Note	When you have an external circuit, the Time Step is controlled from the circuit simulator, and the time step settings in the solution setup dialog are ignored. This can be controlled using the **Maxwell 2D>Excitations>External Circuit>Set Minimum Time Step command**. Time Step settings in the solution setup dialog box are also ignored for transient-transient simulation in which case Twin Builder controls the time step.

Transient Setup (3D)

To set up a 3D transient analysis, define the following parameters on the **General** tab of the **Solve Setup** dialog box:

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
2. Enter the **Time Step** for the analysis, which defines the time increments, and select the units. The time step can also be defined as the function of time, speed, and position.

Note	When you have an external circuit, the Time Step is controlled from the circuit simulator, and the time step settings in the solution setup dialog are ignored. This can be controlled using the **Maxwell 3D>Excitations>External Circuit>Set Minimum Time Step command**. Time Step settings in the solution setup dialog box are also ignored for transient-transient simulation in which case Twin Builder controls the time step.

Defining Settings on the Save Fields Tab for Transient Solutions

To specify the time points at which to save fields, do the following on the **Save Fields** tab of the **Solve Setup** dialog box:

1. Specify the field save times:
   - **None** - only the stop time is saved. This is the default.
   - Every **N** time steps - Enter the number of steps, start time, stop time and select the units. The values can be constants, variables or expressions.

     For example, if the variable start is 2ms, delta is 1ms, and end is 12ms, and the solution is calculated every ms, we would save fields at 3ms, 5ms, 7ms, 9ms, 11ms, and 12ms.

   - **Custom** - select this option to add time points as desired.
2. For **Custom**, click the **Preview** button to view the save field times. Some cases do not support a preview (for example, when variables are used to define the settings or when a user control program is used). You can add and remove rows at your desired locations using the **Add Above**, or **Add Below**, and **Delete Selection** buttons.
3. Click **OK**.

Defining Settings on the Advanced Tab for Transient Solutions

The following settings can be defined on the **Advanced** tab of the **Solve Setup** dialog box:

- Control Program
- Start/Continue from a previously solved setup
- Import mesh

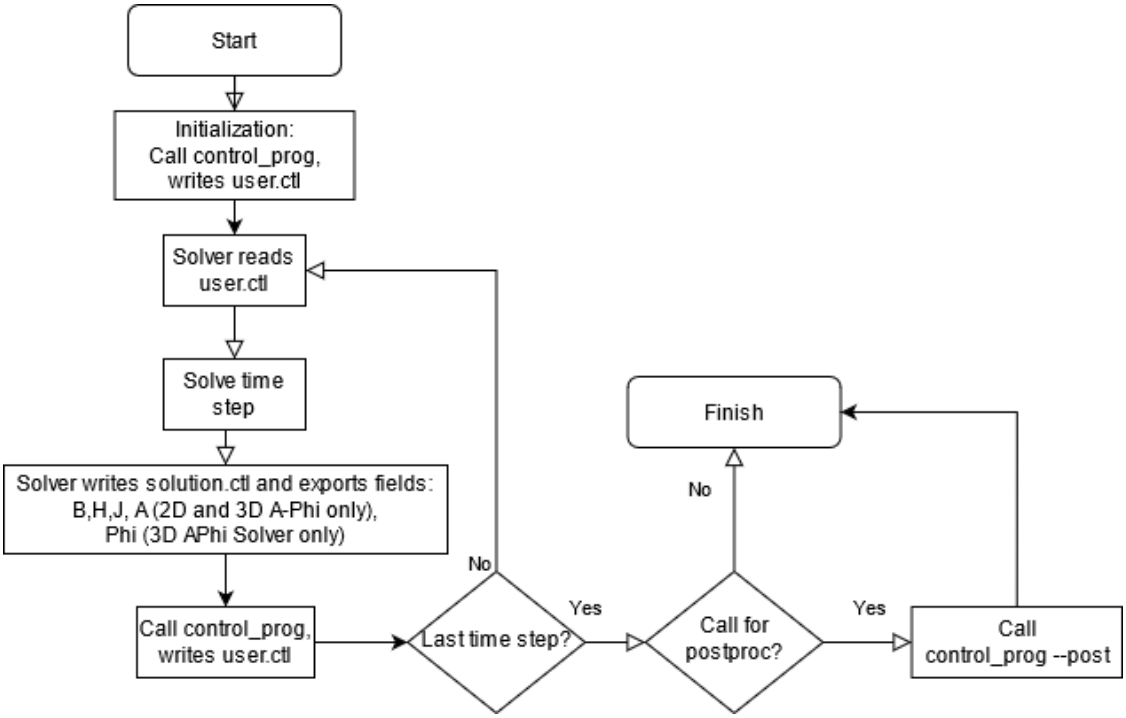
Using a 2D Eddy Current Solution as the Initial Condition for a Transient Solution

Using a Control Program in Maxwell 2D and 3D Transient Solutions

User control programs are externally created executable files, or Python (`*.py`) scripts that are called after each time step, and allow you to control the source input, circuit elements, mechanical quantities, time step, and stopping criteria, based on the updated solutions.

> **Note:** The control program is executed from a temp directory that Maxwell creates for every setup run (For parametric setup a temp folder is create for each task). The solver copies a control program file with name **<setup_name>.py** for Python, or **<setup_name>.ctrlprog** for compiled program to the temp directory.

The user control program uses the file with fixed name **user.ctl** to output control parameters to control the execution of the transient solver. Each file must use a predefined syntax which is flexible enough to cover a wide range of items.



The process shown in the flowchart can be summarized as:

1. The solver calls the user-control program on initialization.
2. The user-control program writes control information to file **user.ctl**.
3. The transient solver reads control parameters from **user.ctl**.
4. The transient solver solves the current time step.
5. The transient solver copies the previous solution to **previous.ctl** and writes out solution information to **solution.ctl**. If requested, the solver exports:
   - B, H, J fields (**bfield.ctl**, **hfield.ctl**, **jfield.ctl**, respectively)
   - A field **afield.ctl** (available in 2D and 3D A-Phi only)
   - Phi field **phifield.ctl** (available in 3D A-Phi only).
6. Return to the transient solver if the control program succeeds with exit status 0 or fails with exit status non-zero.
7. Return to step 1 for the next time step.
8. (Optional) Call script after last time step for post processing. If user selects the **Call after last time step for post processing** check box (refer to *Activating a Control Program in Transient Solutions*), then the control program is called after the simulation is completed.

   If you use a Python control program, the script is called with `--post` flag

   (for example: `my_script.py --post`).

   For a compiled control programs the script is called with `-post` flag

   (for example: `my_tool.exe -post`).

Note: By default a control program script will be called by the pre-installed Python interpreter:
`<install_path>\Win64\commonfiles\CPython\37\winx64\Release\python\python.exe`
however, the user can specify a custom python interpreter to be used by setting following environment variable:
EM_CTRL_PROG_PYTHON_PATH=<*path_to*\python.exe>

Activating a Control Program in Transient Solutions

Use the following steps to access and invoke a user-control program to use with the Maxwell 2D or 3D transient solver. User control programs can be either externally created executable (`.exe`) files, or Python (`*.py`) scripts.

To specify a control program to use to generate the solution:

1. Select the **Use Control Program** check box.

   The control program field becomes active, allowing you to enter the name of the user control program.
2. Click the **...** button to select the user control program you want to use during the solution generation process.

   The **Open** window appears.
3. Select the control program, and click **Open** to return to the **Advanced** tab of the **Solve Setup** dialog box.
4. Enter the arguments to pass to the control program in the **Arguments** text box. The solver calls the program in the following format:

   ```
   program_name specified_arguments
   ```
5. If you select the **Call after last time step for post processing** check box, then the control program is called after the simulation is completed.

   If you use a Python control program, the script is called with `--post` flag

   (for example: `my_script.py --post`).

   For a compiled control programs the script is called with `-post` flag

   (for example: `my_tool.exe -post`).
6. Click **OK** to accept the configuration or **Cancel** to ignore the settings. You return to the **Solve Setup** window.

Control Program File Formats in Transient Solutions

User control programs and related files have their own file formats, which should be followed when creating control program files.

- User Control File Format
- Solution and Previous Control File Formats
- User Control Fields Extraction Format
- Output variable values are output to a file with a fixed name of **outputvar.ctl**. The file contents use the following format:

```
<output variable name> <output variable value>
<output variable name> <output variable value>
...
```

The following summarizes the files related to user control programs for transient solutions.

File Name	Functionality
user.ctl	Input data that controls Maxwell Solver
solution.ctl	Data for global quantities such torque, current, speed etc
previous.ctl	Same data as solution.ctl but for previous time step
outputvar.ctl	Contains expression cache variables
var.data	Variations information from design and project variables
afield.ctl	Magnetic potential (available only in 2D and 3D A-Phi solver)
bfield.ctl	Magnetic flux density
hfield.ctl	Magnetic field strength
jfield.ctl	Electric current density
phifield.ctl	Electric Scalar Potential (available only in 3D A-Phi solver)

User Control File Format

The **user.ctl** file is created by the user control program. Below are descriptions of the keywords that can be used in a **user.ctl** file, and indicating the solver types for which they are valid.

Keyword	Description	2D	3D	3D A-Phi
windingSrc <winding_name> <val>***	Voltage [V]/Current [A] value for Winding	X	X	X
windingR <winding_name> <val>***	Resistance value [Ohm] for Voltage Winding	X	X	X
windingL <winding_name> <val>***	Inductance value [H] for Voltage Winding	X	X	X
loadTorque <value>	Load Torque [N*m] for rotational motion only	X	X	
loadForce <value>	Load force in MotionSetup [N] for translational only	X	X	
damping <value>	Damping coefficient [translational: N*s/m; rotation: N*m*s/rad]	X	X	
loadInertia <value>	Load Inertia in MotionSetup [kg*m²] for rotational only	X	X	
mass <value>	Mass in MotionSetup [kg] for translational only	X	X	
speed <value>	Speed of the moving object [translation - m/s; rotation - rad/s]	X	X	
position <value>	Position of the moving object [[translation - user unit (from Motion Setup); rotation – rad]	X	X	
timeStep <value>	Time step size [s]	X	X	X
stop <0 or 1>	Stop solver if value is equal to 1	X	X	X
exportFieldAtMeshNodeOnAllObjects	Request to export fields on all object in design	X	X	X
exportFieldAtMeshNodeOnObject <objectID>*	Request to export fields on specific object	X	X	X
NStep <value>	Export fields only every N steps (works only in conjunction with exportFieldAtMeshNode<...>)	X		
FieldSelect <value>**	Export only specific field (one of A,B,H,J) (works only in conjunction with exportFieldAtMeshNode<...>)	X		

Keyword	Description	2D	3D	3D A-Phi
Binary <0 or 1>	Export fields in binary format (works only in conjunction with exportFieldAtMeshNode<...>)	X		
voltageSrc <voltage_name> <source_value>***	Voltage source value [V]			X
currentSrc <current_name> <source_value>***	Current source value [A]			X
Full line could be repeated for *multiple object IDs; **multiple fields; ***multiple excitation names				

The following **user.ctl** file example:

- Sets the time step to 5ms.
- Sets Resistance to 1µOhm and Inductance to 1µH for Winding A and Winding B.
- Sets Voltage for Winding A to 10 V and for Winding B to -10 V.
- After time step is completed all fields for the object with ID 88 will be exported.

```
begin_data
 windingSrc WindingA 10
windingR WindingA 1e-6
windingL WindingA 1e-6
windingSrc WindingB -10
windingR WindingB 1e-6
windingL WindingB 1e-6
exportFieldAtMeshNodeOnObject 88
timeStep 5e-3
stop 0
end_data
```

"Activating a Control Program in Transient Solutions " on page 16-32

User Control Fields Extraction Format

The **user.ctl** file is created by the user control program. Depending on the solver the following field types are available during export:

Field	2D	3D	3D A-Phi
B – Magnetic Flux Density	X	X	X
H – Magnetic Field Strength	X	X	X
J – Current Density	X	X	X
A – Magnetic Vector Potential	X		X
Phi - Electric Scalar Potential			X

To extract fields from Maxwell, the control program must create a **user.ctl** file with one of the two following syntax strings:

> **Note:** You can combine field export keywords with other keywords.

Extract fields on all objects

user.ctl

```
begin_data
exportFieldAtMeshNodeOnAllObjects
end_data
```

Extract fields by object ID

user.ctl

```
begin_data
exportFieldAtMeshNodeOnObject <objectID>
exportFieldAtMeshNodeOnObject <objectID>
end_data
```

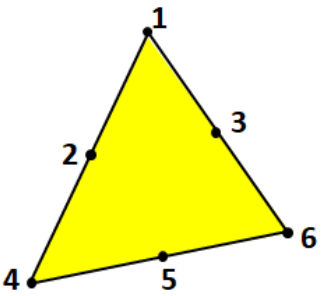
You can get the desired object IDs as follows:

1. Select **Tools -> Open Command Window**.
2. In the following example code snippet, replace "Stator" in the `object_name` with the name of the desired object.

```
object_name = "Stator"
oProject = oDesktop.GetActiveProject()
oDesign = oProject.GetActiveDesign()
oEditor = oDesign.SetActiveEditor("3D Modeler")
object_id = oEditor.GetObjectIDByName(object_name)
print(object_id)
AddInfoMessage(str(object_id))
```

3. Copy and paste the code snippet into the Command Window and execute.
4. Repeat as needed for additional objects.

Data Structure and Nodes Order for 2D Fields Extraction



Node order in Maxwell 2D element

The Maxwell 2D solver writes the data and updates field files (**afield.ctl**, **bfield.ctl**, **hfield.ctl**, **jfield.ctl**) at each time step with the following structure:

Time
M
ID K x_1 y_1 x_4 y_4 x_6 y_6 B_{x1} B_{y1} B_{x2} B_{y2} B_{x3} B_{y3} B_{x4} B_{y4} B_{x5} B_{y5} B_{x6} B_{y6}

where:

- Time – is the time corresponding to the time-stepping FE solution
- M – is the total number of elements
- ID – is the object ID
- K – is the element number
- x_i, y_i – are the coordinates of node i, for i in [1, 4, 6]
- B_{xi} B_{yi} – is the field X, Y component value of node i, for i in range 1 to 6

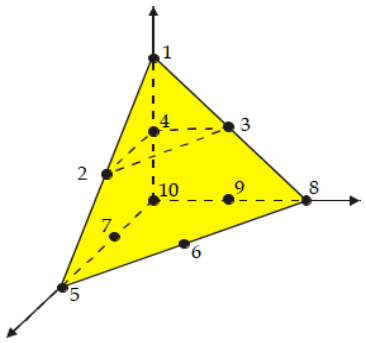
> **Note:** For vector potential, the **afield.ctl** file has one component of the field, which is A_z.

> **Note:** Coordinates of the element are given for the vertices (1, 4, 6) only. Middle points (2, 3, 5) can be calculated from the other given coordinates since they are located in the middle as shown above, for example: $x_2 = (x_1+x_4)/2$.

The following is an example for **bfield.ctl** data extracted in an object with ID 761 that consists of 2 elements at t = 0.04 sec.

```
0.040000
2
761 550 0.002 0.037 0.003 0.037 0.003 0.037 -2.220 0.488 -1.540 0.783 -1.799 0.950 -0.860 1.077 -1.119 1.245 -1.379 1.413
761 573 0.018 0.032 0.021 0.032 0.020 0.031 -0.695 1.266 -0.626 1.433 -0.810 1.378 -0.556 1.599 -0.740 1.544 -0.924 1.490
```

Data Structure and Nodes Order for 3D Fields Extraction



Node order in Maxwell 3D element

The Maxwell 3D solver writes the data and updates field files (**bfield.ctl**, **hfield.ctl**, **jfield.ctl**) at each time step with the following structure:

Time
M
ID K x_1 y_1 z_1 x_5 y_5 z_5 x_8 y_8 z_8 x_{10} y_{10} z_{10} B_{x1} B_{y1} B_{z1} B_{x2} B_{y2} B_{z2} … B_{xi} B_{yi} B_{zi} … B_{x10} B_{y10} B_{z10}

where:

- Time – is the time corresponding to the time-stepping FE solution
- M – is the total number of elements
- ID – is the object ID
- K – is the element number
- x_i, y_i, and z_i– are the coordinates of node i, for i in [1, 5, 8, 10]
- B_{xi} B_{yi}, B_{zi} – is the field X, Y, Z component value of node i, for i in range 1 to 10

> **Note:** The coordinates of the 3D element are given for the vertices (1, 5, 8, 10) only. Middle points (2, 3, 4, 6, 7, 9) can be calculated from the other given coordinates since they are located in the middle as shown above, for example: $x_2= (x_1+x_5)/2$

Solution and Previous Control File Formats

The **solution.ctl** and **previous.ctl** files are created by the transient solver. Below is a list of keywords and definitions applicable to these files.

Keyword	Description	2D	3D	3D A-Phi
time <value>	Current time in simulation [s]	X	X	X
position <value>	Position when motion setup is assigned [translation - user unit (from Motion Setup); rotation – rad]	X	X	
speed <value>	Speed when motion setup is assigned [translation - m/sec; rotation - rad/sec]	X	X	
torque moving_group <value>	Torque [N*m]	X	X	
force moving_group <value>	Force on moving objects [N]	X	X	
strandLoss <value>	Stranded loss for all objects [W]	X	X	X
solidLoss <value>	Solid loss for all objects [W]	X	X	X
coreLoss <value>	Core loss for all objects [W]	X	X	X
timeStep <value>	Time step size [s]	X	X	X
windingFlx <winding_name> <value>*	Winding Flux value [Wb]	X	X	X
windingEmf <winding_name> <value>*	Winding EMF value [V]	X	X	X
windingI <winding_name> <value>*	Winding Current value [A]	X	X	X
windingV <winding_name> <value>*	Winding Voltage value [A] (voltage windings only)	X	X	X
voltageV <voltage_name> <value>*	Voltage value on voltage excitation [V]			X
voltageI <voltage_name> <value>*	Current value on voltage excitation [A]			X
currentV <current_name> <value>*	Voltage value on current excitation [V]			X
currentI <current_name> <value>*	Current value on current excitation [A]			X
* Could be repeated for multiple excitation names				

An example `solution.ctl` file for 2D/3D solvers:

```
begin_data
 time <current_time>
 strandLoss <value>
 solidLoss <value>
 coreLoss <value>
 torque <torque>
 speed <speed>
 position <position>
 windingI <winding_name> <value>
 windingEMF <winding_name> <value>
```

```
 windingFlx <winding_name> <value>
end_data
```

An example `solution.ctl` file for the A-Phi solver:

```
begin_data
 time <current_time>
 strandLoss <value>
 solidLoss <value>
 coreLoss <value>
 windingI <winding_name> <value>
 windingEMF <winding_name> <value>
 windingFlx <winding_name> <value>
 voltageV <voltage_name> <value>
 voltageI <voltage_name> <value>
end_data
```

"Activating a Control Program in Transient Solutions " on page 16-32

Start/Continue from a Previously Solved Setup

Enabling the **Start/Continue from a previously solved setup** option allows the source design solution to be linked to a set of different target designs, where the user can continue the solution based on a different parameter/circuit setup. For example, to speed up the process of either a 2D or 3D transient solution reaching a steady state, you can use this option to link a 2D (or 3D) eddy current solution as the initial condition for a corresponding transient solution.

If the **Start/Continue from a previously solved setup** check box is selected, the **Setup Link** button becomes active, and the **Setup Link** dialog box automatically appears in which the user can link the current design to a project solution set based on a different parameter/circuit setup. Refer to "Setup Link for Transient Solutions " on the next page for details on setting up this link.

Note	**Power loss** and **Force density distribution** cannot be computed when **Start/Continue from a previously solved setup** is enabled.

Related Topics

Using an Eddy Current Solution as the Initial Condition for a Transient Solution

Setup Link for Transient Solutions

Import Mesh for Transient Solutions

The **Import mesh** check box can be selected in the "target" design if the mesh for the same geometry is to be used in the analysis. This setup is designed to be generally applicable to all

transient solutions. This feature is not necessarily related to the dynamic demagnetization distribution capability.

If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box, which includes an **Additional mesh refinements** tab automatically appears, and the mesh will be imported from the source design to the target design. Refer to "Setup Link for Transient Solutions " below for details on setting up this link.

Note	The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

Setup Link for Transient Solutions

If you selected **Start/Continue from a previously solved setup**, or **Import mesh**, do the following to specify the source project, design, and solution containing the information you want to use. You can also view and map variables and, for Import Mesh, specify additional mesh refinements.

1. If the **Setup Link** dialog is not already open, click **Setup Link** (located at the bottom of the **Solve Setup** dialog box **Advanced** tab) to open the **Setup Link** dialog box.
2. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.  To enable settings, you can select **Edit Link**.

3. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

     Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.
4. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs

and solutions. You can use the drop down menus to choose from the available designs and solutions.

The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.”

5. Use the check box to specify whether to **Simulate source design as needed**.
6. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
7. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variable by Name** to automatically map same named variables.
8. The **Additional mesh refinements** tab, which is present only if you chose Import Mesh on the **Solve Setup** dialog **Solver** tab, allows you to choose either to **Apply mesh operations in target design on the imported mesh** (default) or **Ignore mesh operations in target design**.
9. Click **OK** to close the **Setup Link** dialog box and return to the **Solve Setup** dialog box **Advanced** tab.

Using a 2D Eddy Current Solution as the Initial Condition for a Transient Solution

"Start/Continue from a Previously Solved Setup " on page 16-41

"Import Mesh for Transient Solutions " on page 16-41

Using an Eddy Current Solution as the Initial Condition for a Transient Solution

In order to speed up the process of either a 2D or 3D transient solution reaching a steady state, you can set the solution from a 2D or 3D eddy current solver as the initial condition for the corresponding transient solver.

Note	Since the eddy current solution corresponds to a stationary operating condition (zero speed), in order to generate the initial condition for the transient solution with non-zero speed, a transformation of conductivity on the moving objects where eddy current is taken into account is required in the eddy current simulation. The transformation is:

$$\sigma_0 = \sigma \cdot s_n$$

where σ_0 is the transformed conductivity from speed n to speed zero, which is to be set in the eddy current simulation, σ is the real conductivity in transient simulation, and s_n is the slip, defined as:

$$s_n = \frac{n_s - n}{n_s}$$

where n_s is the synchronous speed.

If there is an end connection, the end resistance R used in the transient simulation also has to be referred to the value R_0 associated with zero speed before being used in the eddy current solution by:

$$R_0 = R / s_n$$

Prerequisites

- Source design - Maxwell 2D (or 3D) Eddy Current (Last Adaptive solution only)
- Target design - Maxwell 2D (or 3D) Transient
- The source and target designs must be identical (identical geometries, boundaries, excitations, windings, etc).

To setup and use a 2D (or 3D) eddy current solution as the initial condition for a corresponding 2D (or 3D) transient solution:

1. Create an eddy current source design, and ensure that **Solve Matrix: After last pass** is selected on the **General** tab of the eddy current **Solve Setup** dialog.
2. Solve the eddy current design.
3. Create a transient target design, whose geometry, boundary conditions, excitations, windings, etc., are identical to the the source eddy current design.
4. On the transient target design's **Solve Setup** dialog box, **Advanced** tab, click **Start/Continue from a previously solved setup** to open the **Setup Link** dialog.
5. On the **Setup Link** dialog **General** tab, select the source eddy current design and solution (Last Adaptive solution only). Refer to "Setup Link for Transient Solutions " on page 16-42 for details on setting up this link.
6. Solve the target transient design.

Note	• If the source and target designs are not identical, an error message displays. • If the eddy current source design has not been solved, an error message

	displays. • If a legacy eddy current design solved with a previous release of Maxwell is used as the source design, you must re-solve the eddy current design before solving the target transient design or an error message will be displayed.

Setup Link for Transient Solutions

Defining Expressions for Transient Solutions

You can specify additional evaluation criteria through the use of expressions and output variables.

To set expressions as evaluation criteria:

1. Right-click on the Analysis icon in the Project tree to open the **Solve Setup** dialog box.
2. Click the **Expression Cache** tab and click the **Add...** button to open the **Add to Expression Cache** dialog box.
3. Specify the Context for the expression, including **Report Type**, **Solution**, and **Parameter**.
4. Under the **Trace** tab, select from the **Category**, **Quantity**, and **Function** lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them by selecting the **Output Variables** category. The **Output Variables** button opens a dialog box that lets you define output variables. See Specifying Output Variables.

   When you have created an expression, it appears in the **Expression** field of the **Trace** tab. If desired, you can use the **Range Function** button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis **[...]** button in the **Edit** column opens a list of values from which you can select.
5. When finished defining the expression that you want to add to the cache, click the **Add Calculation** button.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can define additional expressions with contexts and add them in the same way.
6. When finished adding expressions, click **Done** to close the **Add to Expression Cache** dialog box.

   The **Expression Cache** tab lists the expressions you have added in a table.
   - The **Title** field is editable, by default showing the name as built from the expression (with underscores removed).

- The **Expression** field shows the full expression. If necessary, you can resize the **Solve Setup** dialog box. You can also resize each columns in the table.
- The **Context** column for non-field types lists the parameter type specifying the force, torque or matrix setup. For these types the context also can be given as part of the expression. For example, the expression *Force1.Force_x* with a context of *None* is equivalent to an expression of *Force_x* with a context of *Force1*.

For field quantities the **Context** can be the geometry on which to evaluate the field quantity - a point or line. If you use a line you need to use some range function to reduce the dimensionality to a single value (or use the Calculation Range tab to specify a single point along the line). Note that, if you create a named expression in the field calculator that already evaluates to a single value, then the **Context** here will likely be *None*.

- The **Intrinsics** column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the **Intrinsics** column button shows **None** you cannot edit the value. If the button shows variables, click the ellipsis **[...]** in the **Edit** column to display a list of the variable values from which you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the **Expression Cache**.

The **Intrinsics** field lists the values you may have set in the **Calculation Range** tab when you added the expression. This is used to set the values of “other” sweeps. Usually there are no other sweeps because the values of the variables are set in the definition of each variation. In some cases you may need to specify the values of “other” sweeps. For field values with a line for the context, you can specify the (normalized) distance along the line For eddy current field quantities you can also specify the phase for the calculation.

7. In the **Evaluation Time Step** panel, set how often the solver is to output field solutions. Select **Constant** to output solutions at a preset time interval (e.g., every 0.1 s); or **Number of solve steps** to output solutions each preset number of time steps (e.g., every 3 time steps).
8. Optionally, buttons allow you to **Edit** and **Remove** selected expressions, and to **Remove All** expressions in the table.
9. When finished defining expressions, click **OK** to close the **Solution Setup** dialog box.

Specifying Output Variables

Defining Settings on the Solver Tab for Transient Solutions

To define solver settings on the **Solver** tab of the **Solve Setup** dialog box for transient solutions:

1. Enter a residual value in the **Nonlinear Residual** text box.

   To specify a time-dependent non-linear residual, you can simply type in a function of TIME, such as **sin (TIME)**, or enter an expression that uses a dataset, such as **pwlx(*<name of dataset>*, TIME)**. A time-dependent variable can also be used.

You can save the time-dependent expression as the default for the non-linear residual by clicking the **Save Defaults** button on the **Defaults** tab of the **Solve Setup** dialog box. A new solve setup will then use the user-saved default if the expression can be evaluated. A value of “0” will be used when the expression cannot be evaluated. For example, if the expression depends on a variable that is not yet defined in the design/project.

Changing the definition of the residual will NOT invalidate any existing solution; and the next simulation will continue from the stop time of the last simulation.

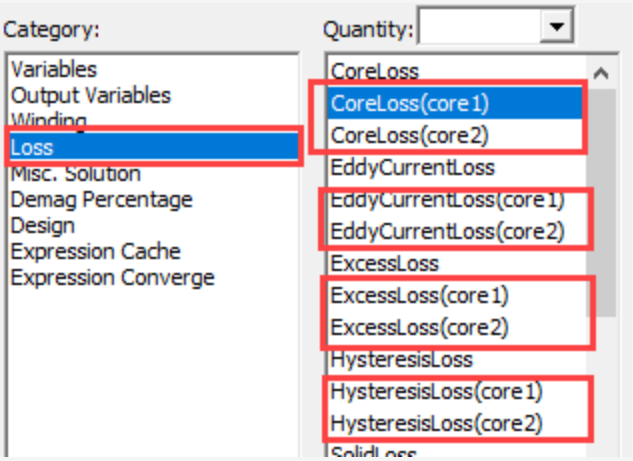
Changing the definition of a *variable* used for the residual value will NOT invalidate any existing solution. The next simulation will be for a different “design variation”.

Changing the definition of a *dataset* used for the residual will NOT invalidate any existing solution. The next simulation will continue from the stop time of the last simulation.

If a variable is used, you can choose to plot a family of curves based on the solved variations of the variable.

2. For both 2D and 3D Transient designs, you can select the **Smooth BH Curve** check box. This allows the solver to "smoothen" the list of points to make a refined BH curve for better solving. If this option is not selected, the solver just uses the discrete points.
3. Select or clear **Output per object core loss**. When this check box is selected:
   - For steel material, the solver will output core loss for each object, as well as the individual components (hysteresis loss, eddy current loss, and excess loss).
   - For ferrite material, the solver will output only core loss.

Note	To report core loss on objects, the objects must be selected in the **Set Core Loss** dialog box. The loss quantities for the core loss objects will show in the reporter.

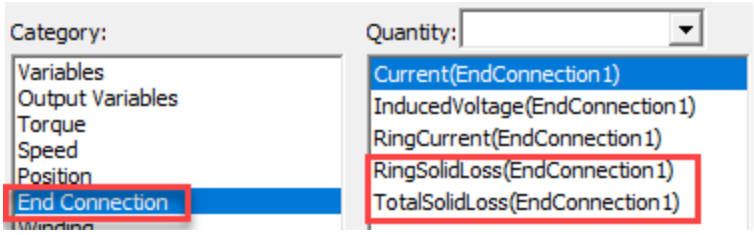


4. Select or clear **Output per object solid loss**. When this check box is selected, solid loss will be output for :
   - The solid loss quantities of the objects selected in the Set Eddy Effects dialog will show in the reporter. (Objects selected should not belong to stranded winding or stranded conductor.)

- Coil objects in solid windings.
- For 2D designs:
  - Solid loss quantities of the coil objects assigned with the solid Current Excitation will show in the reporter.

  - Each bar in an end connection will be considered as a separate object for solid loss output.

  - All ring segments in one end-connection will be combined together as one virtual object for solid loss output.



If there are N end-connections (such as double cages), there will be N virtual objects.

5. Select or clear the **Output error** check box. When this check box is selected, the transient solver generates the output error data, which is then sent back to the desktop. The data can be viewed or used in the post processor, just as other transient solution data (such as power loss or winding).

Note	Output error is the percentage error in the total energy of the solution. This is a measure of the accuracy of the finite element approximation and can be used to judge if the mesh is good enough. Output error is calculated by finding the residual energy (the left-over energy calculated from the field after subtracting out the sources) divided by the total energy including the sources. Computing output error uses significant computation time.

6. For 3D Transient analysis only, select the desired **Scalar Potential** shape function: either **Second Order** (default), or **First Order** from the pull-down list. You can also select the desired **Scalar Potential** on the **Solver** tab in the Properties window.

   Use of the First Order scalar shape function, rather than the Second Order shape function, may be desirable for any of the following cases:

   - If computational time is a main concern and solution accuracy is secondary. This might be useful for the initial design stage, before switching to using the more time consuming, and more accurate, second order scalar shape function.
   - If the contour of the geometry is very complicated, it may not be possible to use the higher second order shape function due to the inability of relatively larger element size to properly represent the original geometry shape
   - If the gradient of the magnetic field changes sharply, it may not be possible to use the higher second order shape function with large element size. Using a larger element size may not be able to adequately model the large change of material property with large element size, and nonlinear convergence may be difficult to achieve.

7. For 2D and 3D Transient designs, you can select the **Number of Nonlinear Iterations** check box. This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.

8. For 2D Transient analysis only, select the algorithm for the **Time Integration Method** using the pull-down list.
   - **Backward Euler** – Default
   - **Runge-Kutta** – third order algorithm for greater accuracy
9. Select or clear the **Steady State** check box.

   For transient simulations whose winding excitations are an AC voltage source, the DC flux linkage component may take a very long time to decay, especially for a device with a large time constant. Selecting **Fast Reach** adds an additional voltage component to the original voltage definition during the first half-cycle to quickly eliminate the DC flux linkage, thus speeding up the solution process. You must also provide a **Frequency of Added Voltage Source** value that is greater than zero. The default value for **Frequency of Added Voltage Source** is 60 Hz. This frequency value is applied to all winding voltage sources.

Note	• This speedup capability is only applicable to voltage sources whose integration of voltage quantity over one period is zero. This means the DC component of all voltage sources is zero. • This feature is intended to be used in conjunction with windings of the type "voltage". If the winding is fed by an external circuit, a similar functionality is available using the alternating flux model defined in the properties of sinusoidal voltage sources. Alternatively, the dedicated **AC_Model** component can be applied if an external circuit is feeding the winding.

10. Select or clear the **Auto Detect** check box.

    This option enables automatic detection of when steady state is reached based on a check of the flux linkage. When this option is selected, you must provide both a **Frequency of Added Voltage Source** value that is greater than zero (default value is 60 Hz), and a **Stop criterion** value that is greater than 0 and less than 1 (default value is 0.005). The smaller the **Stop criterion** value, the longer it will take to auto detect when steady-state is reached. For additional information on auto detect operation, refer to Automatic Detection of Reaching Steady State for Transient Simulations.
11. As needed for your design, select or clear settings in the **Time Decomposition Method Option** panel.

    The Time Decomposition Method (TDM) is an HPC distributed analysis type based on domain decomposition along the time-axis, (rather than the normal geometry division) to parallelize the transient solution. Instead of solving Maxwell transient problems sequentially for each time step, TDM enables time steps to be solved simultaneously in parallel. Thus, TDM can be implemented on distributed memory parallel platforms based on MPI. TDM has very good scalability, resulting in significant speedup for both 2D and 3D transient solutions.

    If you have enabled the **Use Automatic Settings** option in the **Analysis Configuration** dialog box, or if you have enabled the **Transient Solver** distribution type in the **Analysis Configuration** dialog box, you can select:

General Transient	For general transient (Non-Periodic) TDM applications, select **General Transient**. Using this method, TDM solves a collection of

	many time steps simultaneously.
Periodic	TDM method intended for use in steady-state simulation. In such a case, all the setup and solutions at the first time step will be the same as those at the last time step of one period. Setup includes source, boundary, and position in electrical degrees. The solutions include all electrical and magnetic quantities. To use this method, all current in windings and all induced eddy currents in the conducting region should have the same time period. For example, an induction machine cannot be solved using the Periodic method because the time period of the currents in the stator winding is different from the time period of induced eddy current in the rotor bars. Periodical TDM is computationally very efficient if a problem is applicable. But since all time steps over one period have to be solved simultaneously (cannot be divided into subdivision as the case for general TDM transient), the memory requirement may prevent users from using periodical TDM. To this end, the support of half-periodical TDM is able to effectively cut memory usage to roughly half. You can also select a **Half-periodic** option. This TDM option can cut your computer's memory usage when solving Maxwell transient problems. If all physical quantities satisfy anti-periodic condition along Time axis, a problem can be solved using this option so that memory usage can be cut to almost half. Also, since the total time steps to be solved are halved, the total computation time is also cut roughly by half.

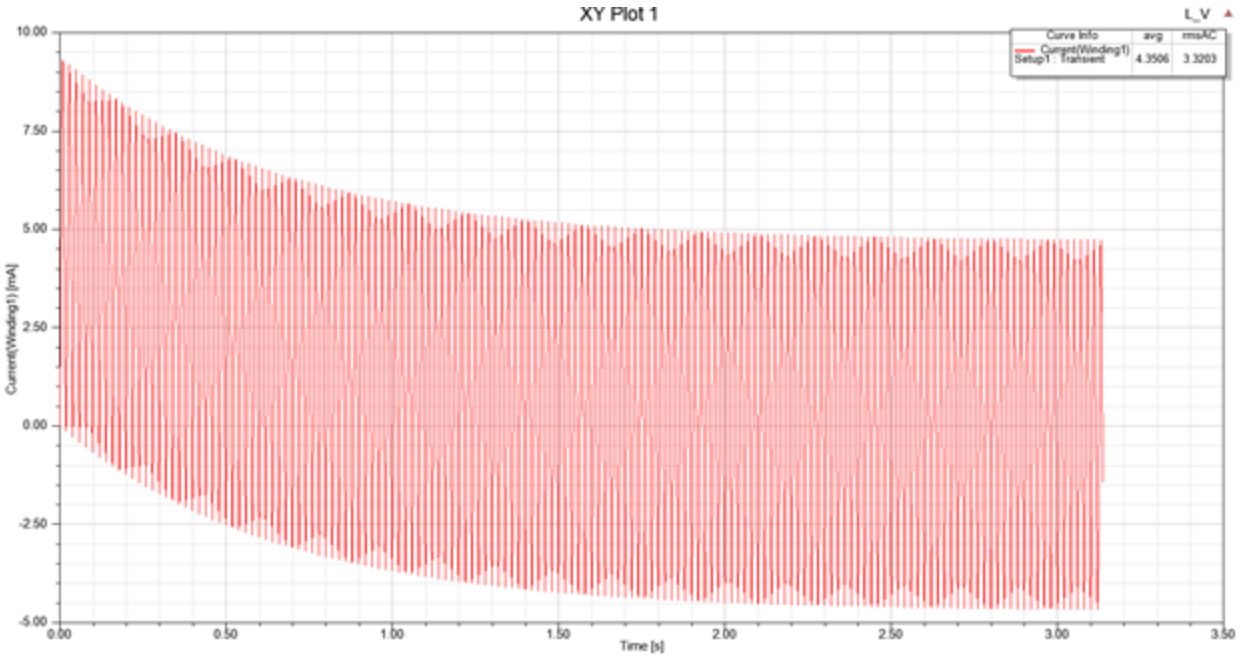
Automatic Detection of Reaching Steady State for Transient Simulations

For transient simulations, when the time constant of the design is large, many cycles may be needed to reach steady state.



Because it is often difficult to predict how many cycles are needed to reach the steady state, the user typically must preset a very long simulation time range (a large stop time) to ensure that steady state can be reached before the end of the simulation. This can result in the waste of significant simulation time for cases in which steady state is reached long before the set stop time.

Enabling the **Auto Detect** setting using a preset **Stop Criterion** causes the solver to check whether steady state has been reached during the simulation, automatically stopping the simulation when steady state is detected. This allows the user to set a very large stop time without concern for wasting needless simulation time, thus improving the efficiency of the simulation without losing the accuracy of the solutions.

Design Considerations

All windings in a project are divided to three categories: AC winding, DC winding, Non-applicable winding.

- For an AC winding, the winding source is periodic with the same frequency as the user-set frequency (**Frequency of Added Voltage Source**) and it has no DC component. A winding which is connected to an external circuit is treated as AC winding.
- For a DC winding the value of the winding source doesn't change throughout the simulation.
- A Non-applicable winding is a winding which cannot be included in either of the first two categories, such as the case when the frequency of the source is different from the frequency set by users.

If a project only includes AC windings and DC windings, automatic detection will be conducted by checking the flux linkages of all AC windings. If a project includes a Non-applicable winding, the automatic detection feature will be disabled.

How Auto Detection Works

Winding information is checked during simulation to determine whether steady state has been reached. If rotational motion is included in the project, the torque is also checked.

Of the three winding parameters that can be used to check whether steady state has been reached during the simulation: *current*, *induced voltage*, and *flux linkage*, **Auto Detect** uses flux linkage for the following reasons:

- Compared with the induced voltage, which is the time derivative of the flux linkage, the flux linkage itself is less sensitive to numerical noise.
- Similarly, current calculations are not as smooth as flux linkage. Also, when the winding excitation is current, the current is not applicable for detecting steady state.

The automatic check for steady state is carried out at the end of each cycle. The cycle time, T is calculated based on the input frequency (**Frequency of Added Voltage Source**) supplied by the user.

$$T=1/f$$

For example, if the check is carried out at time instant t_c, the flux linkage values over the last cycle $[t_c–T, t_c]$ and the second last cycle $[t_c–2T, t_c–T]$ will be used. The first checkpoint, t_c, is at $3T$ since, in general, the first cycle is unsuitable for checking for steady state – especially when **Fast Reach Steady State** is enabled (in which case the first cycle is not even a physical result).

The DC component and the fundamental component of the flux linkage of the two cycles are compared to check for steady state. These components are calculated as follows:

DC component:

$$D = \frac{1}{T}\int_0^T f(t)dt$$

Fundamental component:

$$F = \left|\frac{1}{T}\int_0^T f(t)e^{-2\pi j\frac{t}{T}}dt\right|$$

Assuming the DC component of the flux linkage at the last cycle is D_1, and the fundamental components are denoted by F_1 and F_2 at the last and the second last cycle, the following two criteria are implemented to check for steady state:

$$\left|D_1\right| < r$$

$$\left|F_1 - F_2\right| < r$$

where the reference value r is calculated by:

$$r = |F_1| \times c$$

Coefficient c is the **Stop Criterion** for reaching steady state and is set by the user on the solver tab for transient solutions and must be greater than 0 but less than 1 (default = 0.005). Thus the smaller the coefficient is, the stricter the stop criterion for reaching steady state is, and the longer it will take to auto detect when steady state is reached.

If rotational motion is involved, after the flux linkage has converged, the solver will further check whether the torque has reached steady state. In steady-state, the torque should be constant with small deviation. Such deviation can come from mesh noise, cogging torque, slot effects, etc. This deviation should be small compared to the rms value of the torque. To check whether the torque has reached steady state, the solver compares the difference of the average torques in the last two cycles. The difference should be smaller than the tolerance value. (The tolerance value is normalized by the rms value of the torque in one cycle.)

The average value of the torque and the rms value of the torque in one cycle are calculated as follows:
The average value of the torque:

$$DT = \frac{1}{T}\int_0^T Tor(t)dt$$

The rms value of the torque:

$$RT = \frac{1}{T}\int_0^T Tor(t)^2 dt$$

The following criterion is implemented in the solver to check for steady state for torque:

$$|DT_1 - DT_2| < RT \times 10c$$

As above, *c* is the user-supplied **Stop Criterion.**

Note	Since torque is usually noisier than flux linkage, the tolerance of the torque check is looser than the tolerance of flux linkage.

Time Decomposition Method for Maxwell Transient Designs

If a Maxwell 2D or 3D transient design problem is too large to solve efficiently on one machine, Maxwell can use the **Time Decomposition Method** (**TDM**). The Time Decomposition Method (TDM) is an HPC distributed analysis type based on domain decomposition along the time-axis (rather than the normal geometry division) to parallelize the transient solution. Instead of solving Maxwell transient problems sequentially for each time step, TDM enables time steps to be solved simultaneously in parallel. Thus, TDM can be implemented on distributed memory parallel platforms based on MPI. TDM has very good scalability, resulting in significant speedup for both 2D and 3D transient solutions.

Maxwell supports two time decomposition methods:

- **General Transient (Non-Periodic)** – This method is intended for general transient applications.

  For this method, TDM solves a collection of many time steps simultaneously – a collection of many time steps being defined as one time sub-division. For example, if the end time of the entire transient simulation is 4 seconds, and if we want to solve all time step solutions together for every 1 second, then this 1 second is defined as one time sub-division, and the total time sub-divisions is 4. For the same problem, we can also define every 2 seconds as one time sub-division. Accordingly, the total time sub-divisions becomes 2.
- **Periodic** – This method is intended for use in steady-state simulation. In such a case, all the setup and solutions at the first time step will be the same as those at the last time step of one period. Setup includes source, boundary, and position in electrical degrees. The solutions include all electrical and magnetic quantities. To use this method, all current in windings and all induced eddy currents in the conducting region should have the same time period. For example, an induction machine cannot be solved using this method because the time period of the currents in the stator winding is different from the time period of induced eddy current in the rotor bars.

  You can also select a **Half-periodic** option if all physical quantities satisfy anti-periodic condition along Time axis. In this case, the memory usage can be cut to almost half.

Periodic TDM has the advantage that the problem just needs to be solved over one period of time, while **General Transient** TDM uses many cycles to reach steady state. But to enforce periodical condition along the Time axis, all time steps over one period of time must be solved together. This may require extensive memory usage.

Using TDM

To use TDM, you must do the following:

- Have and use the HPC license Pool option (Refer to "Setting HPC and Analysis Options for Maxwell and RMxprt Designs" on page 4-54).
- Set the total number of Tasks, N, (at least three Tasks) for the solve pool. The actual number of Tasks for parallel computation is N-1 (dependent tasks), since the first Task is used as the independent task, which is responsible for task assembly, dependent task control, synchronization, etc.

- Enable the **Transient Solver** distribution type in the **Analysis Configuration** dialog box (Refer to "Editing Distributed Machine Configurations" on page 21-14 .)

Note	In Maxwell 2D, for **General Transient** TDM, the expression cache will be updated every 10 subdivisions, that is to say, every (task number - 1)*10 time steps. For **Periodic** TDM, the expression cache is updated after the entire solution is completed.

Limitations to using TDM

- Mechanical transient is not supported. This means all moving positions for every time step have to be known in advance so that FEA will take place at that pre-determined position.
- The solution at a time step cannot depend on the arbitrary history of previous time steps (allowed for previous couple of time step solutions required due to the time integration scheme itself). Traditional core loss computation is supported because core loss computation is done in post-processing.

  Strictly speaking, TDM cannot support hysteresis modeling. But for soft hysteresis materials, especially for lamination core loss computation, the hysteresis loop, or the coercivity Hc, is very small. In such a case, the impact of hysteresis on the nonlinear operating point can be ignored. This means we can decouple the nonlinear iteration process with consideration of hysteresis impact. For the first step of the nonlinear iteration process, distributed parallel TDM can still be applied. After the nonlinear iteration has converged, that is, the nonlinear problem has been linearized for all time steps (or all time steps in the sub-division), the second step is applied to take into account the impact of hysteresis. In such a case, the solution process is sequential – to consider the impact of hysteresis behavior from the previous time-step solution on the solution at current time step. It can be expected that the results with TDM enabled and with TDM disabled might differ slightly due to ignoring the impact of hysteresis on the nonlinear operating point. However, from a practical application point of view, the solutions can be considered as sufficiently accurate –especially for lamination core loss computation.
- The purpose of the demagnetization process in a transient simulation is to find the worst operating point during the entire transient simulation. After a new worst operating point is discovered, a linearized representation of the permanent magnet characteristic will be used to construct a new recoil line, which is applied to the simulation for subsequent time steps. Thus, strictly speaking, TDM cannot support demagnetization modeling because all time steps (or all time steps in a subdivision) are solved simultaneously. However, as a reasonable approximation, we can solve all time steps in one subdivision simultaneously based on distributed parallel TDM – and then search for the worst operating point among the solutions of these just-solved time steps. Thereafter, this new worst operating point is used to construct a new recoil line which is applied to all time steps in the *next* subdivision. This means the impact of previous solutions on subsequent searches for the worst operating point is taken into account subdivision-by-subdivision, rather than time step-by-time step.

  It can be expected that the results of the discovered *final* worst operating point might differ slightly between TDM- enabled solutions and TDM-disabled solutions. However, from a

practical application point of view, the solutions can be considered as sufficiently accurate. This error can be reduced with the use of few time steps in one subdivision.

Defining Expressions for Transient Solutions

Defining Settings for Output Variables for Transient Solutions

Any output quantity or expression within either the **Transient Report** or **Field Report** type can be defined as an output variable in the **Output Variables** dialog box, accessed via **Results** in the project tree.

To add an output variable to output with time:

- Click **Add** to select the output variables to be added to the list for output with time. The newly defined variable is added to the list.

Note	The **Add** button will not be enabled if there are no variables defined in the project.

To delete an output variable:

- Select the variable from the list, and click **Delete**.

Do one of the following in the **Evaluation Time Step** section on the **Output Variables** tab of the **Solve Setup** dialog box:

- Select **Using Constant**, type a value, and select the units. Select this option if you want to use a constant value for when you calculate output variable values.
- Select **Evaluate every Nth time step**, and type a value. Select this option if you want to evaluate the output variable after a certain number of solution time steps (i.e., instead of calculating the output variable every fixed time interval, you want to calculate it every certain number of time steps). For example, if you want to evaluate the output variable every third time step, type **3** in this text box.

Defining Settings on the Defaults Tab for Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** dialog box:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.
2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Setting Analysis Parameters for Electric Transient Solutions

When you set up an electric transient analysis, define the parameters on the following tabs of the **Solve Setup** dialog box (which appears when you click **Maxwell**>**Analysis Setup>Add Solution Setup**):

- General (Name, Transient Setup)
- Expression Cache
- Solver
- Defaults

Defining Settings on the General Tab for Electric Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for transient solutions:

- Setup Name
- Time Steps Setup

Setup Name for Electric Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Time Steps Setup for Electric Transient Solutions

To set up a transient analysis, define the following parameters on the **General** tab of the **Solve Setup** dialog box:

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
2. Enter the **Initial Time Step**, which is the time step used to start the simulation and begin the adaptive process.

   > **Note:** The solver calculates the initial time step based on relaxation time Tau=Eps/Sigma of each material and then compares the results with the initial time step defined by the user. The smaller value is used.

3. Also enter the **Maximum Time Step** to set the allowable range the adaptive process use to alter the time step.
4. Check **Save Fields** to enable saving the fields data.

Defining Expressions for Electric Transient Solutions

You can specify additional evaluation criteria through the use of expressions and output variables.

To set expressions as evaluation criteria:

1. Right-click on the Analysis icon in the Project tree to open the **Solution Setup** dialog box.
2. Click the **Expression Cache** tab and click the **Add...** button to open the **Add to Expression Cache** dialog box.
3. Specify the Context for the expression, including **Report Type**, and **Solution**.
4. Under the **Trace** tab, select from the **Category**, **Quantity**, and **Function** lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them by selecting the **Output Variables** category. The **Output Variables** button opens a dialog box that lets you define output variables. See Specifying Output Variables.

   When you have created an expression, it appears in the **Expression** field of the **Trace** tab. If desired, you can use the **Range Function** button to select range functions to apply to the expression.

   Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis **[...]** button in the **Edit** column opens a list of values from which you can select.
5. When finished defining the expression that you want to add to the cache, click the **Add Calculation** button.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can define additional expressions with contexts and add them in the same way.
6. When finished adding expressions, click **Done** to close the **Add to Expression Cache** dialog box.

   The **Expression Cache** tab lists the expressions you have added in a table.
   - The **Title** field is editable, by default showing the name as built from the expression (with underscores removed).
   - The **Expression** field shows the full expression. You can resize the **Solution Setup** dialog box, and also each column in the table, to view the contents of the fields.
   - The **Context** column for non-field types lists the parameter type specifying the force, torque or matrix setup. For these types the context also can be given as part of the expression. For example, the expression *Force1.Force_x* with a context of *None* is equivalent to an expression of *Force_x* with a context of *Force1*.

   For field quantities the **Context** can be the geometry on which to evaluate the field quantity - a point or line. If you use a line you need to use some range function to reduce the dimensionality to a single value (or use the Calculation Range tab to specify a single point along the line). Note that, if you create a named expression in the field calculator that already evaluates to a single value, then the **Context** here will likely be *None*.

- The **Intrinsics** column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the **Intrinsics** column button shows **None** you cannot edit the value. If the button shows variables, click the ellipsis **[...]** in the **Edit** column to display a list of the variable values from which you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the **Expression Cache**.

The **Intrinsics** field lists the values you may have set in the **Calculation Range** tab when you added the expression. This is used to set the values of “other” sweeps. Usually there are no other sweeps because the values of the variables are set in the definition of each variation. In some cases you may need to specify the values of “other” sweeps. For field values with a line for the context, you can specify the (normalized) distance along the line For eddy current field quantities you can also specify the phase for the calculation.

7. In the **Evaluation Time Step** panel, set how often the solver is to output field solutions. Select **Constant** to output solutions at a preset time interval (e.g., every 0.1 s); or **Number of solve steps** to output solutions each preset number of time steps (e.g., every 3 time steps).
8. Optionally, buttons allow you to **Edit** and **Remove** selected expressions, and to **Remove All** expressions in the table.
9. When finished defining expressions, click **OK** to close the **Solution Setup** dialog box.

Related Topics

Specifying Output Variables

Defining Settings on the Solver Tab for Electric Transient Solutions

To define solver settings on the **Solver** tab of the **Solve Setup** dialog box for transient solutions:

1. Enter a value in the **Temporal Tolerance**text box.
2. For the Initial Condition, select either a preset **Value** or a **Static Field**.

   If **Static Field** is selected, the **Setup Link** button becomes active, and the **Setup Link** dialog box automatically appears, and the field will be imported from the source design to the target design.
3. The **Import mesh** check box can be selected in the "target" design if the mesh for the same geometry is to be used in the analysis.

   If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box automatically appears, and the mesh will be imported from the source design to the target design.

Note	The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

Setup Link for Electric Transient Solutions

If you selected **Import mesh** or **Static Field**, do the following to specify the project, design, and solution containing the mesh information you want to use:

1. Click **Setup Link** in the **Solve Setup** dialog box).

   The **Setup Link** dialog box appears.

2. Click the **General** tab.
3. Select the project from the **Project File** pull-down list.
4. Select the saved design from the **Design** pull-down list.
5. Select the specific solution you want to link to from the **Solution** pull-down list.
6. Click the **Parameters** tab.
7. Optionally, edit the **Value** and **Unit** columns for any of the parameters listed
8. Click **OK** to close the **Setup Link** dialog box and return to the **Solve Setup** dialog box.

Defining Settings on the Defaults Tab for Electric Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** dialog box:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.

2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Resetting Analysis to Time Zero

Resetting the analysis to time zero invalidates the current solution and causes you to start over from the beginning the next time you analyze the simulation.

To reset the analysis, do one of the following:

- Click **Maxwell**>**Analysis Setup>Reset to Time Zero** from the Maxwell menus.
- In the project tree, right-click **Setup** under **Analysis**, and select **Reset to Time Zero** from the shortcut menu.

Changing Memory Settings

The Maxwell solver has to make trade-offs between the solution time and the amount of memory used in the solution process.

The software automatically determines the amount of RAM installed on the computer, assuming that it can use up to 75% of this during the solution process. You can override this choice by changing the following two memory settings:

- Desired RAM Limit
- Maximum RAM Limit

Generally, set the RAM value as high as possible to obtain the fastest solutions.

These settings are not an absolute limit on the amount of RAM to be used. When solving small problems, Maxwell tries to respect this limit by choosing to run more slowly with a smaller amount of RAM. When solving a large problem, Maxwell may be unable to use less RAM than the specified limit. In this case, the amount of memory used exceeds the specified limit but tries to minimize how far it goes beyond.

Specifying the Desired RAM Limit

The **Desired RAM Limit** setting requests a restriction on the amount of physical random access memory (RAM) the MPS solver used in Maxwell may use before it must stop solving *on-core - solving processes entirely in RAM* - and start solving off-core. In *off-core mode*, Maxwell creates temporary solution files to which it spills, or shifts, data from RAM, instead of relying on the operating system to start disk swapping. The location of these temporary files is specified in the General Options (**Tools>Options>General Options**). The MPS solver is finely tuned at handling its own memory, and can optimize loading only those blocks of memory required for its immediate needs.

Using this option may help to keep the entire solver from being swapped out in the normal course of process management on your computer. This kind of control may be especially important when multiple solvers are running on the same machine. Of course, if the total memory requirement of all processes grows large enough, the operating system will be forced into disk swapping.

Note	The Iterative solver doesn't go off-core for efficiency reasons. Because the Desired RAM Limit (the soft memory limit) is used for off-core run, it is not appropriate for the iterative solver. Instead, the iterative solver uses the Maximum RAM Limit (the hard memory limit). Once the limit is exceeded, the iterative solver will issue an "Out of memory" error message.

Regardless of this setting, processes are limited to 4TB of address space on 64 bit operating systems - no matter how much physical memory is installed.

Note	Regardless of the **Desired RAM Limit** setting, if allocation fails, the Maxwell solver automatically switches to off-core mode.

In case you receive an error message regarding insufficient memory on a 64-bit operating system, you may have reached a point where the sum of physical RAM plus available swap space exceeds the minimum amount of RAM needed by the off-core solver. Even for the off-core solver, the RAM usage cannot be made arbitrarily small. In that case you can consider increasing the swap space (the virtual memory) in the settings of your system.

To specify the Desired RAM Limit of the machine on which Maxwell is installed refer to the *HPC and Analysis Options* section.

Specifying the Hard Memory Limit

The **Maximum RAM Limit** setting specifies the absolute limit on the amount of physical memory that the solver can use. If the solver attempts to allocate more memory than this setting, the solution process terminates abnormally, and incorrect error messages may appear.

To specify the **Maximum RAM Limit** for the current user and machine refer to the *HPC and Analysis Options* section.

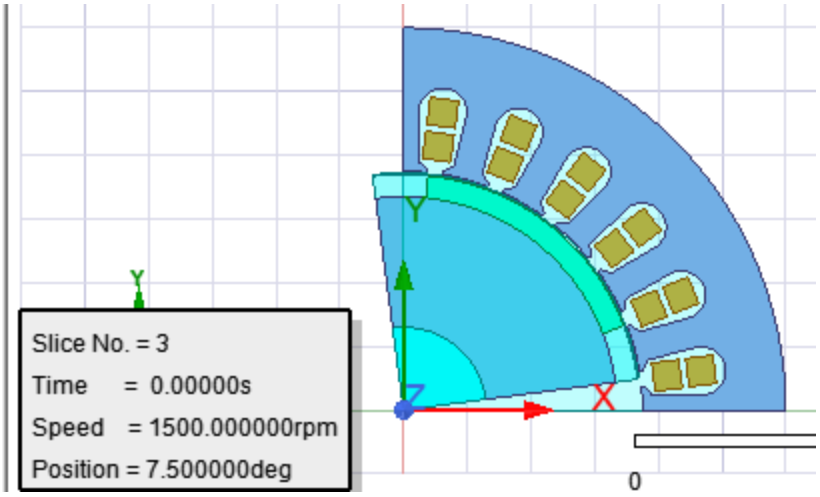
1.

Note	Ansys recommends that you use the **Desired RAM Limit** setting if you want to limit the RAM the solver may allocate.

Setting View Context for Transient Solutions

To set the view context:

1. Click **View>Set Solution Context**.
   The **Set View Context** dialog box appears.
2. Select a solution from the **Solution Name** pull-down list.
3. Select a time instance from the **Time** pull-down list.
4. For Maxwell 2D transient solutions only, in which **Use Skew Model is enabled on the Model Settings tab**, an additional **Slice** field displays, which allows you to select the skew model slice to be displayed in the modeler window.



5. In the **View** area of the dialog, you can choose the location to display the **Solution Context** within the modeler window. **Lower left** was selected for the image above.
6. The position and speed values may be displayed in the **Solution Context** by selecting the **Display Speed and Position values** check box.
7. Click **OK**.

Note	You can also change the view context by double-clicking the solution context text

	label in the bottom left of the model window. **Example of text label showing solution view context:** `Time='0s'`

Speed and Position Display Settings

To set the display setting for speed and position in the view context:

1. Click **View>Set Solution Context**.
   The **Set View Context** dialog box appears.
2. Select the **Motion View Format** tab.
3. In the **Format Speed Unit** section:
   a. Specify the Unit Type from the pull-down list.
   b. Specify the **Field Width** for the display and the number of digits of **Precision** to display.
   c. If you prefer **Scientific Notation**, select the check box.
4. In the **Format Position Unit** section:
   a. Specify the Unit Type from the pull-down list.
   b. Specify the **Field Width** for the display and the number of digits of **Precision** to display.
   c. If you prefer **Scientific Notation**, select the check box.
5. Click **OK**.

Note	You can also change the view context by double-clicking the solution context text label in the bottom left of the model window. **Example of text label showing solution view context:** `Time='0s'`

Renaming a Solution Setup

Do the following to rename a solution setup:

1. In the project tree, under **Analysis**, right-click the setup you want to rename.
   A shortcut menu appears.
2. Select **Rename** from the shortcut menu.
   The setup name text is highlighted in the project tree.
3. Type the new name for the setup, and press **Enter**.

You can also rename the solution setup by changing the text in the **Name** text box of the **Solve Setup** dialog box.

Related Topics

Copying a Solution Setup

Copying a Solution Setup

Solution setups may be copied and pasted within a design or across designs of the same type. This is beneficial for setups having a large number of parameters to specify such as an RMxprt design, or where minor changes to a setup are being evaluated.

Note	Setups cannot be pasted across solution types, across geometry modes such as from 3D to 2D, or across machine types in RMxprt.

Do the following to copy a solution setup:

1. In the project tree, under **Analysis**, right-click the setup you want to copy.

   A shortcut menu appears.
2. Select **Copy** from the shortcut menu.

   The setup parameters are copied to the clipboard.
3. In the project tree, right-click on the **Analysis folder to receive the copied setup**.

   A shortcut menu appears.
4. Select **Paste** from the shortcut menu.

   The setup parameters are copied to the **Analysis** folder as a new setup.

Related Topics

Renaming a Solution Setup

Disabling and Enabling an Analysis Setup

To disable an **Analysis** setup definition without deleting it:

1. Expand the tree hierarchy under the Analysis icon in the project tree.
2. Right-click on the icon for the setup definition. In the shortcut menu that appears, click Disable Setup.

   You can also disable an analysis setup by selecting **Properties** from the shortcut menu to open the **Edit Properties** window. In the upper right corner of the Edit Properties window, uncheck the **Enabled** box. Then click **OK**.

To reactivate an **Analysis** setup:

1. Expand the tree hierarchy under the **Analysis** icon in the project tree.
2. Right-click on the icon for the setup definition. In the shortcut menu that appears, click **Enable Setup**.

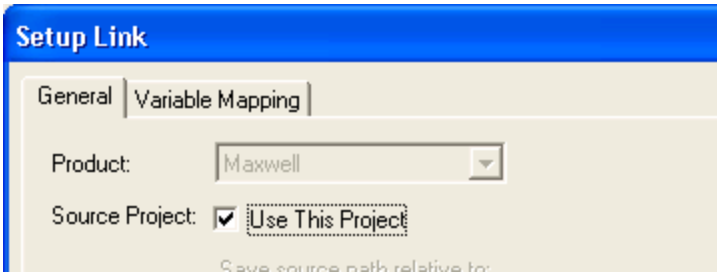
   You can also reactivate the analysis setup by selecting **Properties** from the shortcut menu for the sweep to open the **Edit Properties** window. Check the **Enabled** box in the upper right corner, and click **OK** to apply the change and close the window.

Setup Link Dialog

The **Setup Link** dialog permits you to link the current project to another as described in the following topics:

- Setup Link for Non-Transient Solutions
- Import Mesh for Non-Transient Solutions
- Setup Link for Transient Solutions
- Import Mesh for Transient Solutions
- Setup Link for Electric Transient Solutions

The **General** and **Variable Mapping** tabs are common to all Setup Link dialog boxes.



Depending on the type of link being set up, other tabs such as **Additional Mesh Refinements**, and Advance may also appear. Details of the use of the various tab settings may be found in the topics linked above.

Clearing Linked Data

If you have previously setup links, the **Maxwell>Analysis Setup** menu contains an option to **Clear Linked Data**. This removes the linked data for all links in a target design, therefore invalidating the solutions. Clearing linked data for some link types requires Maxwell to revert to the initial mesh. Thus, in some cases, this command removes the current mesh of the target design.

Setting the Report Updating During Analysis Options

Updating numerous reports may take a significant amount of time. Updating reports during the analysis process can impact the overall time to solution. You may want to vary the times when your reports get updated relative to the impact on overall solve time.

