system to the **Project Schematic**.

   b. Set up the system in Mechanical as usual (as described in Coupled Field Static (p. 391) analysis or Coupled Field Transient (p. 395) analysis), with the following qualifications:

      - Structural and/or thermal variables must be defined.
      - Make sure the initial temperature is set correctly. (This is defined by the **Initial Temperature** and **Initial Temperature Value** fields under **Coupled Field Transient**/**Initial Physics Options**.)
      - A **System Coupling Region** must be used to create the coupling interface and to send both structural and thermal Degrees of Freedom (DOFs) to the co-simulation.

2. Finish setting up CFD participant and System Coupling according to where you want to complete the setup and run the co-simulation, as follows:

   - To complete the setup and solve the co-simulation in Workbench, follow the steps outlined in Setting Up a Coupled Analysis in Workbench and Running a Coupled Analysis in Workbench.
   - To complete the setup outside Workbench and solve the co-simulation in one of System Coupling's user interfaces, follow the steps outlined in Preparing for a Coupled Analysis, Creating a Coupled Analysis, and Running a Coupled Analysis.
   - To complete a full or partial setup in Workbench, export the setup, and solve the co-simulation in one of System Coupling's user interfaces, follow the steps outlined in Exporting a System Coupling Setup and Running an Exported System Coupling Setup.

Coupling Thin Surfaces in CFX

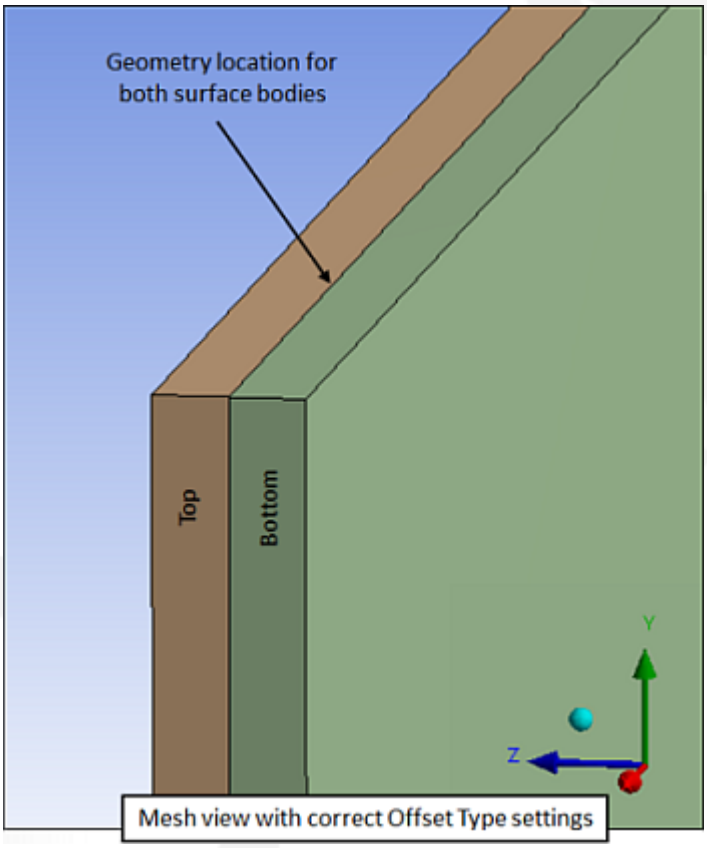
To transfer forces from a thin surface in CFX, you need to have a duplicate surface in Mechanical so that two surfaces exist in Mechanical Mechanicalto match the two surfaces in CFX.

Once you have two surfaces in Mechanical:

1. Use a bonded contact to connect the two surfaces in Mechanical.
2. Assign each surface half the true thickness of the thin surface.
3. Add an offset parameter to each of the Mechanical surfaces to ensure that the shell elements represents the true geometry. Typically, one surface uses **offset** = **top** and the second uses **offset** = **bottom**. Ensure that your elements are similar to those in the image below, where the mesh elements are not overlapping.
4. Create two fluid-solid interfaces in Mechanical, one for each surface body.

In this case, you cannot use a single set of shell elements in Mechanical.

Figure 19: Two Surfaces in Mechanical with the Correct Offset Parameter for Coupling with a Thin Surface



Restarting Structural Mechanical Analyses as Part of System Coupling

For instructions on performing restarts in a given coupling context, see the following sections in the *System Coupling User's Guide*:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Restarting a Coupled Analysis
- Restarting a Coupled Analysis in Workbench

To restart your coupled analysis, you will also need restart information specific to the participants connected to your System Coupling system. For details on other participant systems connected to your System Coupling system, review the participant's documentation on restarts.

For general information on performing restarts, see:

Generating Mechanical Restart Files

Specifying a Restart Point in Mechanical

Making Setup Changes Before Restarting

Recovering the Mechanical Restart Point after a Workbench Crash

Restarting a Thermal-Structural Coupled Analysis

Note:

Mechanical restarts are not supported for:

- Coupled analyses that include **Steady-State Thermal** or **Transient Thermal** systems.
- The transfer of thermal variables.

Generating Mechanical Restart Files

Restarts of a System Coupling analysis requires corresponding restart points to exist in the coupling service and in each of the solvers participating in the analysis.

In order to generate the restart files in Mechanical (`rdb/rXXX` files), perform the following steps:

1. In the Mechanical interface, select **Analysis Settings**.
2. In **Details of "Analysis Settings"**, ensure that **Restart Controls** > **Retain Files After Full Solve** setting is set to **Yes**.

Specifying a Restart Point in Mechanical

The restart point selected in the Mechanical solver must be consistent with the restart points selected for System Coupling and other coupling participants. A run-time error will be issued if an analysis is restarted with incompatible time points.

To specify a restart point in Mechanical, perform the following steps:

1. Double-click the Mechanical's **Solution** cell in Workbench.
2. In the **Outline** view tree, select **Analysis Settings**.
3. In the **Details of Analysis Settings**, under **Restart Analysis**, set **Restart Type** to **Manual** and select the correct restart point from the drop-down menu of **Current Restart Point**.
4. Close the Mechanical application.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. In the **Project Schematic**, right-click the Mechanical system's **Setup** cell and select **Update**.

Making Setup Changes Before Restarting

In some cases, setup changes are desired or are required to avoid failure of the coupled analysis. You may make these changes either by modifying settings in Mechanical or (if working in System Coupling's GUI or CLI) by using a custom restart file.

For instructions, see:

Modifying Settings in Mechanical

Using Custom Restart Files in System Coupling

Modifying Settings in Mechanical

Open Mechanical and save your project before modifying any settings so that, if needed, you can restore the saved project and any deleted restart points.

Make the required changes to the setup, then save the project and close the Mechanical application. The changed settings will be applied for subsequent coupled analyses.

Note:

The modification of some settings in Mechanical may invalidate and cause the deletion of all restart points. This deletion of restart points can cause the runtime error which warns of incompatible restart points. For a list of these settings, see Modifications Affecting Restart Points (p. 1818).

Using Custom Restart Files in System Coupling

Custom restart files are controlled by the Mechanical participant's **Execution Control | Additional Restart Input File** setting in the System Coupling data model. This setting accepts a Mechanical solver input file (`.dat`) and is blank by default.

To use a custom restart file, set Additional Restart Input File to the path of the custom restart script you wish to use.

Note:

Ensure that the specified restart file is valid. System Coupling does not validate restart files before the solution is restarted.

When a value is entered for this setting, System Coupling inserts a line into Mechanical's restart script, just before the **solve** command. The added line will include an **/input** command that references the specified restart file, as in the example below:

```
/batch
/solu
/gst,on,on
antype,4,rest,10,,continue
/input,myCommands.dat,,,,1
solve
```

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
save
finish
exit
```

The insertion of this line allows you to insert command snippets into the restart script. You may use Mechanical APDL commands that are supported restarting Mechanical in a coupled analysis — for example, you may use the **TIMINT** command to control time integration for Mechanical's restart.

System Coupling will use the custom script as the input for the restarted run, issuing the inserted command snippets before restarting the solution.

Recovering the Mechanical Restart Point after a Workbench Crash

Workbench or one of the components may crash such that restart files are available but they are not recognized or populated in the Workbench project.

See Recovering from a Workbench Crash for the steps needed to recover a coupled analysis after a Workbench crash. You will also need the information below about Mechanical, as well as information specific to the other participant systems connected to System Coupling. For other participant systems connected to your System Coupling system, see Supported Coupling Participants for System Coupling in Workbench for a list of supported systems and references to their corresponding documentation regarding restarts.

The result files from the run that crashed may reside in either the system's solution folder or in the `_ProjectScratch` directory. The `_ProjectScratch` directory is a temporary directory used by the Mechanical APDL solver. This directory contains the latest structural results and restart points written during the System Coupling run before Workbench crashed. Mechanical will need to read these file to recover the project using the steps below.

Note that the `.backup` directory contains the original version of any files which have been modified since the last save. These files are useful to recover the last saved state, but they are not useful for restarting your analysis.

To recover Mechanical's restart point after a workbench crash:

1. In the Project Schematic, double-click Mechanical's **Setup** cell. In the Mechanical interface, select the **Solution** entry from the tree.

2. From the **Solution** Context tab, select the **Read Result Files** option from the **Tools** group.

3. Browse to the location of the result files (which may be the systems solution directory or the `_ProjectScratch` directory) and select `file.rst`. Uncombined result files from a distributed-memory parallel solution can also be used instead of a single combined result file. In order to use the uncombined result files, the result file chosen must be `file0.rst`. Mechanical will now patch itself into a state consistent with the results files, with restarts points (if they were written) available for selection in Mechanical.

4. Select the restart point in Mechanical as in Specifying a Restart Point in Mechanical (p. 832) above.

5. Once you have selected Mechanical's restart point, in the Project Schematic, right-click Mechanical's **Setup** cell and select **Update**.

Published: 2023-10-23

Restarting a Thermal-Structural Coupled Analysis

When restarting coupled thermal-structural cases in which Mechanical APDL serves heat flow, use the default solve order, with Mechanical APDL solving first.

Mechanical APDL does not save the heat flows from the previous analysis, so initial heat flows sent to System Coupling are zero. Once Mechanical APDL has solved the first coupling iteration, the correct heat flows are sent to System Coupling.

If the default solve order is used, with Mechanical APDL solving first, then this will have no effect on the simulation because heat flows will have been calculated before Fluent solves the first coupling iteration. If the solution order is changed so that Fluent solves first, then Fluent will receive zero heat flow in the first coupling iteration after a restart, which could cause problems with the solution process.

Note:

The above information is for a coupled thermal-structural system. Mechanical does not support restarts for coupled analyses which include **Steady-State Thermal** and **Transient Thermal** systems.

Running Mechanical as a Coupling Participant in System Coupling's GUI or CLI

System Coupling analyses can be run using either of System Coupling's user interfaces. To run the Mechanical application as a coupling participant:

For coupled analyses set up in a System Coupling interface:

- To set up a coupled analysis in System Coupling's GUI or CLI, follow the steps outlined in Preparing for a Coupled Analysis, Creating a Coupled Analysis, and Modifying Coupled Analysis Settings.
- To run a coupled analysis in System Coupling's GUI or CLI, follow the steps outlined in Running a Coupled Analysis.

For coupled analyses that were set up using System Coupling in Workbench:

- To set up a coupled analysis using System Coupling in Workbench, follow the steps outlined in Setting Up a Coupled Analysis in Workbench.
- To export the coupled analysis setup, follow the steps outlined in Exporting a System Coupling Setup.
- To execute the exported setup in System Coupling's GUI or CLI, follow the steps outlined in Running an Exported System Coupling Setup.

Troubleshooting Two-Way Coupling Analysis Problems

The following files, found in the Mechanical run directory (`SYS/MECH` under a Workbench design point directory), may prove useful in troubleshooting coupled analysis problems:

- `file.err`: This file contains a summary of all of the errors that occurred during the run.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `solve.out` (or other output file): This file contains a complete summary of the current/latest run's evolution. This is one of the most useful files to determine why the coupled analysis failed. To generate extensive debug output during the analysis, enter the following command as a command snippet in the analysis branch when completing the Mechanical problem setup:

```
/debug,-1,,,,,2
```

Provide all of these files when submitting a request for service to Ansys personnel.

Product Licensing Considerations when using System Coupling

A distinct license is required for each coupling participant product, but no additional licenses are required for the System Coupling infrastructure itself.

Note, however, that Ansys EnSight is required for the postprocessing of System Coupling's interface results. If you are using a Multiphysics Licensing Bundle that does not include an EnSight license (e.g., the ***Ansys Mechanical Maxwell*** bundle), you will need a separate EnSight license to visualize co-simulation results.

For more information on applicable licenses, see Product Licensing Considerations in the *System Coupling User's Guide*.

Thermal-Stress Analysis

The Mechanical application enables you to apply temperatures from a thermal analysis as loads in a structural analysis for thermal stress evaluations. The load transfer is applicable for cases when the thermal and structural analyses share the mesh as well as for cases when the two analyses are solved using different meshes. For cases when the meshes are different, the temperature values are mapped and interpolated between the source and target meshes.

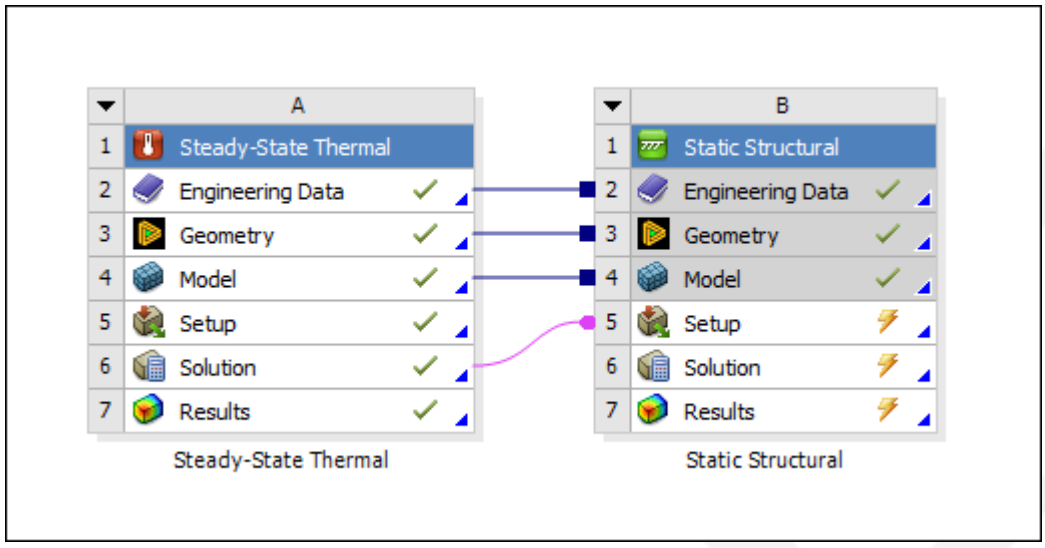
Workflow for performing a thermal stress analysis with:

Shared Model

1. From the toolbox, drag and drop a transient or steady-state thermal template onto the project schematic. Perform all steps to set up a Steady-State Thermal (p. 657) or Transient Thermal (p. 680). Specify mesh controls, boundary conditions, and solution settings as you normally would and solve the analysis.
2. Drag and drop a Static Structural, Transient Structural or LS-DYNA template on top of the thermal system's solution cell to enable the data transfer.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



3. Double-click the structural systems Setup cell. In the Mechanical application an Imported Body Temperature (p. 1740) load is automatically added into the structural system's tree under an Imported Load folder.

4. Select appropriate geometry in the **Details** view of the Imported Body Temperature object using the **Geometry** or **Named Selection** scoping option. If the load is scoped to one or more surface bodies, the **Shell Face** option in the details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.

   Note:

   In a LS-DYNA system, temperatures cannot be scoped to beams.

5. Change any of the columns in the **Data View** tab as needed:

   - **Source Time**: The time at which the data will be imported from the thermal analysis.
   - **Analysis Time**: Select the analysis time at which the load will be applied.

   Note:

   The **Data View** can automatically be populated with the source and analysis times using **Source Time** property in the Details view. Use **All** to import data at all times in the source analysis, or **Range** to import data for a range specified by a **Minimum** and a **Maximum**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

6. Right-click the Imported Body Temperature object and click **Import Load** to import the load. When the load has been imported successfully, a contour plot of the temperatures will be displayed in the Geometry window.

   Note:

   The range of data displayed in the graphics window can be controlled using the **Legend controls** options. See Imported Boundary Conditions (p. 1736) for additional information.

7. You can define multiple rows in the **Data View** tab to import source data at multiple times and apply them at different analysis. If multiple rows are defined in the **Data View**, it is possible to preview imported load vectors/contour applied to a given row or analysis time in the **Data View**. Choose **Active Row** or **Analysis Time** using the **By** property under **Graphics Controls** in the details of the imported load and then specify the **Active Row**/**Analysis Time** to preview the data.

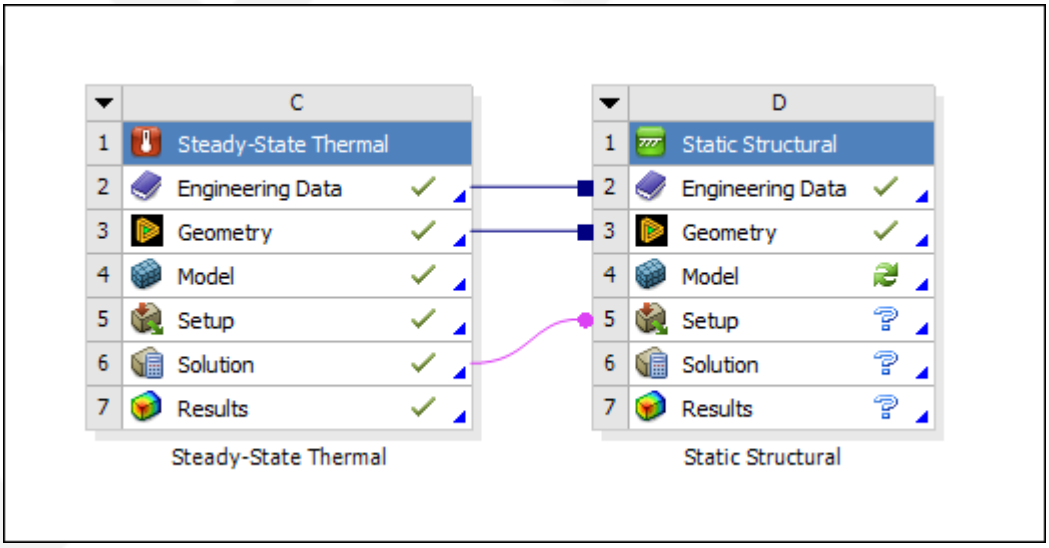
   Note:

   If the **Analysis Time** specified by the user does not match the list of analysis times in the **Data View**, the data is displayed at the analysis time closest to the specified time.

Unshared Model

1. From the toolbox, drag and drop a steady-state or transient thermal template onto the project schematic. Perform all steps to set up a Steady-State Thermal (p. 657) or Transient Thermal (p. 680). Specify mesh controls, boundary conditions, and solution settings as you normally would and solve the analysis.

2. Drag and drop a Static Structural, Transient Structural or LS-DYNA template onto the project schematic. Share the Engineering Data and Geometry cells if required and then drag the Solution cell of the thermal system onto the Setup cell of the structural system.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Double-click the structural systems Setup cell. In the Mechanical application, an Imported Body Temperature (p. 1740) load is automatically added into the structural system's tree under an Imported Load folder.

4. Select appropriate geometry in the **Details** view of the Imported Body Temperature object using the **Geometry** or **Named Selection** scoping option. If the load is scoped to one or more surface bodies, the **Shell Face** option in the details view enables you to apply the temperatures to **Both** faces, to the **Top** face(s) only, or to the **Bottom** face(s) only. See Imported Body Temperature (p. 1740) for additional information.

   Note:

   In a 3D analysis, if the Triangulation mapping algorithm is used, the Transfer Type mapping option defaults to Surface when the load is scoped to shell bodies.

   Note:

   In a LS-DYNA system, temperatures cannot be scoped to beams.

5. The **Source Bodies** option in the **Details** view enables you to select the bodies, from the thermal analysis, that make up the source mesh for mapping the data. You can select one of the following options:

   - **Automatic**: The application uses heuristics based on the geometry to automatically match source and target bodies and map temperature values. A source body is matched with a target body if it satisfies the following criteria:

     – The percent volume difference is within the user-defined tolerance.

     – The distance between the centroid locations divided by the diagonal of the bounding box is within the user defined tolerance.

     The percent tolerance values can be specified in the **Tolerance** field. The default is set at 1%. The matching process is done in increments of 0.1 of the tolerance value, up to the defined tolerance. The process fails if multiple source bodies are found to match a target body or if no match is found for a target body. After the import is completed, a **Load Transfer Summary** is displayed as a comment object in the particular load branch. The summary shows the matched source and target bodies as well as the values that were used to determine the match. It is recommended that you verify the import using this information.

     Important:

     This option requires that:

     – Element volume results are present in the thermal results file. In the thermal analysis, make sure that the **Calculate Thermal Flux** or the

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

General Miscellaneous property under the **Analysis Settings** object is set to **Yes** so that this result is available.

– Each scoped body of the target has a matching source body with a unique material id. Therefore, this option may not work when **Imported Trace** or **Material Assignment** objects are present.

Note:

This option is not allowed when scoped to a node-based **Named Selection** as the heuristic is geometry based.

- **All**: The source mesh in this case will comprise all the bodies that were used in thermal analysis. For cases where the temperature values are significantly different at the boundaries across two or more bodies, this option could result in mapped target values that are generated by taking a weighted average of the source values across multiple bodies. Target regions can exist where the mapped temperatures differ significantly from the source.
- **Manual**: This option enables you to select one or more source bodies to make up the source mesh. The source body selections are made in the **Material IDs** field by entering the material IDs that correspond to the source bodies that you would like to use. Type material IDs and/or material ID ranges separated by commas to specify your selection. For example, type 1, 2, 5-10. The material IDs for the source bodies can be seen in Solution Information Object (p. 1833) of the source analysis. In the example below, text is taken from a solver output,