Four options exist for updating reports during solutions:

- After each variation - when performing an Optimetric or parametric analysis, all reports are updated after analysis of each variation has been completed.
- Automatically - the default. It means update most things immediately.
  For "AdaptivePass" plot context, plots are updated at the end of each solution pass. For "LastAdaptive" or "Transient" the plot is updated at the end of the transient or adaptive solution.
  This option balances report and field plot updating with solution time. For example, reports

may be updated after each adaptive pass but field plots will not be updated until the solution is complete.

- Immediately - update reports and plots as soon as data comes from the solver.
  This option will have the greatest impact on the overall solution time but will have the most rapid updating of reports and field plots. Caution should be used in selecting this option. Some types of reports and field plots may take a long time to update, especially as the mesh size increases.
- Never - only manual intervention updates reports.
  This option will prevent updates from impacting the solution time.
- On Completion - as with Never, but a single update is done when the solve completes. This option should be considered when using dynamic links to other products to provide best solution time with the final data available for the link.

To change the setting for the current project, see Desktop Performance options.

17 - Maxwell Coupling

Coupling is provided in specific contexts between Maxwell and the following products:

- **Ansys Workbench**

  Coupling of Maxwell2D/3D with Ansys Workbench is supported via the Workbench schematic. The following types of coupling with Workbench are supported:

  - Thermal feedback is supported for Maxwell magnetostatic, eddy current, and transient solution types.
  - Stress feedback is supported for Maxwell magnetostatic, eddy current, and electrostatic solution types.
  - Harmonic force is supported for Maxwell transient and Eddy current solutions.
  - Partial Model Coupling

  For more information, see “Maxwell to Ansys Thermal Coupling” and “Maxwell to Ansys Stress Feedback Coupling,” and "Coupling Maxwell with Both Ansys Thermal and Structural via Workbench."

- **HFSS**

  There are two possible coupling mechanisms between HFSS and Maxwell:

  - Near field coupling.
  - Magnetic bias source coupling.

  While they serve different application objectives, they are similar in neither requires the geometry in the coupled designs to be identical.

  For more information, see “Near Field Coupling between Maxwell and HFSS” and "Magnetic Bias Source Coupling between Maxwell and HFSS."

- **Twin Builder**

  Coupling between Maxwell and Twin Builder can take the following forms (initiated through the Twin Builder user interface):

  - Export a parametric matrix from Maxwell to an ECE model file for placement in Twin Builder.
  - Dynamically link a Maxwell capacitance or inductance project to a component in Twin Builder.
  - Dynamically link a Maxwell Transient design to Twin Builder to perform Transient-Transient cosimulation.
  - Dynamically link a Maxwell design to Twin Builder to perform State Space cosimulation.
  - Dynamically link to RMxprt through Dynamic SML.

  Because the thermal and/or stress solutions are derived from the distributed power loss and force density, they are likely to be more accurate than analyses based on average losses/force.

  For more information, see "Coupling Maxwell to a Twin Builder Component."

- **Ansys Fluent**

Coupling without using Ansys Workbench is supported between Ansys Fluent and Maxwell 3D magnetostatic and Eddy current designs in Maxwell. A transient Ansys Fluent simulation can use a Maxwell solution to simulate the magnetic effect in the electric arc of contactors.

For more information, see "Coupling Maxwell Magnetostatic and Eddy Current Designs with Ansys Fluent."

- **LMS Virtual.Lab™**

  Maxwell supports one-way coupling with Siemens® LMS Virtual.Lab™.

Maxwell to Ansys Thermal Coupling

Coupling Maxwell2D/3D with Ansys applications is supported via the Workbench schematic. Thermal feedback is supported for Maxwell magnetostatic, eddy current, ac and dc conduction, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design should be temperature-dependent, and have one or more solve setups that are enabled for thermal feedback.

Note	A Maxwell system can also be coupled with both thermal and stress systems via Workbench.

Maxwell-Specific Considerations

- If there is thermal feedback, each frequency point in an eddy current sweep will be solved with the same feed-back data.
- Temperature distribution data that has already been exported from Ansys Thermal will be invalidated when users continue the Maxwell solution in a way such that the Maxwell mesh is being regenerated.
- Once the Maxwell solution has been integrated with a thermal effect, the adaptive process of a static simulation will be disabled. Users must then manually invalidate the temperature data in the existing solution before the adaptive process will be re-enabled.
- Maxwell solutions can incorporate feedback from both thermal and stress.

Maxwell 2D Coupling Considerations

For Maxwell2D in RZ mode, geometry either must be exported into the XY plane, or the geometry must be rotated into the XY plane after it is imported into **Ansys Mechanical**. This is because Mechanical 2D requires geometry to be in XY plane.

There are two modes in Ansys Thermal 2D. The default mode is called **Planed Stress** where zero stress and non-zero strain are assumed in the z-direction. This is similar to the XY mode in Maxwell 2D. The other mode is called **Axisymmetric**. This mode will be used when a 3D model can be generated by revolving a 2D section 360 degree. This is similar to the RZ mode in Maxwell 2D. Users must ensure that they use the correct geometry mode in Thermal 2D. Invalid geometry mode selection is prohibited by the Thermal2D interface.

There are two types of **Import Load** in Mechanical: **Heat Generation** and **Heat Flux**. **Heat Generation** is used when mapping losses from *objects* in Maxwell2D/3D and **Heat Flux** should be used to map the loss from the *edges* of objects in Maxwell 2D/3D. **Heat Flux** is supported only for eddy current designs with impedance boundary. Users can insert multiple **Heat Generation** or **Heat Flux** loads via the **Imported Load (Maxwell2D/3DSolution)** objects.

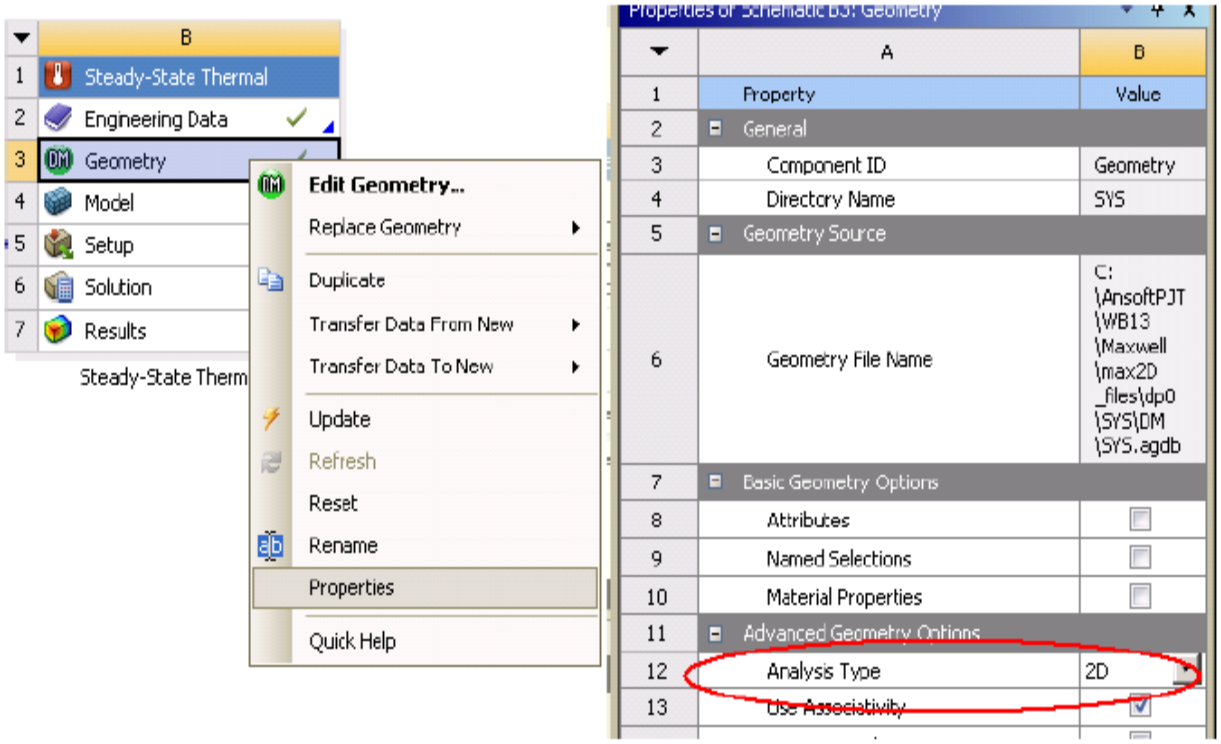
Setting The Temperature of Objects

Coupling Maxwell Designs with Ansys Thermal via Workbench

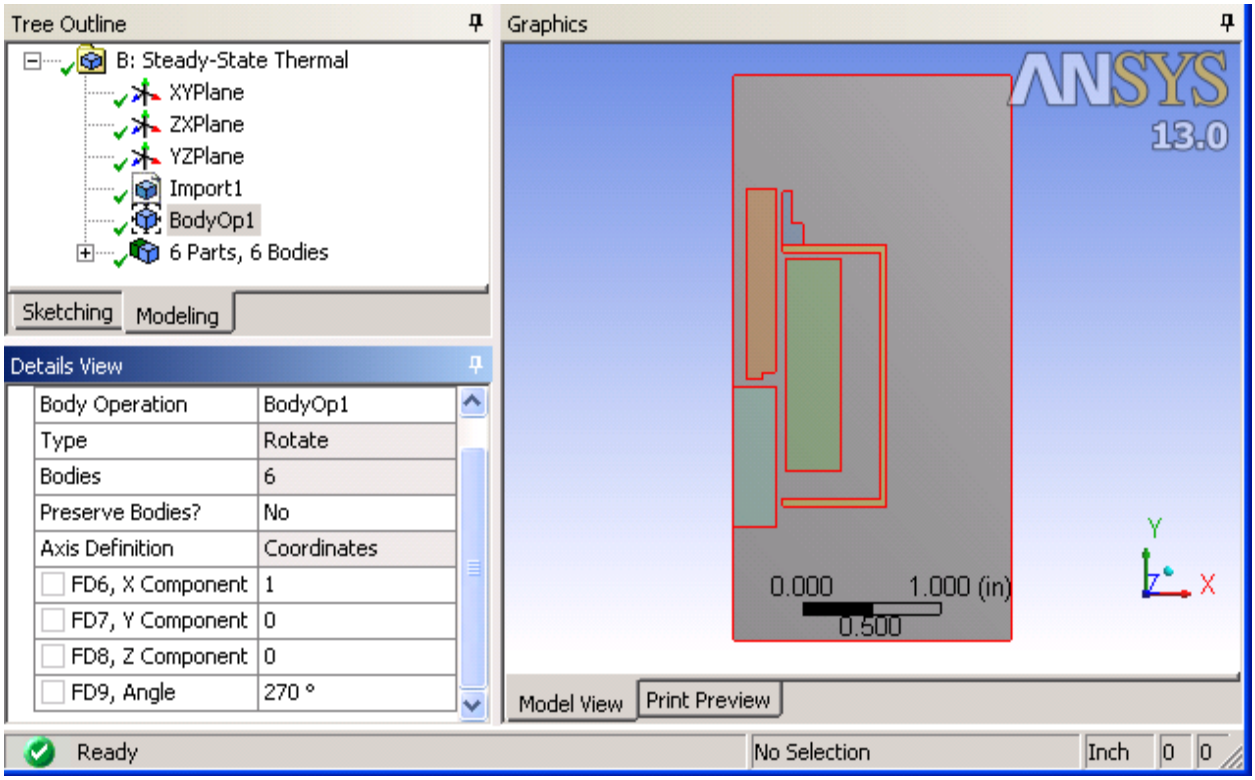
Coupling Maxwell2D/3D with Ansys applications is supported via the Workbench schematic. Thermal feedback is supported for Maxwell magnetostatic, eddy current, ac and dc conduction, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design should be temperature-dependent, and have one or more solve setups that are enabled for thermal feedback.

1. The easiest way to add a Maxwell 2D or 3D design to a Workbench schematic is to import a working design via **WorkbenchFile>Import**. The imported design is placed in the **Workbench** schematic after it is successfully imported.
2. Next, insert a **Steady-State Thermal** system and change its **Analysis Type** to **2D** or **3D**, (depending on the Maxwell design type) by right clicking on the **Geometry** cell and selecting **Properties**. It is important to change the **Steady-State Thermal** system's analysis type *before* setting up its geometry.

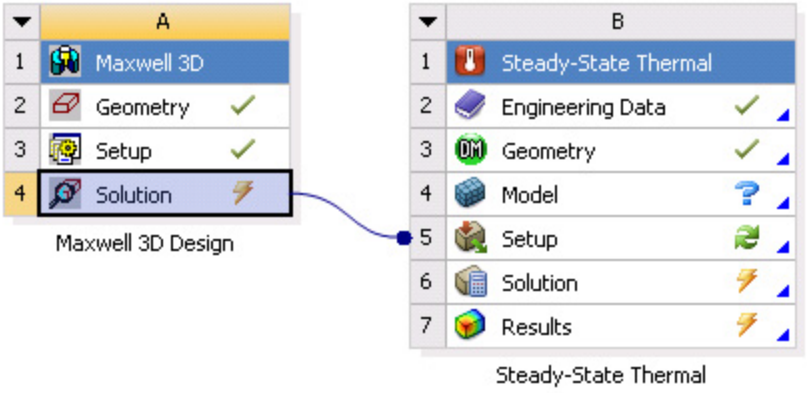


3. to set up the **Steady-State Thermal** system's geometry, you must first export the Maxwell geometry using **sat** or **step** format as follows:
   a. Select the **Modeler>Export** menu item.
   b. Select the desired model geometry format (**sat** or **step**), and the save location in the dialog box and save the file for use by Ansys Workbench.
4. Import the file via the **Geometry** module of the **Steady-State Thermal** system.
   a. To access the **Geometry** module, double click on the **Geometry** cell in the **Steady-State Thermal** system to launch **DesignModeler**.
   b. Select **File>Import External Geometry File** and browse for the geometry file exported from Maxwell.
   c. After the geometry file is imported, right-click on the root folder of the modeler project tree and select **Generate**. (When the geometry file is of a Maxwell 2D RZ design, users

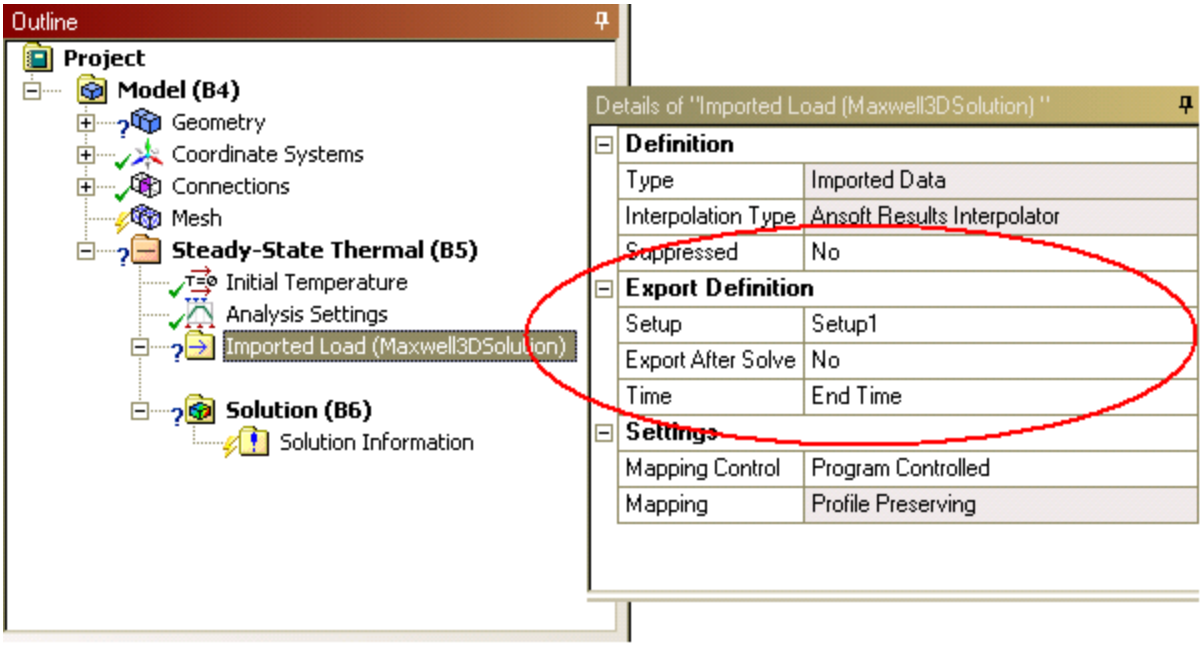
can rotate the geometry in **DesignModeler** by creating a body operation.)



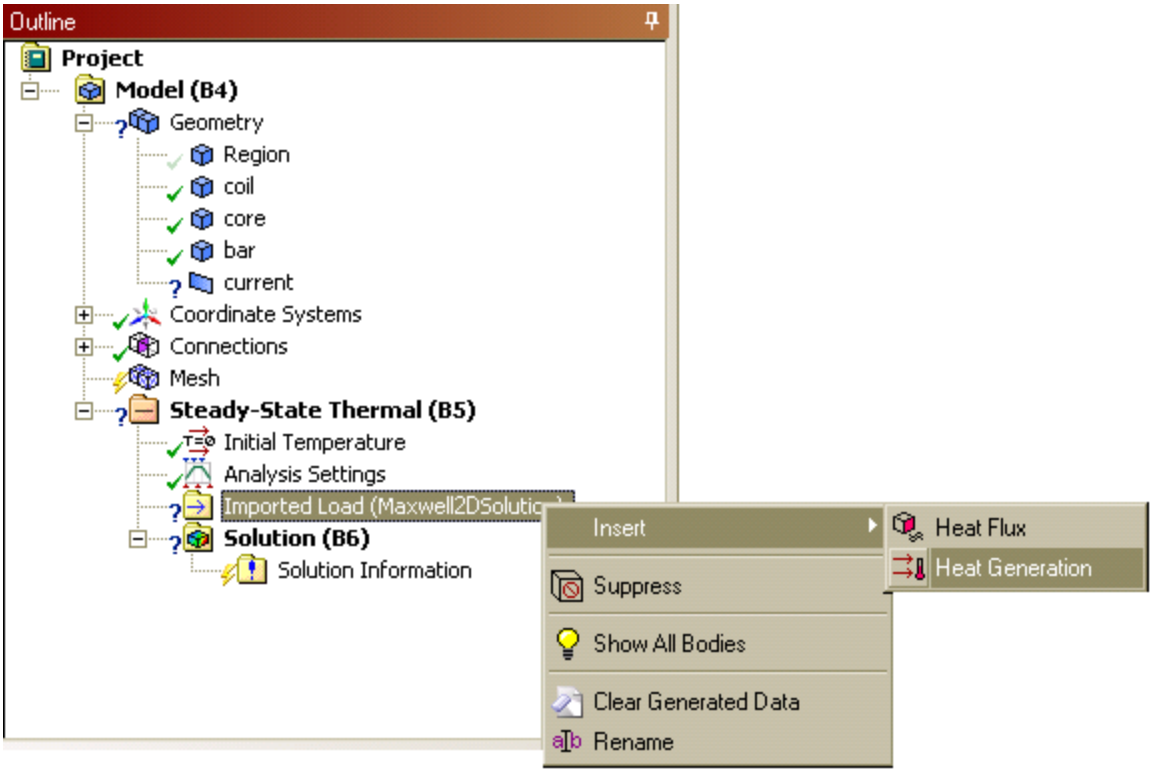
5. Close **DesignModeler** and refresh the **Model** cell of the **Steady-State Thermal** system by right-clicking the **Model** cell and selecting **Refresh**.
6. The geometry mode of the **Steady-State Thermal** system can be changed via the Ansys **Mechanical** user interface.
   a. Launch **Mechanical** by double clicking the **Setup** cell of the **Steady-State Thermal** system.
   b. Select **Geometry** in the project tree and the **Definition** of **Geometry** will be shown in the **Detail** window.
   c. Select either **Plane Stress** or **Axisymmetric** as the value for the property 2D (or 3D) **Behavior**.
7. To set up the coupling, drag the **Solution** cell of the Maxwell system and drop it on the **Setup** cell of the **Steady-State Thermal** system.



8. Note that the Maxwell **Solution** cell is tagged with a “Lighting Bolt” symbol. Right-click on the Maxwell **Solution** cell and select **Update**. This will initiate a Maxwell simulation if it is not already solved. Once Maxwell's solution is available, the “Lighting Bolt” changes to a “Green Check”symbol.
9. To “push” the coupling into **Steady-State Thermal**, right-click on the **Steady-State Thermal Setup** cell and select **Refresh**.
10. After refresh is finished, you can launch Ansys **Mechanical** by double-clicking the **Setup** cell to finish the coupling setup.
11. In the Ansys **Mechanical** application project tree, an **Imported Load (Maxwell2DSolution)**, or **(Maxwell3DSolution)**, item should already be inserted. Select the **Imported Load** folder to view its details. Because the inserted Maxwell2D (or 3D) system supports thermal feedback, the **Details** window shows information regarding how the temperature result should be exported, and what type of mesh mapping should be used.

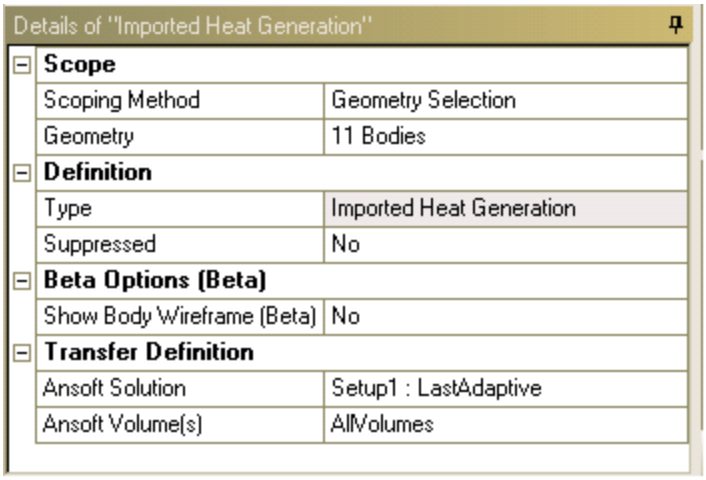


12. To finish the coupling setup, you must insert either an **imported Heat Generation** or an **imported Heat Flux** boundary condition. **Heat Generation** is used when mapping loss from objects in Maxwell; and **Heat Flux** should be used to map the loss from the edges of objects in Maxwell. Users can insert multiple **Heat Generation** or **Heat Flux** loads via the **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)** objects.
13. To insert a **Heat Generation**, use **Body** select by clicking the  icon in the **Mechanical Toolbar**. Then click on the objects where the EM loss should be imported. After all the desired objects are selected, right-click on **Imported Load (Maxwell2DSolution)> Insert > Heat Generation**, or **Imported Load(Maxwell3DSolution) > Insert > Heat Generation**.



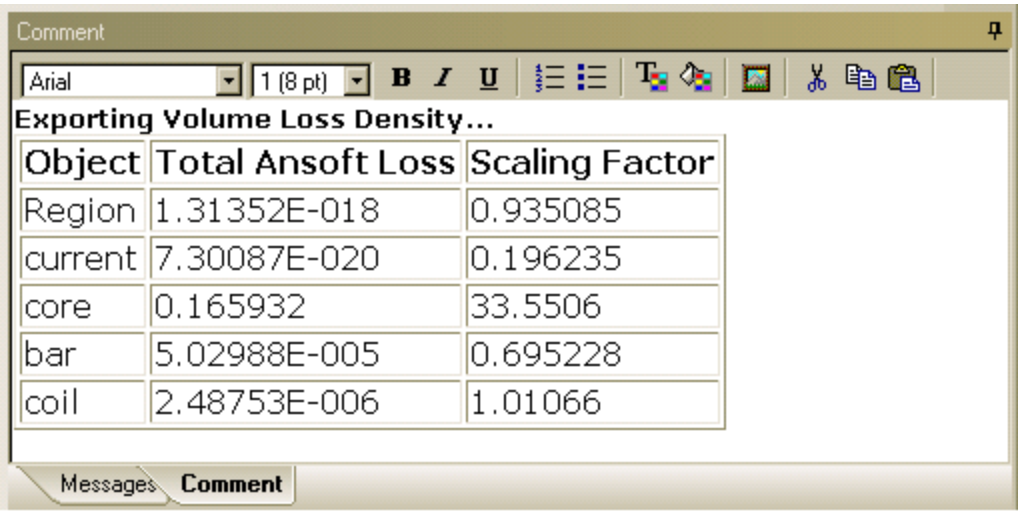
A sub-item named **Imported Heat Generation** will appear in the project tree.

14. Click on the **Imported Heat Generation** tree item to view its details.

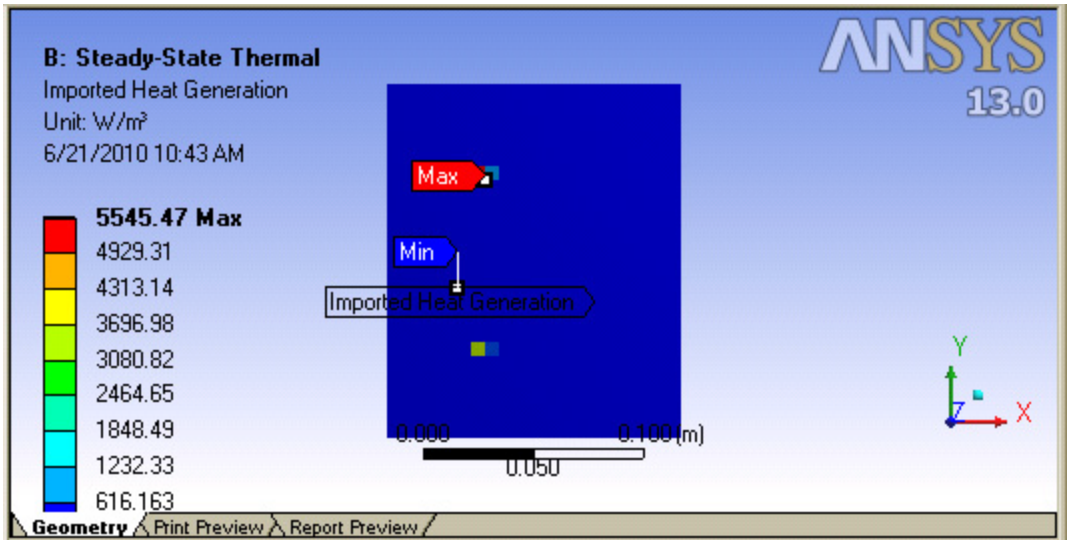


15. In the **Transfer Definition** section, users can set up the source Maxwell solution by pulling down the **Ansoft Solution** combo box and select one of the listed Maxwell solutions.
16. Right-clicking on **Imported Heat Generation > Import Load** will import loss from the **Ansoft Solution** selected for this load. After import has completed, the **Import Heat Generation** item becomes a folder, and an entry called **Imported Load Transfer**

Summary is listed. Select the **Imported Load Transfer Summary** entry and the scaling factors used to export the load from Maxwell will be displayed in the **Comment** window.



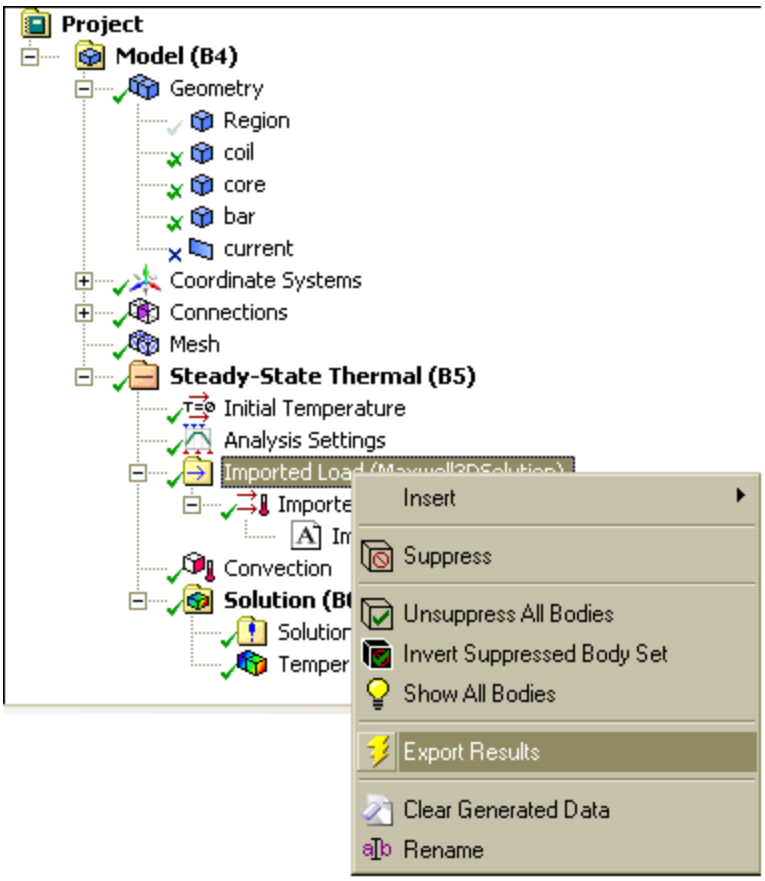
17. Selecting **Import Heat Generation** should show an overlay-plot of the imported load. The loss mapping from Maxwell can be verified by comparing this overlay-plot with an Ohmic-Loss field overlay plot in Maxwell.



18. Create a **Convection** boundary to complete the thermal setup. Use **Edge** select by clicking the  icon at the **Mechanical Toolbar** and then **Edit > Select All**. With the edges selected, right-click on the **Steady-State Thermal** project tree item and insert a **Convection**. With the **Convection** item selected, change its **Film Coefficient** to **5 W/m2** via the **Detail** window. Right-click on the **Solution** tree item and select **Solve**. After the thermal solution is finished, users can insert a **Temperature** plot by right-clicking on

Solution and selecting **Insert > Thermal > Temperature**. Right-click on the newly inserted **Temperature** item and select **Evaluate All Results**.

19. To export the thermal result to Maxwell, right-click on the **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)** and select **Export Results**.



20. To fully utilize the automation capabilities provided in **Ansys Workbench**, select **Imported Load (Maxwell2DSolution)**, or **Imported Load(Maxwell3DSolution)**; and in its **Detail** window, select **Yes** for **Export after Solve**. With this option selected, users can continue the iteration between Maxwell/Thermal simulations from the Workbench schematic.

    To “push” the exported thermal results back to Maxwell, right-click on Maxwell's **Solution** cell on the Workbench schematic and select **Enable Update**. Then, right-click again on Maxwell's **Solution** cell and select **Update**. This will trigger Maxwell to re-simulate its solution with thermal results.

    To continue the solve iterations, repeat the following steps as needed:

    a. Right-click on Thermal's **Setup** cell and select **Refresh**.
    b. Right-click on Thermal's **Setup** cell and select **Update**.
    c. Right-click on Maxwell's **Solution** cell and select **Enable Update**.
    d. Right-click on Maxwell's **Solution** cell and select **Update**.

Maxwell to Ansys Stress Feedback Coupling

Maxwell 2D/3D supports stress feedback coupling for non-transient designs via the Workbench schematic. Any static design type that can support one-way stress coupling can support stress feedback. For both 2D and 3D, the supported design types are: magnetostatic, eddy current, and electrostatic.

Note	A Maxwell system can also be coupled with **both** thermal and stress systems via Workbench.

Maxwell-Specific Considerations

- Users must select object/s (i.e., geometry) in Maxwell upon which displacement data from Ansys Mechanical should be considered. This is done to avoid applying displacement to the whole model while only certain part(s) are sensitive to stress. This is a per-design setting similar to the Set Object Temperature setting for thermal feedback.
- Each frequency point in an eddy current sweep will be solved with the same feedback data.
- Displacement data that has already been exported from Ansys Mechanical Stress is invalidated when the Maxwell design is edited such that the previously simulated solution is considered as invalid or non-current. These edits include:
  a. Modifying the geometries or selecting “Revert To Initial Mesh.”
  b. Modifying the boundary/excitation settings, such as changing the value of a “Current excitation” in a magnetostatic design.
- Maxwell solutions can incorporate feedback from both thermal and stress.
- Once the Maxwell solution has been integrated with displacement/temperature, the adaptive simulation process of a static simulation is disabled. Users must then manually invalidate the displacement/temperature data in the existing solution before the adaptive simulation process is re-enabled.
- Simulation iteration is controlled by user.

Setting the Deformation of Objects

Maxwell to Ansys Thermal Coupling

Force Densities in Maxwell

Force Density Calculation in Maxwell

Maximum force density (AC) components calculation

In Maxwell, there are two options to couple the eddy solver with the Mechanical structure static solver. You can choose either DC force density or Maximum force density. The maximum force density includes the contribution from AC components.

In Maxwell stress tensor,

$$\sigma_{ij} = B_i B_j - \frac{1}{2\mu_0} B^2 \delta_{ij}$$

The DC(averaged) components of B_iB_j is calculated by

$$B_i B_j\big|_{DC} = \frac{1}{2\mu_0} Re\left[\dot{B}_i \dot{B}_j\right]$$

and the AC (fluctuation) components

$$B_i B_j\big|_{AC} = \frac{1}{2\mu_0} Re\left[\dot{B}_i \dot{B}_j\right]$$

where

$$\dot{B} = B_{Re} + jB_{im}$$

And $\dot{B}$ is the complex conjugate of $\dot{B}$. The maximum force is calculated as:

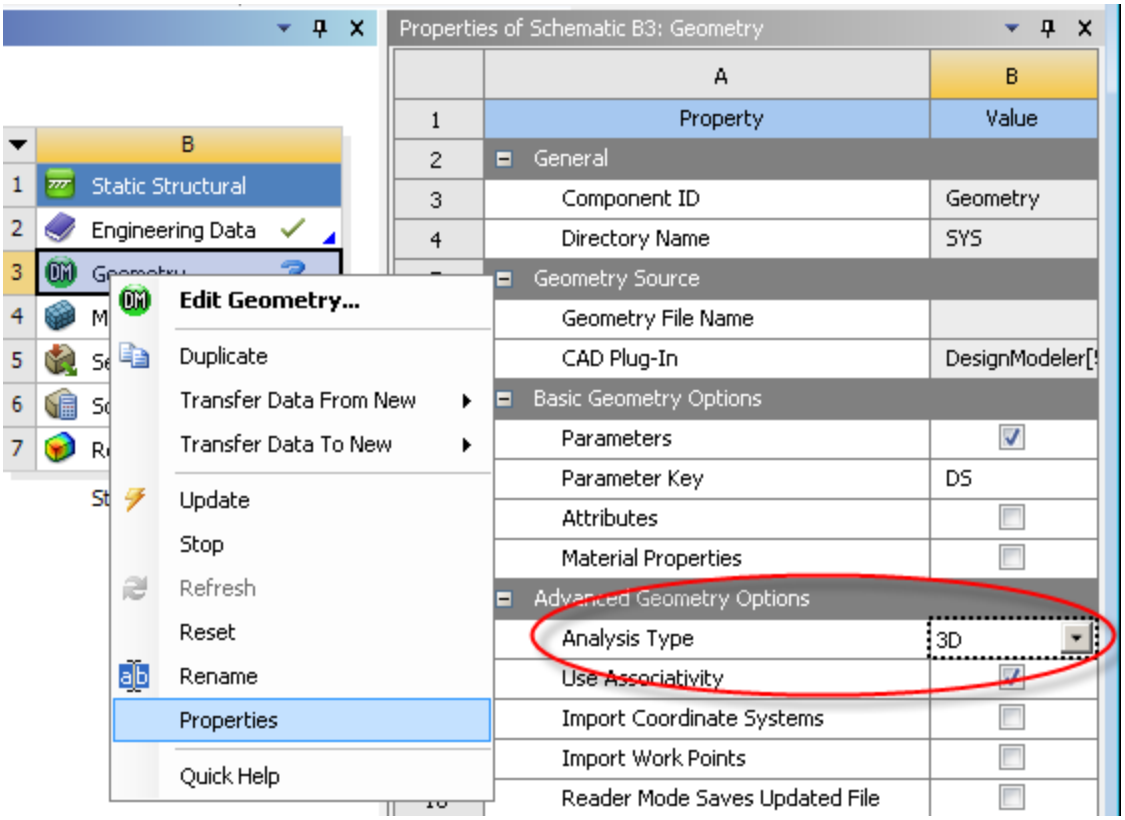
$$\vec{F} = \frac{\vec{F}_{DC}}{|\vec{F}_{DC}|}\left(|\vec{F}_{DC}| + |\vec{F}_{AC}|\right)$$

Coupling Maxwell Designs with Ansys Structural via Workbench

Stress feedback coupling between Maxwell2D/3D and ANSYS Structural 16 is supported via the Workbench schematic. Stress feedback is supported for Maxwell magnetostatic, eddy current, and transient types. Users also need to set up the design and geometry appropriately. An appropriate design has one or more solve setups that are enabled for stress feedback. The process for stress feedback coupling between Maxwell and Ansys Structural is similar to that described in "Coupling Maxwell Designs with Ansys Thermal via Workbench".

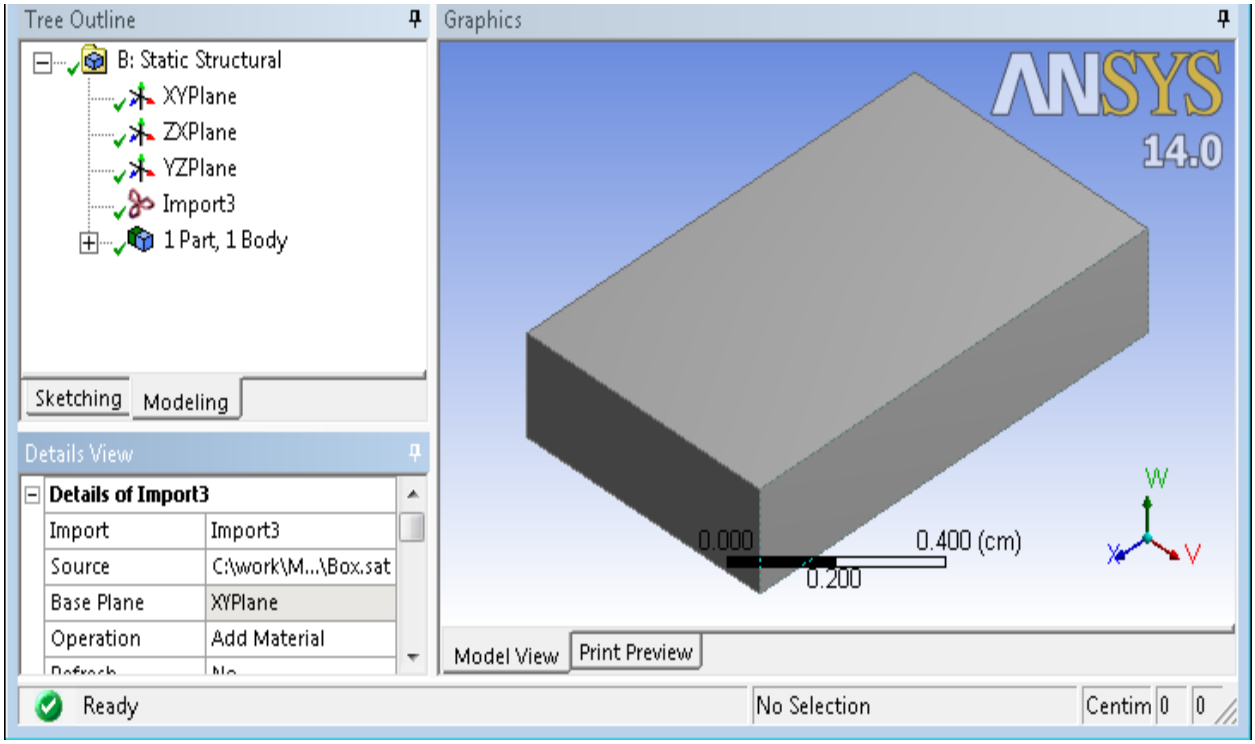
1. The easiest way to add a Maxwell 2D or 3D design to a Workbench schematic is to import a working design via **WorkbenchFile>Import**. The imported design is placed in the **Workbench** schematic after it is successfully imported.
2. Next, insert a **Static Structural** system and change its **Analysis Type** to **2D** or **3D**, (depending on the Maxwell design type) by right clicking on the **Geometry** cell and

selecting **Properties**. It is important to change the **Steady-State Thermal** system's analysis type *before* setting up its geometry.

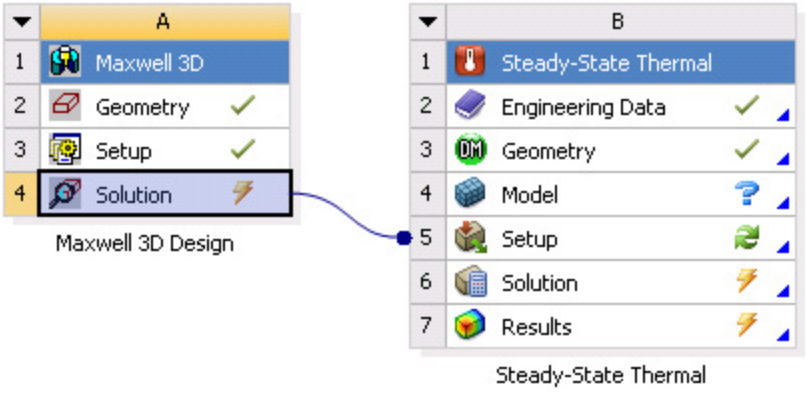


3. to set up the **Static Structural** system's geometry, you must first export the Maxwell geometry using **sat** or **step** format as follows:
   a. Select the **Modeler>Export** menu item.
   b. Select the desired model geometry format (**sat** or **step**), and the save location in the dialog box and save the file for use by Ansys Workbench.
4. Import the file via the **Geometry** module of the **Static Structural** system.
   a. To access the **Geometry** module, double click on the **Geometry** cell in the **Static Structural** system to launch **DesignModeler**.
   b. Select **File>Import External Geometry File** and browse for the geometry file exported from Maxwell.
   c. After the geometry file is imported, right-click on the root folder of the modeler project tree and select **Generate**. (When the geometry file is of a Maxwell 2D RZ design, users

can rotate the geometry in **DesignModeler** by creating a body operation.)



5. Close **DesignModeler** and refresh the **Model** cell of the **Static Structural** system by right-clicking the **Model** cell and selecting **Refresh**.
6. The geometry mode of the **Static Structural** system can be changed via the Ansys **Mechanical** user interface.
   a. Launch **Mechanical** by double clicking the **Setup** cell of the **Static Structural** system.
   b. Select **Geometry** in the project tree and the **Definition** of **Geometry** will be shown in the **Detail** window.
   c. Select either **Flexible** or **Rigid** as the value for the property 2D (or 3D) **Stiffness Behavior**.
7. to set up the coupling, drag the **Solution** cell of the Maxwell system and drop it on the **Setup** cell of the **Static Structural** system.



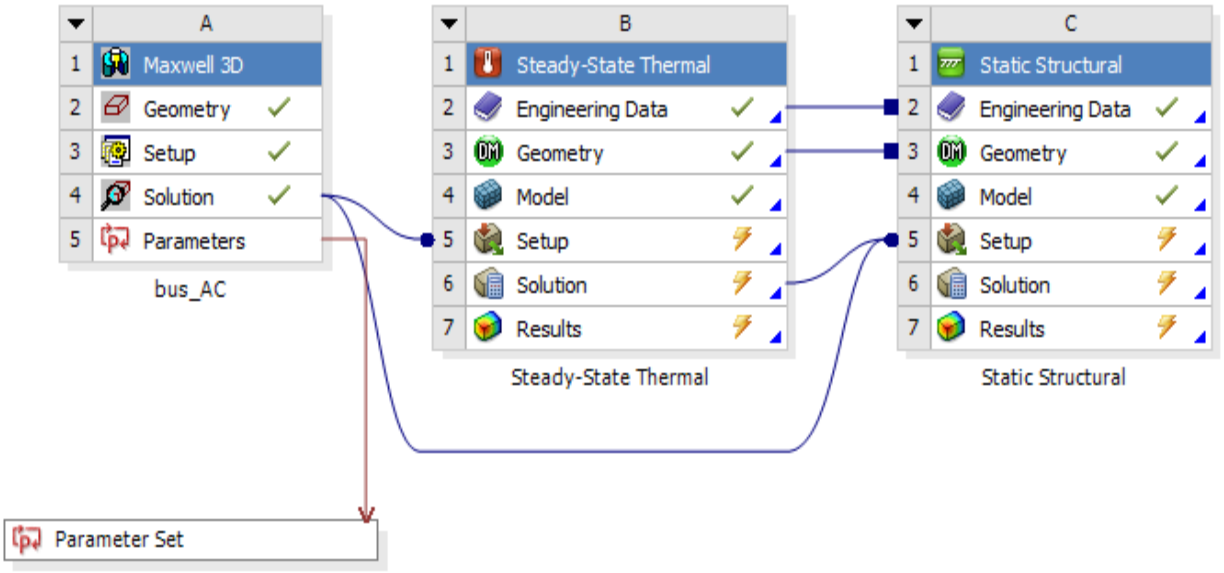
8. Note that the Maxwell **Solution** cell is tagged with a “Lighting Bolt” symbol. Right-click on the Maxwell **Solution** cell and select **Update**. This will initiate a Maxwell simulation if it is not already solved. Once Maxwell's solution is available, the “Lighting Bolt” changes to a “Green Check”symbol.
9. To “push” the coupling into **Static Structural**, right-click on the **Static Structural Setup** cell and select **Refresh**.
10. After refresh is finished, you can launch Ansys **Mechanical** by double-clicking the **Setup** cell to finish the coupling setup, which is similar to that described in “Coupling Maxwell Designs with Ansys Thermal via Workbench”.

stress Stress

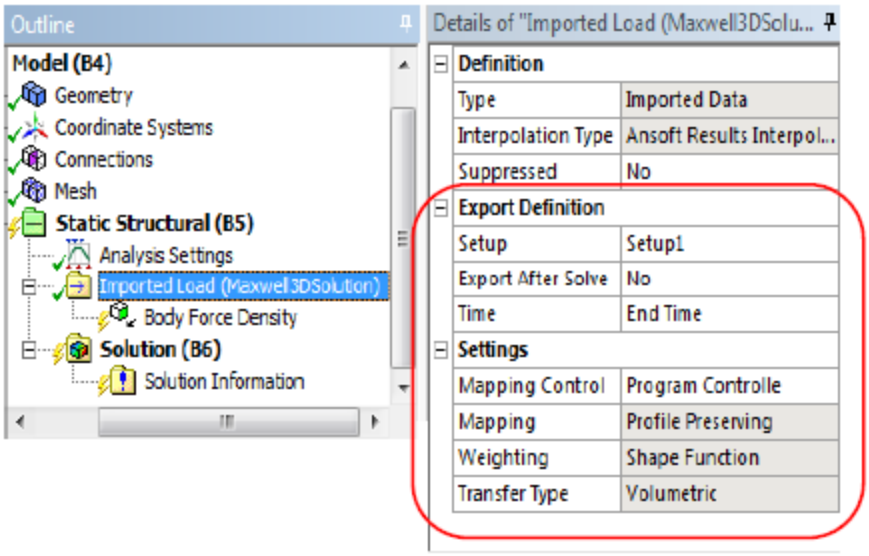
Coupling Maxwell with Both Ansys Thermal and Structural via Workbench

A Maxwell system can also be coupled with *both* thermal and stress systems via Workbench. The thermal system then serves as an “up-stream” system for the stress system. This means that the stress analysis takes both electromagnetic and thermal forces into consideration. In this scenario the user must select the same object(s) in the thermal and stress systems to apply the respective imported loads.

to set up the coupling, drag the “Solution” cell of the Maxwell system and drop it at the “Setup” cell of a Thermal and Static Structural (Stress) system. The user also needs to couple the Thermal and Static Structural systems to capture the effect of thermal force.

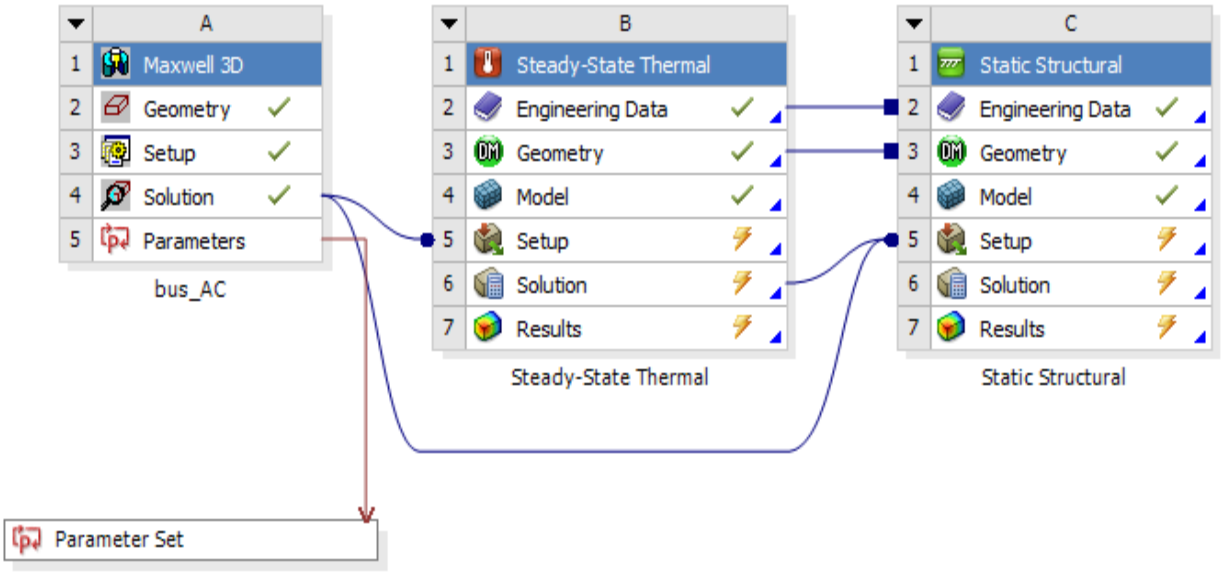


The coupling framework is built on top of the existing Thermal Feedback. The Stress system will have additional Export Definition and Mapping Settings like Thermal.



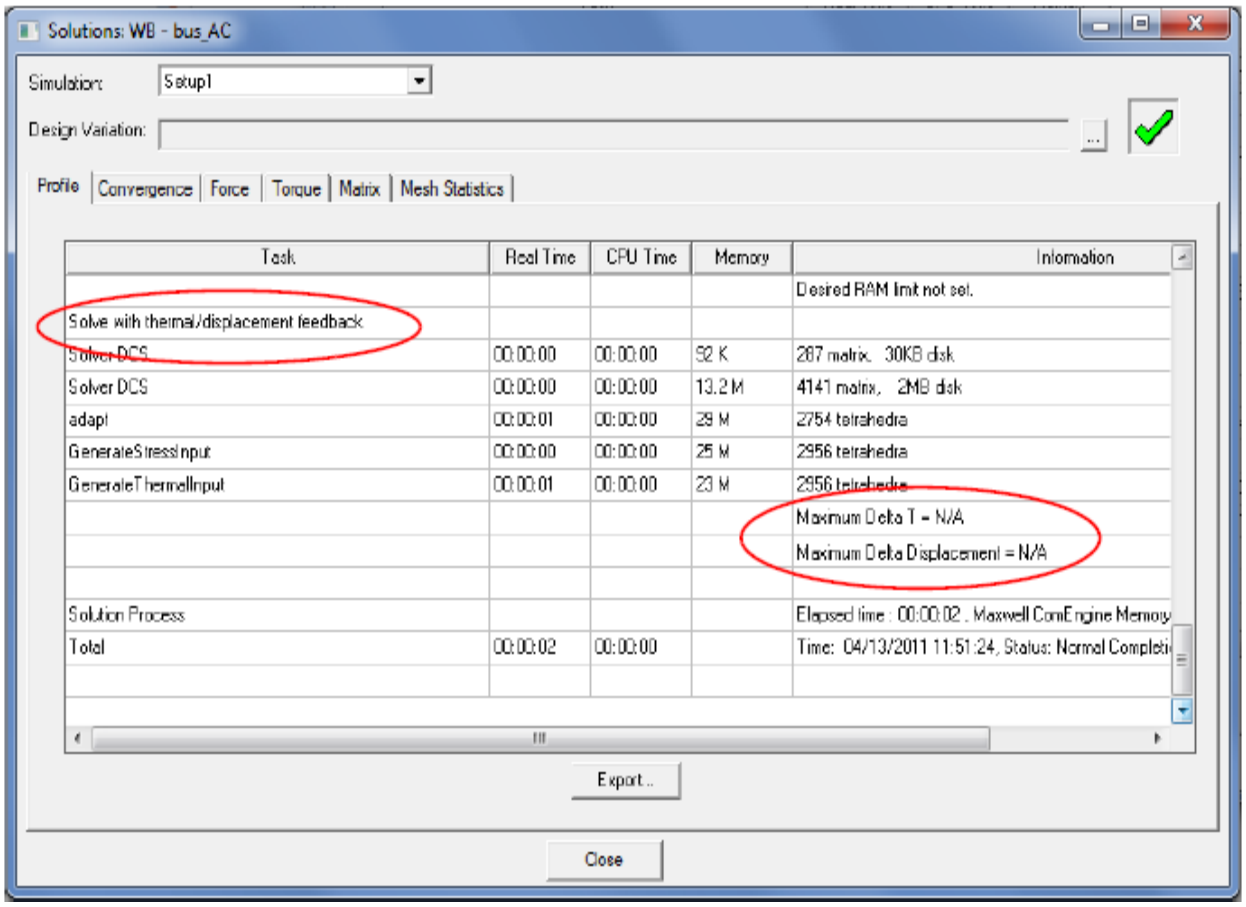
Example 1: “One” iteration

The following image illustrates a coupling setup where both the Thermal and Stress system are ready to be Updated. The Maxwell adaptive solution has converged in 3 passes. The Maxwell system has both thermal and stress feedback enabled.

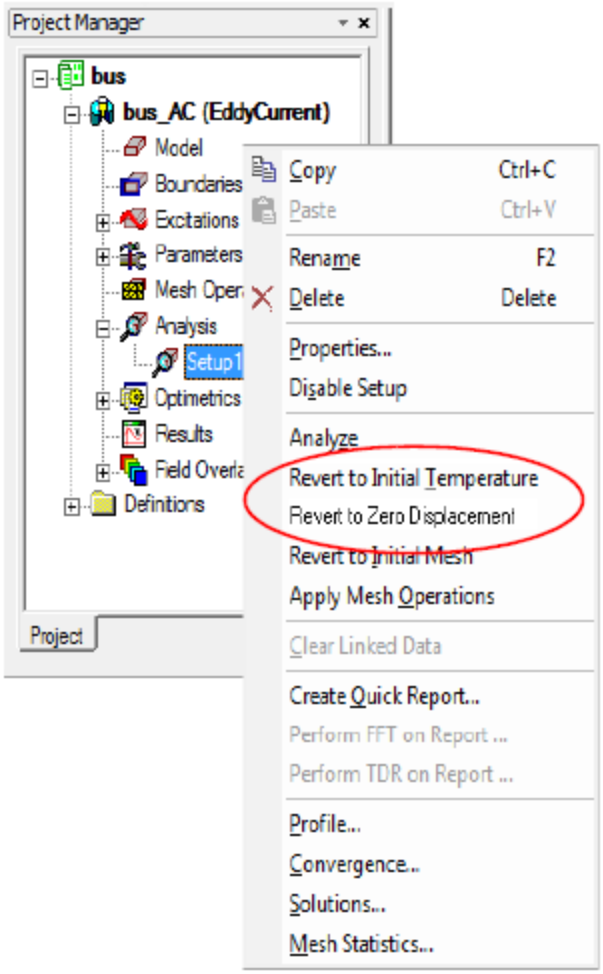


1. Right click on the **Solution** cell of Stress (Static Structural) and select **Update**.
   a. The **Setup** of Thermal will be Updated with “em” loss from Maxwell.
   b. The **Solution** of Thermal will be Updated and temperature will be exported to Maxwell.
   c. The **Setup** of Stress will be Updated with thermal force from Thermal and force density from Maxwell.
   d. Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right click on the **Solution** cell of Maxwell and select **Update**.
   a. Maxwell re-simulates the 3rd pass with its mesh and the temperature/displacement feedback.

b. The profile will show information about the feedback

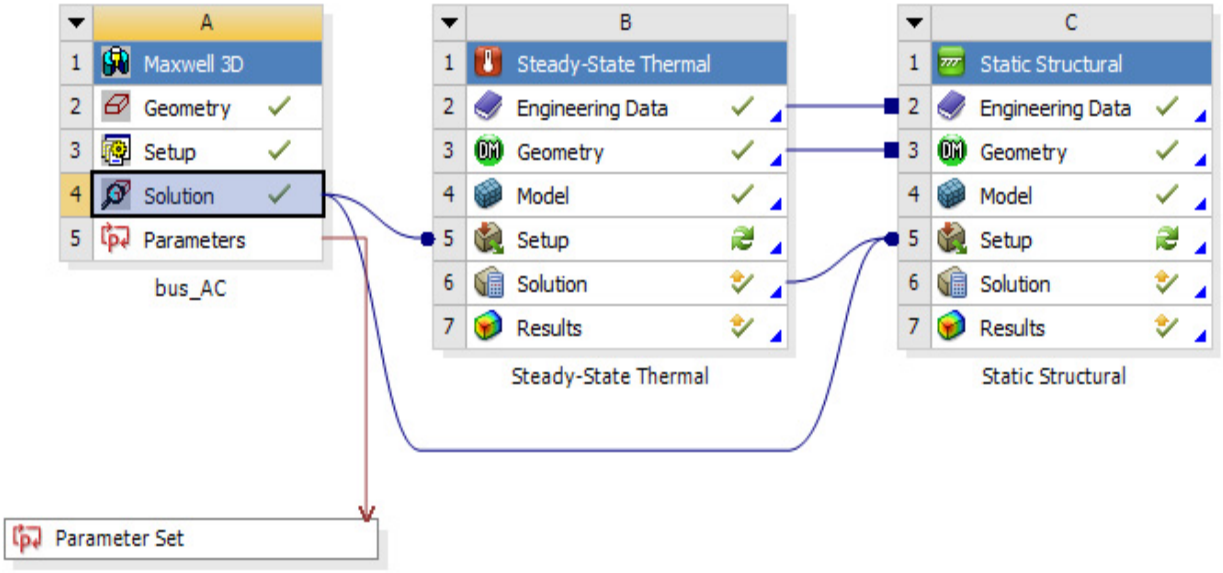


c. Both Revert to Initial Temperature and Revert to Zero Displacement menus are present in the analysis setup context menu.



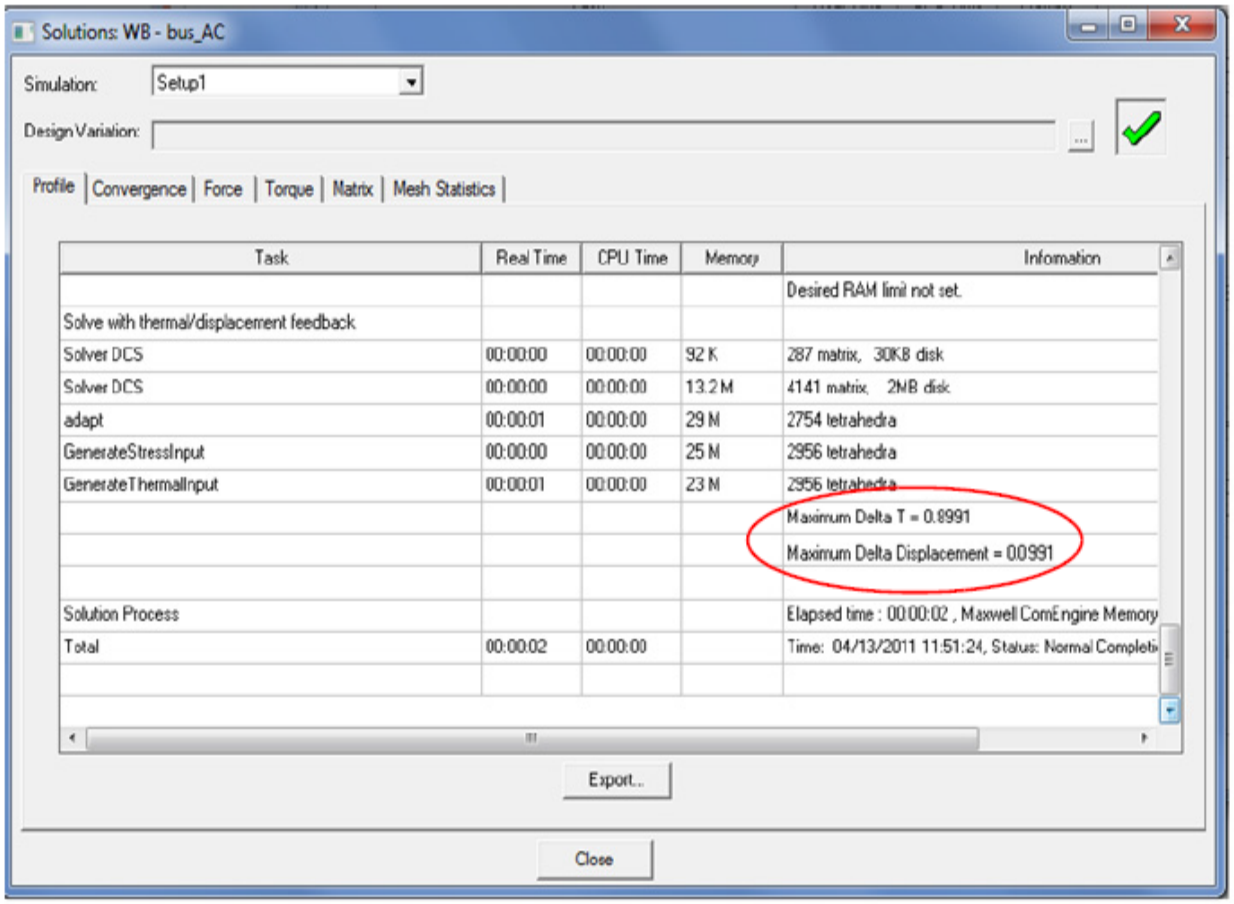
Example 2: Manual iteration

The following image illustrates the Workbench schematic after Example 1, where the 1st iteration has completed.



1. Right click on the **Solution** cell of Stress and select **Update**.
   a. The **Setup** of Thermal will be Refreshed and Updated with “em” loss from Maxwell.
   b. The **Solution** of Thermal will be Updated and temperature will be exported to Maxwell.
   c. The **Setup** of Stress will be Refreshed and Updated with thermal force from Thermal and force density from Maxwell.
   d. Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right-click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right-click on the **Solution** cell of Maxwell and select **Update**.
   a. Maxwell re-simulates the 3rd pass with its mesh and *new* temperature/displacement feedback.

b. The profile will show information about the feedback.

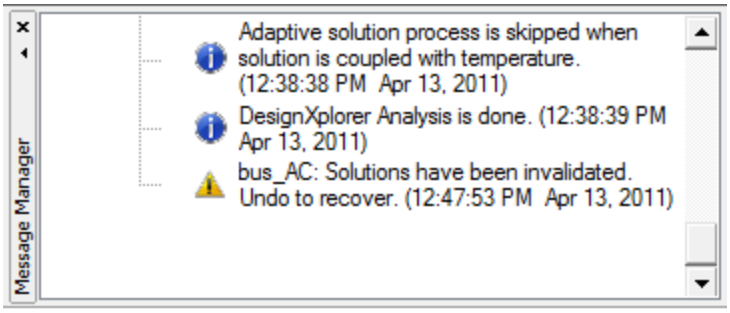


Note that the delta temperature and displacement is being reported in the profile.

Example 3: Revert Maxwell Solution

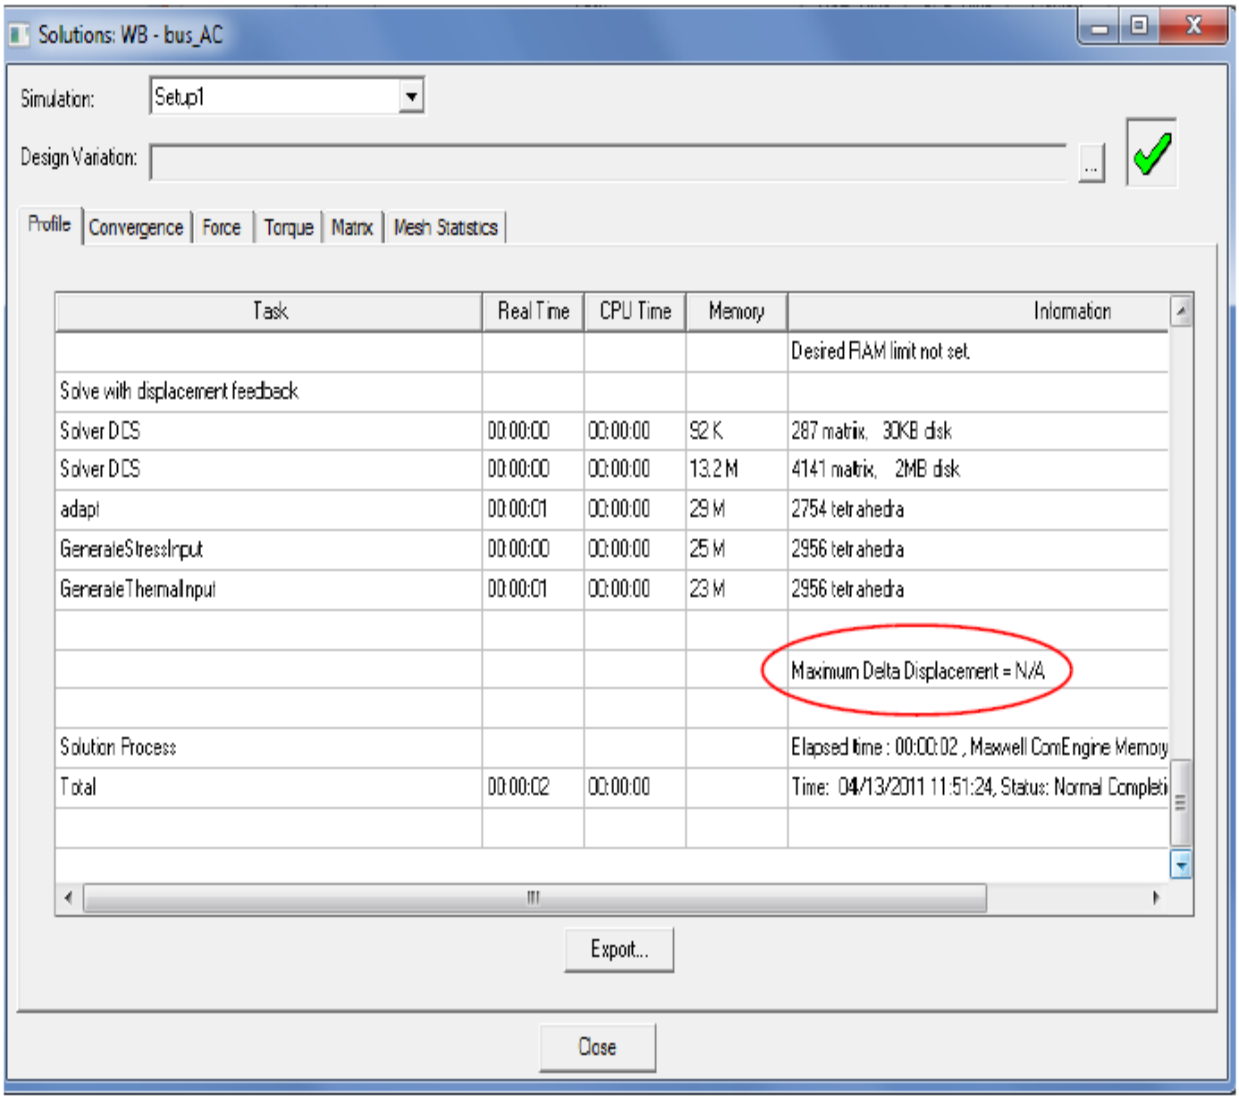
The temperature and displacement in the Maxwell solution can be reverted separately.

1. Users select **Revert to Initial Temperature** in Maxwell.
   A warning message displays notifying users about the invalidation of solution.



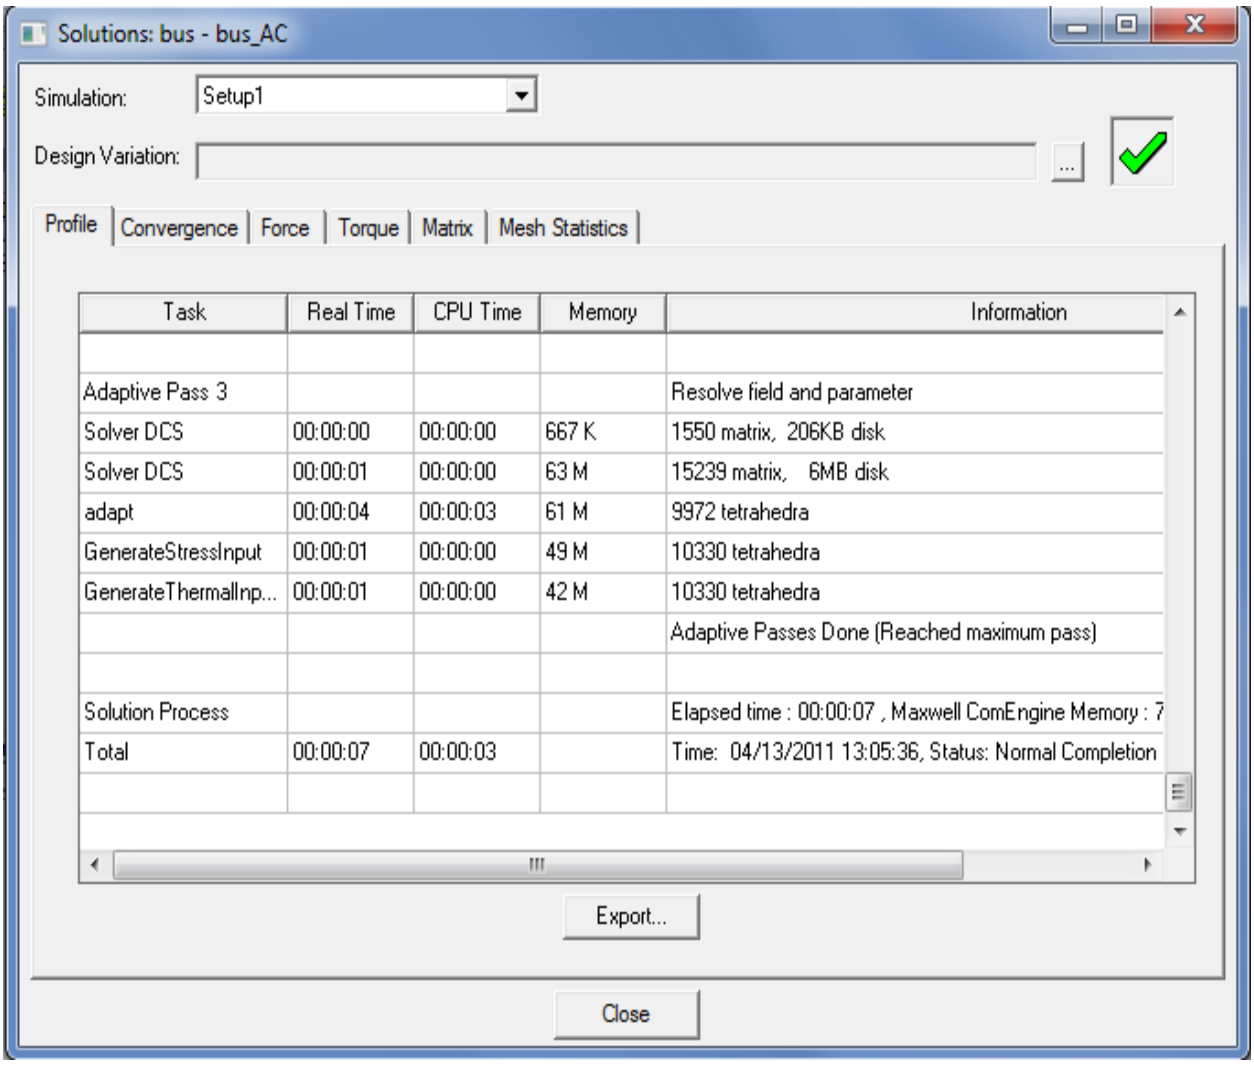
2. Right-click on Maxwell analysis setup and select **Analyze**.

   Maxwell re-simulates the 3rd pass with its mesh and displacement that was previously exported from Mechanical, but without temperature.



3. Users select **Revert to Zero Displacement** in Maxwell, followed by right-clicking on Maxwell analysis setup and selecting **Analyze**.

   Maxwell re-simulates the 3rd pass with its mesh without either temperature nor displacement.

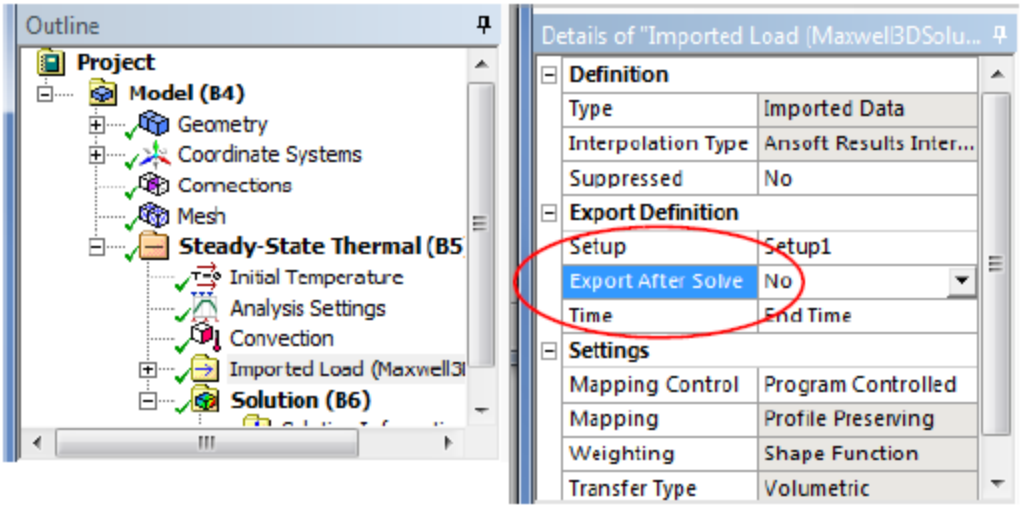


Example 4: Only Stress Feedback

The coupling setup is the same as in Example 1, with either one of the following differences:

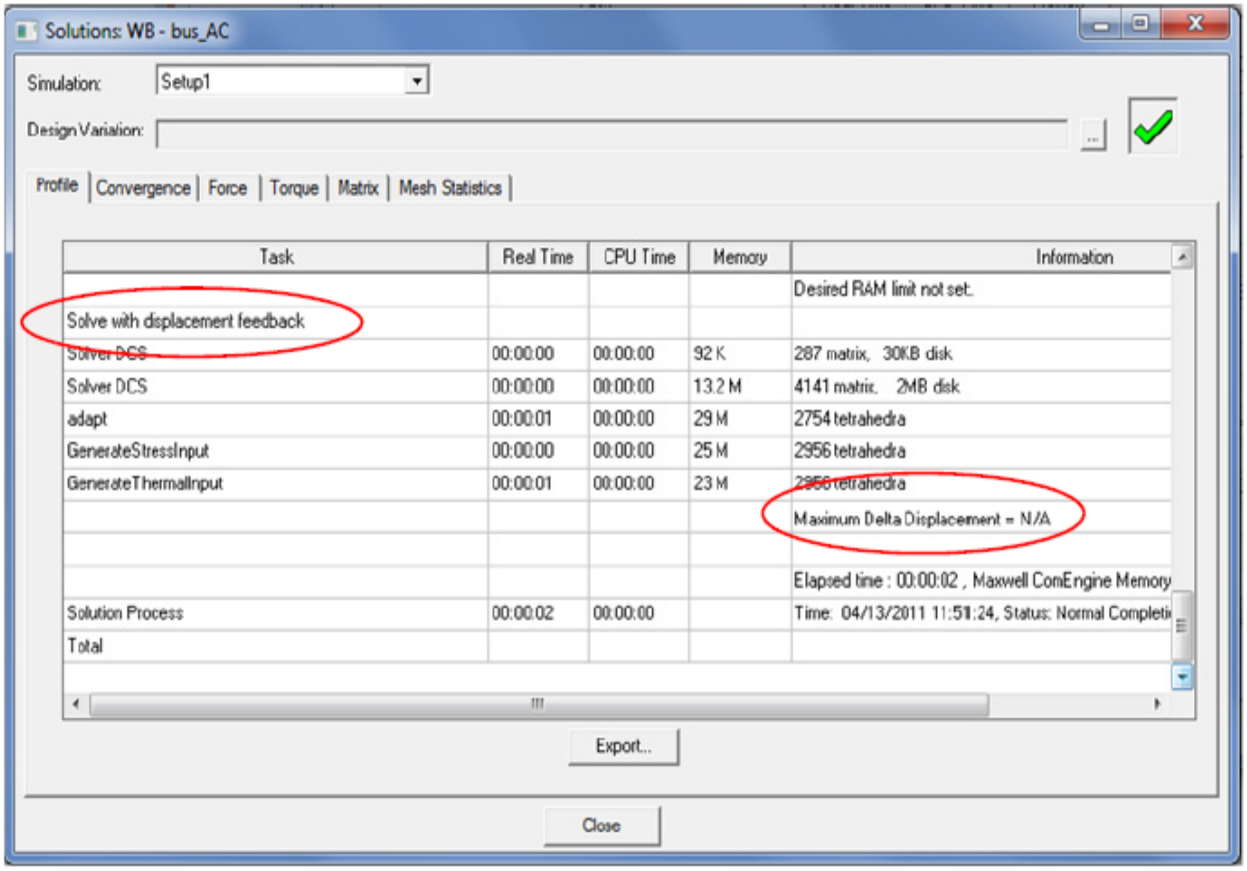
- The Maxwell system is not enabled for thermal feedback (via SetObjectDisplacement). Note that since Maxwell is not enabled to support feedback, the “Export Result” properties should be available in the thermal system.
- The Maxwell system is enabled for thermal feedback, but users choose not to “Export

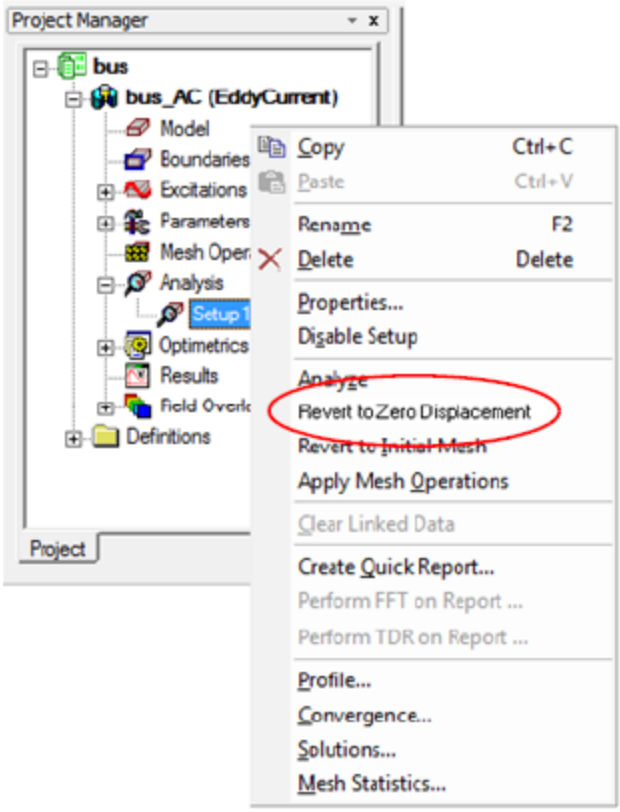
Result' in the thermal system. This is to disable the automatic "Export Results".



1. Right click on the **Solution** cell of Stress and select **Update**.
   a. The **Setup** of Thermal will be Updated with "em" loss from Maxwell.
   b. The **Solution** of Thermal will be Updated.
   c. The **Setup** of Stress will be Updated with thermal force from Thermal and force density from Maxwell.
   d. Displacement will be exported to Maxwell after Stress finishes simulation.
2. Right-click on the **Solution** cell of Maxwell and select **Enable Update**.
3. Right-click on the **Solution** cell of Maxwell and select **Update**.
   a. Maxwell re-simulates the 3rd pass with its mesh and the displacement feedback.
   b. The profile shows information about the feedback and **Revert to Zero Displacement**

will be available in the solve setup context menu.





System Coupling Analyses Using Maxwell

System Coupling facilitates and manages the execution of coupled simulations between multiple physics solvers, coupling active co-simulation participants using either System Coupling's graphical user interface (GUI) or its command-line interface (CLI).

Maxwell can engage as a coupling participant in thermal co-simulations with Ansys Fluent and Ansys Mechanical. System Coupling provides enhanced control over coupled simulation processes, including automatic starts and restarts for participants, the ability to manipulate the System Coupling data model, an interactive solution workflow, and multiple output formats for reviewing and postprocessing results.

In System Coupling analyses, each participant completes its physics and coupling setups in its own user interface generating a Participant Setup (.scp) file along with its solver file(s). The coupled analysis itself includes loading participants, setting values for coupling-related settings, specifying coupled analysis settings, and starting the run. Once the solution has started, System Coupling directs the execution of the coupled analysis – including general coupling management, participant communications, and transfers of data between participants.

Note	For detailed information on System Coupling in general, please refer to the *System Coupling User's Guide*. For details on working in System Coupling's GUI or CLI, see the Using System Coupling's User Interfaces section.

	For examples of Maxwell participating in co-simulations, review the coil-and-core induction heating, bar-and-coil induction heating, bus bar, and electric motor examples in *System Coupling Tutorials*.

Supported Capabilities and Limitations

The following capabilities are supported for System Coupling analyses with Maxwell:

- Multi-region data transfers for Maxwell participants.
- Maxwell 3D Eddy Current, Maxwell 3D Transient, and Maxwell 2D Transient Cartesian, XY geometry mode solutions.
- Update frequency controls for a Maxwell participant running a steady solution.
- Automatic and manual distribution parameters for parallel execution
- Dynamic remeshing and remapping during the execution of Maxwell 3D Eddy Current simulations with time-dependent motion or excitation defined. For details, see Mapping Process in the System Coupling User's Guide.
- Variable displacement for simulations with time-dependent motion defined.
- Thermal data transfers on bodies. EM Loss can be provided to other coupling participants, and temperature can be received from them.
- Motion data transfers on coupled bodies.
- Parallel/distributed processing.

The following are known limitations when using System Coupling with Maxwell:

- Only Maxwell 3D Eddy Current, Maxwell 3D Transient, and Maxwell 2D Transient, Cartesian, XY geometry mode solution types are supported.
- Maxwell 3D Eddy Current solution type is limited to a single frequency.
- Variable velocity is not supported for designs with time-dependent motion and/or excitations.
- Update frequency controls are not supported when Maxwell runs a solution with time-dependencies.
- Restarts from intermediate results are not supported.
- Restarts of transient analyses are not supported. When running an analysis of this type, Maxwell's Restarts Supported setting must be set to False, either in its .scp file or the System Coupling data model.

Using HPC Distribution Settings for Coupled Analyses

System Coupling supports the use of Maxwell's automatic and manual HPC distribution parameters for distributed coupled analyses. Each of these **Execution Control** settings corresponds to one of Maxwell's distributed analysis parameters.

- **Auto Distribution Settings**: Whether job distribution is performed automatically.

When auto-distribution is disabled, the following manual settings are available:

- **Include HPC Distribution Types**: List of the HPC distribution types to be included for distributed runs.
- **Number of Cores Per Task**: Number of HPC cores to be used per task.
- **Batch Options**: Batch option arguments to be applied to the run.

For more information, see *Using AEDT HPC Distribution Options* in the *System Coupling User's Guide*.

Variables Available for System Coupling

The following variables will be available on convective boundaries:

Name / Internal Name	Transfer Direction	Data Type	Physical Type
Loss / Loss	Output	Scalar	Heat Rate
Temperature / Temperature	Input	Scalar	Temperature

System Coupling Related Settings

System Settings

To enable coupling with Maxwell, the environment variable **ANSYSEM_ROOT231** must be set to the location of your Ansys Electromagnetics installation.

> **Note:** The environment variable name is ANSYSEM_ROOT<*major*><*minor*>, where <*major*> is the two digit major version number (the last two digits of the year); and <*minor*> is the one digit minor version number. For example, for the Ansys Electronics 2023 R1 release, the environment variable name is ANSYSEM_ROOT231. For the Student Version of the software, the variable name is ANSYSEM_ ROOTSV<*major*><*minor*>.

- For Windows, this environment variable is automatically set during the installation of the Ansys Electromagnetics Suite (for example, **C:\Program Files\AnsysEM\v231\Win64**).
- For Linux, you must set this environment variable manually (for example, **/opt/AnsysEM/v231/Linux64**).

> **Note:** The environment variable must be set on all hosts if the analysis is distributed to multiple hosts. For Windows, this environment variable must generally be set as a System environment variable (not a user environment variable) for distributed analysis so that it is set for the Ansoft RSM Service. For Linux, the user must ensure that the environment variable is set for the AnsoftRSM Service daemon processes.

Maxwell Settings

Solution Type:

Must be set to one of the following:

- **Eddy Current** for Maxwell 3D designs only.
- **Transient** for either Maxwell 3D or Maxwell 2D designs. For Maxwell 2D designs, you must also specify the **Cartesian, XY** geometry mode when selecting this solution type.

Materials:

Bodies to receive temperature data must have temperature-dependent properties. Note that when the same materials are used in multiple participants, common properties (e.g., conductivity) must be consistently defined.

Motion:

Motion must be appropriately and consistently defined for all bodies involved in the analysis.

Stationary bodies must not move from the reference position or participate in multiple reference frames during the co-simulation.

Motion should be defined with a (rigid body) displacement.

For more information, see Additional Participant Setup Considerations in the *System Coupling User's Guide*.

Creating a System Coupling Setup

The **System Coupling Setup** enables the exchange of data between participants by creating an interface between regions on the participant models.

To create a coupling setup, select (**Optimetrics>Add>System Coupling Setup**), and do one of the following:

- For Eddy Current designs, select the desired solution **Setup**, **Frequency**, and input/output quantities. For the **Temperature** quantity, click the **Object temperature** button to open the **Temperature of Objects** dialog in which you can choose to **Include Temperature Dependence**, and to set the temperatures for model objects composed of materials having temperature-dependent properties.
- For Eddy Current designs with time-dependent motion, create a dataset to define the position of the moving body, and design variables for the coupling time as provided by System Coupling and the displacement vector of the body.
- For Transient designs, select the desired solution **Setup**, **Start time**, **End time**, and input/output quantities. For the **Temperature** quantity, click the **Object temperature** button to open the **Temperature of Objects** dialog in which you can choose to **Include Temperature Dependence**, and to set the temperatures for model objects composed of materials having temperature-dependent properties.

- For Transient designs with time-dependent motion/excitation:
  - Define motion on coupled bodies.

Note	A profile or expression can be used to define rigid body motion using total displacement relative to the original object location.

  - Create design variables for both the coupling time (as provided by System Coupling) and the displacement vector of the body.
  - For Transient designs, Ansys Electromagnetics time is associated with System Coupling time. Maxwell uses this time to calculate excitation and position, but itself always begins its calculations at time zero.
  - Optionally, the following inputs can also be defined as a function of System Coupling time: **Maxwell Time Step Size**, **Loss Averaging Start Time**, **Loss Averaging Stop Time/Duration**.

Generating a System Coupling Participant Setup File

System Coupling uses each participant's Participant Setup (.scp) file and the corresponding Python (.py) configuration file to load the participant and its information into the data model.

To use System Coupling, you must generate a System Coupling participant file (**.scp**). Once the Maxwell setup is complete, generate the file using either of the following options:

- In the **System Coupling Setup** dialog box, the system coupling configuration files are generated when you click the **OK** button.
- In the **Project Manager** under **Optimetrics**, right-click your System Coupling Setup and select **Generate Configuration Files**.

In both cases, the configuration files needed by System Coupling (an **.scp** file and a **.py** file) are generated at the same time and in the same location as the Maxwell project file.

Licensing Considerations when using System Coupling

A distinct license is required for each coupling participant product, but no additional licenses are required for the System Coupling infrastructure itself.

Note, however, that Ansys EnSight is required for the postprocessing of System Coupling's interface results. If you are using a Multiphysics Licensing Bundle that does not include an EnSight license (e.g., the Ansys Mechanical Maxwell bundle), you will need a separate EnSight license to visualize co-simulation results.

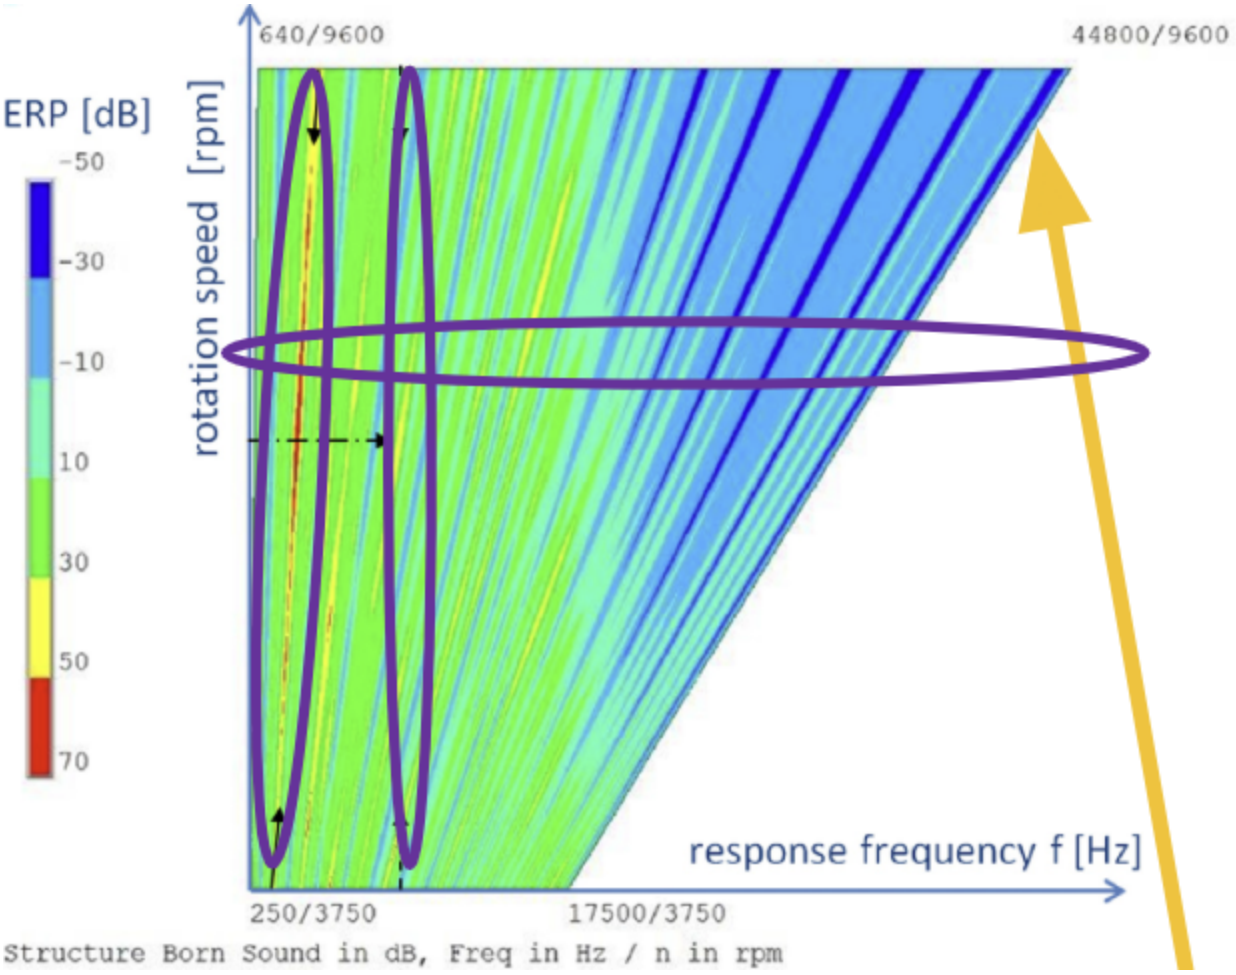
For more information on applicable licenses, see **Product Licensing Considerations** in the *System Coupling User's Guide*.

Maxwell Multiple RPM Harmonic Force Coupling

Waterfall analysis is a tool that is often used to evaluate the acoustic and/or vibratory performance of rotating machinery. Maxwell multiple RPM coupled with Ansys Harmonic Response provides a powerful tool to generate acoustic performance map of electric machines. The process involves calculating harmonic force using discrete Fourier transform (DFT) methods at each rpm

(revolutions per minute), and performing harmonic response analysis at every selected frequency with calculated harmonic force loads.

Waterfall computation is given by ERP=ERP(f, rpm) making use of load interpolation between computed RPM.



The Waterfall contour map showing the full acoustic fingerprint of the machine, where:

- Vertical Line: Given by one fixed eigenfrequency excited at different speeds of rotation.
- Horizontal Line: Single rpm load case yielding one frequency response function.
- Inclined Line: Excitation order of the electromagnetic force-density revealing a large ERP zone with its origin in single eigenfrequency that is met by both frequency and spatial load pattern of excitation and system mode.

To setup a Maxwell design for multiple RPMs coupling:

1. In the **Mechanical** tab of the **Motion Setup** dialog box, specify angular velocity (RPM) with a design variable.
2. In the **General** tab of the **Solve Setup** dialog box, specify the appropriate stop time and time step using the same design variable.

3. Add a parametric setup to sweep the variable.
4. Select the parametric setup as **Embedded Parametric Analysis** in the DesignXplorer setup.

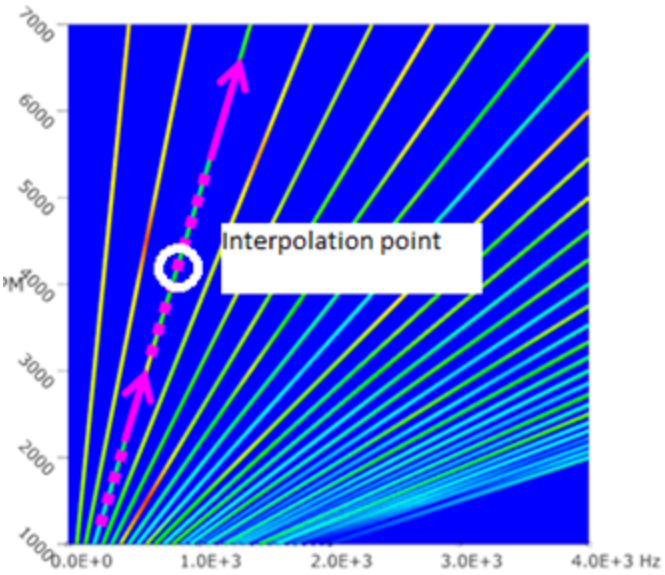
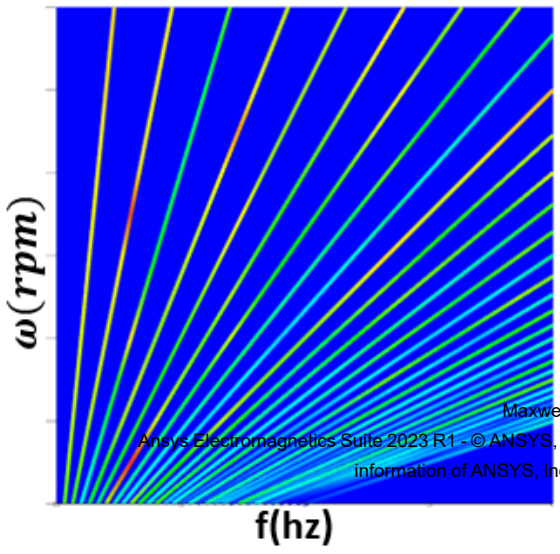
Harmonic Force Interpolation in Frequency-Speed Plane

Harmonic Force Interpolation in Frequency-Speed Plane

In order to generate the ERP waterfall diagram of electrical machines in Ansys Mechanical Harmonic Response, harmonic force distribution at different rotation speeds from Maxwell solver is provided as excitations of Mechanical. In general, the quality of the ERP diagram depends on the number of speed points that are solved. To reduce the workload in Maxwell, an option is provided to interpolate harmonic force in the frequency-speed plane with a limited number of solved speed points.

In electrical machines, harmonic forces only exist at certain frequencies (harmonics) at a given speed (as shown below):





Force components and corresponding frequencies at any given speed can be obtained by interpolation along those lines of harmonics:

$$F_k = F_{i-1,\ k} + \frac{(\omega - \omega_{i-1})}{\omega_i - \omega_{i-1}}\left(F_{i,\ k} - F_{i-1,\ k}\right)$$

$$f_k = f_{i-1,\ k} + \frac{(\omega - \omega_{i-1})}{\omega_i - \omega_{i-1}}\left(f_{i,\ k} - f_{i-1,\ k}\right)$$

$$i = 2,\ \cdots\cdots M$$

where:

F : force vector

f : frequency

ω : speed of rotation

k : index of harmonics

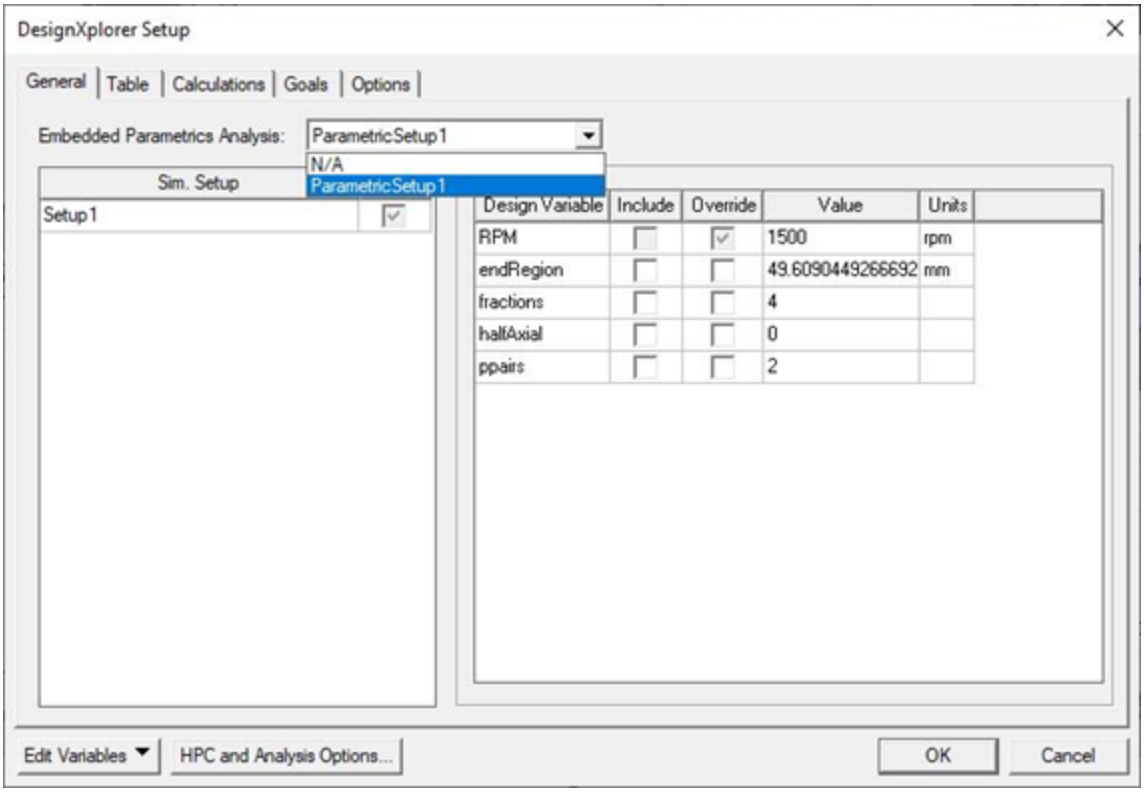
i : index of solved speed points

M : total number of solved speed points

Note	To use this feature you must open Maxwell from within Workbench. For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topic: *Importing Data into a Harmonic Analysis*.

To setup the number of interpolation points per segment:

1. Open the **DesignXplorer Setup** panel and set Parametric Sweep (RPM sweep) as the **Embedded Parametric Analysis**.



2. On the Options tab, enter the **Number of interpolation points per segment**. (This value must be a non-negative integer.)

Maxwell to Ansys Object-based Harmonic Force Coupling

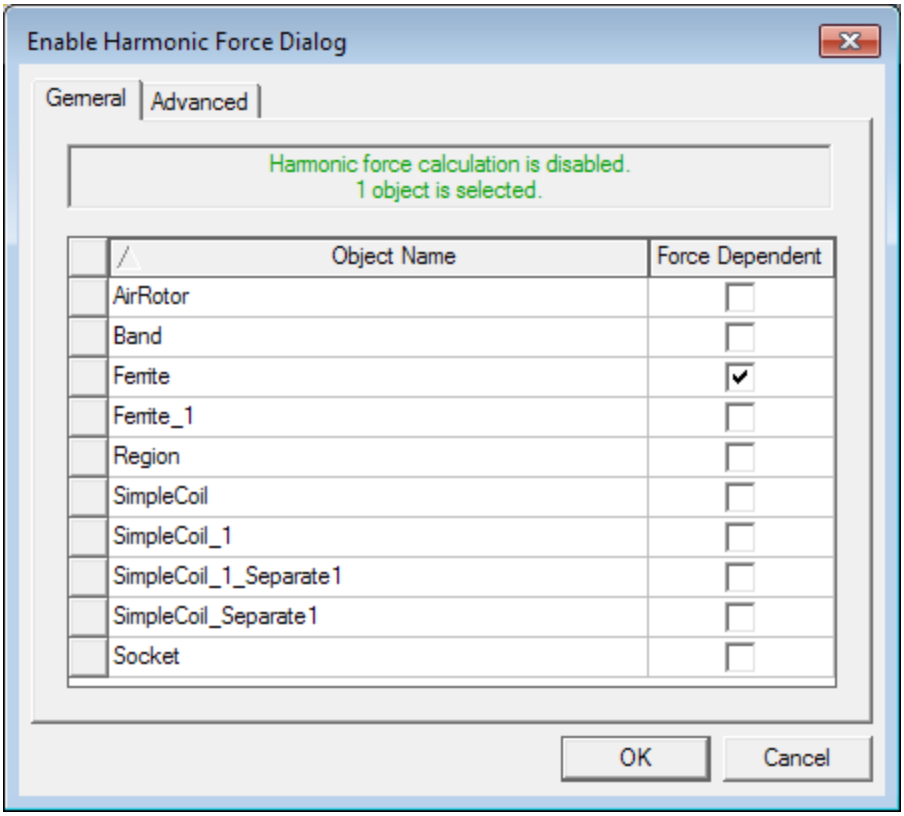
Maxwell 2D/3D supports object-based one-way harmonic force coupling for *transient* and *Eddy current* designs via the Workbench schematic. Maxwell enables the user to select multiple objects for force calculations for harmonic coupling with Workbench. You can also setup multiple RPM Harmonic Force Coupling.

> **Note:** For object-based harmonic force calculation, a full-axial model is required

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*.

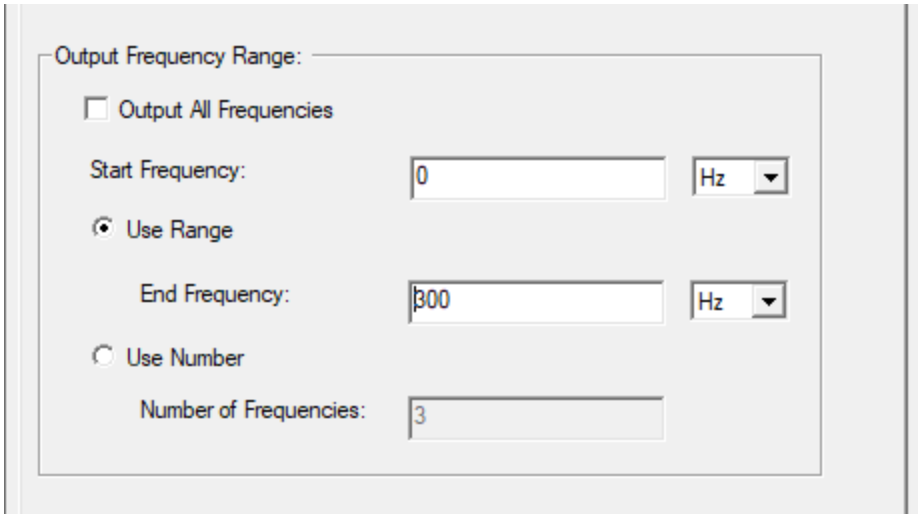
To enable object-based harmonic force calculations in Maxwell for use in Workbench:

1. Either select **Maxwell 2D** (or **Maxwell3D**)**>Enable Harmonic Force Calculation**, or right-click on the Design in the project tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** box. The dialog has two tabs: **General**, and **Advanced**.
2. Do one of the following:
    - For *Eddy current* designs, on the **General** tab, check the **Force Dependent** objects for which force calculations are desired.

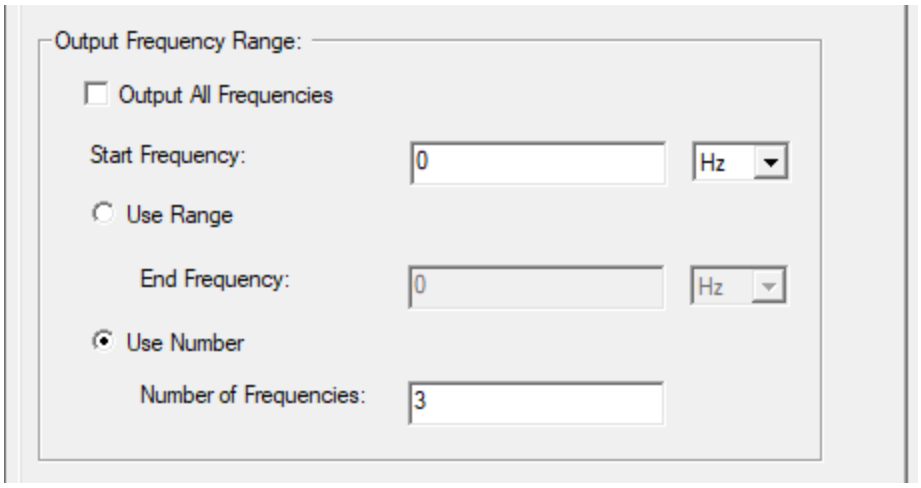


- For *transient* designs, on the **General** tab, select **Object Based** as the harmonic force **Type**. Select the **Harmonic Force** radio button. Then check the **Force Dependent** objects for which force calculations are desired.

3. The **Advanced** tab provides additional settings to allow you to control collection of data from the force calculations.
   - For *2D and 3D transient* designs (either with rotational motion or with non-rotational motion), the **Output Frequency Range** panel allows you to specify the frequency range of calculated harmonic force components. The default is to **Output All Frequencies** that are calculated. There are two options to set the range of output frequencies:
     - **Use Range** – specify the **Start Frequency** and **End Frequency**. Parameterization of **Start Frequency** and **End Frequency** is supported.



- **Use Number** – specify the **Start Frequency** and the **Number of Frequencies**. Parameterization of **Number of Frequencies** is supported.



- For *transient* designs that include rotational motion:

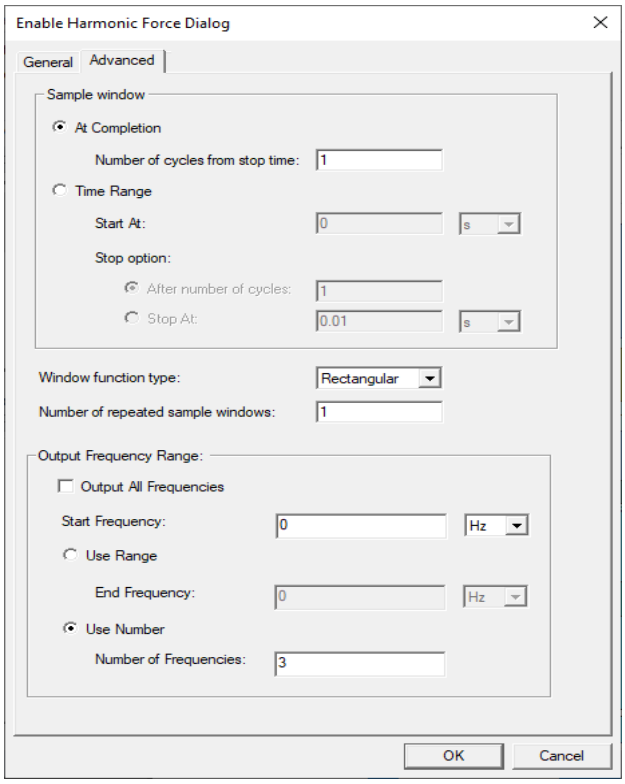
> **Note:** When using Partial Simulation for Full Rotational Machine Models, please select *all* teeth tips as objects for harmonic force calculation

  - The **Sample Window**'s collect samples **At completion** setting allows you to choose the **Number of cycles from stop time** for which data is collected. For example, if one cycle equals 1 second, and you solve for 3.5 seconds, setting the **Number of cycles from stop time** to 2 results in data being collected for the period from 1.5 seconds to 3.5 seconds. Alternatively, user can specify a **Time Range** to collect data, for which user can set a data collection **Start At** and a data collection **Stop option** – either stop data collection after a user-specified number

of cycles (**After number of cycles**) or at a user-specified **Stop At** time.

- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Please refer to *Window Function Options for DFT of Harmonic Forces* for details on this setting.
- In the frequency domain of harmonic force, the base frequency is determined by the range of time window of data collection ($f=1/\Delta T$). In order to get lower base frequencies, one must increase the time window of data collection, which means increasing the simulation time. It is waste of resources to do so when the solution reaches steady state/periodic in a transient simulation. Instead, you can set the **Number of repeated sample windows** to expand the range of time window of data collection without increasing simulation time by repeating the collected data *n* times before doing DFT. By applying this option, you can get a lower base frequency and higher frequency resolution, but the magnitudes of force components are close to zero at the introduced frequencies.

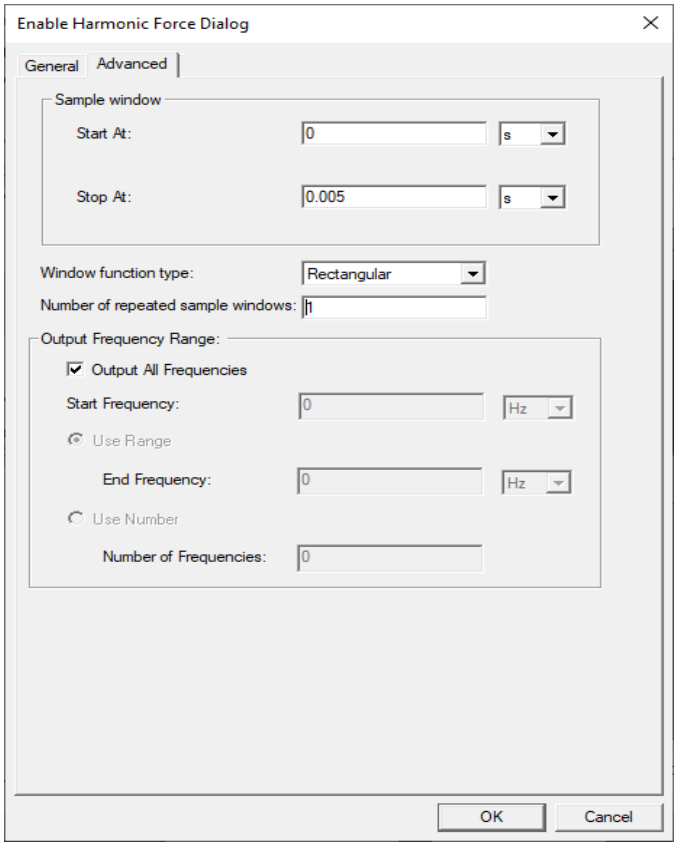
> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.



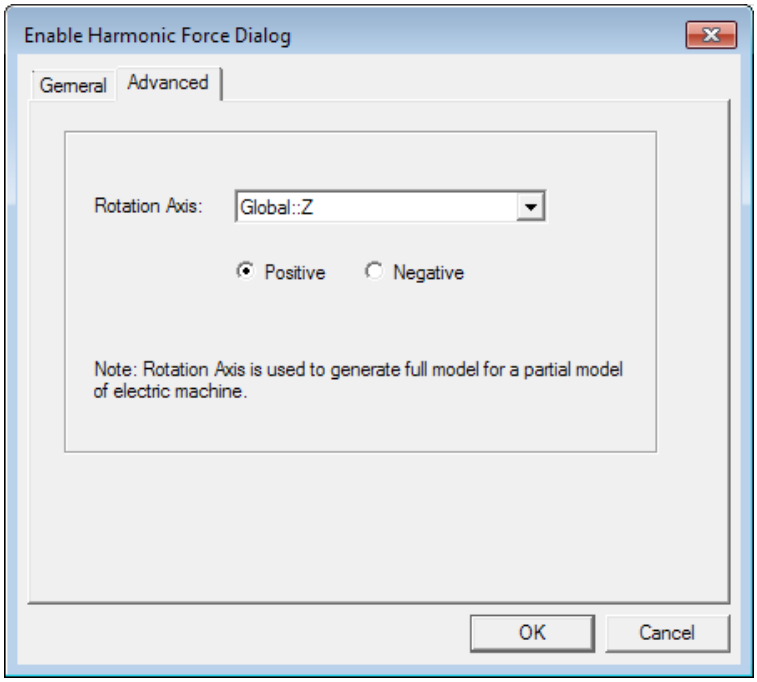
- For *transient* non-rotational motion designs:
  - The **Sample Window** of the **Advanced** tab allows you to set the data collection **Start At** and **Stop At** times.

- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Please refer to *Window Function Options for DFT of Harmonic Forces* for details on this setting.
- You can set the **Number of repeated sample windows** to expand the range of time window of data collection.

> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.



- For *Eddy current* designs, the Advanced tab allows you to set the Rotation Axis and the axis direction so that the Maxwell solver can generate a full model if a partial model is used in the design. You can create relative coordinate systems to add more axes.



Harmonic Eddy force solutions are kept as part of Maxwell design solutions. If Workbench harmonic design settings are changed, the Maxwell solutions will be invalidated.

4. Click **OK** to close the dialog.

Maxwell One-way Coupling with Ansys Mechanical

Force Densities in Maxwell

Let $T_{\alpha\beta}$ be the Maxwell stress tensor (refer to reference [1] for detail of the Maxwell stress tensor). Then the force acting on an object can be calculated by:

$$F_\alpha = \sum_\beta \int_V \frac{\partial}{\partial x_\beta} T_{\alpha\beta} d^3x \qquad (1)$$

Application of the divergence theorem to volume integral gives:

$$F_\alpha = \oint_S \sum_\beta T_{\alpha\beta} n_\beta ds \quad (2)$$

Note that $\sum_\beta T_{\alpha\beta} n_\beta$ is the force per unit area transmitted across the surface. Namely, it is the surface force density, which is denoted as:

$$f_\alpha^s = \sum_\beta T_{\alpha\beta} n_\beta \quad (3)$$

Also, from (1), you can define a volume force density by stress tensor as:

$$f_\alpha^v = \sum_\beta \frac{\partial}{\partial x_\beta} T_{\alpha\beta} \quad (4)$$

For a magnetostatic field (similar forms for electric field), the explicit form of the Maxwell stress tensor is:

$$T_{\alpha\beta} = H_\alpha B_\beta - \frac{1}{2}\vec{B} \bullet \vec{H}\delta_{\alpha\beta} \quad (5)$$

So the surface force density can be calculated as:

$$f_\alpha^s = (\vec{B} \bullet \vec{n})\vec{H} - \frac{1}{2}\vec{B} \bullet \vec{H}\vec{n} \quad (6)$$

The volume force density can be calculated by (4) and using the virtual work principle (refer to reference [2] for details).

Reference [1] J.D. Jackson, Classical Electrodynamics, 3rd edition, Wiley, 1999.

Reference [2] A. Bossavit: "Eddy-currents and forces in deformable conductors", in Mechanical Modellings of New Electromagnetic Materials (Proc. IUTAM Symp., Stockholm, April 1990, R.K.T. Hsieh, ed.), Elsevier (Amsterdam), 1990, pp. 235-42.

Force Density Calculation in Maxwell

Maxwell solvers can be coupled with Ansys Mechanical either one-way or two-way. Maxwell solvers provide volumetric force density/surface force density as load of Mechanical solvers. Force density is calculated by Maxwell stress tensor.

Maxwell stress tensor for magnetic fields:

$$\bar{S} = \frac{1}{\mu_0}\begin{bmatrix} B_x^2 - B^2/2 & B_xB_y & B_xB_z \\ B_xB_y & B_y^2 - B^2/2 & B_yB_z \\ B_xB_z & B_yB_z & B_x^2 - B^2/2 \end{bmatrix}$$

Where $B^2 = B_x^2 + B_y^2 + B_z^2$

The force on a surface can be calculated as:

$$\vec{F} = \frac{1}{\mu_0} \iint dA\overline{S} \cdot \boldsymbol{n}$$

Where $\mathbf{n}$ is outward normal direction of the face.

The surface force density is calculated from:

$$\vec{f} = \frac{\vec{F}}{A}$$

Where ***A*** is the area of the surface.

The volumetric force density in an element is calculated from:

$$\vec{f} = \frac{1}{V}\sum_{i=0}^{N} \vec{F_i}$$

Where ***V*** is volume of the element, and ***N*** is the number of surfaces (sides in 2D) of this element.

Harmonic Force Calculation from Maxwell

Maxwell can calculate the harmonic force on each tooth of a rotating machine. This feature enables the one-way coupling between Maxwell and Harmonic Response of ANSYS. The force is object based, not element based. The harmonic momentum reference to the geometric center of the object is also provided at the same time. This feature is also extended to any individual object.

There are two options to calculate the force of an individual tooth:

a. Split the stator/rotor to form separate tooth object, and integrate forces on all out surfaces of this tooth except the splitting surfaces.
b. Draw an arc (2D) or a cylindrical face (3D) near the tooth in the air gap, and integrate forces on this face.

Discrete Fourier Transform (NDFT) with non-uniform time interval

In the general case, the definition of the Non-uniform Discrete Fourier Transform (NDFT) is the same as the definition with constant time interval, taking into consideration that the samples can be taken at irregular intervals in time (t_n). That is to say that the samples x(k) of the irregular Fourier transform are taken at multiples of a quantity $\Delta\omega$, which is a fixed quantity in the Fourier domain. The fixed quantity $\Delta\omega$ in the regular case corresponds to $2\pi/T$. The extension from regular to irregular sampling, therefore, depends on the duration of the signal *x(t)* and not on the fact that the samples are taken at regular or irregular intervals.

A finite sample measured at ***N*** points in a period of T:

$$x(k) = \begin{cases} 0, & k < 0 \\ F(t_k), & 0 \le k \le (N-1) \\ 0, & k \ge N \end{cases}$$

The definition of the nonuniform discrete Fourier transform (NDFT)is as follows:

$$X(k) = \frac{1}{N}\sum_{n=0}^{N-1} x(n) e^{-j(t_n - t_0)k\frac{2\pi}{T}}$$

The inverse NDFT is given by:

$$x(t_n) = \sum_{k=0}^{N-1} X(k) e^{j2\pi\frac{k(t_n - t_0)}{T}}$$

Data collection:

The solver records the components of force and momentum at all teeth at every time step.

$$F_x: F_x(0),\ F_x(\Delta t),\ F_x(2\Delta t),\ \cdots\cdots,\ F_x(K\Delta t)$$
$$F_y: F_y(0),\ F_y(\Delta t),\ F_y(2\Delta t),\ \cdots\cdots,\ F_y(K\Delta t)$$
$$F_z: F_z(0),\ F_z(\Delta t),\ F_z(2\Delta t),\ \cdots\cdots,\ F_z(K\Delta t)$$
$$M_x: M_x(0),\ M_x(\Delta t),\ M_x(2\Delta t),\ \cdots\cdots,\ M_x(K\Delta t)$$
$$M_y: M_y(0),\ M_y(\Delta t),\ M_y(2\Delta t),\ \cdots\cdots,\ M_y(K\Delta t)$$
$$M_z: M_z(0),\ M_z(\Delta t),\ M_z(2\Delta t),\ \cdots\cdots,\ M_z(K\Delta t)$$

If $t_{end} - t =< \frac{2\pi}{period * rotation\_speed}$, then keep records.

Generate harmonic force from partial model to full model

With symmetry-multiplier (period in 3D)>1, Maxwell solvers automatically generate harmonic force for the full model from the partial model

$$r^* = Ar$$

Where *r* is the vector to be rotated, *r** is the vector after rotation. The rotation matrix in 3D:

$$A = \begin{bmatrix} cos\theta + u_x^2(1-c0s\theta) & u_x u_y(1-c0s\theta) - u_z sin\theta & u_x u_z(1-c0s\theta) + u_y sin\theta \\ u_x u_y(1-c0s\theta) + u_z sin\theta & cos\theta + u_y^2(1-c0s\theta) & u_y u_z(1-c0s\theta) - u_x sin\theta \\ u_x u_z(1-c0s\theta) - u_y sin\theta & u_y u_z(1-c0s\theta) + u_x sin\theta & cos\theta + u_z^2(1-c0s\theta) \end{bmatrix}$$

The rotation matrix in 2D:

$$A = \begin{bmatrix} cos\theta & -sin\theta \\ sin\theta & cos\theta \end{bmatrix}$$

Vectors that need to be rotated: position (**r**), force (**F**) and moment (**M**)

Spatial and Temporal 2D Discrete Fourier Transform (DFT)

Electromagnetic force components on teeth inside an electric machine are spatial (in circumferential direction) and temporal (transient). The magnetic force density acting on the stator along the airgap is dependent on time and on space. This spatial and temporal force distribution can be expanded by means of Fourier analysis to calculate its time and space harmonic waves. This analysis can be used to improve NVH (noise, vibration, and harshness) performance.

The magnetic force density acting on the stator along the air gap is dependent on time and on space. This spatial and temporal force distribution can be expanded by means of Fourier analysis to calculate its time and space harmonic waves.

The force components on teeth can be expressed as function f(x, t), where x represents spatial, and t denotes temporal. The function f (x, t) is decomposed to a linear combination of harmonic (sines and cosines, more generally orthogonal) functions.

Direct Transformation

$$F(u,v) = \frac{1}{MN} \sum_{m=0}^{M-1} \sum_{n=0}^{N-1} f(m,n) \exp\left[-2\pi i \left(\frac{mu}{M} + \frac{nv}{N}\right)\right]$$

Where:

u = 0, 1, …… M-1, wave number in spatial,

v = 0, 1, ……. N-1, wave number in temporal.

Window Function Options for DFT of Harmonic Forces

Window function options for Discrete Fourier Transform (DFT) of harmonic forces are available for Maxwell2D and 3D transient solvers and support both rotational and non-rotational models.

The Discrete Fourier Transform (DFT) operates on a finite-length time sequence to compute its spectrum. For a continuous signal like a sine wave, you need to capture a segment of the signal in order to perform the DFT. Usually, you also need to apply a window function to the captured signal before taking the DFT. A window function (also known as an apodization function or tapering function) is a mathematical function that is zero-valued outside of some chosen interval, normally symmetric around the middle of the interval, usually near a maximum in the middle, and usually tapering away from the middle. The mismatch in amplitude between the two ends of the signal distorts the spectrum, a phenomenon called spectral leakage. Spectral leakage can be caused by discontinuities in the non-integer number of periods in sampled signals that usually happen in asynchronous machines. This can be improved using windowing. Maxwell provides several window functions for the DFT of harmonic forces. These include:

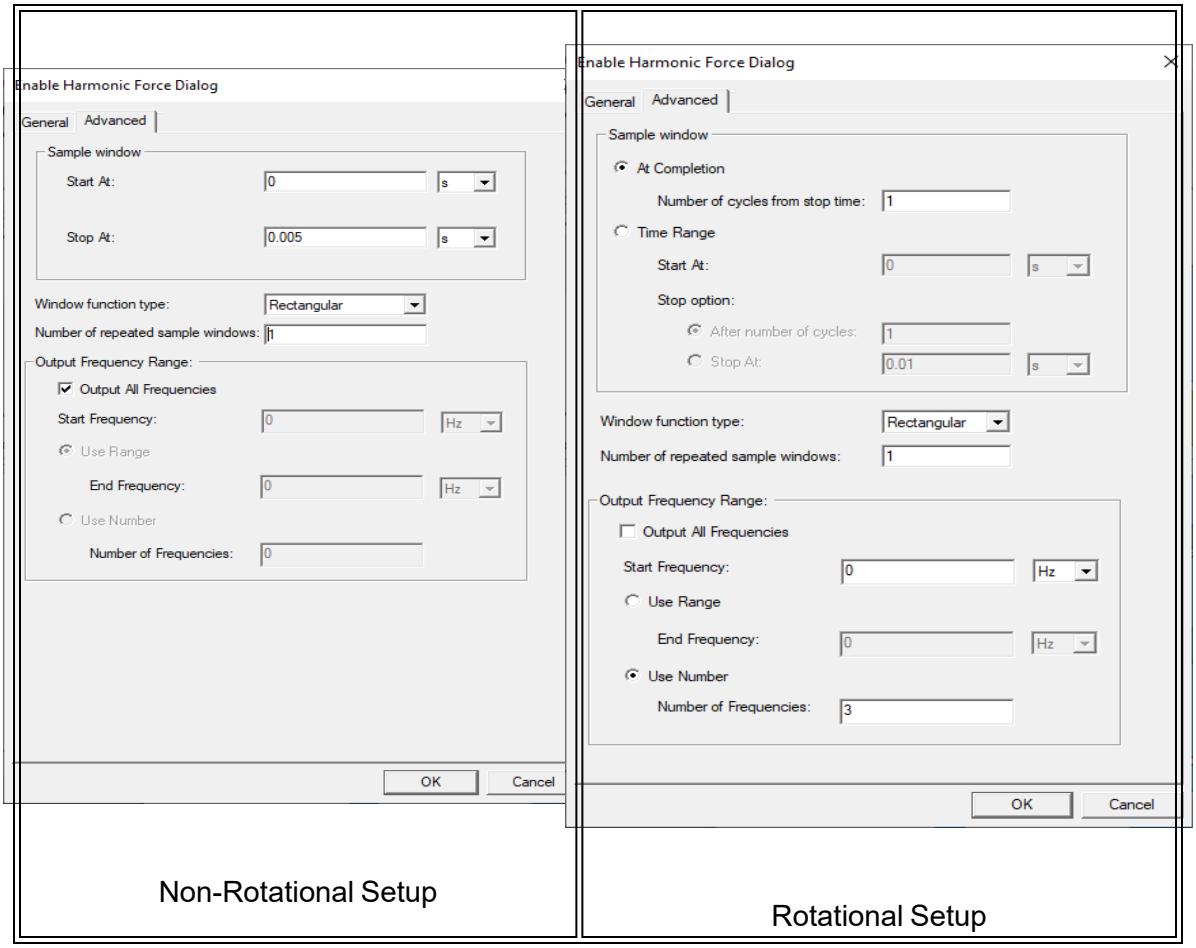
- Rectangular (default)
- Triangular
- Van Hann

- Hamming
- Blackman
- Lanczos
- Welch

Please refer to *FFT Window Functions* for detailed information on each of these window function types.