```
**********Elements for Body 1 "coil" **********
**********Elements for Body 2 "core" **********
**********Elements for Body 3 "bar" ***********
```

body 'coil' has material ID 1, body 'core' has material ID 2 and body 'bar' has material ID 3.

6. Change any of the columns in the Data View tab as needed:
   - **Source Time**: The time at which the data will be imported from the source analysis.
   - **Analysis time**: Choose the analysis time at which the load will be applied.

   Note:

   The **Data View** can automatically be populated with the source and analysis times using **Source Time** property in the Details view. Use **All** to import data at all times in the source analysis, or **Range** to import data for a range specified by a **Minimum** and a **Maximum**.

7. You can transform the source mesh used in the mapping process by using the **Rigid Transformation** properties. This option is useful if the source geometry was defined with respect to a coordinate system that is not aligned with the target geometry system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

8. You can modify the Mapper Settings (p. 2389) to achieve the desired mapping accuracy. Mapping can be validated by using Mapping Validation (p. 2412) objects.

9. Right-click the **Imported Body Temperature** object and click **Import Load** to import the load. When the load has been imported successfully, a contour plot of the temperatures will be displayed in the Geometry window.

10. You can define multiple rows in the **Data View** tab to import source data at multiple times and apply them at different analysis. If multiple rows are defined in the **Data View**, it is possible to preview imported load vectors/contour applied to a given row or analysis time in the **Data View**. Choose **Active Row** or **Analysis Time** using the **By** property under **Graphics Controls** in the details of the imported load and then specify the **Active Row**/**Analysis Time** to preview the data.

    Note:

    If the **Analysis Time** specified by the user does not match the list of analysis times in the **Data View**, the data is displayed at the analysis time closest to the specified time.

    Note:

    a. You can add a template for the linked thermal and structural systems by creating your own template.

    b. The transfer of temperatures is not allowed between a 2D analysis and 3D analysis or vice-versa.

Note:

If the upstream (thermal) system is modified and re-solved after importing the load, a refresh operation on the structural system's Setup cell is required to notify Mechanical that source data has changed and re-import is required. Alternatively, the source data can be refreshed using the Right-click operation on the Imported Load folder and choosing the **Refresh Imported Load** option.

Note:

When there is a shared model that includes a thermal-stress analysis and the structural system is duplicated using the Engineering Data, Geometry or Model cell context menu, the result is the Setup cell of the Thermal system linked to the Solution cell of the duplicated structural system. Temperature transfer to the duplicated structural system will require the data to be mapped and interpolated between the source and target meshes.

Transferring Hydrodynamic Loads to a Structural System

The Hydrodynamic Pressure Mapping ACT extension transfers the surface pressures and line loads calculated in a Hydrodynamic Diffraction analysis or a time domain Hydrodynamic Response analysis

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

to panel and beam elements in a Static Structural analysis, through a link on the Workbench Project Schematic page. This removes the need to create, manipulate and run files external to Workbench. Multiple wave phase angles or time steps can be analyzed in a single Static Structural calculation, to provide a clear picture of finite element results due to hydrodynamic loading over the whole wave cycle or time series. To view the documentation explaining how to load and use the extension, click here.

The Offshore ACT extension exposes the family of OCEAN commands that are offered in Mechanical APDL. In this way the hydrodynamic loads on submerged beam and pipe elements – resulting from the motion of the structure through the fluid, or from the fluid motion around the structure due to current or waves – can be included in Static Structural, Transient Structural, Modal and Harmonic Response analyses. To view the documentation explaining how to load and use the extension, click here.

Twin Builder/Rigid Dynamics Co-Simulation

This feature is a co-simulation link (transient-transient) between Twin Builder and the Ansys Rigid Dynamics solver. This link enables you to combine detailed rigid mechanics models with system models such as complex electronic semiconductor device models used in controls. You can export a rigid dynamics sub-circuit and perform an analysis of the structure in Twin Builder.

Note:

You can also perform an FMU co-simulation with an external tool (co-simulation primary). For more details about the FMI standard and tools that support co-simulation with FMU, see fmi-standard.org. You set up an FMU co-simulation in the same manner as described here for a Twin Builder co-simulation.

- Twin Builder and rigid dynamics models are connected by Co-Simulation Pins (p. 844).
- Simulation is driven by Twin Builder.
- Results can be reviewed in Twin Builder, and then imported back to Ansys Mechanical.

Preparing the Analysis

Create a Rigid Dynamics Analysis System

General *Basic general information about this topic (p. 323)*

Define Engineering Data

General *Basic general information about this topic (p. 328)*

Specifics ***... for this analysis type:***

Density is the only material property utilized in a rigid dynamics analysis. Models that use zero or nearly zero density fail to solve using the Ansys Rigid Dynamics solver.

Attach Geometry

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

General *Basic general information about this topic (p. 330)*

Specifics ***... for this analysis type:***

Only sheet and solid bodies are supported by the Ansys Rigid Dynamics solver. Plane bodies and line bodies cannot be used.

Define Part Behavior

General *Basic general information about this topic (p. 342)*

Specifics ***... for this analysis type:***

You can define a Point Mass (p. 901) for this analysis type. Part stiffness behavior is not required for the Ansys Rigid Dynamics solver in Ansys Workbench.

Define Joints and Springs

General *Basic general information about this topic (p. 348)*

Specifics ***... for this analysis type:***

Applicable connections for this type of analysis are joints (p. 1292) or springs (p. 1395).

When an assembly is imported from a CAD system, joints and constraints are not imported; however, joints can be created automatically or manually after the model has been imported.

Each joint is defined by its coordinate system of reference. The orientation of this coordinate system is essential, as free and fixed degrees of freedom are defined in this coordinate system.

Define Input and Output Pins

General *Basic general information about this topic (p. 844)*

Specifics ***... for this analysis type:***

The quantities that are driven by Twin Builder are defined as input pins. The quantities that are monitored by Twin Builder are defined as output pins.

Define Analysis Settings

General *Basic general information about this topic (p. 349)*

Specifics ***... for this analysis type:***

Some of the analysis settings might be overwritten by those defined in Twin Builder, because Twin Builder drives the co-simulation.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Co-Simulation Pins

Note:

Pins apply for both Twin Builder and FMU co-simulations, but they are discussed here in the context of co-simulation with Twin Builder.

Co-simulation Pins are connection points that describe the interface between a rigid dynamics model and a Twin Builder model.

Pins have two distinct natures:

- **Input Pins** are used by Twin Builder to drive the rigid dynamics model.
- **Output Pins** are sensors used by Twin Builder to monitor the rigid dynamics model state.

Pins are defined by the degrees of freedom of joints (p. 1292). One pin can be attached to each degree of freedom of a joint. The type of joint *quantity* attached to pin depends on the nature of the degrees of freedom.

Translational degrees of freedom can have **Displacement**, **Velocity**, **Acceleration**, and **Force** pins.

Rotational degrees of freedom can have **Rotation**, **Angular Velocity**, **Angular Acceleration**, and **Moment** pins.

Note:

It is not recommended that you place additional joint conditions on degrees of freedom that are associated with pins.

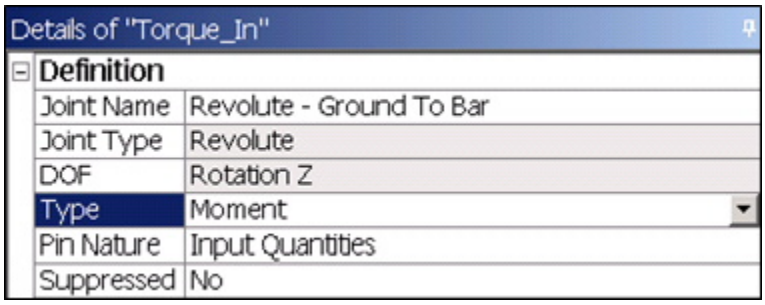
To create pins for a Rigid Dynamics analysis system:

1. Open a **Rigid Dynamics** analysis in Workbench, then double-click the **Model** field to open the model for editing in the Mechanical application.
2. Select the Rigid Dynamics (**Transient**) system in the Outline. From the **Co-simulation** group on the **Environment** Context tab, select the **Co-simulation Pin** option.

   If you select the **Co-simulation Pin** option while a joint is selected, the pin will automatically have joint information associated with it. If no joint is selected, you will need to associate the pin with a joint at a later time.
3. With the new pin selected in the Outline view, edit the **DOF**, **Type**, and **Pin Nature** fields in the Details view to complete the pin setup.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



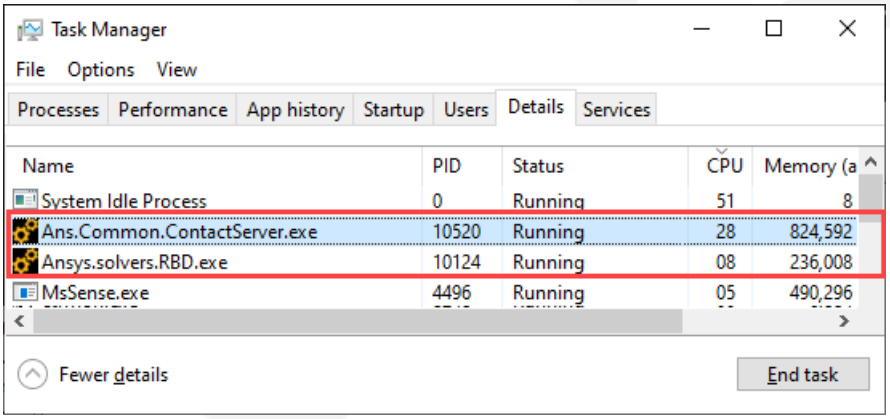
4. Rename the pin as it should appear in Twin Builder.

5. Repeat steps 2, 3, and 4 to add all pins of interest.

6. When finished adding pins, refer to Writing Ansys Rigid Dynamics Files (p. 1867) for more information.

Limitations

The Rigid Dynamics FMU uses a server-client architecture. The FMU is a thin client layer which uses the Rigid Dynamics solver in the background. Consequently, if the FMU primary abruptly aborts the simulation, the Rigid Dynamics solver executable may be left running. This orphan process prevents further solves. You must manually kill the solver process (`Ansys.Solvers.RBD.exe`), and the contact server (`Ans.common.ContactServer.exe`) using, for instance, the Windows Task Manager.



Typically, this problem occurs with Twin Builder when the simulation is aborted with the **Abort** option. Always use the **Clean Stop** as described here.

Bolt Tools Add-on

Geometry Introduction

While there is no limit to the number of parts in an assembly that can be treated, large assemblies may require unusually high computer time and resources to compute a solution. Contact boundaries can be automatically formed where parts meet. The application has the ability to transfer structural loads and heat flows across the contact boundaries and to "connect" the various parts.

The following topics are addressed in this section:

Parts and Bodies
Multibody Behavior and Associativity
Geometry Conditions and Requirements
Stiffness Behavior
Integration Schemes
Common Geometry Display Features

Parts and Bodies

Parts imported into Mechanical are a grouping or a collection of bodies as defined by the CAD application you use to define the parts.

Multibody Parts

Imported parts are a grouping or a collection of bodies. Parts can include multiple bodies and are referred to as *multibody parts*. Parts may consist of:

- One or more solid bodies.
- One or more surface bodies.
- One or more line bodies.
- Combinations of line and surface bodies.
- Combinations of solid and shell bodies (for models imported from DesignModeler, SpaceClaim, or External Model).

All other combinations are not practically supported.

Note:

Body objects in the tree that represent a multibody part do not report centroids or moments of inertia in their respective Details view.

Meshing Multibody Parts

The mesh for multibody parts created in SpaceClaim or DesignModeler share nodes where the bodies touch one another. This facilitates the multiple parts having common nodes at the part interfaces.

Collapsing Line Bodies in SpaceClaim

For line body models in SpaceClaim, by default, the application imports one line body for every edge present in the body in SpaceClaim. This may create an undesirable number of bodies in Mechanical. To facilitate a more manageable model, SpaceClaim enables you to "collapse" all of the line bodies that have the same cross section, material, and that touch one another, into one body by setting the **Share Topology** property to either **Share** or **Group**. See the **Shared topology in Ansys** section in the *SpaceClaim Online Help* for additional information about the **Share Topology** property.

Working with Parts

There are several useful and important manipulations that can be performed with parts in an assembly.

- The part can include solid and shell geometries.
- Each part may be assigned a different material.
- Parts can be hidden for easier visibility.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Parts can be suppressed, which effectively eliminates the parts from treatment.
- The contact detection tolerance and the contact type between parts can be controlled.
- When a model contains a Coordinate Systems object, by default, the part and the associated bodies use the Global Coordinate System to align the elements. If desired, you can apply a local coordinate system (p. 1191) to the part or body. When a local coordinate system is assigned to a Part, by default, the bodies also assume this coordinate system but you may modify the system on the bodies individually as desired.
- When you click **Freeze Mesh on All Parts**, the generated mesh on all parts of the model is frozen. To access **Freeze Mesh on All Parts**, right-click **Geometry** in the **Tree** outline and click **Freeze Mesh on All Parts** to freeze the mesh. If you try to modify the mesh on the body on which the freeze mesh is applied, a warning message is displayed to unfreeze the mesh. To unfreeze the mesh, right-click **Geometry** in the **Tree** outline and click **Unfreeze Mesh on All Parts**.
- When you click **Freeze Mesh**, only mesh on the selected part is frozen. To access **Freeze Mesh**, right-click the part on which you want to freeze the mesh in the **Tree** outline and click **Freeze Mesh**. The mesh on the selected part will be frozen while the mesh for other parts can be cleared and generated. When you try to modify mesh on the part on which **Freeze Mesh** is applied, a warning message is generated to unfreeze the mesh on the part. To unfreeze the mesh on the part, right-click the part and click **Unfreeze Mesh** in the **Tree** outline.

Note:

– **Freeze Mesh** can be applied only if all bodies of the part are meshed.

– **Mesh Edit**, **Generate Mesh** and **Clear Generated Data** are disabled on frozen mesh parts. When you perform **Mesh Connection**, **Node merge**, **Contact Match**, **Node Move**, **Morph**, **Fracture**, **Generate Mesh**, **Clear Generated Data** on a frozen mesh part, a warning message stating "The mesh on the part is frozen. Please unfreeze the mesh and then mesh edit generate/clear should be allowed." is displayed.

Working with Bodies

There are several useful and important manipulations that can be performed with bodies in a part.

- Bodies grouped into a part result in connected geometry and shared nodes in a mesh.
- Each body may be assigned a different material.
- Bodies can be hidden for easier visibility.
- Bodies in a part group can be individually suppressed, which effectively eliminates these bodies from treatment. A suppressed body is *not* included in the statistics of the owning part or in the overall statistics of the model.
- Bodies can be assigned **Full** or **Reduced** integration schemes, as described above for parts (p. 857).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- When bodies in part groups touch they will share nodes where they touch. This will connect the bodies. If a body in a part group does not touch another body in that part group, it will not share any nodes. It will be free standing. Automatic contact detection is not performed between bodies in a part group. Automatic contact detection is performed only between part groups.
- Bodies that are not in a part group can be declared as rigid bodies (p. 852).
- When a model contains a Coordinate Systems object, by default, bodies use the Global Coordinate System. If desired, you can apply a local coordinate system (p. 1191).

Note:

Freeze Mesh cannot be applied on individual bodies.

Multibody Behavior and Associativity

Associativity that you apply to geometry attached from SpaceClaim or DesignModeler is maintained in the Mechanical and Meshing applications when updating the geometry despite any part groupings that you may subsequently change in SpaceClaim or DesignModeler. See Associativity (p. 850) for further information.

When transferring multibody parts from SpaceClaim or DesignModeler, the multibody part has the body group (part) and the prototypes (bodies) beneath it. When the part consists of just a single body the body group is hidden. If the part has ever been imported as a multibody part you will always see the body group for that component, regardless of the number of bodies present in any subsequent update.

Associativity

Associativity that you apply to geometry originating from SpaceClaim or DesignModeler is maintained in the Mechanical and Meshing applications when the geometry is updated despite any part groupings that you may subsequently change in SpaceClaim or DesignModeler. Types of associativity that you can apply include contact regions, mesh connections, loads, and supports. For example, consider the following scenario:

1. A model is created in SpaceClaim or DesignModeler and has six independent parts with one body per part.
2. The model is attached to Mechanical where loads and supports are applied to selected geometry.
3. In SpaceClaim or DesignModeler, the model is re-grouped into two multibody parts with each part including three bodies.
4. The geometry is updated in Mechanical. The loads and supports remain applied to the same selected geometry.

Note:

This feature does not hold true for instanced parts in SpaceClaim or DesignModeler.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The associativity is maintained only with geometry attached from SpaceClaim or DesignModeler and Mechanical systems created in release 13.0 or later. To ensure that the data necessary for retaining associativity is present in legacy dsdb/wbpj databases, you should perform the following:

1. Open the Mechanical session and open the SpaceClaim or DesignModeler session. This will ensure that both the Mechanical and SpaceClaim or DesignModeler files are migrated to the current version of the software.
2. Update the geometry model without making any changes to the model. This will ensure that the new data necessary for associativity is transferred from the migrated DesignModeler file into the migrated Mechanical file.
3. You can now modify and update the geometry as necessary.

Geometry Conditions and Requirements

Note the following for assemblies, parts, and bodies:

- Automatic contact detection will detect contact between bodies within a multibody part.
- To connect multiple bodies within a part using a shared node, the bodies must share a face or an edge. If they do not, the application may not achieve appropriate contact for the analysis and the analysis could experience rigid body motion.
- Removing (for example, suppressing) a body or a part from your source geometry and then refreshing and/or updating the geometry in Mechanical causes the application to remove the body or part from the tree Outline. If you subsequently return the body/part to the source and return it to Mechanical through a refresh or update, the body/part returns to default settings (Stiffness Behavior, material, etc.).

Stiffness Behavior

All geometry Bodies have an associated **Stiffness Behavior** property in Mechanical that you can modify during an analysis. This is most often performed when Defining Part Behaviors (p. 342) once you have imported your model into the application.

The **Stiffness Behavior** property is available for a body, a body group, surface bodies, and 2D models.

To set the **Stiffness Behavior** in the Mechanical application:

1. Select the desired Body in the **Geometry** folder.
2. In the Details view, set the **Stiffness Behavior** property to **Flexible**, **Rigid**, **Gasket**, or **Stiff Beam** (Line Bodies (p. 872) only).

See the following sections for more information about body stiffness behaviors:

Flexible Bodies

Rigid Bodies

Gasket Bodies

Stiff Beam

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Flexible Bodies

The **Flexible Stiffness Behavior** option is the default option.

Rigid Bodies

When you define a body's **Stiffness Behavior** as **Rigid**, you are telling to the application to not allow the body to deform during the solution process. This feature is useful if a mechanism has only rigid body motion or, if in an assembly, only some of the parts experience most of the strains. It is also useful if you are not concerned about the stress/strain of that component and wish to reduce CPU requirements during meshing or solve operations.

The application does not mesh a rigid body and the solver represents the body as a single mass element. However, the system maintains the mass element's mass and inertial properties. The **Mass**, **Centroid**, and **Moments Of Inertia** properties for the body are available in the Details view of the body object.

The following restrictions apply to rigid bodies:

- Rigid bodies are only valid in Static Structural (p. 652), Transient Structural (p. 665), Harmonic Response (p. 496), Modal (p. 515), Rigid Dynamics (p. 550), Random Vibration (p. 524), and Response Spectrum (p. 533) analyses for the objects listed below. Animated results are available for all analysis types *except* a Modal analysis.
  - Point Mass
  - Joint
  - Spring
  - Remote Displacement
  - Remote Force
  - Moment
  - Contact
- Rigid bodies are valid when scoped to solid bodies, surface bodies, or line bodies in an Explicit Dynamics analysis for the following objects:
  - Fixed Support
  - Displacement
  - Velocity
  - Spring
  - Remote Displacement

The following outputs are available for rigid bodies, and are reported at the centroid of the rigid body:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Results: Displacement, Velocity, and Acceleration.
- Probes: Deformation, Position, Rotation, Velocity, Acceleration, Angular Velocity, and Angular Acceleration.

Note:

- If you highlight **Deformation** results in the tree that are scoped to rigid bodies, the corresponding rigid bodies in the **Geometry** window are not highlighted.
- You cannot define a line body, 2D plane strain body, or 2D axisymmetric body as rigid, except that in an Explicit Dynamics analysis, 2D plane strain and 2D axisymmetric bodies may be defined as rigid.
- All bodies in a body group (of a multibody part) must have the same Stiffness Behavior. When **Stiffness Behavior** is **Rigid**, the body group acts as one rigid mass regardless of whether or not the underlying bodies are topologically connected (via shared topology).

Gasket Bodies

Gasket joints are essential components in most structural assemblies. Gaskets as sealing components between structural components are usually very thin and made of various materials, such as steel, rubber and composites. From a mechanics perspective, gaskets act to transfer force between components. The primary deformation of a gasket is usually confined to one direction, namely, through thickness. The stiffness contributions from membrane (in plane) and transverse shear are much smaller in general compared to the through thickness.

A typical example of a gasket joint is in engine assemblies. A thorough understanding of the gasket joint is critical in engine design and operation. This includes an understanding of the behavior of gasket joint components themselves in an engine operation, and the interaction of the gasket joint with other components.

Gaskets can be defined in one of two ways:

- By setting the **Stiffness Behavior** as **Gasket**. In this case, a Gasket Mesh Control will be added as a child of the gasket body in the model tree. You need to define the source face of the gasket in the Gasket Mesh Control to define the gasket material orientation.
- By setting the **Stiffness Behavior** as **Flexible**. In this case, you need to define a Gasket Mesh Control in the mesh folder. The gasket mesh control in the mesh folder can be applied to multiple bodies, so if there are many gasket bodies this option may be a more convenient approach to setting up the gaskets.

You must also specify a material with a valid gasket model in Engineering Data.

The following restrictions apply to Gasket bodies:

- Gasket bodies are valid only in Static Structural analyses.
- Gasket bodies are valid for 3D solids only, that is, 2D gasket bodies cannot be specified.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- A valid gasket material model must be specified.
- In addition to gasket bodies, a multibody part may also include flexible bodies but not rigid bodies.
- Gasket bodies are not supported for cyclic symmetry analyses.

The overall procedure for simulating gaskets in Ansys Workbench is to run a Static Structural analysis and perform the following specialized steps:

1. Specify a material with a valid gasket model in Engineering Data.
2. Define the gasket using one of two ways:
   a. **Body-based approach**:

      Set the **Stiffness Behavior** of the **Body** object to **Gasket**. This produces a **Gasket Mesh Control** object beneath the **Body** object.

      Adjust Details view settings for the **Gasket Mesh Control** object and generate the mesh. See the Gasket Meshing (p. 854) section for details.

   b. **Mesh control approach**:

      Set the **Stiffness Behavior** of the **Body** object to **Flexible**.

      Define a **Gasket** mesh control object in the **Mesh** folder. Adjust the Details view settings for the **Gasket** mesh control object and generate the mesh. See the Gasket Meshing (p. 856) section for details.
3. Specify the value for the **Gasket Initial Gap** property. The default value is **0**. Valid entries must be greater than or equal to **0**.
4. Solve and review the gasket result. See the Gasket Results (p. 2131) section for more information.

Gasket Meshing

A Gasket body is meshed with the INTER194 elements (if using **Element Order** = **Quadratic**, in such cases a single layer of elements are generated with midside nodes on top and bottom faces, but linear edges across thickness) or INTER195 elements (if using **Element Order** = **Linear**).

Define the gasket using one of two ways:

- Body-based approach (p. 854)
- Mesh control approach (p. 856)

Body-Based Gasket Meshing

Upon setting the **Stiffness Behavior** as **Gasket**, a **Gasket Mesh Control** object is added beneath the **Body** object in the tree. The **Mesh Method** property for the object is automatically set to **Sweep** and is read-only. By default, this property instructs the application to drop mid-side nodes on gasket element edges that are parallel (Normal To) to the scoped sweep direction. You may wish to refer

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

to the Sweep Method Control section of the *Meshing User's Guide* for additional information about this property. The **Gasket Mesh Control** operates in the same fashion.

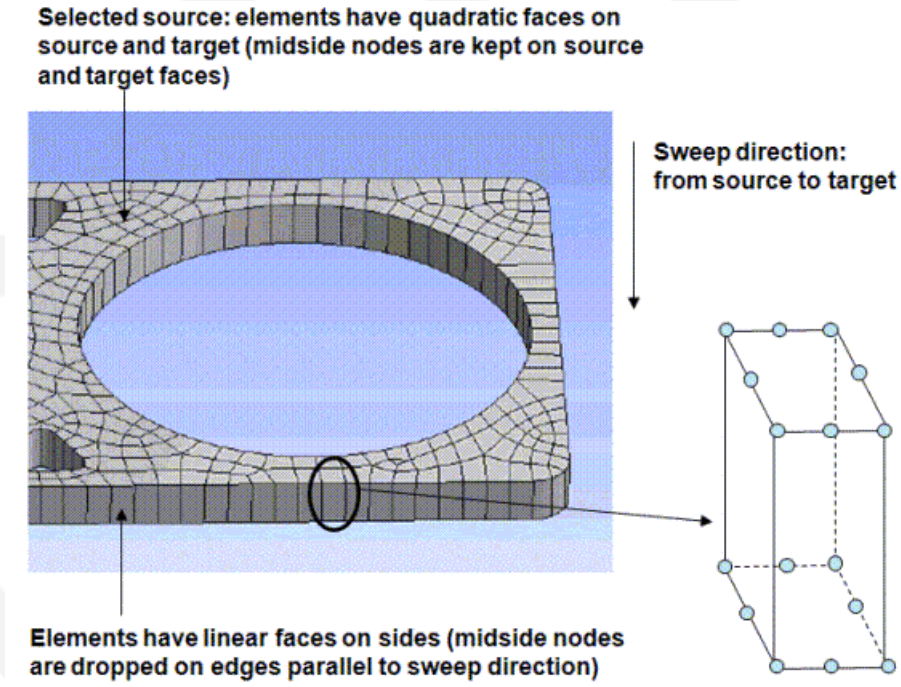
After setting the 3D **Body** object's **Stiffness Behavior** to **Gasket**:

1. If desired, you can change the setting of the **Free Face Mesh Type** property. Options include **All Quad**, **Quad/Tri** (default), or **All Tri**.
2. The **Mesh Method** is automatically set to **Sweep** and is read-only.
3. The **Element Order** property is set to **Use Global Setting** by default. This setting (as well as the **Quadratic** setting) results in quadratic elements with midside nodes to be dropped in the normal direction. When **Element Order** is set to **Linear**, the midside nodes are dropped, resulting in linear elements.
4. **Src/Trg Selection** is set to **Manual Source**. These are the default settings.
5. Select a **Source** face. The selected face must lie on the gasket body.
6. The **Target** selection is **Program Controlled** by default. If desired, you can set **Src/Trg Selection** to **Manual Source and Target**. You can then choose a **Target** face manually.

Note:

Mesh object property changes affect the state of the **Gasket Mesh Control** object.

When generating the gasket element mesh with **Element Order** set to **Quadratic**, the application drops the midside nodes on the edges that are parallel to the sweep direction. For example, consider the mesh shown below. To define the sweep method, **Src/Trg Selection** was set to **Manual Source**; one face (the "top" face) was selected for **Source**. In the resulting mesh, the gasket element faces on the source and target are quadratic, but the faces on the sides are linear.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Mesh Control for Gasket Meshing

After setting the **Stiffness Behavior** as **Flexible**, define a **Gasket** mesh control object beneath the **Mesh** object. The **MultiZone** mesh method is used for this approach. Refer to the MultiZone Method Control section of the *Meshing User's Guide* for additional information about this method.

Adjust the Details view settings for the **Gasket** mesh control object as follows:

1. Select the **Scoping Method** for choosing the gasket bodies. The options available are **Geometry Selection** (default) or **Named Selection**. Based on your selection, you need to select the desired geometry or Named Selection.
2. The **Element Order** property is set to **Use Global Setting** by default. This setting (as well as the **Quadratic** setting) results in quadratic elements with midside nodes to be dropped in the normal direction. When **Element Order** is set to **Linear**, the midside nodes are dropped, resulting in linear elements.
3. Select the **Source Scoping Method** for choosing the source faces. The options available are **Geometry Selection** (default) or **Named Selection**. Based on your selection, you need to select the desired geometry or Named Selection. The selected faces must lie on the gasket body.

   The target faces are determined automatically.
4. If desired, you can change the setting of the **Free Face Mesh Type** property. Options include **Quad/Tri** (default), **All Quad**, or **All Tri**.

   As in the example (p. 855), when generating the gasket element mesh with **Element Order** set to **Quadratic**, the midside nodes are dropped on the edges that are parallel to the sweep direction.

Tip:

The gasket mesh control in the mesh folder can be applied to multiple bodies, so if there are many gasket bodies this option may be a more convenient approach to setting up the gaskets.

Note:

If a gasket is part of multibody part and the MultiZone mesh method is defined on the connected body/bodies, the MultiZone method generates linear elements even though the element order is set to quadratic when the mesh is generated for the whole part/assembly together. This does not occur for selective meshing or if the gasket body is meshed first.

Gasket Results

Specialized results are available for analyzing gaskets. See Gasket Results (p. 2131) for details.

Stiff Beam

Supported for line bodies only, when you define a line body's **Stiffness Behavior** as **Stiff Beam**:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Only structural analyses support this feature. For example, thermal or electrical analyses are unaffected.
- The application approximates a rigid beam by making the Young's modulus *1e4* times higher than defined in the Engineering Data Workspace.
- The body must be assigned a material that is valid for Isotropic Young's Modulus.
- The application automatically specifies this option on a line body if the "RIGID" setting in SpaceClaim Direct Modeler is equal to True (this is triggered by the SpaceClaim Split Operation).
- A body specified with this option is meshed and will have results.

Integration Schemes

The **Brick Integration Scheme** property provides the options **Full** and **Reduced**. Use the **Full** setting for linear analyses or when the model has only one layer of elements in each direction. This method does not cause hourglass mode, but can cause volumetric locking in nearly incompressible cases.

In order to help prevent volumetric mesh locking in nearly incompressible cases, use the **Reduced** setting. However, hourglass mode might propagate in the model if there are not at least two layers of elements in each direction.

Important:

This property supports hexahedral elements only.

Common Geometry Display Features

This section examines the following display features of the **Geometry** object.

- Hide or Suppress Bodies (p. 857)
- Hide or Show Faces (p. 858)
- Color Coding of Parts (p. 858)

Hide or Suppress Bodies

For a quick way to hide bodies (turn body viewing off) or suppress bodies (turn body viewing off and remove the bodies from further treatment in the analysis), select the desired body objects in the tree or select the bodies in the **Geometry** window (using the **Body** selection filter (p. 261)). Then right-click and choose **Hide Body** or **Suppress Body** from the context menu. Choose **Show Body**, **Show All Bodies**, **Unsuppress Body**, or **Unsuppress All Bodies** to reverse the states.

The following options are also available:

- **Hide All Other Bodies**: show only selected bodies.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Hide** or **Show**: contains menu options to hide specific body types. Based on the body types of your model, options include: **Solid Bodies**, **Surface Bodies**, and **Line Bodies**.
- **Invert Visibility**: This option inverts the visibility of hidden bodies versus those that are visible. That is, all hidden bodies become visible and all visible bodies become hidden.
- **Suppress All Other Bodies**, allows you to unsuppress only selected bodies.

Note:

- If another model level object, such as a Remote Point, Joint, or Contact Region, is scoped to a Body that becomes Suppressed, that object also becomes suppressed until it is re-scoped or the body is Unsuppressed.
- Results from hidden bodies are used in the formulation of the maximum and minimum values in the contour legend and in the Details View.
- Results from suppressed bodies are suppressed and are **not** used in the formulation of maximum and minimum values.

Hide or Show Faces

You can hide selected faces on a model such that you are able to see inside the model. This feature is especially useful for bodies with interior cavities, such as engine blocks. To use the feature, first select faces on the model that you want to hide, then right-click anywhere in the **Geometry** window and choose **Hide Face(s)** in the context menu. This menu choice is only available if you have already selected faces.

Choose **Show Hidden Face(s)** from the context menu to restore the visibility of faces previously hidden using **Hide Face(s)**. The **Show Hidden Face(s)** menu choice is only available if there are hidden faces from choosing **Hide Face(s)**. It *cannot* be used to restore the visibility of faces previously hidden by setting **Visible** (p. 1078) to **No** in the Details view of a Named Selection object.

Note:

The selected faces will appear hidden only when you view the geometry. The feature is not applicable to mesh displays or result displays.

Color Coding of Parts

You can visually identify parts based on a property of that part. For example, if an assembly is made of parts of different materials, you can color the parts based on the material; that is, all structural steel parts have the same color, all aluminum parts have the same color and so on.

Select a color via the **Display Style** property of the **Details** view when the **Geometry** object is selected. You can specify colors based on:

- **Body Color** (default): Assigns different colors to the bodies within a part.
- **Part Color**: Assigns different colors to the different parts.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Shell Thickness** (surface bodies only): Assigns different colors based on specified body thicknesses. This coloring property does not apply to imported thicknesses or Thickness object based specifications. For those specifications, use the **Shell Thickness** display option of the Mesh object.
- **Assembly Color** (Model assembly only): Assigns a common color to the bodies of each source system (assembly).
- **Material**: The part colors are based on the material assignment. For example, in a model with five parts where three parts use structural steel and two parts use aluminum, you will see the three structural steel parts in one color and the two aluminum parts in another color. The legend will indicate the color used along with the name of the material. You can now assign colors to materials from the Outline Pane (p. 858) in the Engineering Data Workspace and have these colors display in Mechanical. For composite materials, the color assignment is program controlled.
- **Nonlinear Material Effects**: Indicates if a part includes nonlinear material effects during analysis. If you chose to exclude nonlinear material effects for some parts of a model, then the legend will indicate **Linear** for these parts and the parts will be colored accordingly.
- **Stiffness Behavior**: Identifies a part as **Flexible**, **Rigid**, or **Gasket** during analysis.
- **Body Type**: This option assigns a color based on the different types of bodies within a part, such as beam and link types within a Line Body.
- **By Cross Section** (line bodies only): The application assigns a color to a body based on its specified cross section.
- **Condensed Parts Colors** (Rigid Dynamics analysis only): the application assigns colors per condensed part.

Note:

A maximum of 15 distinct materials can be shown in the legend. If a model has more than 15 materials, coloring by material will not have any effect unless enough parts are hidden or suppressed.

You can reset the colors back to the default color scheme by right-clicking on the Geometry object in the tree and selecting **Reset Body Colors**.

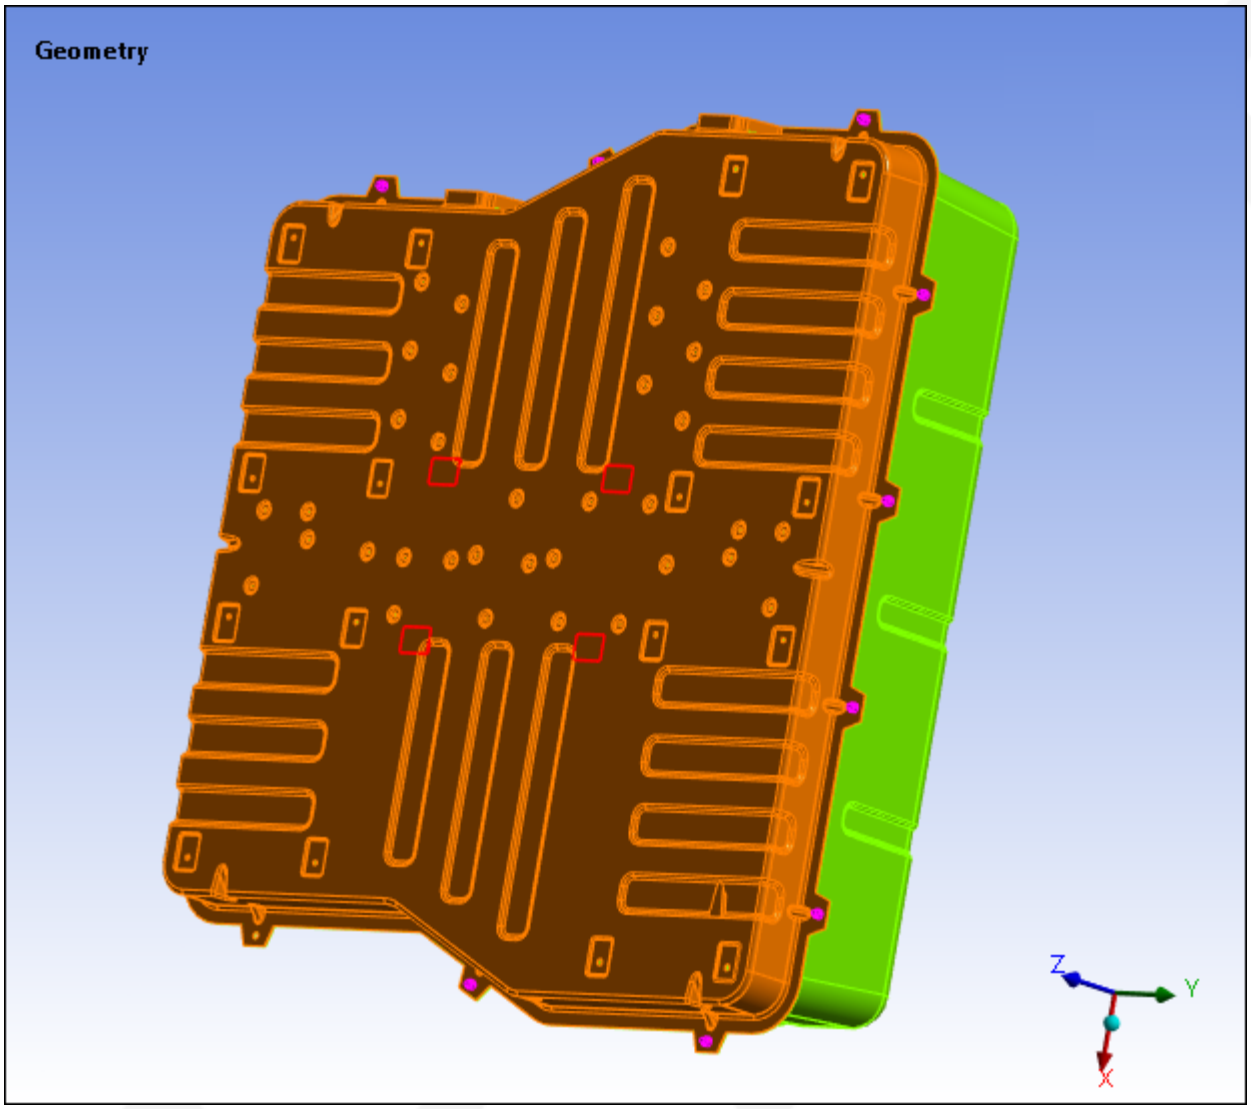
Published: 2023-10-23

Example 3: Color by Parts



Solid Bodies

You can process and solve solid models, including individual parts and assemblies. An arbitrary level of complexity is supported, given sufficient computer time and resources.

Surface Bodies

You can import surface bodies from an array of sources (see Geometry Preferences). Surface bodies are often generated by applying mid-surface extraction to a pre-existing solid. The operation abstracts away the thickness from the solid and converts it into a separate modeling input of the generated surface.

Surface body (see Body object reference section) models may be arranged into parts. Within a part there may be one or more surface bodies; these may even share the part with line bodies.

Parts that feature surface bodies may be connected with the help of spot welds and contacts.

The following topics are addressed in this section.

Preparing Assemblies of Surface Bodies
Using Thickness Mode
Importing Surface Body Models
Importing Surface Body Thickness
Understanding Surface Body Shell Offsets
Specifying Surface Body Thickness
Specifying Surface Body Layered Sections
Specifying Surface Body Reinforcements
Specifying Faces With Multiple Thicknesses and Layers

Preparing Assemblies of Surface Bodies

While preparing an assembly of surface bodies for solution you may find the need to understand and modify the connectivity of the bodies involved. Mechanical offers tools to help you accomplish these tasks. For example, you may:

- Confirm whether two surface bodies are topologically connected. This may be especially useful for surface bodies obtained from a mid-surface operation on solids and created artificial gaps in their proximity.
- Confirm the connectivity of individual elements in the mesh of the surface bodies.
- Mend missing connections between surface bodies by joining their meshes with shared nodes.

To confirm the connectivity of surface bodies it is useful to review the connectivity of their edges using a number of features in both Mechanical and DesignModeler. Edges can be classified depending on the number of faces they topologically connect. For example, the boundary edge of a surface body connects to a single face and is classified as a "single edge", whereas an interior edge connecting two faces of the surface body will be classified as a "double edge". Single and double edges can be distinguished visually using the options of the **Edge** group (p. 84) on the **Display** tab. As an alternative, you can Create a Named Selection Object (p. 1057) that groups all edges of a given topological connectivity by using the **Face Connections** (p. 1061) criterion.

Edge group (p. 84) options can also be used to review the connectivity of not only the geometry, but also the mesh elements. The same principles applied to the connectivity of a surface body edge apply to element edges.

Mechanical provides Mesh Connections to mend surface body assemblies at locations that are disjointed. With this feature, the meshes of surface bodies that may reside in different parts can be connected by joining their underlying elements via shared nodes. The Mesh Connection does not alter the geometry although the effect can be conveniently previewed and toggled using the option in the **Edge** group (p. 84).

Using Thickness Mode

You can determine the source that controls the thickness of a surface body using the **Thickness Mode** indication combined with the **Thickness** field, both located in the Details view of a surface **Body** object. Upon attaching a surface body, the **Thickness Mode** reads either **Auto** or **Manual**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- In **Auto** Mode the value of thickness for a given surface body is controlled by the CAD source. Future CAD updates will synchronize its thickness value with the value in the CAD system.
- In **Manual** mode the thickness for the surface body is controlled by the Mechanical application, so future updates from the CAD system will leave this value undisturbed.
- A **Thickness Mode** will be **Automatic** until the **Thickness** is changed to some non-zero value. Once in **Manual** mode, it can be made **Automatic** once again by changing the **Thickness** value back to zero. A subsequent CAD update will conveniently synchronize the thickness with the value in the CAD system.

Thicknesses for all surface bodies are represented in a dedicated column on the **Worksheet** that is displayed when you highlight the **Geometry** object.

Importing Surface Body Models

To import a surface body model (called a sheet body in NX), open the model in the CAD system and import the geometry as usual. If your model mixes solid bodies and surface bodies, you should select which type of entity you want to import via the **Geometry** preferences in the Workbench **Properties** of the **Geometry** cell in the **Project Schematic**. Once in the Mechanical application, you can adjust the **Geometry** preferences in the Details view (p. 119), where they take effect upon updating.

Note:

If you want to retain a preference selection in the Workbench **Properties**, you must first save before exiting the Ansys Workbench.

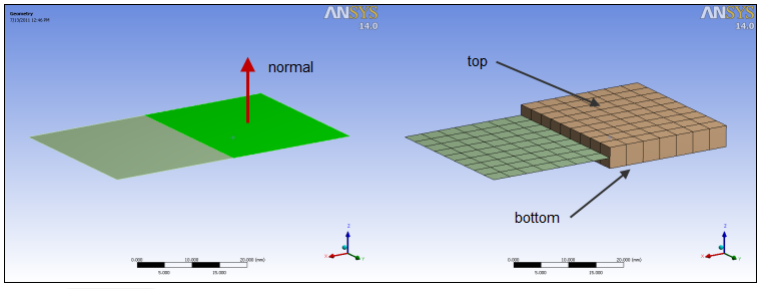
Importing Surface Body Thickness

When thickness is defined on the entire surface body

Surface body thickness will be imported from CAD (including DesignModeler) if, and only if, the existing surface body thickness value in the Mechanical application is set to 0 (zero). This is true on initial attach and if you set the surface body thickness value to zero prior to an update. This allows you the flexibility of updating surface body thickness values from CAD or not.

Understanding Surface Body Shell Offsets

Surface bodies have a normal direction, identified by a green coloring when the surface body face is selected. Shell elements have a "top" surface (farthest in the positive normal direction) and a "bottom" (farthest in the negative normal direction).

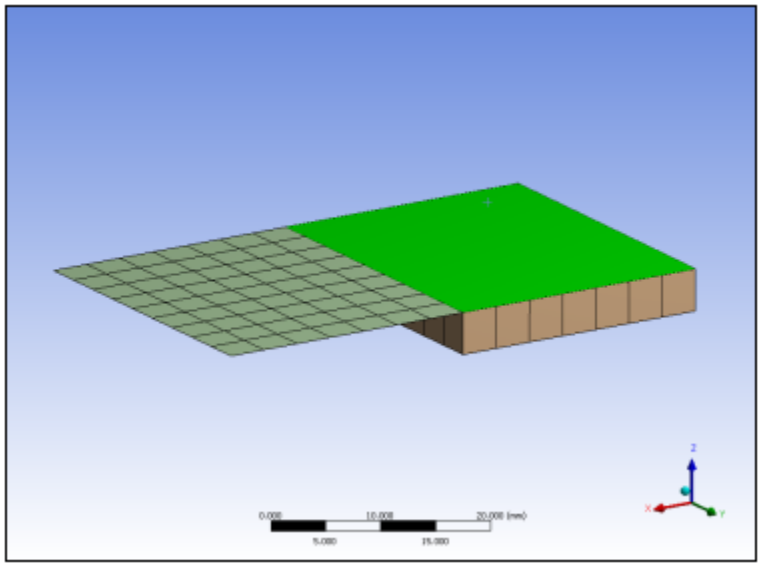


Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

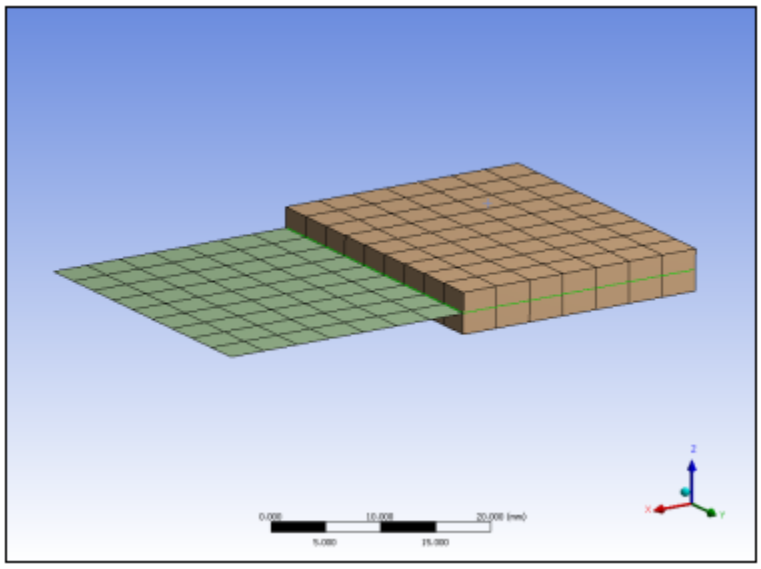
Published: 2023-10-23

By default, the shell section midsurface is aligned with the surface body, but you can use the **Offset Type** drop-down menu located in the Details view of a **Surface Body** object or an object scoped to a surface body to offset the shell section midsurface from the surface body:

- **Top** - the top of the shell section is aligned with the surface body.

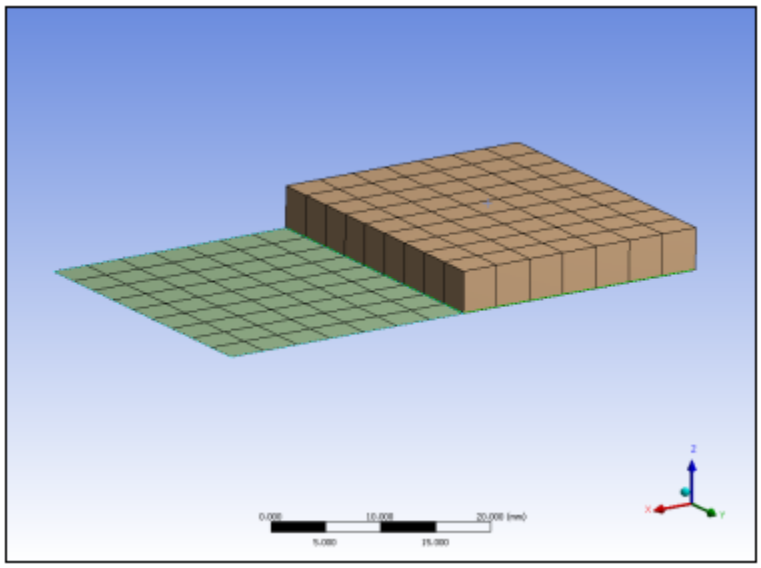


- **Middle (Membrane)** (default) - the middle of the shell section is aligned with the surface body.

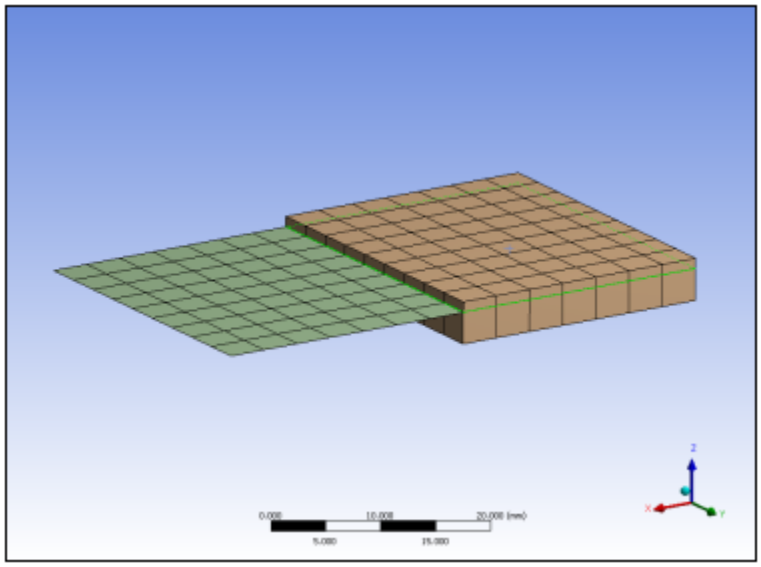


- **Bottom** - the bottom of the shell section is aligned with the surface body.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



- **User Defined** - the user defines the amount of offset (**Membrane Offset**), measured in the positive normal direction from the middle of the shell section to the surface body (may be positive or negative value).



Specifying Surface Body Thickness

The thickness of surface bodies can be defined in several ways:

1. A uniform thickness over the entire body which can be defined inside Mechanical or imported from a CAD system (p. 862). Thicknesses imported from CAD can be overridden by the Thickness Mode (p. 861)
2. A constant or spatially varying thickness applied to a selection of surfaces or bodies.
3. Thickness values imported from an upstream system.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

4. Layer information can be specified using a Layered Section (p. 868) object or imported through an Imported Plies object.

Note:

See Specifying Faces With Multiple Thicknesses and Layers (p. 871) for information on how Mechanical resolves conflicts when multiple thickness specifications are applied to the same geometry.

Application

To specify the thickness of an entire surface body:

Highlight the Surface Body object and, in the Details, enter a value in the **Thickness** property. A value greater than 0 must be present in this field.

To specify the thickness of selected faces on a surface body:

1. Highlight the **Geometry** object and insert a Thickness object from the **Geometry** Context tab or right-click and select **Insert** > **Thickness**.

Note:

The **Thickness** object overwrites any element that is scoped to the selected surfaces that has thickness greater than 0 defined in the Details of the Surface Body object (See above).

2. Scope the Thickness to a desired geometric or mesh entity. The application supports Body, Face, and Element scoping.
3. Define the thickness as a constant (default), with a table, or as a function:
   a. To define the thickness as a constant, enter the value in the **Thickness** field in the Details view.
   b. To define the thickness with a table:
      i. Click the **Thickness** property in the Details, then select **Tabular** from the flyout menu.
      ii. Set the **Independent Variable** in the Details to **X**, **Y**, or **Z**.
      iii. Select a **Coordinate System**. The **Global Coordinate System** (Cartesian) is the default.
      iv. Enter data in the **Tabular Data** window. The **Graph** window displays the variation of the thickness.
   c. To define the thickness with a function:
      i. Click the **Thickness** field in the Details, then click **Function** from the flyout menu.
      ii. Enter the function in the **Thickness** field. (Example: 45+10*x/591)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

iii. Adjust properties in the **Graph Controls** category as needed:

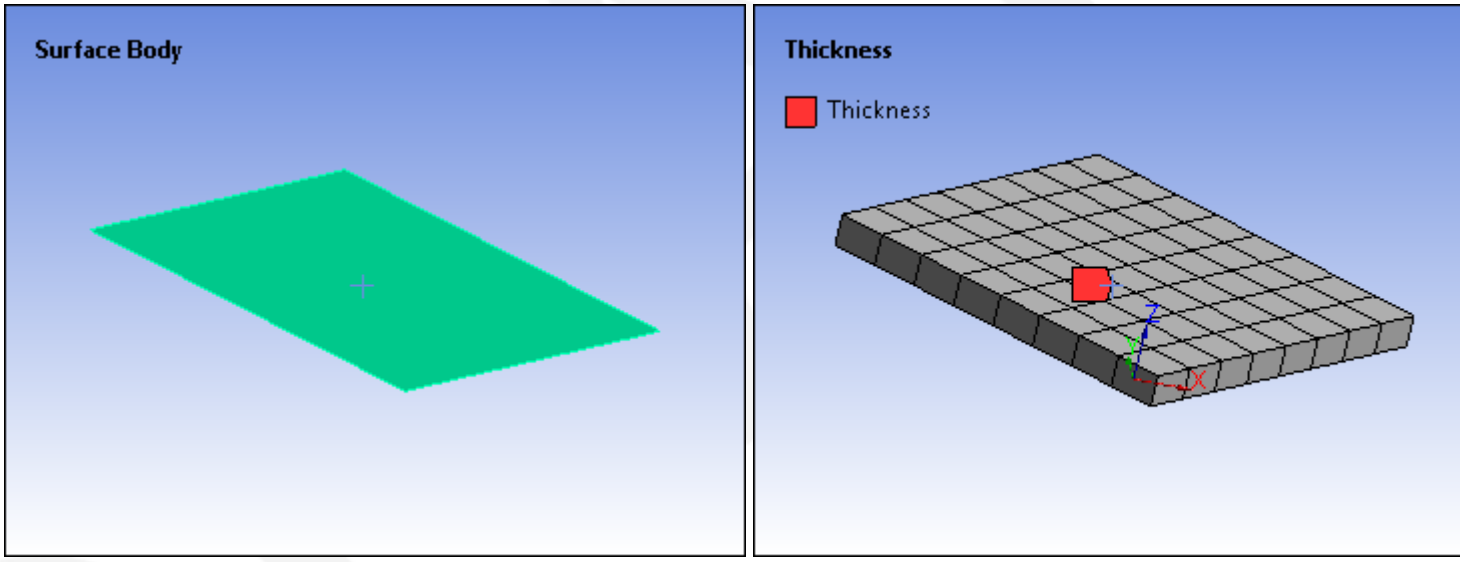
- **Number of Segments** - The function is graphed with a default value of 200 line segments. You can change this value to better visualize the function.
- **Range Minimum** - The minimum range of the graph.
- **Range Maximum** - The maximum range of the graph.

4. Set the desired shell offset (p. 862).

Review the requirements and limitations for this feature in the notes (p. 866) topic below.

Thickness Display Options

In the **Geometry** window, the application draws the thickness value you specify in the **Thickness** *property* when you 1) select the **Show Mesh** option and the **Thick Shells and Beams** option, 2) when you have the **Mesh** object selected, or 3) when you have a result selected. An example of this display is shown below. As illustrated, there is a Surface Body with no thickness and a **Thickness** object selected with a **Thickness** property value of 20mm displayed using the **Show Mesh** and **Thick Shells and Beams** options.



Important:

This display feature is not supported when you 1) scope the **Thickness** object to Elements and 2) specify the **Thickness** property using the **Tabular** or **Function** options.

Note:

- Surface body thicknesses must be greater than zero. Failures will be detected by the solver.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- When importing surfaces bodies from DesignModeler, the associated thickness is automatically included with the import. See Importing Surface Body Thickness (p. 862) for details.
- For the following, the nominal thickness of the body is used as opposed to the thickness controlled by the **Thickness** objects being added (**Thickness**, **Layered Thickness**, **Imported Layered Thickness**):
  - **Geometry**: the read-only physical properties, **Volume**, **Mass**, **Centroid**, and **Moment of Inertia** provided under the Details view **Properties** category of the Geometry object, Part object, and the Body object. The properties based on any variable thickness are correctly calculated in the solver and can be verified through miscellaneous record results for Mechanical APDL based solutions.
  - **Meshing**: during the meshing process, auto-detection based on surface body thickness, automatic pinch controls, surface body thickness used as mesh merging tolerance.
  - **Solution**: Heuristics used in beam properties for spot welds as well as moments applied to vertices.
- **Thickness** objects are not supported for rigid bodies.
- Variable thickness is displayed only for mesh and result displays. Location probes, **Path** scoped results, and **Surface** scoped results do not display nor account for variable thickness. They assume constant thickness.
- If multiple **Thickness** objects are applied to the same face, only those properties related to the last defined object will be sent to the solver, regardless of whether the object was defined in DesignModeler or in Mechanical. See Specifying Faces With Multiple Thicknesses and Layers (p. 871) for details.

You can import thicknesses from an upstream system. Basic setup steps are given below. You can find more information on mapping data in the Mechanical application in the appendix (Appendix B: Data Transfer Mapping and Validation (p. 2389)).

Note:

Thickness import is supported for 3D shell bodies or planar 2D bodies using Plane Stress. The Mechanical APDL Solver for 3D shell bodies will use the nodal thicknesses directly via the **SECFUNCTION** command. For the Explicit Solver or MAPDL solver for 2D bodies, the element's nodal thicknesses are converted to an average element thickness.

To import thicknesses from an upstream system:

1. In the project schematic, create a link between the **Solution** cell of a system and the **Model** cell of an upstream system.
2. Attach geometry to the analysis system, and then double-click **Model** cell to open Mechanical. An **Imported Thickness** folder is added under the **Geometry** folder and an imported thickness is added to the **Imported Thickness** folder, by default.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Select the appropriate options in the Details.
4. Select Imported Thickness and select **Import Thickness** from the context menu.

Specifying Surface Body Layered Sections

Layers applied to a surface body can be prescribed in several ways:

- A defined Layered Section object can be scoped to a selection of surfaces on the geometry.
- An Imported Plies object can provide layer information for the elements within a surface body.

Note:

Layered Section objects can only be used in the following analysis types:

- Explicit Dynamics
- Harmonic Response
- Eigenvalue Buckling
- Modal
- Random Vibration
- Response Spectrum
- Static Structural
- Transient Structural

The following sections describe the use of the Layered Section object.

Defining and Applying a Layered Section
Viewing Individual Layers
Layered Section Properties
Notes on Layered Section Behavior

Defining and Applying a Layered Section

1. Select the **Geometry** object in the tree and insert a **Layered Section** object from the **Geometry** Context tab or choose **Insert > Layered Section** (right-click and choose from context menu).
2. Select the **Scoping Method** that you will use:
   - Geometry Selection: Click in the **Geometry** field that appears, to enable you to pick surface bodies or individual faces from the model and select **Apply**.
   - Named Selection: Click on the **Named Selection** drop down that appears and select one of the available named selections.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

3. Choose a **Coordinate System**. You may choose any user-defined Cartesian or Cylindrical coordinate system. The Body Coordinate System option specifies that the coordinate system selected for each body will be used. There is no default.

4. Set the desired **Offset Type** (p. 862). Offset Type is not supported in Explicit Dynamics analyses.

5. Click on the arrow to the right of Worksheet in the **Layers** field then select **Worksheet** to enter the layer information for this Layered Section. The Layered Section worksheet can also be activated by the **Worksheet** option.

   The worksheet displays a header row, and two inactive rows labeled +Z and -Z to indicate the order in which the materials are layered. Layer one will always be the layer at the bottom of the stack (closest to -Z). When you insert a layer, all of the layers above it will renumber.

   To add the first layer, right-click anywhere in the Layered Section Worksheet and select **Add Layer**. Once the layer is added:

   - Click in the **Material** column of the row and select the material for that layer from the drop-down list.
   - Click in the **Thickness** column and define the thickness of that layer. Individual layers may have zero thickness, but the total layered-section thickness must be nonzero.
   - Click in the **Angle** column and define the angle of the material properties. The angle is measured in the element X-Y plane with respect to the element X axis. This value can be entered as degrees or radians, depending on how units are specified.

   To add another layer, do one of the following:

   - With no layers selected, you can right-click the header row, +Z row, or -Z row to display a context menu. Select Add Layer to Top to add a layer row at the top (+Z) of the worksheet. Select Add Layer to Bottom to add a layer row to the bottom of the worksheet (-Z).
   - With one or more layers selected, you can right-click any selected layer to display a context menu. Select Insert Layer Above (which inserts a layer row above the selected row in the +Z direction) or Insert Layer Below (which inserts a layer row below the selected row in the -Z direction).

   To delete a layer, select one or more rows, right-click any selected row, and select **Delete Layer**.

6. Select the **Nonlinear Effects** (p. 345) and **Thermal Strain Effects** (p. 346) settings in the Material category of the Details view. The reference temperature specified for the body on which a layered section is defined is used as the reference temperature for the layers.

   Nonlinear Effects and Thermal Strain Effects are not supported in Explicit Dynamics analyses.

Viewing Individual Layers

In the Graphics Properties section of the Details panel, the **Layer To Display** field allows the visualization of the thickness/offset/layer sequence of the layers composing a Layered Section object. To view a particular layer, click the field and enter the layer number. You can use the up and down buttons or enter a layer number directly. If you enter a number larger than the maximum number

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

of layers in that layered section, the value will be set to the maximum number of layers in that layered section. If layer zero is selected, all the layers will be drawn (without the delineation between layers) as a compact entity, shown the same as when the Mesh node is selected in the tree. All other geometry not scoped to the current Layered Section object is shown with thickness zero.

Individual layers will be visible only when Show Mesh is enabled (if the model has been meshed previously), and only on Layered Section objects. If Show Mesh is not enabled, just the geometry and the scoping will be shown on the model.

When a layer is selected to display, the layer with its defined thickness, offset, and sequence will be displayed in the graphics window. Due to the limitations described for the Show Mesh option, it is recommended that the user switch back and forth if needed to Wireframe/Shaded Exterior View mode to properly see annotations.

Note:

When viewing Imported Plies, the thickness that you see is not relative to the geometry like it is with a **Layered Section** object.

Layered Section Properties

The following Properties are displayed in Details panel for Layered Sections:

- **Total Thickness** - Total thickness of the section, including all of the layers defined for the section. Used when displaying the mesh.
- **Total Mass** - Total mass of all of the layers in the section. The density of the material for each layer is calculated at a reference temperature of 22° C.

Notes on Layered Section Behavior

Note:

- If multiple thickness objects (including **Layered Section** objects) are applied to the same face, only those properties related to the last defined object will be sent to the solver, regardless of whether the object was defined in DesignModeler or in Mechanical. See Specifying Faces With Multiple Thicknesses and Layers (p. 871) for details.
- If adjacent elements within the same part have different thickness values, the elements will appear to be ramped.
- Layered Sections cannot be scoped to rigid bodies.
- Layered Sections do not affect the following items:
  - Assembly properties: volume, mass, centroid, and moments of inertia. This is for display in the Details view only. The correct properties based on any variable thickness are correctly calculated in the solver and can be verified through miscellaneous record results for Mechanical APDL based solutions.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - Meshing: auto-detection based on surface body thickness, automatic pinch controls, surface body thickness used as mesh merging tolerance.
  - Solution: Heuristics used in beam properties for spot welds.
- A Thermal Condition applied to a Layered Section is only valid if applied to both shell faces (**Shell Face** is set to **Both**, not to **Top** or **Bottom**).
- Layered Sections are not valid with cyclic symmetry.
- The following material properties are supported by Layered Sections in an Explicit Dynamics analysis:
  - Isotropic Elasticity, Orthotropic Elasticity
  - Johnson Cook Strength, Zerilli Armstrong Strength, Steinberg Guinan Strength, Cowper Symonds Strength
  - Orthotropic Stress Limits, Orthotropic Strain Limits, Tsai-Wu Constants
  - Plastic Strain, Principal Stress, Stochastic Failure,
- For orthotropic materials in Explicit Dynamics, the Z material direction is always defined in the shell normal direction. The X material direction in the plane of each element is determined by the x-axis of the coordinate system associated with the Layered Section. If the x-axis of this coordinate system does not lie in the element plane, then the x-axis is projected onto the shell in the coordinate system z-axis direction. If the z-axis is normal to the element plane, then the projection is done in the coordinate system y-axis. For cylindrical systems, it is the y-axis that is projected onto the element plane to find the Y material direction.

Specifying Surface Body Reinforcements

The **Model Type** property for the Surface Body object enables you to specify the body as a reinforcement. The options for the property include **Shell** (default) and **Reinforcement**. The **Shell** setting treats the body as a surface body - there is no reinforcement treatment.

See the Reinforcement Specification Using Mesh-Independent Method (p. 775) section for the steps to specify a Surface Body as a reinforcement.

Specifying Faces With Multiple Thicknesses and Layers

Thickness and **Layered Section** (p. 868) objects may be scoped to more than one face of a surface body. As a result, a face may have more than one thickness definition.

The order of precedence used to determine the thickness that will be used in the analysis is as follows:

1. Imported Plies objects
2. Imported Thickness objects

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Layered Section objects
4. Thickness objects
5. Thickness as a property of a body/part

For multiple objects of the same type, the object lower in the tree (more recently created) will be used in the analysis.

This thickness may not be the desired thickness to be used in the analysis. In a large model, you may want to fix this problem prior to solving the model.

You can search for faces with multiple thicknesses by selecting **Search Faces with Multiple Thicknesses** from the context menu of any of the following: the **Geometry** folder, a **Body** object (individual or group of objects), a **Thickness** object or a **Layered Section** object. For each face found with multiple thicknesses, a warning message similar to the one shown below will be displayed in the message box.

This face has more than one thickness defined. You may graphically select the face via RMB on this warning in the Messages window.

To find the face and its corresponding thickness objects for a particular message, highlight that message in the message pane, right-click the message and choose **Go To Face With Multiple Thicknesses** from the context menu. The face associated with this message is highlighted in the **Geometry** window and the corresponding thickness objects are highlighted in the tree.

If there is no face with multiple definitions, the following information will be displayed in the message box.

```
No faces with multiple thicknesses have been found.
```

A related Go To (p. 110) option is also available. If you highlight one or more faces with thickness definition of a surface body, then right-click in the **Geometry** window and choose **Go To** > **Thicknesses for Selected Faces**, the corresponding thickness objects will be highlighted in the tree.

Note:

You cannot search for Imported Plies that overlap with other thickness objects. However a warning will be generated during the solution if this situation might exist.

Line Bodies

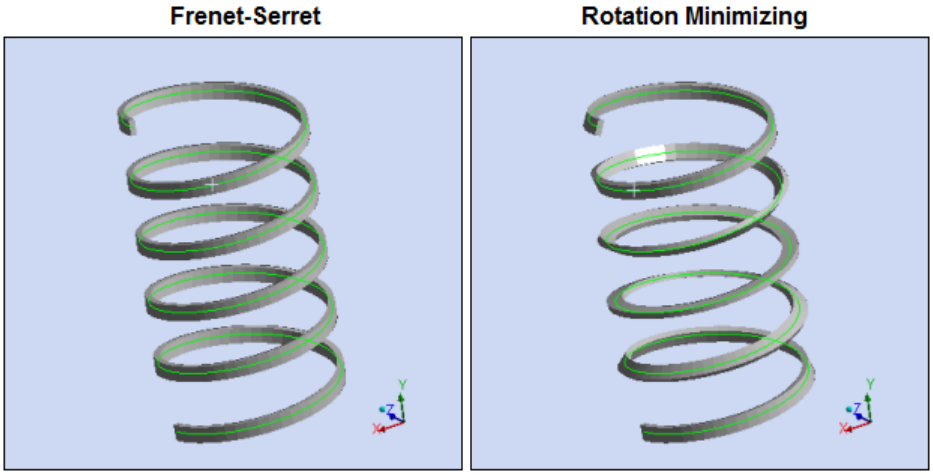
A line body consists entirely of edges and does not have a surface area or volume. Although multiple CAD sources can provide line bodies to Ansys Workbench, only DesignModeler and Ansys SpaceClaim Direct Modeler provide the additional cross section data needed to use line bodies in an analysis. For those CAD sources that cannot provide the cross section data, you need to import them into DesignModeler or Ansys SpaceClaim Direct Modeler, define the cross sections, and then send the geometry to the Mechanical application in Ansys Workbench. Cross sectional data is imported into Mechanical and provided by Cross Section Objects.

In addition to specifying the cross section type and offset, DesignModeler and SpaceClaim also allow you to align cross sections to ensure they have the proper orientation. For more information on Frame

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Alignment and how to override the default alignment algorithm, see Cross Section Alignment. Illustrated below are examples of the alignment algorithm options from DesignModeler.



Go to a section topic:

- Overview (p. 873)
- Application (p. 875)
- Thickness Display (p. 876)
- Cross Sections (p. 877)

Note:

See the Line Body Results (p. 1938) section for additional information about the display of results scoped to line bodies.

Overview

Once imported, a line body is represented by a **Line Body** object in the tree, where the **Details** pane includes the associated cross section information of the line body that was defined in SpaceClaim Direct Modeler, DesignModeler, or supported CAD system. Depending on your application, you can further define the line body using the **Model Type** property. Options include **Beam**, **Pipe**, **Link/Truss**, **Cable**, **Thermal Fluid** (thermal analysis only), **Reinforcement**, or the read-only option **Axisymmetric Shell**. Review the following guidelines:

- **Beam** (BEAM188/BEAM189): This option is usually a suitable option when analyzing thin to moderately thick beam structures. A variety of cross-sections can be associated with beams.

Note:

When a beam body is meshed with BEAM188, KEYOPT(3) = 2 (the quadratic shape function) is written to the input file. This differs from the usual default setting of BEAM188 in Mechanical APDL (KEYOPT(3) = 0, linear shape function). Note that this element is a lower order element and is only used when the Mesh object property **Element Order** is specified

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

as **Linear**, either by you as the user or by the application. See the *Mechanical APDL Element Reference* for BEAM188 for more information.

- **Pipe** (PIPE288/PIPE289/ELBOW290): This option is suitable for analyzing initially circular cross-sections and thin to moderately thick pipe walls. You can apply special loads on pipes such as Pipe Pressure (p. 1532) and Pipe Temperature (p. 1534). Curved pipe zones or high deformation zones in pipes can be further modeled using the Pipe Idealization (p. 1704) object.
- **Link/Truss** (LINK180): This option is a suitable option when analyzing uniaxial tension-compression scenarios. For stress and strain output, the Mechanical APDL solver only produces the AXL component (such as SX, EPELX, EPPLX, ...). This element type is not supported by the Beam Tool or the Beam Probe.

  Note:

  Meshing does not distinguish between the different types of 1D elements in the meshing process. Hence, beam orientation nodes are created for beam elements and Link elements even though Link elements do not need any orientation nodes. The beam orientation nodes created for the Link elements are not getting connected to the Link elements but are simply ignored during the solution process.

- **Cable** (LINK180/CABLE280): This option enables you to simulate tensile load transfer along the length of the line body. For a linear order mesh, this option uses the LINK180 element. When the **Element Order** property of the Mesh object is set to **Program Controlled** or for a quadratic order mesh, this option uses the CABLE280 element. For stress and strain output, the Mechanical APDL solver only produces the AXL component (for example, SX, EPELX, EPPLX,...). The element types do not support the **Beam Tool** or the **Beam Probe**.

  Note:

  Linear element order creates LINK180 elements with **Tension** and **Compression** setting as default TENSKEY for **SECCONTROL**.

- **Thermal Fluid**: Thermal fluid flow models heat distribution between fluid and solid bodies during steady-state and transient thermal analyses. This selection activates the Mechanical APDL element FLUID116 with **TEMP** (Temperature) as the degree of freedom. Activating Fluid Flow (via **Convection** (p. 1602)) is equivalent to a reduced-order model for a Computational Fluid Dynamic (CFD) analysis, for a one-dimensional fluid flow. This provides an accurate solution that does not require significant computation time. Heat flow is generated by the conduction within the fluid and the mass transport of the fluid (p. 1622).

  Note:

  If your analysis includes the material property **Specific Heat**, defined in Engineering Data, the **Thermal Fluid** setting only supports Specific Heat defined at Constant Pressure.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Reinforcement** (p. 775) (REINF264): This option models a line body as a reinforcement within a structure. It is supported for 3D Static Structural and Steady-State Thermal analyses only and requires that your imported model already include the line bodies you wish to specify as reinforcements as well as an appropriate material to assign to the reinforcement bodies.
- **Axisymmetric Shell** (SHELL208/SHELL209): This read-only option is **only** displayed when you create a Line Body from a Line Coating (p. 1038) using the Pull feature.

Note:

For the **Link/Truss** and **Cable** options, the application meshes the line body with only one element if the body is a line with a single edge. You can override this behavior by specifying a mesh **Sizing** control that has the **Behavior** property set to **Hard**.

Application

To define your line body, highlight the **Line Body** object and set the following in the Details view:

1. **Stiffness Behavior** (p. 343): As applicable, use this property to modify the stiffness behavior of the line body. Options include **Flexible** (default) and **Stiff Beam**.
2. **Coordinate System** (p. 343): As needed, use this property to change the assigned default coordinate system.
3. **Reference Temperature** (p. 344): As needed, use this property to change the default reference temperature that is taken from the environment.
4. **Cross Section**: Select a cross section from the drop-down list of available Cross Section Objects. This property is not visible when the **Model Type** property (below) is set to **Thermal Fluid**.
5. **Offset Mode**: Set to **Refresh on Update** (default) to enable the values in the Details view to update when the CAD system updates or to **Manual**, to enable the Details view values to override the CAD system updates.
6. **Offset Type**: Set to **Centroid**, **Shear Center**, **Origin**, or **User Defined**, where **Offset X** and **Offset Y** are available.
7. **Model Type**: Options include **Beam** (default), **Thermal Fluid** (thermal analysis only), **Pipe**, **Link/Truss**, **Cable**, or **Reinforcement**. Note the following specifics for certain options.

   Thermal Fluid

   When you select the **Thermal Fluid** option, you need to evaluate the following additional properties:

   - **Fluid Cross Area**: Defines the fluid cross-section area of the Line Body. You can modify this value, however; by default, the application uses the value provided by your geometry application. And, updating your source Geometry resets this property to the default value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **Discretization**: Options include **Upwind/Linear**, **Central/Linear**, and **Upwind/Exponential**. Refer to the Discretization scheme described in the *Mechanical APDL Element Reference* for FLUID116.

Link/Truss

When you select the **Link/Truss** option, the **Behavior** property also displays. Options include **Tension and Compression** (default), **Tension Only**, and **Compression Only**.

Reinforcement

This option enables you to specify line bodies as reinforcing fibers (p. 775) inside of a structure.

Axisymmetric Shell (Read-Only)

Only visible for a Line Body created from a Surface Coating (p. 1038). This is available using the mesh-based Pull feature. Review display characteristics in the Line Body Results (p. 1938) section.

8. **Cross Section (For Solver)**: This property displays when your Line Body includes a user-defined cross-section. It enables you to send user-defined cross-sections to the MAPDL solver as either a **Pre-Integrated** (default) cross-section or as a **Mesh** section. These options are specified in the Geometry (p. 225) preference category of the **Options** dialog.

   Selecting **Pre-Integrated** sends the integrated cross-section inertia properties, calculated in DesignModeler or Ansys SpaceClaim Direct Modeler, to the solver using the **SECTYPE**,,**BEAM**,**ASEC** command. The **Mesh** option sends the mesh section data, generated in DesignModeler or Ansys SpaceClaim Direct Modeler, to the solver using the **SECTYPE**,,**BEAM**,**MESH** command. The **Mesh** option enables you to post process results on the entire mesh section.

   Note:

   You may see slight result differences between the **Pre-integrated** and **Mesh** settings as a result of how the application performs the calculations. There are certain limitations associated with the cross-section input data when using the **Pre-integrated** setting.

9. Specify **Material** category properties as needed.

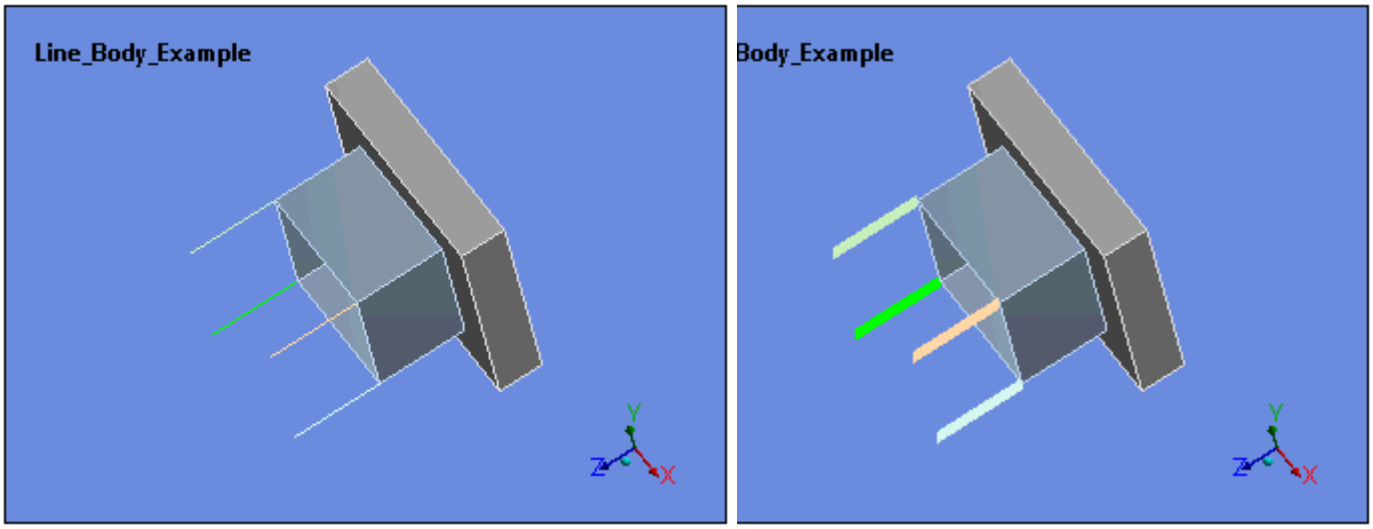
See the Body object reference section for a complete listing of all **Line Body** properties.

Thickness Display

As illustrated below, you can increase the thickness of a line body's graphical display in the **Geometry** window by changing the default setting of the **Line Body Thickness** property in the **Graphics** (p. 228) preference of the application **Options**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



- Beams can also be used as connections within a model. See Beam Connections (p. 1404) for further information on this application.
- Pipes are only realized in structural analyses. All line bodies defined in other analysis types are always realized as beams. This extends to linked analyses as well. For example, in a thermal-structural linked analysis where line bodies are defined as pipes, the thermal component of the analysis will only realize the line bodies as beams.

Cross Sections

By default, line bodies are displayed as lines in the **Geometry** window, with no graphical indication of a cross section. If cross sections are defined in a line body, you can select the **Cross Section** option from the **Style** (p. 80) group of the **Display** tab to display the line bodies as solids (3D), enabling you to visually inspect the cross sections. This visualization can be useful in determining the correct orientation of line bodies. For circular and circular tube cross sections, the number of divisions used for rendering the line bodies as solids has an adjustable range from 6 to 360 with a default of 16. You can adjust this using the **Number of Circular Cross Section Divisions** option in the **Graphics** (p. 228) category of the **Options** dialog.

The **Cross Section** display option has the following characteristics:

- By default, the feature is not enabled. However, when activated, it will persist as a session preference.
- Only geometry displays are applicable. The feature is not available for mesh displays.
- When the feature is enabled, both normal lines and solid representations are drawn.
- The solid representation of the geometry cannot be selected nor meshed, and has no effect on quantitative results.
- The feature supports section planes and works with all line body cross sections (primitive and user defined).
- User Integrated cross sections (direct entry of the properties) have no display.
- The feature is not available for use with viewports (p. 284).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- This feature is not supported on the Linux platform.
- When you import geometry from an External Model system, geometric edges may be collapsed and not display the actual orientations that are specified in the external model file.

Tip:

Use the **Show Mesh** (p. 97) option to visualize the proper orientations as defined in the file. These are the orientations that the application sends to the solver.

Simulation without Geometry

The application does not require you to import a geometry for your analysis. You can open an analysis system without importing a geometry and then specify all of your desired environmental conditions. Once complete, you save your project for use with any desired model. See the Create a Simulation Template (p. 346) section for additional information.

2D Analyses

Mechanical enables you to run two-dimensional (2D) simulations for structural and thermal analyses. Two-dimensional simulations can save processing time and conserve machine resources for models and environments that involve negligible effects from a third dimension. You specify your analysis as two-dimensional on the Workbench project page (**Analysis Type** property for the **Geometry** cell set to **2D**). However, as desired, you can change the setting of the Analysis Type property to switch your analysis to 3D at any time.

Important:

- Switching your analysis from 2D to 3D (or vise versa) could invalidate certain specifications you have defined in your analysis. Specifically, if you have defined parameters, they may become invalid and although it would display in the Parameter Manager, it would not be available in Mechanical.
- When you are performing a 3D simulation on shell bodies (only), you can specify a shell body as 2D using the **Dimension** property of the Body object.
- For a line body in a 2D thermal analysis, you can set the **Model Type** property to **Thermal Fluid**.

Go to a section topic:

- Specify 2D Analysis in Workbench (p. 879)
- Define the 2D Behavior of Geometry (p. 879)
- Review Requirements and Limitations (p. 880)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Specify 2D Analysis in Workbench

For a 2D analysis, Mechanical supports surface (p. 860) and line (p. 872) bodies that are planar bodies on the X-Y plane. To create a 2D analysis:

1. Add an analysis to the Workbench Project page
2. Open your model in the appropriate Ansys application, such as Discovery, or another supported CAD system, and specify that the model's orientation is in the x-y plane.
3. On the project page, select the **Geometry** cell of the analysis system and set the **Analysis Type** property to **2D** (Advanced Geometry Options).
4. Open the model in Mechanical.

Define the 2D Behavior of Geometry

Specify the **2D Behavior** property of the Geometry object. Options include:

- **Plane Stress** (default): Assumes zero stress and non-zero strain in the z direction. Use this option for structures where the z dimension is smaller than the x and y dimensions. Example uses are flat plates subjected to in-plane loading, or thin disks under pressure or centrifugal loading. A **Thickness** field is also available if you want to enter the thickness of the model.
- **Axisymmetric**: Assumes that a 3D model and its loading can be generated by revolving a 2D section 360^{o} about the y-axis. The axis of symmetry must coincide with the global y-axis. The geometry must lie on the positive x-axis of the x-y plane. The y direction is axial, the x direction is radial, and the z direction is in the circumferential (hoop) direction. The hoop displacement is zero. Hoop strains and stresses are usually very significant. Example uses are pressure vessels, straight pipes, and shafts. You may wish to review the Axisymmetric Loads and Reactions section, of the *Mechanical APDL Basic Analysis Guide*, for a description about how to apply constraints in order to prevent unwanted rigid-body motions.

  Note:

  Certain CAD applications automatically increase the bounding box size beyond the exact limits of the geometry and can cause the geometry to appear in the negative X plane. This causes Mechanical to generate an error and prohibit a solution. In this scenario, you can change the error setting to a warning in order to perform a solution. You use the **Geometry** (p. 225) preference **2D Axisymmetric Check** in the **Options** dialog to change this setting.

- **Plane Strain**: Assumes zero strain in the z direction. Use this option for structures where the z dimension is much larger than the x and y dimensions. The stress in the z direction is non-zero. Example

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

uses are long, constant, cross-sectional structures such as structural line bodies. **Plane Strain** behavior cannot be used in a thermal analysis (steady-state (p. 657) or a transient (p. 680)).

Note:

Since thickness is infinite in plane strain calculations, different results (displacements/stresses) will be calculated for extensive loads (that is, forces/heats) if the solution is performed in different unit systems (MKS vs. NMM). Intensive loads (pressure, heat flux) will not give different results. In either case, equilibrium is maintained and thus reactions will not change. This is an expected consequence of applying extensive loads in a plane strain analysis. In such a condition, if you change the Mechanical application unit system after a solve, you should clear the result (p. 1981) and solve again.

- **Generalized Plane Strain**: Assumes a finite deformation domain length in the z direction, as opposed to the infinite value assumed for the standard **Plane Strain** option. **Generalized Plane Strain** provides more practical results for deformation problems where a z direction dimension exists, but is not considerable. See the next section, Using Generalized Plane Strain (p. 881), for more information.

  The **Generalized Plane Strain** option requires you to specify the following properties:

  – **Fiber Length**: Sets the length of the extrusion.

  – **End Plane Rotation About X**: Sets the rotation of the extrusion end plane about the x-axis.

  – **End Plane Rotation About Y**: Sets the rotation of the extrusion end plane about the y-axis.

- **By Body**: Enables you to set the **Plane Stress** (with **Thickness** option), **Plane Strain**, or **Axisymmetric** options for individual bodies that appear under **Geometry** in the tree. If you choose **By Body**, then click an individual body, these 2D options are displayed for the individual body.

Review Requirements and Limitations

Requirements for Specifying Boundary Conditions

For a 2D analysis, you use the same procedure for applying loads and supports (p. 1497) as you would use in a 3D analysis. However, the loads and results are in the x-y plane and there is no z component. All loads and supports, except the following:

- Line Pressure
- Simply Supported
- Fixed Rotation

Important:

When your 2D analysis includes any of the following boundary conditions, the results may not be accurate in certain cases where more than one element type has already been created on the scoped surface.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Hydrostatic Pressure
- Force (Applied By property set to Surface Effect)
- Pressure (Applied By property set to Surface Effect)
- Bearing Loads
- Elastic Support
- Heat flux
- Radiation
- Convection

Please review the output file carefully for related messages before looking at the results. See the SURF151 and SURF153 sections in the Mechanical APDL Element Reference for more information.

General Limitations

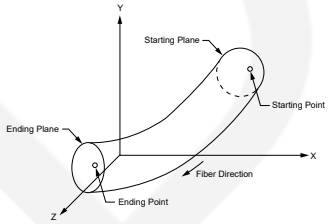
Note the following limitations:

- A Pressure load can only be applied to an edge.
- A Bearing Load and a Cylindrical Support can only be applied to a circular edge.
- For analyses involving axisymmetric behavior, Rotational Velocity loads can only be applied about the y-axis.
- For loads applied to a circular edge, the direction flipping in the z axis will be ignored.
- Only Plain Strain and Axisymmetric are supported for Explicit Dynamics analyses.
- Mechanical does not support Cyclic results for a 2D Analysis.

Using Generalized Plane Strain

This feature assumes a finite deformation domain length in the z direction, as opposed to the infinite value assumed for standard plane strain. It provides a more efficient way to simulate certain 3D deformations using 2D options.

The deformation domain or structure is formed by extruding a plane area along a curve with a constant curvature, as shown below.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

The extruding begins at the starting (or reference) plane and stops at the ending plane. The curve direction along the extrusion path is called the fiber direction. The starting and ending planes must be perpendicular to this fiber direction at the beginning and ending intersections. If the boundary conditions and loads in the fiber direction do not change over the course of the curve, and if the starting plane and ending plane remain perpendicular to the fiber direction during deformation, then the amount of deformation of all cross sections will be identical throughout the curve, and will not vary at any curve position in the fiber direction. Therefore, any deformation can be represented by the deformation on the starting plane, and the 3D deformation can be simulated by solving the deformation problem on the starting plane. The **Plane Strain** and **Axisymmetric** options are particular cases of the **Generalized Plane Strain** option.

All inputs and outputs are in the global Cartesian coordinate system. The starting plane must be the x-y plane, and must be meshed. The applied nodal force on the starting plane is the total force along the fiber length. The geometry in the fiber direction is specified by the rotation about the x-axis and y-axis of the ending plane, and the fiber length passing through a user-specified point on the starting plane called the starting or reference point. The starting point creates an ending point on the ending plane through the extrusion process. The boundary conditions and loads in the fiber direction are specified by applying displacements or forces at the ending point.

The fiber length change is positive when the fiber length increases. The sign of the rotation angle or angle change is determined by how the fiber length changes when the coordinates of the ending point change. If the fiber length decreases when the x coordinate of the ending point increases, the rotation angle about y is positive. If the fiber length increases when the y coordinate of the ending point increases, the rotation angle about x is positive.

For Eigenvalue Buckling (p. 487) and Modal (p. 515) analyses, the **Generalized Plane Strain** option usually reports fewer Eigenvalues and Eigenvectors than you would obtain in a 3D analysis. Because it reports only homogeneous deformation in the fiber direction, generalized plane strain employs only three DOFs to account for these deformations. The same 3D analysis would incorporate many more DOFs in the fiber direction.

Because the mass matrix terms relating to DOFs in the fiber direction are approximated for Modal and Transient analyses, you cannot use the lumped mass matrix for these types of simulations, and the solution may be slightly different from regular 3D simulations when any of the three designated DOFs is not restrained.

Overall steps to using Generalized Plane Strain

1. Attach a 2D model in the Mechanical application.
2. Click on **Geometry** in the tree.
3. In the Details view, set **2D Behavior** to **Generalized Plane Strain**.
4. Define extrusion geometry by providing input values for **Fiber Length**, **End Plane Rotation About X**, and **End Plane Rotation About Y**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

5. Add a **Generalized Plane Strain** load (p. 1582) under the analysis type object in the tree.

   Note:

   The **Generalized Plane Strain** load is applied to all bodies. There can be only one **Generalized Plane Strain** load per analysis type so this load will not be available in any of the load drop-down menu lists if it has already been applied.

6. In the Details view, input the x and y coordinates of the reference point, and set the boundary conditions along the fiber direction and rotation about the x and y-axis.
7. Add any other loads or boundary conditions that are applicable to a 2D model.
8. Solve. Reactions (p. 2107) are reported in the Details view of the **Generalized Plane Strain** load.
9. Review results.

Construction Geometry

The **Construction Geometry** object is a **Model**-level object in the Outline hierarchy. The **Construction Geometry** drop-down menu in the **Prepare** group of the **Model Context** tab enables you to insert a desired **Construction Geometry** type, including:

Path

Surface

Solid

STL

Construction Line

Note:

The **Path** and **Surface** construction geometry features enable you to create a specific geometry scoping (curve or plane) and then use this scoping to specifically define a result item.

Path

A **Path** is categorized as a form of construction geometry and is represented as a spatial curve to which you can scope path results (p. 1940). The results are evaluated at discrete points along this curve.

You defined a **Path** using the following methods:

By Start and End Point

These points can be specified directly or can be calculated from the entry and exit point (intersections) of the positive X-axis of a coordinate system through a mesh. The path may be a straight line segment or a curve depending on the type of coordinate system (Cartesian or Cylindrical).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

You can control the discretization by specifying the number of sampling points, and these will be evenly distributed along the path up to a limit of 200.

Note:

Paths defined in this manner will only be mapped onto solid or surface bodies. If you wish to apply a path to a line body you must define the path by an edge (as described below).

Edge

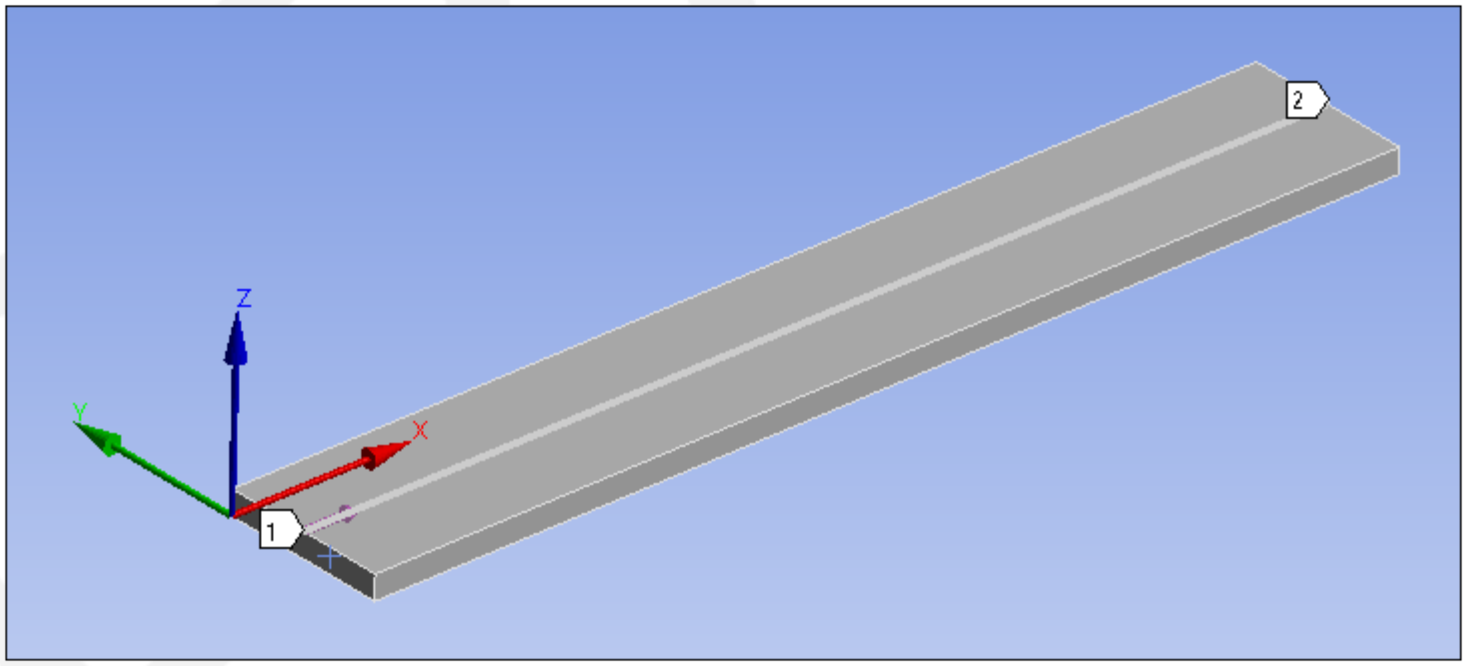
The discretization will include all nodes in the mesh underlying the edge. Multiple edges may be used but they must be continuous.

Result Graphical Display

For each result scoped to a **Path**, the **Graph Controls** category provides an option to display the result in the **Graph** on **X-axis**, as a function of **Time** or with **S**, the length of the path. Note that Path results have the following restrictions:

- They are calculated on solids and surfaces but not on lines.
- They can be collected into charts as long as all of the other objects selected for the chart have the same **X-axis** (**Time** or **S**).
- You can define a path in the geometry by specifying two points, an edge, or an axis. Before you define a path, you must first add the **Path** object from the **Construction Geometry** context toolbar.

You can then define the path using any of the methods presented below.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Application

There are a number of methods to define a **Path**, including:

- Defining a Path using Two Points (p. 885)
- Defining a Path using an Edge (p. 886)
- Defining a Path from Results Scoped to Edges (p. 886)
- Defining a Path using X-axis Intersection (p. 886)
- Defining a Path from Probe Labels (p. 887)

Additional options for this feature include:

- Snap to Mesh Nodes (p. 888)
- Exporting Path Data (p. 890)

Defining a Path using Two Points

Using this method you define the path by specifying two points in any of the following ways:

Define path using the Hit Point Coordinate option:

1. In the Details, select **Two Points** in the **Path Type** list.
2. Under **Start**, choose **Click to Change** in the **Location** row.
3. Select the **Hit Point Coordinate** option on the Graphics Toolbar (p. 97).

   As you move the cursor across the model, the coordinates display and update as you reposition the cursor.
4. Click at the desired start location for the path. A small cross hair appears at this location. You can click again to change the cross hair location.
5. Click **Apply**. A "1" symbol displays at the start location. Also, the coordinates of the point display in the Details view. You can change the location by repositioning the cursor, clicking at the new location, and then clicking **Click to Change** and **Apply**, or by editing the coordinates in the Details view.
6. Repeat steps 2 through 5 to define the end point of the path under **End** in the Details view. A "2" symbol displays at the end location.
7. Enter the **Number of Sampling Points**.

Define path using coordinates:

1. In the Details view, select **Two Points** in the **Path Type** list.
2. Under **Start**, enter the X, Y, and Z coordinates for the starting point of the path.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

3. Under **End**, enter the X, Y, and Z coordinates for the ending point of the path.
4. Enter the **Number of Sampling Points**.

Define Path using vertices, edges, faces, or nodes:

1. In the Details view, select **Two Points** in the **Path Type** list.
2. Select one or more vertices or nodes, a single edge, or a face where you want to start the path, and then click **Apply** under **Start**, **Location**. An average location is calculated for multiple vertex or node selections.
3. Select the vertices, nodes, face, or the edge where you want to end the path, and then click **Apply** under **End**, **Location**.
4. Enter the **Number of Sampling Points**.

Note:

The start and end points need not both be specified using the same procedure of the three presented above. For example, if you specify the start point using the **Coordinate** toolbar button, you can specify the end point by entering coordinates or by using a vertex, edge, or face. Any combination of the three procedures can be used to specify the points.

Defining a Path using an Edge

This method helps you define a path by selecting an edge. To define a path:

1. In the Details view, select **Edge** in the **Path Type** list.
2. Specify an edge geometry using **Geometry Selection** or by specifying an edge-based **Named Selection**.

Defining a Path from Results Scoped to Edges

In order to help better quantify the variation of a result along a set of edges, path results are available. For a result that is scoped to an edge or multiple contiguous edges, you can convert the scoping to the equivalent **Path**, by:

1. Selecting the result object that is scoped to an edge or contiguous edges.
2. Display the context menu by right-clicking the mouse, and the select **Convert To Path Result**.

A **Path** object is automatically created under the Construction Geometry folder and the **Path Type** property is set to **Edge**.

Defining a Path using X Axis Intersection

For this option, the application automatically creates the path on the first body the line intersects from the coordinate system origin, as illustrated below. A line is extended along the positive X axis

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

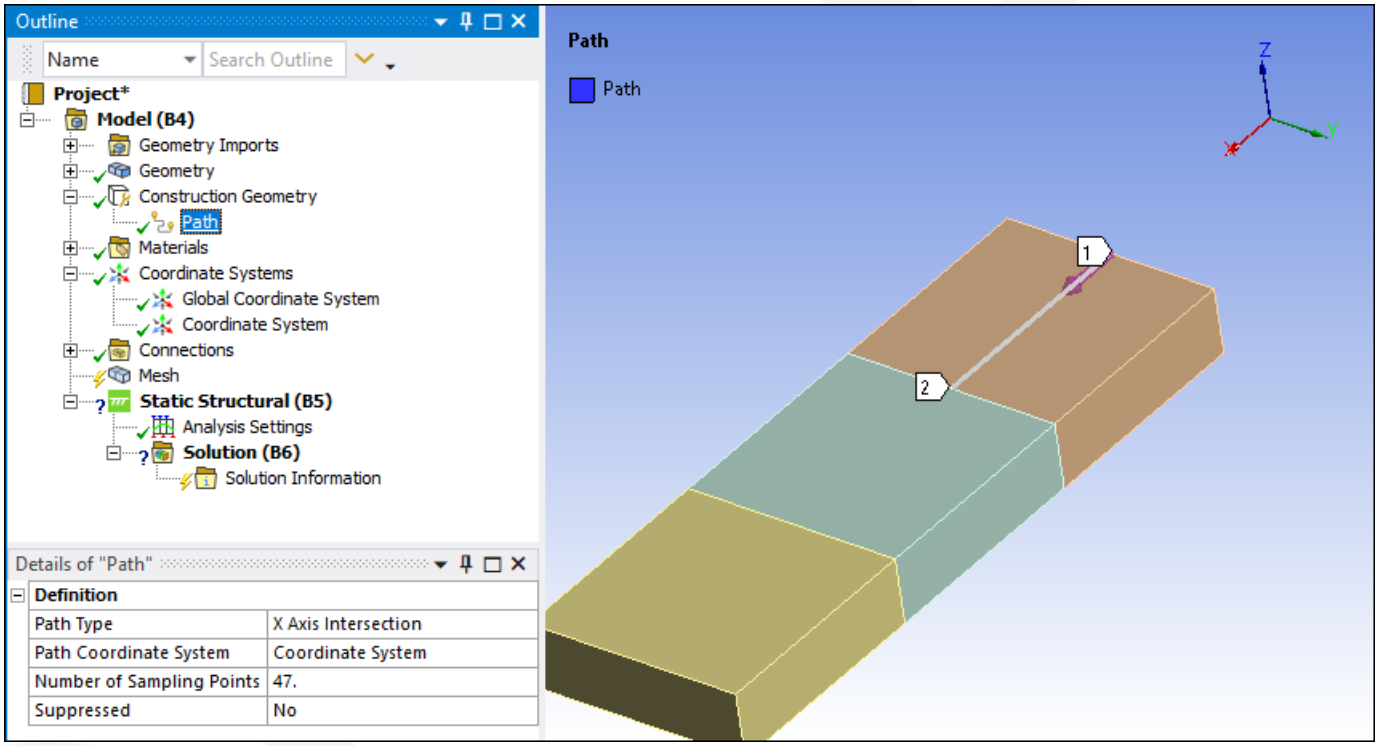
Published: 2023-10-23

of the selected coordinate system, and the path is created between the first and last points where this line intersects the first body. To create this Path:

Important:

When you specify a **Path** as the scoping for a result (p. 1940), the application re-calculates the path using the mesh instead of geometry. As a result, the locations of path points may vary slightly.

1. Set the **Path Type** property to **X Axis Intersection**.
2. Select the desired coordinate system that defines the x-axis using the **Path Coordinate System** property.
3. Specify the **Number of Sampling Points**. The default is value is **47**.



Defining a Path from Probe Labels

While reviewing results, you can define a path automatically from two probe labels. To define the path:

1. Create two probe annotations (p. 207) by choosing the **Probe** button from the Result Context Tab (p. 62).
2. Choose the **Label or Imported Objects** button from the Graphics Toolbar (p. 97) and select the two probe annotations. (Hold the **Ctrl** key to select both probe annotations.)
3. Right-click in the **Geometry** window and choose **Create Path From Probe Labels** from the context menu.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

4. A path is automatically created between the probe annotations. A corresponding **Path** object is displayed in the tree with a **Path Type** of **Two Points**.

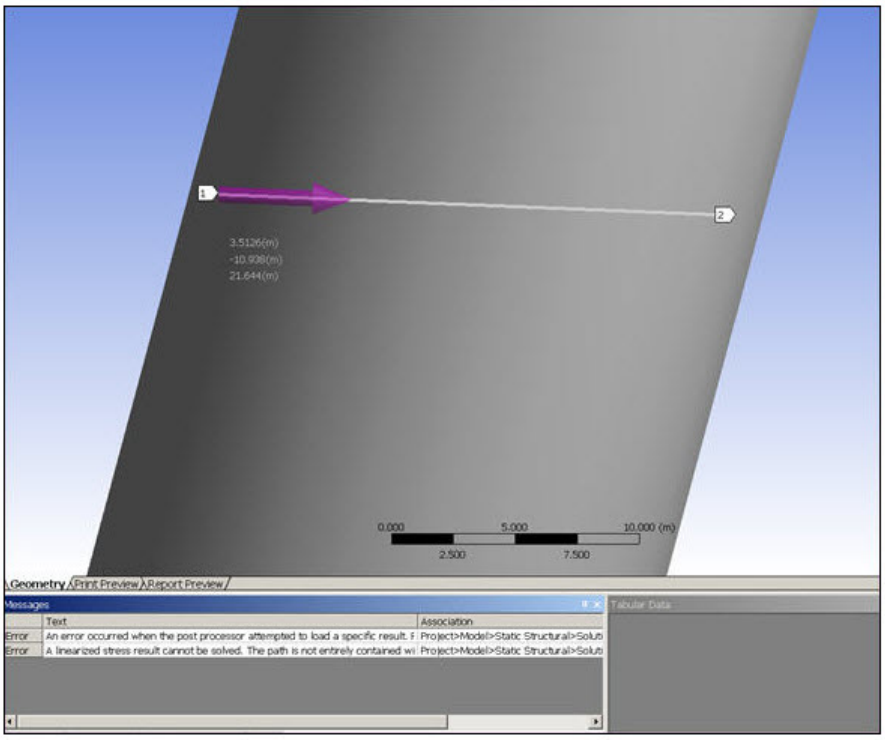
Snap to Mesh Nodes

When solving linearized stresses (p. 2041), the path you define by two points must be contained within the finite element mesh to avoid an error. Because the two points can be derived from the tessellation of the geometric model, the points may be contained within the geometry but may not be contained within the mesh. This is especially true for curved geometry faces. After defining the two points using the **Coordinate** toolbar button method (see above), you can ensure that the path is contained within the mesh by using the **Snap to mesh nodes** feature. To use the feature, set **Show Mesh** to **Yes** in the Details view of the **Construction Geometry** object in order to see the location of the nodes in the mesh. Then, right-click the **Path** object and select **Snap to mesh nodes** from the context menu. This action alters the path, as necessary, such that both the start point and end point of the path snap to the closest node in the mesh.