To select the various window function options:

1. Either select **Maxwell 2D** (or **Maxwell3D**)**>Enable Harmonic Force Calculation**, or right-click on the Design in the project tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** box.
2. Specify the **Window function type** using the drop-down list on the **Advanced** tab.



Harmonic Force Calculation in Maxwell 2D with Skew Model

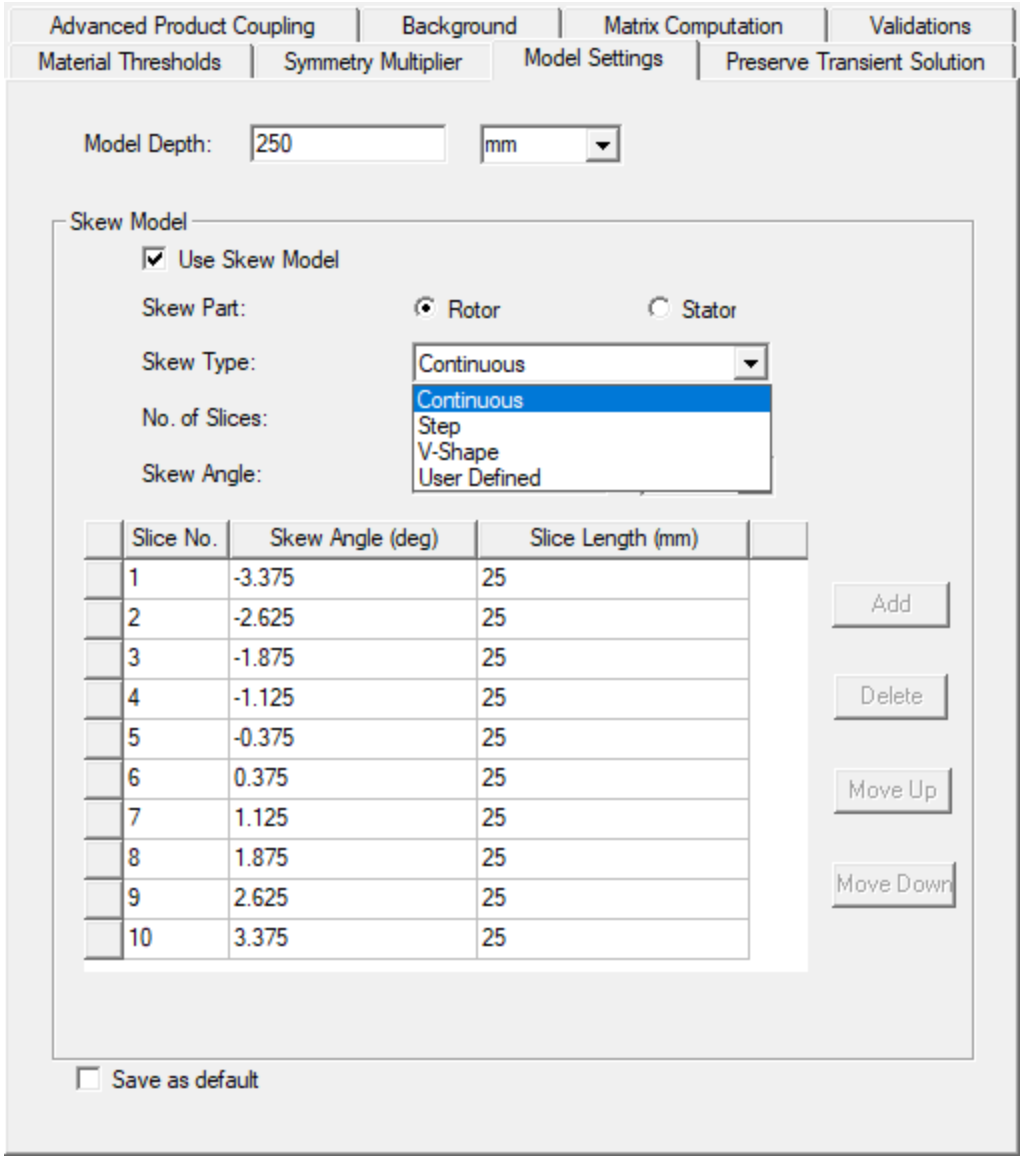
Maxwell 2D supports object-based harmonic force calculation using a multi-slice skew model along the axial direction of rotating machines. (Element-based harmonic force calculation is not applicable to 2D multi-slice skew model.)The multi-slice skew model can improve the accuracy of Maxwell 2D simulation when the slot/teeth on the stator/rotor are skewed. By using a skew model,

2D vibration modeling in Ansys Mechanical is no longer valid; thus, 3D simulation must be performed instead by applying object-based harmonic force calculation slice-by-slice.

Skew Model Setup

Note	For detailed information on Skew Model settings, refer to the *Model Settings Tab* topic.

Skew model setup in Maxwell 2D is defined on the **Model Settings** tab of the **2D Design Settings** dialog as described in the *Model Settings Tab* topic.

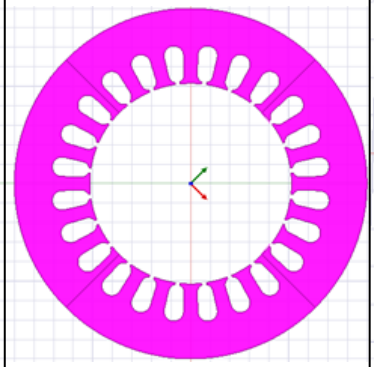


To create 3D geometry, the center position of each slice must be set properly:

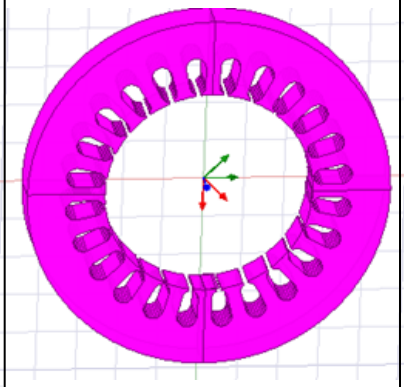
1. Create a 2D full model in Maxwell (do not unite half teeth at the M-S boundary), and generate 3D geometry of one slice; then create a Maxwell 3D design, and duplicate one slice in the Maxwell 3D.
2. Move the center of the 3D geometry to the origin of the global coordinate system; then set the Z axis as the rotating axis.
3. Rotate each slice to its individual circumferential position: slice angle is taken from the skew model settings (see figure above). The slice number indices are arranged from least to greatest, corresponding to Z coordinates of slice position (from least to greatest).

   For object-based harmonic force calculation, only one group of harmonic force components is generated for each selected object when skew model in not enabled in Maxwell 2D transient solver; and the Z coordinate of the object is set to zero by default. The “zero” Z position is used to match the selected geometry in Mechanical if coupled with the Harmonic response 3D solver.

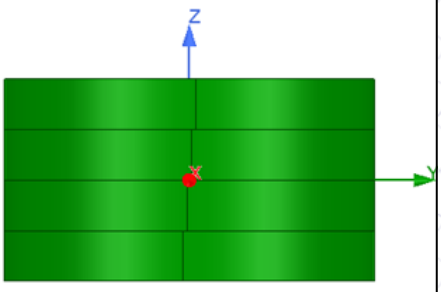
Maxwell 2D Partial Model



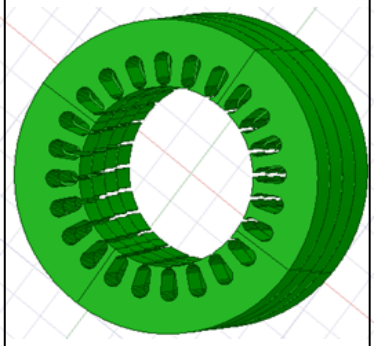
2D full model (stator only)



3D geometry of stator (one slice)



3D geometry after moving and rotating



3D geometry in harmonic response solver

Harmonic force calculation requirements for the Maxwell 2D slice model

Because the harmonic force calculated from the 2D slice model will be applied to a 3D model in Ansys Mechanical, it is very important to have a rule to link the skew angle to the slice number, and the slice number to the z-position in the Maxwell 2D solver. The relationship between slice number and z-position will determine how the 3D model will be generated.

The general rule is as follows:

- The sequence of slice number: from least to greatest with z position (this is for customer, not in the solver)
- The z-position: from least to greatest
- The skew angle: one-to-one with slice number, from slice 1 to slice N

The user generates 3D model based on skew angle, slice by slice, from least z-position to greatest z-position.

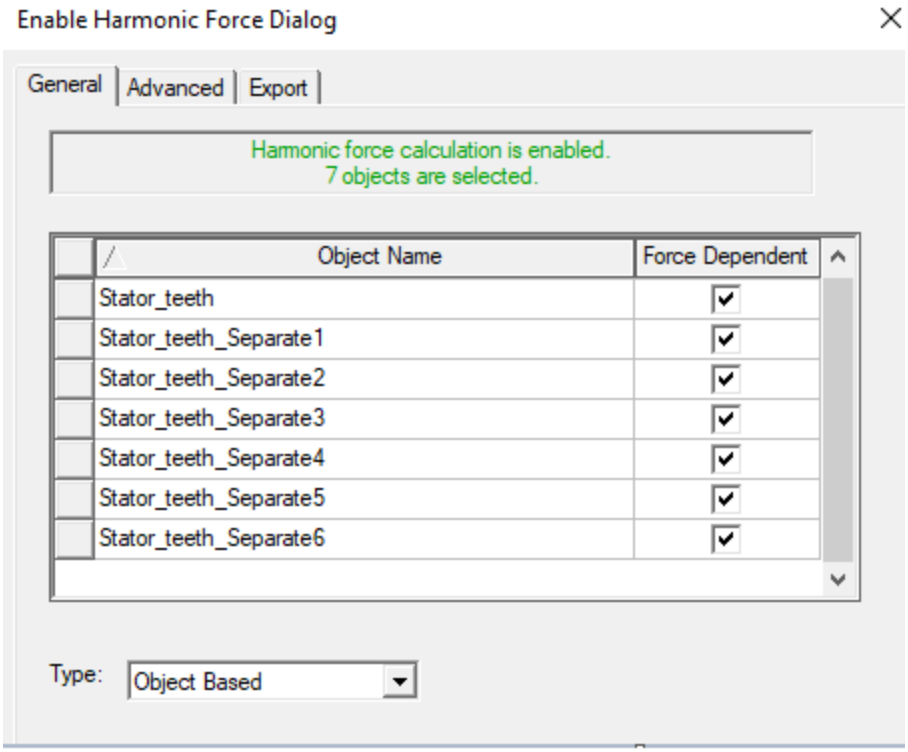
Maxwell to Ansys Element-based Harmonic Force Coupling

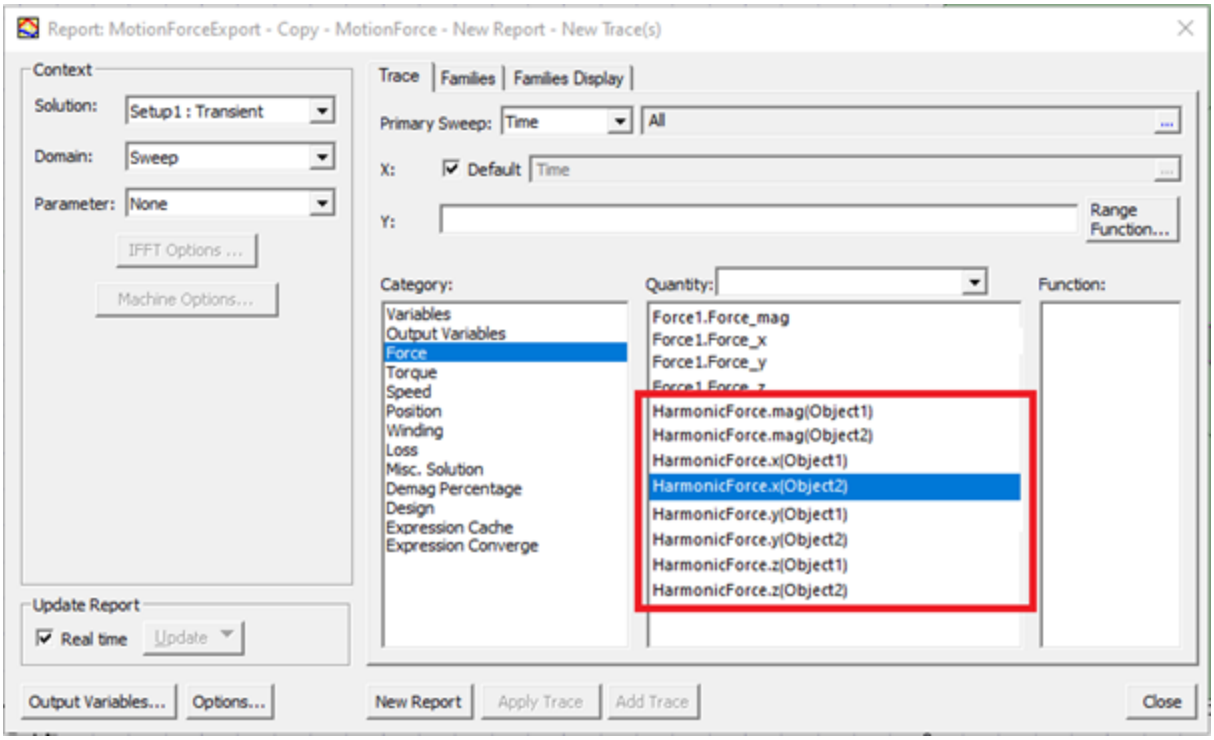
Transient Report of Object-based Harmonic Force Components

When object-based harmonic force is activated, the transient force data of selected harmonic force objects are available for plot in Maxwell transient solvers. The force component data is recorded at every time step, starting from time zero. To create a transient report of object-based harmonic force components:

1. In the **Enable Harmonic Force Calculation** dialog box, on the **General** tab, select **Object Based** as the harmonic force **Type**. Then check the **Force Dependent** objects for which force calculations are desired.

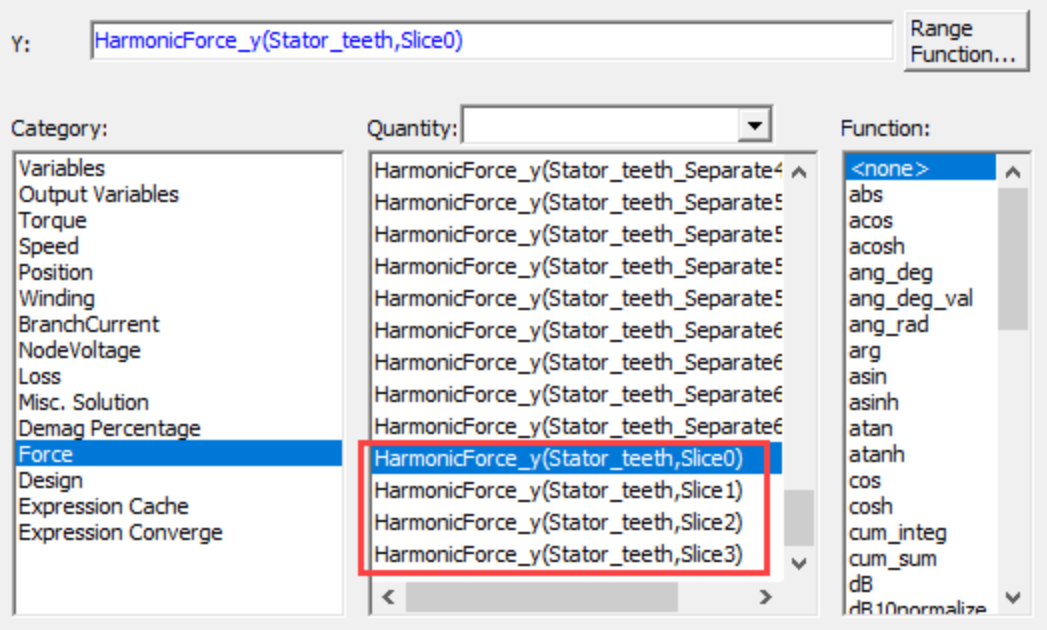


2. Create a **Transient Report** under **Results** in the project tree.



3. Select **Force** as the **Category**, and then select the harmonic force components you want to plot:
    - For 2D (XY) designs: **HarmonicForce_mag**, **HarmonicForce_x**, **HarmonicForce_y**.
    - For 3D designs: **HarmonicForce_mag**, **HarmonicForce_x**, **HarmonicForce_y**, **HarmonicForce_z**.
    - For 2D (RZ) designs: **HarmonicForce.z**.

Transient force reports also support Maxwell 2D with skew slice model. The transient force is calculated on each slice, and there are *n* forces available to be plotted for each selected object.



Note	For detailed information on Skew Model settings, refer to the *Model Settings Tab* topic.

Maxwell to Ansys Element-based Harmonic Force Coupling

Maxwell provides element-based solutions for one-way harmonic force coupling via Ansys Workbench schematic for:

- 2D/3D Eddy Current design element-based harmonic force coupling
- 2D/3D Transient design element-based harmonic force coupling

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*

Related Topics

Element-based Harmonic Force Coupling for Eddy Current Designs
Element-based Harmonic Force Calculations and Coupling for Transient Designs

Element-based Harmonic Force Calculations and Coupling for Transient Designs

Maxwell 2D/3D supports *element-based* one-way harmonic force coupling for *transient* designs via the Workbench schematic. Maxwell enables the user to select multiple objects for force calculations for harmonic coupling with Workbench.

- For element-based (Surface) harmonic coupling, the force density is calculated at each surface element of the selected objects at every time step in the specified time window. Then, Discrete Fourier Transform is performed to transfer data from the time domain to the frequency domain. In the WB Harmonic response solver, surface force density is applied as surface pressure to the selected surfaces. There is no restriction on surface selection. Mapping is involved and it is done by post processor. Magnetostriction is not included for surface element-based harmonic force.
- For element-based (Volumetric) harmonic coupling, the force density is calculated at each element of the selected objects at every time step in the specified time window. Then, Discrete Fourier Transform is performed to transfer data from the time domain to the frequency domain. In the WB Harmonic response solver, volumetric force density is applied as body force to the selected objects. There is no restriction on object selection. Mapping is involved and it is done by post processor. Magnetostriction can be included for volumetric element-based harmonic force.

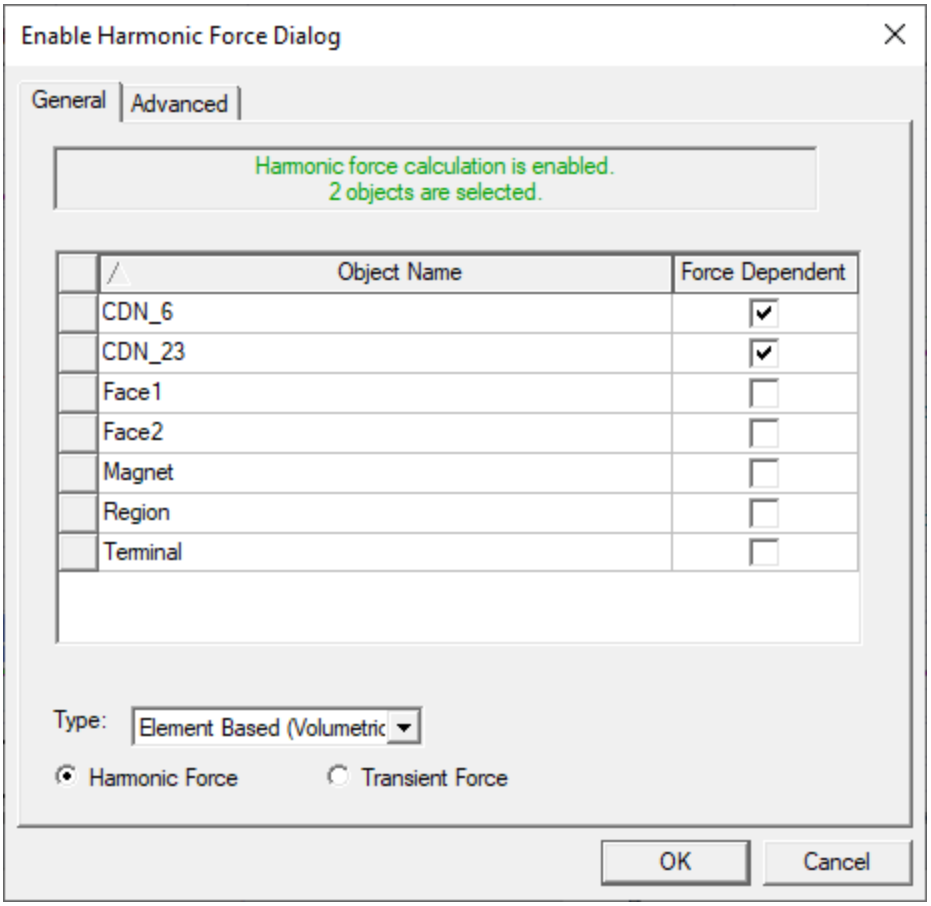
You can also setup multiple RPM Harmonic Force Coupling.

Note	Element-based harmonic force calculations can also be enabled for stand-alone transient designs.

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*.

To enable element-based harmonic force calculations for transient designs in Maxwell:

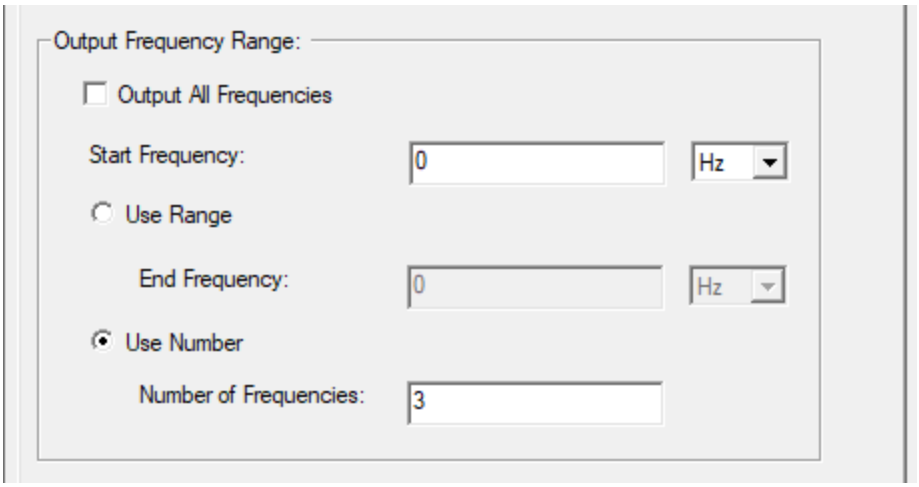
1. Either select **Maxwell 2D** (or **Maxwell3D**)**>Enable Harmonic Force Calculation**, or right-click on the Design in the project tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** box.
    - For *transient* designs, the dialog has two tabs: **General**, and **Advanced**.
2. On the **General** tab, select **Element Based (Surface)** or **Element Based (Volumetric)** as the harmonic force **Type**.



Check the **Force Dependent** objects for which force calculations are desired.

3. The **Advanced** tab provides additional settings to allow you to control collection of data from the force calculations.
    - For *2D and 3D transient* designs (either with rotational motion or with non-rotational motion), the **Output Frequency Range** panel allows you to specify the frequency range of calculated harmonic force components. The default is to **Output All Frequencies** that are calculated. There are two options to set the range of output frequencies:
        - **Use Range** – specify the **Start Frequency** and **End Frequency**. Parameterization of **Start Frequency** and **End Frequency** is supported.

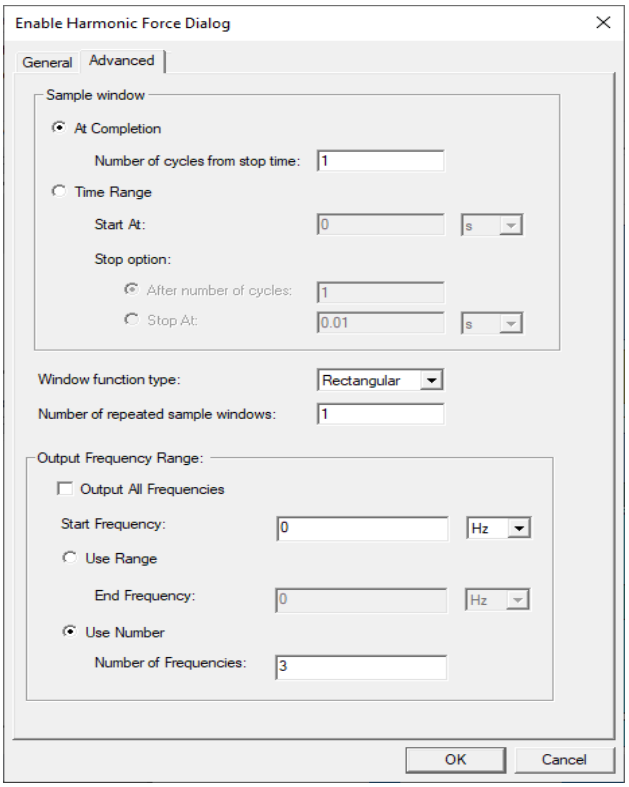
  - **Use Number** – specify the **Start Frequency** and the **Number of Frequencies**. Parameterization of **Number of Frequencies** is supported.



- For *transient* designs that include rotational motion:
  - The **Sample Window**'s collect samples **At completion** setting allows you to choose the **Number of cycles from stop time** for which data is collected. For example, if one cycle equals 1 second, and you solve for 3.5 seconds, setting the **Number of cycles from stop time** to 2 results in data being collected for the period from 1.5 seconds to 3.5 seconds. Alternatively, user can specify a **Time Range** to collect data, for which user can set a data collection **Start At** and a data collection **Stop option** – either stop data collection after a user-specified number of cycles (**After number of cycles**) or at a user-specified **Stop At** time.

- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Please refer to *Window Function Options for DFT of Harmonic Forces* for details on this setting.
- In the frequency domain of harmonic force, the base frequency is determined by the range of time window of data collection (f=1/ΔT). In order to get lower base frequencies, one must increase the time window of data collection, which means increasing the simulation time. It is waste of resources to do so when the solution reaches steady state/periodic in a transient simulation. Instead, you can set the **Number of repeated sample windows** to expand the range of time window of data collection without increasing simulation time by repeating the collected data *n* times before doing DFT. By applying this option, you can get a lower base frequency and higher frequency resolution, but the magnitudes of force components are close to zero at the introduced frequencies

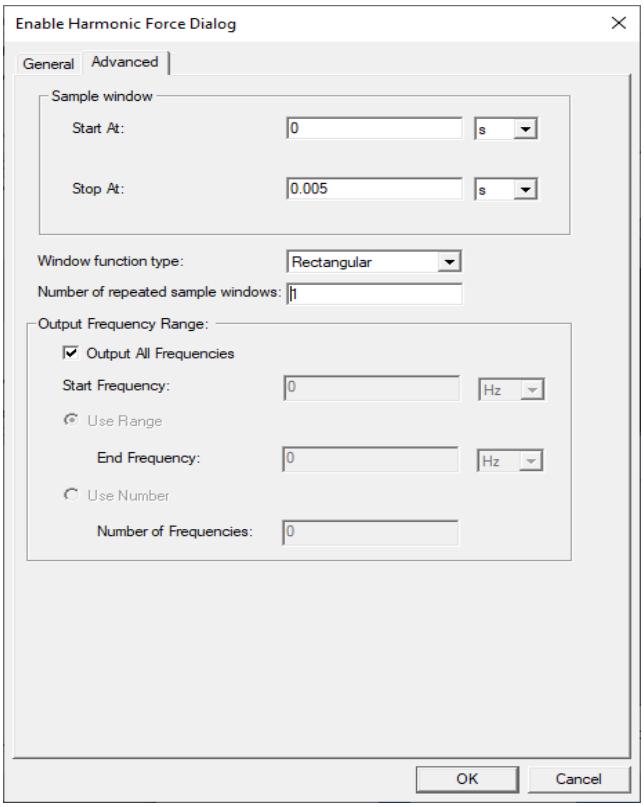
> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.



- For *transient* non-rotational motion designs:
  - the **Sample Window** of the **Advanced** tab allows you to set the data collection **Start At** and **Stop At** times.

- The **Window function type** options setting is used for Discrete Fourier Transform (DFT) of harmonic forces. Please refer to *Window Function Options for DFT of Harmonic Forces* for details on this setting.
- You can set the **Number of repeated sample windows** to expand the range of time window of data collection.

> **Note:** The **Number of repeated sample windows** setting is enabled only for the **Rectangular** (the default) **Window function type**.



Once Maxwell is linked to the Workbench harmonic solver, it can export the harmonic force results to the Workbench Harmonic design. Harmonic transient force solutions are kept as part of Maxwell design solutions. If Workbench harmonic design settings are changed, the Maxwell solutions will be invalidated.

4. Click **OK** to close the dialog.

Force Density Calculation in Maxwell

Element-based Harmonic Force Coupling for Eddy Current Designs

For 2D/3D *eddy current* designs, Maxwell provides *element-based* solutions for one-way harmonic force coupling via Ansys Workbench. For element-based solutions, there is no need to select objects in Maxwell, because harmonic surface force is a default output in the solver.

For element-based (surface) coupling, there is a harmonic force vector on each surface node for objects. The user must select surfaces on the Workbench Mechanical side before these forces can be mapped. This mapping is done by the Maxwell post-processor.

For element-based (volumetric) harmonic coupling, the force density is calculated at each element of selected objects. The user must select bodies on the Workbench Mechanical side before these forces can be mapped. This mapping is done by the Maxwell post-processor.

For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topics: *Importing Data into a Harmonic Analysis* and *Importing Data into a Thermal or Structural (Static or Transient) Analysis*

Export Transient/Harmonic Force from Maxwell

There are four options to export transient forces and one option to export transient/harmonic force from Maxwell transient solvers:

- **LMS** – provides element-based transient surface node force and mesh to link to Virtual lab, only for stator of electric machine.
- **Romax** – provides object-based transient force for the stator of electric machines and torque information.
- **UNV** – UNV file format is a standard universal file format, and it can be read by most of third-party software. Element-based transient surface/volumetric node force will be outputted with mesh.
- **Ansys Motion** – provides object-based transient force, and element-based surface transient force to Ansys-Motion for structure and acoustic simulation.

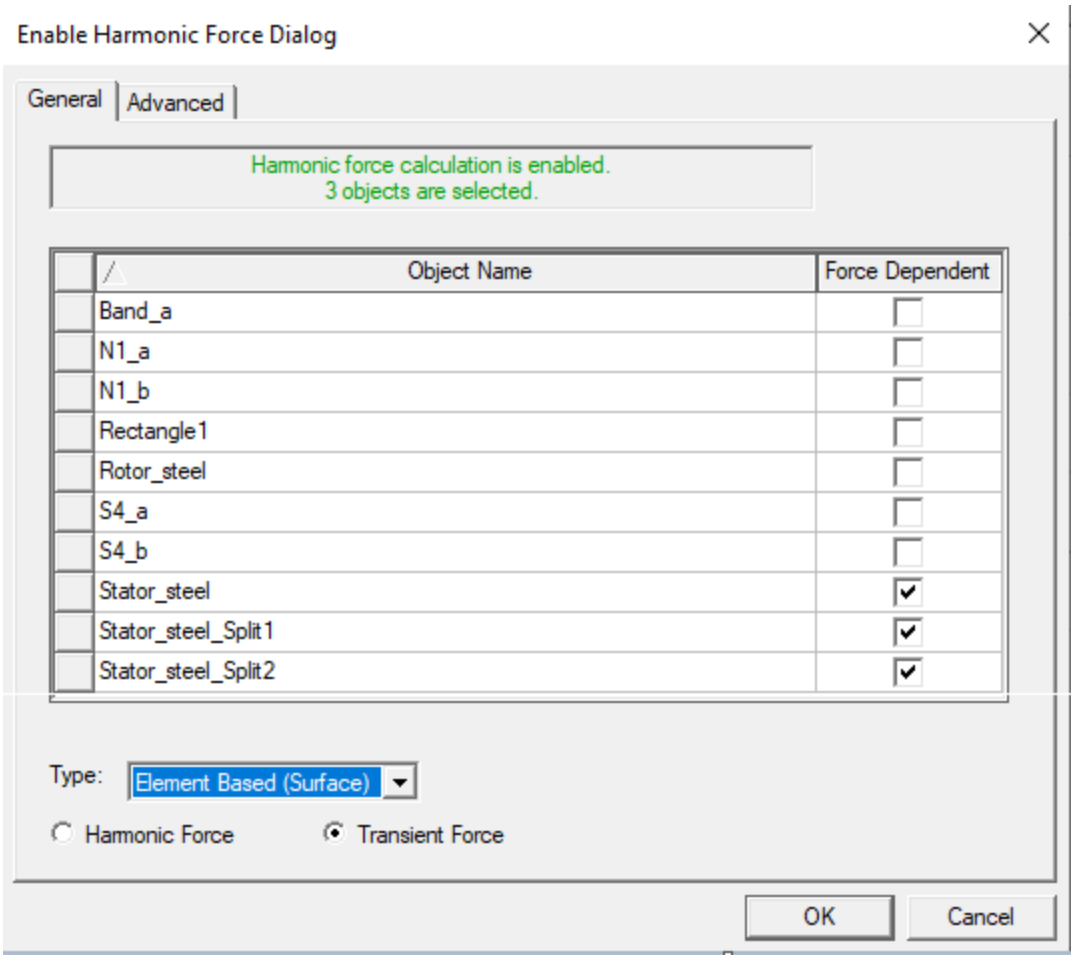
  > **Note:** Ansys Motion does not currently support harmonic force.

- **Ansys Mechanical**
  - For 3D transient solver, if **Element Based (Volumetric)** harmonic force selected, this option provides element-based volumetric harmonic force in `.csv` file format to *Ansys-Harmonic Response* for acoustic simulation.
  - If **Object Based** harmonic force is selected, this option provides object-based

harmonic force with RPM parametric sweep to generate waterfall diagram in *Ansys Mechanical*.

All forces and mesh are output with the full model. To enable “Export transient/harmonic force” from Maxwell, following steps must be done before solving the design:

1. Either select **Maxwell 2D** (or **Maxwell3D**)**>Enable Harmonic Force Calculation**, or right-click on the Design in the project tree and select **Enable Harmonic Force Calculation** to open the **Enable Harmonic Force Dialog** box.



2. On the **General** tab, select the **Force Dependent** objects for which force calculations are desired. For LMS, select only one object (stator).
3. Select **Type** of force for output. Choices are: **Object Based**, **Element Based (Surface)**, or **Element Based (Volumetric)**.
4. Check **Transient Force** if you want to export transient forces. (**Harmonic Force** is for Workbench Harmonic Response Coupling.)

> **Note:** Ansys Motion does not currently support harmonic force.

5. Check **Harmonic Force** if you want to export element-based volumetric harmonic force in `.csv` file format. This export option is only available for the Maxwell 3D magnetic transient solver.

> **Note:** Ansys Motion does not currently support harmonic force.

After solving the design, select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force** to generate transient forces.

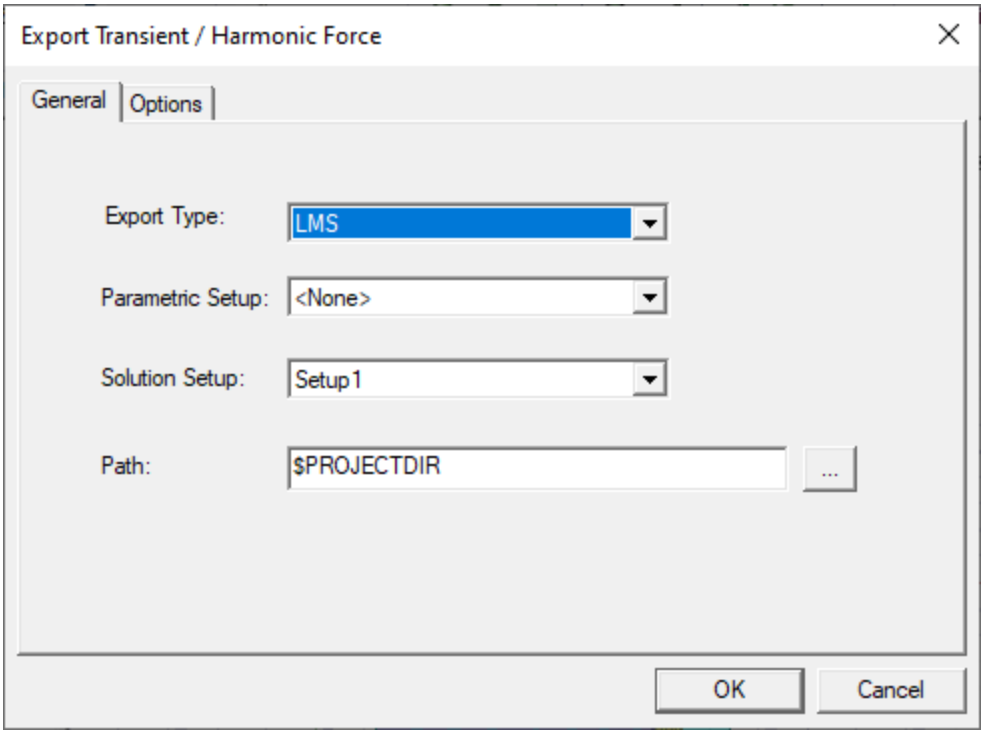
Maxwell to LMS Virtual.Lab Coupling

Maxwell supports one-way coupling with Siemens® LMS Virtual.Lab™.

To enable output of Maxwell solutions for use in Virtual.Lab:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:
   - Select **LMS** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - Select a **Solution Setup**.

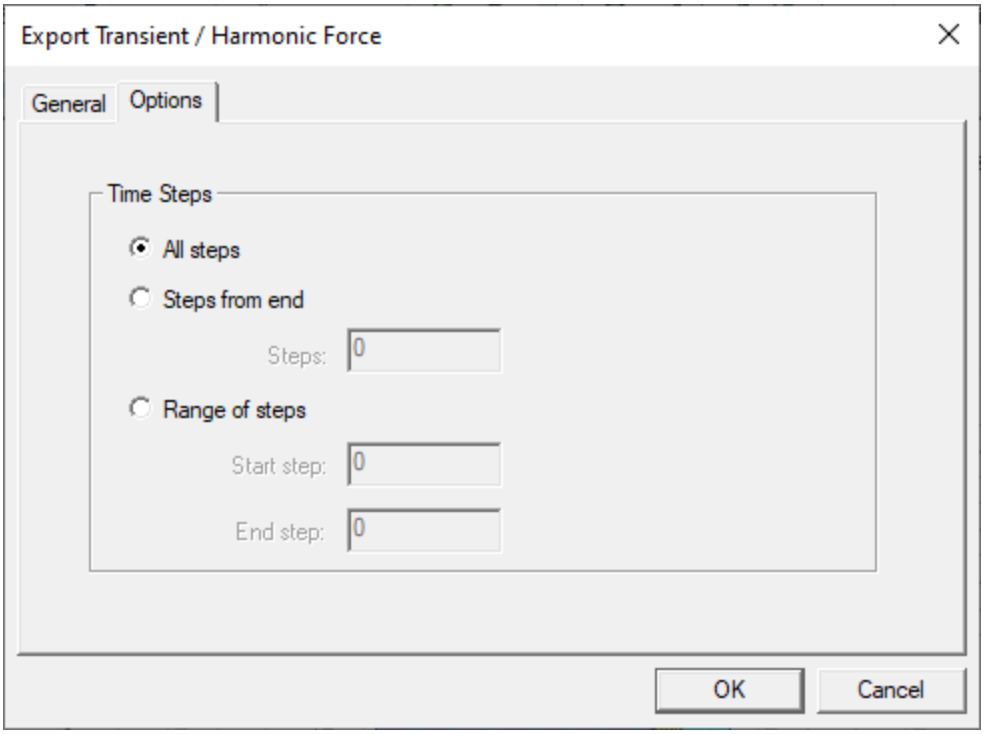
- Specify the path of the location of output file (the default is the project directory).



4. On the **Option** tab, settings allow you to control collection of data for export to Virtual.Lab. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.



5. Click **OK** to close the dialog box. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

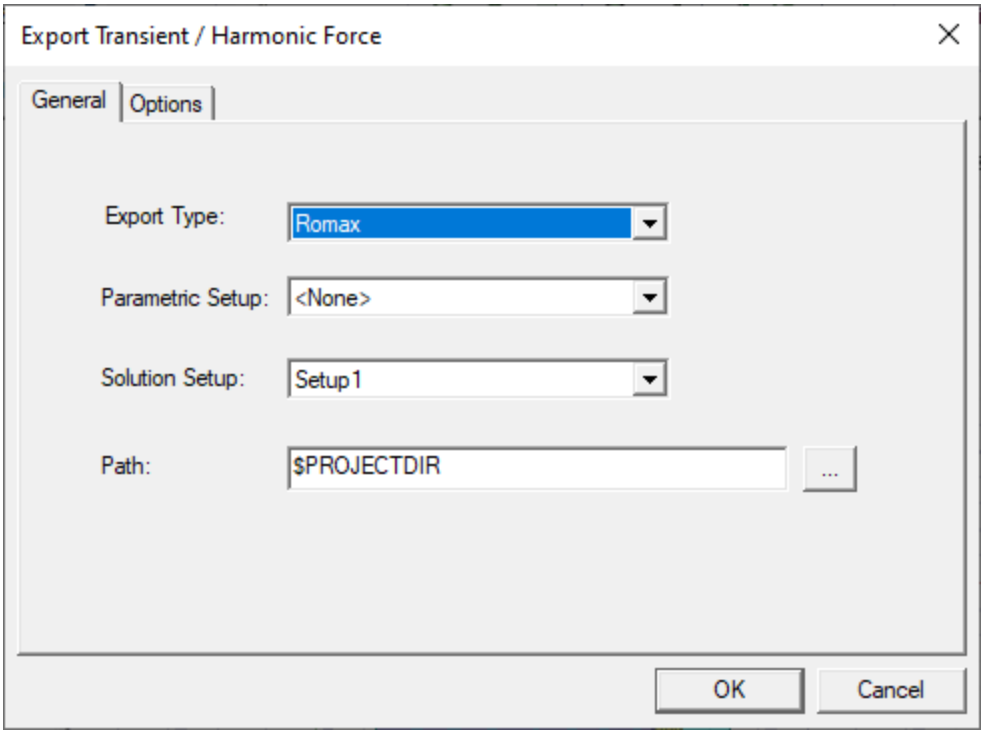
Maxwell to Romax Coupling

Maxwell provides object based transient force and torque components on selected objects. Maxwell supports one-way coupling with Romax.

To enable output of Maxwell solutions for use with Romax:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:
   - Select **Romax** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - Select a **Solution Setup**.

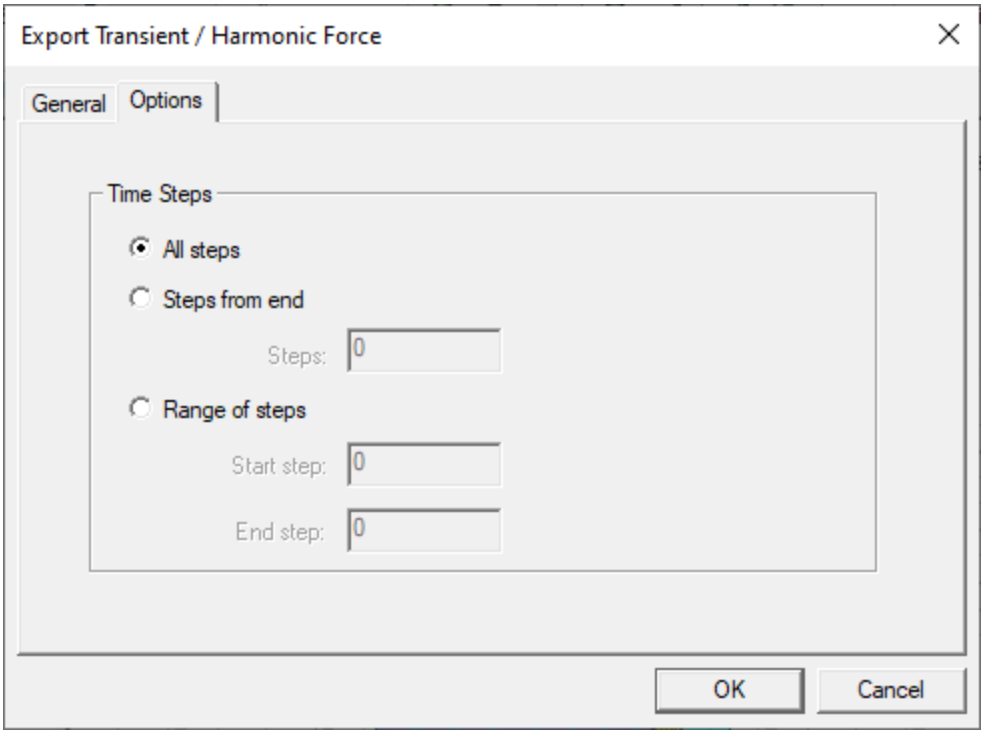
- Specify the path of the location of output file (the default is the project directory).



4. On the **Option** tab, settings allow you to control collection of data for export to Romax. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.



5. Click **OK** to close the dialog box. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

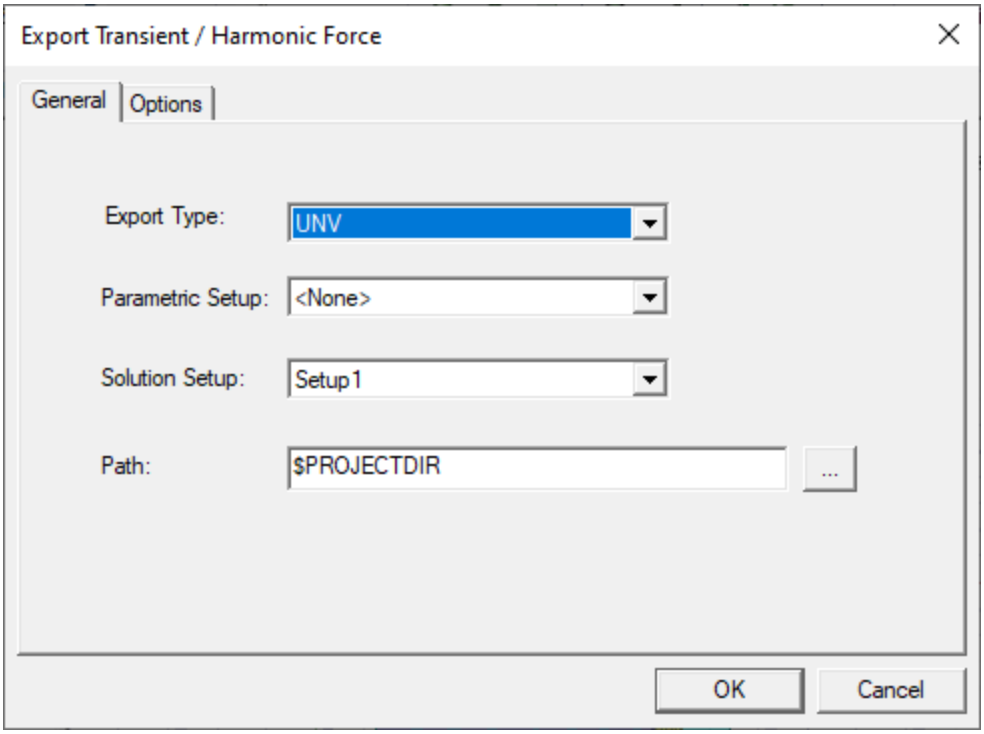
Maxwell to Third-Party Coupling by UNV File

Maxwell provides option of one-way transient force coupling with any third party through standard universal (**UNV**) file format.

To enable output of Maxwell solutions for use with any third-party through UNV file format:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:
   - Select **UNV** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - Select a **Solution Setup**.

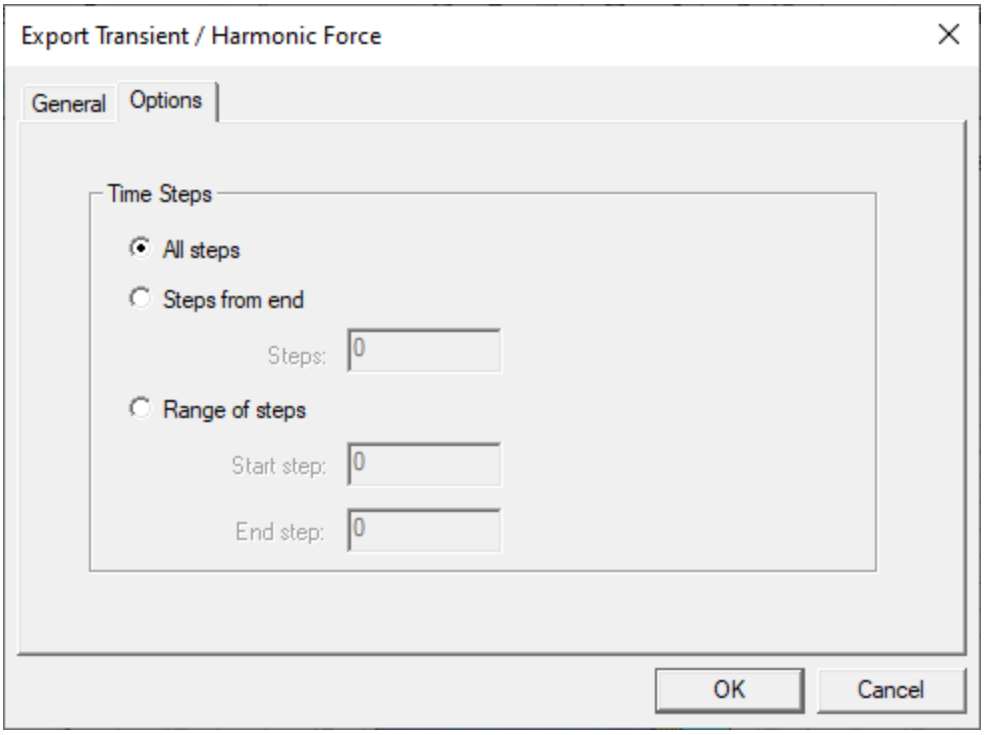
- Specify the path of the location of output file (the default is the project directory).



4. On the **Option** tab, settings allow you to control collection of data for export to a UNV file. You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.



5. Click **OK** to close the dialog box. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

Maxwell One-way Coupling with Ansys Motion

Maxwell exports transient force to couple with Ansys Motion for acoustic simulation. There are 2 options to link to Motion software in Maxwell:

- Object-based: provides object based transient force and torque components on selected objects.
- Element-based (surface): provides element-based transient surface node force and mesh.

All forces and mesh are output with full model.

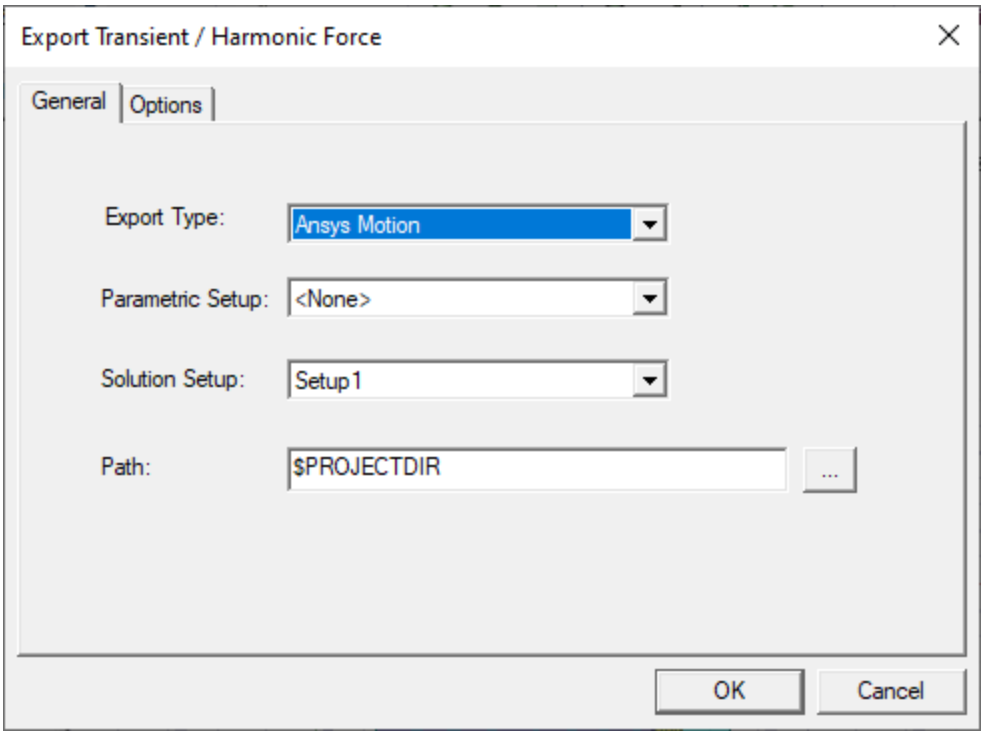
To enable output of Maxwell transient force solutions for link with Ansys Motion:

1. Follow the steps in **Export Transient/Harmonic Force from Maxwell** to enable transient force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.

> **Note:** Ansys Motion does not currently support harmonic force.

3. On the **General** tab:

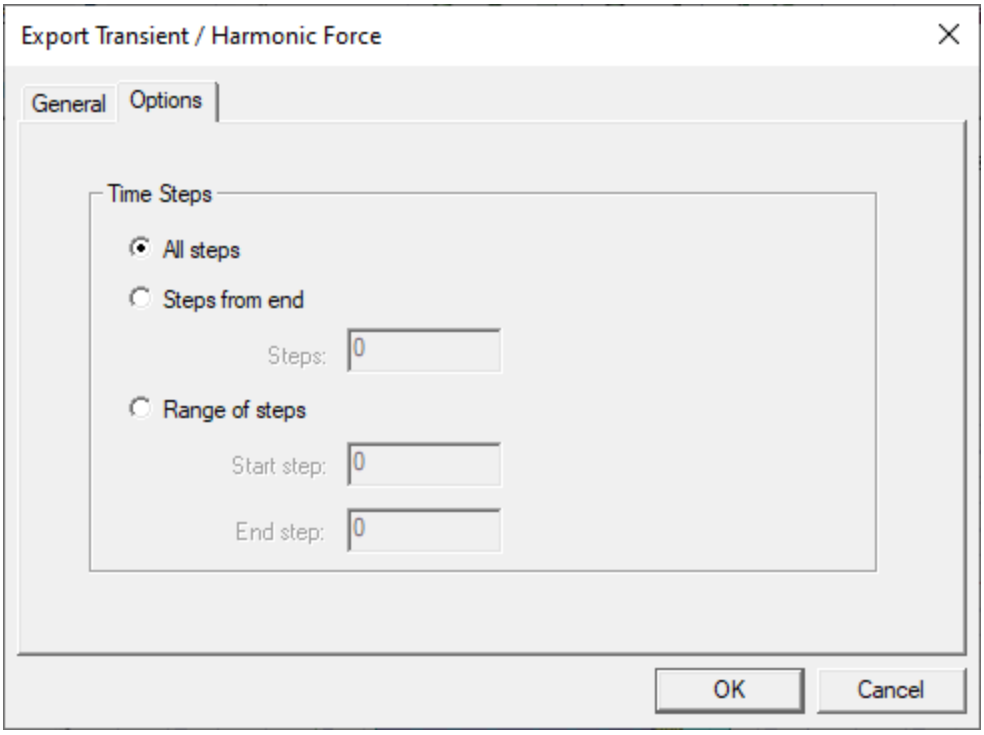
- Select **Ansys Motion** for the **Export Type**.
- Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
- Select a **Solution Setup**.
- Specify the path of the location of output file (the default is the project directory).



4. On the **Option** tab, settings allow you to control collection of data for export to UNV file (and .AMESH and .ANF files if element-based selected). You can choose to include **All steps**. The **Steps from end** setting allows you to choose the number of **Steps** from the end for which data is collected.

   > **Note:** If rotation motion is defined in the project, the input number of steps will be ignored. Instead the last cycle will be the time window.

   Alternatively, you can select a **Range of steps**, for which you can set a data collection **Start step** and a data collection **End step**.



5. Click **OK** to close the dialog box. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

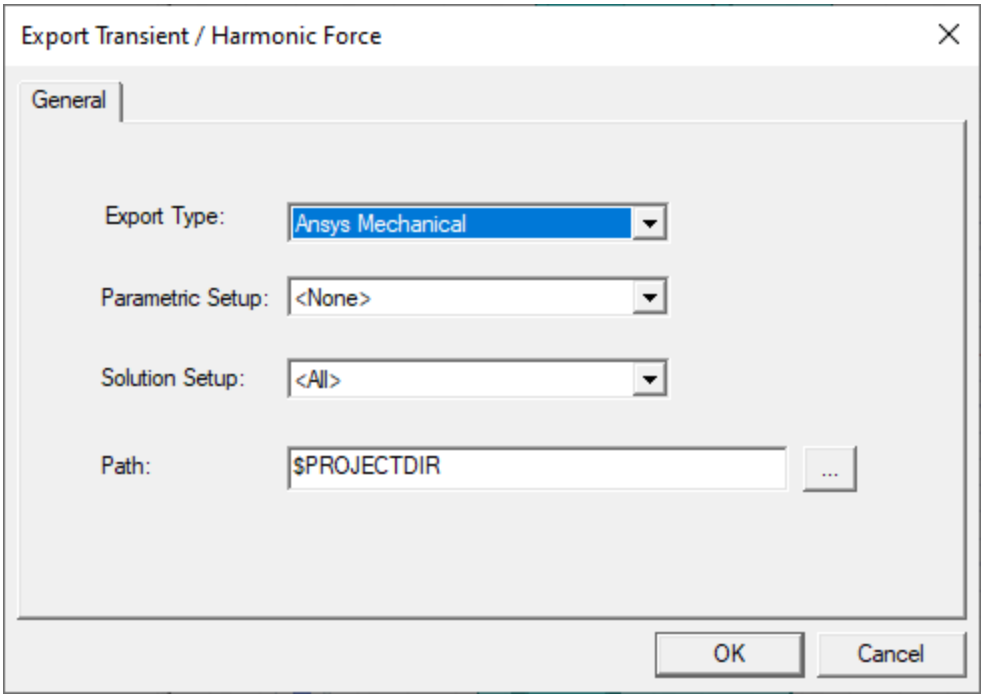
Maxwell One-way Coupling with Ansys Mechanical

Maxwell 2D and 3D transient designs can export object-based harmonic force to couple with Ansys Mechanical for acoustic simulation.

To enable output of Maxwell harmonic force solutions for link with Ansys Mechanical:

1. Follow the steps in **Maxwell to Ansys Object-based Harmonic Force Coupling** to enable object-based harmonic force output before solving the Maxwell design.
2. After solving, either select **Maxwell 2D** (or **Maxwell3D**)**>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force Dialog** panel.
3. On the **General** tab:
   - Select **Ansys Mechanical** for the **Export Type**.
   - Specify a **Parametric Setup** if any (If **<None>** is selected, only the nominal results will be exported).
   - All solved solution setups will be exported, so the **Solution Setup** pull-down list will always be **<All>**.

- Specify the path of the location of output file (the default is the project directory).

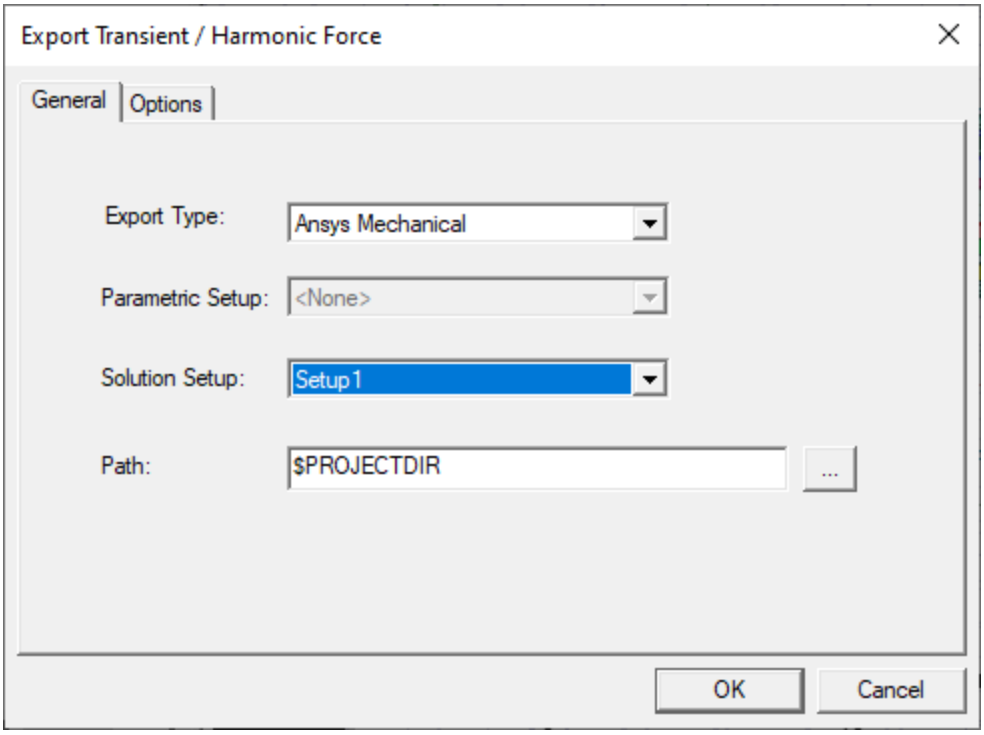


4. Click **OK** to close the dialog box. When you click **OK**, all the results (nominal or parametric solution) will be exported to the specified folder.

   You can then import the file into a WB harmonic component. For detailed information on setting up and using harmonic force coupling in Workbench, refer to the Workbench help topic: *Importing Data into a Harmonic Analysis*.

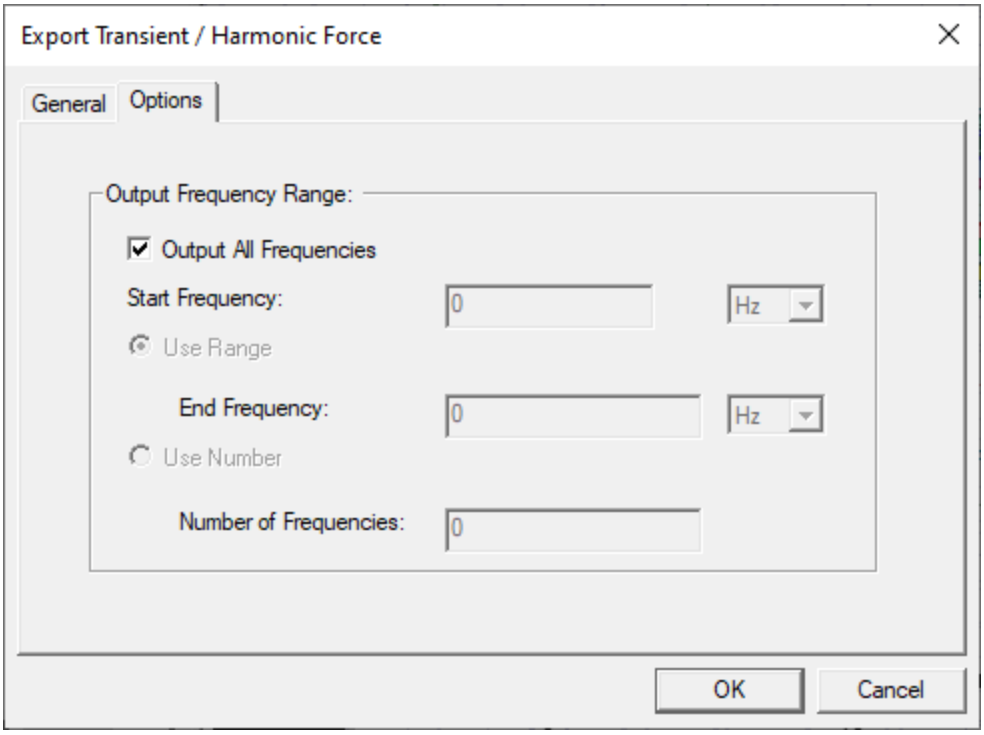
To enable output of Maxwell harmonic force solutions in a `.csv` file to couple with Ansys Mechanical:

1. Follow the steps in *Maxwell to Ansys Element-based Harmonic Force Coupling* to enable element-based harmonic force output before solving the Maxwell design.
2. After solving, either select **Maxwell3D>Export Transient/Harmonic Force**, or right-click on the Design in the project tree and select **Export Transient/Harmonic Force** to open the **Export Transient/Harmonic Force** dialog box.
3. On the General tab:
   - Select **Ansys Mechanical** for the **Export Type**.
   - Specify a **Parametric Setup** as **<None>**.
   - Select a **Solution Setup** in the pull-down list.
   - Specify the path of the location of output file (the default is the project directory).



On the **Options** tab, specify the **Output Frequency Range**. The file format in `.csv` file is (in line): Xc, Yc, Zc, Volume, Fx_re, Fx_im, Fy_re, Fy_im, Fz_re, Fz_im, Frequency1, Fx_re, Fxim, ……., Frequency2, ……

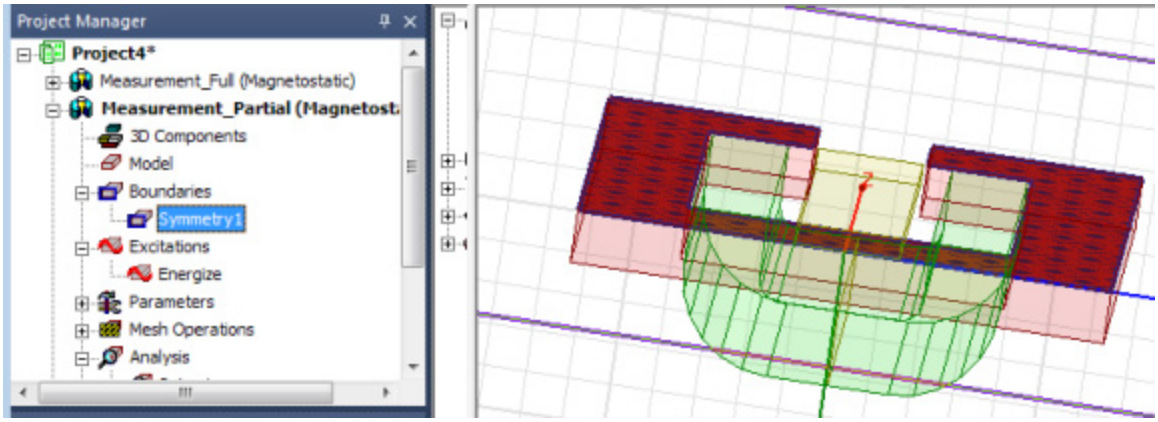
> **Note:**
>
> The frequency 0 (DC component) will be exported for either of the following conditions:
>
> - for **Output All Frequencies**: the first frequency will be 0.
> - for **Use Range**: if the **Start Frequency** is zero.

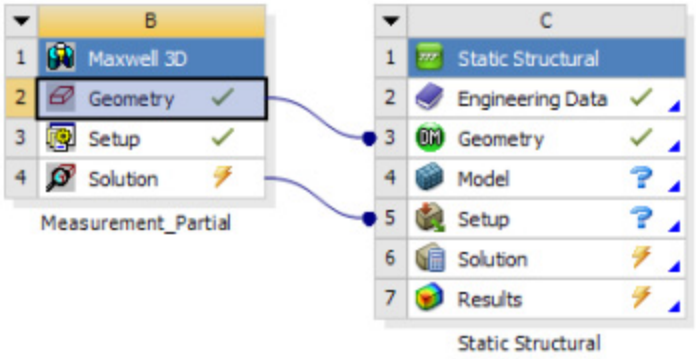


4. Click **OK** to close the dialog box. When you click OK, the `.csv` file will be exported to the specified folder. You can then import the file into a WB harmonic component.

Maxwell Partial Model Coupling with Workbench

This feature allows Maxwell 2D and 3D partial model coupling with Workbench applications such as Mechanical and Thermal. The full model geometry and solution can be extracted through symmetry from the partial model. Symmetry boundary conditions are used to solve problems with symmetry and, thus, allow the users to take advantage of the significantly reduced problem size for a given accuracy.





The following conditions must be observed for the Maxwell partial model:

- The model must be physically correct.
- Independent and dependent boundaries must be planar. If there is more than one pair of independent and dependent boundaries, all independents are coplanar and all dependents are coplanar.
- There are at most three mirroring symmetries, which are orthogonal to each other. If there is a pair of independent and dependent boundaries, then only one mirroring symmetry is allowed and it must be perpendicular to the axis of the independent and dependent boundaries.
- When the Maxwell side is a partial model and the Mechanical side is full model, full model loss / force will be mapped to the Mechanical side.
- When the Maxwell side is a partial model and the Mechanical side is also a partial model, only partial model loss / force will be mapped to the Mechanical side.

The user must ensure that the Maxwell partial model is physically correct, and that the full model in Workbench Mechanical, Thermal, etc. matches the partial model. The loss/force data from the partial Maxwell model is then mapped to the full model in Workbench Mechanical, etc. for solving. The mapping is handled implicitly.

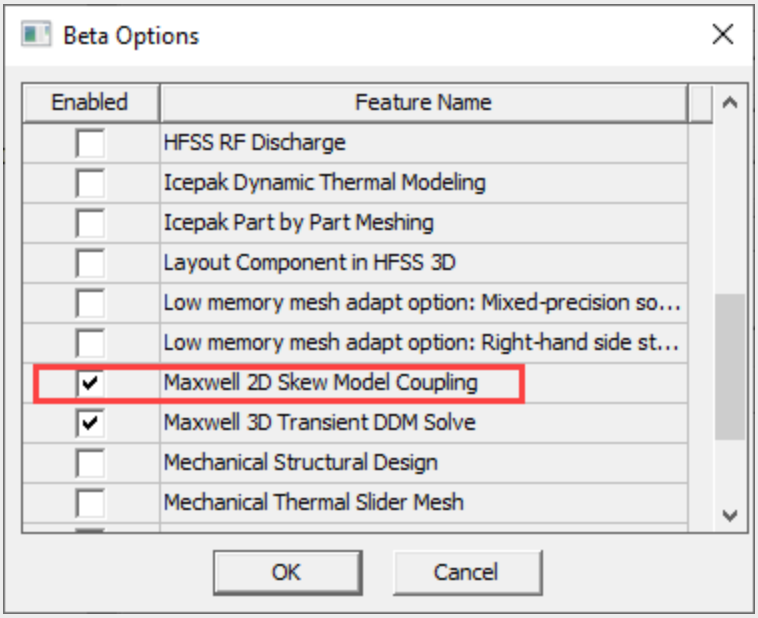
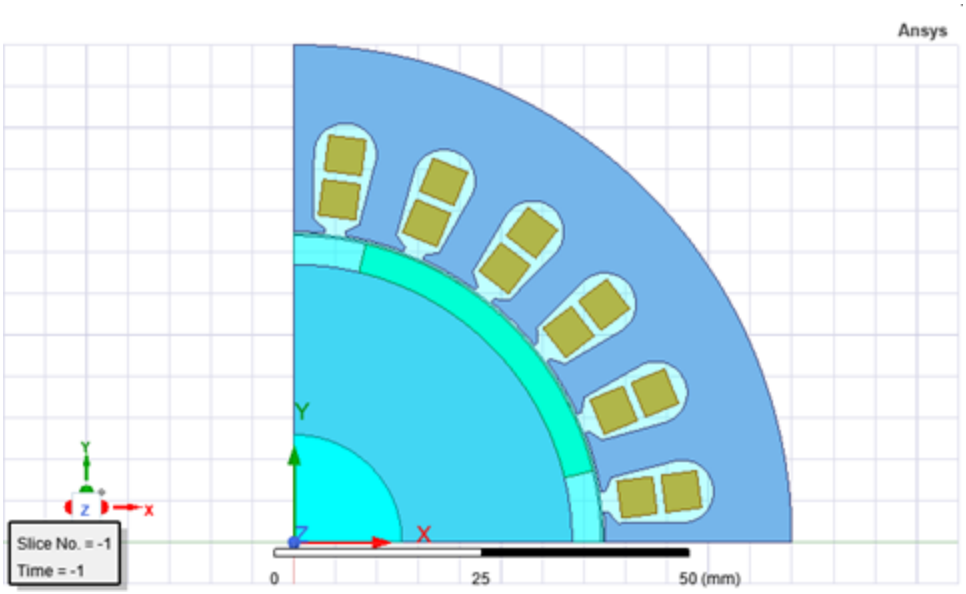
[Beta] Element-based Multi-physics Coupling for 2D Multi-slice Skew Model

Note: You must enable this feature in General Options:Desktop Configuration before you can use it.



For Maxwell 2D transient skew models, this beta feature enables element-based multi-physics coupling to steady-state thermal and static/transient structural designs in Work bench. The target design could be 2D with matching geometry or 3D with equivalent geometry, i.e., extrusion of 2D geometry with matching skew type.



Currently, RMxprt can only generate corresponding 3D models from electric machines with the continuous skew type, and corresponding 3D designs cannot be automatically generated from 2D skew model designs.

The Maxwell 2D skew model itself can be a partial model with an independent/dependent boundary, in which case, the target could be either a partial or a full model. If the target geometry is 2D, data from the default slice (middle) will be mapped. If the target geometry is 3D, it should be an extrusion of the 2D geometry with matching skew type. Any geometry in 3D that is beyond the 2D model depth will not be mapped.

Limitations

- 3D geometry creation from 2D Skew models is not supported. This needs to be done manually and then couple the two designs.
- Stress feedback on Structural is not supported. Regarding 3D to 3D coupling, Maxwell-Structural coupling provides forces from Maxwell and receives displacement and stress from Structural.
- 2D to 3D EM coupling is not supported.

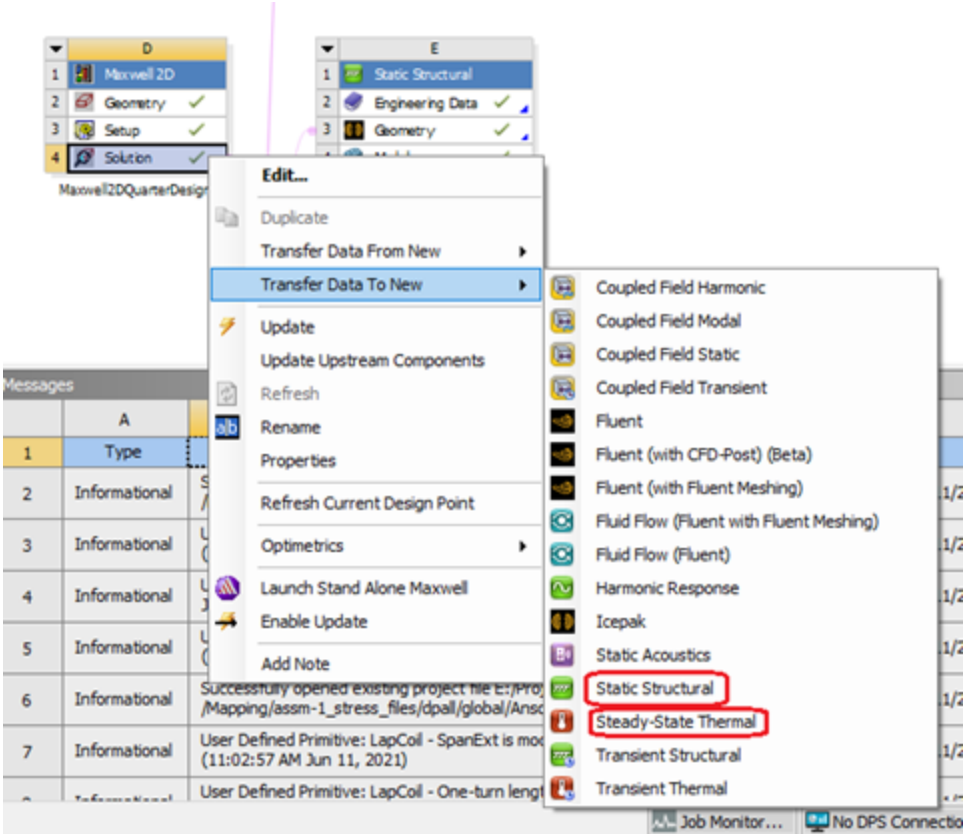
Use the following work flow:

1. From RMxprt, create a 2D skew model design and corresponding 3D design.

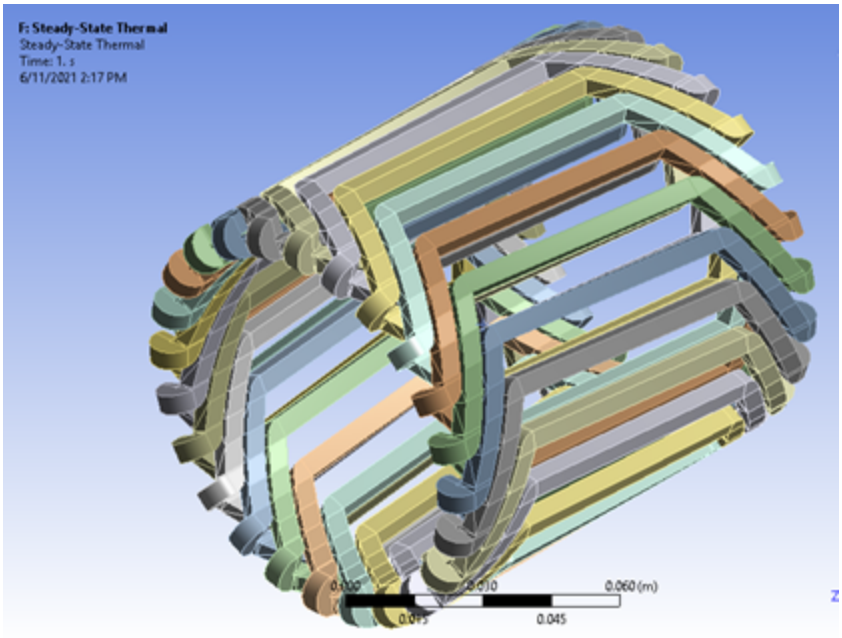
   > **Note:** For detailed information on Skew Model settings, refer to the *Model Settings Tab* topic.

2. Solve the 2D design and save the project.
3. Drag the project into Workbench.

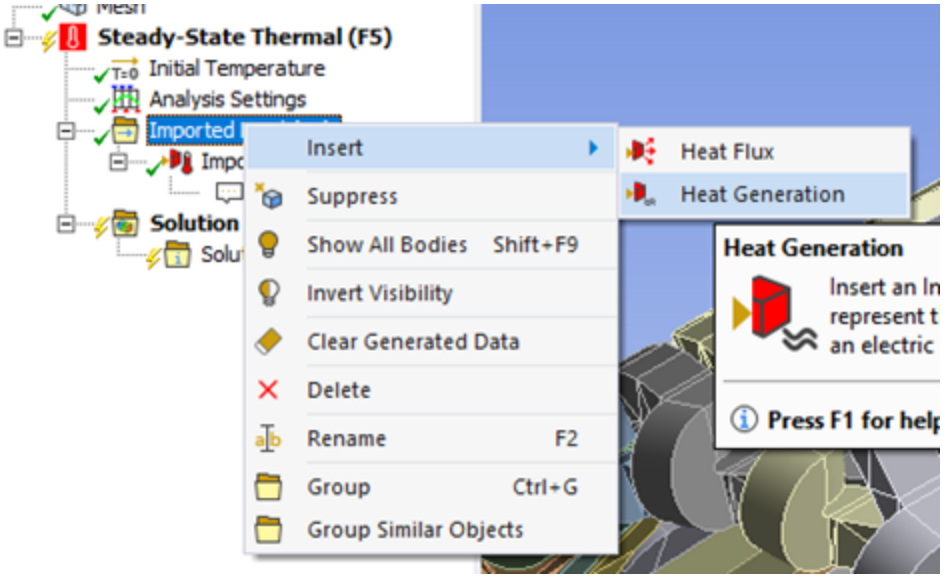
4. In the Maxwell 2D design, select **Solution>Transfer Data To New>Steady-State Thermal** or **Static Structural**.



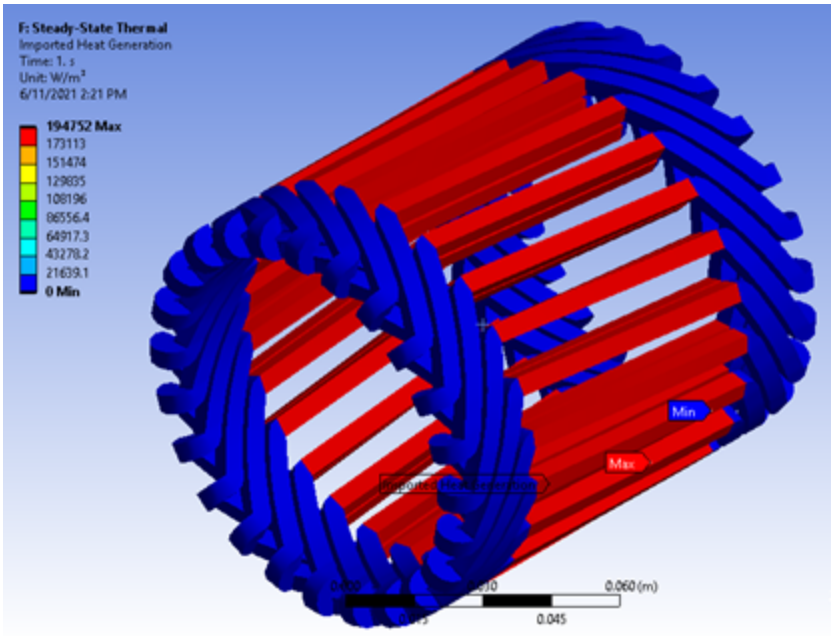
5. Drag the Geometry from the Maxwell 3D design to the Geometry of the newly created Mechanical design.
6. Refresh and/or Update the Geometry and Model in the Mechanical design.



7. In the Maxwell 2D, select **Solution>Update**.
8. In the Mechanical design, **Setup>Refresh**.
9. Double click **Setup**.
10. **Imported Load>Insert>Heat Generation**, select lossy objects and set end time.



11. Import the loads. Forces could be imported similarly.



Near Field Coupling between Maxwell and HFSS

The purpose of this coupling is to allow **Maxwell3D** frequency domain solution magnetic fields to be used as a near field source in the coupled **HFSS** design at exactly matched frequency.

Note	There is no **Far Field Wave** coupling datalink between **HFSS** and **Maxwell**.

The suggested sequence of steps to create the link between **Maxwell** and **HFSS** is as follows.

1. Create and solve the **Maxwell3D** frequency domain application at the chosen frequency.
2. Create the **HFSS** model.
3. Add "mapping" object to **HFSS** model.
4. Select all faces of the mapping object and apply a radiation boundary:
   - check the **Advanced Options** check box.
   - select the **Enforced field** radio button.
5. Click **HFSS>Excitations>Assign>Incident Wave>Near Field Wave**.

   The **Incident Wave** wizard appears. In the wizard:
   - Enter a **name** for the source or accept the default name and click **Next**;
   - In the **Incident Wave Source: Near Field Wave Options** dialog:
     a. Leave the translation and rotation data fields at their default zeros if the objects in the coupled designs have the desired location / orientation or change the values as needed;.

Note	You can change the location of the source design origin and orientation (rotation) to perform different **HFSS** simulations without re-solving the **Maxwell** design.

b. Click the **Setup Link** button to specify the location of the source, Maxwell design.

Select **OK** to exit the **Setup Link** dialog.

- Select **Finish** to finalize the Near Field link setup.

Magnetic Bias Source Coupling between Maxwell and HFSS

HFSS designs featuring ferrite materials can take advantage of non-uniform, static magnetic biasing fields to provide accurate design and simulation results. To achieve this goal it is possible to set up a coupling datalink between **HFSS** (target design) and a **Maxwell3D** magnetostatic design (source).

The suggested sequence of steps to create the link between the **HFSS** and **Maxwell3D** designs is as follows:

1. Create and solve the **Maxwell3D** design which contains the ferrite object and the corresponding non-uniform biasing fields.
2. Create the **HFSS** design which can have entirely different geometry but which contains the ferrite object(s) present in the linked **Maxwell3D** design;

Note	Make sure that in the coupled designs (**HFSS** and **Maxwell**) the ferrite objects have the same position and orientation in the global coordinate system.

3. In **HFSS** design, assign appropriate ferrite material property to object.
4. In **HFSS** design set the magnetic bias source (only one allowed per **HFSS** design):
   - Select the object(s) to be assign the non-uniform magnetic bias.
   - Click **HFSS>Excitation>Assign>Magnetic Bias** in the menu.

   The **Magnetic Bias Source** dialog appears:

   a. Enter a **Name** for the source.
   b. Select the **Non-Uniform** radio button.
   c. Click the **Setup Link** button to specify the applicable **Maxwell3D** project, design and solution for the link.

   Select **OK** when done.

   d. Select **Finish** to finalize the Magnetic Bias link setup.

Hint	It is possible to have the datalink create the **Maxwell** project automatically if it doesn't exist. When selecting the "Setup Link" button above, entering non-existent **Maxwell** project and design names will result in the creation of the needed **Maxwell** entities with the entire **HFSS** geometry included. All unneeded **HFSS** objects can be removed and the rest of the **Maxwell** model can be built around the ferrite object(s).

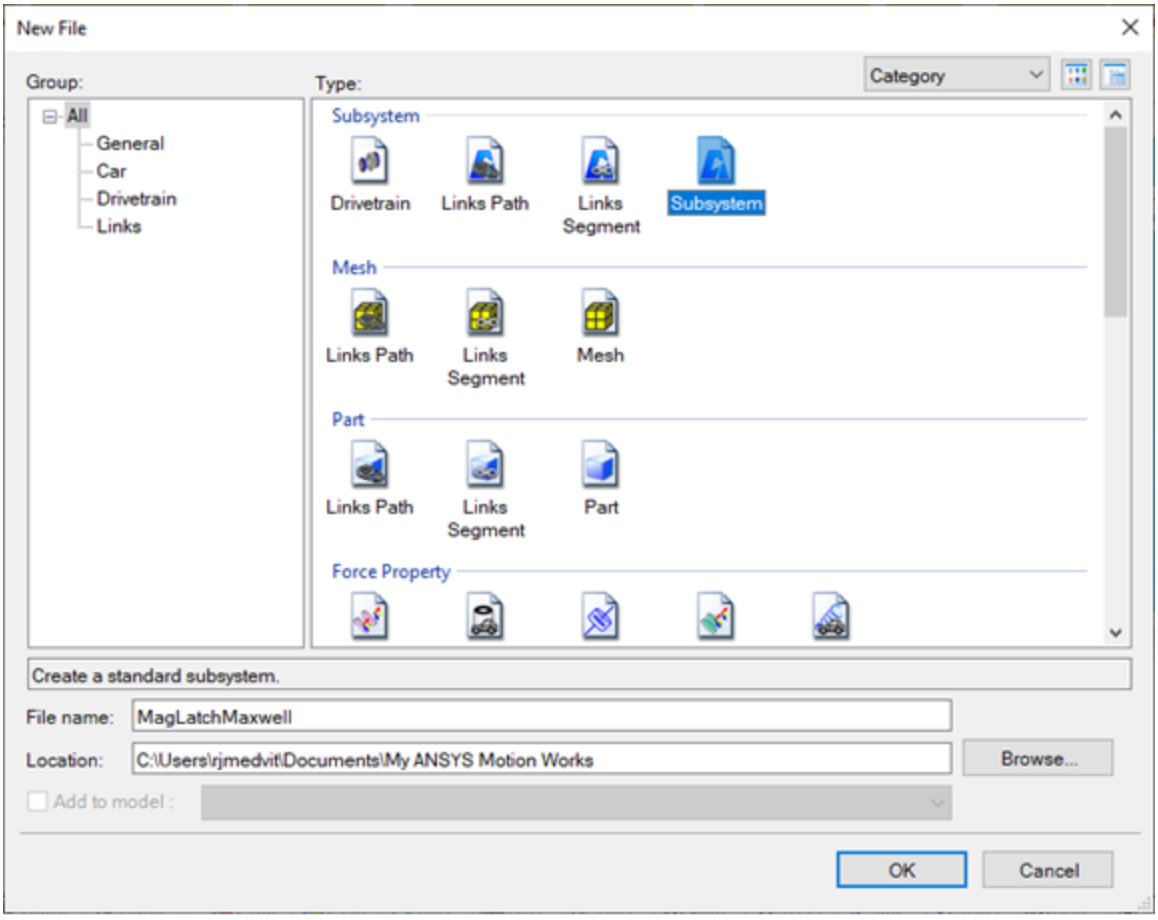
Magnetic Latch Model Co-simulation between Maxwell and Ansys Motion

Magnetic latch modeling is used typically for modeling magnetic latching structures such as magnetic chargers used by mobile devices. Magnetic latch modeling uses direct co-simulation between Maxwell and Ansys Motion. Ansys Motion is the primary (controlling) design, while Maxwell serves as the secondary design. During the co-simulation, Motion provides objects position data to Maxwell, then Maxwell feeds force/torque data for these objects back to Motion.

The suggested workflow for magnetic latch modeling using co-simulation between Ansys Motion and Maxwell is as follows:

> **Note:** Please refer to the *Ansys Motion Preprocessor Manual* installed with the Ansys Motion software for details on using the Motion Preprocessor for the following steps.

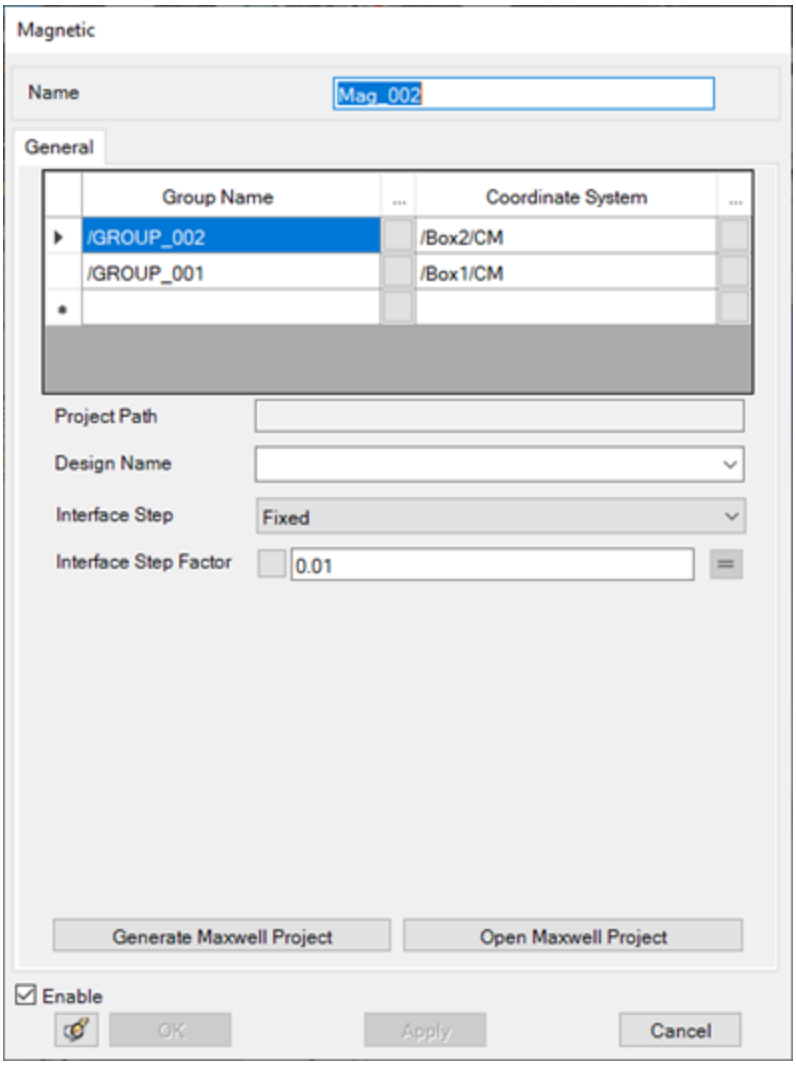
1. In **Ansys Motion Preprocessor**, create a new **Subsystem** file for which you specify a project path and project name.



2. Import a CAD file of the model. You can modify object properties such as materials as needed.
3. After creating the model, **Group** objects of interest that have position changes and/or need force/torque calculations in the Maxwell design.

> **Note:** For performance considerations, it is recommended that you not perform force/torque calculations on all objects.

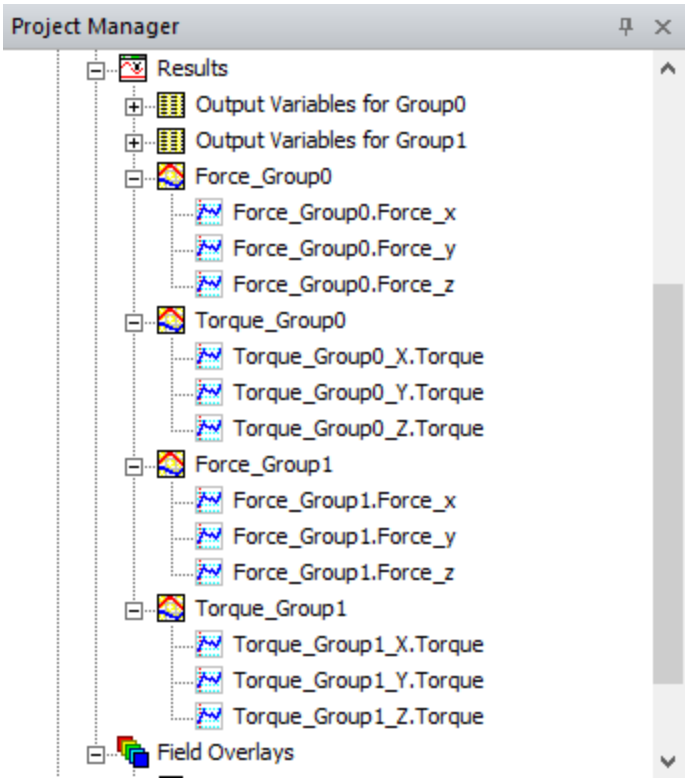
4. On the Ansys Motion Preprocessor **Force** tab, click the **Magnetic** button, pick the desired **Groups**, then click **OK**. In the **Magnetic** dialog box enter the desired **Interface Step Factor** (in seconds) or accept the default 0.01. This sets the Maxwell simulation rate. The **Coordinate System** assigned to each group defaults to center-of-mass.



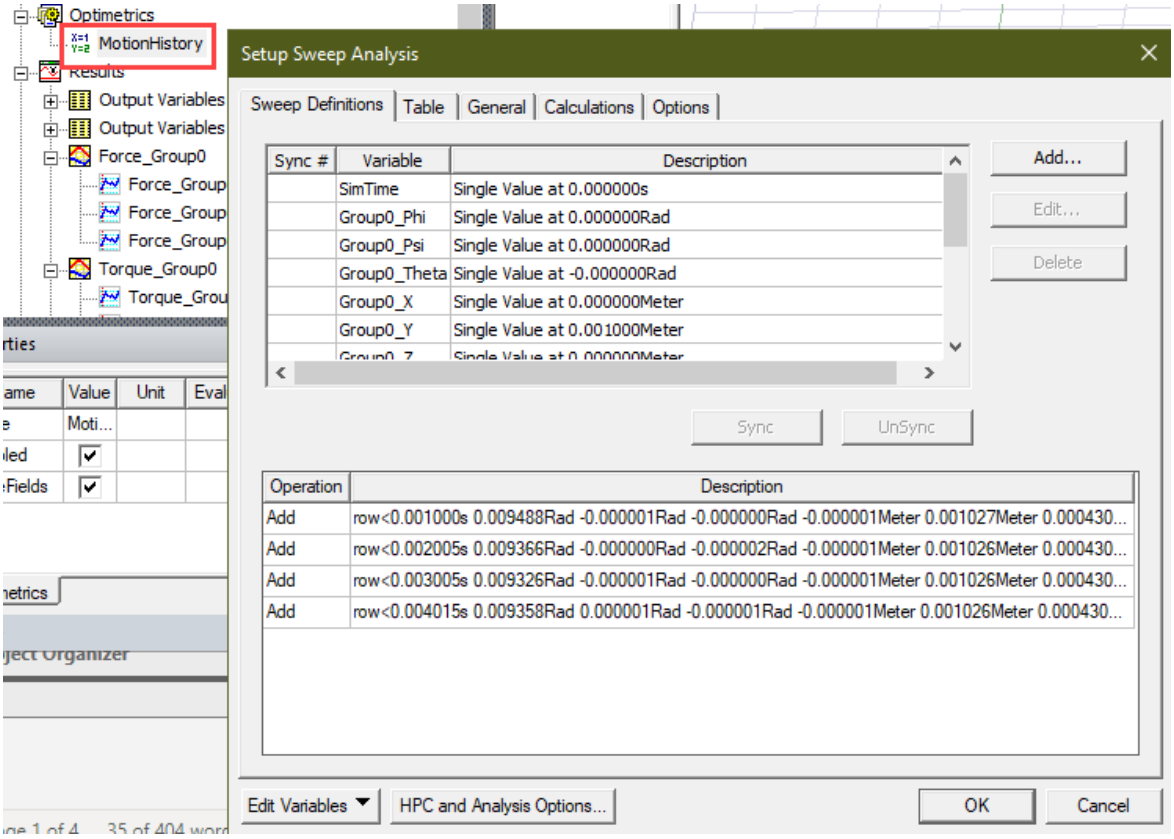
5. Click **Generate Maxwell Project**. A Maxwell desktop will be launched automatically with the generated Maxwell magnetostatic design, which includes the following:
    - The model geometry (including necessary coordinate systems)
    - If a Material is not found in the Maxwell system or user libraries, a new material with the default properties of *vacuum* will be created.
    - Force/torque calculation setups
    - A [default] Solve setup
    - Data table for force/torque parameters
    - Field plot for magnetic objects
    - Ansys Motion passes the Motion solve time step as a variable named **SimTime** to Maxwell. Excitations can be created depending on this variable.

    - A parametric setup called **MotionHistory** will be automatically created and will be updated for each time step, keeping a table of variations for all the simulation steps. This data can be used to create an animation of all the simulation steps.
6. Optionally, you can customize various settings manually in Maxwell, such as:
    - Material properties for objects, especially characteristics for permanent magnets
    - Excitations can be created dependent on the **SimTime** variable.
    - Coordinate system settings
    - Mesh setup
    - Solve setup
7. After the setups on both Ansys Motion and Maxwell (if any) are completed, you can start the co-simulation solve in Motion by selecting **Simulation>Run** on the **Home** tab.

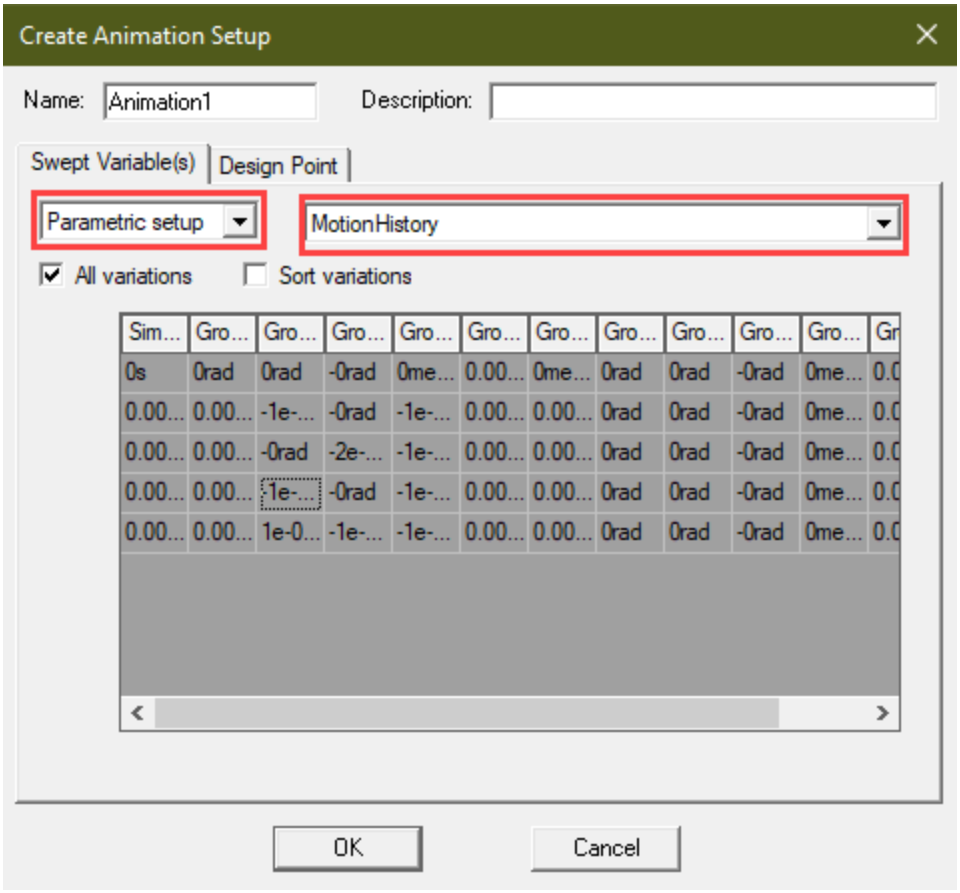
8. After co-simulation is completed, Maxwell Project Manager Results should show two reports for each group, one for force, one for torque. The reports plots are force/torque against **SimTime**.



9. Optionally, you can create an animation of all the simulation steps. A parametric setup called **MotionHistory** is automatically created and updated for each time step, keeping a table of variations for all the simulation steps.



10. Optionally, to create an animation using the automatically generated **MotionHistory** parametric setup:
    a. Right-click on the desired field plot and click **Animate…**
    b. In the **Create Animation Setup** dialog, select **Parametric setup** in the first box, then select the parametric design called **MotionHistory** in the second box.



c. Click **OK** to create the animation.

Coupling Maxwell to a Twin Builder Component

Maxwell designs may be dynamically coupled to Twin Builder components through the Twin Builder user interface. The Twin Builder interface allows Maxwell 2D, 3D, and RMxprt designs to be linked as dynamic components. Source windings set to **External** are available as conservative pins in Twin Builder.

- Transient coupling links must be enabled in Maxwell on the **Design Settings>Advanced Product Coupling** tab for Transient Cosimulation with Twin Builder.
- The ECEIM_Model component must be used in a Maxwell eddy current design to enable Twin Builder to couple to the design.

Dynamically linked components provide the ability to have Twin Builder vary a variable in a Maxwell design and have Maxwell solve the design at the new design point and provide the solution data back to Twin Builder for use in the circuit simulation.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Coupling Components* and *RMxprt Dynamic Coupling Component* topics in the **Twin Builder Help**.

Related Topics

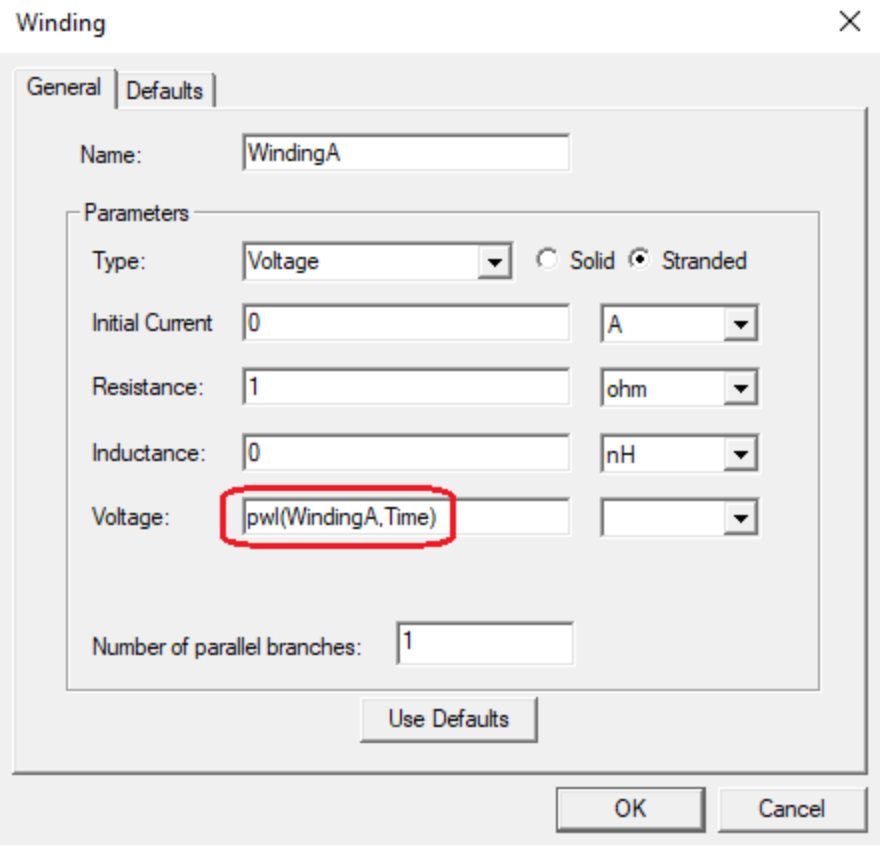
Advanced Product Coupling Tab (for Transient-Transient coupling only.)

Coupling Maxwell to a Twin Builder Excitation Component

You can couple a Maxwell 2D or 3D transient, or a 3D A-phi transient design using the Twin Builder **Excitations Component**. The Excitations component user interface allows you to assign output quantities in the Twin Builder design to windings in the coupled Maxwell design. Based on Maxwell excitations (voltage/current), Twin Builder will perform simulation, then generate detailed PWL expressions and dataset data. These expressions and data can then be pushed back to Maxwell as excitations for further analysis.

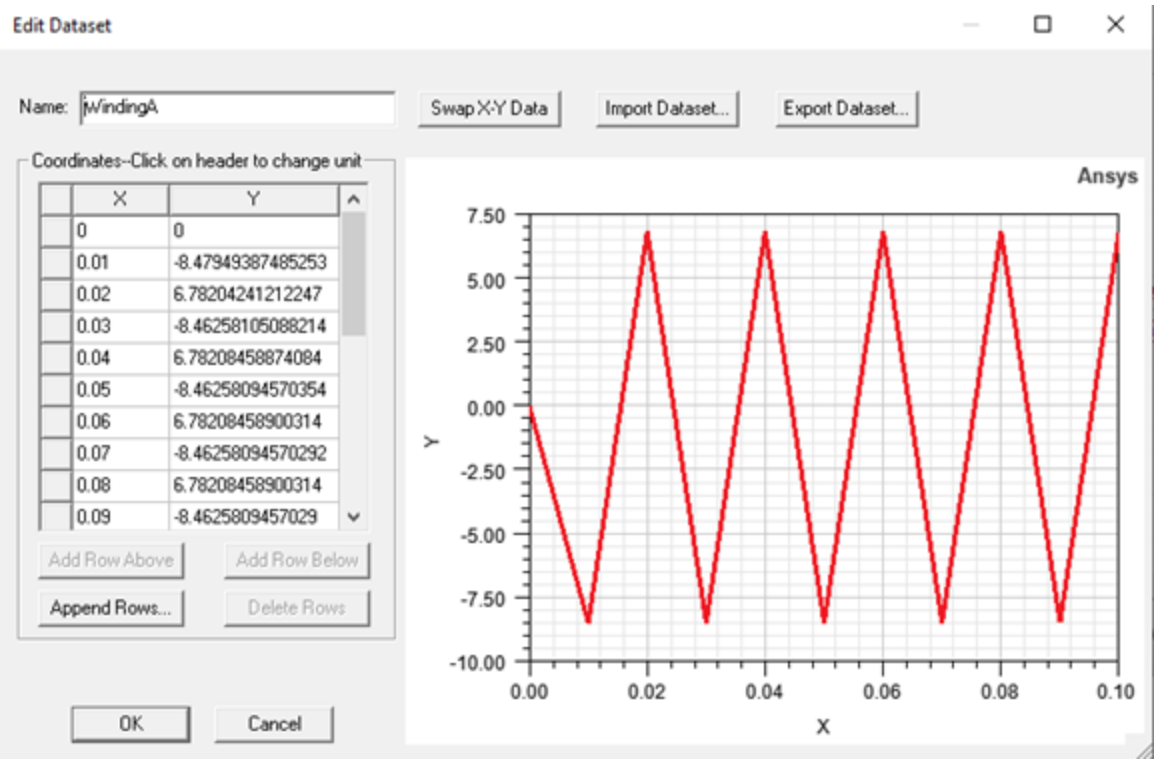
Refer to the *Maxwell Excitation Component* section in the **Twin Builder** help for the procedures on coupling a Twin Builder **Excitations Component** to a Maxwell 2D or 3D transient, or a 3D A-phi transient design; and sending **Push Excitations** data back to the coupled Maxwell design.

After the excitations push-back, you can see the push-back excitation expression in Maxwell. For example, for winding voltage:



The dataset for the PWL function can be viewed by selecting **Maxwell>Design Datasets**. In the Dataset dialog box, you can see the data set details.

To view the data set in a table, click **Edit**.



Coupling Maxwell Magnetostatic and Eddy Current Designs with Ansys Fluent

Coupling is supported between Ansys Fluent and Maxwell 3D magnetostatic and Eddy current designs. For example, a transient Fluent simulation can use a Maxwell solution to simulate the magnetic effect of the electric arc of contactors. This coupling supports designs that have a datalink defined, such as mesh, demagnetization, and so on. A design that is enabled for thermal and stress feedback is not supported.

In Ansys Fluent, during a transient simulation that requires exchanging data with Maxwell, a user-defined function (UDF) invokes the Maxwell solver. Ansys Fluent and Maxwell exchange inputs and solution data in a coupling directory that you specify. Maxwell calculates the B field based on the mesh-based conductivity (and meshed-based permeability in eddy current designs); and current excitation provided by Ansys Fluent. Ansys Fluent calculates flow field, temperature, and feedback electrical conductivity (and permeability in eddy current designs) to Maxwell.The Maxwell GUI does not provide direct access to the data in this coupling directory.

Follow these steps to set up the coupling:

1. Set up the magnetostatic or Eddy current project in Maxwell 3D.
2. In the project tree, right-click **Setup** under **Analysis** and select **Configure Fluent Conductivity Coupling**.
3. In the **Configure Fluent Conductivity Coupling** dialog box, browse to select the coupling directory or type a path, and click **OK**. You can enter a local directory, such as where Maxwell desktop is running, or you can enter a mapped network location.
   - If you enter an existing directory that contains files, a warning notifies you that all files in that directory will be permanently deleted. Click **Yes** to use that directory and delete all files contained in it. Click **No** if you do not want to select that directory. When you click No, the dialog box stays open for you to enter a different directory.
   - If the directory you entered does not exist, Maxwell creates the directory. If the directory is not successfully created, the dialog remains open.

Note	• If there are errors during the process or if you terminate the process, the coupling directory is not configured. • If there is version incompatibility between ANSYS Fluent and Maxwell, the process is stopped and an error message is displayed. • If you Clean Stop the process and there is enough solution data to configure the directory, the coupling directory will still be configured.
4. Set up the Ansys Fluent project as described in the *Ansys Fluent User's Guide*.
5. Build and load the UDF that was developed for your application. For more information about UDFs, see the *ANSYS Fluent UDF Manual*.
6. In the **input.txt file** that is specific to the UDF, provide the information that is required by the UDF. For more information about the required information and format, see Sample Input.txt File Format.

   The UDF is invoked during the transient simulation. When there is a need to exchange data, the UDF invokes the Maxwell solver.

Magnetostriction in Maxwell Magnetostatic to Workbench Mechanical Coupling

Maxwell supports magnetostriction and inverse magnetostriction forces in Workbench Mechanical coupling for Maxwell 2D/3D Magnetosatic designs. Both one-way and two-way coupling are supported.

One-way coupling

- The Maxwell solver calculates force density which includes magnetostriction force data. The force density data including magnetostriction force data is output to the Workbench Mechanical system .

Two-way coupling

- Maxwell provides force density data to the Mechanical system as it does for one-way coupling.
- The Workbench Mechanical system solves and sends stress/strain data (plus displacement data) to Maxwell, which will be used in the Maxwell solution for the next iteration.

Related Topics

Magnetostriction and Inverse Magnetostriction

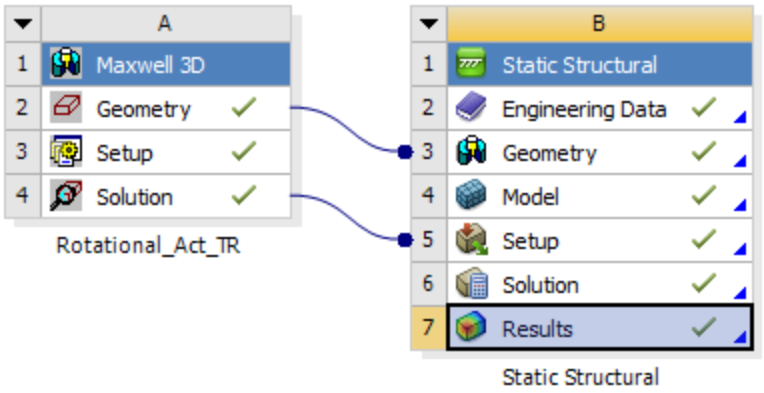
Magnetostriction Stress Coupling Between Maxwell 2D/3D Transient and Workbench Mechanical

Maxwell supports magnetostriction forces in two-way coupling between Workbench Mechanical and Maxwell 2D/3D Transient designs.

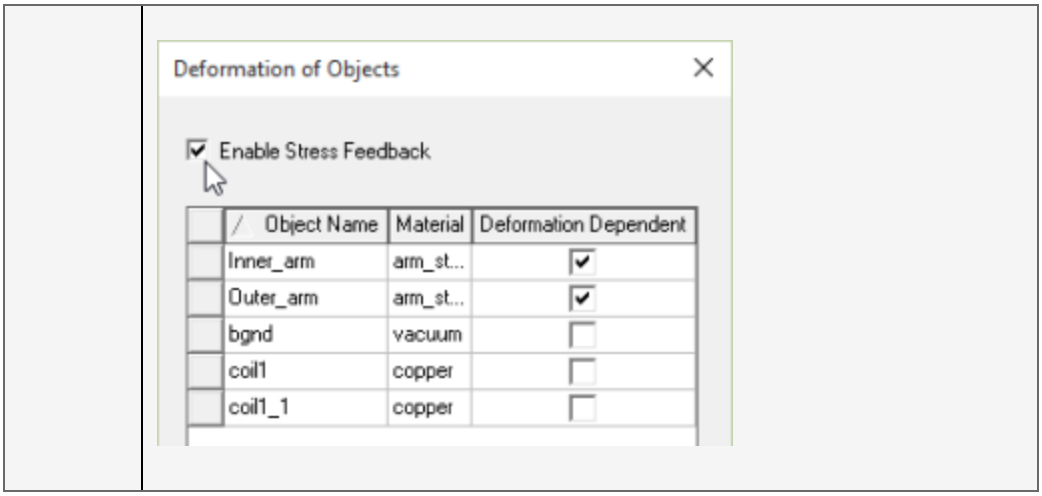
- Maxwell 2D/3D transient provides force density data to the Mechanical system.
- The Workbench Mechanical system solves and sends stress/strain data (plus displacement data) to Maxwell, which will be used in the Maxwell solution for the next iteration.

To analyze the effect of stress due to magnetostriction forces on objects in a design using two-way coupling between a Maxwell 2D/3D transient design and Workbench Mechanical:

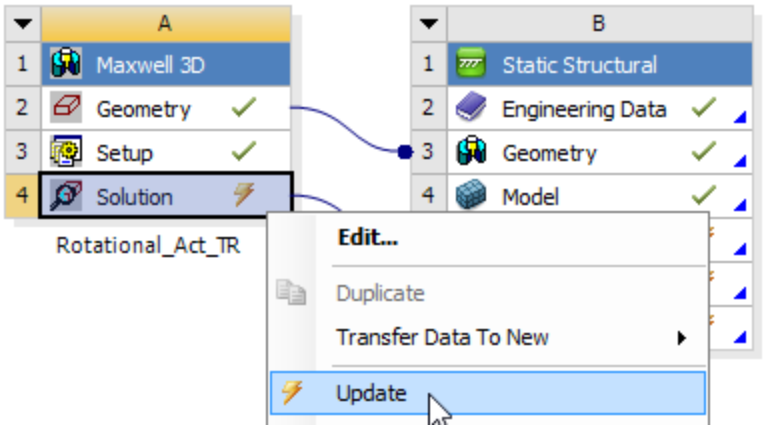
1. Set up the Maxwell3D/2D transient Mechanical structure coupling.



Note	You must manually Enable Stress Feedback and select the desired stress feedback objects in the Maxwell design.

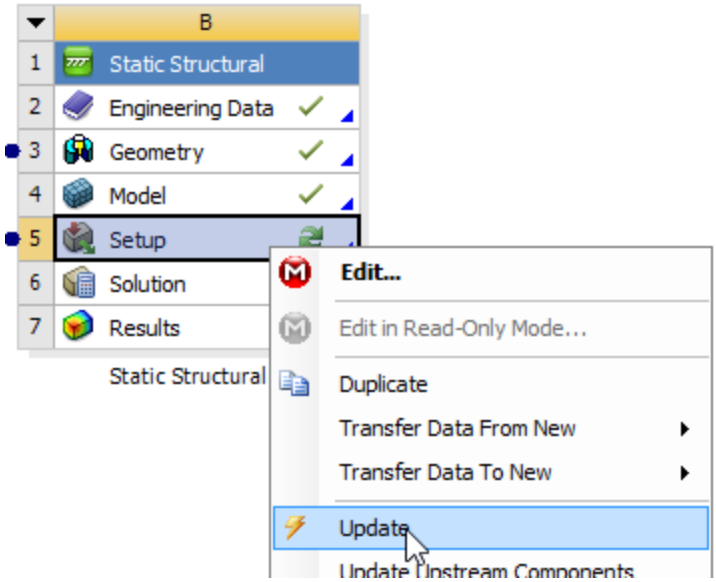


2. **Update** the Maxwell **Solution** cell to initiate a Maxwell solve.

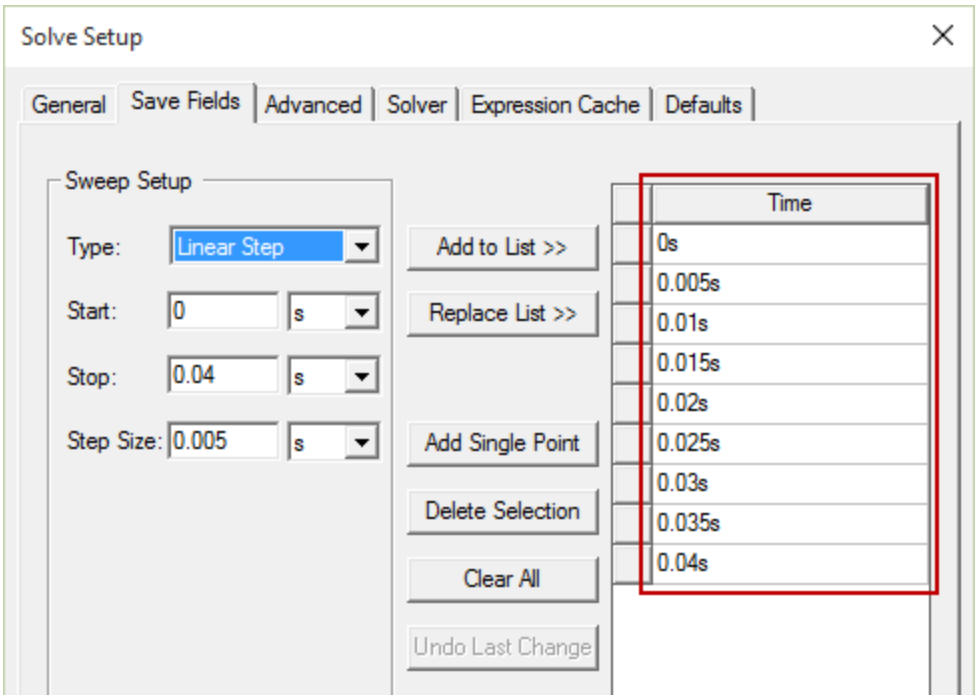


The Maxwell transient solver generates force density data, which can be used by Workbench Mechanical.

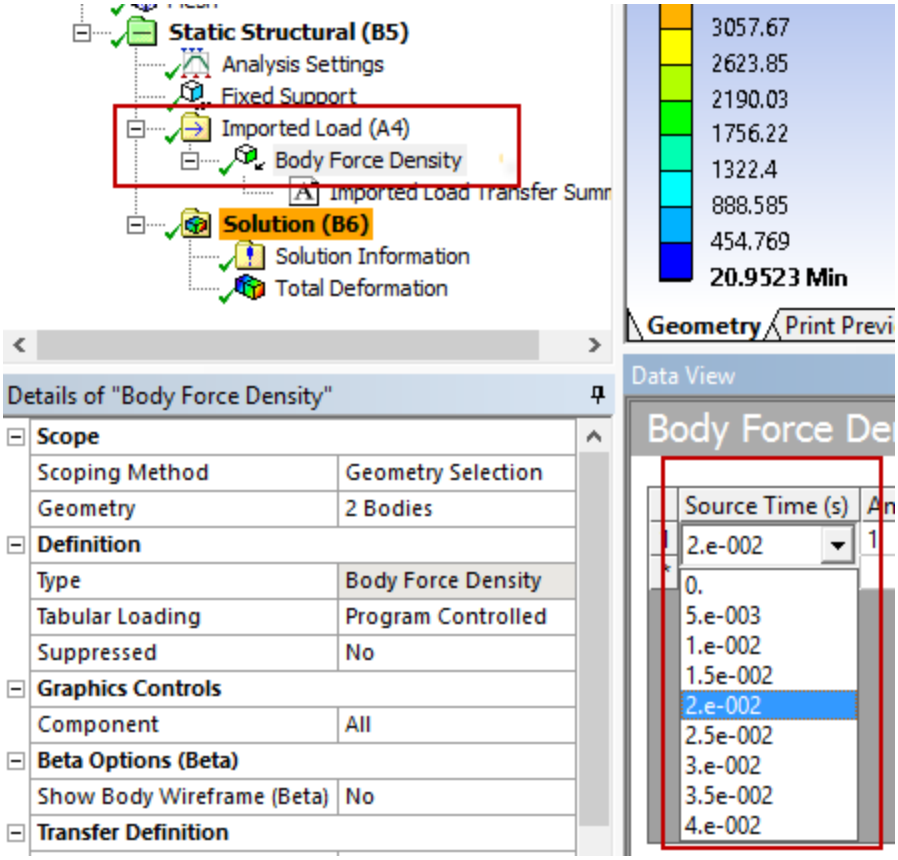
3. **Update** the Workbench Mechanical **Setup** cell to import the force density data generated by Maxwell.



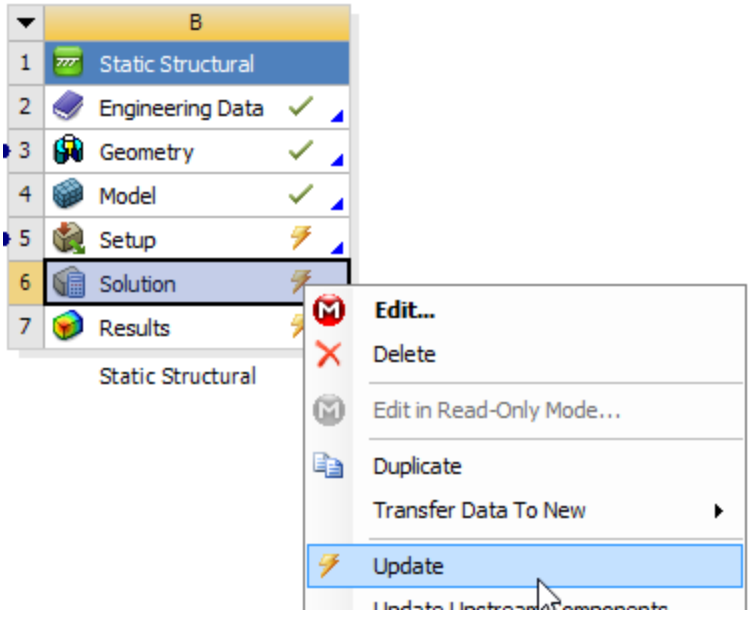
Maxwell maps the Maxwell mesh to the Workbench Mechanical mesh; and the calculated force density values for the time points you set up on the Maxwell transient **Solve Setup** dialog **Save Fields** tab are loaded into Workbench Mechanical.



4. In Workbench Mechanical, select the desired source time point you want to use for the force density calculations.



5. **Update** the **Solution** cell of the Mechanical panel.



Workbench Mechanical solves the structural project using the force density at the selected source time, then outputs displacement and stress/strain data to be used as feedback by the Maxwell transient solver.

6. To re-solve using the feedback data, set the **Solution** cell of the Maxwell panel to **Enable Update**, then perform an **Update** for the Solution cell. (You can also use the feedback iterator to automatically update the Maxwell Solution cell.)

   The Maxwell 3D/2D transient solver uses the feedback displacement and stress/strain data to re-solve from time 0.

18 - Ansys Workbench Integration Overview

Ansys Workbench combines the strength of its core product solvers with the project management tools necessary to manage project workflow. In Ansys Workbench, analyses are built as *systems*, which can then be combined into a *project*. The project is driven by a schematic workflow that manages the connections between the systems.

From the schematic, you can interact with applications (called workspaces) that are native to Ansys Workbench and that display within the Ansys Workbench interface. Native workspaces include: Project Schematic, Engineering Data, and Design Exploration (Parameters and Design Points).

You can also launch applications that are data-integrated with Ansys Workbench, meaning the application's interface remains separate, but the data from the application communicates with the native ANSYS Workbench data. Thus, data can be passed back and forth between any Ansys Electromagnetics product on a Workbench Project Schematic and any supported Ansys or Ansys Electromagnetics desktop product. Depending on the application, data integration can include basic actions such as saving projects, as well as more complex actions such as the coupling of Ansys Electromagnetics product variables to Workbench Design Exploration parameters.

Data-integrated applications include the following Ansys Electromagnetics products: Circuit, HFSS, Maxwell/RMxprt, Q3D Extractor, and Twin Builder.

Note	For detailed information on working with Ansys Workbench, please refer to the Workbench documentation.