The **Snap to mesh nodes** feature avoids the error and allows the solve to continue provided the path you define does not traverse through any discontinuities in the model, such as a hole. For these cases, even though the **Snap to mesh nodes** feature alters the path endpoints to coincide with the nearest nodes in the mesh, the linearized stress result still fails because the path is defined through the discontinuity.

The following pictures illustrate this feature.

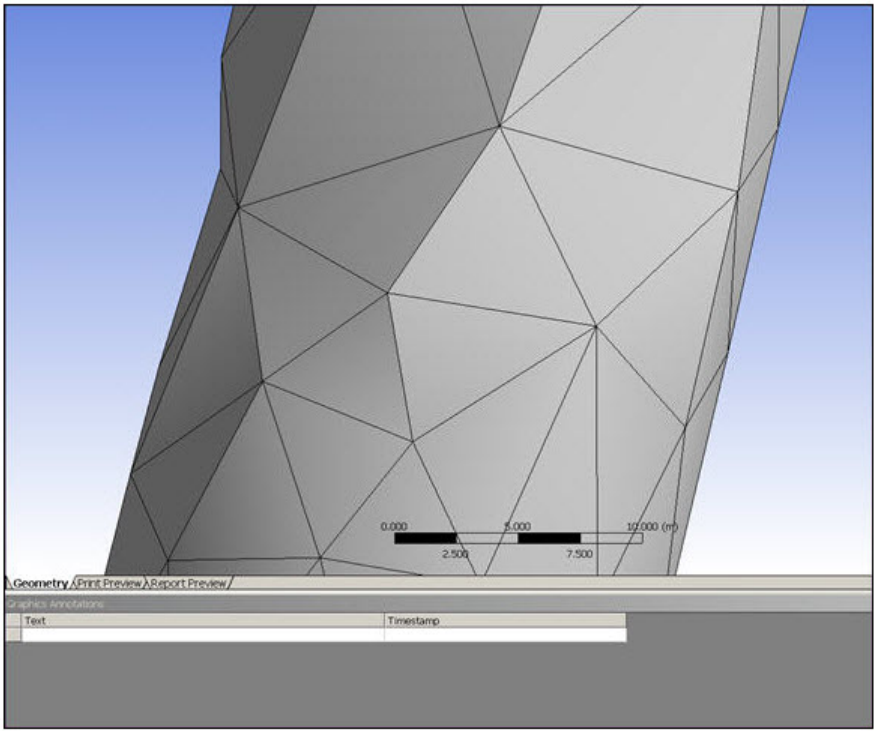
Attempt to solve for linearized stress. Path defined within geometric model:



*Corresponding mesh used for geometric model, obtained by setting **Show Mesh** to **Yes**:*

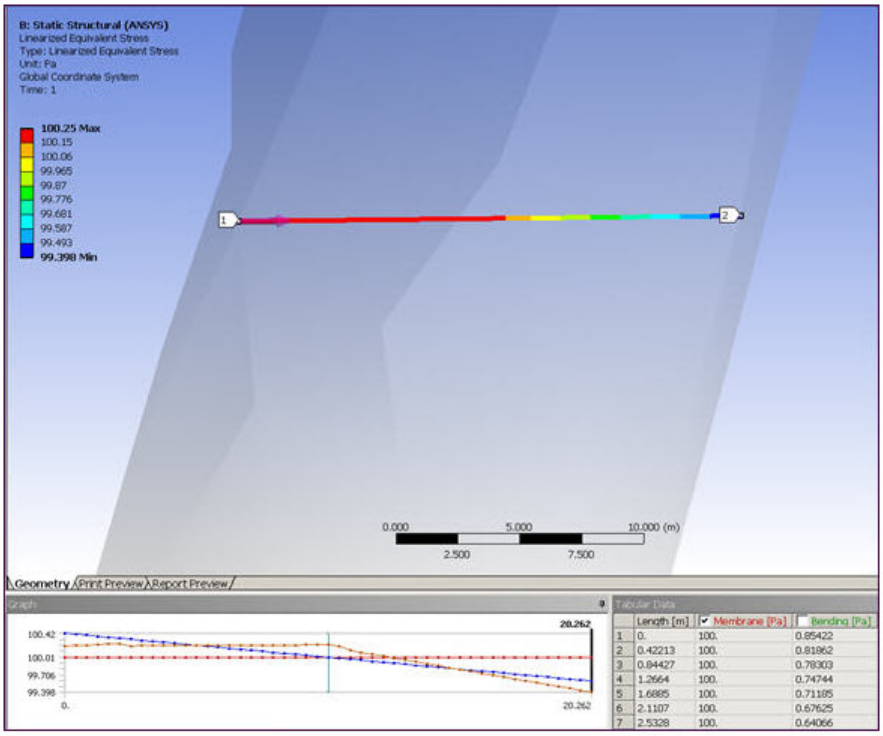
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



*Path contained within mesh after choosing **Snap to mesh nodes**. Solution completes:*

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Note:

If the model is re-meshed after choosing **Snap to mesh nodes**, the feature is not automatically applied to the newly meshed model. You must choose **Snap to mesh nodes** again to alter the path start and end points to the new mesh.

Exporting Path Data

You can export coordinate data for a defined path by clicking the right mouse button on a **Path** object and choosing **Export** from the context menu.

Surface

A surface is categorized as a form of construction geometry and is represented as a section plane to which you can scope surface results (p. 1959) or reaction probes (p. 2107).

To define a surface:

1. Highlight the **Model** object, open the **Construction Geometry** drop-down menu on the **Model** Context Tab (p. 48), and select **Surface**.
2. Define a coordinate system whose X-Y plane will be used as a cutting plane, as follows:
   a. Create a local coordinate system (p. 1192).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

b. Define the origin (p. 1192) of the local coordinate system.

Note:

With respect to the facets of the surface:

- For a Cartesian coordinate system, the surface is the intersection of the model with the X-Y plane of the coordinate system.
- For a cylindrical coordinate system, the surface is the intersection of the model with the cylinder whose axis is the Z axis of the coordinate system. In this case, you must specify the radius in the Details view of the **Surface** object.

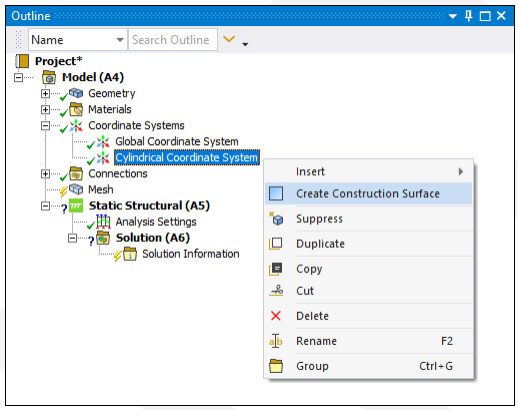
Tip:

For an existing coordinate system, you can define a **Surface** Construction Geometry object by selecting a desired Coordinate System object, right-clicking, and selecting **Create Construction Surface**. This feature allows you to define the coordinate system first. See the procedure below.

Create Construction Geometry Surface from Coordinate System

As illustrated below, you can create a **Surface Construction Geometry** from any existing coordinate system using the right-click feature **Create Construction Surface**.

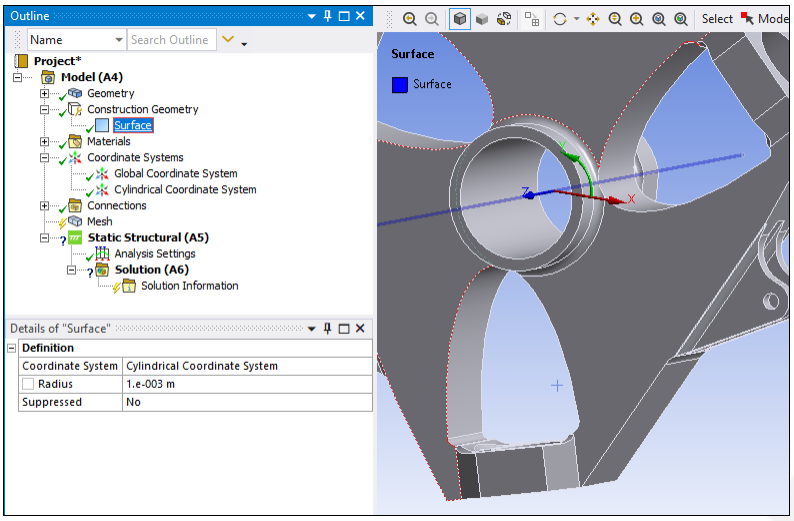
Right-click Menu for



Details for Surface Object

The **Details** display the defined coordinate system, Radius, and enables you to suppress the object if desired.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Solid

The **Solid** option of the Construction Geometry feature enables you to create and add a solid part to the model you have imported into Mechanical.

To define a **Solid** Construction Geometry:

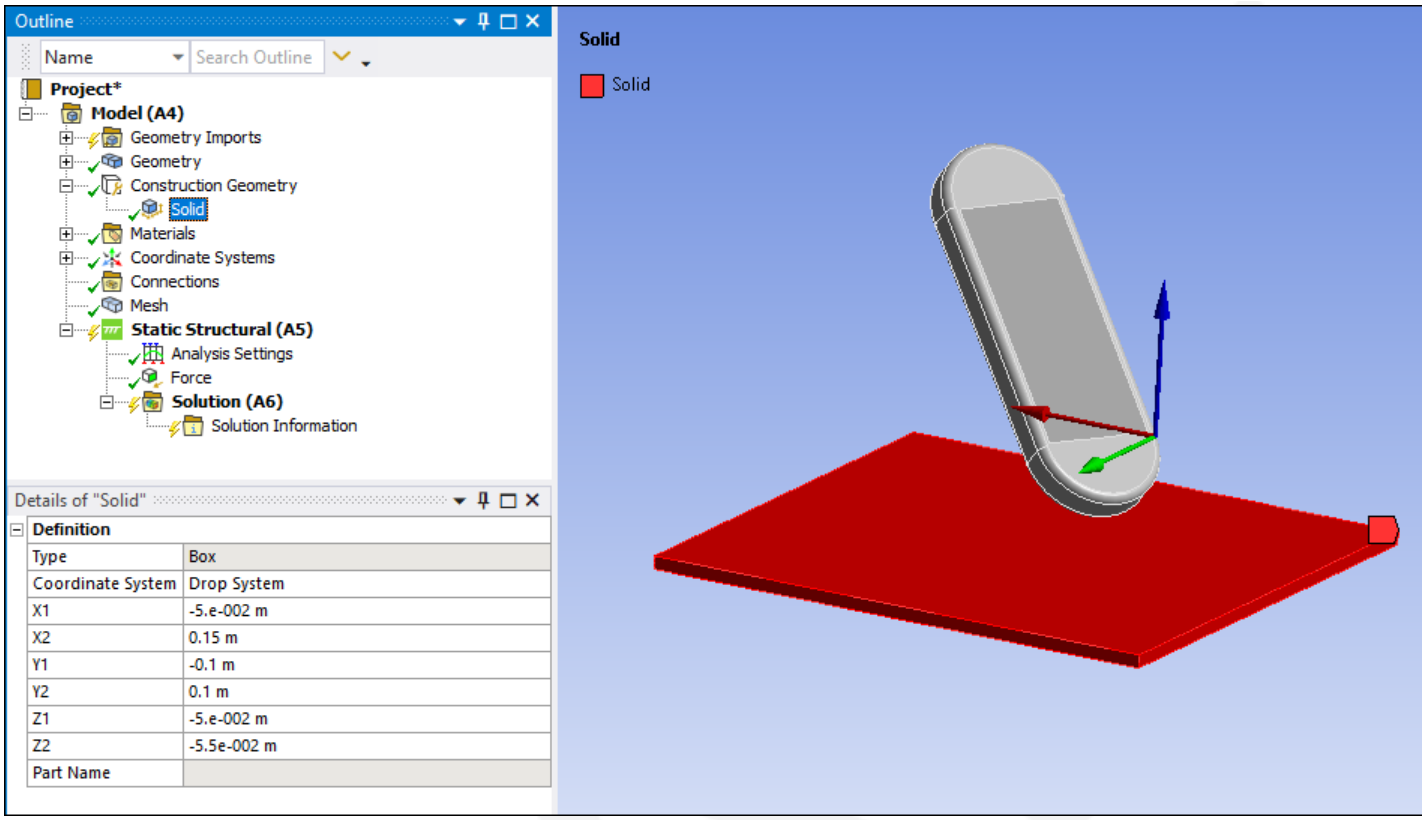
1. Highlight the **Model** object, open the **Construction Geometry** drop-down menu on the **Model** Context Tab (p. 48), and select **Solid**.

2. As needed, specify a coordinate system. The default is the **Global Coordinate System**.

3. Specify the dimensions of the solid part using the **X1** through **Z2** properties. These properties define the start point and the end point for each dimension. The application displays a frame of your geometry as you enter values.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

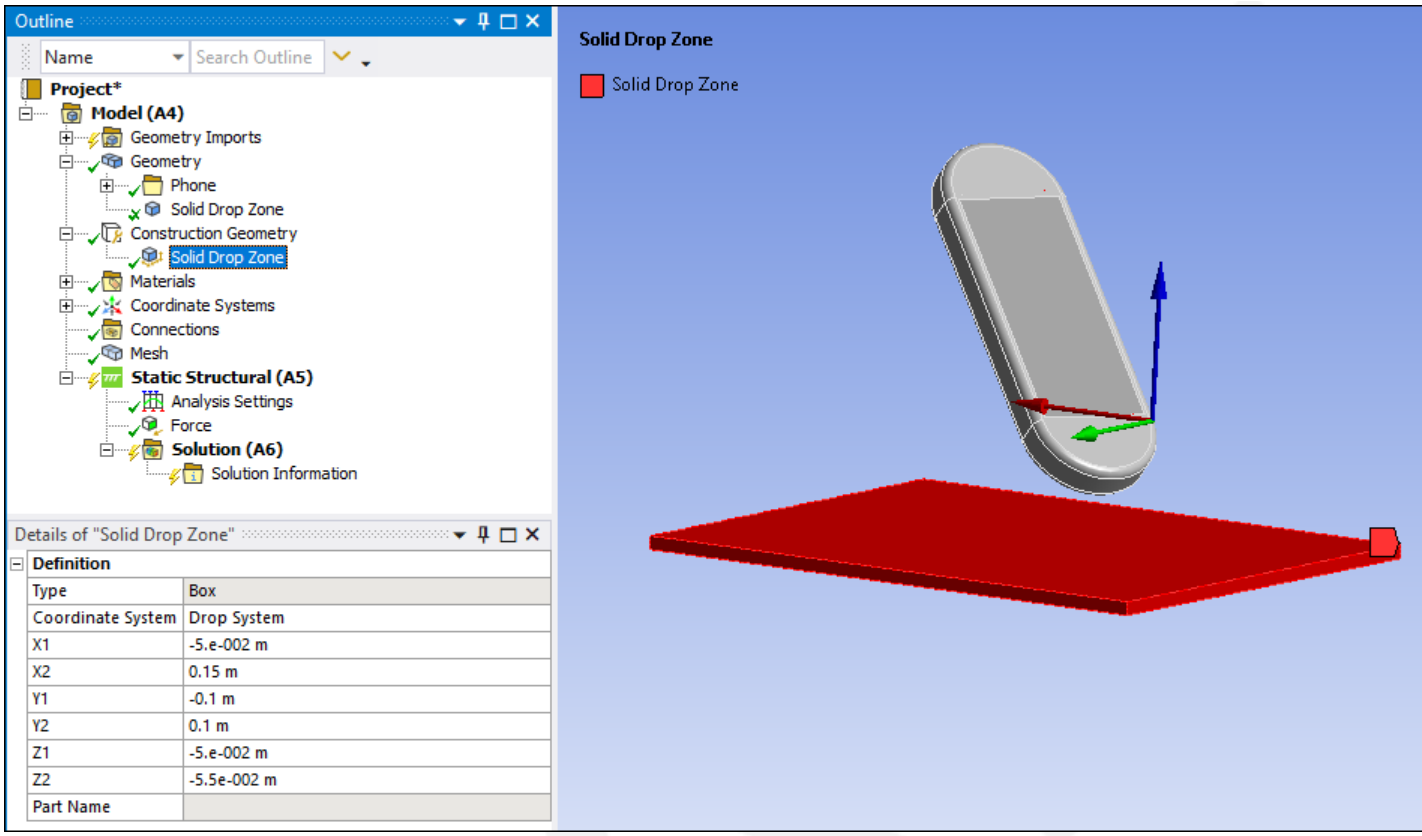


Important:

- The difference between the X, Y, and Z values must be greater than zero and within a tolerance of $1e^{-10}$. All comparisons are performed in the associated CAD units.
- Automatic contact detection is not performed when a solid part is generated. In order for the solid part to be included in automatic contact generation, you need to either select **Create Automatic Connections** option via the **Connections** folder or update the geometry from the CAD source by selecting the **Update Geometry from Source** option via the **Geometry** folder.
- Making a vertex or node selection on your model displays the Location of the vertex/node in the Status Bar (p. 135). This information can be helpful when constructing your solid part.

4. Right-click the object and select **Add to Geometry**. Once created, a new Part is placed in the **Geometry** folder. This part behaves as and may be used like any part of the model.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Note:

Review the following requirements:

- You must update the Geometry object (**Update Geometry from Source** option) in order to transfer changes made on the Solid object to the Part object.
- In order to delete a **Solid** object, you must first right-click the object and select **Remove Geometry**. This action removes the part from the **Geometry** folder. You can then delete the **Solid** object as needed.
- Selective Update (p. 340) is not supported for solids created in Mechanical.

STL

The **STL** option of the **Construction Geometry** feature enables you to import and view an STL (Stereolithography) file in Mechanical.

To import an **STL** file:

1. Highlight the **Model** object, open the **Construction Geometry** drop-down menu on the **Model** Context Tab (p. 48), and select **STL**.
2. At this point, define the following properties as needed:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Length Units**: Meters is the default setting. Changing this property rescales the STL geometry according to the new unit. Changing from Meters to Centimeters resizes the model accordingly.
- **Show Always**: Options include **No** (default) and **Yes**. If you set this property to **Yes**, the application displays the STL geometry in the **Geometry** window regardless of what object is selected in the tree.
- **Color**: Change the color of the STL geometry. This enables you to easily identify your STL geometry.

3. Right-click the **STL** object and select **Import STL File**. This option imports and displays the new model in the **Construction Geometry** folder.

Note:

When generated, the position of the imported STL geometry in the **Geometry** window is determined by the coordinates from which the original STL file is generated. To ensure that you can see the geometry, use the **F7** key (**Zoom to Fit**) to properly display all geometries.

The **Statistics** property displays the number of triangles included in the STL geometry.

Also see the STL object reference page of the Help for more information.

Construction Line

The **Construction Line** feature is a unique geometry sketching tool you use to create line segments on or around your model that you eventually convert into line bodies. This section describes the methods and options used to sketch and produce these line bodies.

- Defining a Construction Line (p. 895)
- Generating Line Bodies (p. 897)
- Understanding the Tools (p. 897)

Defining a Construction Line

Select the **Construction Line** option from the **Construction Geometry** drop-down menu on the **Model** Context tab (p. 48). Once you have inserted the object, several additional options are available to insert additional objects. See the **Construction Line** object reference section for the other methods.

Note:

Using the Image Plane from File option of the **Insert** (p. 42) group on the **Home** tab, you can import an image into Mechanical and place it on or around your model based the on XY-plane of the selected coordinate system. You then use this image to very accurately sketch line segments. To properly trace over an imported image, you need to position your

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

model using the same orientation that was used to capture the image, otherwise, your new sketch may be in an incorrect position compared to the model.

Once inserted, the object has the following **Details** pane categories and properties:

Category	Property/Description
Sketch Selection	**Method**: Options for this property include: • **Interactive** (default): This option enables you to sketch line s using the **Planar** (p. 898) or **Freeform** (p. 898) options. • **Coordinate System**: This option enables you to sketch line s hand using the **Planar** (p. 898) or **Freeform** (p. 898) options.
Active Sketch Details	**Sketch ID**: This read-only property shows an application define Line ACT APIs. **Association Type**: This read-only property shows the entity typ **System**. **Association ID**: This read-only property shows the ID of the ske property, either **Geometric** or **Coordinate System**. If set to **Geo** the ACT API Reference Guide). If set to **Coordinate System**, the **Note:** These ID values are compatible with the Mechanical ACT A
Image Plane Properties	The properties of this category enable you to import and overl or around your model. **Image File**: Import an image that overlays on the XY-plane of t can very accurately sketch one or more line segments. Note tha your model using the same orientation that was used to captur position compared to the model. **Coordinate System**: Specify where to place your image based **Show Coordinate System**: Show the selected Coordinate Syste **Width**: Specify the physical width of your image. For the best re physical height matches the aspect ratio of your image. **Height**: Specify the physical height of your image. For the best physical height matches the aspect ratio of your image. **Translucency**: Increasing the value makes your image more and line. **Horizontal Flip**: Reverse your image horizontally.

Published: 2023-10-23

Category	Property/Description
	Vertical Flip: Reverse your image vertically.

For an individual **Construction Line** object, you can create as many line bodies as desired. You can switch back and forth between each of the above methods for each line body, or group of line bodies, you create. The **Sketch Selection** property simply defines the method to select the active plane for planar sketching. The option specified for this property has no effect on the final geometry that will be added to the model. See the Understanding the Tools (p. 897) topic below for descriptions of the various tools and options available for this feature.

Generating Line Bodies

Once you have completed sketching your line bodies, use the **Construction Line** object's context (right-click) menu option **Add to Geometry** to generate line bodies. Use the **Update Geometry** option to incorporate any desired additions/changes.

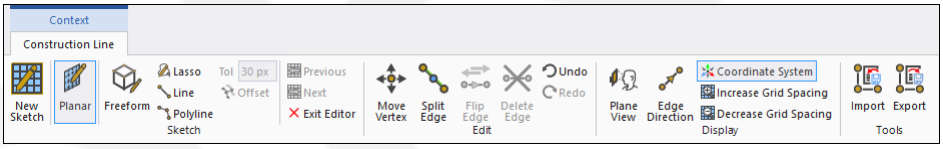
Once you have created a Line Body (p. 872), you need to specify a cross section and assign a material. Review the Cross Section and material assignment (p. 345) topics as well and the Body object reference section for descriptions of all of the associated geometry properties.

Understanding the Tools

This topic describes the features and tools of the **Construction Line** Context menu that are organized into the following groups:

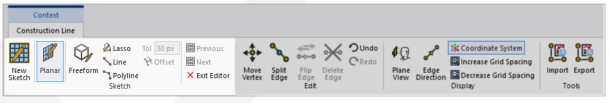
- Sketch (p. 897)
- Edit (p. 899)
- Display (p. 900)
- Tools (p. 900)

This is the default display of the Context tab for the **Construction Line** object.



Sketch

The **Sketch** options group (highlighted below) contains draw tools that enable you to create line segments.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

New Sketch

This option is active by default when you insert the object. Select a desired plane on your model (based on a face selection) or you can set the **Sketch Selection** property to **Coordinate System** and select a user-defined coordinate system (p. 1192).

Available when the **Sketch Selection Method** property is set to **Interactive**, the **New Sketch** option specifies a new sketch plane on a face of your model that you select. Once specified, the **Planar** editor becomes active. Select a desired sketch option and create line segments.

Planar

The **Planar** editor enables you to sketch 2D line segments on a given specified plane. Your line segments are bound to the specified geometry face or a Coordinate System, that is, your sketch can only be performed within this plane.

To begin sketching line segments, select the **Lasso** (p. 898), **Line** (p. 898) or **Polyline** (p. 898) tool. You can also use the **Offset** tool.

Freeform

The **Freeform** editor enables you to sketch 3D line segments between geometric entities (including face centroids) or the vertices of existing line segments. To begin sketching line segments, select the **Line** (p. 898) or **Polyline** (p. 898) tool.

Lasso

The **Lasso** tool, only available for the 2D (Planar) editing mode, enables you to click and drag the mouse cursor to trace a line segment (beginning to end). This tool has an accompanying Tolerance (**Tol**) field that defines the number of pixels in between each vertex the tool automatically creates. Use the **[Esc]** key to complete a sketch.

Line

The **Line** tool is available for both editing modes and enables you to make individual line segments. By default, when you create a line segment using this tool, point selections "snap" into place:

- Using the **Planar** editor. This snapping takes precedence for sketch vertex points and to cursor placement. Holding the **[Shift]** key enables you to snap to a point on the plane grid.
- On sketch vertices, edges, and face centroids using the **Freeform** editor. However, using **Freeform**, you can freely place points on faces without any snapping.

Polyline

The **Polyline** tool is available for each editing mode and enables you to make a series of line segments that the application will use to generate a single line. The snapping capability is the same as it is for the **Line** tool. Use the **[Esc]** key to complete a sketch.

Offset

The **Offset** option only becomes active when you 1) select one or more edges, and 2) select the **Planar** option. It enables you to create an offset of an edge(s), within the 2D sketching plane.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

When you activate the tool, drag and drop the edge(s) to a desired offset location. You can define multiple offsets. Note that you can also click a location on the plan where you would like the offset located.

Previous/Next

The **Previous** and **Next** options cycle through the sketch planes you have created for the current Construction Line object.

Exit Editor

The **Exit Editor** option deactivates all **Construction Line** Context tab options.

Tip:

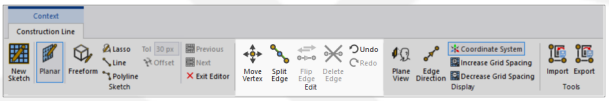
Note the following selection features:

- Holding the **[Shift]** key enables grid point "snapping." The application highlights a point on the grid to which you can connect your selection. This is helpful when placing and/or moving a vertex.
- **Box Selection**: You can perform box selections by holding the **[Shift]** key and left mouse button and dragging right or dragging left.
  - Dragging Left: Select only segments that have both vertices in the box.
  - Dragging Right: Select segments with at least one vertex in the box.

  For **Planar** mode, box-selection selects segments with both vertices lying in the sketching plane only.

Edit

The **Edit** group (highlighted below) contains tools for modifying or moving existing lines and edges.



Move Vertex

When you select this option, you can highlight an existing vertex and move it via drag and drop. You can select multiple vertices using the **[Ctrl]** key. When you hold the **[Shift]** key and move a vertex, the application will snap it to the grid.

Split Edge

The **Split Edge** option creates a new vertex on an existing line segment. You can use the **[S]** key to perform this action.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Flip Edge

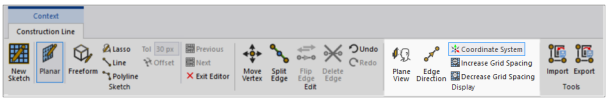
Active when a line is segment selected, this option enables you to invert the Edge Direction of the line segment. You can also use the **[F]** key to perform this action. Edge direction is the direction of the vector of the first point of your line segment to the second point. This direction can be displayed using the **Edge Direction** option.

Delete Edge

Active when a line segment is selected, this option deletes the selected line segment. You can also use the **[Delete]** key.

Display

The options of the **Display** group are highlighted and described below.



Plane View

Reorient the view of the active sketch plane to the XY-plane.

Edge Direction

Display line segment edge direction. Edge direction is the direction of the vector of the first point of your segment to the second point.

Coordinate System

Toggles the display of the triad for the active sketch's Coordinate System on and off.

Increase/Decrease Grid Spacing

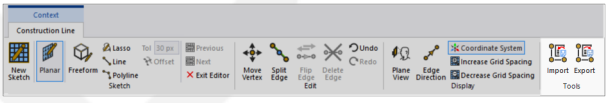
Increase or decrease the spacing of the grid display (by power of 10 based on the CAD unit).

Tip:

You can use the key combinations **[Ctrl]**+**[+]** and **[Ctrl]**+**[-]** to increase and decrease the grid.

Tools

The **Import** options group (highlighted below) contains tools to import or export currently or previously defined line bodies.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Import

Import previously exported line bodies in XML file format.

Export

Export the currently defined line bodies in XML file format.

Point Mass

Overview

You can idealize the inertial effects from a body using a **Point Mass**. Applications include applying a force with an acceleration or any other inertial load; or adding inertial mass to a structure, which affects modal and harmonic solutions.

The location of the **Point Mass** can be anywhere in space and can also be defined in a local coordinate system if one exists. The default location is at the centroid of the geometry. The **Point Mass** will automatically be rotated into the selected coordinate system if that coordinate system differs from the global coordinate system. You can also input moment of inertia values for each direction.

The Rigid Body Dynamics and Explicit Dynamics Solvers consider moments of inertia in the selected coordinates system, rather than in the global coordinate system.

Application

To define a **Point Mass**:

1. Select the Geometry object (or a child object).
2. You can then add a **Point Mass** object by:
   - Selecting the **Point Mass** option from the **Mass** group on the **Geometry** Context tab (p. 56).

     or...

   - Right-clicking the mouse button and selecting **Insert** > **Point Mass**.

     or...

   - Selecting the desired geometry in the graphics window, right-clicking the mouse, and then selecting **Insert** > **Point Mass** from the context menu.
3. Specify the **Scoping Method** property as either **Geometry Selection**, **Named Selection**, or **Remote Point**. Based on the selection made in this step, select a:
   - Geometry (faces, edges, or vertices) and click **Apply** in the Details view for the **Geometry** property.

     or...

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Single node and click **Apply** in the Details view for the **Geometry** property. In order to select an individual node, you need to first generate a mesh on the model, and then select the **Node** filter on the Graphics Toolbar (p. 97).

  or...

- User-defined node-based named selection from the drop-down list of the **Named Selection** property.

  or...

- User-defined remote point from the drop-down list of the **Remote Point** property.

  or...

4. Specify the **Point Mass** as a **Remote Attachment** (default) or a **Direct Attachment** using the **Applied By** property. The **Remote Attachment** option uses either a user-defined or a system-generated **Remote Point** as a scoping mechanism. **Remote Attachment** is the required **Applied By** property setting if the geometry scoping is to a single face or multiple faces, a single edge or multiple edges, or multiple vertices. The **Direct Attachment** option allows you to scope directly to a single vertex (Geometry) or a node (using an individually selected node or a node-based Named Selection) of the model.

5. Enter a **Mass** value.

6. Modify Point Mass object Details properties as needed.

When defined as a **Remote Attachment**, the **Point Mass** is considered a remote boundary condition (p. 1735). It can make use of remote points that are either specifically defined or created internally by the application. As a visual check, you can display connection lines between your scoping and remote points by selecting the **Remote Point Connections** option of the Style (p. 80) group (**Display** tab).

Support Limitations

A **Point Mass** cannot:

- span multiple bodies if the **Stiffness Behavior** of the bodies is declared as **Rigid** (see Rigid Bodies (p. 852) section for additional information).
- be applied to a vertex scoped to an end release (p. 1409).

Explicit Dynamics solutions do not allow scoping via a Direct Attachment.

Distributed Mass

You can use this feature to distribute additional mass across the faces or edges of the flexible parts in your model. Using this feature, you can idealize the inertial effects from the bodies/entities that are evenly spread across the surfaces of your model, for example, mass contribution from paint, external equipment, a large number of small objects spaced evenly across the surfaces, etc.

To define a **Distributed Mass**:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

1. Select the Geometry object (or a child object).
2. You can then add a **Distributed Mass** object by:
   - Selecting the **Distributed Mass** option from the **Mass** group on the **Geometry** Context tab (p. 56).

     or...

   - Right-clicking the mouse button and selecting **Insert**>**Distributed Mass**.

     or...

   - Selecting the desired geometry in the Geometry window, right-clicking the mouse, and then selecting **Insert**>**Distributed Mass**.
3. Specify the **Scoping Method** property as either **Geometry Selection** or **Named Selection**. Based on the selection made in this step, select a:
   - Geometry (faces and edges *only*) and click **Apply** in the Details view for the **Geometry** property.

     or...

   - Face-based or edge-based user-defined named selection from the drop-down list of the **Named Selection** property.
4. Specify the **Mass Type** as either **Total Mass** or **Mass per Unit Area**. Based on this selection, enter a value for **Total Mass** or **Mass per Unit Area**.

See the Distributed Mass object reference page for additional information about the properties of this feature.

Limitations

Note the following with regards to a **Distributed Mass**. A Distributed Mass can only be:

- Applied in 3D analyses.
- Scoped to faces or edges of bodies whose **Stiffness Behavior** is set as **Flexible**.
- Used in structural analyses (that is, Static Structural Analysis (p. 652), Transient Structural Analysis (p. 665), Transient Structural Analysis Using Linked Modal Analysis System (p. 674), and Linear Dynamic Analysis (p. 486) types).

Surface Coating

This feature enables you to apply a surface coating (shell layer) of a specified material and thickness over one or more faces of your model. This feature is beneficial when you want to include the ability to accurately evaluate surface stresses or to overlay your structure with thin parts, such as modelling Thermal Barrier Coatings or sheet metal over support structures. To accurately model this type of ap-

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

plication, Mechanical enables you to specify the thickness, stiffness behavior, coordinate system, and material.

Note:

Surface Coating (p. 2008) is also a **Scoping Method** option for results.

Important:

During a Cyclic Symmetry analysis, the application does not expand Surface Coating results.

Requirements

Note the following requirements for the **Surface Coating** feature:

- It can only be applied to the surfaces (faces) of solid bodies (shells/sheets are not supported.).
- Supported by 3D analyses only.
- Is only supported for structural analysis types that are using the Mechanical APDL Solver. Analyses include Static Structural Analysis (p. 652), Transient Structural Analysis (p. 665), Transient Structural Analysis Using Linked Modal Analysis System (p. 674), and Linear Dynamic Analysis (p. 486) types.
- It uses SHELL181 and SHELL281.
- The mesh of the bodies onto which you apply a Surface Coating should contain same **Element Order** (**Linear** or **Quadratic**).

Application

To create a **Surface Coating**:

1. You can either:
   a. Select the Geometry object and click **Surface Coating** option from the **Modify** group on the **Geometry** Context tab (p. 56).

      Or...

   b. Right-click on the Geometry object or in the **Geometry** window and select **Insert** > **Surface Coating**.

      Or...

   c. Select the desired faces available in the **Geometry** window, right-click, and select **Insert** > **Surface Coating**. This option automatically specifies the Geometry property in the Details view and therefore negates the next step.
2. Specify the **Scoping Method** property as either **Geometry Selection** or **Named Selection**. Based on the selection made in this step, select a:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Geometry (faces *only*) and click **Apply** in the Details view for the **Geometry** property.

  or...

- Face-based user-defined named selection from the drop-down list of the **Named Selection** property.

3. Specify the **Stiffness Behavior** as either **Stress Evaluation Only** (default), **Membrane Only**, or **Membrane and Bending**. If you set this property to **Stress Evaluation Only**, no **Thickness** entry is necessary.

   Note:

   By default, Mechanical automatically sets the Shell Offset to Bottom for all **Stiffness Behavior** settings.

4. Select a material for the surface coating from the fly-out menu of the **Material** property.
5. Specify a **Thickness** for the surface body.
6. As needed, change the **Coordinate System** setting. The **Default Coordinate System** option is based on the geometry scoping specified above.

See the Surface Coating object reference page for additional information about the properties of this feature.

Thermal Point Mass

Overview

For **Transient Thermal** analyses, you can idealize the thermal capacitance of a body using a thermal point mass. Thermal Capacitance replaces the need to calculate the body's internal thermal gradient. The **Thermal Point Mass** is commonly used as a medium to store or draw heat from surrounding objects. Applications include the heat dissipation of refrigerators, cooling electronic devices, and heat sinks of computer motherboards.

This section examines the following feature applications and requirements:

- Apply Thermal Point Mass Object (p. 905)
- Behavior Property Specifications (p. 907)
- Support Limitations (p. 908)

Application

To define a **Thermal Point Mass** in your Transient Thermal analysis:

1. Select the Geometry object (or a child object).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

2. You can then add a **Thermal Point Mass** object by:

   - Select the Geometry object and click **Thermal Point** option from the **Mass** group on the **Geometry** Context tab (p. 56).

     or...

   - Right-clicking the mouse and selecting **Insert** > **Thermal Point Mass**.

     or...

   - Select the desired geometry in the graphics window, right-click the mouse, and then select **Insert** > **Thermal Point Mass**.

3. Specify the **Scoping Method** property as either **Geometry Selection**, **Named Selection**, or **Remote Point**. Based on the selection made in this step, select a:

   - face, edge, or vertex of a solid or surface model or on an edge or vertex of a surface model and click **Apply** in the Details view for the **Geometry** property.

     or...

   - single node and click **Apply** in the Details view for the **Geometry** property. In order to select an individual node, you need to first generate a mesh on the model, and then select the **Node** filter on the Graphics Toolbar (p. 97).

     or...

   - user-defined node-based named selection from the drop-down list of the **Named Selection** property.

     or...

   - user-defined remote point from the drop-down list of the **Remote Point** property.

4. Specify the **Thermal Point Mass** as a **Remote Attachment** (default) or a **Direct Attachment** using the **Applied By** property. The **Remote Attachment** option uses either a user-defined or a system-generated **Remote Point** as a scoping mechanism. **Remote Attachment** is the required **Applied By** property setting if the geometry scoping is to a single face or multiple faces, a single edge or multiple edges, or multiple vertices. The **Direct Attachment** option allows you to scope directly to a single vertex (Geometry) or a node (using an individually selected node or a node-based Named Selection) of the model.

   Note:

   The location of the **Thermal Point Mass** can be anywhere in space. The default location is at the centroid of the geometry.

5. Modify coordinate system properties as needed.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

6. Enter a **Thermal Capacitance** value. **Thermal Capacitance** refers to ability of the material to store heat. The higher the thermal capacitance, the more heat can be stored for each degree rise in temperature of the **Thermal Point Mass**.

7. When the **Thermal Point Mass** is defined as a **Remote Attachment**, the **Behavior** property displays: define as **Isothermal**, **Coupled**, or **Heat-Flux Distributed**. See the *Behavior Property Specifications* topic below for additional information about how to make the appropriate selection.

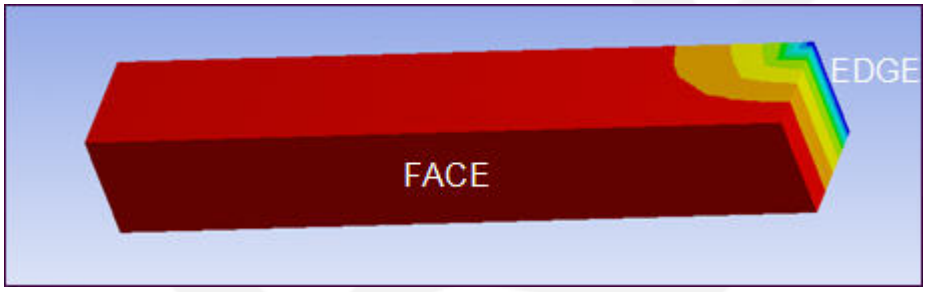
8. Modify additional Thermal Point Mass object Details view properties as needed.

When defined as a **Remote Attachment**, the **Thermal Point Mass** is considered a remote boundary condition (p. 1735). It can make use of remote points that are either specifically defined or created internally by the application. As a visual check, you can display connection lines between your scoping and remote points by selecting the **Remote Point Connections** option of the Style (p. 80) group (**Display** tab).

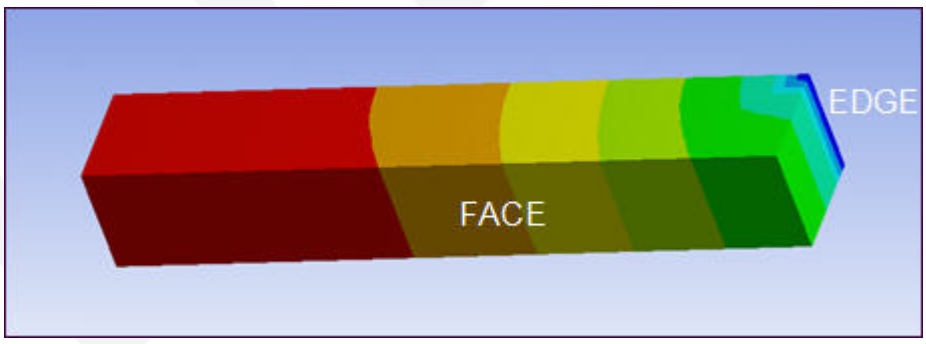
Behavior Property Specifications

The **Thermal Point Mass** includes three **Behavior** options in the Details View that control its interaction with the bodies in the geometry selection: **Isothermal**, **Coupled**, and **Heat-Flux Distributed**:

- For the **Isothermal** behavior, temperatures throughout the geometry selections and the **Thermal Point Mass** are constrained to be the same. The following is an example of a **Thermal Point Mass** using **Isothermal** behavior applied to the FACE while a temperature boundary condition is located at the EDGE. While there is a temperature distribution from the boundary condition (EDGE) up to the surface (FACE), the temperature on the FACE in the pinball region, itself takes a single value that matches that of the **Thermal Point Mass**.



- For **Heat-Flux Distributed** behavior, however, the temperature of the geometry selection and the point mass are not constrained to be the same. The temperature of the **Thermal Point Mass** becomes a weighted average of those on the geometry selection. For comparison, the previous example has been modified to use the **Heat-Flux Distributed** behavior. The FACE, no longer constrained to be isothermal to the point mass, displays a gradient.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- For **Coupled** behavior, the geometry has the same DOF solution on its underlying nodes as the remote point location. This formulation is similar to the Mechanical APDL constraint defined by the **CP** command.

Support Limitations

A **Thermal Point Mass** cannot be applied to a vertex scoped to an end release (p. 1409).

Models from External Meshes and Model Assemblies

The following sections examine the features in Ansys Workbench and Ansys Mechanical that enable you to generate and assemble geometries from external component systems:

Importing Mesh-Based Geometry

Assembling External Models and Mechanical Models

Importing Mesh-Based Geometry

The Workbench External Model system enables you to either import your mesh or to synthesize a geometry from the mesh file. When generating a geometry, supported geometric entities include solids, shells, as well as beam element-based bodies (that have an assigned cross-sectional definition). The resulting geometry is the culmination of the use of the implicit (angle-based tolerance) and explicit (based on node-based components in the file) methods that work in combination to synthesize geometry and create surfaces that enclose the mesh volume.

This feature supports data import of lines, shells, or solids or a mix of lines, shells, and solids. See the External Model Supported Element Types (p. 969) section for a list of the available element types for the Mechanical APDL common database (.cdb), NASTRAN, and ABAQUS file formats.

This feature supports all Mechanical analysis types. For the specific instructions to import a finite element mesh file using this tool, see the Creating and Configuring an External Model System section of the Workbench Help.

The following sections describe how to work with the finite element data that you import from an upstream **External Model** system.

Supported External File Types

Import Workflow and Interface Options

Supported Finite Element Data Types

Automatic Material Assignment

Reference Node Naming

Importing Mesh-Based Databases in Batch