Integrating Ansys Electromagnetics Suite Products with Ansys Workbench

You can integrate Ansys Electromagnetics products with Ansys Workbench in one of two ways:

- During product installation, or
- After product installation

Integration with Ansys Workbench during Ansys Electromagnetics Product Installation

You can choose to integrate Ansys Electromagnetics products with Ansys 2023 R1 during installation as follows:

1. If you have not already installed Ansys 2023 R1, do so before proceeding. Refer to the Ansys documentation for instructions on installing the Ansys 2023 R1 software.
2. Launch **Autorun.exe** or **Setup.exe** for the Ansys Electromagnetics product you wish to install.
3. Proceed through the installation dialogs.
4. When the **Integration with Ansys 2023 R1** dialog displays, select the **Yes** radio button to have the installer automatically integrate the Ansys Electromagnetics product with Ansys 2023 R1.

Note	If you choose not to integrate the product with Ansys 2023 R1 during installation, you can perform this step after installation.

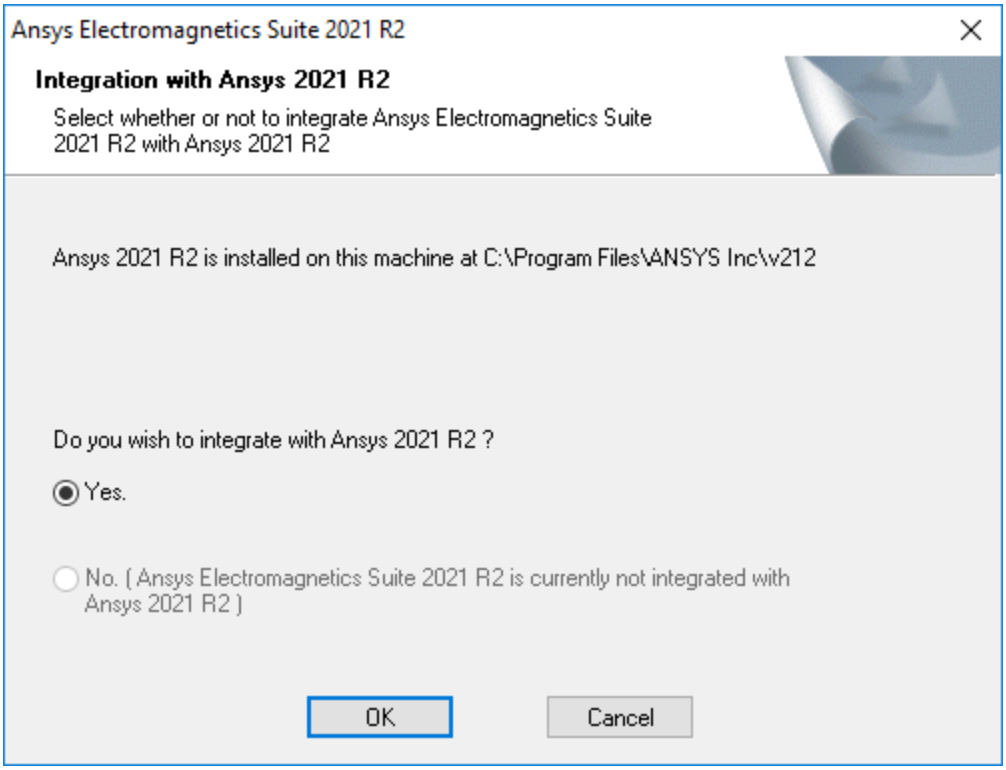
4. Complete the product installation and exit the installer.

Integration with Ansys Workbench after Ansys Electromagnetics Product Installation

If you want to integrate Ansys Electromagnetics Suite with Ansys 2023 R1 after installation, do the following:

1. From the **Start** menu, select **Ansys EM Suite 2023 R1** > **Modify Integration with Ansys 2023 R1**.
2. In the **Integration with Ansys 2023 R1** dialog box, ensure that the **Yes** radio button is selected, then click **OK** to complete the integration process. Then **OK** the information

dialog.



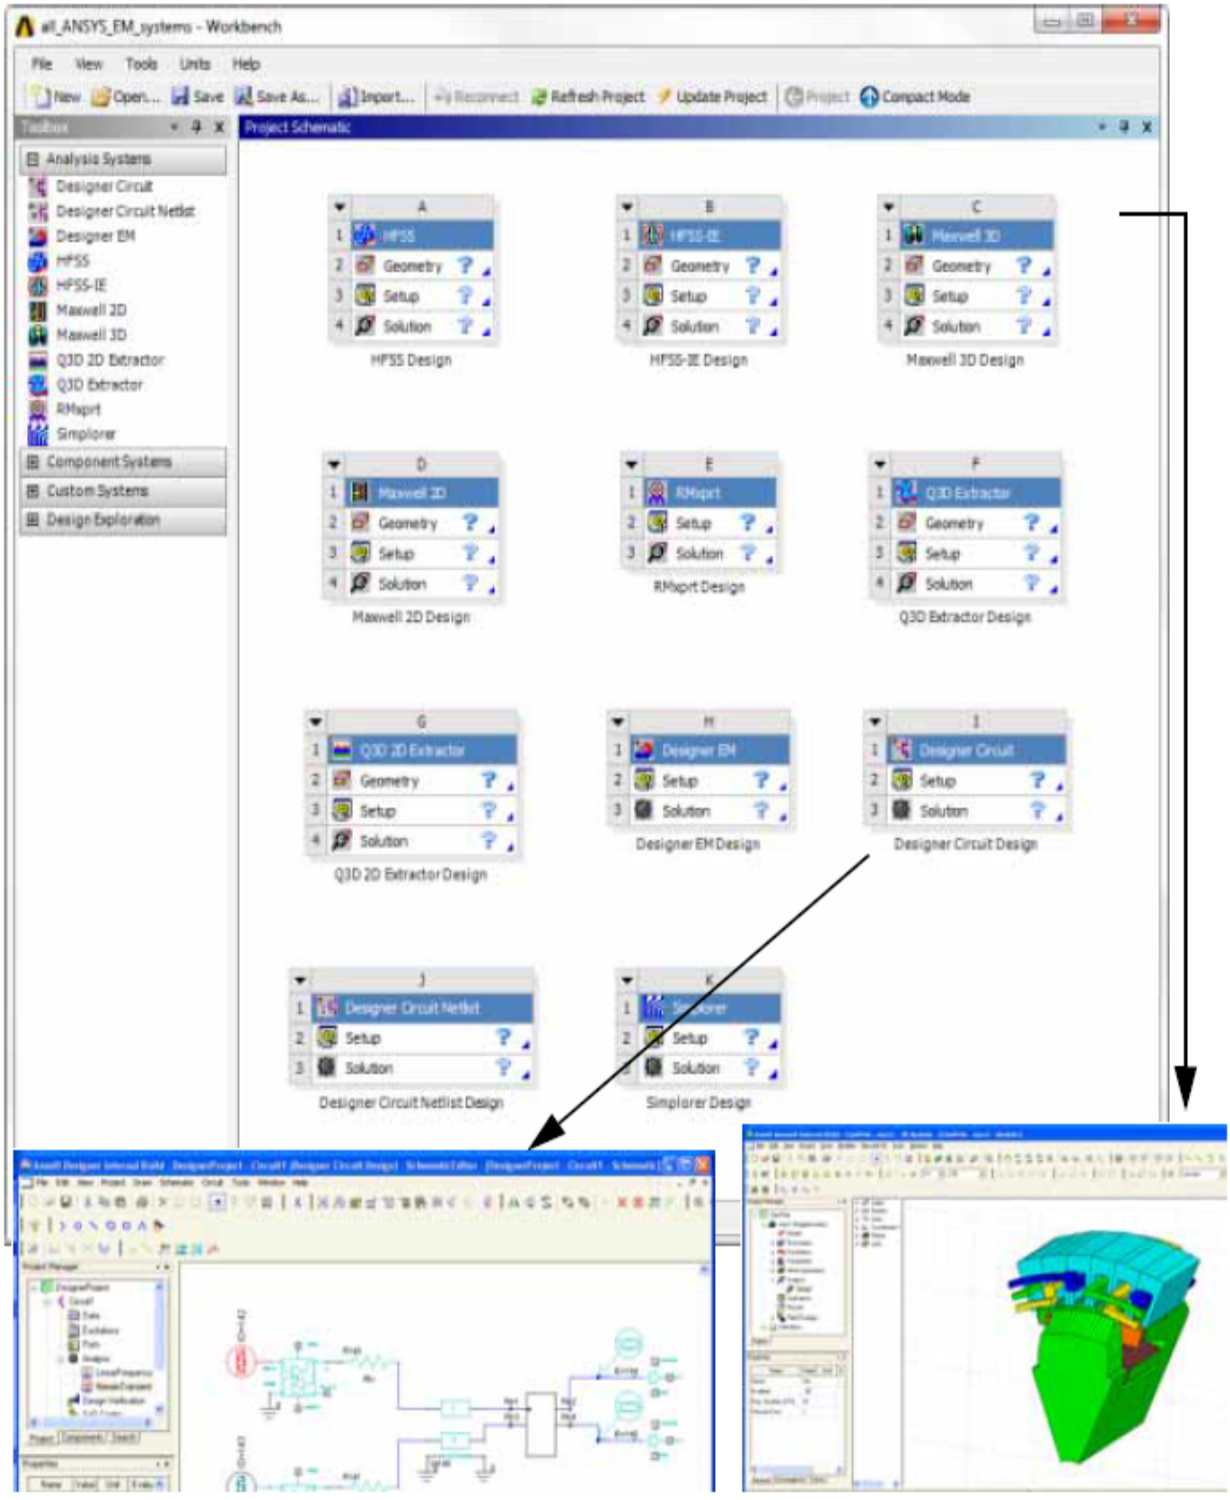
You can confirm that Ansys 2023 R1 is “aware” of the Ansys Electromagnetics Electronics Desktop application via the Ansys Workbench Options dialog box, which shows the Electronics Desktop install path.

The Journal Recording Language option permits you specify the default journal recording language.

- The default language is IronPython. You can change the recording language to VB.
- Changes in the recording language option apply to any Ansys Electromagnetics desktop launched after the change.
- Any open Ansys Electromagnetics desktop will continue recording in the language that was in effect when it was launched.

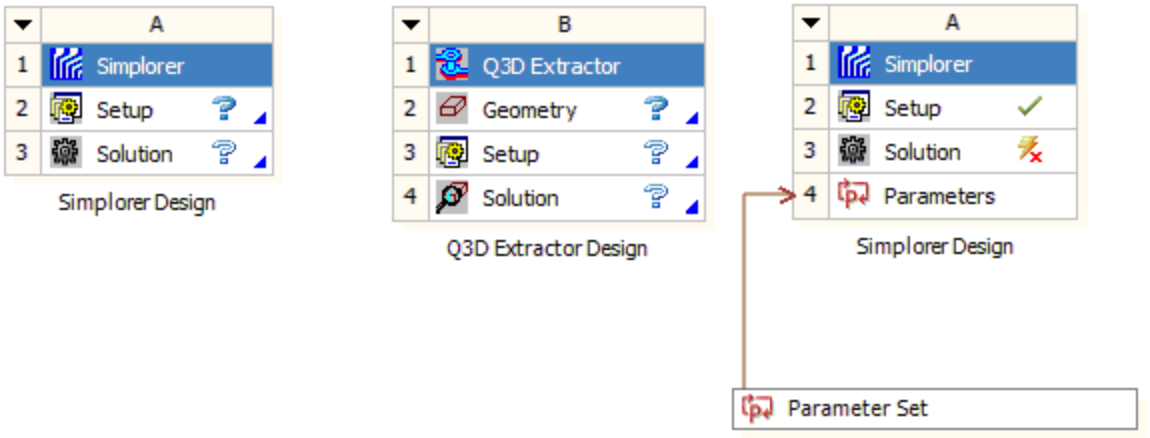
Workbench Data Integration Overview

Ansys Electromagnetics data-integrated applications can reside on a Workbench **Project Schematic** as shown below.



Objects, such as instances of Ansys Electromagnetics projects, that are placed on a Workbench Project Schematic are referred to as *systems*. Ansys Electromagnetics circuit/system products: RMxprt, Circuit, and Simplorer, appear on Workbench Project Schematics as systems with two

"cells" – **Setup** and **Solution**. Ansys Electromagnetics field products: HFSS, Maxwell, and Q3D Extractor add an additional **Geometry** cell. If you invoke Ansys **DesignXplorer** to use variables for refining a design, a **Parameters** cell is added with a link to the associated Workbench **Parameter Set**. Refer to the Ansys 2023 R1 Workbench help for details on working with systems, cells, and parameter sets.



Ansys Electromagnetics desktop products integrate with Workbench commands, services, and DesignXplorer in a similar manner. Here are some of the ways in which Ansys Electromagnetics products integrate with Workbench:

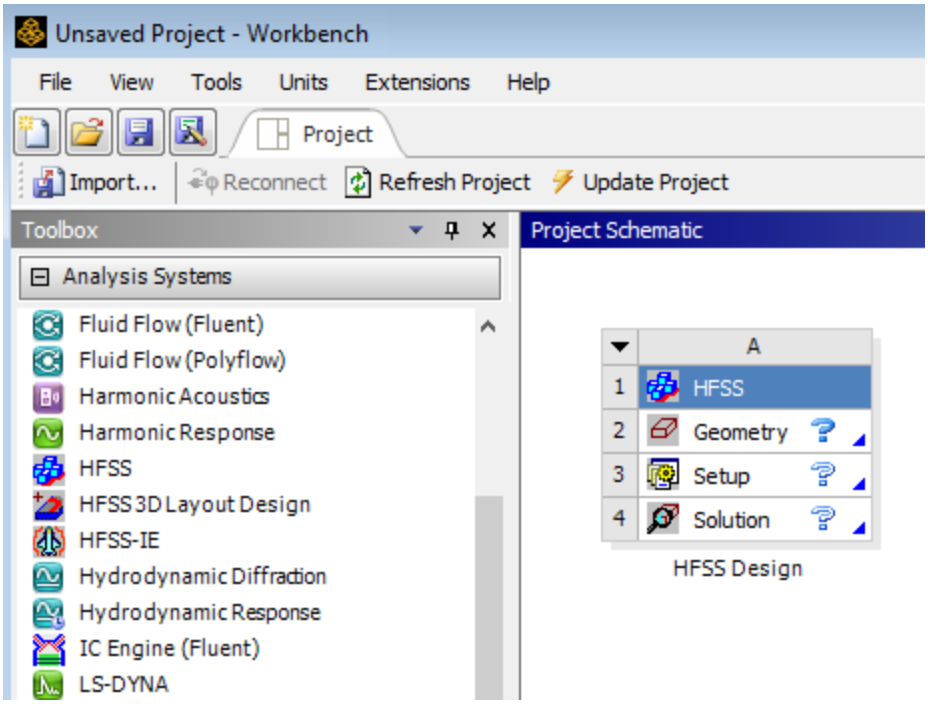
- Adding new analysis systems
- Importing existing desktop projects
- Editing models
- Analyzing models
- Performing parameter studies
- Scripting

In addition to these major features, Workbench also allows you to Archive, Save, Backup, Duplicate, and Delete Ansys Electromagnetics projects used in a Workbench project. Progress information and messages from integrated Ansys Electromagnetics projects are also displayed in Workbench.

Note	Detailed information for using these operations can be found in the Ansys Workbench help.

Adding New Ansys Electromagnetics Analysis Systems

A new Ansys Electromagnetics Analysis System can be added to a Workbench Project Schematic either by dragging and dropping it from the Toolbox:



or by selecting it from the context menu in the Workbench Project Schematic window:

Adding New Ansys Electromagnetics Analysis Systems

Importing Ansys Electromagnetics Projects into Ansys Workbench

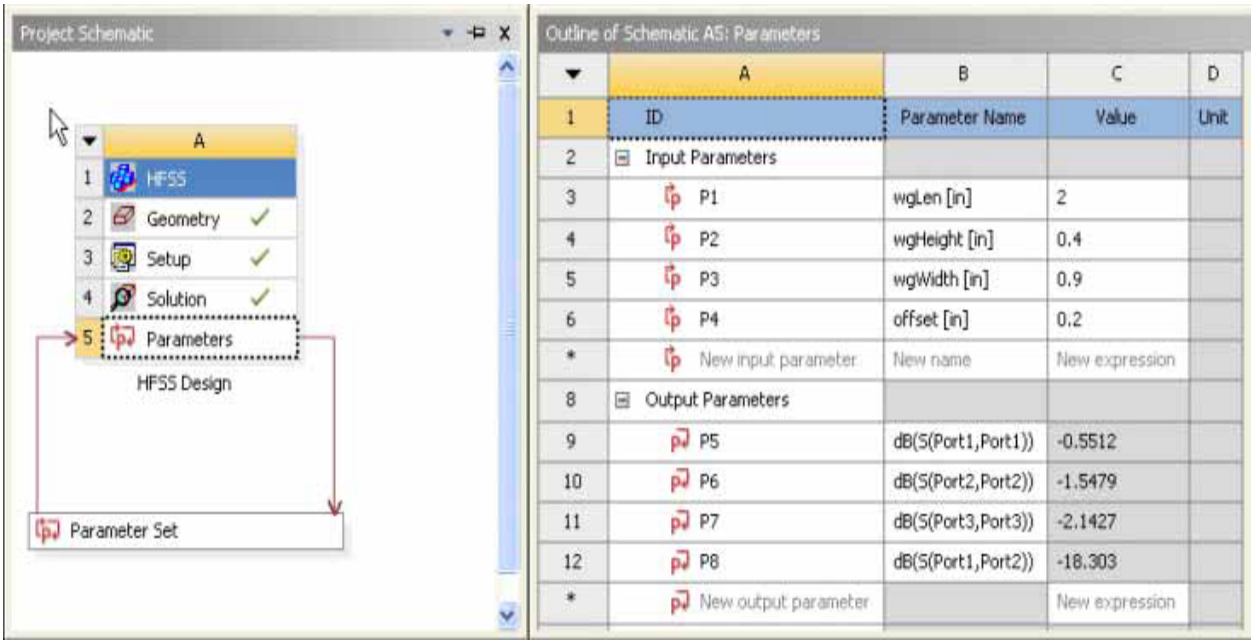
Editing Ansys Electromagnetics Models in Workbench

Performing Parameter Studies in Workbench

Scripting in Workbench

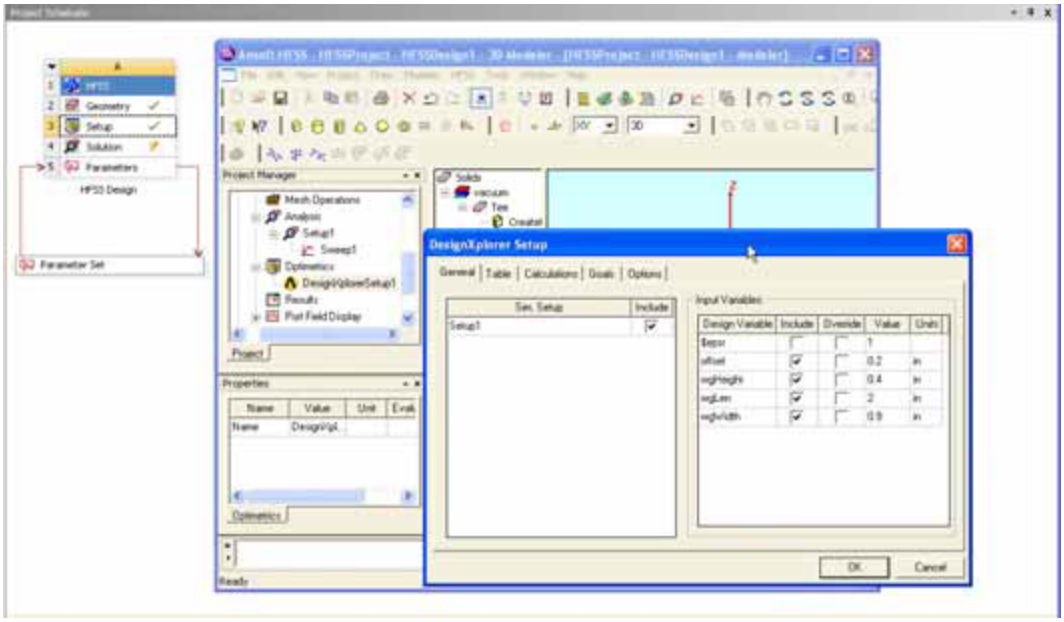
Performing Parameter Studies in Workbench

Workbench **Parameter Sets** allow you to change parameter values and units of measure, or add new parameters. Parameter data is passed back to the Ansys Electromagnetics application for updated analyses. After analysis, the Workbench Parameter table should be updated correctly for all design points.



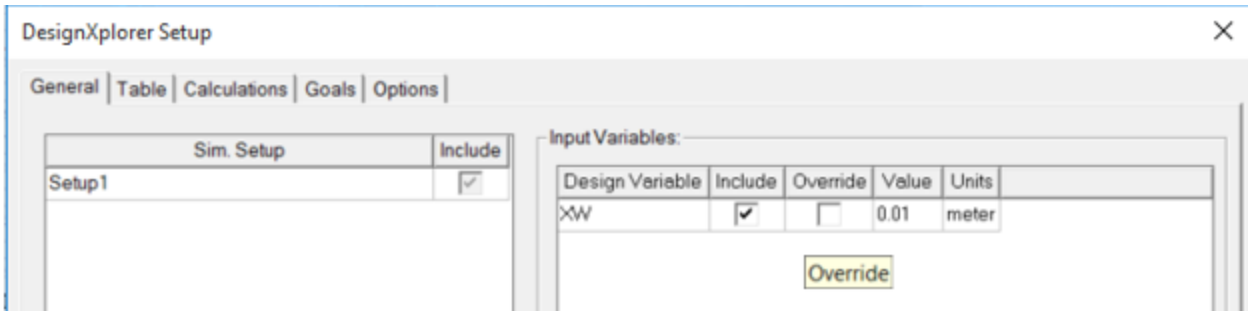
Note	Because Workbench and Ansys Electromagnetics Desktop have different unit systems, units defined in Desktop are Dimensionless in the Workbench Parameters table and thus cannot be changed. Refer to the *ANSYS Design Modeler User's Guide* > *Project Schematic Operations* > *Parameters in Project Schematic* > *Parameter Units* topic for additional information.

Parameters from the Ansys Electromagnetics project are exposed to Workbench through the **DesignXplorer** setup. The Ansys Electromagnetics system's cell status on the Workbench project is updated as changes are made in the Ansys Electromagnetics application desktop.

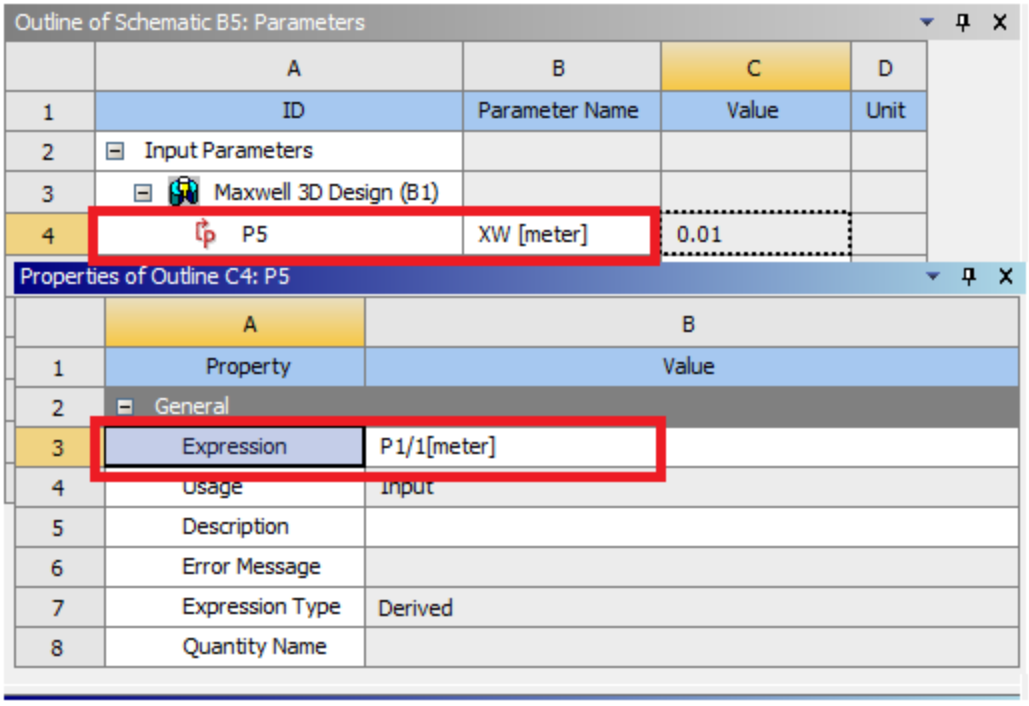


The workflow for using Electronics Desktop systems with the Workbench to take advantage of Distributed Analysis is as follows.

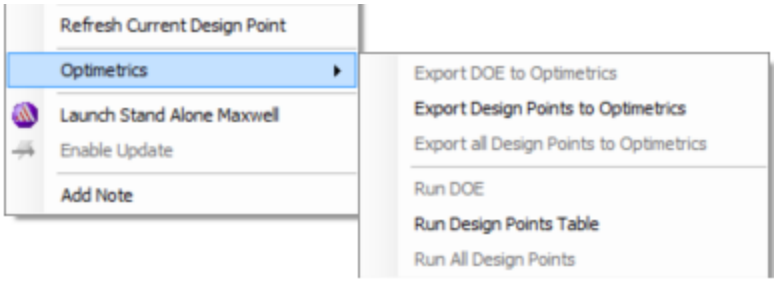
1. In the Ansys Electronics Desktop, specify a variable an as input parameter. The following figure shows a DesignXplorer Setup that includes a geometry variable called XW This variable is mapped to a variable in the corresponding Workbench Design, in this example, P5.



2. In the Workbench Design, change the P5 expression to a new value (in this example figure, the P5 parameter is assigned and expression of P1/1[meter] to tie it to the geometry system's variable.



In the Workbench, the **Export Design Points to Optimetrics** and **Run Design Points Table** commands are enabled.



3. In the Electronics Desktop, you can click on the default DesignXplorer Setup, and choose **Generate Variation Data**.

   If you have configured your Analysis Configuration for multiple machines, the Project is ready for Distributed Analysis. After analysis, the Workbench Parameter table should be updated correctly for all design points.

Ansys Electromagnetics - Ansys Multiphysics Coupling

Data integration provides improved multiphysics workflow between Ansys Electromagnetics designs and Ansys applications such as Mechanical and Thermal. Coupling is provided through project schematic links. Heat losses and force data are automatically transferred to Ansys Mechanical - there is no need to export/import “transfer xml files”. Edits you make in Ansys Electromagnetics applications are automatically transferred to the Ansys application through a Workbench **Refresh** command. Workbench commands also enable easier automation of iterative coupling of thermal feedback. The following sections provide some examples of multiphysics coupling.

Multiphysics Coupling on Workbench with Ansys Thermal

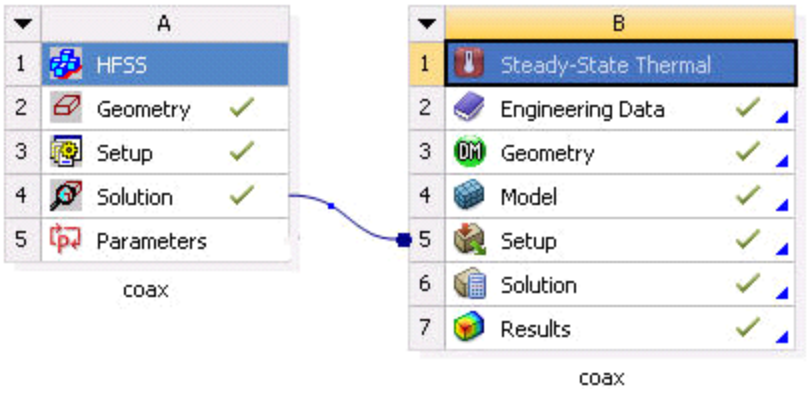
Multiphysics Coupling on Workbench with Ansys Structural

Multiphysics Coupling between Ansys Electromagnetics Field Systems on Workbench

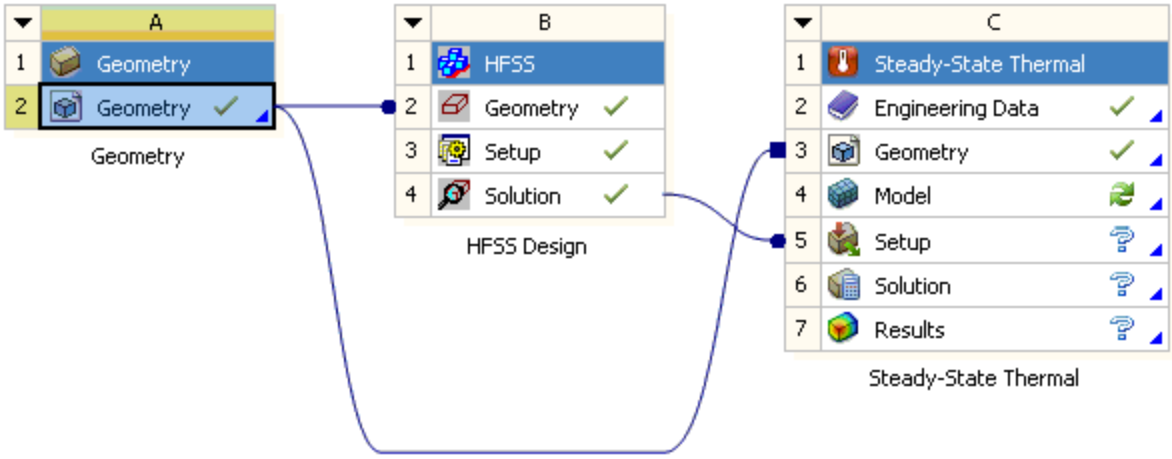
Multiphysics Coupling on Workbench with ANSYS Thermal

Using data integration, HFSS, Maxwell, and Q3D Extractor provide heat losses (heat generation and heat flux) to Ansys Thermal. You first need to enable feedback as described in Setting the Temperature of Objects.

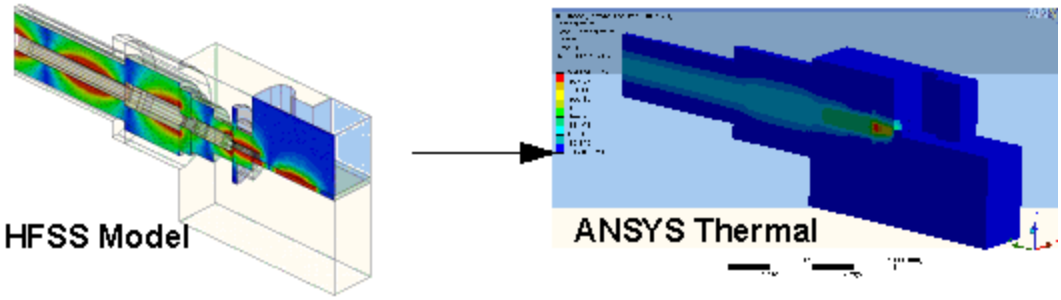
Note how the HFSS design is linked visually to ANSYS Thermal on the Workbench project schematic.



A geometry from the Component Systems in the Toolbox in Workbench Schematic can be shared as shown in the image below.



In this example, HFSS coax model Solution provides heat loss data as a thermal load to the Ansys Thermal Setup. The resulting analysis shows a thermal “hotspot”, providing the user with the information needed to adjust the design’s material to fix the problem.



You enable this feature by checking Enable Feedback in the dialog for Setting the Temperature of Objects.

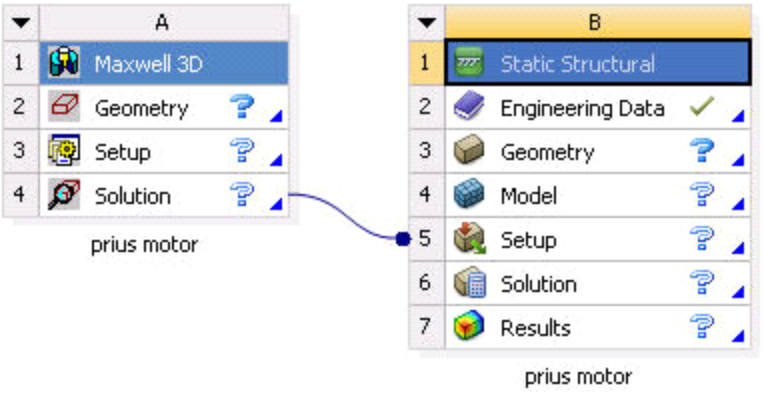
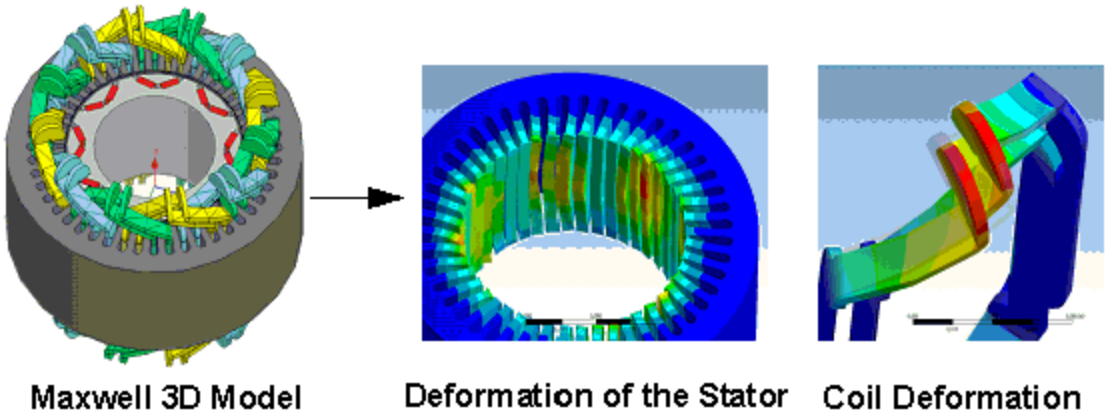
Feedback Iterator

Multiphysics Coupling on Workbench with Ansys Structural

Using data integration, Maxwell 2D and Maxwell 3Dcan provide forces to Ansys Structural.

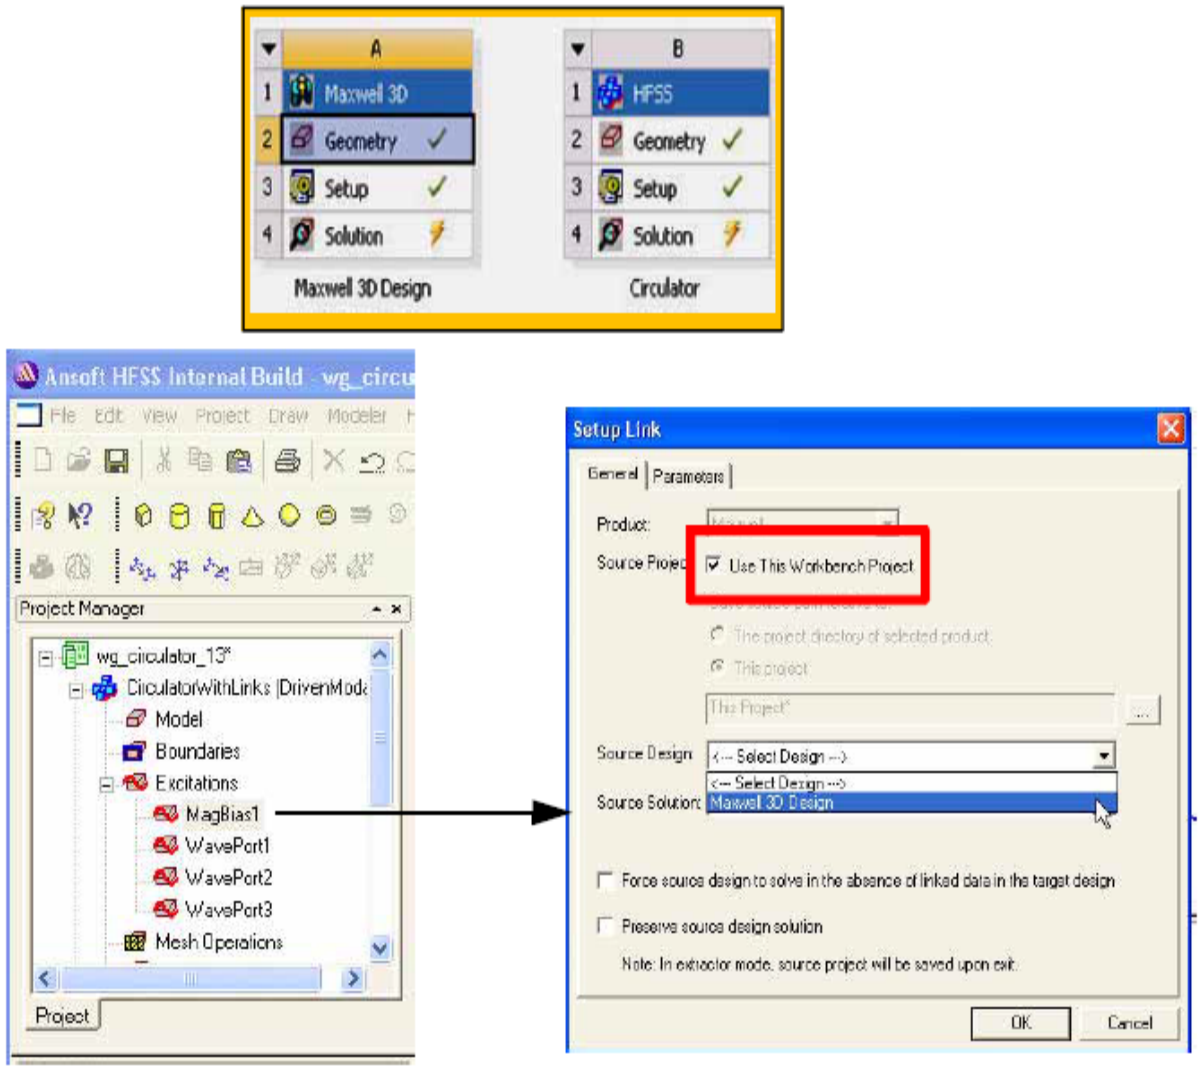


In this example, the Maxwell 3D electromagnetic force density **Solution** is used as the load in Ansys Structural to determine how these forces deform the motor's stator and coils.



Multiphysics Coupling between Ansys Electromagnetics Field Systems on Workbench

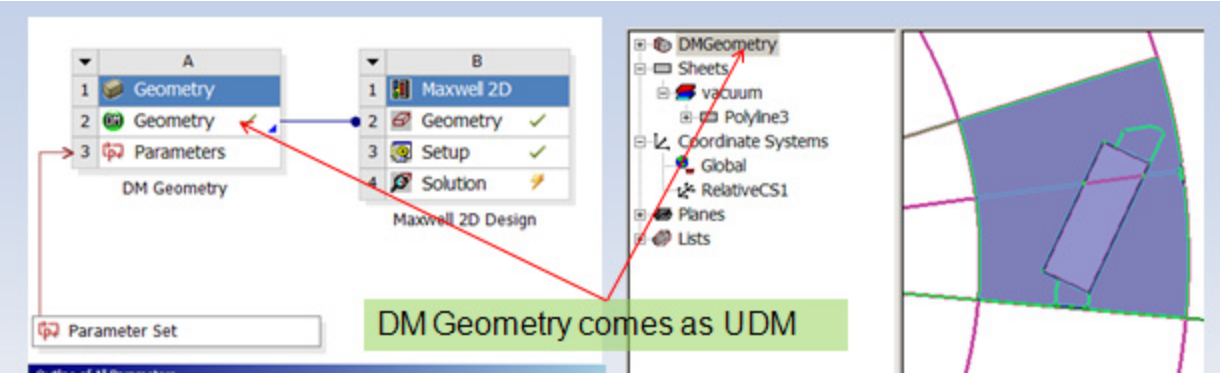
You can setup links between Ansys Electromagnetics field systems that reside on a Workbench project schematic. Linking is setup in the Ansys Electromagnetics application as shown in the following example.



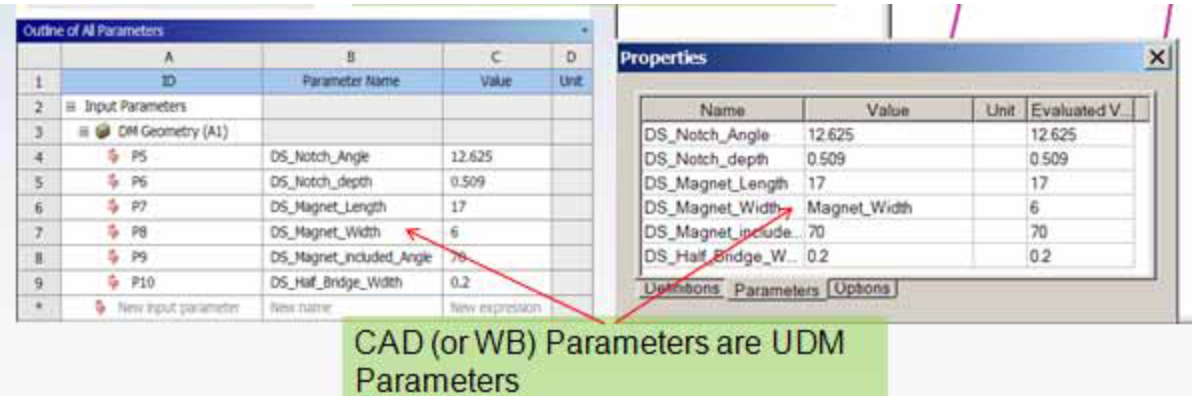
CAD Integration through Workbench

Ansys Electromagnetics CAD integration is a Workbench feature available for Ansys Electromagnetics 3D Products - HFSS, Maxwell, and Q3D as the Ansys Framework for Ansys Electromagnetics package. This feature is available only through Workbench, and is not available in standalone Ansys Electromagnetics products.

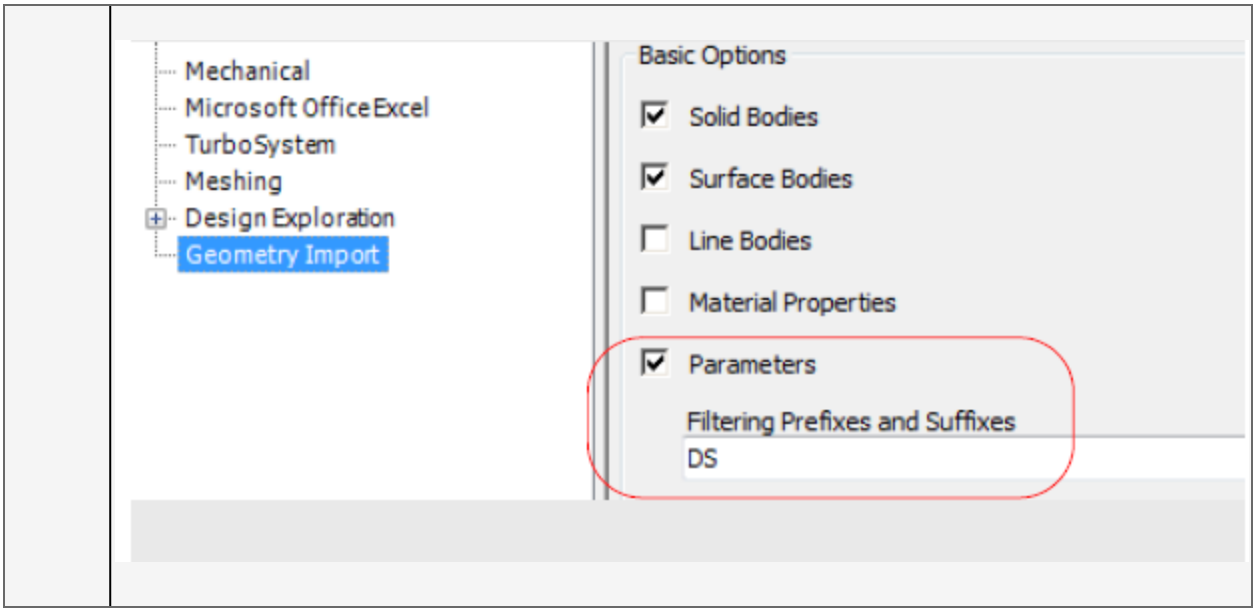
Ansys Electromagnetics CAD integration provides a bi-directional dynamic link through Workbench, which makes it possible to get updated geometry from CAD, to modify the CAD parameters in Ansys Electromagnetics products, and return updated geometry. The feature is non-associative due to a need to reassign boundaries if the modified CAD model is to be used. The process creates a User Defined Model (UDM) for each geometry source



The User Defined Model (UDM) format makes it possible to exchange parameters.



Note	The parameters shown in the previous example all have a **DS** prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import.** If you want to import parameters with different prefixes or names, you should assign an appropriate prefix, or clear the Filtering Prefixes field, depending on your needs.



See here for further description of the UDM feature and function.

Ansys Electromagnetics CAD integration makes it possible to consume geometry from multiple upstream source which can be any CAD or Ansys Electromagnetics product. This feature supports direct interfaces with all major CAD systems.

- Creo Parametric
- UG NX
- CATIA V5
- SOLIDWORKS
- Autodesk Inventor
- Ansys Design Modeler (DM)
- Ansys SpaceClaim Direct Modeler (SCDM)

CAD software must be installed on user machine

- Not required on solve nodes

Platforms Supported

- Windows 64 bit
- Linux

See the following sections:

CAD Integration and Geometry Sharing

Bi-Directional CAD Integration

CAD Integration Model Edits

Multiple Geometry Links for CAD Integration

CAD Integration Functionality

Healing with CAD Integration

Important Geometry Options for CAD Integration

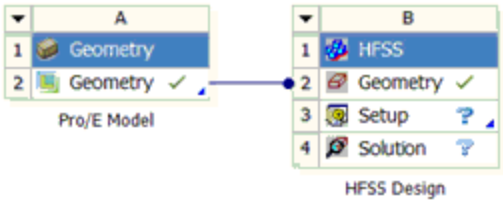
CAD Integration and Geometry Sharing

CAD model comes into Ansys Electromagnetics as User Defined Model (UDM).

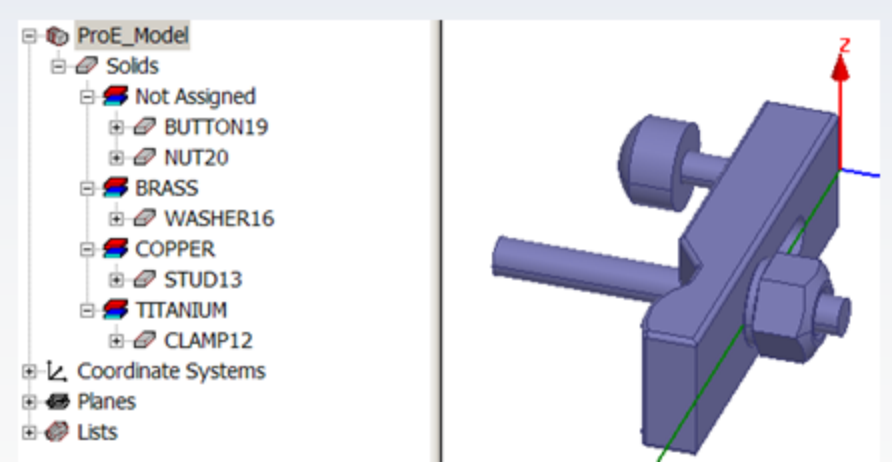
The input to Ansys Electromagnetics from CAD is:

- Geometry/Topology with persistent IDs
- CAD parameters
- Material assignment
- Attributes like name, and color

For example, in Workbench, a Pro/E Model can be linked to HFSS.



The geometry can then be viewed in HFSS as a UDM.

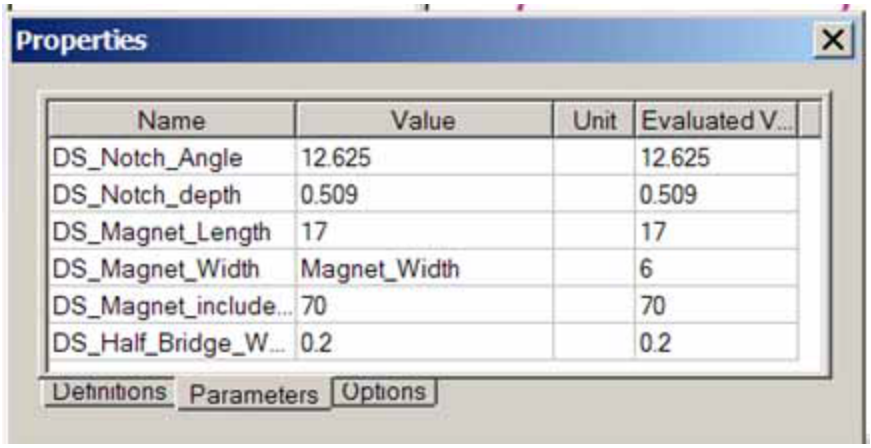


The CAD or WB model parameters appear in the Workbench:

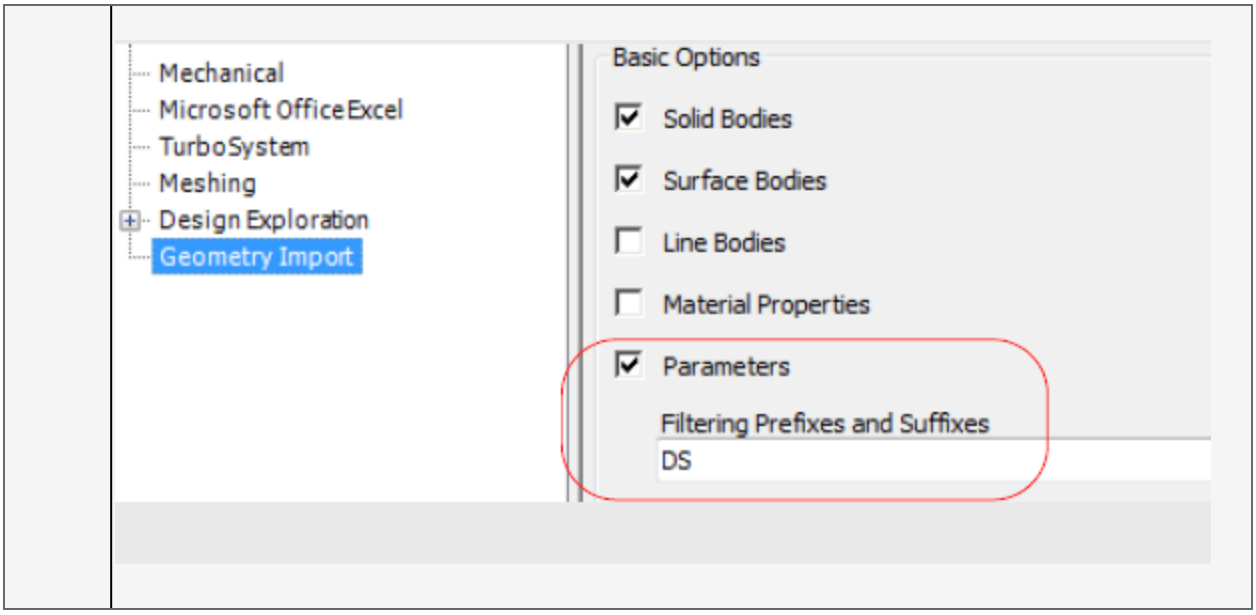
Outline of All Parameters

	A	B	C	D
1	ID	Parameter Name	Value	Unit
2	Input Parameters			
3	DM Geometry (A1)			
4	P5	DS_Notch_Angle	12.625	
5	P6	DS_Notch_depth	0.509	
6	P7	DS_Magnet_Length	17	
7	P8	DS_Magnet_Width	6	
8	P9	DS_Magnet_included_Angle	70	
9	P10	DS_Half_Bridge_Width	0.2	
*	New input parameter	New name	New expression	

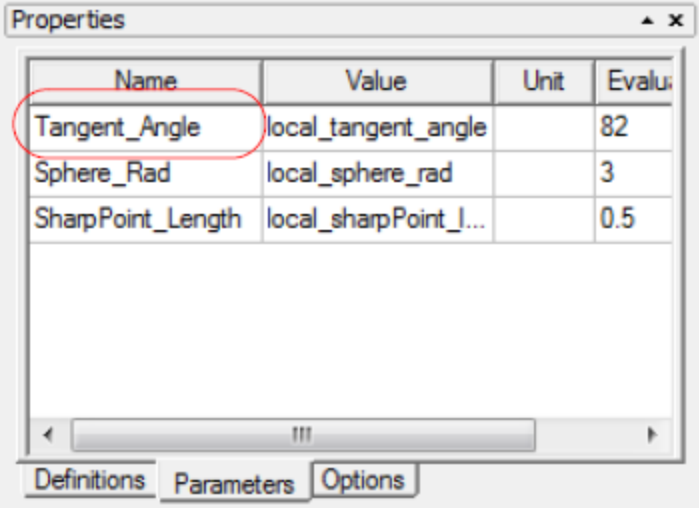
Though the Ansys Electromagnetics CAD Integration, the linked UDM includes the same parameters.



Note	The parameters shown in these examples all have a “DS” prefix. This is the default for the Workbench **Tools>Options** for **Geometry Import.** If you want to import parameters with different prefixes or names, you should assign an appropriate prefix, or clear the Filtering Prefixes field, depending on your needs.



Once you import a geometry with parameters to an Electromagnetics application in the desktop, you need to map them to local variables. That is, in the target Electromagnetics application, select the geometry associated with the parameters. Update the geometry, and view the Parameters tab in the Property window. The Values column will show the values of the imported parameters. You then type names for local variables in the values column.



Once you have local variables for the imported Design Modeler parameters, you are ready to use Design Xplorer for multiple design parameters.

Table of Schematic D2: Design of Experiments (Custom)

	A	B	C
1	Name	P3 - Tangent_Angle (degree)	P4 - Sphere_Rad (in)
2	1	80	3
3	2	75	3
4	3	85	3

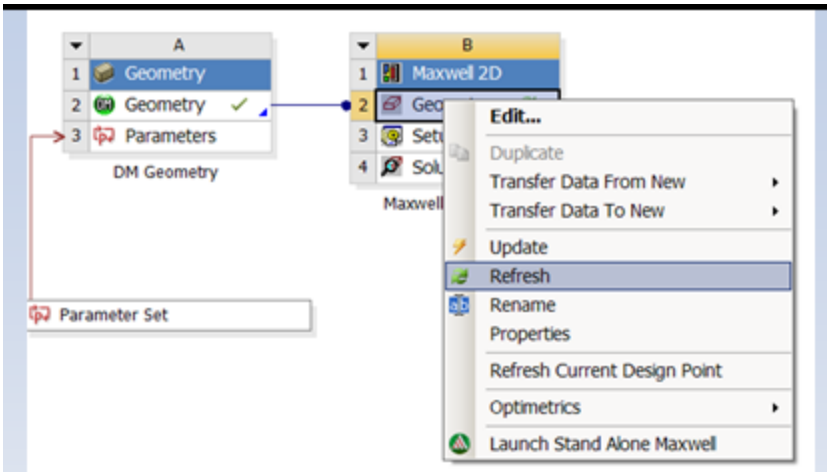
Important Geometry Options for CAD Integration

Bi-Directional CAD Integration

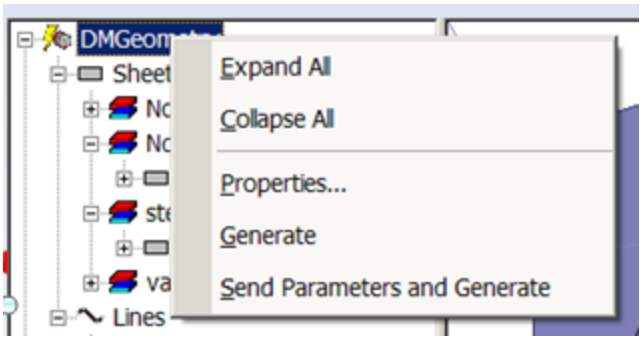
Ansys Electromagnetics CAD Integrations uses Refresh (or Generate) CAD Model to pass updates.

For example, you can make an edit in a CAD application and either run **Refresh** on an Ansys Electromagnetics Geometry Cell or run **Generate** on the UDM in the Ansys Electromagnetics window



Refresh pulls the current state of CAD model (geometry, parameters, materials etc) and updates the corresponding data in the Ansys Electromagnetics application.

If you edit UDM (CAD) parameters in the Ansys Electromagnetics modeler window you can run the **Send Parameters and Generate** command



The command passes the edited parameters to the linked CAD application and then pulls corresponding CAD geometry.

CAD Integration Model Edits

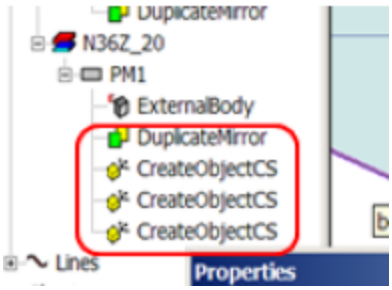
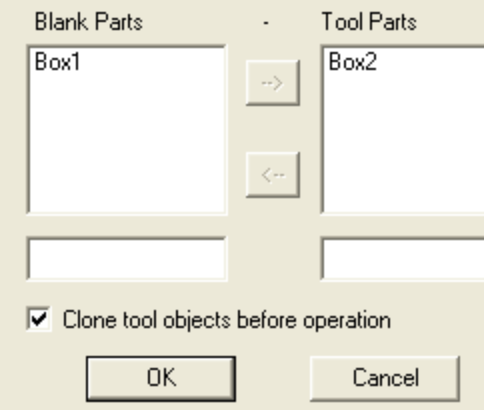
Several modeling operations are allowed on a CAD model in the Ansys Electromagnetics Modeler window. Operations will included in the History tree and retained during model **Refresh**.



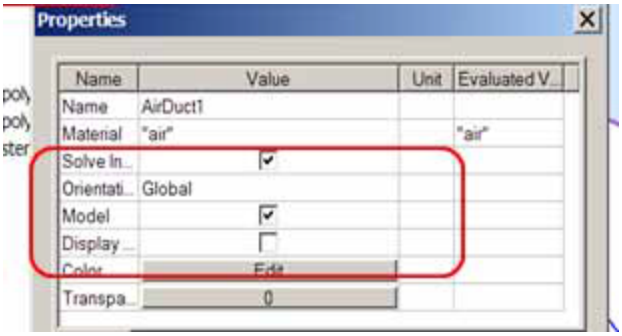
The following operations are not allowed:

- Non-history tree operations like Heal or defeature.
- Operations which use UDM parts as Tool such as Sweep, or Boolean operations like Split or Unite (but allowed when you select the clone tool option).



The following part attributes can be modified for UDM parts.

- Model/Non Model flag
- Solve Inside flag
- Part orientation
- Color
- Display Wireframe



It is not possible to delete individual parts of UDM

Important Geometry Options for CAD Integration

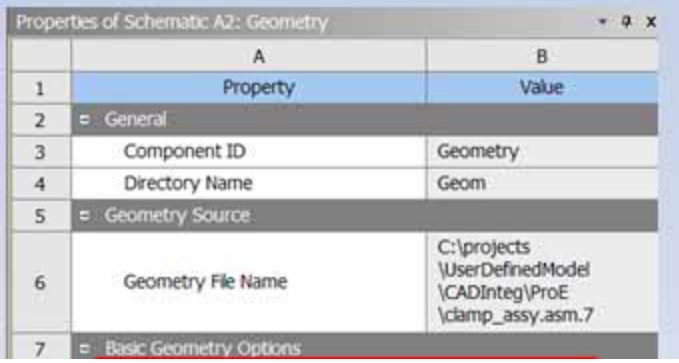
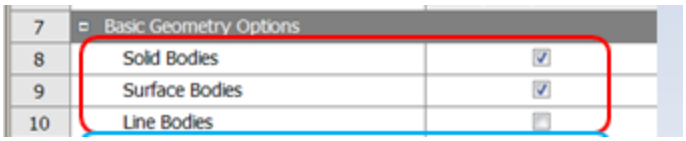
Select a Geometry Cell in Workbench to see options in Properties window.

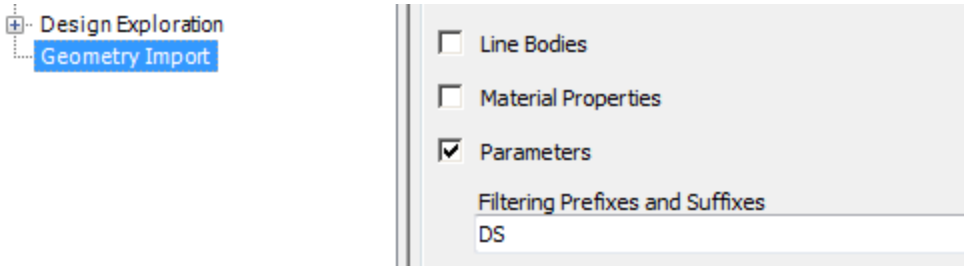


- Control dimension of bodies coming from CAD



- Make sure parameters is checked and parameter key (filter) is appropriate to bring CAD parameters.

This (default) parameter key filtering means that only parameters whose names start with DS will come through. Notice that the Parameter Key value (default DS) is set via the Workbench **Tools>Options...** dialog box, under Parameters, in the Filtering Prefixes and Suffixes field.



- Attributes key should be empty or Color to bring in CAD Colors

- Material properties must be checked to bring in the material assignment.

- The Mixed import resolution option is used to resolve parts with mixed dimension (typically from Pro/E)

Refer to Ansys Workbench Help for details.

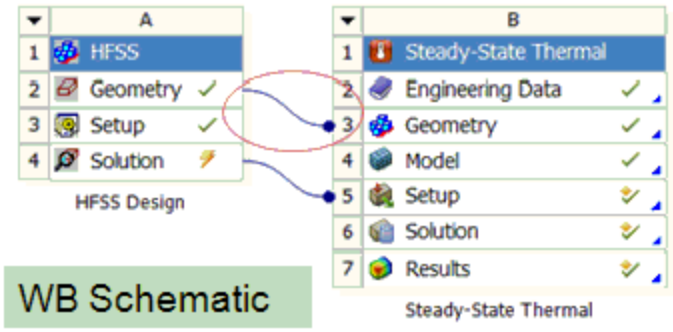
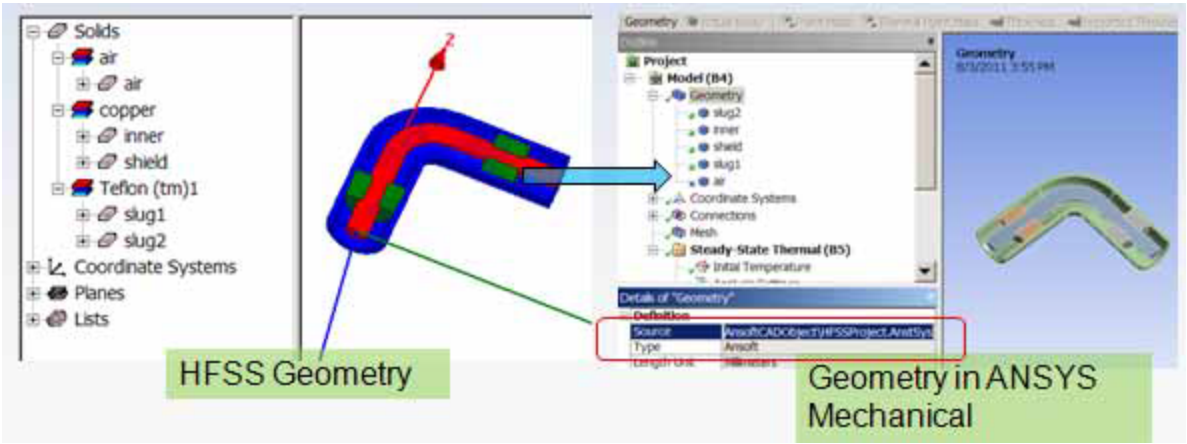
Ansys Electromagnetics to Ansys Geometry Transfer

Ansys Electromagnetics CAD Integration transfers model information based on Workbench links.