External Model Supported Element Types

Supported External Model Commands

Accessing Imported Mesh-Based Databases through ACT

Examples of a Synthesized Mesh using Tolerance Angles

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Supported External File Types

You can import the following finite element mesh files directly into Mechanical using the Workbench External Model system:

- Mechanical APDL common database (.cdb)[1]
- Workbench mesh data file (.acmo)
- ABAQUS Input (.inp)[2]
- NASTRAN Bulk Data (.bdf, .dat, .nas)
- Fluent Input (.msh, .cas)
- ICEM CFD Input (.uns)
- LS-DYNA Input (.k and .key)[3]

[1] The Mechanical APDL application defines contact conditions as elements and writes this data as such to the Mechanical APDL .cdb file. Conversely, the Mechanical application does not consider contact conditions as a part of the geometry (defined through elements). Mechanical defines its own entity. Therefore, when you import Mechanical common data base (.cdb) files into Mechanical, the application:

- Translates MAPDL contact elements to the equivalent Mechanical Connections entry.
- Does not process components (as Named Selections) that include contact elements. Furthermore, if you have a .cdb files that contains only contact element-based components, the application does not transfer these components.

As a result, these process requirements can lead to differences in the number of elements displayed by each application as well as the absence of Named Selections specified in one application but not available in the other.

[2] Note the following Workbench support limitations when importing **ABAQUS Input files**:

- Parts and Assemblies are not supported. That is:
  - → Only the data from the very first **Instance* command is read by External Model. All other data from any additional **Instance* command is ignored.
  - → The element and node sets, as well as the materials, that are associated with the first **Instance* command are processed. Any data that follows the first **End Part* or **End Instance* commands is ignored.
- Workbench does not support keywords that generate additional items, such as keyword **NGEN*. The commands **NSET*, **ELSET*, and **NODAL THICKNESS* are the only commands that support the Generation parameter.
- Only the first load step of the ABAQUS file is read by External Model.

[3] Note the following Workbench support limitations when importing **LS-DYNA Input files**:

- Workbench will generally only import mesh information. For a list of supported keywords, go to the List of LS-DYNA supported keywords (p. 972)
- Workbench does not support the *INCLUDE feature of LS-DYNA, and will only read the file you supply as an input.

Published: 2023-10-23

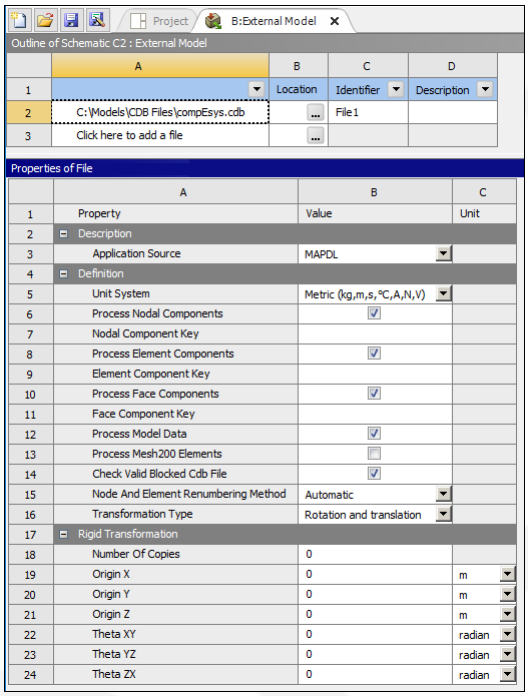
Import Workflow and Interface Options

Go to a section topic:

- External Model Properties in Workbench (p. 910)
- Model Cell Properties in Workbench (p. 910)
- Mechanical Interface Options (p. 913)
- Requirements and Limitations (p. 917)

External Model Properties in Workbench

The **External Model** tab is illustrated below. From this tab, you to modify various properties prior to importing your finite element data into Mechanical. Refer to the Creating and Configuring an External Model System topic in the **External Model** section for a description of the properties available on the External Model tab.

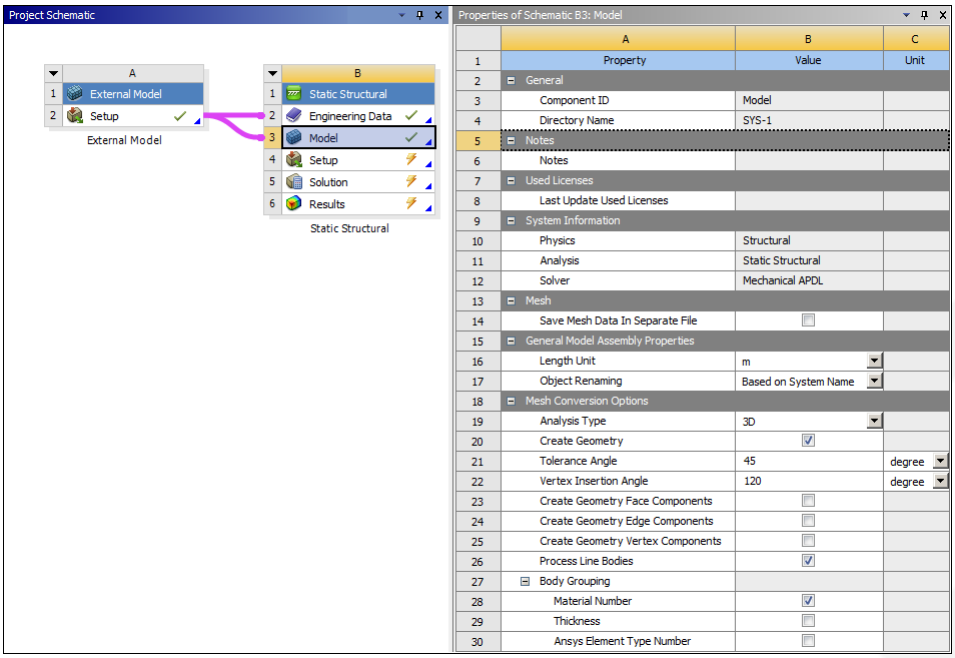


Model Cell Properties in Workbench

The properties of the **Model** cell on the Workbench **Project** page are illustrated below. You use the **Mesh Conversion Options** group of properties to specify import processes used on the finite element data. Properly defining these properties is important for you to accurately generate the desired geometries in Mechanical.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Mesh Conversion Options include:

- **Analysis Type**: Defines the mesh file as **3D** (default) or **2D**. When working with 2D analysis types, make sure that all of your model's surface normals point in the same direction using the **Rigid Transformation** properties available through the **External Model** feature.

  When you set this property to the **2D** option, in Mechanical, the application validates that the geometry is two-dimensional (2D) by checking the value of the **Length Z** property, using CAD units, in the **Bounding Box** category of the Geometry object. The tolerance used for this check is based on the setting of the **2D Tolerance** property (**Properties** category of the **Geometry** object). If you change the value of the **2D Tolerance** property, you must refresh the analysis on the Workbench project page in order for the application to re-validate the geometry.

- **Create Geometry**: This option is active by default. When selected, the application automatically creates your geometry in Mechanical based on solids, shells, and beam elements (that have an assigned cross-sectional definition) present in the mesh. When imported, a **Geometry** object is placed in the **Outline**. Deselecting this option instructs the application to import the mesh only (elements and nodes). When imported, an **Element Groups** object is placed in the **Outline**. **Element Groups** object and its children behave as a **Geometry** object and its children. That is, the Solid, Surface, and Line elements behave as bodies.

  Not creating a geometry dramatically decreases your import time as well as significantly reducing the amount of memory used during the process.

- **Tolerance Angle**: This value determines if adjacent elements are of the same face during the geometry creation process. The geometry creation process identifies groups of element facets on the exterior of the mesh. These generated facets create geometric faces in Mechanical. Then skin detection algorithm scans the exterior element facets and groups them based on a tolerance angle. For example, two adjacent element facets are grouped into the same face if the angle between their normals is less than or equal to the given tolerance angle. Therefore, an angle tolerance of 180^{o} creates only a single face for the whole body while a tolerance of 1^{o} creates

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

an amount of geometric faces which approaches the number of element faces if any curvature is present.

Calculations to synthesize geometries using tolerance angles use the implicit method. Processing nodal components on the same topology will override this method. See the illustrations below for examples of this behavior.

The default **Tolerance Angle** is **45** degrees. This is the recommended setting.

- **Vertex Insertion Angle**: The Vertex Insertion Angle is the minimum angle to insert a vertex between two free edges of mesh. The default value is **120** degrees. During the generation of the geometry, if two segments of an edge abruptly make an angle greater than the Vertex Insertion Angle, then the edge is split and a vertex is inserted.
- **Create Geometry Face/Edge/Vertex Components**: These options become active when your mesh file contains node-based named selections. When active, the application automatically creates geometric named selections (face/edge/vertex). For a vertex or an edge, the node-based named selection can include only include one node or one edge. For faces, nodes from multiple faces can be included in the node-based named selection. This option will not affect the geometry creation algorithm itself, which is based purely on the mesh adjacency angles as detailed above.

  Note:

  The application automatically transfers geometry-based Named Selections for faces.

- **Component Key**: If you select one or more of the **Create Geometry Face/Edge/Vertex Components** option, this property enables you to generate geometric components specific to the key name that you enter. The application evaluates keys from the beginning of the string value. For example, a given mesh file has the following components: Fixed_Support1, Fixed_Support2, and Force1. If you enter "Fixed_Support", Mechanical automatically produces Named Selections for Fixed_Support1 and Fixed_Support2, but not Force1.
- **Process Line Bodies**: This property enables you to import finite element line bodies (see Line Bodies (p. 872)) that have a properly defined cross-section. For these finite element line bodies, the following element types are supported (p. 969).
  - For CDB files: see the **Beam Shape Category** in the External Model Supported Element Types (p. 969) section of the Help.
  - For NASTRAN files: the CBAR and CBEAM element types are supported and require a cross-section property defined via PBAR, PBARL, PBEAM, or PBEAML.
  - For ABAQUS files: multiple options are available. Primary properties include: *BEAM SECTION, *FRAME SECTION, and *BEAM GENERAL SECTION.
- **Body Grouping**: This property tells Mechanical how to group the elements (of the same type) from the data file. Elements are always grouped by shape and different shaped elements are placed in separate groups. This option controls the number of element groups/bodies created in Mechanical. You use the following options to specify how you want to group elements. You can select one or more (or all) options. Property options include:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- **Material Number** (default): Group elements based on the material number assigned to the elements. The application creates a group for **each** Material Number.
- **Thickness**: Group all elements that have the same thickness number.
- **Ansys Element Type Number**: For Mechanical APDL common database (.cdb) files only, this option enables you to group elements by their local Ansys element type that was assigned from the element library. Note that the element type number is the first argument to the **ET** command in the (.cdb) file.

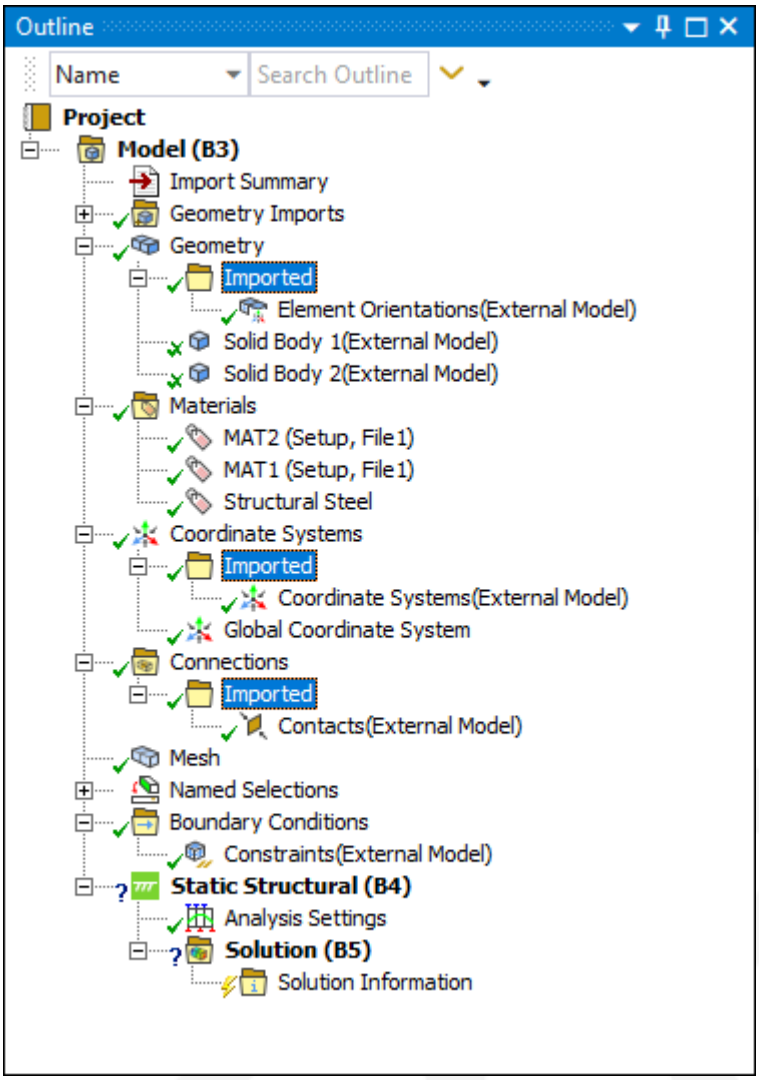
Important:

- For LS-DYNA files, Mechanical creates only one part. Elements are grouped into bodies first by element shape then by Part ID as defined in the LS-DYNA file and then (if chosen), by **Material Number** or **Thickness**. Therefore each element in a body will have same shape, LS-DYNA Part ID and (if chosen), and same Material Number and Thickness. In addition, each body listed in the Outline has its part name specified using the *PART keyword in the input file.
- For ICEM CFD Files, the application uses data internal to ICEM CFD files to group elements into bodies and to create geometric faces. Therefore, the **Tolerance Angle** is ignored.

Mechanical Interface Options

When you import an **External Model** source file that includes any of the finite element data listed below (p. 918), Mechanical inserts an "Imported" folder (excluding Named Selections) beneath the corresponding **Outline** object. As illustrated in the example **Outline** below, this **Imported** folder object is a simple group folder that contains child objects for the associated data type.

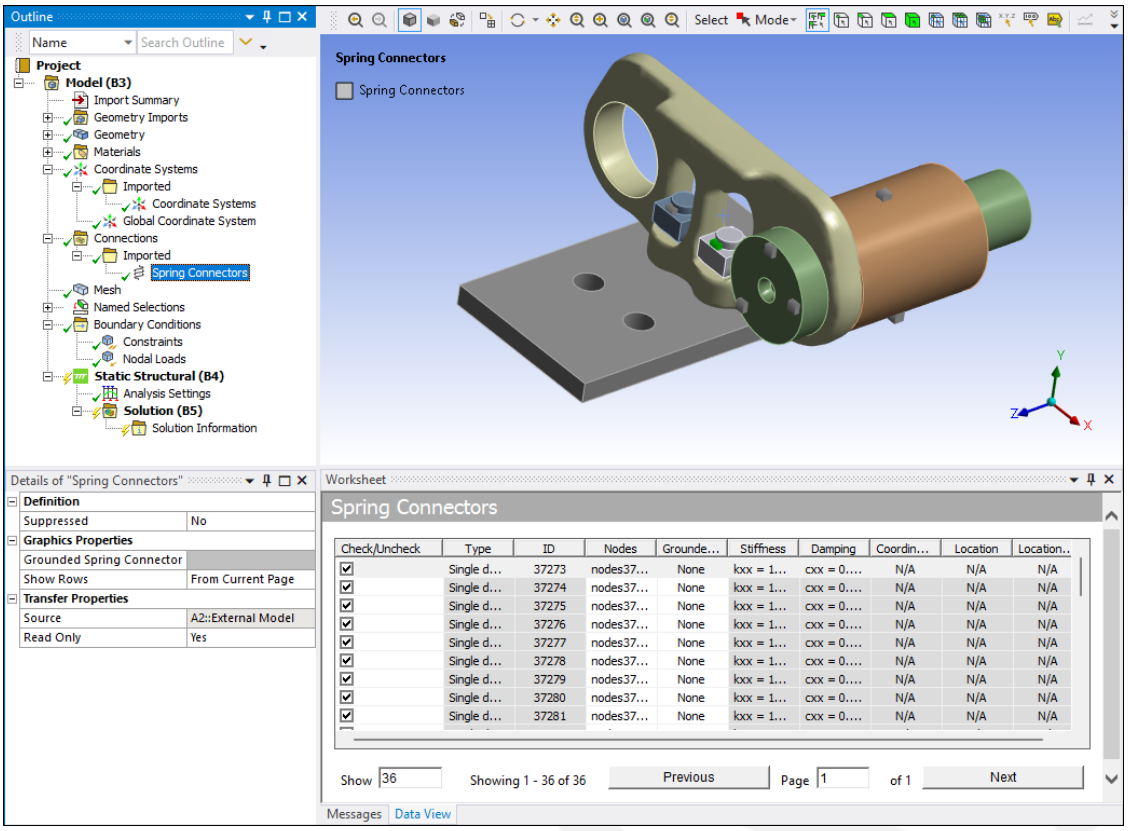
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Selecting a child object of the **Imported** folder displays the mesh/geometry in the **Geometry** window, with the imported data type highlighted on the mesh/geometry, as well as the **Worksheet**. An example of a selected imported spring (p. 956) is illustrated below. The **Worksheet** displays a summary of all imported data including column headings for the specific data associated with each data entry (connection Type, node ID, etc.). Each row of the **Worksheet** represents a different set of data. You can sort the table data by clicking on a column heading. The check-box for each **Worksheet** row enables you to deactivate (suppress) the row. And, based on the number of data items imported, the **Worksheet** displays 500 (default) data items per worksheet page. Use the display and/or navigational options at the bottom of the window to display more data items per page as well as to step through the available pages of data.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



A graphical representation of the data is also shown in the **Geometry** window. You can choose which data is displayed in the **Geometry** window using the **Show Rows** property under **Graphics Properties** category in the **Details** view. The **Show Rows** property includes the following options:

- **From Current Page** (default): Only display the data from the current page in the **Worksheet**.
- **From All Pages**: Display all of the data for the object independent of the rows visible in **Worksheet**.
- **None**: Do not display any data in the **Geometry** window.

In addition, for the following objects, you have the ability to select the color used for the displayed data in the **Geometry** window through a color selection property in the **Details** view:

- Imported Boundary Conditions (p. 919)
- Imported Constraint Equations or Coupling (p. 928)
- Imported Flexible Remote Connectors (p. 942)
- Imported Point Masses (p. 947)
- Import Rigid Bodies (p. 950)
- Imported Rigid Remote Connectors (p. 951)
- Imported Spring Connectors (p. 956)

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Worksheet

Furthermore, when you select a **Worksheet** row, the graphical representation of the data in the **Geometry** window becomes highlighted, such as the green spring shown in the above image. You can also select the graphical representation directly in the **Geometry** window by activating the **Imported Data Highlight** option on the Graphics Toolbar (p. 97). Normal mouse and key combinations for selecting, deselecting, modifying, or clearing selections act just as they do with geometry selections, etc. This selection feature is available for the following types of imported data:

- Imported Constraint Equations or Coupling (p. 928)
- Imported Contacts (p. 930)
- Imported Flexible Remote Connectors (p. 942)
- Imported Point Masses (p. 947)
- Imported Rigid Remote Connectors (p. 951)
- Imported Spring Connectors (p. 956)

In addition, for the above data types, when you select the graphical representation (Point Mass, Spring, etc.) in the **Geometry** window and right-click, the context menu provides the following applicable options:

- **Go To** > **Corresponding Bodies in Tree**: This option navigates to attached bodies in the tree.
- **Filter Worksheet Based on Selection**: This option only displays the selected objects in the worksheet. You can revert to viewing a specified number of rows in the Worksheet by editing the column headings via the right-click **Show** option in the Worksheet.

When the finite element data is displayed in the **Worksheet**, there are common options you can employ when you right-click on a **Worksheet** row, including:

- **Promote**: When you promote a **Worksheet** entry, the data, in whichever form (Coordinate System, Element Orientation, etc.), remains linked to the external system. You can modify the data within Mechanical, however; your changes are not transfer to the external system. In addition, any changes made in the external system will overwrite any modifications you make in Mechanical. Generally, you promote a Worksheet as a scoping in the form of a Named Selection. However, for Imported Bolt Pretensions, you can promote a Bolt Pretension, to a desired environment, in the form of a load.
- **Copy as new**: When you copy a Worksheet entry, a new independent object, based on the type of data, is inserted into the Tree outline. The application assigns a default name to the object based on the data type (Coordinate System, Element Orientation, etc.).
- **Show**: This option enables you to select which columns you wish to display on the Worksheet.
- **Check/Uncheck**: This option enables you to deactivate (suppress) a worksheet row.
- **Go To Promoted**: This option becomes available after you have promoted a Worksheet entry. This option takes to you the corresponding Tree outline object. This is typically related

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

to a scoping that you have created through promotion. However, for Imported Bolt Pretensions, it can correspond to a Bolt Pretension promoted in the form of a load.

- **Edit Items**: This option becomes available when your finite element data type has editable Worksheet content. It enables you to make changes to the associated data items, such as a node ID. You can select individual or multiple rows as well as the data type tree object. When you select multiple rows or the tree object, the application applies all changes to all of the selected rows or to all of the Worksheet content, respectively.

Note:

Currently, Mechanical supports the Promote and Copy options for the following imported data:

- **Bolt Pretensions**
- **Contacts**
- **Coordinate Systems**
- **Element Orientations**
- **Flexible Remote Connectors**
- **Point Masses** (when scoped to a node of the geometry only)
- **Rigid Remote Connectors**

Requirements and Limitations

Note the following requirements and limitations for importing mesh-based geometries:

- The application does not copy input files specified in **External Model** into the project folders of downstream systems. The application references these files by absolute path only. Be sure you don't move or rename these files.
- Geometry construction is for 3D lines, solids, and shells and 2D planar bodies only. Mechanical ignores any other element types contained in the mesh file.
- Mechanical only processes node-based components when attempting to create geometry-based Named Selections for the faces. The application ignores element components.
- You cannot change the meshes. That is, you cannot change, clear, or re-mesh once the file has been imported into Mechanical.
- Mesh controls (Refinement, etc.) are not supported.
- Adaptive Mesh Refinement is not supported.
- Geometry is not associative. As a result, if you update the environment, for example, by adding another mesh file, any scoping that you have performed on an object will be lost. To avoid losses

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

to your analysis environment, make sure that you have properly defined the imported Named Selections or criterion-based Named Selections.

- The application specifies the **Stiffness Behavior** property as either **Flexible** or **Rigid**. This is a read-only property.
- The **Scale Factor Value** property on the **Geometry** object is not supported.

Supported Finite Element Data Types

Mechanical enables you to import the following finite element data types from **External Model**:

Imported Bolt Pretensions and Premeshed Bolt Pretensions

Imported Boundary Conditions

Imported Composite Plies

Imported Constraint Equations or Coupling

Imported Contacts

Imported Coordinate Systems

Imported Cross Sections

Imported Element Orientations

Imported Flexible Remote Connectors

Imported Named Selections

Imported Nodal Orientations

Imported Point Mass

Imported Rigid Bodies

Imported Rigid Remote Connectors

Imported Shell Thicknesses

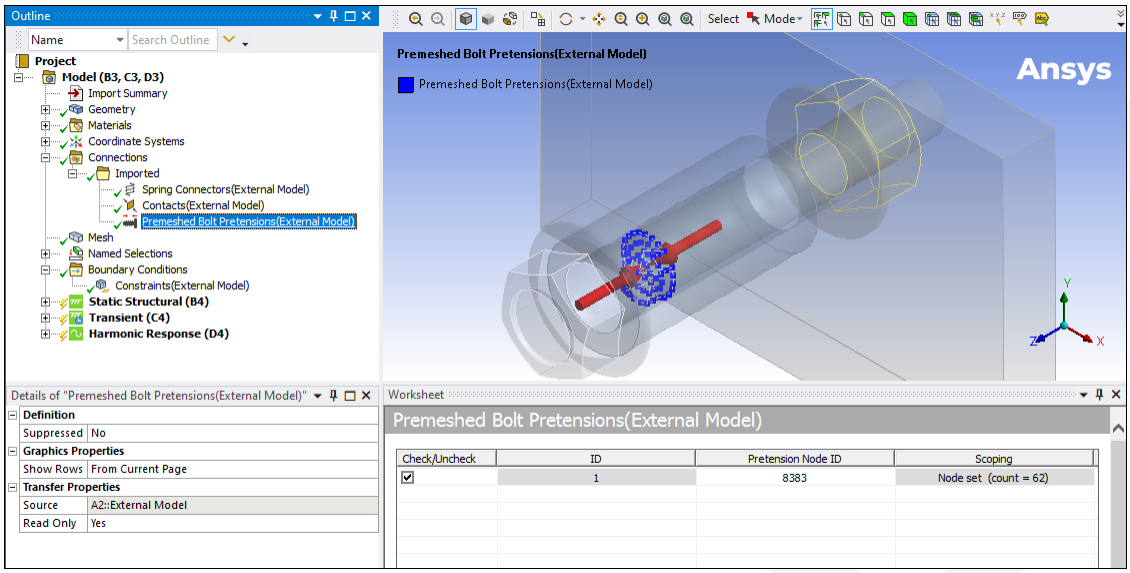
Imported Spring Connectors

Imported Initial Stresses

Imported Bolt Pretensions and Premeshed Bolt Pretensions

When your upstream External Model source file includes bolt pretension loads, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder. It contains the child object: **Bolt Pretensions** (or **Premeshed Bolt Pretensions**). The data associated with the imported bolt pretension is provided through the **Worksheet**.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Note:

For **Premeshed Bolt Pretensions**, the nodes at the pretension section interface are coupled using **CP** commands to provide continuity for all other analyses types where Bolt Pretension is not applicable.

Supported Analysis Types

Imported Bolt Pretensions and Premeshed Bolt Pretensions is supported by the following analysis types:

- Coupled Field Analyses
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data as contact:

- **CDB**: PRETS179 elements are processed as Pre-meshed Bolt Pretensions.
- **NASTRAN**: Not supported.
- **ABAQUS**: The **PRE-TENSION** and **PRE-TENSION SECTION** commands are processed as Bolt Pretensions. **NODE** (as integer or component name), **SURFACE** (as component name), and **ELEMENT** (as integer or component name) are the supported parameters.

See the Imported: Bolt Pretensions object reference section for additional information.

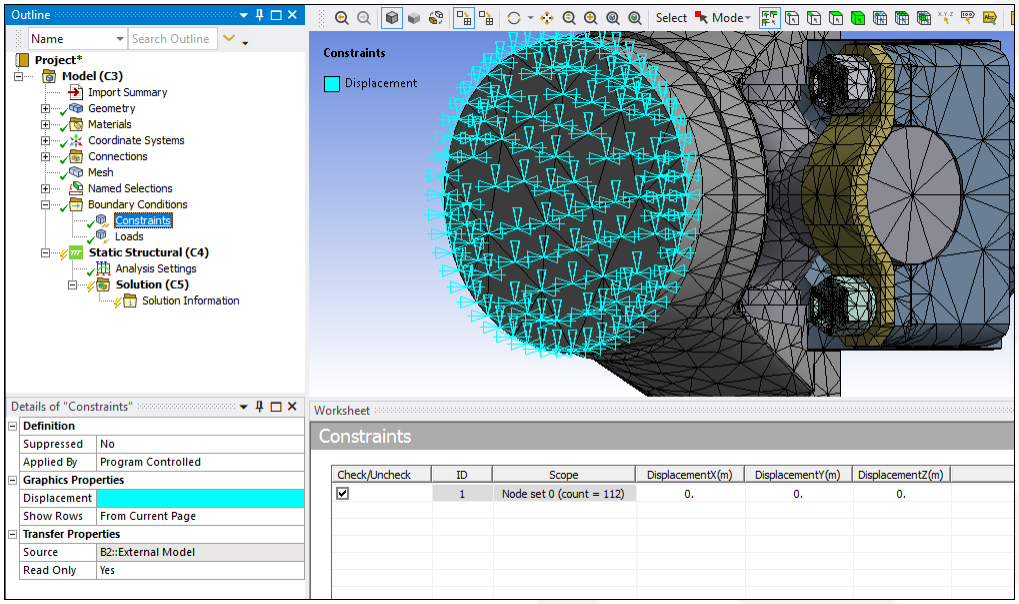
Imported Boundary Conditions

When your upstream External Model source file includes constraint and/or loading conditions, a **Boundary Conditions** folder appears beneath the **Model** parent folder when you open the file

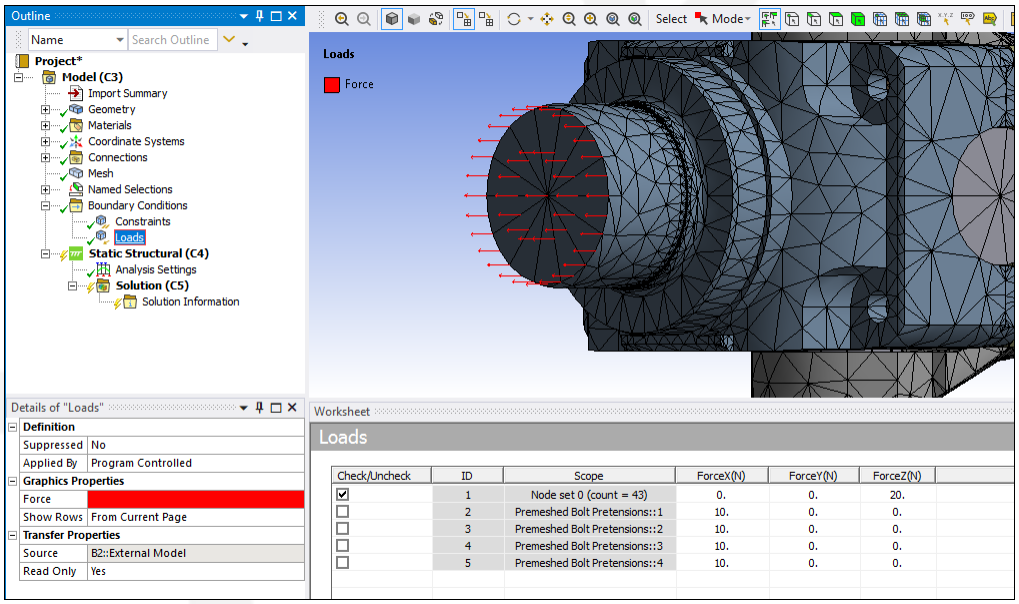
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

in Mechanical. It can contain the child objects: **Constraints**, **Nodal Loads**, **Surface Loads**, **Body Loads**, and **Acceleration**. When required, the data associated with the imported boundary conditions is provided through the **Worksheet**. **Worksheet** content, including all default settings, is based on the data in the external file.

Constraints Example



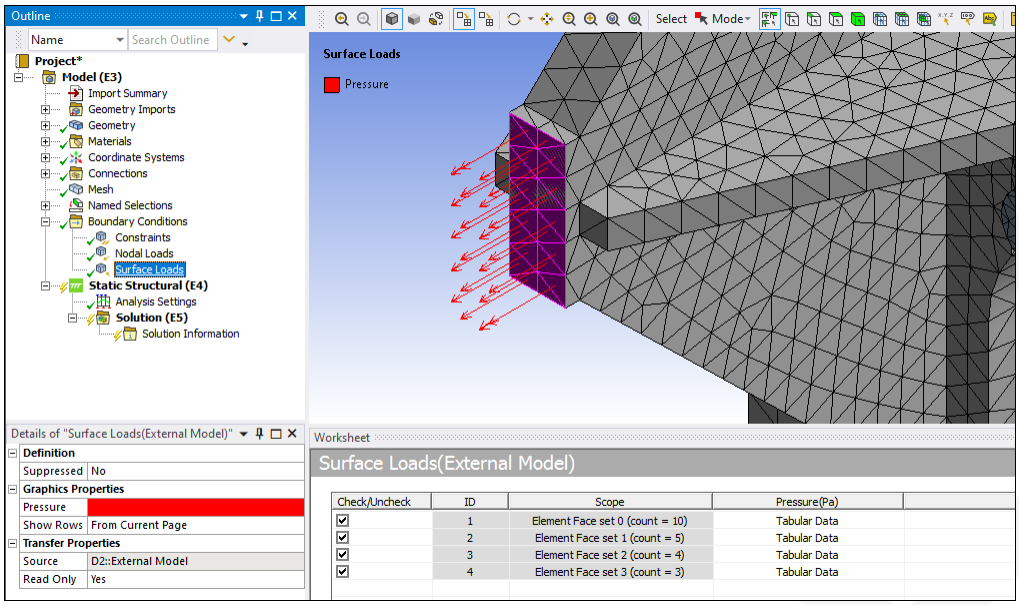
Nodal Loads Example



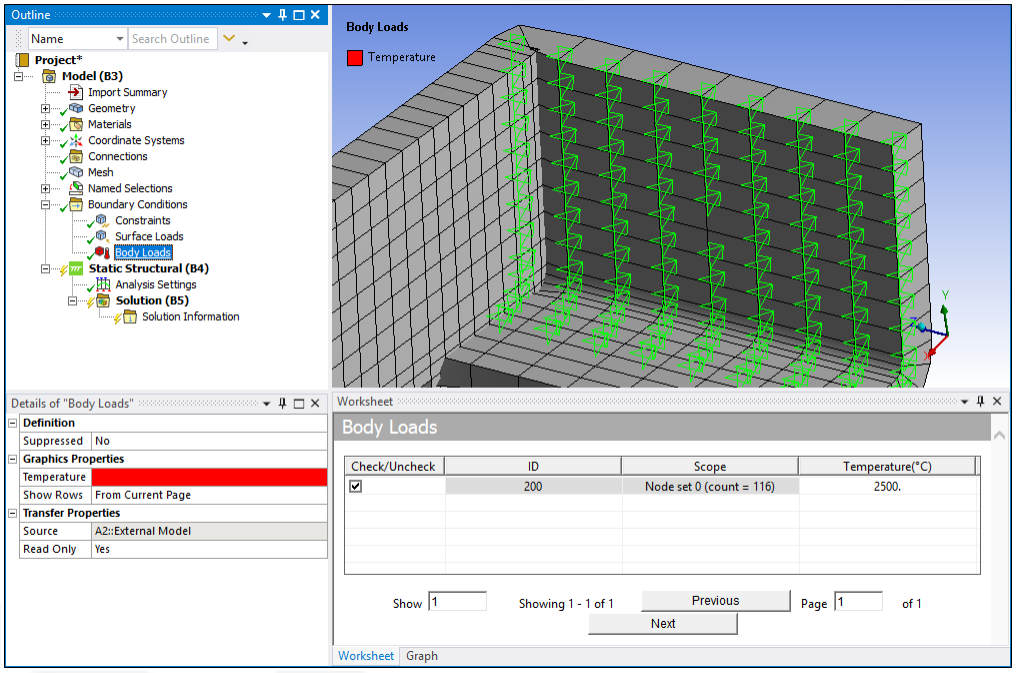
Surface Loads Example

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



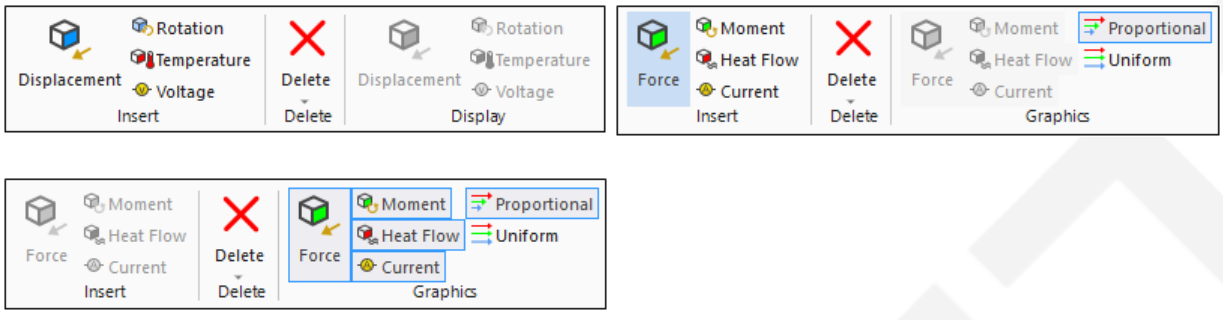
Body Load Example



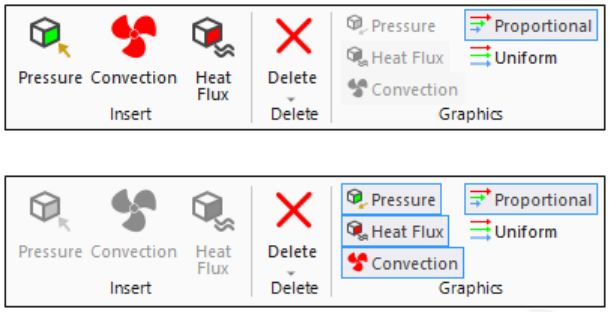
In addition to the degrees of freedom (DOFs) imported from the source file, you have the ability to expand the applicable DOFs for an imported Constraints/Nodal Loads/Surface Loads object. For example, an imported file used to define a thermal analysis that you also wish to use for a structural analysis. The group options illustrated below display when you select the **Constraints**, **Nodal Loads**, or the **Surface Loads** objects. These options enable you to add (or remove) additional DOFs to the existing Constraints/Nodal Loads/Surface Loads. Once added, the DOFs show up in the worksheet, where you can then specify desired values. No ribbon options are available for Body Loads as there is only one DOF.

Constraints Options **Nodal Loads Options**

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Surface Loads Options



Graphics Options for Constraints, Nodal, Surface, and Body Loads

When you have one of the objects selected, a corresponding **Graphics** group, as illustrated above, is also displayed. These tab groups enable you to turn the display of any of the options, Displacement, Rotation, etc., on or off. In addition, the graphics options for Nodal Loads and Surface Loads provides two buttons that change the display of vectors from a Proportional display to a Uniform display.

Load Step Support

The imported Constraint/Nodal Load/Surface Load objects support step dependent loading. Selecting a row in the worksheet activates the **Tabular Data** window that displays the constraint/load values for each step present in the analysis. You can edit the data in tabular view to apply values varying across steps. In addition, user has the ability to activate/deactivate the constraint/load components for each step through the context (right-click) menu on the **Tabular Data** window. See the Activation/Deactivation of Loads (p. 1423) topic for additional information.

Supported Analysis Types

Imported Boundary Conditions (**Constraints**, **Nodal Loads**, **Surface Loads**, and **Body Loads**) support the following analysis types:

- Coupled Field Analyses
- Static Structural
- Transient Structural (except when linked to Modal Solution with Mode-Superposition Solution Method.)
- Eigenvalue Buckling
- Harmonic Response

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

- Modal
- Steady-State Thermal
- Transient Thermal
- Electric
- Thermal-Electric

Supported Source File Commands

The application imports the following source file data/commands as loading conditions:

- **CDB**: The supported Mechanical APDL commands include:
  - **BF**/**BFBLOCK** and **BFE**/**BFEBLOCK** commands, with the degree of freedom **TEMP**, imported as body loads. Note that the **BFE**/**BFEBLOCK** commands support the elements SHELL181 and SHELL281 only.
  - **D** commands, imported as constraints.
  - **F** commands, imported as loads.
  - **SFE**/**SFEBLOCK** commands, imported as surface loads, applied using the elements SURF154, SOLID185, SOLID186, SOLID187, SHELL181, SOLID285, and SHELL281. Only normal pressures are supported. Tractions pressures are not supported. Thermal convection and heat flux loads, for solids and surfaces, are applied using the elements SURF152, SHELL131, SHELL132, SOLID70, SOLID87, SOLID90, SOLID278, and SOLID279.
  - **ACEL** command to simulate gravity.

  Important:

  Mechanical does not import **ACEL**, **D**, **F**, **SFE**/**SFEBLOCK**, **BF**/**BFBLOCK**, and **BFE**/**BFEBLOCK** commands specified using tables.

- **NASTRAN**: The supported NASTRAN commands include:
  - **SPC** command is imported as a constraint for a NASTRAN structural analysis and a thermal constrain for a NASTRAN thermal analysis.
  - **SPC1**, **SPCD**, and **SPCADD** commands that are imported as constraints.
  - **LOAD** and **SUBCASE** commands imported as load cases.
  - **FORCE**, **FORCE1**, **FORCE2**, **MOMENT**, **MOMENT1**, and **MOMENT2** commands that are imported as loads.
  - **TEMP** command, is imported as either a temperature Load (Body) for NASTRAN structural analyses or as temperature Constraint for NASTRAN thermal analyses.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

  - **TEMPD** command, is imported as a temperature Load (Body) for NASTRAN structural analyses.

  - **PLOAD**, **PLOAD2**, and **PLOAD4** commands are imported as Surface Loads. Only normal pressures are supported. Tractions pressures are not supported.

  - **GRAV** command defines gravity vectors to determine gravity loading on the model.

  In the absence of **SPC** or **LOAD** and **SUBCASE**, all of the above commands are imported. If the input file includes the **LOAD**, **SPC**, or **SUBCASE** commands, then load steps are determined and only those commands which are selected in the Case Control Section are imported.

- **ABAQUS**: The supported ABAQUS commands include:

  - *BOUNDARY command. The supported include TYPE with value as DISPLACEMENT, FIXED, or OP. The data lines using both Direct format and Type format are supported. For the type format, all are supported except NOWARP, NOOVAL, and NODEFORM.

  - *CLOAD command imported as loads. The OP parameter is supported. And, all of the data lines are supported in this command category.

  - *STEP and *END STEP commands are processed as load steps in the analysis. The parameters for both the commands are ignored.

  - *DSLOAD and *DLOAD commands are supported for surface and gravity loads. For surface loads, the OP parameter is the only optional parameter supported. And, all of the data lines whose distributed load type label is P are supported in this command category. For gravity loads, use the GRAV option.

  - DSFLUX and *DFLUX commands are supported for Heat Flux. The OP parameter is the only optional parameter supported. And, all of the data lines whose distributed load type label is S are supported in this command category.

  - *SFILM and *FILM commands are supported for Convection. The OP parameter is the only optional parameter supported. And, all of the data lines whose distributed load type label is F are supported in this command category.

- **LS-DYNA**: The supported LS-DYNA commands are *BOUNDARY_SPC_NODE and *BOUNDARY_SPC_SET.

Also see the Imported: Boundary Conditions object reference section for additional information.

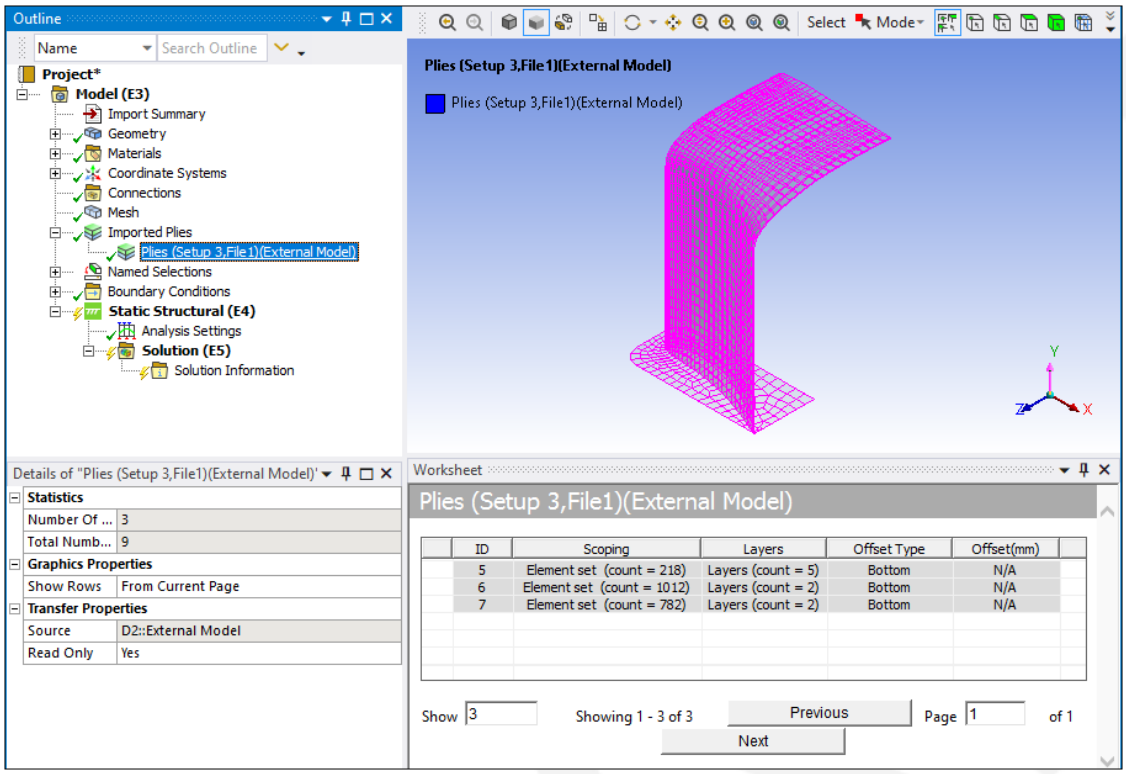
Imported Composite Plies

When your upstream External Model source file includes composite data, an **Imported Plies** folder appears beneath the **Model** parent folder when you open the file in Mechanical.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

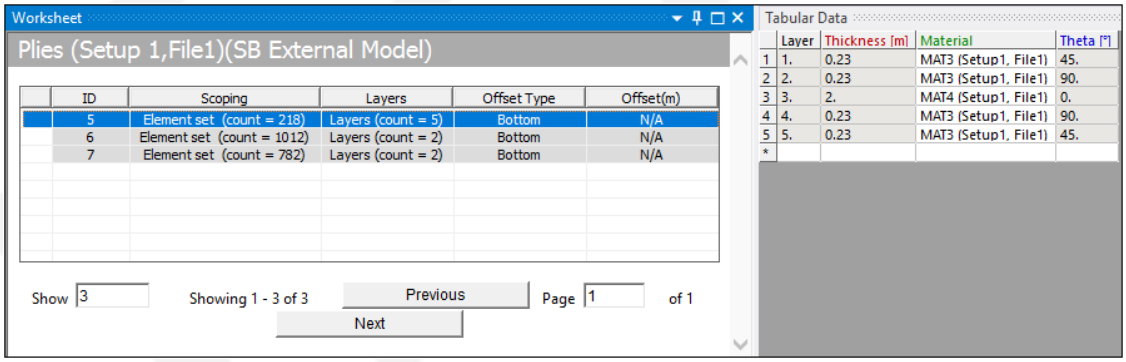
Published: 2023-10-23

Imported Plies Object



Plies Object

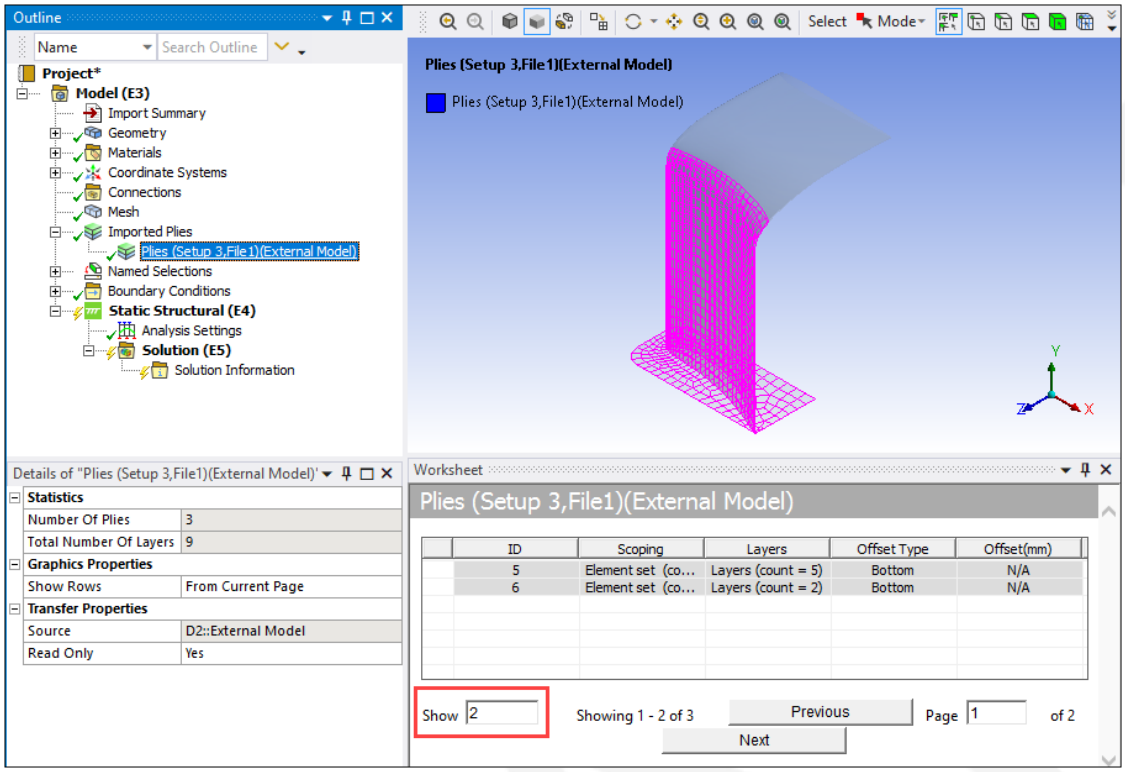
The **Imported Plies** object includes the child object **Plies**. This object displays a parenthetical that displays the upstream Component ID and file Identifier (Setup 1, File 1) as well as the system name (External Model). When selected, the **Worksheet** displays the source file data, and all ply data is highlighted in the Geometry window.



Display Feature

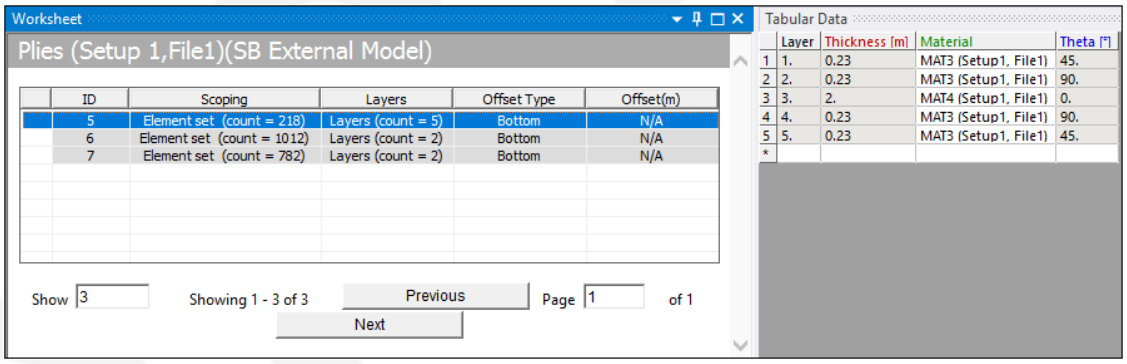
To visually check the sections, you can change the entry of the **Show** field, based on the available rows, to change which sections are highlighted in the Geometry window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Worksheet and Tabular Data

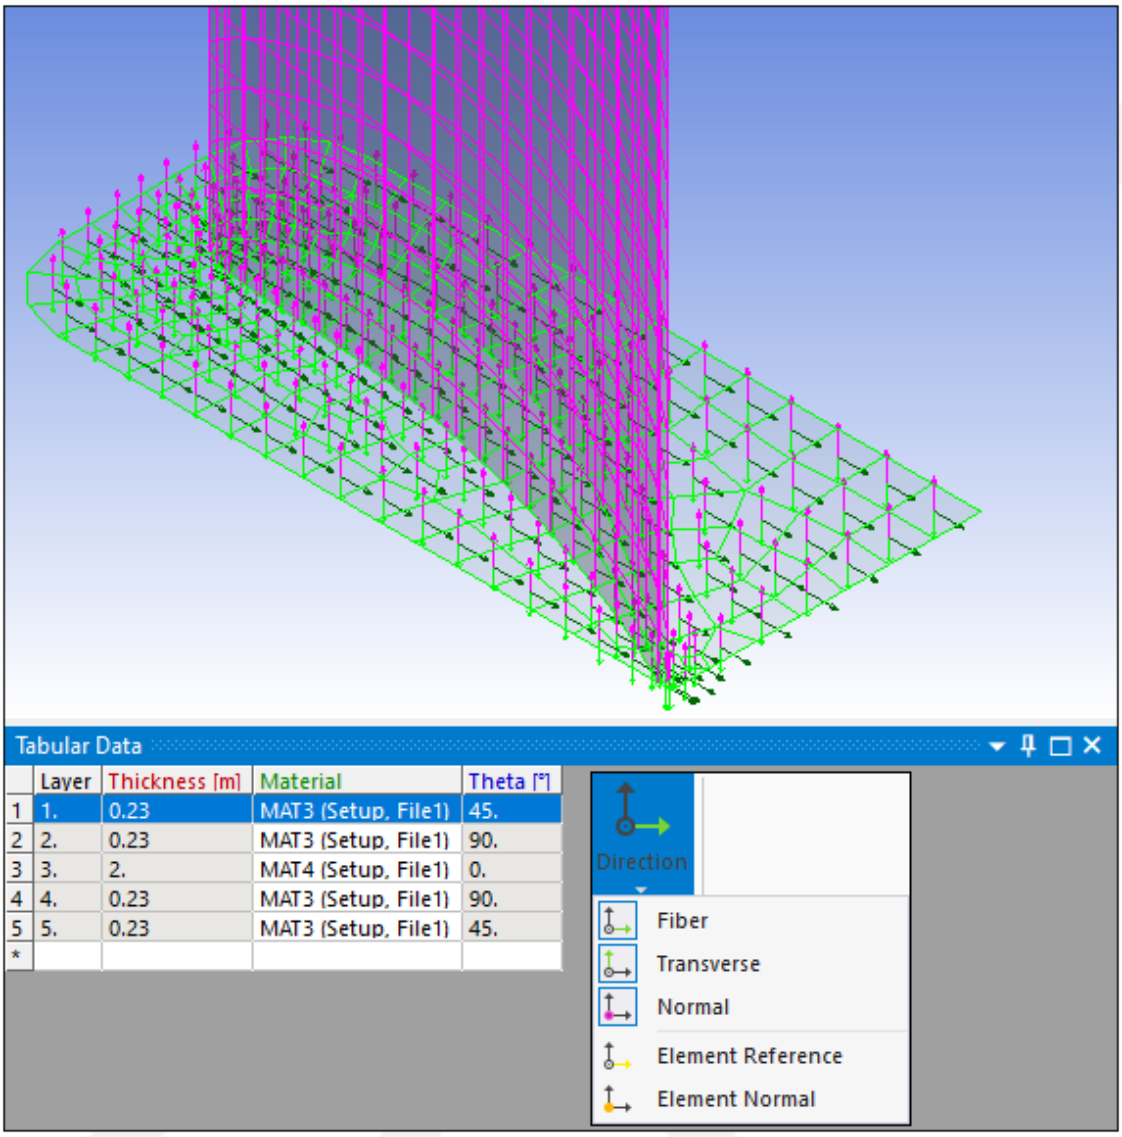
When you select a row in the **Worksheet**, 1) the elements for the selected row are highlighted in green in the Geometry, and 2) the **Tabular Data** window displays the associated layer data. You can modify the **Material** for the ply as needed in this window.



When you select a row in **Tabular Data**, you can use the ply-based display options of the **Direction** drop-down menu of the **Ply** group (p. 50) on the **Model** tab to display ply and element directions for imported ply structures.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Supported Analysis Types

The composite plies import type supports the following analysis types:

- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands for composites:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **CDB**: **SECTYPE**, **SECDATA**, **SECBLOCK**, and **SECOFFSET**.

  Note:

  Sections defined with the SECBLOCK command that have a single layer, where theta=0.0, are only imported as **Imported Plies** if the section is defined with one of the following element types: SOLID185, SOLID186, SOLSH190, SOLID278, and SOLID279.

- **NASTRAN**: PCOMP, PCOMPS, PCOMPG.
- **ABAQUS**: *SHELL SECTION. Note the following processing requirements:
  - The *SHELL SECTION command uses the ORIENTATION parameter to define ply directions. External Model only supports the use of ORIENTATION parameter on the command line. That is, the application does not support the use of the ORIENTATION parameter on data lines (for each layer). Here is an example of a supported *SHELL SECTION composite definition:

Command	*SHELL SECTION, ORIENTATION=Orient1, elset=elset1, composite, layup=Composite_Layup
Data Lines	0.125, 3, Glass-Epoxy, 45, L1_IS_1 0.500, 3, Glass-Epoxy, 0, L1_IS_2 0.125, 3, Glass-Epoxy, -45, L1_IS_3

  - If an ORIENTATION parameter is specified, the SYSTEM parameter must be set to RECTANGULAR for the associated ORIENTATION (SYSTEM= RECTANGULAR).
  - External Model only supports the STACK DIRECTION parameter value equal to 3 for the *SHELL SECTION commands. If this parameter has any other value specified in the input file, the associated *SHELL SECTION command is not imported/processed.

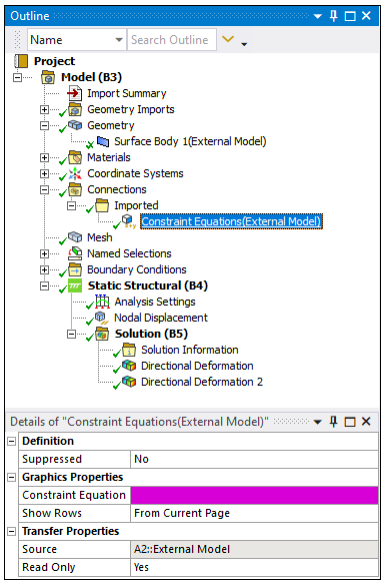
For additional information, see the Imported: Composite Plies object reference section as well as the **SECBLOCK for Shells** topic in the SECBLOCK Command section of the *Mechanical APDL Programmer's Reference*

Imported Constraint Equations or Coupling

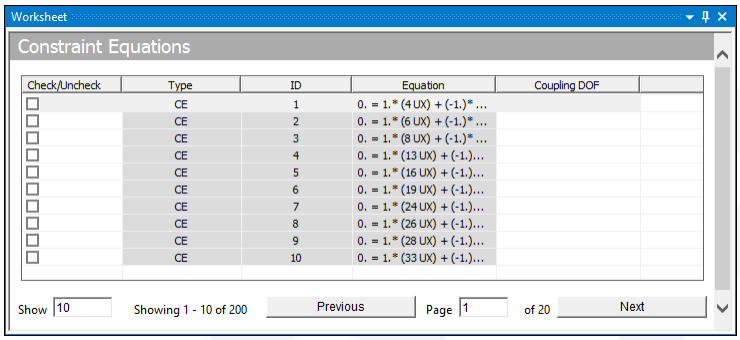
When your upstream External Model source file includes constraint equations or coupling, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder. It contains the child object: **Constraint Equations**. The data associated with the imported equations is provided through the Worksheet. You can Check/Uncheck (p. 916) Worksheet entries using the selection box in the table or through the right-click context menu.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

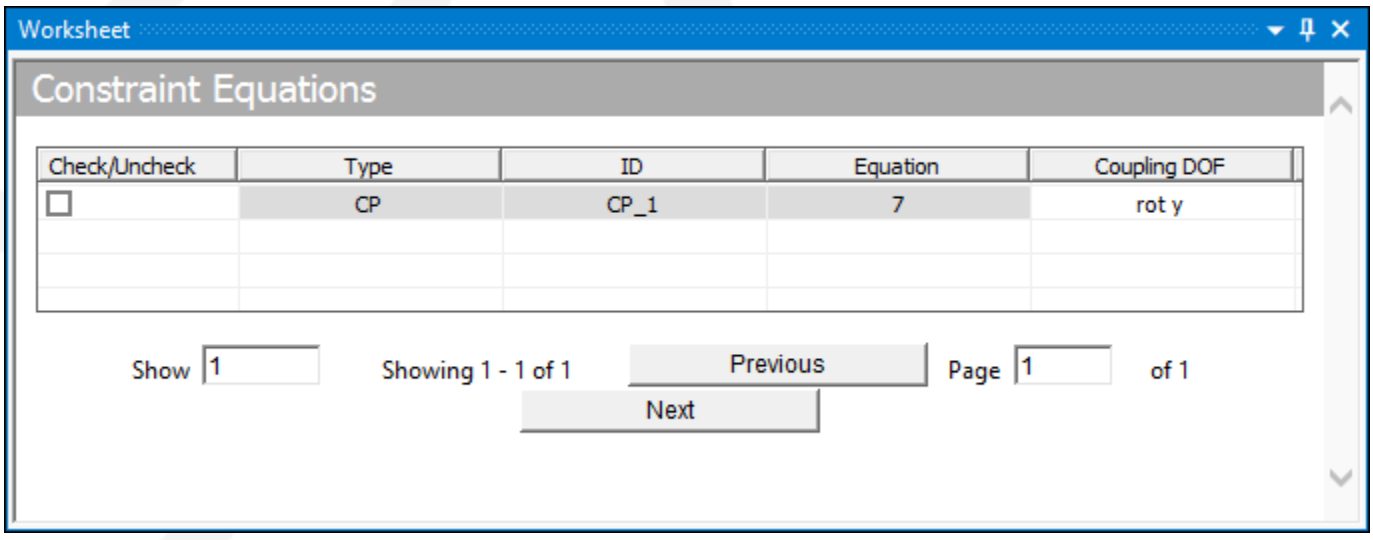
Published: 2023-10-23



Imported Constraint Worksheet Data



Imported Coupling Worksheet Data



Supported Analysis Types

Constraint Equations and Coupling import types are supported by the following analysis types:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural
- Steady-State Thermal (Coupling only)
- Transient Thermal (Coupling only)

Supported Source File Commands

The application imports the following source file data/commands as constraint equations or coupling:

- **CDB**: The **CE** commands are processed as constraint equations and the **CP** commands are processed as couplings.
- **NASTRAN**: MPC commands are processed as constraint equations.
- **ABAQUS**: *EQUATION commands are processed as constraint equations and *MPC TIE commands as couplings.

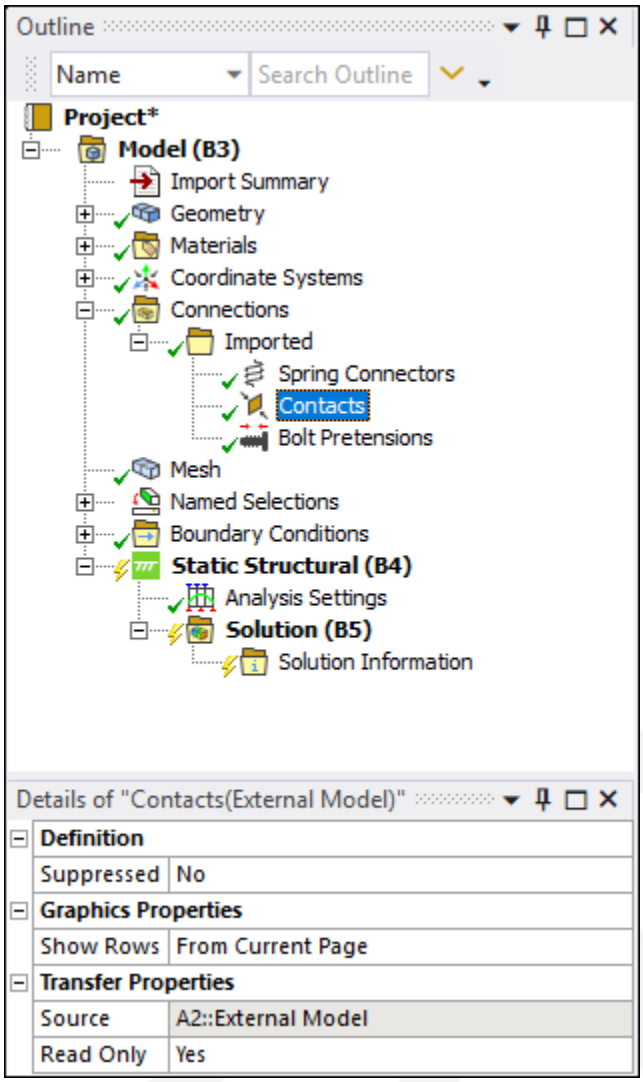
See the Imported: Constraint Equation object reference section for additional information.

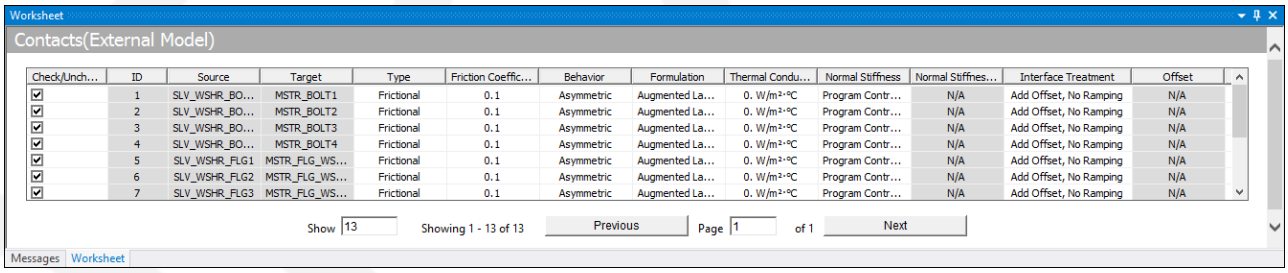
Imported Contacts

When your upstream External Model source file includes surface to surface contact, from either solid or shell bodies, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder. It contains the child object: **Contacts**. The data associated with the imported contact is provided through the **Worksheet**. You can Check/Uncheck (p. 916) Worksheet entries using the selection box in the table or through the right-click context menu.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23





Supported Analysis Types

Imported contact is supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Transient Structural
- Steady State Thermal
- Transient Thermal

Note:

The application imports thermal conductivity data for thermal analyses.

Supported Source File Commands

The application imports the following source file data as contact:

CDB

- Surface contacts in the form of CONTA173 (source) and CONTA174 (source), CONTA175 (source), and TARGE170 (target) elements.
- Target elements will usually define the element shape using the element shape flag (column 8) in the EBLOCK section. If not defined, the number of nodes for that target element will be used. The following target element shapes are supported:
  - Linear triangular shape – 6
  - Linear quadrilateral shape – 7
  - Quadratic triangular shape – 8
  - Quadratic quadrilateral shape - 9
- The following Element Type Options (KEYOPT) are supported:
  - KEYOPT(2) - Contact Algorithm
  - KEYOPT(3) – Units of normal contact stiffness