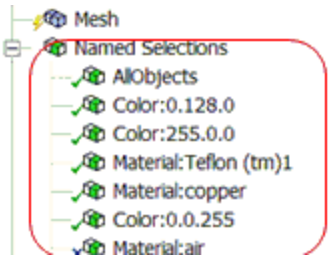


The following figure shows how the information is transferred between simulators.

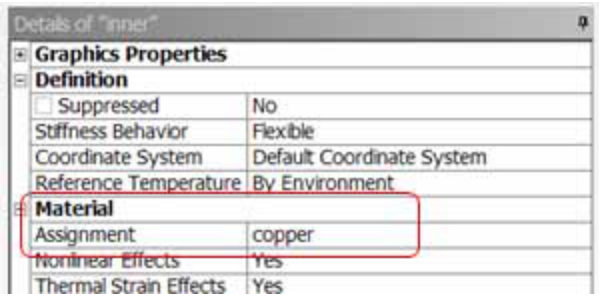


The information transferred includes:

- Geometry
- Ansys Electromagnetics lists and material assignment as Named Selection



- Material assignment



The CAD Integration geometry link is

- Dynamic because you can get updated geometry from Ansys Electromagnetics
- Associative because IDs persist between Ansys Electromagnetics model and Ansys model during model refresh.

  Boundary conditions in Ansys are preserved.

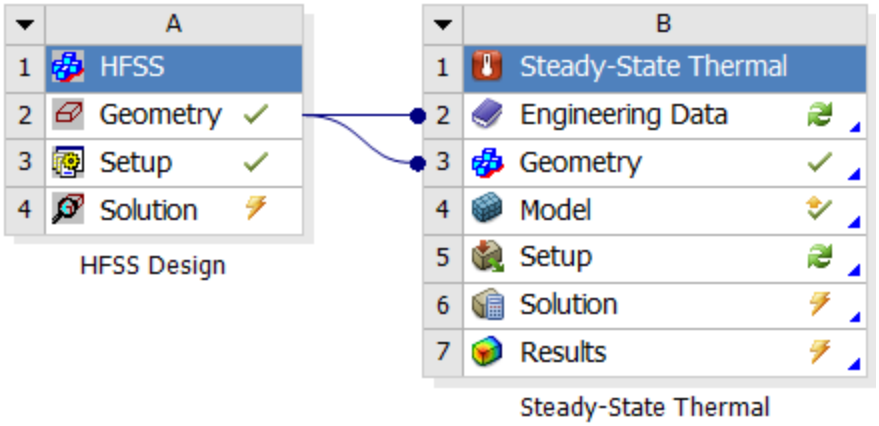
Workbench Material Data Transfer

A link can now be created from an Ansys Electromagnetics Desktop project (HFSS, Maxwell, etc.) geometry cell to a downstream Engineering Data (ED) cell. When the downstream ED cell is refreshed, it will be updated with materials data (names and properties defined in the upstream project) that are used by the upstream project. This ensures that the geometry-to-geometry link connecting the same two systems, which specifies the material assignments for various parts, refers to the correct materials and their properties.



Detailed Behavior

The geometry-to-ED link can be created, for example, by dragging the Ansys Electromagnetics Desktop project geometry cell to the ED cell of a downstream system. When the downstream system's ED cell is refreshed, the upstream system generates a MatML formatted XML file which is used by Workbench to update the downstream system. This file is stored in the workbench project files according to design point. Note that Workbench ED cell material names are case-sensitive, as are material names within the Ansys Electromagnetics Desktop designs.

For the material assignments to work with the ED in the downstream model, the downstream geometry cell must have the **Material Properties** checkbox selected/checked. A convenient way to do this is to have this property checked by default, by setting it in **Tools>Options>Geometry Import**. Designs created after this default option is set will have Material Properties checked automatically for the geometry cell.

When the downstream model cell is refreshed or updated, the material properties from the ED in the same system are used in the model's materials, based on the material assignments set during the geometry cell refresh. Note that if material assignment fails, the Workbench default material Structural Steel will be used.

Workbench resolves name conflicts by changing the name of any materials being transferred over from the upstream system. For example, if the upstream Ansys Electromagnetics Desktop design uses a material named “Structural Steel”, this will conflict with the existing downstream default material with the same name. The update will result in the Ansys Electromagnetics Desktop material being named “Structural Steel 2", which will silently break the material assignment, because the resulting model will refer to "Structural Steel" as it originally did, and use the default workbench property values, instead of using the properties which were supplied by Ansys Electromagnetics Desktop. If this occurs, rename the material in the Ansys Electromagnetics Desktop project (in such a way that there is no more conflict), reset the downstream ED cell, reset the downstream geometry cell, and then refresh those cells in the downstream system.

Note that some materials may not satisfy all of the requirements for the downstream system physics. For example, vacuum has no thermal conduction coefficient, but downstream steady state thermal systems require a non-zero value for this property. Material properties in the Workbench ED cell of the downstream system can be edited/modified after the refresh to ensure that validity criteria can be met. Any property added to a material in the downstream ED will be preserved in subsequent ED cell updates. However, any existing property (i.e., a property that was given by the upstream system material definition) that is edited in the downstream ED will be overwritten by a subsequent ED cell update.

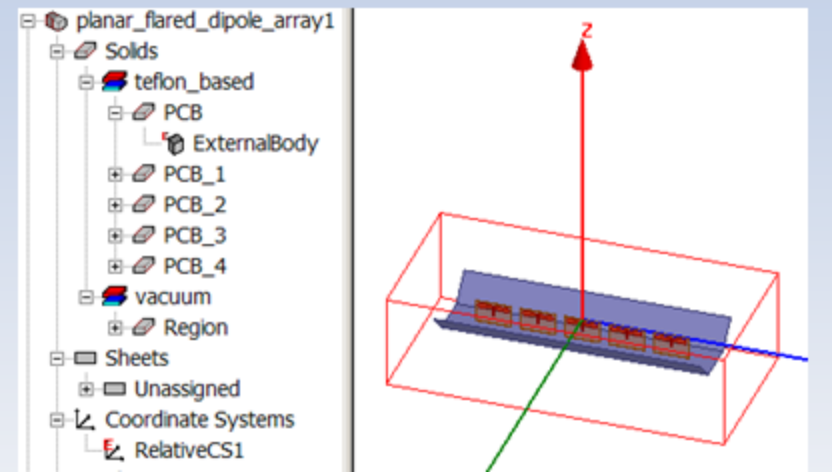
User Defined Model (UDM)

A User Defined Model (UDM) is collection of externally defined parts imported into an Ansys EM 3D Modeler or created using a C or Python script.

- UDM includes part attributes (like name, color etc) and material assignment
- UDM can also have external coordinate systems and corresponding planes
- UDM parts can be parameterized and manipulated in Ansys Electromagnetics modeler just

like any other part



UDM can either represent Static geometry models or

- Dynamic links to models of external geometry editors
- Used for supporting CAD integration in WorkBench

  UDM uses same plugin technology as User Defined Part (UDP)

UDM compared to User Defined Primitives

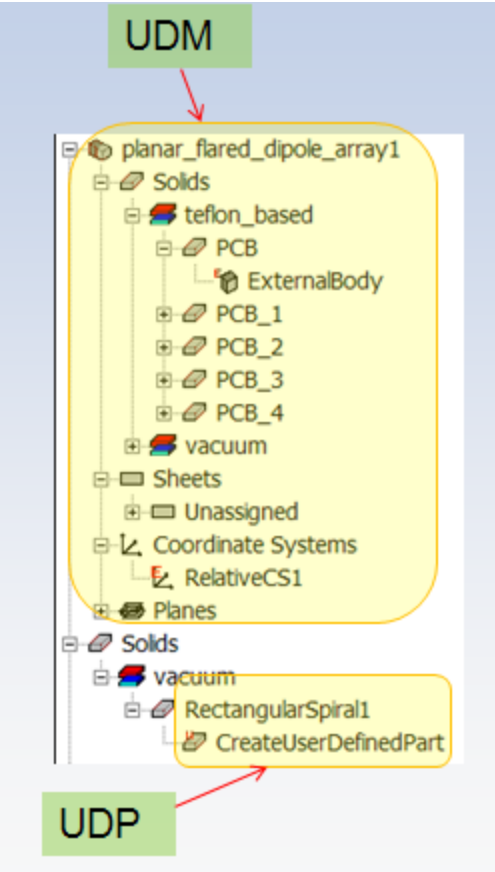
User Defined Models (UDM) resemble User Defined Primitives (UDP):



- Ansys Electromagnetics products can be extended by users through new UDMs.
- UDM plugins are discovered by searching standard directory paths.
- Plugins for static UDM can build model using 'callback interfaces' (like create-box, create-cylinder, subtract etc) similar to UDP.
- UDMs run inside Ansys Electromagnetics application.
- UDMs provide geometry, topology, persistence and parameters.

In contrast to UDP:

- UDM provides multiple Parts/CS/etc.

  UDP provides primitive operation only for a single Part.
- UDM provides part attributes and material assignment.

  UDP does not define part attributes or material.

UDM Properties have four tabs – Definitions, Parameters, Options and Info.

- Definition tab has:

  UDM name

  Coordinate system used to position UDM

  May have external reference to file
- Info tab has:

UDM dll name, dll location, version etc.

- Option tab:
  may have options

UDM Parameters

UDM geometry can be manipulated through its parameters

- Can be mapped to design or project variable for animation, parametric analysis
- IDs are persisted (allowing to retain boundaries) during parameter edit

UDM geometry is not dynamically updated upon parameter edits

- UDM shows a lightning bolt icon by the model name when parameters are edited.

- You must run the **Send Parameters and Generate** command to synchronize parameters with geometry

UDM Properties

UDM Part Edits

UDM Part Edits

Several modeling operations are allowed on UDM parts

- Operations will be part of history tree and retained during model refresh

The following operations are not allowed

- Non history tree operations like healing, defeature.
- Operations which use UDM parts as tool, such as sweep or boolean (but allowed when clone tool option is selected)

Following part attributes can be modified for UDM parts

- Model/Non Model flag
- Solve Inside flag
- Part orientation

Related Topics

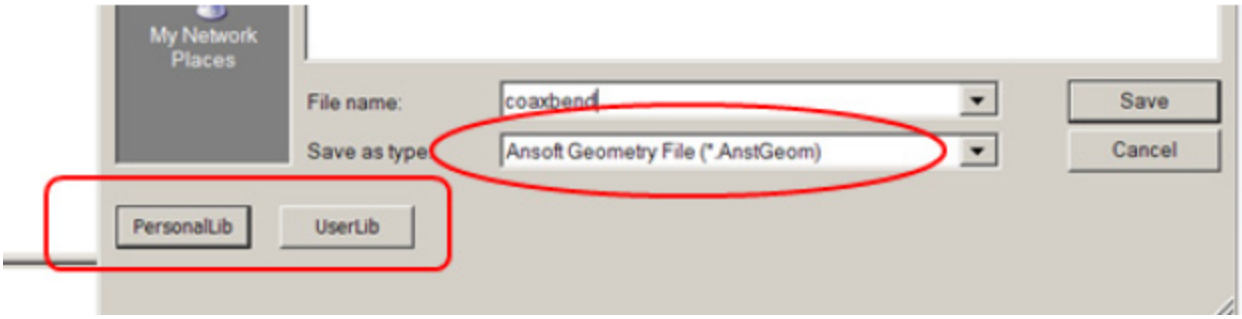
UDM Properties

UDM Parameters

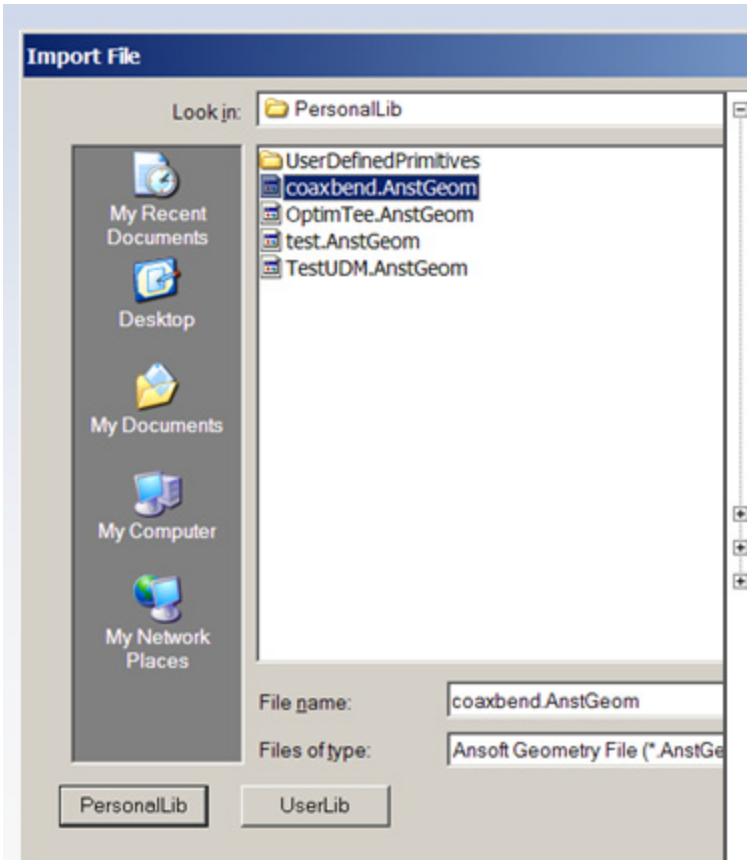
Library of Models for CAD Integration

UDM technology allows library of models

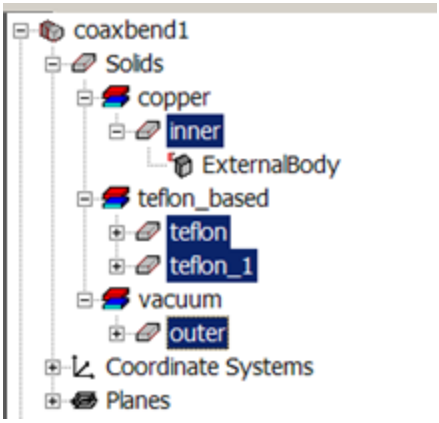
- Any Ansys Electromagnetics model can be exported as ‘Ansoft Geometry File’



- An Ansoft Geometry File can be imported back as a UDM.



- Any Design/project variables associated with model are brought in as UDM parameters.



Geometry computation for UDM (and also UDP) can be specified in the Modeler options as either done on.

- Engine side (default):

  Requires deployment of UDM on each node
- Desktop side:

  UDM need not be deployed on each engine

  Desktop will be busy during parametric analysis

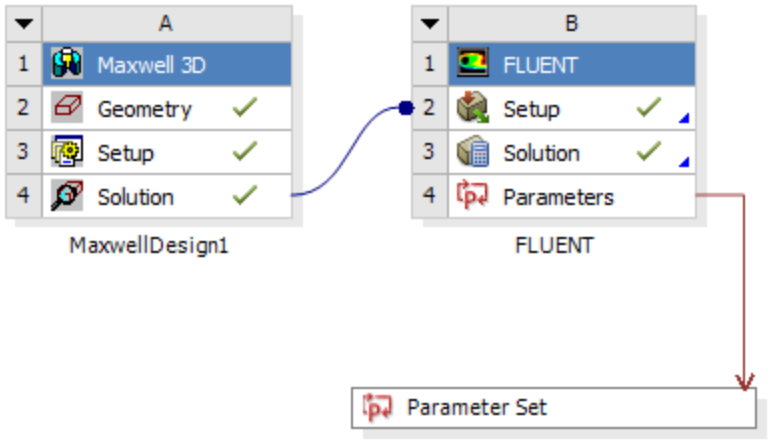
Feedback Iterator

Background Information

Prior to the introduction of the Feedback Iterator, ANSYS Workbench supported a two-way loose-coupling protocol with Ansys Electromagnetics products.

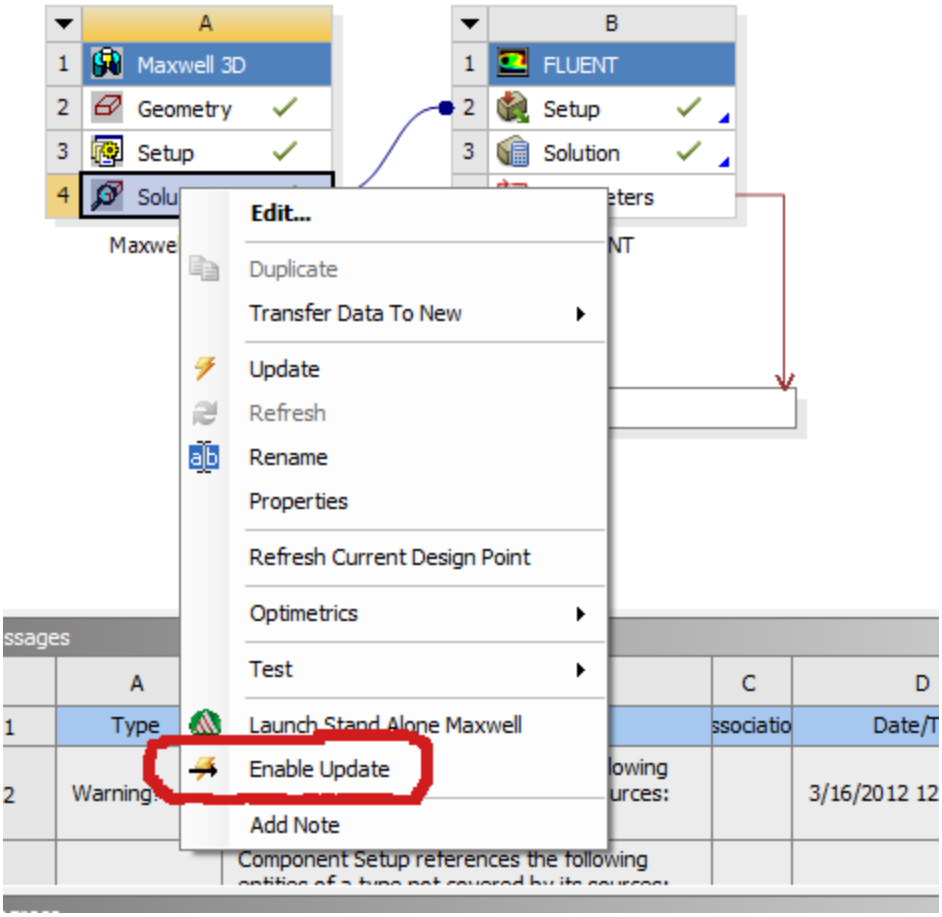
- System Coupling uses the word “coupling” to mean low-level solver coupling. Existing Ansys Electromagnetics coupling is “loose” when compared to System Coupling and is limited to file transfers at the end of a complete solve in a stand-alone system/product. No communication occurs during a solve.
- The coupling is two-way:

  The one way portion (Upstream source component to Downstream target component) is handled via existing Workbench data/transfer connection mechanism.



The round trip is handled by a separate protocol agreed upon by the participating systems when the downstream system exports a set of file to a location specified by the upstream system (via its one way transfer). This exported data is then incorporated by the upstream system in its next update.

If the user chooses to run the next coupled solve iteration, the user invokes the Enable Update command as shown below and then updates all systems involved. These steps (Enable Update, Update Project) are continued as long as needed



The **Feedback Iterator** system automates this process as detailed in the following related topics:

The Feedback Iterator System

Feedback Iterator in Use

Feedback Iterator Component Properties

Feedback Iterator GUI Operations

Resetting the Feedback Iterator

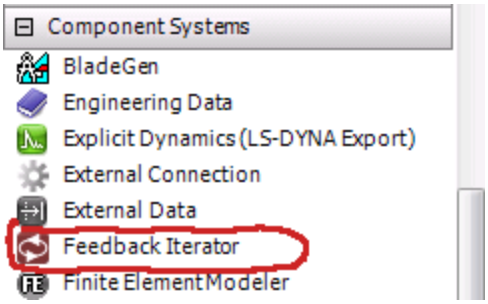
Callback Interface

Example Scenarios for Feedback Iterator

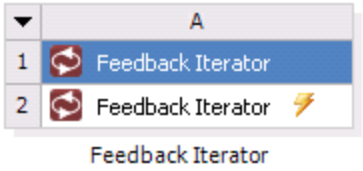
The Feedback Iterator System

Ansys Electromagnetics Suite provides the Feedback Iterator system for automating the manual steps needed for driving a feedback utilizing system-pair to convergence. In addition to automating feedback incorporation over a user-specified number of iterations, the Feedback Iterator also allows you to control the number of iterations (decide iteration termination criteria) and set target temperature and displacement convergence criteria.

The Feedback Iterator appears in the Workbench Toolbox user interface under Component Systems.

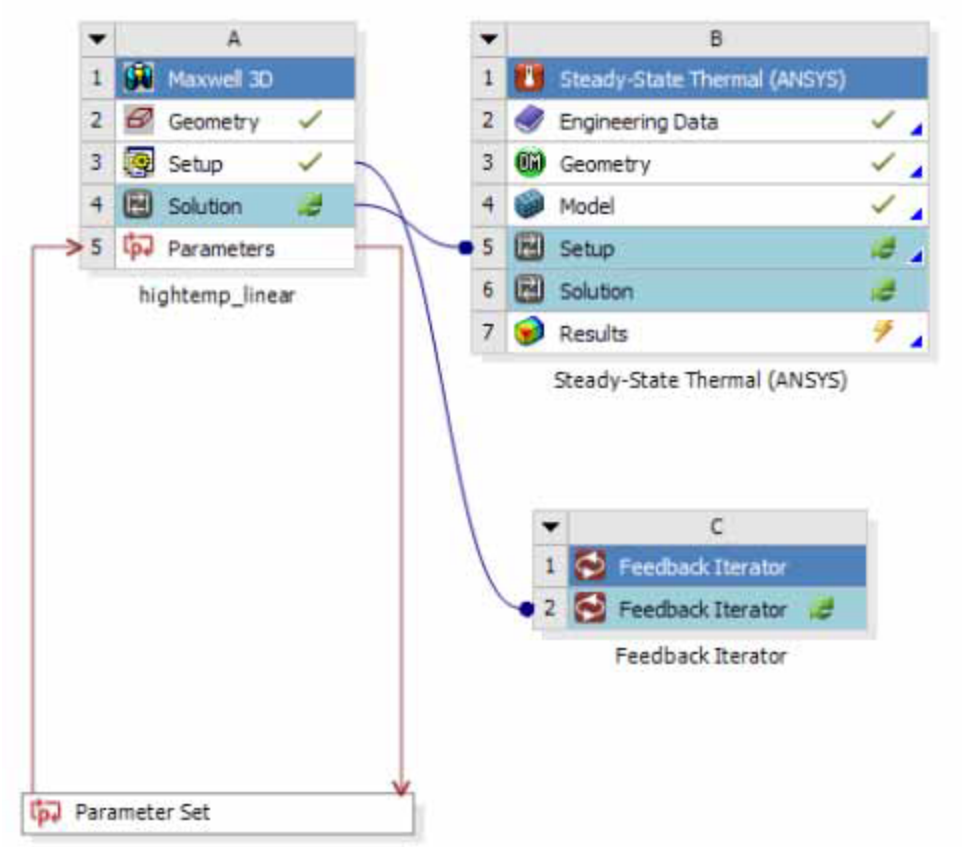


If you drag and drop an instance of the Feedback Iterator into Workbench Schematic, the default system name is Feedback Iterator.



Feedback Iterator in Use

You attach the Feedback Iterator system to the Workbench schematic like any other system. For example, given a Maxwell system providing AnsoftHeatLossData to a Thermal system, if you drop the Maxwell setup cell onto the Feedback Iterator component, the following links result



While the examples deal with Maxwell and Steady-State Thermal. the Feedback Iterator add-in functions the same way with Maxwell or HFSS as sources and Fluent or Structural as targets – essentially all systems that participate in Electromagnetics two-way loose coupling.

Feedback Iterator Component Properties

The Feedback Iterator's primary role is to control iterative solves and its properties support this end.

For Maxwell and HFSS, the Feedback Iterator properties are as shown below:

	A	B
1	Property	Value
2	⊟ General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	⊞ Notes	
7	⊞ Used Licenses	
9	⊟ Iterations	
10	Iterations Completed	0
11	Max Iterations	100
12	⊞ Callback	
14	⊟ Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	⊟ Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

- **Iterations Completed**: displays the number of iterations completed. A “read-only” property.
- **Max Iterations**: sets the maximum number of iterative solve loops to perform before terminating iterations in case the **Target Delta Temperature %** or **Target Delta Displacement %** is not achieved. Default value is 100.
- **Target Delta Temperature %**: specifies the maximum **Target Delta Temperature %** which signifies convergence. Default value is 5%. Value must be 0.01 or greater.

Note	• The delta temperature error is calculated base on the SI unit: Kelvin. • The Maxwell and HFSS design Profile tabs display absolute/relative delta data, while the delta temperate in Workbench means the relative delta (expressed as %).

- **Target Delta Displacement %**: specifies the maximum **Target Delta Displacement %** which signifies convergence. Default value is 5%. Value must be 0.01 or greater.

The Feedback Iterator properties also display the most recently achieved **Latest Delta Temperature %** and **Latest Delta Displacement %** values, allowing the user to manually abort when suitably satisfied with the achieved deltas.

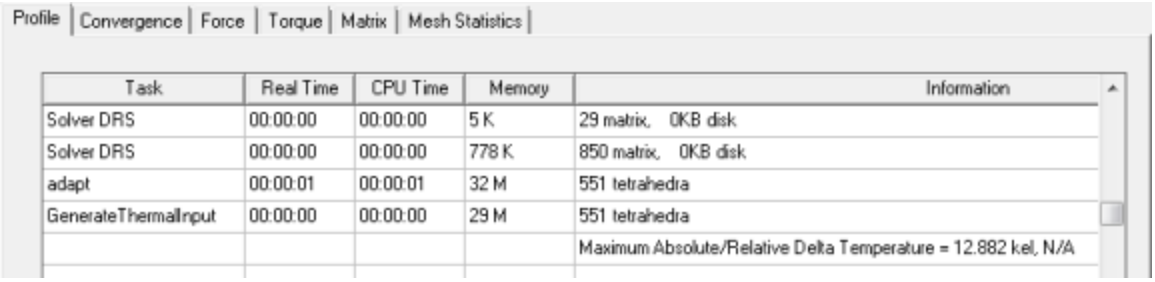
Note	Both the Temperature and Displacement Convergence properties sections are always shown irrespective of which feedback types are actually enabled for the project.

When we run a two-way feedback simulation from WB, and keep the Maxwell or HFSS Profile tab open (right-click on Results in the Project Manager and select Solution Data, then select Profile tab), you will see that the 3D solver keeps track of two feedback related quantities:

- Maximum Absolute/Relative Delta Temperature (if temperature feedback is enabled)

Note	The delta temperature error is calculated base on the SI unit: Kelvin.

- Maximum Absolute/Relative Delta Displacement (if displacement feedback is enabled)

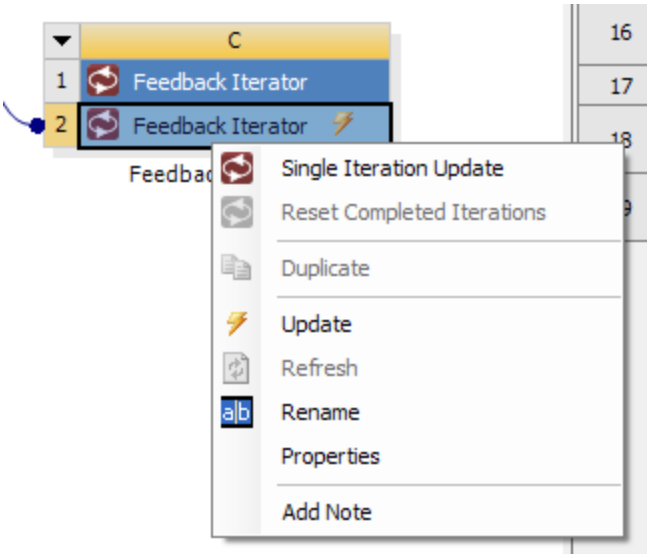


These signify the maximum difference on the solution mesh of the quantity in question from one feedback iteration to the next (thus the value is only available from iteration #2 onward). This data is the basis for the convergence controls in the Feedback Iterator. These controls allow the user to base the termination of the feedback iterations based on a target max delta T and/or max delta displacement. Thus the target max delta forms the convergence condition.

Feedback Iterator GUI Operations

When you project is ready to run, right-clicking on the Feedback Iterator component and selecting **Single Iteration Update** allows you to run a single iteration worth of updates. A Single Iteration Update operates as follows:

- The Electromagnetics product system (Maxwell, etc.) is updated, which will incorporate any previous feedback from the downstream system.
- The downstream system (Fluent, Thermal, etc.) is updated.
- All coupled systems: Electromagnetics product, Electromagnetics product Downstream and the Feedback Iterator will then be in the UpToDate state.
- The Feedback Iterator's **Iterations Completed** property will increment by 1.



Right-clicking on the Feedback Iterator component and selecting **Update** allows you to run iterations automatically. Iterations continue to run either until convergence criteria are met, or until the **Max Iterations** value is reached.

Note	After getting temperature feedback from Fluent, Maxwell solving starts from the *last adaptive*, which means there is NO adaptive pass solving anymore. Consequently, instead of looking for the expression cache value in the adaptive solution, users should look for it in the *last adaptive* solution. For *Last Adaptive*, the expression cache value can be displayed from **Results > Create Fields Report > Data Table**.

Resetting the Feedback Iterator

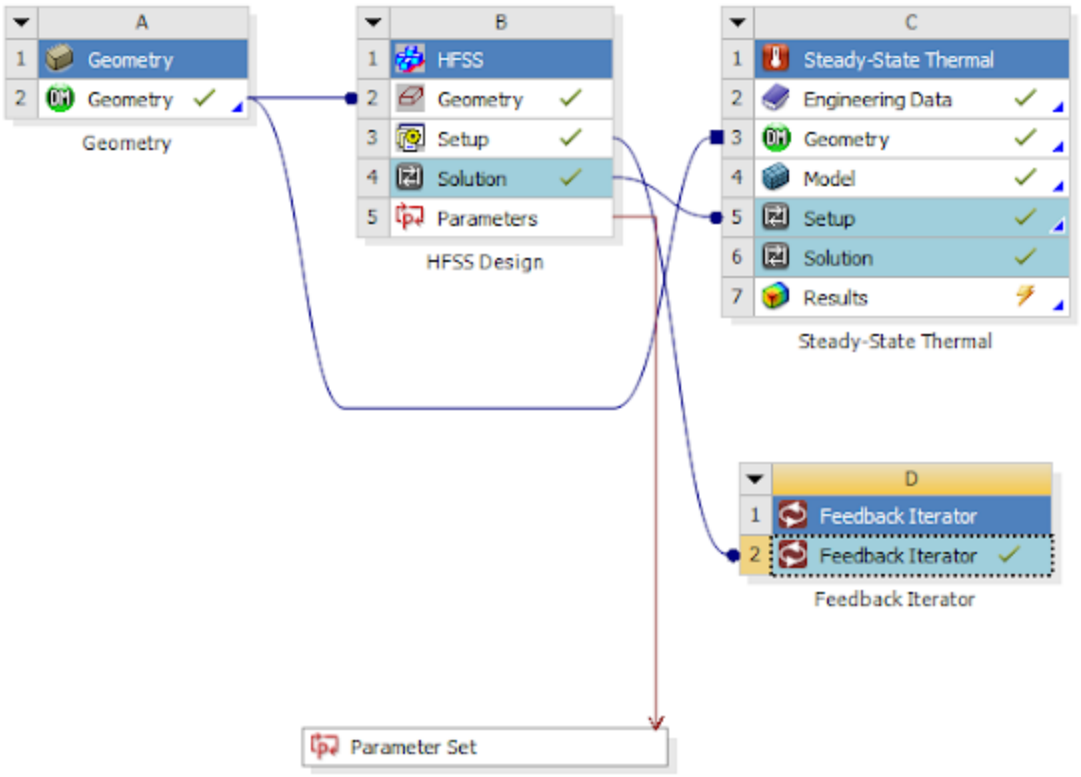
Resetting the iterator essentially means starting from iteration-0 conditions, that is:

- No Displacement or Temperature feedback from another system is incorporated.
- The first iteration solution will be purely an Ansys EM analysis solution.

Resetting the Feedback Iterator cannot easily be done entirely within Workbench. However, the following two processes can be used:

- Resetting via the Ansys EM user interface
- Resetting via a WB journal script

The following example uses an HFSS/Thermal project. (This same approach applies to the other Ansys EM design types.)

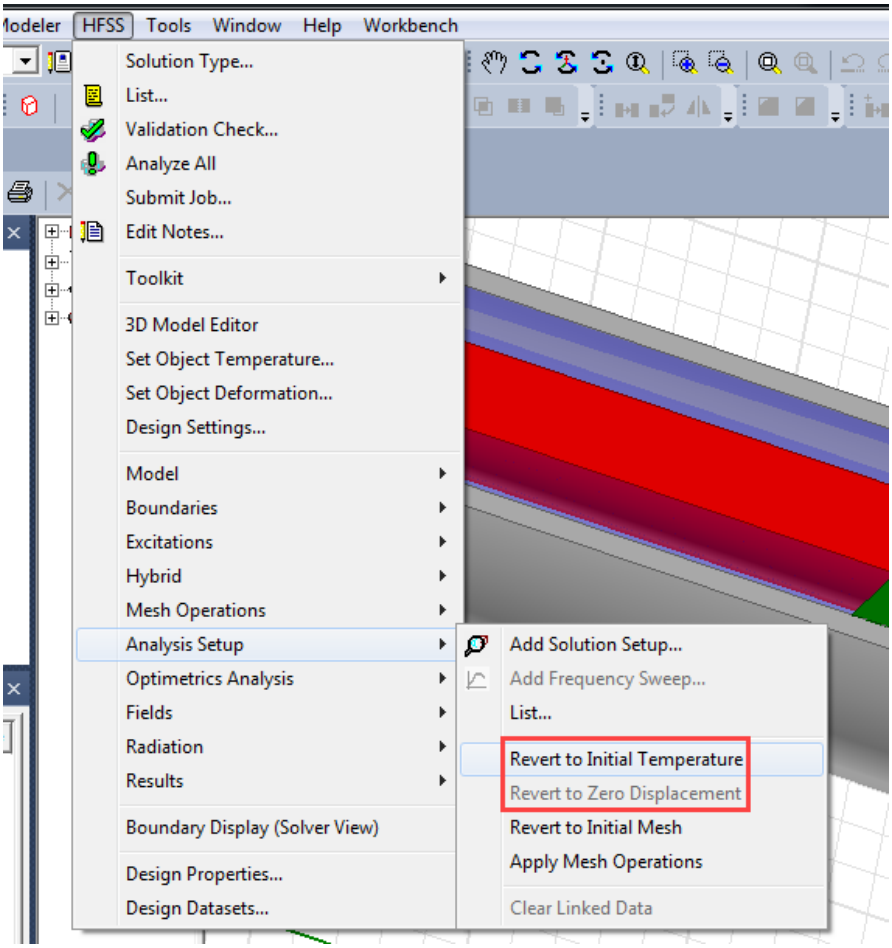


Resetting via the Ansys EM User Interface

Depending on the type(s) of feedback involved, this typically means reverting back to initial conditions for one or both of the following settings:

- **Revert to Initial Temperature**
- **Revert to Zero Displacement**

You can find these under the respective design type menu, such as HFSS shown below.



Resetting via a WB Journal Script

Note	The above Ansys EM user interface actions can be recorded into a WB journal script and played back for the easiest approach.

You also can build a script from scratch using the following as the template – simply update the system name as appropriate, include the appropriate "Revert..." commands, and either save as a script or enter into the WB Command window.

```
oDesign = Ansoft.GetDesign(GetSystem(Name="HFSS"))
oDesign.GetModule("AnalysisSetup").RevertAllToInitialTemperature()
oDesign.GetModule("AnalysisSetup").RevertAllToZeroDisplacement()
```

Callback Interface

The callback interface allows you to react to each step of the iteration process as implemented by the Feedback Iterator component. This is useful for you to implement special iterations or even solve transient simulations (with a limited scope). To this end, there are four main API features provided:

- Callback functions which the Feedback Iterator calls at various points in each iteration
- Utility functions that the Callback functions can use to extract properties of the containers being processed
- Output functions that allow you to debug the script or supply additional messages
- Limited state management allowing the script to store and retrieve state across callback functions and iterations

Related Topics

Callback and State API

Callback and State API

State is managed somewhat simply but in a limited fashion. All the API methods take a final dictionary argument. This dictionary is limited to using **string keys** and **number or string values**. Within this limitation, simply add new keys, read old keys, clear the dictionary, etc., and it will be persisted across functions calls and even across Updates. When the **Iterations Completed** property is **rest**, the dictionary is also cleared out.

It is advisable for the callback script to initialize the dictionary at Iteration 1.

All the API methods use a subset of the following arguments:

iterationNumber	An integer representing the current iteration. This always starts from 1.
ContainerList	A python list of containers (DataContainerReference). This is the entire list of the coupled containers managed by the Feedback Iterator. You typically loop through them and using the utility methods listed below, identities them.
Container	A single container that is being processed. This is a DataContainerReference
State	A read/write python dictionary that is used to maintain state across function calls and iterations.

Only return values from BeforeIterationEx are processed. Returns from all other functions are discarded.

1. BeforeIteration(IterationNumber, ContainerList, State): This method is called before each iteration. Ideally used to initialize the state dictionary, open editors as required, or initialize setups as needed for each iteration.
2. BeforeIterationEx(IterationNumber, ContainerList, State): Similar to the BeforeIteration method except that this allows you to control the number of iterations via the return value.
   - Return: “more” to request one more iteration
   - Return “last” to indicate that this is the last iteration

- Any other return (including none) will be treated as a return of “last” and terminate iterations.

3. AfterIteration(IterationNumber, ContainerList, State): This method is called after each iteration. This can be used to copy result files over, check results, implement any possible convergence calculations, logging of results, etc.
4. BeforeContainerRefresh(IterationNumber, Container, ContainerList, State): Is called before each of the coupled containers is refreshed. The “Container” argument represents the container about to be refreshed.
5. AfterContainerRefresh(IterationNumber, Container, ContainerList, State): Is called after each of the coupled containers is refreshed. The “Container” argument represents the container just refreshed.
6. BeforeContainerUpdate(IterationNumber, Container, ContainerList, State): Is called before each of the coupled containers is Update (after a refresh). The “Container” argument represents the container about to be updated.
7. AfterContainerUpdate(IterationNumber, Container, ContainerList, State): Is called after each of the coupled containers is updated. The “Container” argument represents the container just updated.

If the callback scripts uses other files to send commands to various containers (vb, js, apdl, python, etc.), all of those files are best saved under the user_files directory. This allows you to use the FBGetUserFilePath(str) to get the absolute path of the file and allows the files to be packaged with any created archive.

Utility Functions

FBSystemForContainer (container)	system	Given a container, returns the system it belongs to.
FBSystemDisplayName (system)	string	Given a system, returns its display name on the schematic.
FBSystemID(system)	string	Given a system, returns its ID. This is the same as the UniqueDIrectory for the system.
FBGetUserFilesPath (relativePath)		Given a relative path located under the user_files directory, say "hello.py", this returns the absolute path of the file.

Output/Debugging Functions

FBAddInfoMessage(string)	Adds an info message to the WB message window.
FBAddWarningMessage (string)	Adds a warning message to the WB message window.
FBAddErrorMessage(string)	Adds an error message to the WB message window.
FBMessageBox(string)	Pops up a dialog with the supplied string with an “OK”

	button.

Example Scenarios for Feedback Iterator

This section describes several scenarios for using the Feedback Iterator.

Set up Iteration with Feedback Iterator

User Breaks Iteration Control

Start an Iterative Update

Run a Single Iteration

Interrupt an Iterative Loop

Resume an Interrupted Iterative Loop

Modify any of the Systems Involved in Iteration (coupled clients)

Iterating to Convergence

Set up Iteration with Feedback Iterator

Scenario	Steps to execute	Outcome
Electromagnetics product solution provides solution data to a single downstream setup	• Drop Feedback Iterator system on the Setup component of the Electromagnetics product OR • Create Feedback iterator system and connect Electromagnetics product setup component to the Feedback Iterator component AND User clicks on the Iterator component and sets the desired Feedback Iterator properties.	Electromagnetics product Setup component is connected to the Iterator. Electromagnetics product solution and downstream Setup and Solution components are coupled as clients to the iterator. The iterator component is the coupled master and the rest are coupled clients. Any coupling changes schematic visuals: • Coupled cells including coupling master are colored differently from normal cells. • Coupled cell icons change to reflect the icon of the coupling master. • Coupled client cells no longer display the **Update** context menu item and cannot be updated via script commands either. • The cell states of all coupled cells (master and clients) are synchronized to be the most pessimistic state among any of them. e.g., after an update, any modification will set all of them to the “Modified” state.
Electromagnetics	same as above	All the downstream components (Setup and

Scenario	Steps to execute	Outcome
product Solution provided to multiple downstream setup cells		Solution in each downstream system) are coupled as clients. The update order in this case depends on any additional data-flow connections between the systems that consume the upstream Electromagnetics product solution data.
Electromagnetics product Solution cell does not have any downstream targets	same as above	No changes occur beyond what is expected when you create a new connection (no coupling). Coupling only occurs when Electromagnetics product Solution cell has a downstream connection. If a downstream connection is added after the link to the iterator, coupling will be performed as described in the first row.

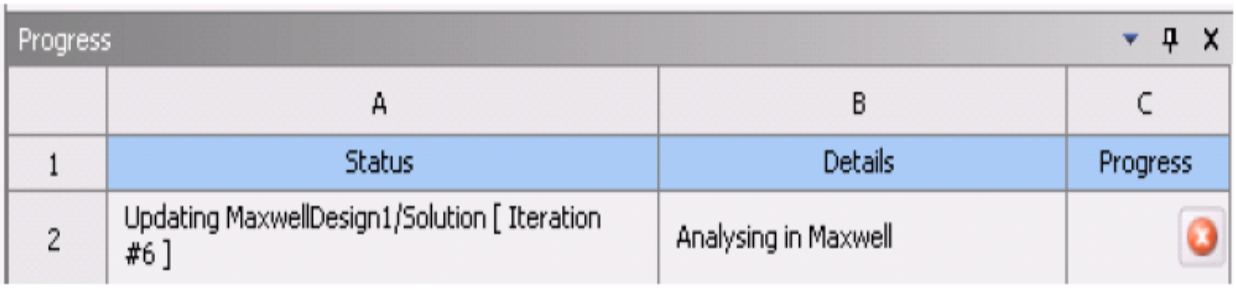
User Breaks Iteration Control

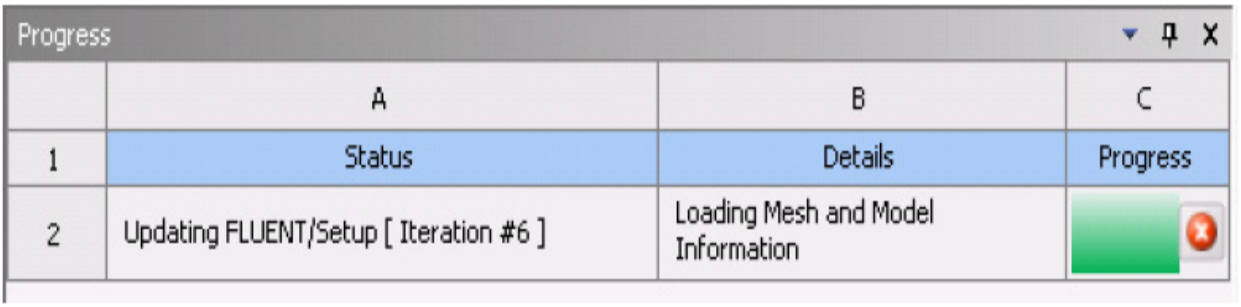
Scenario	Steps to execute	Outcome
Iterator coupled to Electromagnetics product solution cell and downstream setup/solution cells	• Break Electromagnetics product Solution cell's provides link -or- • Break Electromagnetics product Setup link to Feedback Iterator -or- • Delete Electromagnetics product Solution consumer system -or- • Delete Feedback Iterator system	In addition to what is normally expected from the user actions, all coupled clients are de-coupled (their icons and colors on UI are restored).
Electromagnetics product Setup cell is connected to the Feedback Iterator but the Electromagnetics product solution	• Break Electromagnetics product Setup link	No coupling exists in this scenario so nothing visible changes beyond

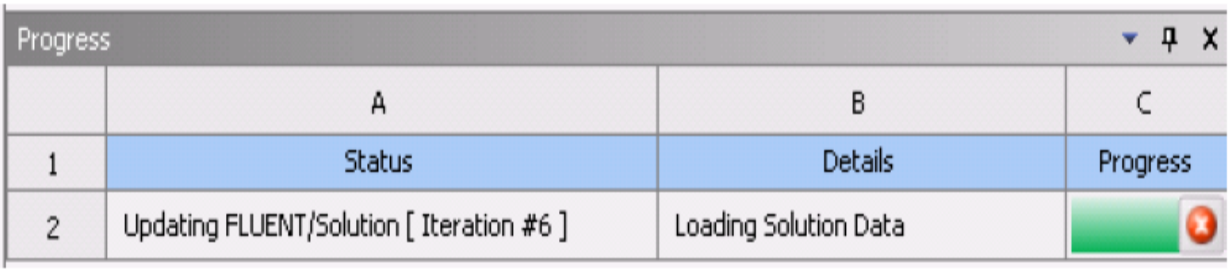
Scenario	Steps to execute	Outcome
does not provide anything. No components are coupled to the Feedback Iterator	to Feedback Iterator • Delete Feedback Iterator system	what is expected from the user actions.

Start an Iterative Update

Scenario	Steps to execute	Outcome
Standard update scenario	• Right-click on Feedback Iterator component and select Update operation -or- • Update Project -or- • Update all design points -or- • DX Update	For each iteration, the Electromagnetics product solution is updated followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration).







Run a Single Iteration

Scenario	Steps to execute	Outcome
NumCompleted < NumIterations	Right-click on Feedback Iterator component and select Single Iteration Update	One iteration is run. “Iterations Completed” property is incremented.
NumCompleted >= NumIterations	same as above	same as above

Interrupt an Iterative Loop

Currently, there is no special progress or interruption control. The progress monitor of the individual components is displayed as they are updated, and any control they choose to provide (interrupt, abort or both) are available. If the user chooses to abort any of the client component

updates, the current iteration is aborted and the Completed Iterations property remains unchanged from the previous iteration.

Resume an Interrupted Iterative Loop

Scenario	Steps to execute	Outcome
Single step	Right-click on Feedback Iterator component and select Single Iteration Update	One iteration is always run and the “Iterations Completed” property is incremented.
Run until completion	• Right-click on iterator component and select Update or- • Select the Project Update menu option from the toolbar etc.	If the user specified number of operations are already completed, nothing is done. Otherwise, the remaining iterations are run.

Modify any of the Systems Involved in Iteration (coupled clients)

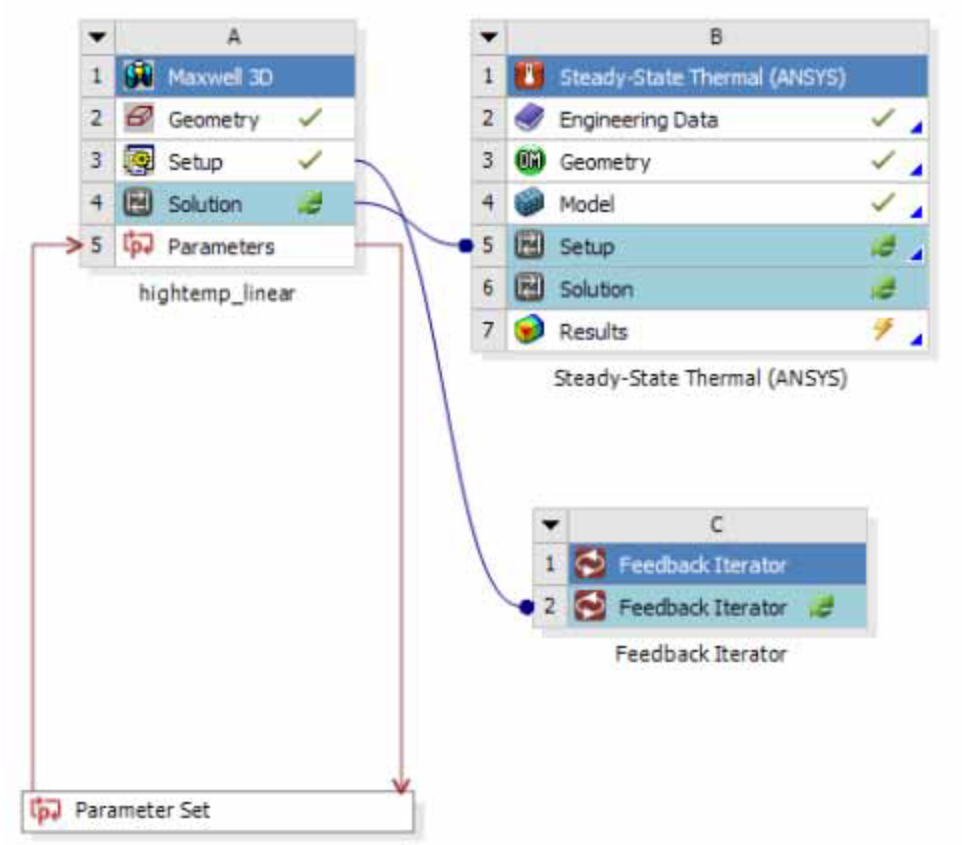
When the user modified any of the coupled client components either in Workbench by changing some non-extrinsic property, design point etc or in an external editor, the coupled clients and master will be marked as modified. Additionally, the Completed Iterations property will be set to 0.

Iterating to Convergence

Scenario	Steps to execute	Outcome
Standard update scenario	• Right-click on the Feedback Iterator component and select Update -or- • Update Project -or- • Update all design	For each iteration, the Electromagnetics product solution is updated followed by the downstream setup and the downstream solution. Each of the client component updates display their progress monitor and can be aborted (resulting in aborting the current iteration).

Scenario	Steps to execute	Outcome
	points -or- • DX Update	

The following temperature convergence example uses a Feedback Iterator with a Maxwell design coupled with a Steady-State Thermal component. Iterating to convergence operates similarly for HFSS projects.



The example uses defaults of 5% for the convergence targets and a value of 100 max iterations. Recall that the max iterations value is set as a "safety" measure to ensure that iterations do not continue indefinitely if the solution does not converge. As we progress through the iterations, we observe the following:

End of Iteration #1

The first iteration, since it has no previous iteration, cannot return a meaningful delta value.

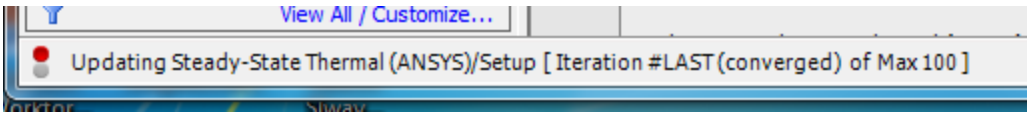
		started. (9:51:41 PM Jun 11, 2013)		
6	Informational	After iteration#: 1, Max temperature delta % = NaN, Max displacement delta % = NaN		6/11/2013 9:51:39 PM

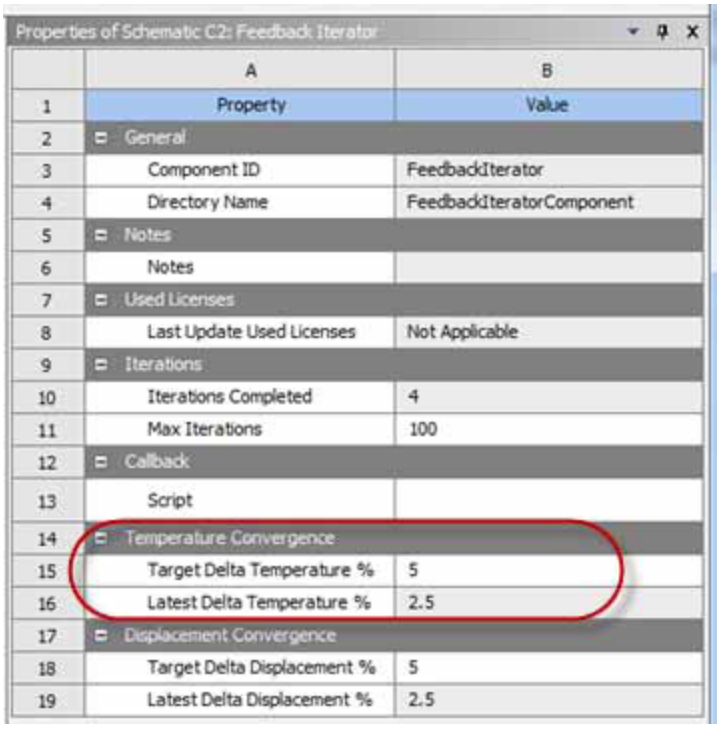
At the end of this iteration, the Latest Delta value will still be listed as Not Available.

	A	B
1	Property	Value
2	General	
3	Component ID	FeedbackIterator
4	Directory Name	FeedbackIteratorComponent
5	Notes	
6	Notes	
7	Used Licenses	
8	Last Update Used Licenses	
9	Iterations	
10	Iterations Completed	1
11	Max Iterations	100
12	Callback	
13	Script	
14	Temperature Convergence	
15	Target Delta Temperature %	5
16	Latest Delta Temperature %	Not Available
17	Displacement Convergence	
18	Target Delta Displacement %	5
19	Latest Delta Displacement %	Not Available

Convergence Achieved

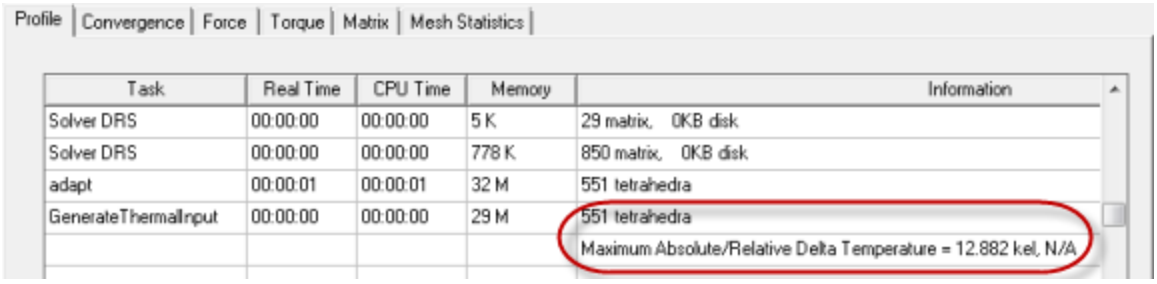
In this example, convergence has been achieved by the third iteration.





When the convergence criteria are met, the simulation stops. If you attempt to do an update after convergence has been achieved, the simulation will not be launched since the current solutions satisfy the convergence criteria.

You can also monitor the iteration progress by opening the Maxwell editor and from the Results menu, select the Solution data dialog box. Choose the Profile tab and keep the dialog open. As you solve each iteration, you can observe the reported Delta-T (with thermal feedback) and/or delta-displacement (with displacement feedback) and abort the iterations (or stop single iteration updates) when the values reach acceptable convergence levels.



19 - Exporting Equivalent Circuit Data

You can export lumped R, L, C data from a Maxwell solution to Ansys Twin Builder. Importing the new data file to Twin Builder enables you to include wave effects in the circuit simulations.

An equivalent circuit can be exported from a parametric solution or from an imported table.

Note	You can only export an equivalent circuit from a parametric solution when the following two criteria are met: • The solution type is **Magnetostatic** or **Electrostatic**. • A parametric setup exists.

Exporting a Circuit From a Parametric Solution

To create a circuit from parametric solutions, you first need to set up and solve a problem that contains a parametric sweep. Any force, torque, and matrix solutions are automatically available to use in the equivalent circuit. Other solutions can be treated as extra inputs/outputs if they have been added as calculations in the parametric setup — that is, extra inputs/outputs come from the parametric table.

Note	In Maxwell, global variable names begin with the **$** character. However, when you are creating an ECE **.sml** model, this character causes the circuit to fail when importing it to Twin Builder. To resolve this, when the circuit is exported, the **$** character is replaced by the **_** character. For example, the project variable **$MyVar** is converted to **_MyVar**.

To export a circuit from a parametric solution:

1. Click **Maxwell 3D>Export Equivalent Circuit>From Parametric Solutions** or **Maxwell 2D>Export Equivalent Circuit>From Parametric Solutions**.

   The **General** window appears, allowing you to specify basic information about the circuit model.

Note	This command is enabled only when the following two criteria are met: • The solution type is **Magnetostatic** or **Electrostatic**. • A parametric setup exists.

2. Select one of the following from the **Model Type** pull-down list depending upon the Design Type (2D or 3D):
   - **Linear Motion**
   - **Rotational Motion**
   - **Transformer**
   - **Matrix**
   - **Lookup Table**
3. Select a **Parametric Setup** from the pull-down list.
4. Select a **Solution Setup** from the pull-down list.
5. Select a **Matrix Setup** from the pull-down list.

6. Select a **Force Setup** or a **Torque Setup** from the pull-down list, depending on which parameter you have set up for your design.
7. For the force or torque setup, select **X**, **Y**, or **Z** as the **Component**.
8. Select either **Ampere-Turns** or **Amperes** as the **Current Source Variables** option.
9. Click **Next**.

   The **Table** window appears, allowing you to set up the inputs and outputs for the circuit equivalent. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.
10. To apply deep spline interpolation to all inputs in the circuit PWL model, select the **Use Bezier Interpolation** check box.
11. To export the data to a table that you can edit and use to export an equivalent circuit at a later time, do the following:
    a. Click **Export Table**.

    The **Save As** dialog box appears.

    b. Select a location, and type a name in the **File name** box.
    c. Click **Save**.

    The **Table** window reappears. The file that is created contains header rows with information such as name, i/o, and type, plus all of the actual data. You may export the table to view or use in external programs. You can also modify the exported table file and then re-import it to create an equivalent circuit. On import, the information in the header rows is used as default settings in the circuit export dialog box.

Note	The **Table** window is the last step for the **Lookup Table** model type. For all other model types, there is one more step: the **Terminals** window.

12. For model types **Linear Motion**, **Rotational Motion**, **Transformer** and **Matrix**, click **Next**.

    The **Terminals** window appears, allowing you to set up terminals, which are nodes with "through" and "across" data. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.
    1. Enter a **Scaling Factor** in the text box. The scaling factor is applied to all output quantities and can be used, for example, to scale data from partial models that take advantage of symmetry.
    2. Optionally, specify the **Model depth** for 2D XY models for scaling.
    3. Optionally for 2D XY **Rotational Motion** model type, specify the **Skew** angle.

       When a stator core or rotor core is skewed for a 2D Rotational Motion model, the flux linkages and torque of the look-up table will be modified based on the skew angle θ_k .

       For any output of the look-up table, $f(\theta)$, where θ is rotor position, the modified output will be:

$$f_m(\theta) = \frac{1}{\theta_k} \int_{\theta - \theta_k/2}^{\theta + \theta_k/2} f(\theta)\,\delta\theta$$

4. Specify the **Terminals**:
   - To specify a coil terminal:
     a. Select a **Source** for the **Flux** or **Charge**, depending on whether your design is mechanical or electrical.
     b. Enter a **Resistance**.
     c. Enter the number of **Turns** in the coil winding.
     d. Enter the number of **Branches**.
   - To specify a mechanical terminal:
     a. Select the **Force** or **Torque** variable from the pull-down list.
     b. Select the **Position** variable from the pull-down list.
     c. Optionally for Rotational Motion model type, select **Use rotational velocity**.
5. Click **Finish** to export the equivalent circuit.

Types of Equivalent Circuit Models

Currently, you can generate the following model types:

- **Linear Motion** - Models inductance (or capacitance) and force as functions of current (or voltage) and position. The parametric solution should cover the range of motion and conductor current (or voltage).
- **Rotational Motion** - Models using rotational rotor position sweep.
- **Transformer** - For one coil only, models nonlinear mutual (magnetizing) inductance with a linear leakage inductance branch. Therefore, this model is only valid for 1-phase transformers. The parametric solution should cover the range of current for one coil only in an open-circuit test. Nonlinear mutual inductances for 3-phase (or more) transformers are better solved using the transient solver.
- **Matrix** - Models an inductance or capacitance matrix for one or more conductors, as a function of current or voltage. The parametric solution should cover the range of each conductor's current or voltage.
- **Lookup Table** - This option creates a lookup table model in Simplorer format.

Exporting a Circuit From an Imported Table

To create a circuit from an imported table, you need to have a table file containing tabular data. The first row in the file must contain the column names. The table export feature writes other useful information into subsequent rows, but the import succeeds whether or not this information is present. The rows of tabular data come next.

Note	In Maxwell, global variable names begin with the **$** character. However, when you are

	creating an ECE **.sml** model, this character causes the circuit to fail when importing it to Twin Builder. To resolve this, when the circuit is exported, the **$** character is replaced by the **_** character. For example, the project variable **$MyVar** is converted to **_MyVar**.

To export a circuit from an imported table:

1. Click **Maxwell3D>Export Equivalent Circuit>From Imported Table or Maxwell2D>Export Equivalent Circuit>From Imported Table**.

   The **Select File** dialog box appears.
2. Find and select the file containing the table you want to use.
3. Click **Open**.

   The **General** window appears, allowing you to specify basic information about the circuit model.
4. Select one of the following from the **Model Type** pull-down list:
   - **Linear Motion**
   - **Rotational Motion**
   - **Matrix**
   - **Lookup Table**
5. Select either **Ampere-Turns** or **Amperes** as the **Current Source Variables** option.
6. Click **Next**.

   The **Table** window appears, allowing you to set up the inputs and outputs for the circuit equivalent. Most of the values have been automatically filled in, based on your design. You can keep the defaults or change the selections and values for the various parameters.
7. To apply deep spline interpolation to all inputs in the circuit PWL model, select the **Use Bezier Interpolation** check box.
8. To export the data to a table that you can edit and use to export an equivalent circuit at a later time, do the following:
   a. Click **Export Table**.

      The **Save As** dialog box appears.
   b. Select a location, and type a name in the **File name** box.
   c. Click **Save**.

      The **Table** window reappears. The file that is created contains header rows with information such as name, i/o, and type, plus all of the actual data. You may export the table to view or use in external programs. You can also modify the exported table file and then re-import it to create an equivalent circuit. On import, the information in the header rows is used as default settings in the circuit export dialog box.

Note	The **Table** window is the last step for the **Lookup Table** model type. For all other model types, there is one more step: the **Terminals** window.

9. For model types **Linear Motion**, **Rotational Motion**, and **Matrix**, click **Next**.

   The **Terminals** window appears, allowing you to set up terminals, which are nodes with “through” and “across” data. Most of the values have been automatically filled in, based on

your design. You can keep the defaults or change the selections and values for the various parameters.

1. Enter a **Scaling Factor** in the text box. The scaling factor is applied to all output quantities and can be used, for example, to scale data from partial models that take advantage of symmetry.
2. Optionally, specify the **Model depth** for 2D XY models for scaling.
3. Optionally for 2D XY **Rotational Motion** model type, specify the **Skew** angle.

   When a stator core or rotor core is skewed for a 2D Rotational Motion model, the flux linkages and torque of the look-up table will be modified based on the skew angle θ_k .