    Values 0 and 1 only
  - KEYOPY(8) – Symmetric Contact Behavior
  - KEYOPT(9) – Effect of Initial Penetration or Gap

    Values 0, 1, 2, 4, and 5 supported
    All other values default to 0
  - KEYOPT(12) – Behavior of Contact Surface
  - KEYOPT(18) – Sliding Behavior
- The following Real Constants are supported:
  - REAL(3) - Normal Penalty Stiffness Factor

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

  - REAL(10) – Contact Surface Stiffness
  - REAL(14) – Thermal Contact Conductance
- Material Property MU – Coefficient of Friction

NASTRAN

Not supported.

ABAQUS

Mechanical supports the following ABAQUS contact keywords:

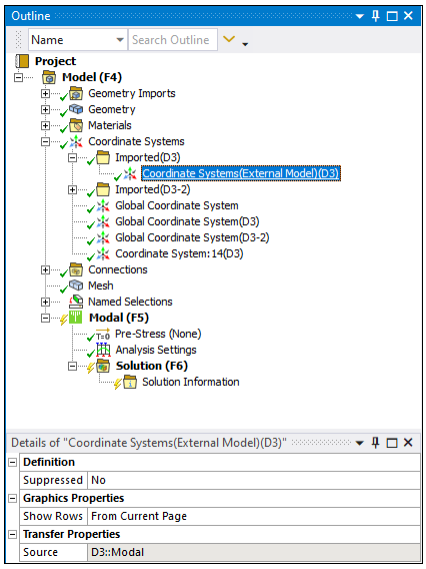
- *CONTACT PAIR. Supported parameters:
  - TYPE
  - SMALL SLIDING
  - HCRIT
  - INTERACTION
  - TIED
- *CONTACT INTERFERENCE (TYPE = CONTACT PAIR). SHRINK is the only option supported.
- *CLEARANCE. Parameters MASTER, SLAVE, and VALUE are supported.
- *SURFACE BEHAVIOR. Supported parameters:
  - NO SEPARATION
  - AUGMENTED LAGRANGE
- *FRICTION. Supported parameters:
  - ROUGH
  - LAGRANGE
- *CHANGE FRICTION: This keyword is supported for the first *STEP keyword specified in the input file only. Only the INTERACTION parameter is supported on this keyword.
- *GAP CONDUCTANCE: The application supports gap conductance as a table of gap pressure or gap clearance. All the tabular values are averaged and used as a single thermal conductance value in the contact pair.
- *TIE: Parameters NAME and POSITION TOLERANCE are supported.

See the Imported: Contact object reference section for additional information.

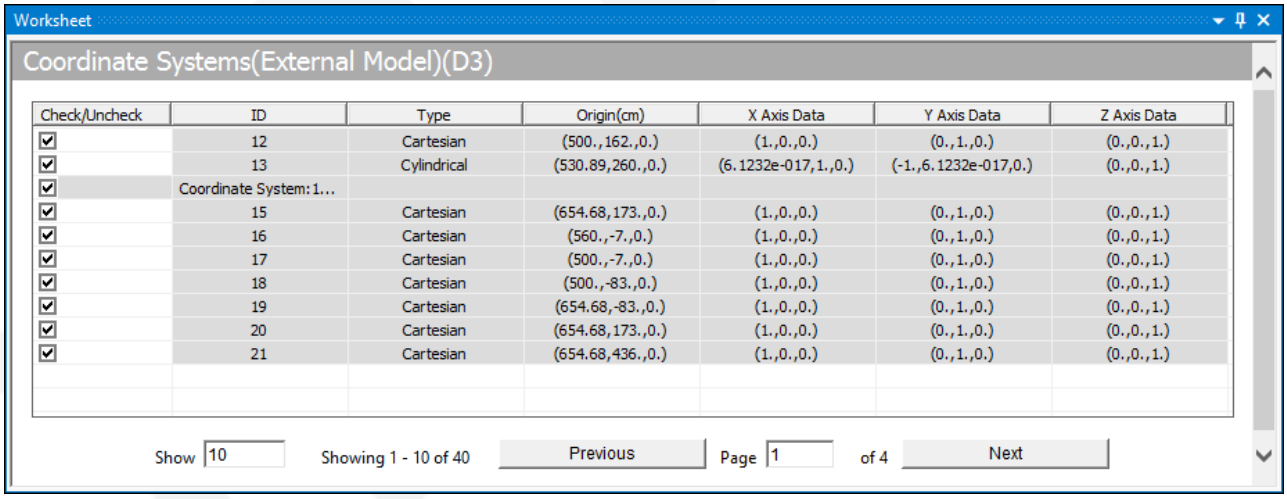
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Imported Coordinate Systems

When your upstream External Model source file includes coordinate systems, an **Imported** folder appears beneath the Coordinate System parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child object: **Imported Coordinate Systems (External Model)**.

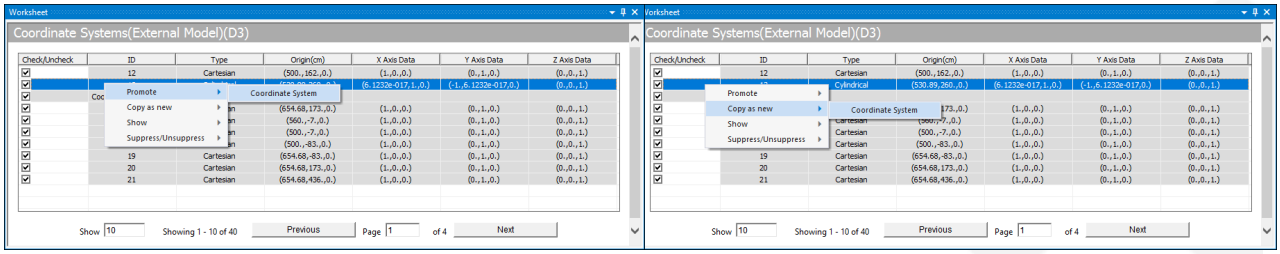


Selecting this singular object displays the Worksheet. The Worksheet displays all imported coordinate systems. Each coordinate system includes an ID from the source file, the Type of coordinate system (Cartesian or Cylindrical), and the location and orientation of the coordinate system.



As shown in the following illustrations, on the individual coordinate systems, you can **Promote** or **Copy as New** (p. 916).

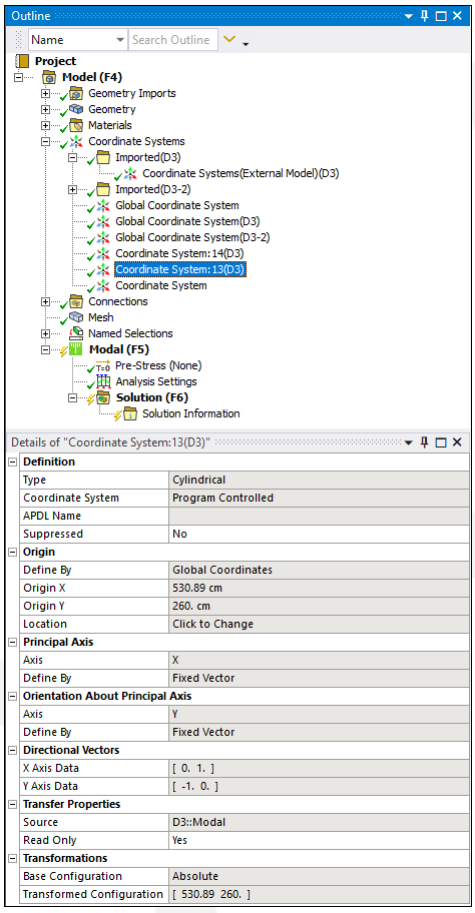
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



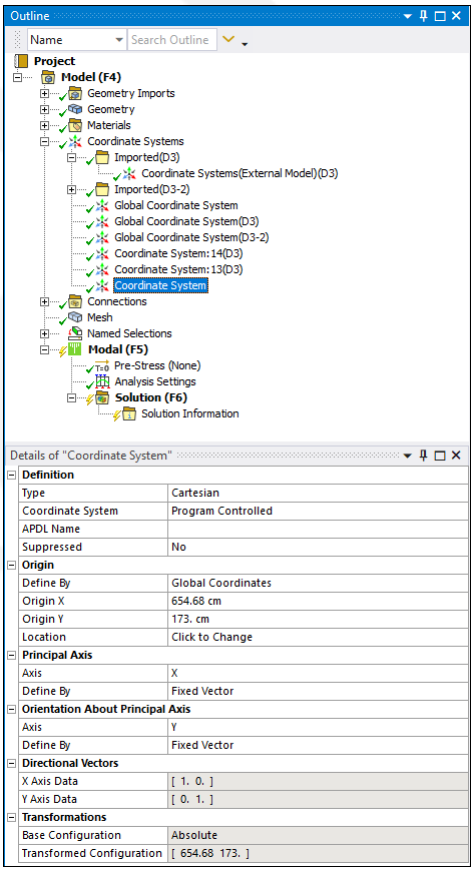
As illustrated below, the application creates new coordinate objects through promotion or copy. It renames promoted coordinates using the ID and the source file name and maintains a link (Transfer Properties) to the source system. Any source system updates or changes affect the promoted coordinate. You can make changes to promoted coordinates by setting the **Read Only** property of the Transfer Properties to **No** (default = **Yes**).

Copied coordinates are simply a new independent coordinate and named as such. These promote and copy features support multiple Worksheet selections.

Promoted Coordinate System



Copied Coordinate System



Supported Analysis Types

Imported Coordinate Systems are supported by the following analysis types:

- Coupled Field Analyses

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands as coordinate systems:

- **CDB**: **LOCAL** command.
- **NASTRAN**: Coordinate systems are defined by the following commands:
  - cord1c
  - cord1r
  - cord2c
  - cord2r
- **ABAQUS**: *ORIENTATION command.

  This command must be defined by coordinates or nodes. Any other definition is not supported. The types of coordinate system supported are Cartesian and cylindrical.

See the Imported: Coordinate System object reference section for additional information.

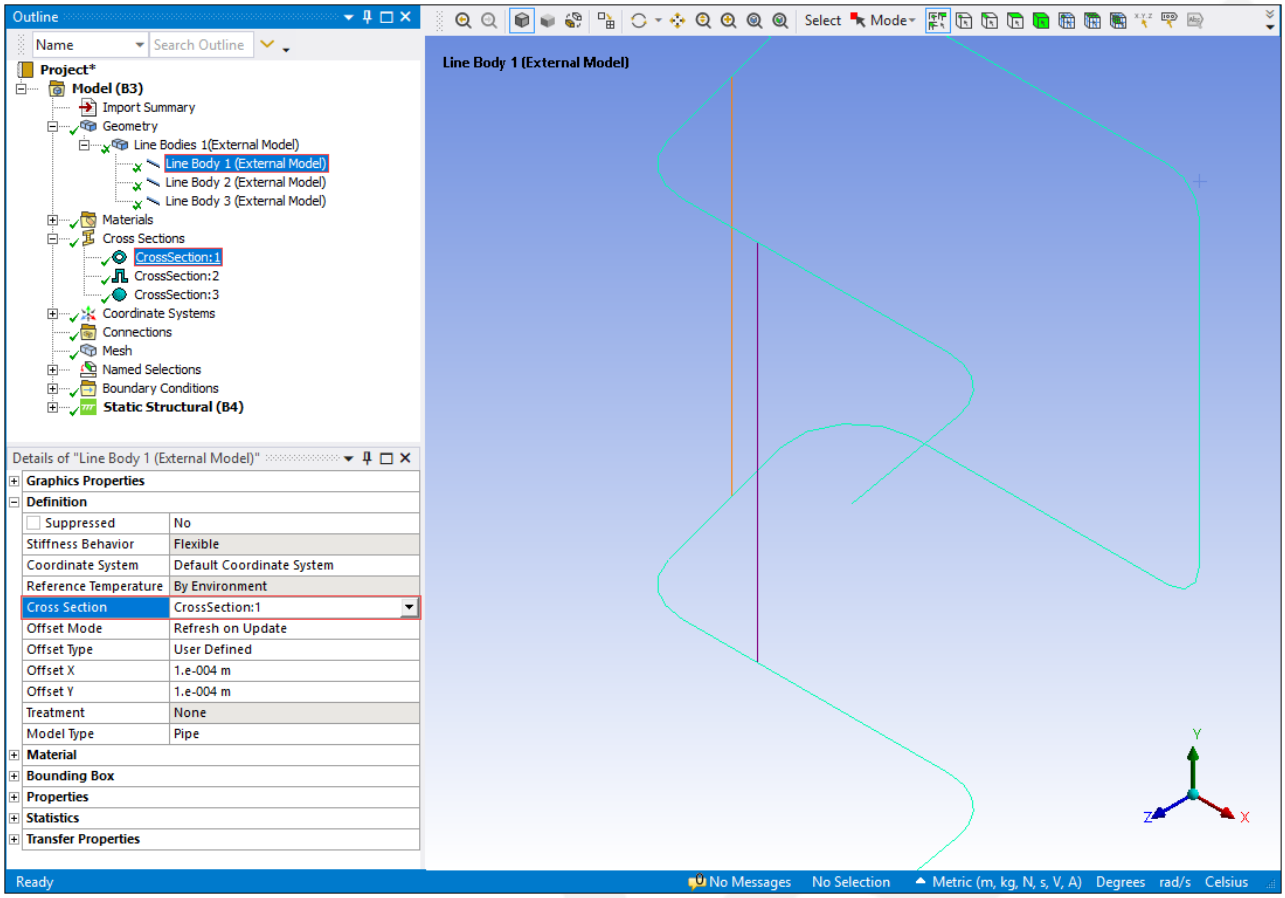
Imported Cross Sections

When your upstream External Model source file includes Line Body (p. 872) cross section data, cross section objects are automatically created/inserted under the Cross Sections folder. These imported cross sections act as any other user-defined cross section.

Highlighted below is an example of an imported Line Body. It automatically includes a property reference to the accompanying imported cross section (**CrossSection1**).

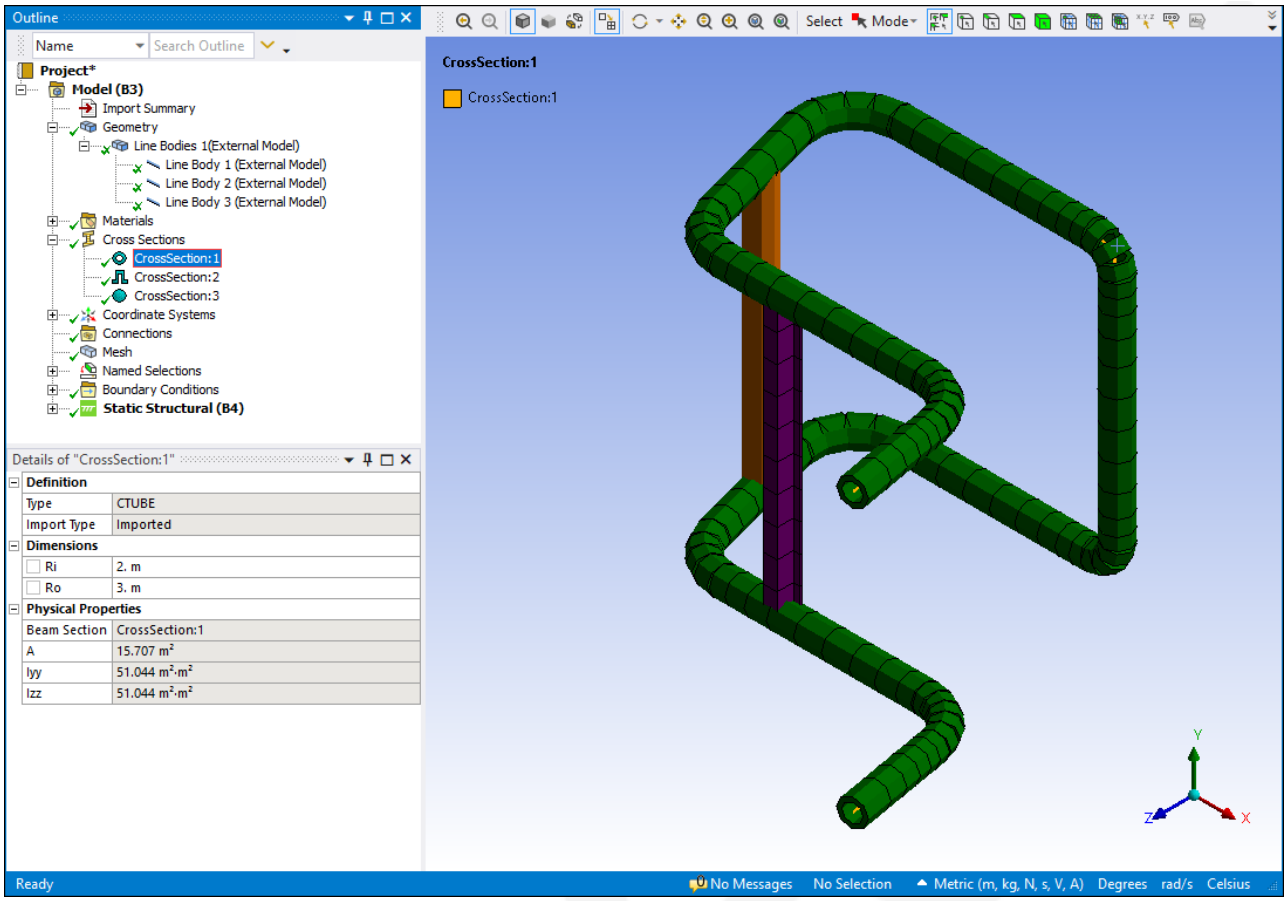
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



Here is **CrossSection1** highlighted. The mesh display is turned on for this image.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Supported Source File Commands

The application imports the following source file data/commands as line body/beam cross sections:

- **CDB**: The SECTION/REAL attribute defined with the element in the EBLOCK section.
  - BEAM, LINK and PIPE Types are supported.
  - The MESH Subtype is not supported.
- **NASTRAN**: Property ID designated with the PBAR, PBARL, PBEAM, PBEAML, PROD and CONROD bulk data entry.
  - CHAN2, H, CROSS, T1, HEXA, and HAT1 section types are not supported in Mechanical. The equivalent ASEC properties are calculated and used for these sections.
- **ABAQUS**: On the each "*BEAM SECTION","*BEAM GENERAL SECTION" and "FRAME SECTION" keyword:
  - ARBITRARY, HEX, TRAPEZOID, and ELBOW Sections are not supported and are not used.
  - Tapered beams are not supported in Mechanical. If a tapered beam is specified in the CDB or ABAQUS file the section data from the first node is used.

Also see the Cross Section Objects section for more information.

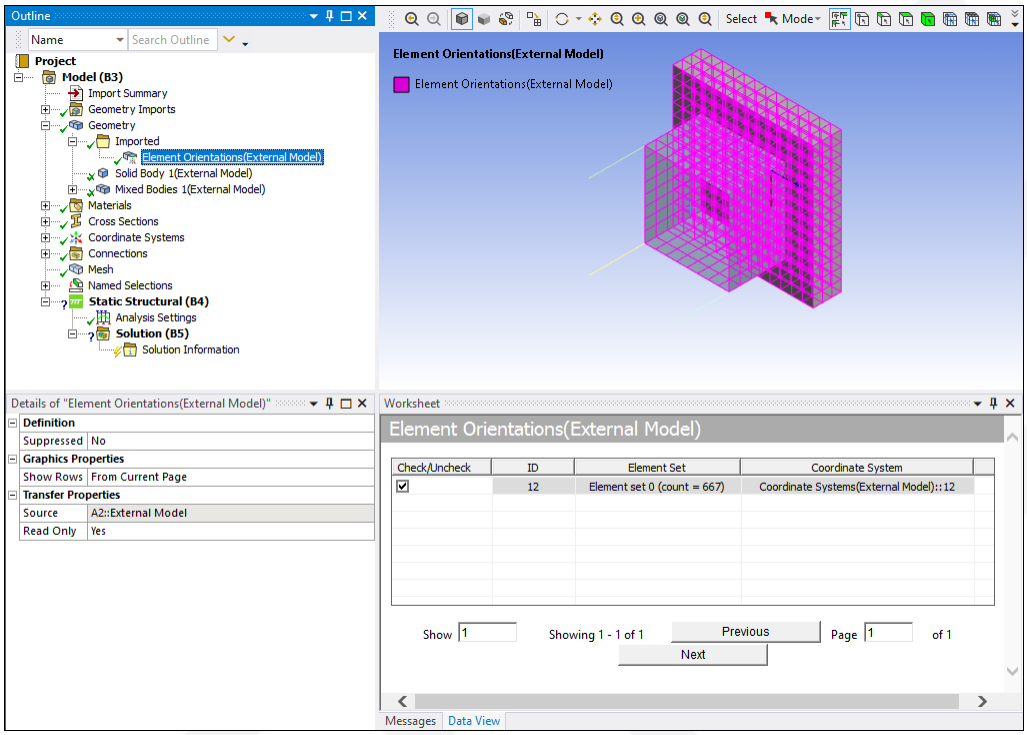
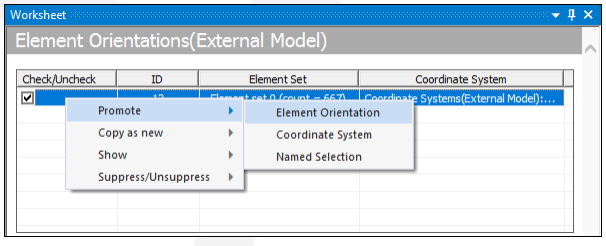
Imported Element Orientations

When your upstream External Model source file includes element orientation data, an **Imported** folder appears beneath the **Geometry** folder when you open the file in Mechanical. As with the imported coordinate systems, this object is a simple group folder (p. 208). It contains the child object: **Element Orientations** (p. 1008). Selecting this singular object displays the Worksheet. The Worksheet displays all of the imported element orientations, including a source-system ID, the Element Set, and the coordinate system of the element orientation.



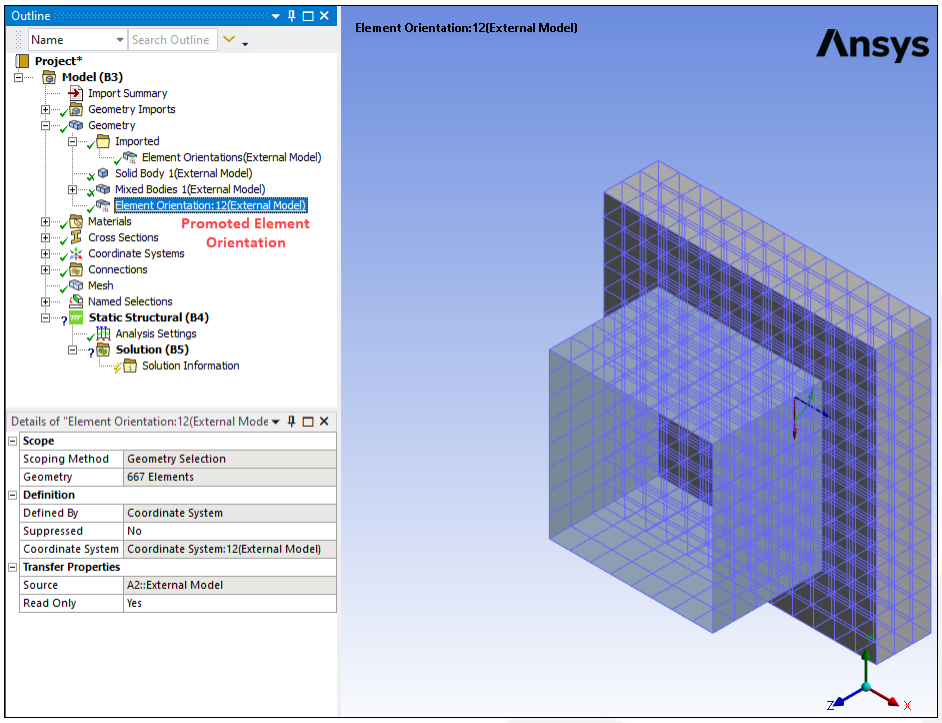
Promoting Element Orientations

As illustrated below, the application gives you the option on the Worksheet to promote or copy your Element Orientations. In addition, you can promote or copy (p. 916) the scoped Element Orientation set as a Named Selection and the coordinate system as a native coordinate system. Promoted objects maintain a link to the source file. Any source system updates or changes affect the promoted object.

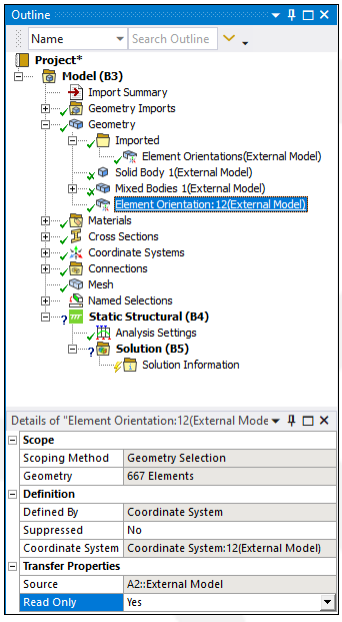


As illustrated here, the promoted Worksheet entry becomes read-only and no operations are supported for the row. The newly promoted object is highlighted below.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



The Details view of the promoted object is illustrated below. You can make changes to promoted objects by setting the **Read Only** property of the **Transfer Properties** category to **No** (default = **Yes**).

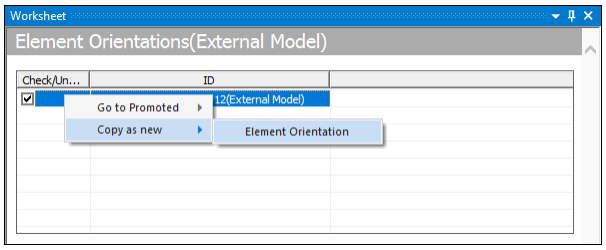


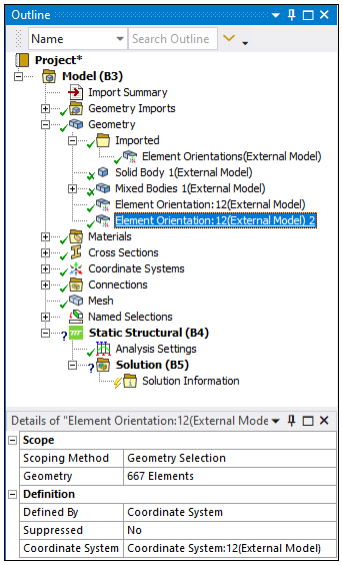
Copying Element Orientations

Copied Worksheet entries become a new independent object and are named based on your selection: Element Orientation, Coordinate System, or Named Selection.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23





Supported Analysis Types

Imported Element Orientations are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands as element orientations:

- **CDB**: All the elements defined by the **ESYS** command are processed.
- **NASTRAN**: For the Material Coordinate System field of the supported NASTRAN elements, Mechanical uses the default coordinate system if the field is blank or the imported coordinate system if the field contains an integer value. If the field contains a real value (angle), the application generates a coordinate system for each element based on the centroid of the elements and rotated by the given angle.
- **ABAQUS**: It is processed via the *ORIENTATION command.

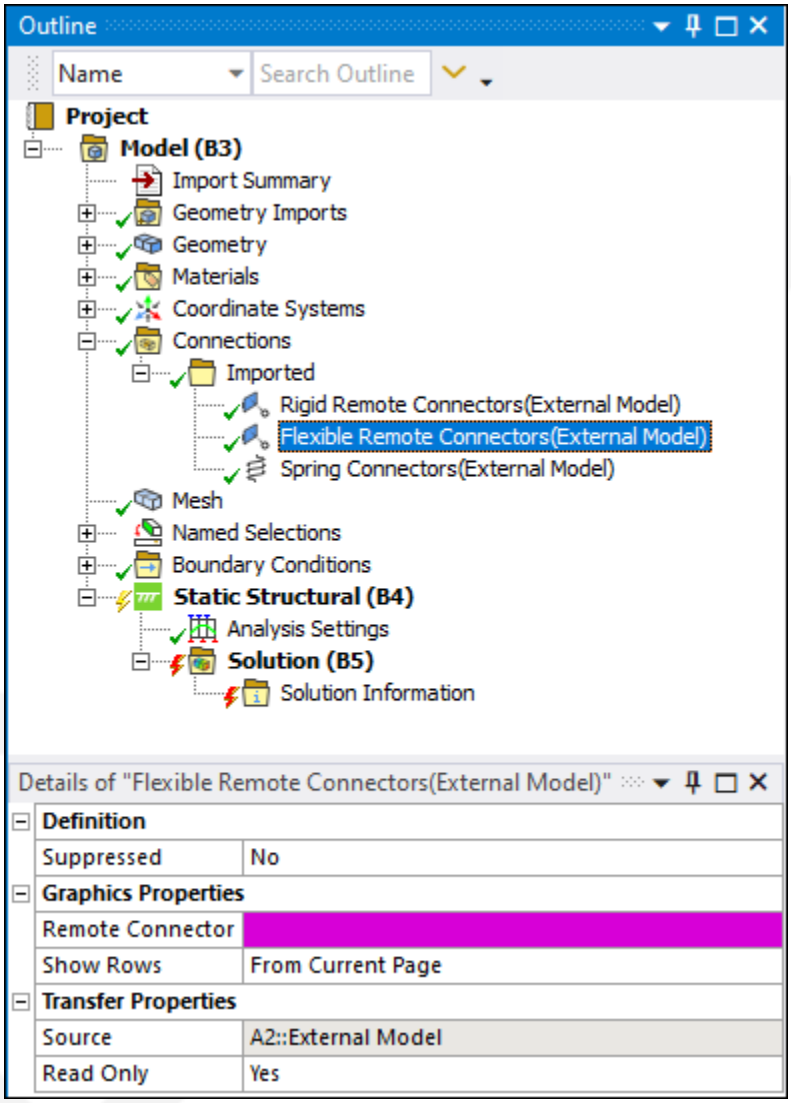
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

See the Imported: Element Orientation object reference page as well as the associated object reference pages for additional details about the properties and use of Element Orientation, Coordinate System, or Named Selections objects.

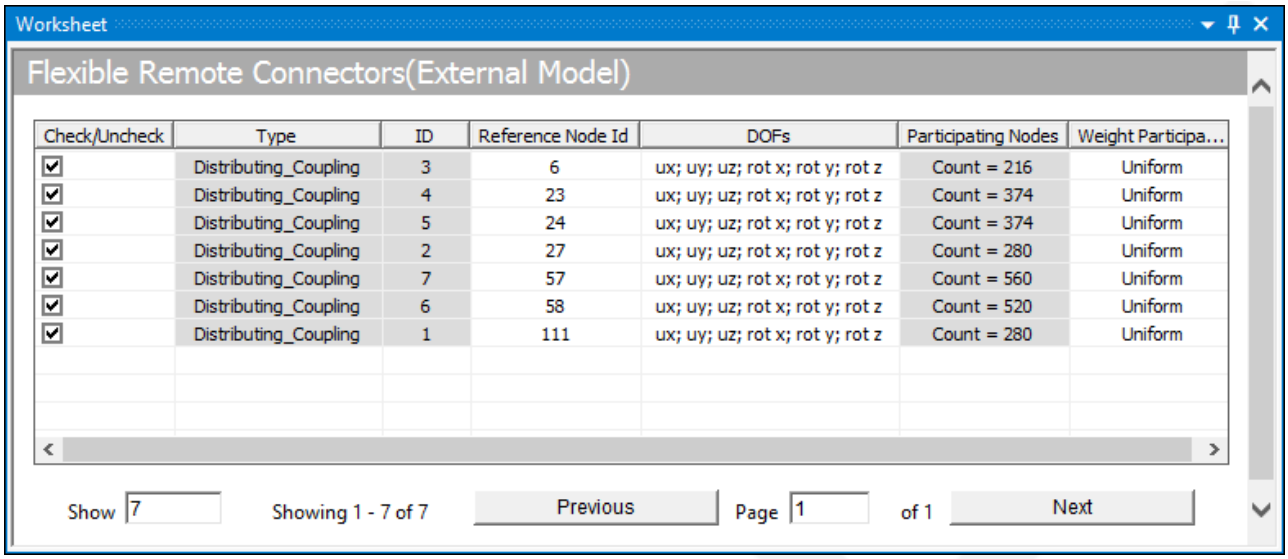
Imported Flexible Remote Connectors

When your upstream External Model source file includes flexible remote connections, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child objects: **Flexible Connectors**. The data associated with the imported connections is provided through the Worksheet. Worksheet content, including default settings, is based on the data in the external file. If a connector is scoped to a node that is **not** attached to the geometry, you can promote and/or copy (p. 916) the connector, otherwise, no promote and/or copy options are available.

Worksheet content is generally read-only, however, you can Check/Uncheck (p. 916) Worksheet entries using the selection box in the table, through the right-click context menu, or you can select the cell at the top of the column to check/uncheck all table rows.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Supported Analysis Types

Imported Flexible Remote Connectors are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural
- Steady-State Thermal
- Transient Thermal

Supported Source File Commands

The application imports the following source file data/commands as flexible remote connections:

- **CDB**: Contact/Target pairs with TARGE169/TARGE170 elements with pilot node (**TSHAP**, *PILO*) and Contact elements with the following KEYOPT settings:

KEYOPT (2) = 2	MPC-based approach.
KEYOPT (12) = 5	Bonded (always).
KEYOPT (4) = 1	Force-distributed constraint for CONTA171, CONTA172, CONTA173, CONTA174, CONTA175, CONTA176, and CONTA177.

- **NASTRAN**: RBE3. For this command:
  - The reference node the reference node's degrees of freedom (DOFs) are considered.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

– For a single dependent DOFs/Weight Set, the connection is considered Uniform.

– For multiple dependent DOFs/Weight Sets, the connection is considered user-defined.

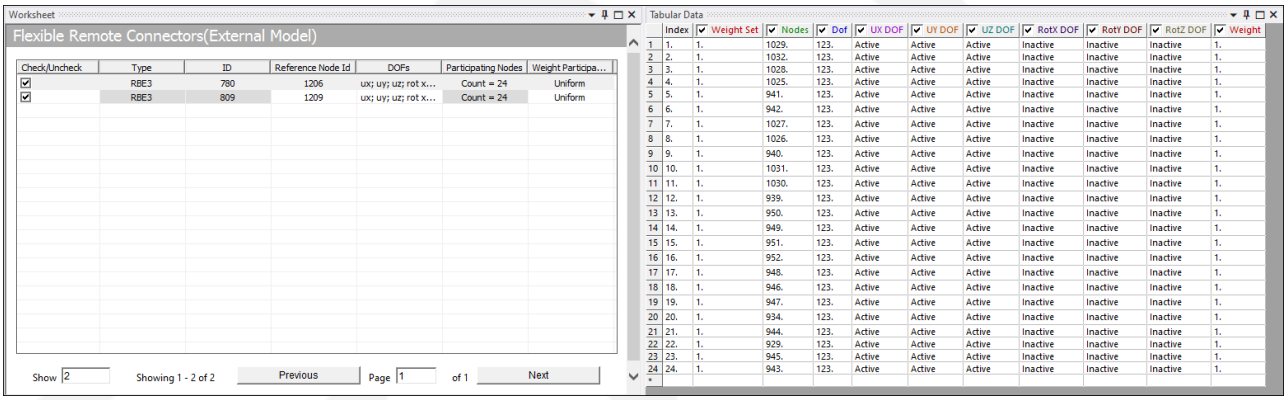
– If the reference DOFs are 123456 (UX, UY, UZ, ROTX, ROTY, ROTZ) and all the dependent DOFs are 123, a combination DOFSEL/RBE3 command will be sent to the solver for these DOFs. The dependent weights are also considered.

– For multiple slave DOF/Weight Sets with all the dependent DOFs that are not 123 and the reference DOFs are 123456, the connection is considered user-defined, but the dependent DOFs will be ignored. The dependent weights are also considered.

– For all other conditions the connection will be sent to the solver as a deformable RBE3 style bonded contact.

– If a non-structural analysis is being solved, the connection will be seen in the solver as a deformable RBE3 style bonded contact.

– When you select a connection (row) in the **Worksheet**, the **Tabular Data** window displays and includes the degree of freedom for each participating node.



– The dependent data table is not shown if there are no dependent nodes for a row or if any dependent nodes are not selected or active (a body is suppressed).

Note:

If you are resuming an earlier version of Mechanical and there are no dependent DOFs present, you must specify the DOFs for each set.

- **ABAQUS**: *DISTRIBUTING COUPLING and *COUPLING, *DISTRIBUTING.

  Processing is limited to required parameters only, not the optional parameters, such as orientation or mass.

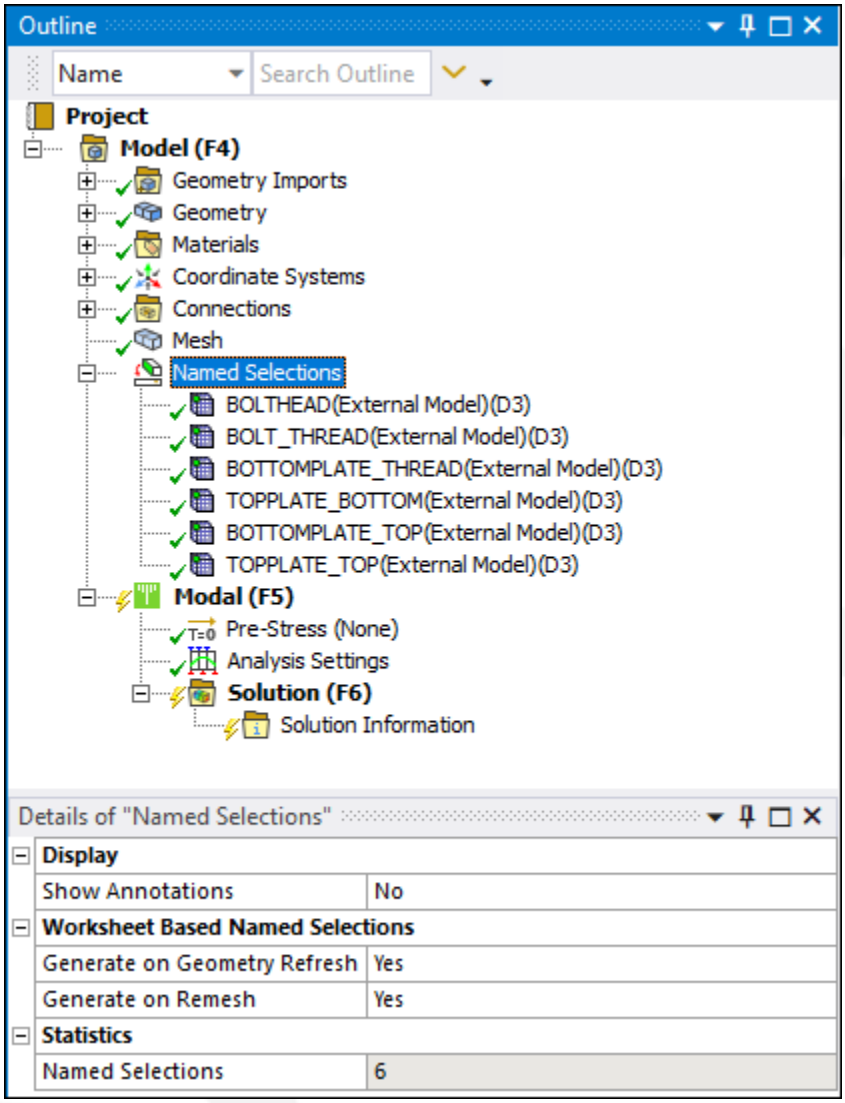
See the Imported: Flexible Remote Connectors object reference section for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Imported Named Selections

When your upstream External Model source file includes Named Selections, they are inserted under the Named Selections folder. These imported Named Selections act as any other user-defined Named Selection.



Review the Named Selections object reference page as needed for additional details about the properties and use of Named Selection objects.

Imported Nodal Orientations

When your upstream External Model source file includes Nodal Orientations. An **Imported** folder appears beneath the **Geometry** folder when you open the file in Mechanical. This object is a simple group folder. It contains the child object: **Nodal Orientations**.

Supported Analysis Types

Imported Nodal Orientations are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands as nodal orientations:

- **CDB**: All orientations from the `.cdb` file that are included in NBLOCK are processed.
- **NASTRAN**: Orientations are processed via the commands of the Imported Coordinate Systems (p. 934).
- **ABAQUS**: Orientations are processed via the *TRANSFORM command.

Also see the Imported: Nodal Orientation object reference section for additional information.

Imported Point Mass

When your upstream External Model source file includes Point Masses, an **Imported** folder appears beneath the **Geometry** folder when you open the file in Mechanical. This object is a simple group folder. It contains the child object: **Point Masses**. If the Point Masses are scoped to a node attached to the geometry, you can promote and/or copy (p. 916) them, otherwise, no promote and/or copy options are available.

Show 6 | Showing 1 - 6 of 6 | Previous | Page 1 of 1 | Next

Important:

If your Imported Point Mass is connected to a body through an imported connection, i.e. Remote Connection, Constraint Equation, or Spring, Mechanical does not include the Imported Point Mass in any Rotational Velocity or Rotational Acceleration scoping.

Supported Analysis Types

Imported Point Masses are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands as point masses:

- **CDB**: Element MASS21 is processed.
  - If 2D, MASS and IZZ are supported.
  - If 3D, MASSX, IXX, IYY and IZZ are supported.
  - Rotary Inertia only if KEYOPT(3) = 0 or 3.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

- **NASTRAN**: The CONM2 command is processed. We process the complete command comprising of Node IDs, Coordinate System IDs, Mass Value, offset distances, and mass moments of inertia. Any defined orientation is processed via the nodes (p. 945).

  Note:

  If there are any non-zero offsets, you must set them to zero in order to proceed with the solution.

- **ABAQUS**: Only the *ELEMENT, TYPE=MASS and *ELEMENT, TYPE=ROTARYI Point Mass elements are supported. The Mass Value is the only value obtained from the MASS command. All other *MASS command values are ignored. Any defined orientation is processed via the nodes (p. 945).

  Rotary Inertial and Orientation from *Rotary Inertia command are processed and all other data from *Rotary Inertia command are ignored.

Review the Point Mass object reference page as needed for additional details about the properties and use of Point Mass objects.

Imported Rigid Bodies

When the source file contains rigid body (p. 852) definitions, Mechanical imports them as bodies with the **Stiffness Behavior** property of the Body object automatically set to **Rigid** (read-only). Currently this feature is only supported for ABAQUS files.

Supported Analysis Types

Imported Rigid Bodies are supported by the following analysis types:

- Harmonic Response
- Modal
- Static Structural
- Transient Structural
- Response Spectrum
- Random Vibration

Supported Source File Commands

The application imports the following source file data/commands as a rigid body:

CDB

Imported Rigid Bodies are not currently supported by CDB files.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

ABAQUS

The ABAQUS command *RIGID BODY command is processed to import rigid bodies. The command supports the following arguments:

*RIGID BODY, ELSET=<elset_name>, REF NODE=<ref_node>

Where:

"<elset_name>" is the name of an element set (*ELSET). Supported elements are usual 2D and 3D continuum elements and rigid elements R3D3, R3D4.

"<ref_node>" is either a node number or a name of a nodal NSET that contains only one node number.

Note:

- Once imported, the reference node (REF NODE) is available as a normal node and Mechanical automatically generates a node-based Name Selection for each REF NODE. You can use these system generated Name Selections to scope loads and boundary conditions.
- The application supports contact between flexible and rigid bodies only when defined in the ABAQUS file. This means that manual contact definition (after import) is not supported as this requires to remesh your Model and will invalidate all your objects scoped on mesh entities.
- Mechanical does not support multi body parts that have a mix of flexible and rigid bodies. In this instance, the application automatically sets the **Stiffness Behavior** to **Flexible** and issues a warning.

NASTRAN

Imported Rigid Bodies are not currently supported by NASTRAN files.

LS-DYNA

Imported Rigid Bodies are not currently supported by LS-DYNA files.

Imported Rigid Remote Connectors

When your upstream External Model source file includes rigid remote connections, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child objects: **Rigid Connectors**. The data associated with the imported connections is provided through the Worksheet. Worksheet content, including default settings, is based on the data in the external file. If a connector is scoped to a node that is **not** attached to the geometry, you can promote and/or copy (p. 916) the connector, otherwise, no promote and/or copy options are available.

Worksheet content is generally read-only, however, you can Check/Uncheck (p. 916) Worksheet entries using the selection box in the table, through the right-click context menu, or you can select the cell at the top of the column to check/uncheck all table rows.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Show 14 Showing 1 - 14 of 14 Previous Page 1 of 1 Next

Supported Analysis Types

Imported Rigid Remote Connectors are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural
- Steady-State Thermal
- Transient Thermal

Supported Source File Commands

The application imports the following source file data/commands as rigid remote connections:

- **CDB**: Contact/Target pairs with:
  - TARGE169/TARGE170 elements with pilot node (**TSHAP**, *PILO*) and Contact elements with the following KEYOPT settings:

KEYOPT (2) = 2	MPC-based approach.
KEYOPT (12) = 5	Bonded (always).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

KEYOPT(4) = 2	Rigid surface constraint for CONTA171, CONTA172, CONTA173, and CONTA174.
KEYOPT(4) = 0	Rigid surface constraint for CONTA175, CONTA176, and CONTA177

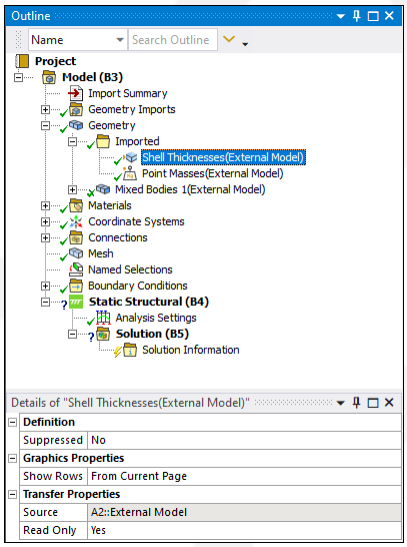
  - TARGE170 line segment (**TSHAP**, *LINE*) and no Contact elements.

- **NASTRAN**: RBE2. For this command, Mechanical processes the master node and the dependent nodes and their degrees of freedom (DOFs). All other data is ignored.
- **ABAQUS**:
  - *COUPLING and *KINEMATIC commands are processed but the orientation field is ignored.
  - *KINEMATIC COUPLING command is processed but the orientation field is ignored.
  - *MPC, TYPE = BEAM.
- **LS-DYNA**: *CONSTRAINED_NODAL_RIGID_BODY is processed, but the INERTIA option of this keyword is not supported.

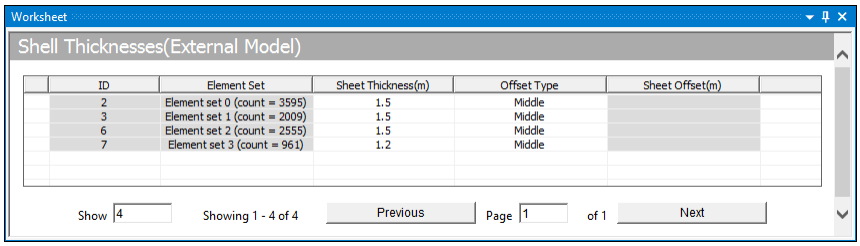
See the Imported: Rigid Remote Connectors object reference section for additional information.

Imported Shell Thicknesses

When your downstream External Model source file includes shell thicknesses, an **Imported** folder appears beneath the **Geometry** parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child objects: **Shell Thickness**.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



For Shell Thicknesses, you can modify the following Worksheet table options:

- **Sheet Thickness**: This field enables you to change the value of the Shell Thickness.
- **Offset Type**: This field provides a drop-down list of options, that include **Top**, **Middle**, **Bottom**, and **User Defined**.
- **Sheet Offset**: You use this property when the **Offset Type** is **User Defined**.

Supported Analysis Types

Imported Shell Thicknesses are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural
- Steady-State Thermal (Coupling only)
- Transient Thermal (Coupling only)

Supported Source File Commands

The application imports the following source file data/commands as shell thicknesses:

- **CDB**: The SECTION/REAL attribute defined with the element in the EBLOCK section.
- **NASTRAN**: Property ID designated with the PSHELL bulk data entry.
- **ABAQUS**: On the each "*MEMBRANE SECTION", "*SHELL GENERAL THICKNESS" or "*SHELL SECTION" keyword. If the NODAL THICKNESS parameter is used with one of these keywords, the application automatically sets element thickness to the thickness of the lowest node number. You cannot change the thickness values.
- **LSDYNA**: *SECTION_SHELL keyword

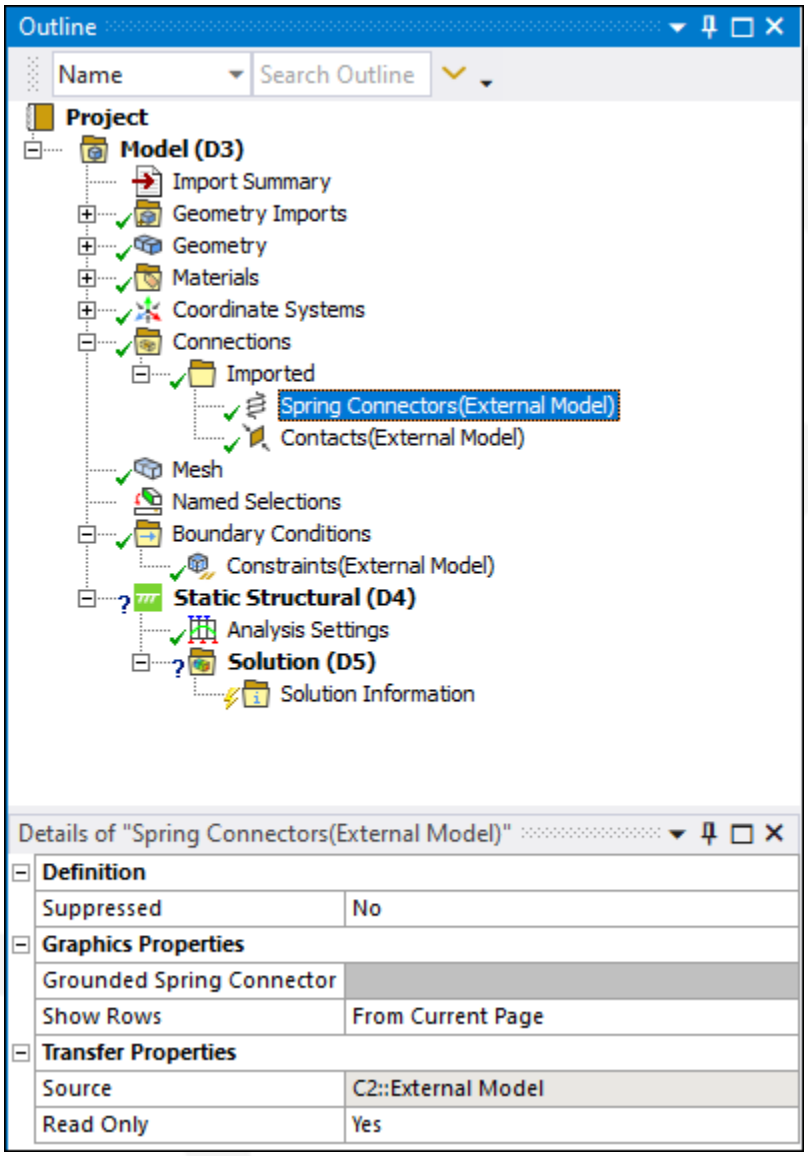
See the Imported: Shell Thicknesses object reference section for additional information.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

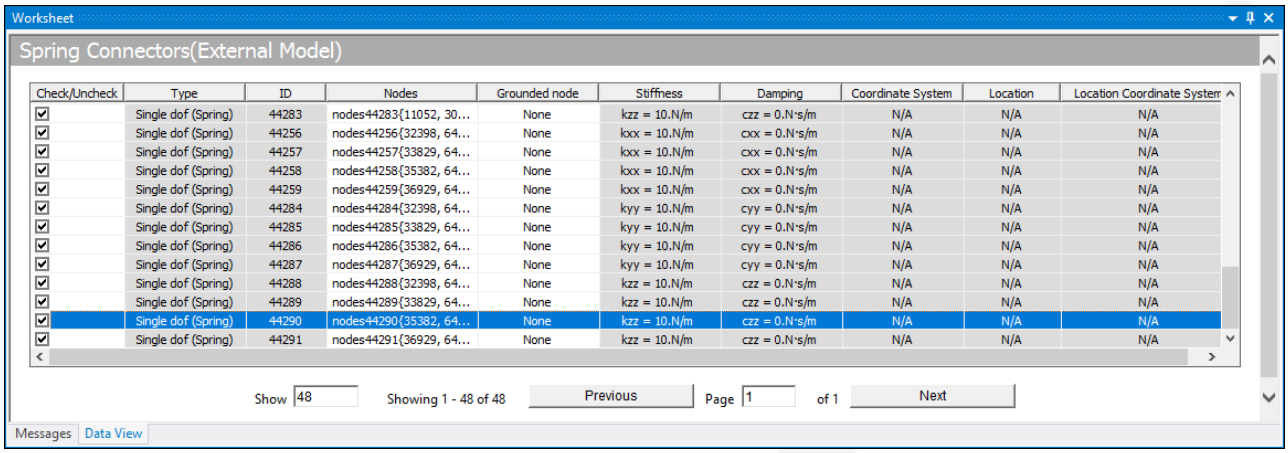
Imported Spring Connectors

When your upstream External Model source file includes spring connections and bushings, an **Imported** folder appears beneath the **Connections** parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child objects: **Spring Connectors**. The data associated with the imported springs and bushing is provided through the Worksheet. Worksheet content, including default settings, is based on the data in the external file.

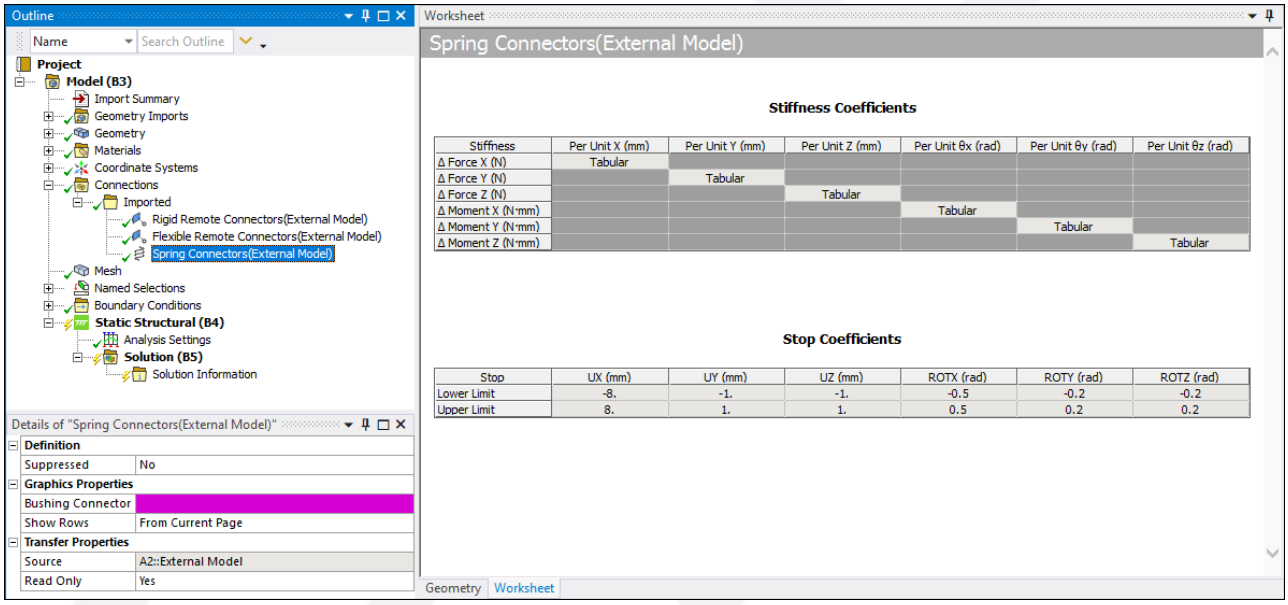
Spring Example



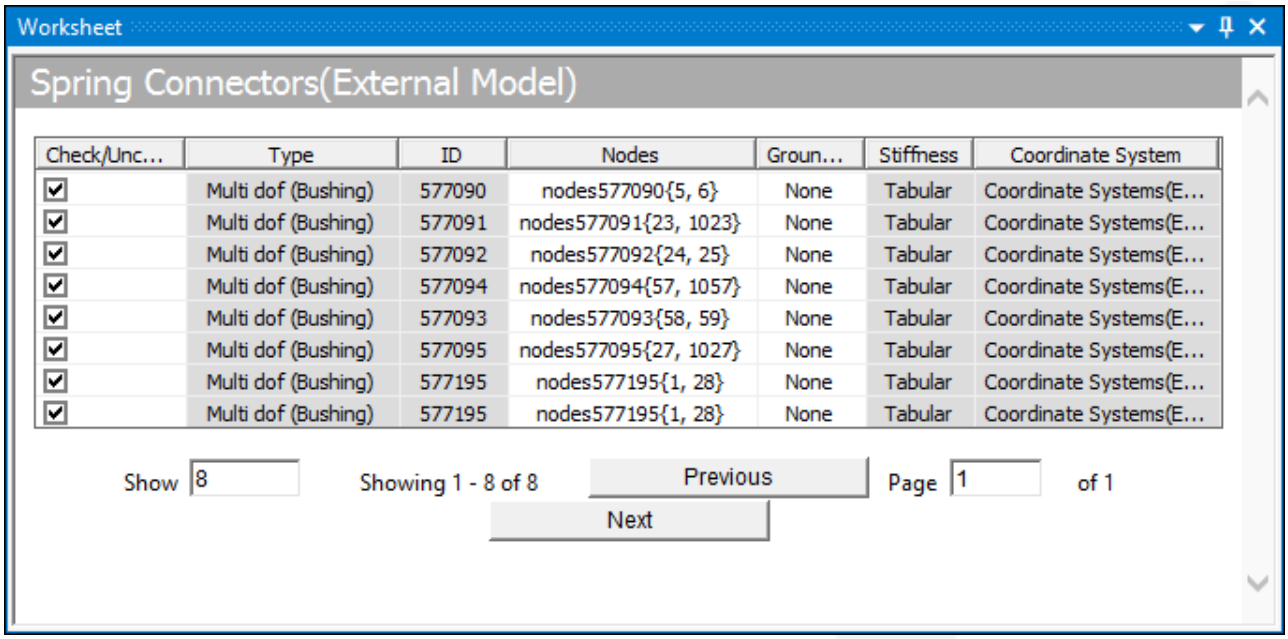
Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



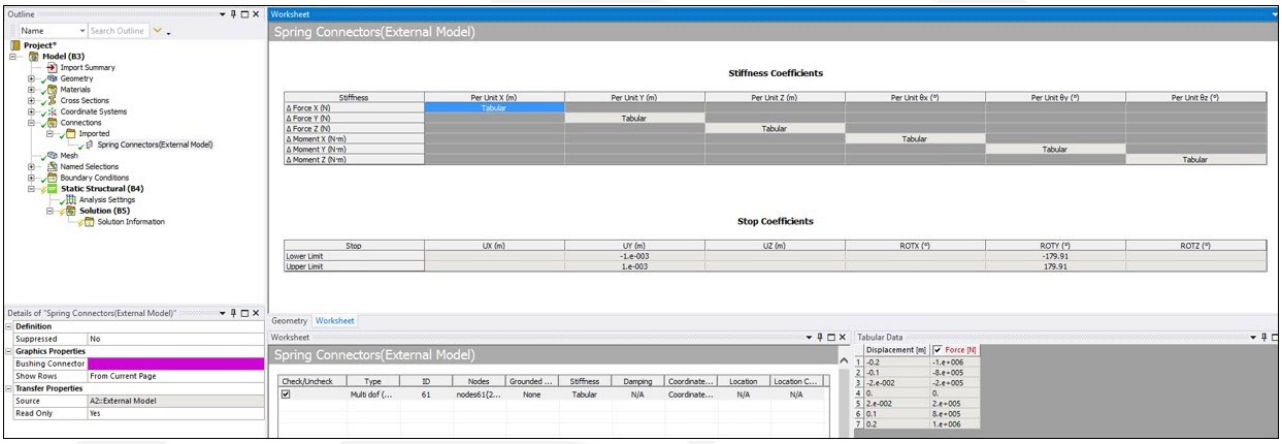
Bushing Example



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23



Nonlinear Bushing Example



Supported Analysis Types

Imported Spring Connectors are supported by the following analysis types:

- Coupled Field Analyses
- Harmonic Response
- Modal
- Static Structural
- Transient Structural

Supported Source File Commands

The application imports the following source file data/commands as springs:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

CDB

For the CDB file type imported into Mechanical through **External Model**, the application only processes:

- COMBIN14 linear spring elements with the following restrictions:
  - For the supported constants of this element type, Mechanical only processes Real Constants Stiffness (K) and structural Damping Coefficient (CV1). If your input data includes any real constant in addition to K or CV1 (such as CV2), these additional values are not processed.
  - Mechanical does not process material commands.
  - Supported KEYOPT,2 numbers include structural degrees of freedom only.
- COMBIN39 nonlinear spring elements with the following restrictions:
  - Supported KEYOPT,3 numbers include translational degrees of freedom only.
  - Mechanical does not process material commands.

NASTRAN

Mechanical supports the processing the CELAS1, CELAS2, CBUSH, and PBUSH commands only from a NASTRAN file with the following requirements:

- Mechanical only processes stiffness(K) and structural damping (GE). The stress coefficient is not processed.
- If GB (grid point B) is blank, the application assumes that the next node is grounded and creates a new node with the same location as the previous node.
- For CELAS1 and CELAS2 commands the first DOF will be taken as the operating DOF for the spring.
- For the PBUSH command, Mechanical supports the stiffness coefficients K1, K2, K3, K4, K5, K6 and structural damping coefficients (GE1, GE2, ... GE6).

ABAQUS

Spring Connections

For spring data imported from ABAQUS, Mechanical processes the element types:

- SPRING1 (spring element between a node and ground acting in a fixed direction).
- SPRING2 (spring element between two nodes acting in a fixed direction). For this element type, the application will import nonlinear force-displacement spring data that contains the origin, if the NONLINEAR parameter is used with the *SPRING keyword.
- SPRINGA (spring element between two nodes with its line of action being the line joining the two nodes).

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

In addition, the application supports the following *SPRING options, however, all other fields are ignored:

- Orientation via Imported Nodal Orientation (p. 945).
- Degree of freedom, stiffness and structural damping coefficients.
- Linear and nonlinear behavior.

Important:

For SPRING1 elements, an additional node is created in the same spot as the given node and that node is grounded when sent to the solver.

Bushing Connections

Mechanical supports the following ABAQUS bushing keywords:

- *ELEMENT: This keyword requires the TYPE parameter CONN3D2 as well as the Data Lines that include the Element IDs and two node IDs (two nodes must be present). You can also use the optional parameter ELSET. Note that the ELSET Name must match name the *CONNECTOR SECTION keyword. Grounded bushings are not supported.
- *ELSET: This keyword requires the ELSET parameter whose name must be included on either the *ELEMENT or *ELSET keywords as well as the name of the *CONNECTOR SECTION keyword.
- *ORIENTATION: This keyword requires the NAME Parameter and this parameter must match the name given on the second line of the *CONNECTOR SECTION keyword.
- *CONNECTOR SECTION: This keyword requires the ELSET and BEHAVIOR parameters whose names must be included on either the *ELEMENT or *ELSET keywords or the *CONNECTOR BEHAVIOR keyword. In addition, the first Data Line must define BUSHING as the type of connector and the second line must define the name of the coordinate system and must match a name on the *ORIENTATION keyword. Only the first Orientation name is used.
- *CONNECTOR BEHAVIOR: This keyword requires the NAME Parameter. This Parameter must also match name used with the BEHAVIOR parameter on the *CONNECTOR SECTION keyword. In addition, the *CONNECTOR BEHAVIOR keyword must be immediately followed by the keywords *CONNECTOR ELASTICITY and *CONNECTOR STOP (as described below).
- *CONNECTOR ELASTICITY: This keyword may be repeated up to six times for the values of a DOF. It requires the COMPONENT Parameter and the COMPONENT Parameter must represent a DOF direction. Directions values include: 1 = UX, 2 = UY, 3 = UZ, 4 = ROTX, 5 = ROTY, 6 = ROTZ

  The NONLINEAR Parameter is optional unless your input includes a table of Stiffness vs Constraint, in which case it is required.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

The solution does not allow both nonlinear and linear data. Linear data is ignored during the solution. To ensure proper nonlinear effects, set the **Large Deflection** property to **Yes**.

Corresponding Data Lines include, if Nonlinear, Stiffness and Constraint. And, the line is repeated for each Stiffness, Constraint pair in a table. If the Data Line is Linear, it includes Stiffness.

- *CONNECTOR STOP: This keyword requires the COMPONENT Parameter and a data line that includes an Upper limit and a Lower limit value.

Also see the Imported: Spring Connectors object reference section.

Imported Initial Stresses

When your downstream External Model source file includes initial stresses and initial equivalent plastic strains, an **Imported** folder appears beneath the **Geometry** parent folder when you open the file in Mechanical. This object is a simple group folder (p. 208). It contains the child objects: **Initial Stresses**. The External Model can only reference LS-DYNA (. k) files.

For Initial Stresses, none of the fields can be modified.

Supported Analysis Types

Imported Initial Stresses are supported by the following analysis types:

- Coupled Field Analyses
- Static Structural
- Transient Structural
- LS-DYNA

Supported Source File Commands

The application imports the following **LSDYNA** source file data/commands as initial stresses:

*INITIAL_STRESS_SOLID

*INITIAL_STRESS_SHELL

See Explicit-to-Implicit Sequential Solutions for additional information.

Automatic Material Assignment

If more than one body in your upstream **External Model** system is assigned the same material, Mechanical automatically creates a Material Assignment object for the associated bodies. This action makes sure that each body has the same unique material identifier.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Reference Node Naming

For the imported FE data types listed below, Mechanical enables you to assign custom names to reference nodes in the Worksheet. This enables you to access the nodes in the solver file (through command snippets (p. 2303)). Your name can contain only standard English letters and numbers, spaces, underscores, hyphens, and/or parenthesis characters.

- Imported Bolt Pretensions and Premeshed Bolt Pretensions (p. 918)
- Imported Flexible Remote Connectors (p. 942)
- Imported Point Masses (p. 947)
- Imported Rigid Remote Connectors (p. 951)
- Imported Spring Connectors (p. 956)

Mechanical automatically makes the following changes to your custom name in order to prepare the new reference name for the Mechanical APDL application:

- A name exceeding 32 characters is truncated.
- A name that begins with a number, space, hyphen, or parentheses character, is renamed to include “C_” before the character.
- Spaces, hyphens, or parentheses between characters in a name are replaced with underscores.

For example, a Reference Node in the Mechanical application called "1 Edge" appears as component "C_1_Edge" in the Mechanical APDL application input file.

Importing Mesh-Based Databases in Batch

The Mechanical installation includes an executable file (`Ans.StandaloneExternalModelConsole.exe`) that enables you to import solver input files. This input file describes a model through various data, including, but not limited to, mesh data, materials, loads and boundary conditions, as well as analysis settings. The executable is able to parse an input file and produce two types of output files:

1. A solver file that is based on a specific solver, such as the Mechanical APDL solver or the LS-DYNA solver. This means that the output solver file can be processed by the specified solver. Furthermore, you can optionally choose to save this output file as a Mechanical database (`*.mechdb`) file, which includes a Mechanical system as well as the target system.
2. A Mechanical database (`*.mechdb`) file. You can then use this database in the Mechanical application, where you can add a target analysis system. When opened in the application, `*.mechdb` files produce an analysis system in Mechanical that generates objects included with the Model object, not including an analysis system. Although it is the simplest workflow, this method requires you to manually complete setting up the analysis.

Based on your platform, the executable file is located in the following directory:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Windows

"<installation_directory>\aisol\bin\winx64\Ans.StandaloneExternalModelConsole.exe"

Linux

"<installation_directory>/aisol/.workbench -cmd <installation_directory>/aisol/bin/linx64/Ans.StandaloneExternalModelConsole.exe"

Go to a section topic:

- Requirements and Limitations (p. 963)
- Required Command Arguments (p. 963)
- Command Entry (p. 963)
- Supported Arguments (p. 965)
- TOML File (p. 966)

Requirements and Limitations

This feature supports:

- The input of the following solver files:
  - Mechanical APDL common database (`.cdb`)
  - ABAQUS Input (`.inp`)
  - LS-DYNA Input (`.k` and `.key`)
- Single input files only. This feature does not support model assembly.

Important:

For ABAQUS and LS-DYNA input files that contain the *INCLUDE keyword, the application also processes the dependent files.

Required Arguments

You must use one of the following arguments:

- **`--input_solver_file`** (Import a solver file using default settings).
- **`--input_settings`** (Import a solver file using settings specified in TOML file format).

Command Entry

Use the following to execute the command and specify the required and optional arguments.

1. Open the Command Prompt window.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

2. At the command prompt, specify the desired directory location. For example:

   "C:\ANSYS Inc\v241\aisol\bin\winx64\Ans.StandaloneExternalModelConsole.exe"

3. Based on your desired output, specify one of the following required argument combinations:

   - **--input_solver_file**: Import a solver file and create a Mechanical database (up to **Model** object level).

     For example: **Ans.StandaloneExternalModelConsole.exe --input_solver_file <file_path to solver input file> --save_mech_db**

   - **--input_settings**: Create solver file based on target analysis as well as creating an optional Mechanical database with the analysis system.

     For example: **Ans.StandaloneExternalModelConsole.exe --input_settings <file_path to TOML file> --save_mech_db**

4. As desired, specify additional arguments as described below.

Tip:

You can drag and drop files into the Command Prompt window to automatically generate the file path entry.

Command Entry Example 1

"C:\Program Files\ANSYS Inc\v241\aisol\bin\winx64\Ans.StandaloneExternalModelConsole.exe" --input_solver_file \\Parts\Mesh\Mech_CDB\Esys.cdb --save_mech_db --output_dir_path c:

This command entry imports a cdb solver file and generates a Mechanical database.

Where:

This entry initiates the execution of the file.

"C:\Program Files\ANSYS Inc\v241\aisol\bin\winx64\Ans.StandaloneExternalModelConsole.exe"

This argument specifies that you want to import a cdb file during the batch process.

--input_solver_file \\Parts\Mesh\Mech_CDB\Esys.cdb

This argument specifies that you want to generate and save a Mechanical database to a file during the batch process.

--save_mech_db

This argument specifies where you want the executable to save the generated file.

--output_dir_path c:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Command Entry Example 2

```
"C:\Program Files\ANSYS Inc\v241\aisol\bin\winx64\Ans.StandaloneExternalModelConsole.exe" --input_settings Example2.toml --write_solver_file --output_dir_path c:\
```

This command entry uses the `Example2.toml` file to 1) import a solver file (as defined in the **`--input settings argument`**) and 2) output a solver file (as defined by the **`SolverType`** option).

The output solver file is written to **`c:\`** as prescribed by the **`--output_dir_path`**.

The `Example2.toml` file is a text file with the following content:

```
[MeshFileOptions]
FilePath = 'C:\Example2.k'
FileUnitSystemName = "MKS_STANDARD"

[ConversionOptions]
TopologyCreationMode = "MeshOnly"

[EnvironmentOptions]
AnalysisType = "Static"
PhysicsType = "Structural"
SolverType = "ANSYS"
```

These entries specify the following:

`FilePath`: The path to and location of the input file.

`FileUnitSystemName`: Units system.

`TopologyCreationMode`: Specify whether to import the mesh, geometry, or both.

`AnalysisType`: Analysis type.

`PhysicsType`: Physics type.

`SolverType`: Specifies the solver output file type.

Supported Arguments

Supported arguments include:

Argument	Description
`--help`	Produce a help message.
`--input_solver_file <file_path>`	Import a solver input file and output a Mechanical `*.mechdb` file. Mesh data, materials, loads and boundary conditions will be created in the Mechanical database for objects included at the **Model** object level. Analysis specific settings will not be processed because a target solver is not known.
`--input_settings <file_path>`	Point to a TOML file, which in turn points to a solver input file and additional settings. The TOML file needs to be complete as describes below. The **[MeshFileOptions]** need to point to an input solver file and the **[EnvironmentOptions]** need to point to the desired target solver system.
`--logging`	Create External Model and Mechanical log files in the temporary directory.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Argument	Description
--output_dir_path <directory_path>	Create output files in the provided directory. If this argument is missing, the directory behind the Temp environment variable is used.
--save_mech_db	Save the current session as a Mechanical database.
--write_solver_file	Write a solver file. This argument requires the **--input_settings** argument that includes defined analysis options.

TOML File

To use the **--input_settings <file_path>** argument, you must create a TOML file - Tom's Obvious, Minimal Language TOML (`.toml`). This file is referenced by the input argument. The settings in the TOML file are grouped in categories (as a TML table) and each category contains a list of options as pairs: name = value.

This file has mandatory and optional entries.

Example File

The following example shows the settings for the categories **MeshFileOptions**, **ConversionOptions**and **EnvironmentOptions**:

```
# Example TOML File
[MeshFileOptions]

FilePath =
FileUnitSystemName = 'BIN_CONSISTENT'
NodeComponentPrefixes = 'ROT'
ElementComponentPrefixes = 'ROT'
ElementFaceComponentPrefixes = 'ROT'

[ConversionOptions]
FaceAngle = 45.0
EdgeAngle = 120.0
TopologyCreationMode = 'GeometryAndMesh'
CreateGeometryFaceComponents = true
CreateGeometryEdgeComponents = true
CreateGeometryVertexComponents = true

[EnvironmentOptions]
AnalysisType = 'Static'
PhysicsType = 'Structural'
SolverType = 'ANSYS'
```

Categories and Options

The supported TOML categories and their options are described below.

[MeshFileOptions]

Category	Option
FilePath: [string][mandatory]	Specify the full path to the solver file to be imported. Use single quotes to enclose the value.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Category	Option
FileUnitSystemName: [string][optional]	Unit system name to use when importing. Supported values include: "**SI**" "**MKS_STANDARD**" "**CGS_STANDARD**" "**NMM_STANDARD**" "**NMMTON_STANDARD**" "**BFT_STANDARD**" "**BIN_STANDARD**" "**UMKS_STANDARD**" "**MKS_CONSISTENT**" "**CGS_CONSISTENT**" "**NMM_STANDARD**" "**BFT_CONSISTENT**" "**BIN_CONSISTENT**" "**UMKS_CONSISTENT**" "**KGMMMS_CONSISTENT**" "**MKS_CONSISTENT**" "**CGS_CONSISTENT**" "**NMM_STANDARD**" "**BFT_CONSISTENT**" "**BIN_CONSISTENT**" "**UMKS_CONSISTENT**" "**KGMMMS_CONSISTENT**"
SupportingFiles: [array of strings][optional]	List of included files to use as included file paths. These paths appear in the commands *INCLUDE for ABAQUS, *INCLUDE/*INCLUDE_TRANSFORM for LS-Dyna, INCLUDE for Nastran. If specified, only the specified files will be processed. If not specified, all the included files will be processed.
ProcessMesh200FromCdb: [boolean][optional]	For `.cdb` files process, MESH200 element types. Supported values include **true** and **false**.
NodeComponentPrefixes: [string][optional]	Only import nodal components whose names start with the provided prefixes. The prefixes are to be separated by ';' in the provided string.
ElementComponentPrefixes: [string][optional]	Only import elemental components whose names start with the provided prefixes. The prefixes are to be separated by ';' in the provided string.
ElementFaceComponentPrefixes: [string][optional]	Only import element-face components whose names start with the provided prefixes. The prefixes are to be separated by ';' in the provided string.

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

[ConversionOptions] (Optional Entries)

Option	Description
FaceAngle: [double][optional]	Tolerance angle for faces.
EdgeAngle: [double][optional]	Tolerance angle for edges.
ProcessLineBodies: [boolean][optional]	Import line elements as line bodies. Supported values include **true** and **false**.
BodyGrouping: [array of strings][optional]	Body grouping to use for import. Supported values include: "**Material**" "**Thickness**" "**AnsysElementNumber**"
TopologyCreationMode: [string][optional]	Specifies whether geometry and/or mesh should be generated by the import. Supported values: "**GeometryAndMesh**" "**MeshOnly**" "**GeometryOnly**"
KeepOnlyXYPlanarElements: [boolean][optional]	Only import 2d elements in the X-Y plane. Supported values include **true** and **false**.
TwoDTolerance: [double][optional]	Tolerance value to use for the **KeepOnlyXYPlanarElements** option.
CreateGeometryFaceComponents: [boolean][optional]	Attempt to create geometric face named selections from components. Supported values include **true** and **false**.
CreateGeometryEdgeComponents: [boolean][optional]	Attempt to create geometric edge named selections from components. Supported values include **true** and **false**.
CreateGeometryVertexComponents: [boolean][optional]	Attempt to create geometric face vertex selections from components. Supported values include **true** and **false**.

[MechanicalOptions]

The only option for this is **AutoContactDetectionOnAttach** [boolean][optional]. This option runs Mechanical auto-contact detection when importing the solver file. Supported values include **true** and **false**.

[EnvironmentOptions] (Mandatory Entries only when **--write_solver_file** is used.)

Option	Description
AnalysisType: [string][mandatory]	Specify the analysis type. Supported values include: "**Static**"

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Option	Description
	"**SteadyState**" "**Harmonic**" "**Transient**" "**RandomVibration**" "**ResponseSpectrum**" "**Buckling**" "**Modal**" "**ShapeOptimization**" "**TopologyOptimization**" "**SubstructureGeneration**"
PhysicsType: [string][mandatory]	Specify the physics type. Supported values include: "**Structural**" "**Thermal**" "**Electromagnetics**" "**Electric**" "**ThermalElectromagnetics**" "**Multiphysics**"
SolverFileName: [string][optional]	Specify the solver file name produced when using with --write_solver_file. If missing, the defaulted value is `ds.dat`.
SolverType: [string][mandatory]	Specify the solver. The only supported value is "**ANSYS**"

External Model Supported Element Types

Mechanical APDL Elements

The following element types are supported when `.cdb` files are processed via the **External Model** system.

Shape Category	Supported Mechanical APDL Element Type
2D and 3D Point	MASS21
2D Linear Quadrilateral	PLANE13[a], PLANE25[a], FLUID29[a], PLANE55[a], PLANE75[a], PLANE182[a], INTER192, INTER202, CPT212[a], PLANE292[a], MESH200[b]
3D Linear Quadrilateral	FLUID136, SHELL281, SHELL131[a], SHELL157[a], SHELL181[a], MESH200[b]
2D Quadratic Triangle	PLANE35, MESH200[b]

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

Shape Category	Supported Mechanical APDL Element Type
2D Quadratic Quadrilateral	PLANE77 [a], PLANE78[a], PLANE83[a], PLANE121[a], PLANE183[a], INTER193, INTER203, CPT213[1], PLANE223[a], PLANE230[a], PLANE233[a], PLANE293[a], MESH200[b].
3D Quadratic Quadrilateral	FLUID139, FLUID136, SHELL132[a], SHELL281, MESH200[b]
Beam	BEAM4, BEAM188[c], BEAM189[b], and PIPE288/PIPE289, MESH200[b].
Linear Hexahedral	SOLID5 [a], FLUID30[a], PLANE223, SOLID65[a], SOLID70[a], SOLID96[a], SOLID185[a], SOLID278[a], SOLSH190[a], INTER195, CPT215[a], , MESH200[b]
Link	LINK33, LINK34, LINK180, FLUID116[d]
Quadratic Tetrahedral	SOLID87, SOLID98, SOLID123, SOLID187, CPT217, SOLID227, SOLID232, SOLID237, SOLID285, SOLID291, FLUID221, MESH200[b]
Quadratic Hexahedral	SOLID90 [a], SOLID122[a], SOLID186[a], INTER194, INTER204, CPT216[a], SOLID226[a], SOLID231[a], SOLID236[a], SOLID279[a], FLUID220, , MESH200[b]

[a] This element supports multiple shapes. This list displays the elements in their most basic and fundamental form.

[b] Section data and Real Constants are not imported for this element type.

[c] Pre-integrated composite beam sections are not supported by these elements types.

[d] The application does not use KEYOPTs for FLUID116. Therefore, you should verify the Fluid Descretization setting. In addition, this element uses the Flow cross-sectional area only.

NASTRAN Elements

The following element types are supported when NASTRAN Bulk Data (.bdf, .dat, .nas) files are processed via the **External Model** system.

Shape Category	Supported NASTRAN Element Type
2D Linear Quadrilateral	CQUAD
3D Linear Quadrilateral	CQUAD4, CQUADR
3D Linear Triangle	CTRIAR , CTRIA3
2D Quadratic Triangle	CTRIAX, CTRIAX6
3D Quadratic Triangle	CTRIA6
2D Quadratic Quadrilateral	CQUADX
3D Quadratic Quadrilateral	CQUAD8
Beam	CBAR, CBEAM
Link	CROD[a], CONROD[a]

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

Shape Category	Supported NASTRAN Element Type
Quadratic Tetrahedral	CTETRA[b]
Quadratic Hexahedral	CHEXA[b]
Quadratic Prism	CPENTA[b]

[a] The torsional constant specified with rod element types is not used if you change the **Model Type** property is changed from **Link** to **Beam**. Instead, a circular cross section is assumed and the calculated torsional constant of the cross section is used.

[b] These elements have the option of being linear.

ABAQUS Elements

The following element types are supported when ABAQUS Input (.inp) files are processed via the **External Model** system.

Shape Category	Supported ABAQUS Element Type
2D Linear Quadrilateral	CPE4, CPE4H, CPE4I, CPE4IH, CPE4R, CPE4RH, CPS6, CPS6M, CPS6MH, CPS6MT, CPS6E, CPEG4, CPEG4H, CPEG4I, CPEG4IH, CPEG4R, CPEG4RH, CPEG4HT, CPEG4RT, CPEG4RHT, DC2D4, DCC2D4, DCC2D4D, DC2D4E, AC2D4, AC2D4R, CAX4, CAX4H, CAX4I, CAXEIH, CAX4R, CAX4RH, DCAX4, DCCAX4, DCCAX4D, DCAX4E, CAXET, CAX4HT, CAX4RT, CAX4P, CAX4PH, CAX4RP, CAX4RPH, ACAX4, ACAX4R, CAX4E, CGAX4, CGAX4H, CGAX4R, CGAX4RH, CGAXET, CGAX4HT, CGAX4RT, CGAXERHT, CAXA4N, CAXA4HN, CAXA4RN, CAXA4RHN
2D Linear Triangle	CPE3, CPE3H, CPE3S, CPE3T, CPE3E, CPS3, CPS3T, CPS3E, CPEG3, CPEG3H, CPEG3HT, CPEG3T, C2D3, DC2D3, DC2D3E, AC2D3, WARP2D3, CAX3, CAX3H, CGAX3, CGAX3H, DCAX3, DCAX3E, CAX3T, CGAX3T, CGA3HT, ACAX3, CAX3E

Supported External Model Commands

The following sections contain lists of Interfaces provided by the supported commands repository.

External Model CDB Commands

External Model NASTRAN Commands

External Model ABAQUS Commands

External Model FE Commands Repository

External Model CDB Commands

This is the list of Interfaces provided by CDB Commands Repository. All the processed commands are represented by their specialized types, like I**CE**Command, I**CP**Command etc. The unprocessed commands are represented by the IGenericCommand.

```
IGenericCommand : public ICommand
{
    int ArgumentCount();
    string GetArgument(int index);
};

ICETerm
{
    uint Node();
    string Dof();
    double Coefficient();
};
```

External Model NASTRAN Commands

This is the list of Interfaces provided by the NASTRAN Commands Repository. All Bulk Data entries are represented by IGenericCommand, except ADAPT, OUTPUT and OUTRCV which are represented

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23

by the IOptionsControlCommand. And, the case control section commands are represented by ICaseControlCommand.

```
IGenericCommand : public ICommand
{
    int ArgumentCount();
    string GetArgument(int index);
};

ICaseControlCommand : public ICommand
{
    string Text();
};

INastranOption
{
    string Name();
    string Value();
};

INastranOptionLine
{
    int OptionCount();
    INastranOption GetOption(int index);
};

IOptionsControlCommand : public ICommand
{
    int ArgumentCount();
    string GetArgument(int index);
    int OptionLineCount();
    INastranOptionLine GetOptionLine(int index);
}
```

External Model ABAQUS Commands

This is the list of Interfaces provided by ABAQUS Commands Repository.

```
IAbaqusKeywordArgument
{
    string Key();
    string Value();
};

IAbaqusKeywordArgumentColl
{
    int Count();
    IAbaqusKeywordArgument Item(uint index);
};

IAbaqusKeywordDataLine
{
    int Count();
    string Item(uint index);
};

IAbaqusKeywordDataLineColl
{
    int Count();
    IAbaqusKeywordDataLine Item(uint index);
};

IAbaqusKeyword : public ICommand
{
    IAbaqusKeywordArgumentColl Arguments();
    IAbaqusKeywordDataLineColl DataLines();
};
```

External Model FE Commands Repository

```
enum Ansys.ACT.Automation.Mechanical.FECommandsType
{
 Processed,
 UnProcessed,
 All = Processed | UnProcessed
};

ICommand
{
 string Name ();
 uint Index ();
};

ICommandColl
{
 uint Count ();
 ICommand Item (uint lNum);
};

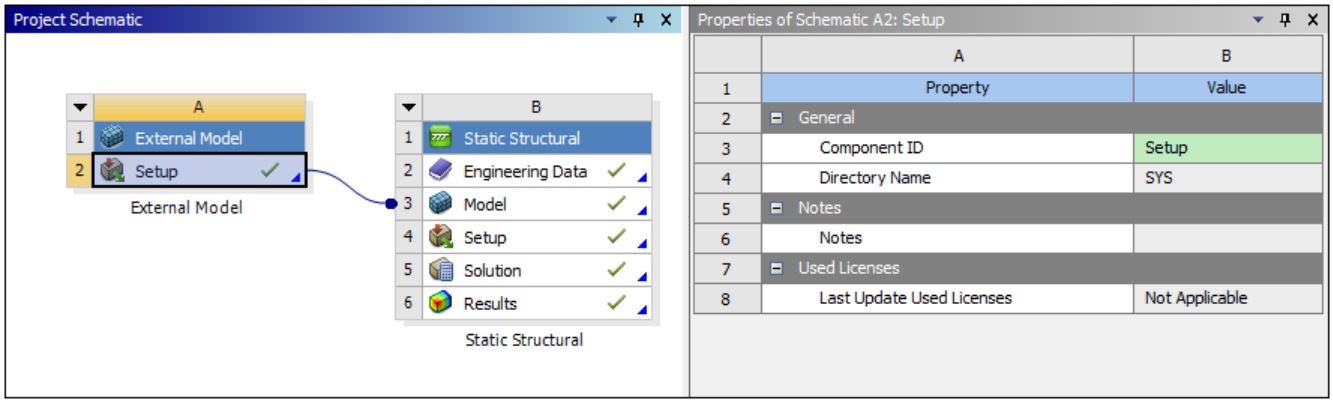
ICommandRepository
{
 ICommandColl GetCommandsByName (string name);
 ICommand GetCommandByIndex (int index);
 int GetCommandNamesCount (FECommandsType eCommandsType);
 string GetCommandName (FECommandsType eCommandsType, int index);
};
```

Accessing Imported Mesh-Based Databases through ACT

The Mechanical application enables you to import supported finite element data types from External Model and represents them natively through various imported objects in the tree. In addition, imported databases almost always contain additional commands that are not natively supported by the application. Mechanical exposes these commands (along with the commands natively processed in Mechanical) through the ACT extensions and console window. The following APIs enable you to access the underlying commands repository for a file specified in **External Model**.

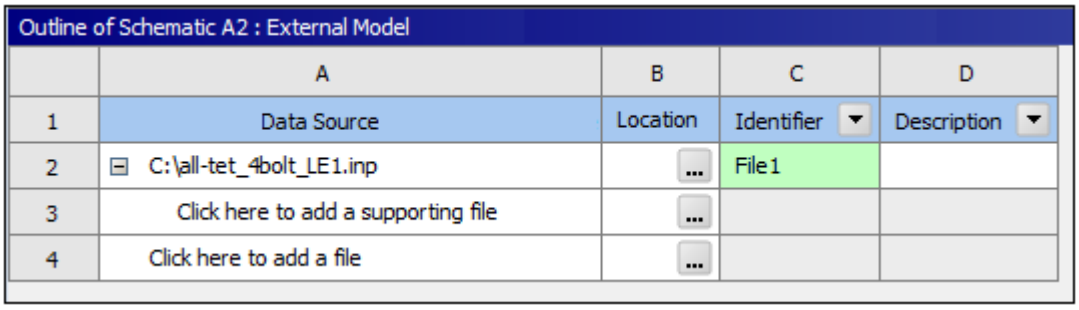
```
commands = ExtAPI.DataModel.Project.Model.GetFECommandsRepository("Setup", "File1");
```

Users familiar with ACT APIs for Ansys Mechanical will notice that the command **`GetFECommandsRepository`** on the **Model** object provides access to the commands repository. The two arguments ("Setup" and "File1") specify the source External Model **Component Id** and "File Identifier" in the External Model Component.



Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Published: 2023-10-23



The return object commands is an instance of the interface **ICommandRepository** (p. 980).

Once user has access to the commands database, you can access:

- Processed Commands: Commands processed and natively represented in Mechanical.
- Unprocessed Commands: Everything other than Processed Commands.

User can access the unprocessed commands names using the combination of following commands:

```
unprocessedCmdNamesCount = commands.GetCommandNamesCount(Ansys.ACT.Automation.Mechanical.FE.CommandsType.UnPro
```

And...

```
unprocessedCmdName = commands.GetCommandName(Ansys.ACT.Automation.Mechanical.FE.CommandsType.UnProcessed, inde
```

As you might notice, the command **GetCommandNamesCount** on **ICommandRepository** (p. 980) provides the count of the command names of type specified as first argument:

```
Ansys.ACT.Automation.Mechanical.FE.CommandsType.UnProcessed
```

Or...

```
Ansys.ACT.Automation.Mechanical.FE.CommandsType.Processed
```

And the command **GetCommandName** provides the command name given the type and index (index is 1 based, therefore, if the **unprocessedCmdNamesCount = n**, the valid index value are **(1,n)**).

Given a command name, user can access all instances of a command with a given name as:

```
namedCommands = commands.GetCommandsByName(commandName);
```

The return value **namedCommands** is an instance of the interface **ICommandColl**. A command can be accessed from the **namedCommands** as:

```
namedCommand = namedCommands.Item(index);
```

The index argument is **1** based, therefore valid index value are **(1,namedCommands.Count())**)

The return value **namedCommand** is a derived instance of the interface **ICommand**, i.e. the **namedCommand** instance exposes the methods available on the **ICommand** interface:

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

```
Name(): Command name

Index(): 1 based global index of the command in command repository
```

And any additional methods exposed the specific instance of the command. For example, if the **namedCommand** is an instance of **ICECommand** (a type of processed command from CDB file), then the following additional methods are available:

```
Nce(): Constraint Equation ID

Constant(): Constant Term

TermCount(): Number of Terms

GetTerm(int index): Term at Index
```

Similarly, if the **namedCommand** is an instance of **IGenericCommand** (unprocessed command from CDB file), then the following additional methods are available:

```
ArgumentCount(): Number of arguments

GetArgument(int index): Argument at index
```

Refer to the External Model CDB Commands (p. 973), External Model NASTRAN Commands (p. 978), and the External Model ABAQUS Commands (p. 979) sections for all the available processed and unprocessed commands from CDB, NASTRAN, and ABAQUS databases.

In addition, you can traverse the command repository by going to the next and previous commands in the database using the following APIs:

```
prevCommand = commands.GetCommandByIndex(currentCommand.Index()-1);
```

```
nextCommand = commands.GetCommandByIndex(currentCommand.Index()+1);
```

Given the information provided in the above section, let's take a look at some examples.

CBD File Examples

The following examples describe how to query the command repository.

```
commands = ExtAPI.DataModel.Project.Model.GetFECommandsRepository("Setup", "File1")
```

Example: List All Command Names

This example enables you to generate a listing all command names in the command repository.

```
commandType = Ansys.ACT.Automation.Mechanical.FE.CommandsType.All
commandCount = commands.GetCommandNamesCount(commandType)
commandsNames = []
for iCommand in range(0, commandCount):
 commandsNames.append(commands.GetCommandName(commandType, iCommand+1))
commandsNames
```

Example: List All Nodes

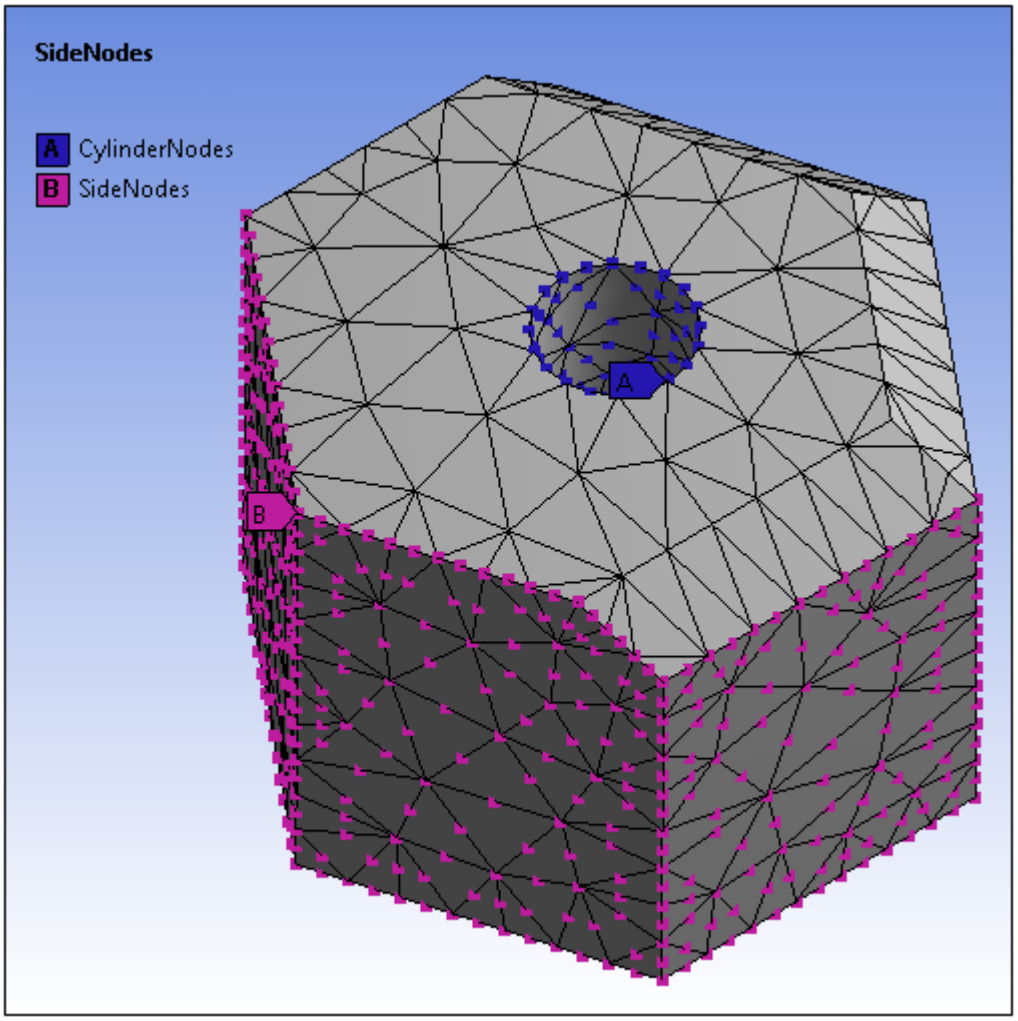
Examples of a Synthesized Mesh using Tolerance Angles

Examples of a geometry that results from a synthesis for a given mesh with different **Tolerance Angle** settings and **Component Key** specifications are illustrated below.

Meshed Model

This illustration is a graphical representation from Mechanical of the node data provided by a `.cdb` file. Two nodal components have been processed: **CylinderNodes** and **SideNodes**.



45° Tolerance Angle

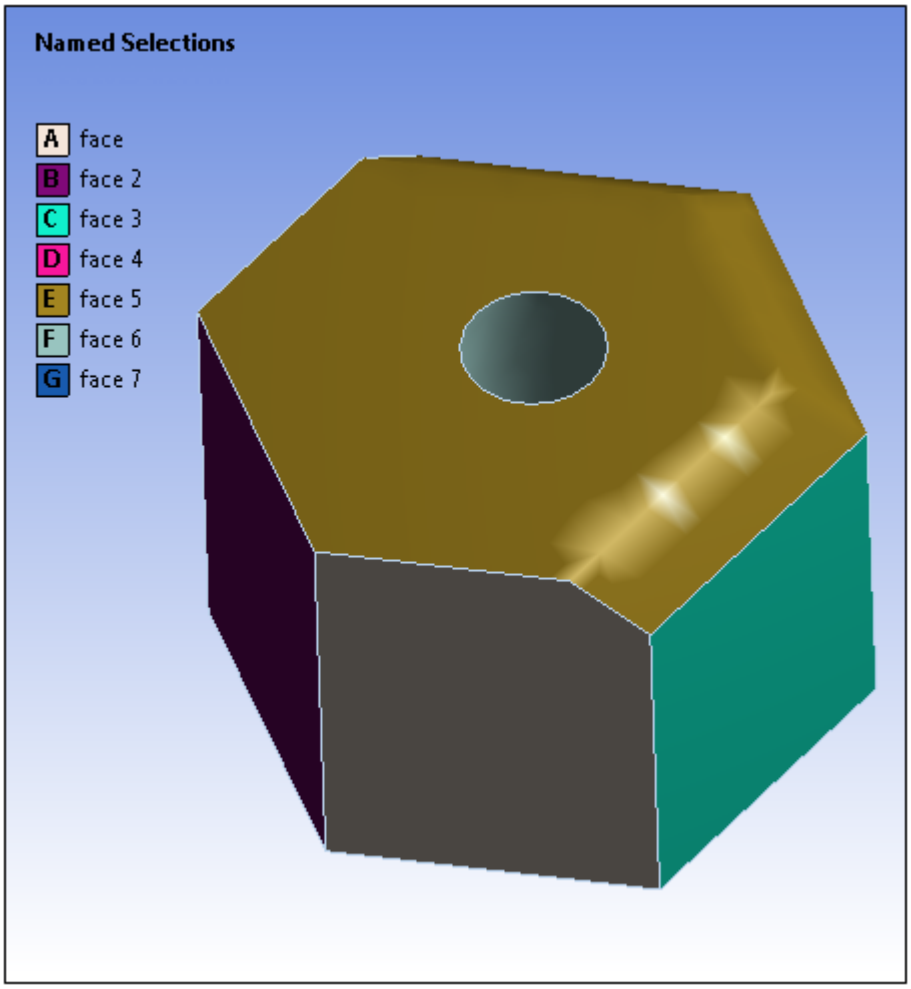
Published: 2023-10-23

This illustration represents a synthesized geometry that includes faces created using a 45° Tolerance Angle.



25° Tolerance Angle

In this illustration, the **Tolerance Angle** was specified as 25°. This resulted in an accurate synthesis of the geometry.

180° Tolerance Angle

This example illustrates how only one face is generated for the geometry when no tolerance angle (180°) is specified and no node-based components are processed. This type of result can also occur when a node-based component contains all of the nodes for a given body.

Assembling External Models and Mechanical Models

You can import multiple meshed-based geometries into the **Model** cell of a Mechanical analysis system. The sources of these geometries can be:

- **External Model** component systems
- **Mechanical Model** component systems
- Mechanical analysis systems

The source systems define the geometry and meshes for the downstream Mechanical system. In addition, upstream Mechanical Models, Mechanical analysis systems, and External Model systems support the capability to transfer the following data/objects:

Mechanical Model/Mechanical Analysis System	*External Model*
• Beam Connections (p. 1404) • Contacts (p. 1222) and Spot Welds (p. 1407)	• Constraint Equation (p. 2269) • Coordinate Systems • Element Orientation

Release 2024 R1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.
Published: 2023-10-23

• Commands Object (p. 2303) (that are children of objects that are transferred) • Coordinate Systems (p. 1191) • Element Orientation (p. 1008) (supported only when defined using a Coordinate System) • Engineering Data • Grouping (p. 208) Objects • Joints (p. 1292) • Named Selections (p. 1057) • Point Mass (p. 901) • Remote Points (p. 1089) • Springs (p. 1395)	• Flexible Remote Connectors • Named Selections (p. 1057) • Nodal Orientation • Point Mass • Rigid Remote Connectors • Shell Thicknesses • Spring Connectors

Note:

Model-to-Model linking does not support upstream **End Release** objects.

Assembly Examples

Examples of the Model Assembly feature are illustrated below. Model cells are linked (Model-to-Model linking). You must first mesh all of the upstream systems in order to open the models in Mechanical.

Assembling Mechanical Model Systems	**Assembling Mechanical Model Systems and Analysis Systems**

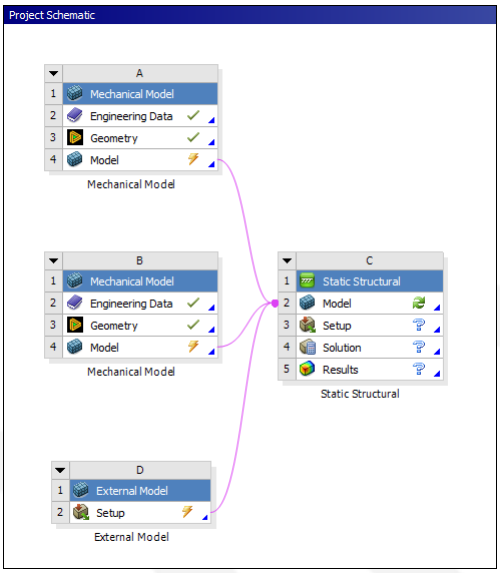
This example incorporates the **External Model** feature.

Assembling Mechanical Model Systems and External Model Systems



Model Assembly Specification

Similar to defining Mesh-to-Mesh Connections, Model-to-Model linking provides certain **Project Schematic** properties on the downstream **Model** cell prior to import. These properties can be grouped into two categories as described below.