   For any output of the look-up table, $f(\theta)$, where θ is rotor position, the modified output will be:

$$f_m(\theta) = \frac{1}{\theta_k} \int_{\theta - \theta_k/2}^{\theta + \theta_k/2} f(\theta)\,\delta\theta$$

4. Specify the **Terminals**:
   - To specify a coil terminal:
     a. Select a **Source** for the **Flux** or **Charge**, depending on whether your design is mechanical or electrical.
     b. Enter a **Resistance**.
     c. Enter the number of **Turns** in the coil winding.
     d. Enter the number of **Branches**.
   - To specify a mechanical terminal:
     a. Select the **Force** (or **Torque)** variable from the pull-down list.
     b. Select the **Position** variable from the pull-down list.
     c. Optionally for Rotational Motion model type, select **Use rotational velocity**.
5. Click **Finish** to export the equivalent circuit.

Setting Up Current Variables

For problems with current, the **Current Variables Represent** setting allows you to specify one of the following two options:

- **Ampere-Turns**
- **Amperes**

This setting provides flexibility in setting up current sources with different numbers of turns and branches.

In Maxwell, current source values are specified in Ampere-turns, meaning that if a given source is driven with 2 Amps through 100 turns, then the source value must be set to 200. Inductance is calculated per-turn; therefore, to calculate EMF, the flux must be scaled by the number of turns to give the total flux.

You can create two kinds of circuit models:

- A model format where the data table is based on current in Amp-turns and flux per turn. This model internally converts currents and fluxes using the specified turn ratio. This model format was the only one available in versions of Maxwell before Maxwell 11.
- A model format where the data table is based on current in Amps and total flux. This model does *no* internal scaling of values, since the data is already in a form the outside circuit expects. This model format is available in Maxwell 11 and later versions.

For either model type, you can view the inductance setup to obtain information about the specified groups, turns, and branches.

Current Variables Represent Ampere-Turns

How to use this format:

- Apply variables directly to sources. *Source1* value = *Current1*.
- Sweep variable values in Ampere-turns. *Current1* sweeps from 100 to 200.
- In an inductance setup, specify the number of turns consistent with the source setup. Make sure all sources in a group have the same number of turns.

When to use this format:

- If all sources in a group have the same number of turns.
- If you want to be able to modify the number of turns in the exported circuit.
- If you are more comfortable thinking of variables in Ampere-turns.

When using this format, the grouping is taken from the inductance setup. The number of turns and branches per group from the inductance setup are used as a default but can be modified either before exporting the circuit or in the exported circuit.

Current Variables Represent Amperes

How to use this format:

- Define sources as the current variable times turns. *Source1* value = *100*Current1*.
- Sweep variable values in Amperes. *Current1* sweeps from 1 to 2.
- In an inductance setup, specify the number of turns consistent with the source setup.

When to use this format:

- In cases where one current is applied through sources with different numbers of turns.
- If you do *NOT* need to modify the number of turns in the exported circuit.
- If you are more comfortable thinking of variables in Amperes.

When using this format, the groups, turns, and branches are taken from the inductance setup and are used as is. You will *not* be able to modify them during circuit export or in the exported circuit.

Setting Inputs and Outputs in the Table Window

The table includes rows for all of the following that are appropriate to the model type:

- Swept variables from the parametric setup.
- Components of flux or charge from the selected matrix.
- Force or torque.
- Calculations from the parametric setup.

Where possible, the columns are set with reasonable defaults based on the information from the design. In many cases, you should not have to change anything.

Additional information about the columns:

- Under **I/O**, the choices are **Input**, **Output**, or **Unused**. **Unused** means that the quantity will not be included in the circuit.
- Under **Type**, the choices are **Position**, **Rotation**, **Current**, **Voltage**, **Flux**, **Charge**, **Force**, **Torque**, and **Other**. These choices affect the terminal setup in the next window. **Other** is typically used for extra inputs/outputs.
- Under **Extrapolate**, the choices are all standard extrapolations plus **None**. For inputs, the **Extrapolate** column is automatically set to **None** and is disabled.

Linear	This option takes the last two points of the data and generates a straight line extending beyond the range of the parametric sweep. Periodic	repeat the data outside the range of the parametric sweep. HalfPeriod	mirror then repeat the waveform outside the range of parameter sweep.

	Constant	extrapolate a constant value from the last point in the interpolation. Even	repeat the wave outside the range of parametric sweep. Odd	repeat a reflection of the waveform outside the range of the parametric sweep.

Setting Coil and Mechanical Terminals

There are currently two types of terminals:

- Coil Terminals
- Mechanical Terminals

For models with motion, the mechanical terminal setup determines which force (or torque) causes the motion and which position (or rotation) is affected.

When setting up coil terminals, flux and current are used for magnetic models, and charge and voltage are used for electric models.

In the coil terminal setup, there is one row for each flux (or charge) group. In the **Current** (or **Voltage**) column, each cell is a selection box where you can choose the current (or voltage) that applies to that flux (or charge) group. Usually the software can choose the correct current by default, based on the source setup in the design. The **Resistance** column is set to **0** by default; you can enter any value here. The **Turns** and **Branches** columns only appear for magnetic models where current variables represent Ampere-turns. These columns are initialized with the turns and branches specified in the inductance matrix setup.

In the **Current** column, in addition to each current, there is another choice, **<Dependent>**. This feature allows you to solve some problems using fewer parametric rows. This is explained using the following example:

> Suppose you are working on a three phase machine. You create three sources, CurrentA, CurrentB, and CurrentC. In previous versions of Maxwell (before version 11), you would have to create three current variables, iA, iB, and iC, and sweep all three of these variables — even though for this type of machine iC is always equal to -(iA + iB). This means that if you want to sweep through 10 values of current, the parametric table would have 1000 rows. In Maxwell 11 and beyond, you can create only variables iA and iB and then set the value of CurrentC to
> -(iA + iB). The parametric table will have 10 values each for iA and iB, so it will only have 100 rows. When exporting the circuit, you would set the current for Flux[CurrentA] to iA, Flux[CurrentB] to iB, and Flux[CurrentC] to <Dependent>. In the circuit model, the PWL table will contain two input currents (iA and iB), but it will contain all three fluxes. So it will

look up all three flux values based on only the two current values. As long as you always connect a current of -(iA + iB) to CurrentC, this model will be valid.

Note	A dependent source can have a different number of turns from the sources that it depends on (in the example above, CurrentA, CurrentB, and CurrentC can all have different numbers of turns). But, in this case, you would have set up the current variables as Amperes instead of Ampere-turns — otherwise there would be no way to obtain the correct scaling of currents iA and iB for both their own current sources and for CurrentC. Therefore, this is another case where specifying current variables in Amperes (rather than in Ampere-turns) is useful.

20 - Scripting in Maxwell

Maxwell uses the Microsoft® Visual Basic® Scripting Edition (VBScript) scripting language to record macros. VBScript is based on the Microsoft Visual Basic programming language.

Using scripts is a fast, effective way to accomplish tasks you want to repeat.

You can write a script using any text editor, or you can record a script from within the Maxwell interface. After recording the script from within Maxwell, you can then modify it using a text editor.

For information on how to create, edit, and use scripts in Maxwell, see the Scripting help, which you can access from Maxwell via the following menu options:

- **Help >Maxwell Scripting Help**
- **Help >Maxwell PDFs >Maxwell Scripting**

Recording a Script

You can choose either to record a script to a file, or to record a script to the Project. Once you start to record a script, your subsequent actions are added to the script. Each interface command has one or more associated script commands that are recorded to the script.

To record a script to the project:

1. Click **Tools>Record Script to Project** to open the **Save Script to Project** dialog box.
2. In the **Save Script to Project** dialog box, type the name of the script and click **OK**.
3. Perform the steps that you want to record.
4. When you have finished recording the script, click **Tools>Stop Script Recording**. The script is recorded to a text file in .vbs (VBScript) file format and placed in the Project Manager Definitions>Scripts folder.

To record a script to a file:

1. Click **Tools>Record Script to File**.
   The **Save As** dialog box appears.
2. Use the file browser to locate and select the folder in which you want to save the script.
3. Type the name of the script in the **File name** text box and choose the file type (IronPython Script .py, or Visual Basic Script .vbs), and then click **Save** to save script in the folder you selected and begin recording.
4. Perform the steps that you want to record.
5. When you have finished recording the script, click **Tools>Stop Script Recording**.

Editing a Script

You can edit a script that was saved to a file, or edit a script that was saved to the project.

To edit a script that was saved to the project:

1. In the Project Manager Definitions>Scripts folder, right-click on the script you want to run to open the context menu.
2. Select **Edit Script** to open the script in the text editor.
3. When finished editing, select **Script> Save Script**.

To edit a script that was saved to a file:

1. Open the script file in any text editor.
2. When finished editing, save the script.

Stopping Script Recording

To stop recording a script:

- Click **Tools>Stop Script Recording**.
  Maxwell stops recording to the script.

Running a Script

To run a script from the Project Manager:

1. In the Project Manager Definitions>Scripts folder, right-click on the script you want to run to open the context menu.
2. Select **Run Script**.

To run a script from Maxwell:

1. Click **Tools>Run Script**.
   The **Open** dialog box appears.
2. Use the file browser to locate the folder in which you saved the script, and then double-click the folder's name.
3. Type the name of the script in the **File name** text box, or click its name, and then click **Open**.
   Maxwell executes the script.

Note	To supply script arguments when running from **Tools>Run Script**, use the edit field at the bottom of the file selection dialog box. You can access the script arguments using the AnsoftScriptHost.arguments collection from vbscript. This is a standard COM collection.

To run a script form a command line:

1. Type one of the following command line options at the command line:

   ```
   -runscriptandexit or -runscript
   ```

2. Press **Enter**.

You can also pass the **-scriptargs** parameter to the script and specify arguments.

Note	If you run the script from DOS prompt as a .vbs file (that is, you do not launch Maxwell, but simply launch vbs directly, or use wscript.exe or cscript.exe), the arguments will be in the WSH.arguments collection, not the AnsoftScriptHost.arguments collection. To

handle this, write the following:

```
on error resume next
dim args
Set args = AnsoftScript.arguments
if(IsEmpty(args)) then
Set args = WSH.arguments
End if
on error goto 0
'At this point, args has the arguments no matter if you are
running
'under windows script host or Ansoft script host
msgbox "Count is " & args.Count
for i = 0 to args.Count - 1
msgbox args(i)
next
```

Pausing and Resuming a Script

To pause a script during its execution:

- Click **Tools>Pause Script**.

To resume a script after pausing it:

- Click **Tools>Resume Script**.

Stopping a Script

To stop a script:

- Click **Tools>Stop Script**.

Maxwell stops executing the script that has been paused.

21 - Running Simulations

After you specify how Maxwell is to compute the solution, you need to begin the solution process. In general, the **Analyze** command applies to the selected setup and associated sweeps, if any, or to a select sweep. To use this command, right-click on a setup or sweep in the Project tree, and click the command on the context menu. The **Analyze All** command applies to all enabled setups at or below the level invoked in the Project tree. To use this command, either click Maxwell 2D or Maxwell 3D**>Analyze All** or right-click on the Analysis icon in the Project tree and select **Analyze All** from the popup menu.

What do you want to do?

- Local Analysis
- Solve a single setup with or without sweeps
- Solve a specific sweep
- Enable a queue so that multiple simulations can run sequentially as resources become available.
- Run more than one simulation, whether multiple setups, or multiple sweeps under a single setup, or setups with dependencies.
- Enable or Disable one or more solution setups or sweeps
- Monitor queued simulations
- Configure and run remote analysis
- Configure and run distributed analysis
- RSM Integration with Job Management UI
- Large Scale DSO for Parametric Analysis
- High Performance Computing (HPC) Integration
- Interactive Scheduler Jobs
- Monitor the solution process
- Change a solution priority for system resources
- Abort an analysis
- Re-solve after modifying a design
- Re-solve after Ansys Workbench Feedback

Local Analysis

Ansoft RSM Service does not need to be installed or running for local analysis and should not be running if the user only will be running local analysis.It is suggested that you refer to the Distributed Analysis page if running distributed analysis.

Note: MPI distribution may be affected by starting or stopping a VPN, even if the MPI distribution is limited to the local host.

To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

Related Topics:

Distributed Analysis

High Performance Computing (HPC) Integration

Running an Optimetrics Analysis

Disabling or Enabling an Analysis Setup

Solving a Single Setup

To solve a single setup or sweep:

1. In the project tree, under the design you want to solve, select a solution setup.
2. Right-click and select **Analyze** from the shortcut menu.

   Maxwell computes the 3D field solution inside the structure for a solution, and for a select sweep, does so for the sweep variables.

To run more than one analysis at a time, follow the same procedure while a simulation is running. If you have enabled queuing, the next solution setup will be solved when the previous solution is complete.

Note	If a linked dependency in the setup is already simulating (for example, due to setup links to the same external source for a near or far field wave, or a magnetic bias), Maxwell will not allow another dependent simulation to start until the first use of the source has completed.

Related Topics

Running an Optimetrics Analysis

Running More Than One Simulation

To solve every enabled solution setup in a design:

1. In the project tree, under the design you want to solve, select **Analysis**.
2. Click **Maxwell3D>Analyze All** or **Maxwell2D>Analyze All**.

Each enabled solution setup is solved in the order it appears in the project tree.

Note	The **General** tab for the Setup includes an **Enabled** check box. By default, this is checked. Unchecking the **Enabled** check box excludes a setup from running

Note	You can also simulate all designs in a project by clicking **Project>Analyze All**.

To solve *two or more sweeps or two or more parametric analyses under a setup*:

1. In the project tree, under the design you want to solve, right-click **the setup** icon that includes the setups or sweeps of interest.
2. Click **Analyze on the shortcut menu**.

   Each solution sweep under that setup is solved in the order it appears in the project tree, using the available machines.

Monitoring the Solution Process

Aborting Analyses

Running an Optimetrics Analysis

Monitoring Queued Simulations

If you have multiple setups for a design, and have selected **Analyze All**, the simulations can be queued until there is a machine available. You enable queuing in the HPC and Analysis Options: Options tab. If queuing is enabled and you run multiple setups, they are solved in the order that they appear in the project tree. You can prioritize setups by changing the order in the queue.

1. To view the solution queue, click **Tools >Show Queued Simulations**.

   This displays a dialog that displays each simulation and its current status. You select and remove any simulation from the queue.

   You can also select any setup and use the **Move up** and **Move down** buttons to prioritize them.
2. To remove a simulation from the queue, select the simulation, and click **Remove from Queue**.

This removes the selected simulation from the queue.

Monitoring the Solution Process

While a simulation is running, you can monitor the solution's progress in the **Progress** window. Above the green progress bar, messages describe the setup and step. The progress bar shows the relative progress of each step. Under the bar, messages note the part of the design being solved, and give memory estimates during the factoring process.

You can also view the following solution data at any time during or after the solution:

- The convergence data:
- The matrices computed for the S-parameters, impedances, and propagation constants.
- A profile of status of the adaptive analysis, including the number of valid passes completed.

To view the **Solutions** window:

1. Right-click the solution **Setup** in the project tree.

   A shortcut menu appears.

2. **Select Convergence**, **Solution**, **Matrix Data**, **Profile**, or **Mesh Statistics from the shortcut menu**.

   The **Solutions** window appears with the corresponding tab selected and the current data displayed.

For "out of core" problems, quite different amounts of memory may be used for factorization and for solution. So if the amount for factorization is displayed under the progress bar and the amount used is calculated for the profile at the end of the solution, they may be quite different numbers.

To view the status of the adaptive analysis:

- Click **Maxwell>Results>Browse Solutions**.

  The **Solutions** dialog box appears with the **Browse** tab selected. It displays data about the number of valid passes completed. It contains a tree structure showing the solutions listed according to Setup, Solution, and Variation. A table lists the Setup, the solution, the sweep variable, and the state of the solution.

- You can use the **Properties** button to display a dialog that lets you change the way the Setup, Solution, and Variation are listed in the tree structure of the **Solutions** dialog.
- The **Statistics** tab of the **Solutions** dialog displays path information, as well as format, number of files, and size.
- You can delete one or more solutions by selecting from the table and clicking **Delete**. Click on a solution to select it, and use Ctrl-click to select multiple solutions, or Shift-click to select a range of solutions. You can also select all solutions using the **Select All** button.

Note	If Maxwell loses its license, it waits for the license to be regained, checking every 2 minutes or until you abort.

Deleting Solution Data

Changing a Solution Priority for System Resources

You can modify the priority of Maxwell simulations so that system resources are allocated to other computer processes before the solver. If you reduce the priority of Maxwell simulations, your other software tools will respond as they normally would, but Maxwell simulations may take longer.

Note	The Windows Task Manager does not indicate a reduced priority for the Maxwell solver. It only lists the priority of the engine manager, which appears normal, not the actual engine. The actual engine is in a separate thread, whose priority is not visible in the Windows Task Manager.

To change the priority of simulations for the system's resources:

1. While a solution is running, right-click the **Progress** window, and click **Change Priority** on the shortcut menu.
   - To affect priority for future simulation runs, click the **Tools>Options>HPC and Analysis** dialog box, and click the **Options** tab.
2. From the **Change Priority** menu (or the **Default Process Priority** pull-down menu), select one of the following priorities:

Critical	
Above Normal	
Normal	The default.
Below Normal	
Idle	

3. Click **OK**.

Related Topics

Monitoring Queued Simulations

Aborting Analyses

To end the solution process before it is complete:

- Right-click In the **Progress** window and click **Abort**.

Maxwell ends the analysis immediately.

The data for the currently solving pass or frequency point is deleted. All previously solved solutions are retained. For example, if you abort between the third and fourth adaptive pass, the solutions for the third pass will be available, and any solutions for the fourth pass are discarded.

To stop the solution process after the current adaptive pass or solved frequency point is complete:

- Right-click the **Progress** window, and click **CleanStop** on the shortcut menu.

  Maxwell ends the analysis after the next solved pass or frequency point.

If you request a clean stop between the third and fourth adaptive pass, the solutions for the third and fourth pass will be available once the fourth pass has finished solving.

Ansys Electromagnetics Application as an LSF Job

If you have an Ansys Electromagnetics application running as an LSF job, you can use the command “bkill –s SIGTERM *jobid*” to terminate an Ansys Electromagnetics application. Here *jobid* is the LSF job id. The response will be “Job <jobid> is being signaled”. The response is the same whether the job is actually being signaled or not.

In cases where the SIGTERM parameter is ignored, the command kills the LSF job, but does not clean the lock files, and other files may not be in a consistent state. See http://www.vital-it.ch/support/LSF/programmer/advanced.html for a detailed description under *Signal Handling in Windows*.

Unix/Linux

For UNIX/Linux, you can use TERM commands. Sigterm handling for Unix is done in Desktop library. You can abort a running batchsolve on Unix by sending a TERM signal to maxwell.exe

Re-solving a Problem

In some cases, if you modify a design after generating a solution, the solution in memory will no longer match the design. In such cases you receive a warning message that "Solutions have been invalidated. Undo to recover."

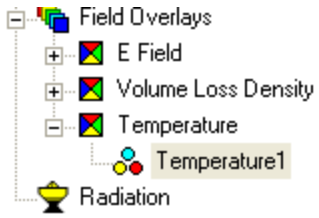
To generate a new solution after modifying a design, follow the procedure for running a simulation:

Also see Re-Solving with Ansys Workbench Thermal Feedback.

Re-solving after Ansys Workbench Thermal Feedback

With the Enable Feedback box in Setting the Temperature of Objects dialog is checked, you can manage analysis with feedback in Ansys Workbench. After solving a Maxwell design, after performing the corresponding linked thermal analysis in Ansys Workbench, you can receive a temperature distribution back from the thermal solution. Ansys Workbench will write the feedback files directly to the Maxwell Project Solution directory.

After an analysis that includes thermal feedback from Ansys Workbench, you can see temperature changes expressed in Temperature field overlays (both visually in the overlay and in the color key) as well as in the Solution data.



In the **Solution** data Profile tab you will see a new entry for Maximum Delta T, for the change in temperature from the previous simulation. The solver calculates delta in the first iteration by comparing the temperature distribution output from thermal with the initial temperature setting in Maxwell. Subsequent simulation iterations provide a number for the temperature delta.

Solver MCS4	00:00:00	00:00:00	31.4 M	Disk = 0 KBytes, matrix size 3468 , matrix bandwidth
Field Recovery	00:00:00	00:00:00	31.4 M	Disk = 310 KBytes, 2 excitations
				Maximum Delta T = 7.0685

This simulation feedback loop from Ansys Electromagnetics to Ansys Workbench and back can continue until you decide that Temperature delta reported in the Solution Report low and stable for the designs.

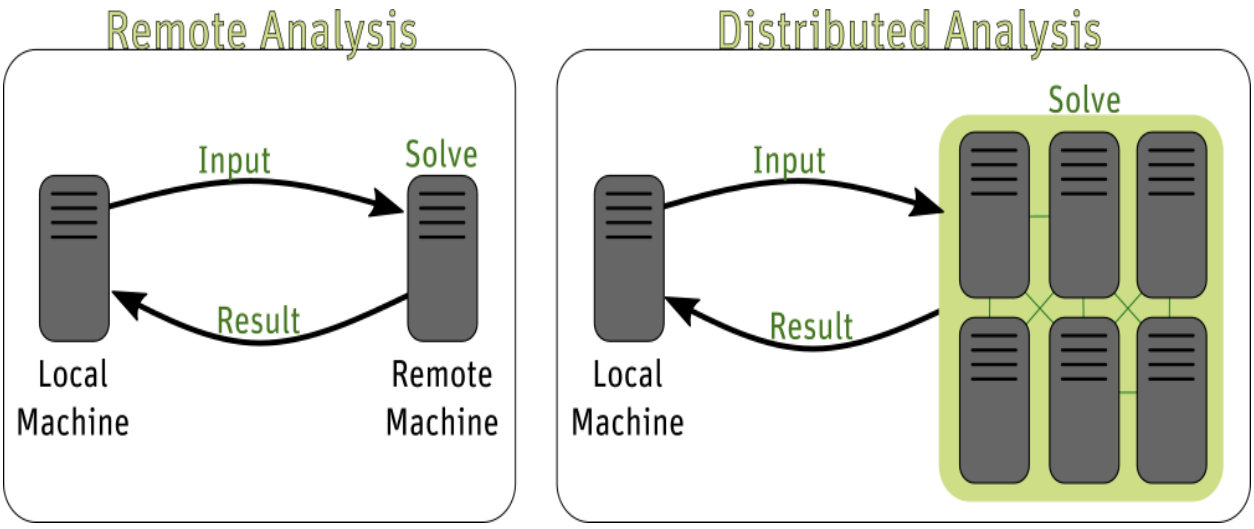
Ansys Workbench Integration Overview

Remote Analysis

It is possible to solve a project on a different machine from the one on which you set up your designs. This is particularly useful when you want to take advantage of a more powerful machine but it is not convenient to access that machine. This process involves configuring the machine that is to perform the solving (the remote machine), as well as the machine from which the simulation is to be launched (the local machine). This can also be extended into distributed analysis, where a specified analysis, if supported, is concurrently solved on multiple remote machines.



Note	In both Remote and Distributed Analysis, communication between machines can drastically affect performance. Use of a high-speed network system, such as Gigabit or Infiniband, is recommended for optimal performance.

- Prerequisites for Remote and Distributed Analysis
- Configuring the Local Machine to Solve Remotely
- Remote Analysis Options
- Running Remote Analysis

The Tools > Options > Export Options Files command writes xml files containing the Options settings at all levels to the specified directory. The **Tools > Options > Export Options** feature is intended to make it easier for different users to use Ansys Electromagnetics tools installed on shared directories or network drives. The Example Uses for Export Options Features section outlines some use cases enabled by this feature.

Prerequisites for Remote and Distributed Analysis

1. You must have Ansys Electromagnetics Remote Simulation Manager (RSM) or a supported High Performance Computing (HPC) management software program. (See High Performance Computing (HPC) Integration). The list of currently-supported HPC software includes
   - Platform's Load Sharing Facility or LSF
   - Altair's PBS
   - GridEngine
   - Microsoft® Windows® Compute Cluster Server 2003
   - Microsoft® Windows® HPC Server 2008 R2 SP4, HPC Server 2012
2. All types of distribution use MPI, except when only distributing rows of a parametric table, either as a regular DSO or as Large Scale DSO performed through command line. MPI may also be used if Auto mode is specified, and rows of a parametric table are distributed. MPI must be correctly configured if the distributed analysis uses MPI. See Distributed Analysis

for information on whether MPI is needed for the analysis.

3. If you use RSM, it must be accessible from all remote machines. In addition, the Maxwell engines must be registered with each initialization of RSM. To do this, on each remote machine:
   - On Windows on the local and remote machines, click **Start > All Programs > Ansys Electromagnetics Suite [version] > Register with RSM**. You can also run **RegisterEnginesWith RSM.exe**, located in the product subdirectory (for example, C:\Program Files\AnsysEM\v231\Win64\RegisterEnginesWithRSM.exe).

   In each case, you see a dialog confirming the registration. OK the dialog.

   - On Linux, run **RegisterEnginesWithRSM.pl**, located in the product installation directory. (for example, /apps/AnsysEM/v231/RegisterEnginesWithRSM.pl).

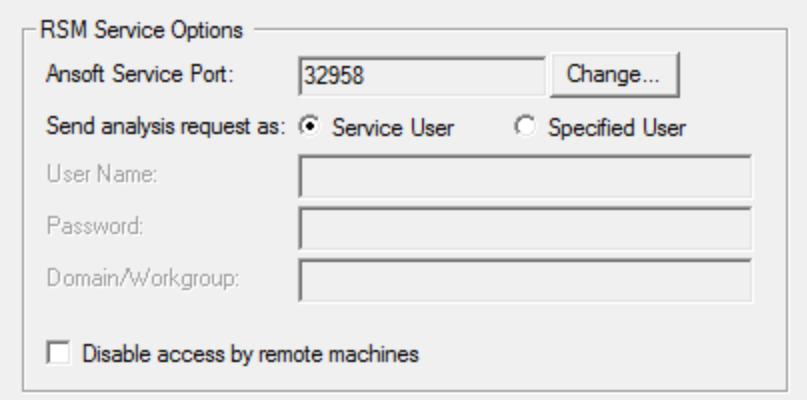
If the RSM service cannot run due to permission issues for the configuration file, it issues an error message and exits. If your product is not registered with RSM, the analysis will run locally.

Configuring the Local Machine to Solve Remotely

To set the Analysis options in Maxwell see Configuring Distributed Analysis.

Remote Analysis Options

You also set the Remote Analysis Options in the **General options** dialog box, **RSM Analysis Options** tab.



Select whether to run simulation processes as the user running RSM (Service User), or a Specified User. If you select Specified user, you must provide the User Name, Password, and any Domain/Workgroup on which this user is defined. If the name or password is incorrect, the Message window issues a warning message, and the solver attempts to perform the analysis as the Service User.

Running Remote Analysis

When you run a simulation remotely, you should see a message in the Progress window identifying the design name, and the specified remote machine. You will see Progress messages

as the simulations continues. When the simulation is complete, you will see a message in the **Message** window.

Troubleshooting
Running from a Windows Remote Terminal

Troubleshooting

Problem: When you try to solve from local to remote machine, an MAXWELLCOMENGINE process starts on the remote machine, but the Maxwell user interface hangs indefinitely.

This occurs if the remote solve option is enabled after the COM daemon is started, or when the option "Don't allow exceptions" is selected for the Windows firewall.

Resolution: Remote solve needs either firewall exceptions to be ON or firewall to be completely turned off.

Problem: When you try to solve from a local to a remote machine, you receive the following error message:

[error] Unable to locate or start COM engine on 'nomachine' : Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication. (10:57:13 PM Aug 13, 2009)

Resolution: This message can happen if the machine is not present, the network connection is down, if there are firewall issues or if the service is not running.

Problem: A solve that is distributed to multiple hosts using MPI fails because the AnsysEM installation path is different on different hosts.

Resolution: Ansys Electronics Desktop must be accessible from all remote machines as well as on the local machine. If the analysis uses MPI, then the path of the Ansys Electronics installation must be the same on all of the machines used for the analysis (remote and local). This may be a shared network path accessible from all hosts. Alternatively, it may be a local installation on each host; in this case the installation path must be the same for all hosts. If using a shared network path, there should not be a local installation of the same Ansys Electronics version on any of the hosts. See Distributed Analysis for information on whether MPI is needed for the analysis.

Remote Solve Node = Windows

Error: "Unable to locate or start COM engine on <remote node> : Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication."

Resolution:

1. Try disabling the firewall.
2. Confirm that you have not changed the Ansoft Service Port in **Tools > Options > General Options > Remote Analysis Options** from the default 32958. If you have, change it back to 32958, restart Maxwell, and try to solve again.
3. Make sure that the local machine is able to contact the RSM port on the remote node. Open a command prompt on the local machine and type telnet <remote node name> 32958. If the terminal appears to be hanging then the connection was successful.
4. Make sure the user listed in the service is an administrator.
5. Make sure the COM engine is registered with the Ansys Electromagnetics RSM Service. From the Windows menu, choose **Start>All Programs>Ansys Electromagnetics>Ansys EM Suite [version]>Register with RSM** to register the engines.
6. If none of these steps fixes the problem, contact Ansys Support.

Error: "Unable to locate or start COM engine on <remote node>: Engine is not registered with the Ansys Electromagnetics RSM service which is running on this machine."

- **Resolution:** To register the engine, from the Windows menu, select **Start>All Programs>Ansys Electromagnetics>Ansys Electromagnetics Suite [version]>Register with RSM**.

Remote Solve Node = Linux

Error: "Unable to locate or start COM engine on <remote node>: Unable to reach AnsoftRSMService. Check if the service is running and if the firewall allows communication."

Resolution:

1. Try disabling the firewall.
2. Confirm that you have not changed the Ansoft Service Port in **Tools >Options >General Options >Remote Analysis Options** from the default 32958. If you have, change it back to 32958, restart the Ansys Electromagnetics product, and try to solve again.
3. Make sure that the local machine is able to contact the RSM port on the remote node. Open a command prompt on the local machine and type telnet <remote node name> 32958. If the terminal appears to be hanging then the connection was successful.
4. Check to make sure Remote Simulation Manager is running. To do this:
   a. Go to the 'rsm' subdirectory of the Ansys Electromagnetics Remote Simulation Manager installation directory, <RSM installdir>/rsm.
   b. Type `./ansoftrsmservice status`
   c. If the status query indicates that the service is stopped, type `./ansoftrsmservice start`
5. Make sure the COM engine is registered with RSM. Type `./RegisterEnginesWithRSM.pl status` from within the Maxwell installation directory. If the status query indicates "Not registered", type:

   ```
   ./RegisterEnginesWithRSM.pl add
   ```

Error: "Unable to locate or start COM engine on <remote node>: Engine is not registered with the Ansys Electromagnetics RSM service which is running on this machine."

Resolution:

- To register the engine, go to the Ansys Electromagnetics product installation directory and type:

  ```
  ./RegisterEnginesWithRSM.pl add
  ```

Distributed Analysis

Distributed analysis allows users to split certain types of analyses and solve each portion of an analysis simultaneously on multiple machines. Simulation times can be greatly decreased by using this feature.

> **Note:** When using distributed analysis, the Temp folder must be accessible by all machines set up in the HPC configuration.

Maxwell supports the following forms of distributed analysis:

- Distributing rows of a parametric table, either as a regular DSO, or as Large Scale DSO performed through command line. Large Scale DSO generates a reduced set of outputs.
- Distributing a single or discrete interpolating sweep.
- Maxwell 2D and Maxwell 3D designs support distribution of frequencies, transient solver, solution matrix and skew model.

> **Note:** Communication between machines in remote analysis and distributed analysis can drastically affect performance. Use of a high-speed network system, like Gigabit or Infiniband, is recommended for optimal performance.

Maxwell Circuit and RMxprt designs do not support MPI. As a result, the supported forms of distribution depend on the design type.

All types of distribution for Maxwell 2D and Maxwell 3D use MPI, except when only distributing rows of a parametric table, either as a regular DSO or as Large Scale DSO performed through command line. MPI may also be used if Auto mode is specified, and rows of a parametric table are distributed. MPI must be correctly configured if the distributed analysis uses MPI. See Setting HPC and Analysis Options for setting MPI Licensing and the *Ansys Electronics Desktop Installation Guide* for details on installing MPI.

To configure a distributed analysis, you must select a distributed machine configuration containing a list of machines to use for a simulation, based on memory and CPU considerations (See: Selecting an Optimal Configuration for Distributed Analysis). To create an new distributed machine configuration or to edit an existing one, see Editing Distributed Machine Configurations.

Before you can select a configuration, it must be active. See: Setting HPC and Analysis Options.

To select an existing, active configuration:

- From the **Simulation** tab, use the **Active** drop-down menu to select a configuration.

Editing Distributed Machine Configurations

Selecting an Optimal Configuration for Distributed Analysis

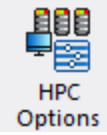
Large Scale DSO for Parametric Analysis

Configuring Distributed Analysis

To configure distributed analysis you select a distributed machine configuration. This is a list of machines to use for a simulation, based on considerations such as whether the simulation is more memory intensive or more CPU intensive, relative to the resources available on your network. (See Selecting an Optimal Configuration for Distributed Analysis for a discussion of issues.) To create an new distributed machine configuration. or to edit an existing one, see Editing Distributed Machine Configurations.

To select from an existing configuration:

1. Click the **HPC Options** icon on the **Simulation** ribbon,

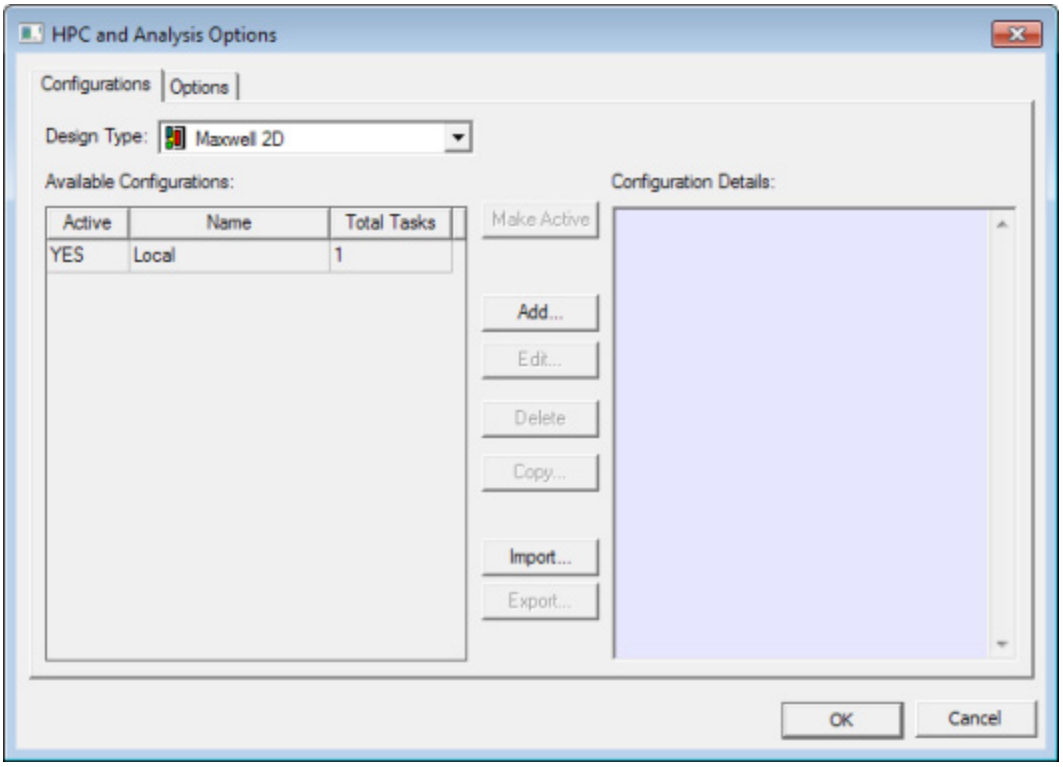


or click **Tools>Options>HPC and Analysis Options.**

This opens the **HPC and Analysis Options** dialog box. You can define and select configurations for Maxwell 2D, 3D, and RMxprt design types separately. You can view a list of Available configurations, and a report of the configuration details. From the current, list, you can select a configuration to **Make Active**. You can also **Add** a new configuration, **Edit** an existing one, or **Export** as a Ansys Configuration file (*.acf). You can also **Import** a configuration file. This lists existing configurations, and shows all machines in the selected configuration, enabled or not. You can **Copy** an existing configuration, typically to edit the name and contents for other purposes.

In the **Options** tab you can enable queuing, set the design type, set licensing options and specify default process priority.

For a more detailed discussion of this dialog, see Setting HPC and Analysis Options.



2. To define a new configuration, on the **Analysis Settings** dialog box, click the **Add** button to open the **Analysis Configuration** dialog box. See Editing Distributed Machine Configurations.

Related Topics

Editing Distributed Machine Configurations

Selecting an Optimal Configuration for Distributed Analysis

Setting Options in Maxwell

Setting HPC and Analysis Options

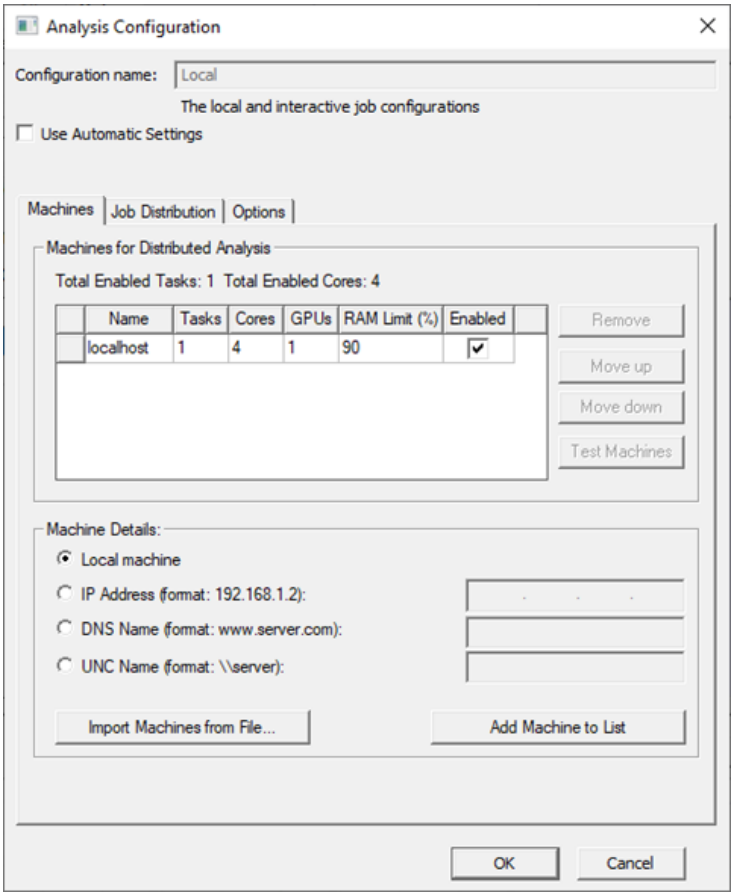
Editing Distributed Machine Configurations

To edit an existing machine configuration:

1. Click **Tools>Edit Active Analysis Configuration** to open the **Analysis Configuration** dialog directly or click the **Analysis Config** icon on the Simulation ribbon.

   This opens the **Analysis Configuration** dialog directly. You can also access this dialog from the **HPC and Analysis Options** dialog by clicking the **Add..,**, **Edit...,** or **Copy...** buttons.

If you select **Add...** from the **HPC and Analysis Options** dialog box, the fields are empty. If you select **Edit...** or use **Tools>Edit Active Analysis Configuration**, or click **Copy** from the **HPC and Analysis Options** dialog box, the fields show the selected configuration.



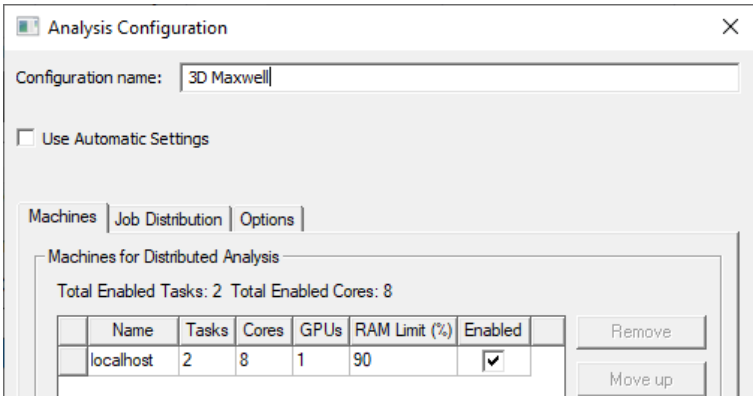
The option and features available differ for the various solvers.

Note	The **GPUs** column does not appear for Maxwell 2D solves. Use of GPUs is not currently supported for Maxwell 2D.

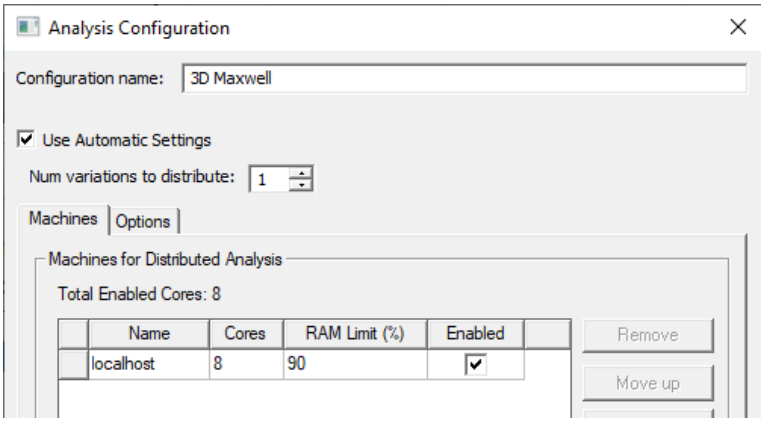
2. If you **Add** a new configuration, you must specify the name of the new or edited configuration. It cannot be empty and cannot be a previously used name or a reserved word.

3. If the solver supports automatic settings, you can select the **Use Automatic Settings** check-box to assign resources automatically, or you can uncheck the box to specify job distribution manually in the **Job Distribution** tab, as discussed below. For Maxwell, this

setting currently is supported only for 2D and 3D Transient, and 2D and 3D Eddy Current designs.



Selecting **Use Automatic Settings** removes the **Job Distribution** tab, setting those parameters automatically based on the best use of available resources for the current analysis.

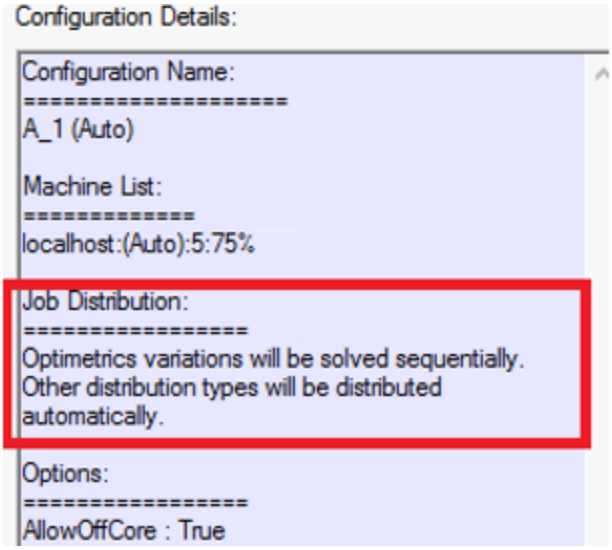


For Maxwell 2D and Maxwell 3D designs **Use Automatic Settings** must be checked to enable **Num variations to distribute**. In such cases, if you specify more than 1, the distribution of variations is in proportion to RAM availability on the machines listed. Depending on the resources available, and whether the simulation defines Optimetrics variations and other distributed types, the simulation can include up to three levels of distribution. When you close the **Analysis Configuration** dialog box, the **HPC and Analysis Options** dialog **Configuration Details** field provides details of the Job Distribution for 3 level distribution.

For 2D and 3D Transient designs, the **Use Automatic Settings** option distributes one excitation to each machine listed in the configuration. When this option is enabled, a minimum of 2 cores must be assigned. Each machine uses all cores assigned to it while solving its excitation. Unlike automatic frequency setup, the machines are assigned

sequentially without regard to machine capability. For 2D and 3D Eddy Current designs with **Use Automatic Settings**, a minimum of 4 cores must be assigned.

Variations will not be distributed when the number of variations to distribute is set to 1. In this case when you close the **Analysis Configuration** dialog box, the **HPC and Analysis Options** dialog box, **Configuration** tab provides details of the Job Distribution that does not use 3 level distribution.



4. The **Machines Tab** contains the machine list for the analysis configuration.

   Here you can provide machine information, either by specifying Machine Details, or by importing a list of machines from a file. You can then remove, order, test, and enable machines on the list. Control buttons let you **Add machine to List** or **Remove** machines from the list.

   Numbers of Tasks and Cores

   If automatic settings are either not used or not available, note that each machine has an associated number of tasks and number of cores. The number of tasks specifies the total number of compute jobs that will be run on that machine simultaneously. Each separate solver, or distribution is one task. The total cores specifies the total number of cores that will be used on the given machine. This is how you specify multiprocessing. For example, if you want to run two threads for each task, you specify Total Cores = 2 x Number of Tasks. The number of cores must always be greater than or equal to the number of tasks. If the number of cores is not an exact multiple of the number of tasks, some tasks will use more cores than others. For example, if Number of Tasks is 4 and Total Cores is 10, 2 tasks will use 3 cores, and 2 tasks will use 2 cores.

   GPUs

Note	• The **GPUs** column does not appear for Maxwell 2D solves. Use of GPUs is not currently supported for Maxwell 2D.

	• The Electronics Desktop supports GPU acceleration only for Maxwell 3D Eddy Current Solution Matrix solves.

To enable use of GPU acceleration for Maxwell 3D solves, you set **Enable GPU** to **True** on the **Options** tab in the **HPC and Analysis Options** dialog (see Setting HPC and Analysis Options); and disable (uncheck) **Use Automatic Settings** in the **Analysis Configuration** dialog box. The matrix solver automatically determines if all cores should be used, or if one GPU should be used to give the best performance. For example, for a Maxwell 3D Eddy Current Solution Matrix distribution, if you specify 4 cores for the simulation, the 3D eddy current solver will use 4 cores in parallel during matrix assembly while the matrix solver will use either 4 cores or 1 GPU.

RAM Limit (%)

Here you can specify the maximum percentage of the machine's RAM to be used for processing.

Import Machines from File...

You can import a machine list from a file, and an enhanced the file format handles the new flexibility. Each line of the file can contain a machine specifier of the form:

<MachineName>:<NumTasks>:<NumCores>

Note: this same format is used with the "-machinelist file=" command line option.

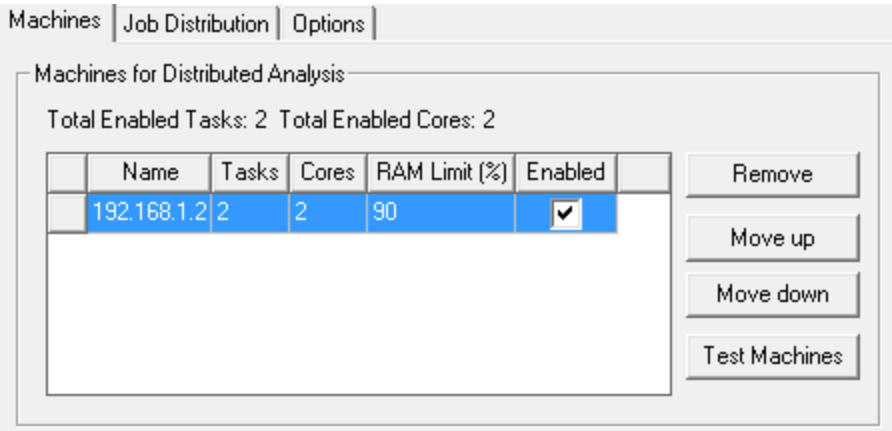
Local Machine Radio Button

To streamline the common case of running jobs on the current machine, use the dedicated radio button to specify the local machine.

5. For each machine to manually add to the list, under Remote Machine Details, specify an IP address, a DNS name, or a UNC name.

   The remote machines must have the same ANSYS Electromagnetics Suite version installed in the same OS and version, and have the RSM service active.

   Once you have specified the remote machine details, either directly or by **Importing Machine from a File**, you select a machine from the table to enable the buttons to **Remove** a machine, or to **Move** a machine up or down on the list.



The displayed list shows the order in which you entered them irrespective of the load on the machines. If you have selected **Use Automatic Settings**, the Tasks column field is disabled because you no longer need to make those assignments. To control the list order, select one or more machines, and use the **Move up** or **Move down** buttons. **Move up** and **Move down** are enabled when you select one or more adjacent machine names.

Enabled Machines

Each machine on the current list has an **Enabled** checkbox. Here you can enable or disable the listed machines according to circumstance. Above the table, the dialog gives a count of the total enabled tasks, and the total enabled cores.

For distributed tasks, the software will allocate the total cores on a given machine to that machine's tasks. If a machine with 8 cores is running 2 distributed tasks, the software will automatically allocate 4 cores to each task. If it is running 4 distributed tasks, each gets 2 cores. And if it is running 3 distributed tasks, the first two tasks get 3 cores and the last task gets 2 cores.

For a given variation (for example, frequency or geometry), you should make assignments so that each task has the same number of cores. This is because the solvers attempt to make each task computationally balanced. For example, with two machines, one with eight cores, and another with four, assuming that the memory is proportionally equivalent, you could assign two tasks for machine 1, and one task for machine 2, giving all tasks the same number of cores.

In general, Ansys Electromagnetics Suite solvers use machines in the distributed analysis machines list in the order in which they appear. If you select a distributed configuration (rather than Local) on the ribbon Simulation tab, and you launch multiple analyses from the same UI, Ansys Electromagnetics Suite solvers select the machines that are running the fewest number of distributions in the order in which the machines appear in the list. For example, if the list contains 4 machines, and you launch a simulation that requires one machine, the solver chooses the first machine in the list. If another simulation is launched while the previous one is running, and this simulation requires two machines, the solver

chooses machines 2 and 3 from the list. If the first simulation then terminates and we launch another simulation requiring three machines, the solver chooses 1, 4, and 2 (in that order)

Test Machines

Test Machines- When multiple users on a network are using distributed solve or remote solve, they should check the status of their machines before launching a simulation to ensure no other Ansys Electromagnetics processes are running on the machine. To do this, you can select one or more machines and click the **Test Machine**s button. A **Test Machines** dialog opens.

The test goes through the current machine list and gives a report on the status of each machine. A progress bar shows how far testing has gone. An Abort button lets you cancel a test. When the test is complete, you can Close the dialog box. If you need to disable or Enable machines from the list based on the report, you can do so in the **Distributed Analysis Machines** dialog.

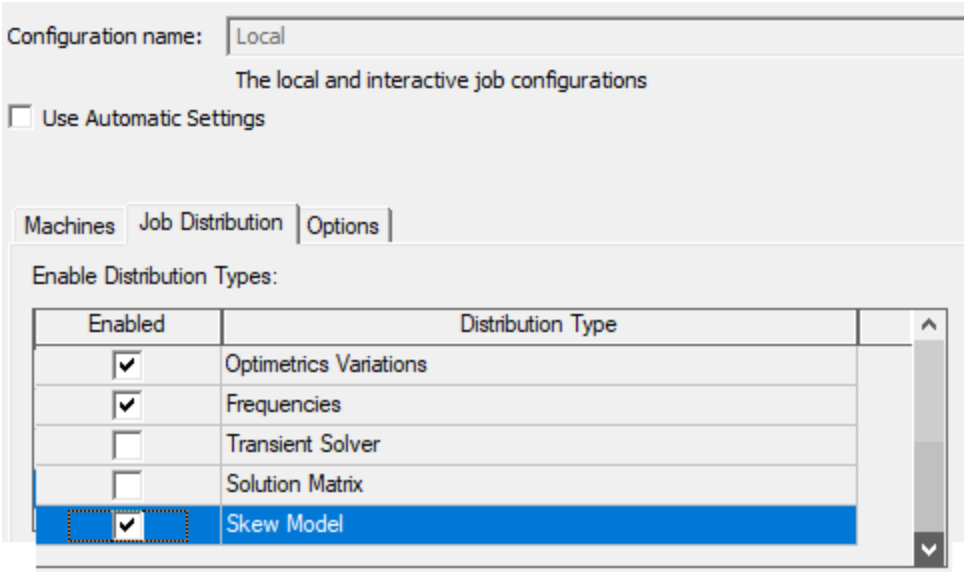
Job Distribution Tab

Use this tab to manually enable specific job distribution types, and to enable multilevel solves. The **Job distribution** tab is disabled if you select **Use Automatic Settings**. Use this tab to manually enable specific types of job distribution and to enable multi-level solves.

Job distribution types are design type specific and will differ between solvers.

- Maxwell 2D and 3D design types can use **Optimetrics Variations**, **Frequencies**, **Transient Solver**, **Solution Matrix**, and **Skew Model** distribution types.

- RMxprt can use only **Optimetrics Variations**.



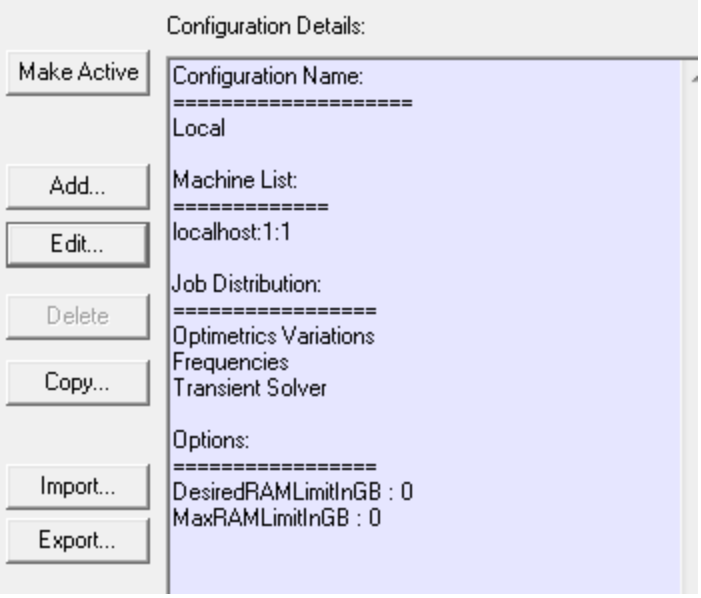
Use the check boxes to enable/disable available distribution types. The job distribution list box allows you to specify which job distribution types to allow for the current analysis configuration. At solve time, the Ansys Electromagnetics software automatically selects the best distribution type from the enabled distribution types. By enabling/disabling distribution types, you can control the job distribution.

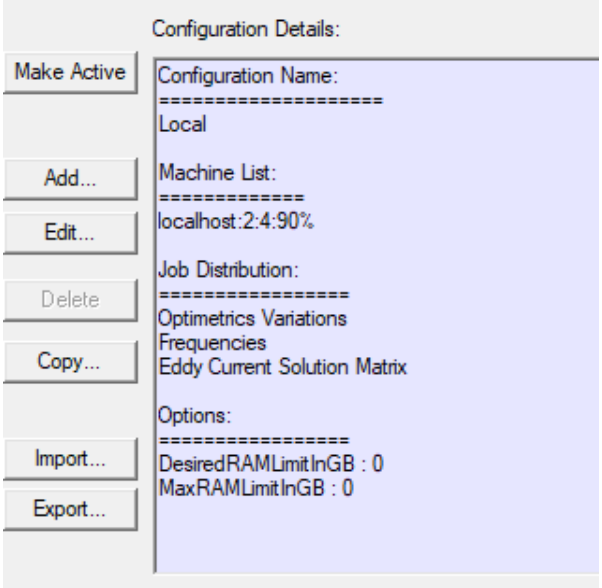
Enabling a distribution type does not necessarily mean it will be used. It must also be allowed by the solve setup. For example:

- the **Transient Solver** distribution type that enables use of the Time Decomposition Method, will only be *used* with Maxwell 2D and Maxwell 3D transient designs.
- The **Solution Matrix** distribution type that enables use of the Matrix-based Domain Decomposition Method will be used with both 3D eddy current designs and 3D magnetostatic designs.
- The **Skew Model** distribution type for use with Maxwell2D XY transient designs that use multi-slice skew models. Both single and two level distributions are supported.

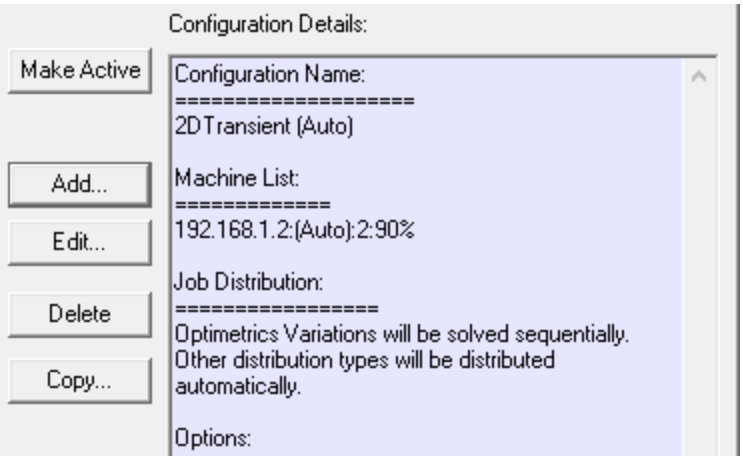
Note that the enabled distribution types will apply to all setups of the given design type, so it is possible for different setups in a design to be solved using different distribution types.

The distribution types that you enable here are listed in the HPC and Analysis Settings dialog box in the Configuration details pane when select that configuration from the list.





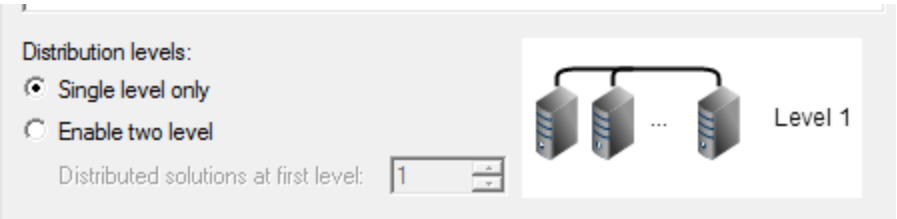
If your solver permits, and you have selected **Use Automatic Settings**, the Job Distribution notes that Optimetrics Variations will be solved sequentially. Other distribution types will be distributed automatically.



For products that support two-level distribution, when the design is appropriate, you can turn on two level distributed solves, and specify the number of distributed solutions for level 1.

Distribution Levels

The radio buttons let you specify **Single level only** or **Enable two level** distribution.



If you select Single level only, one distribution type will be applied at each stage of the solution process. If multiple types are available, the higher level solution will generally be distributed. All machine tasks will be used by the single-level distribution.

Single Level Distributions

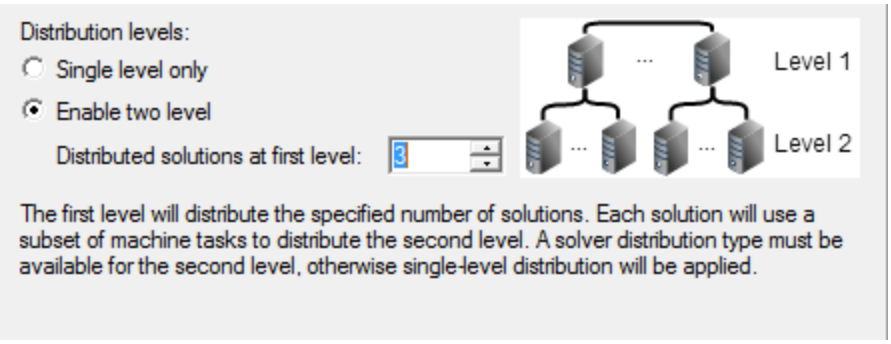
Supported distribution types are **Optimetrics Variations**, **Frequencies**, **Transient Solver**, **Solution Matrix**, and **Skew Model**. Frequencies and solver distributions require MPI.

- Parallel distribution types such as **Optimetrics Variations**, and **Frequencies** are considered as not required. If these types are not able to distribute, the simulation can be run sequentially.
- **Transient Solver**, **Solution Matrix**, and **Skew Model** distribution types are considered as required. If these types are enabled the software will assume that distribution is necessary to extend the simulation scale or add fundamental solution capabilities.
- When multiple distribution types are available, the higher level solution will generally be distributed. The priority order is : **Optimetrics Variations**, **Transient Solver**, **Frequencies**, **Solution Matrix**, and **Skew Model**. If Iterative Solver is enabled in the Eddy Current solve setup, the priority order will be: **Solution Matrix**, **Optimetrics Variations**,

Transient Solver, and **Frequencies**. For example, **Optimetrics Variations** will be distributed when both **Optimetrics Variations** and **Transient Solver** are selected.

Two Level Distributions

Selecting **Enable two level** enables the Distributed Solutions at first level selection box.



The first level will distribute the specified number of solutions. Each solution will use a subset of machine tasks to distribute the second level. The **Transient Solver** distribution type must be available for the second level for a Transient design; otherwise single-level distribution will be applied. The **Solution Matrix** or **Frequencies** distribution type must be available for the second level for an Eddy Current design; otherwise single-level distribution will be applied.

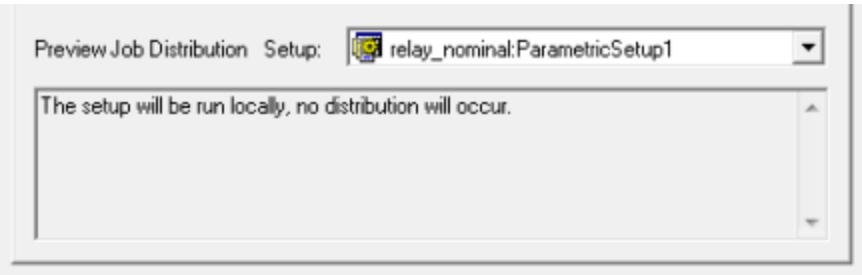
- Distribution types that can be distributed at Level 1 are **Optimetrics Variations**, and **Frequencies**(Maxwell 3D).
- **Frequencies**, **Transient Solver**, **Solution Matrix** (Maxwell 3D only), and **Skew Model** (Maxwell 2D XY transient only) distribution types can be distributed as Level 2.

The following are examples of a two-level distribution:

- A parametric setup distributing **Optimetrics Variations** as level 1, and a **Frequencies** distribution as level 2.
- A parametric setup distributing **Optimetrics Variations** as level 1, and a **Skew Model** distribution as level 2.

Preview Job Distribution

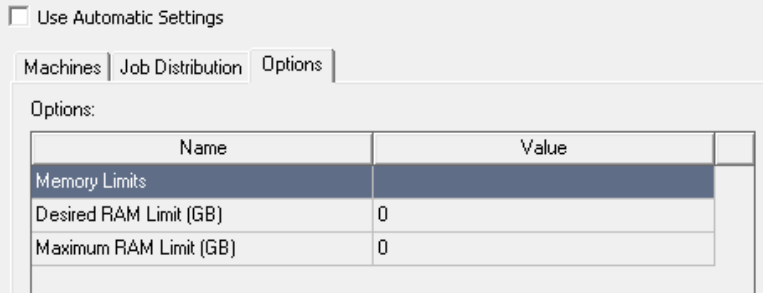
The Preview Job Distribution Setup menu and field lets you view how the selected setup will be distributed.



Options Tab (Analysis Configuration Dialog)

Use the **Options** tab to specify options for the current analysis configuration. Different design types may have different options available in their analysis configurations.

Note	The Options tab is not displayed for RMxprt analysis configurations.

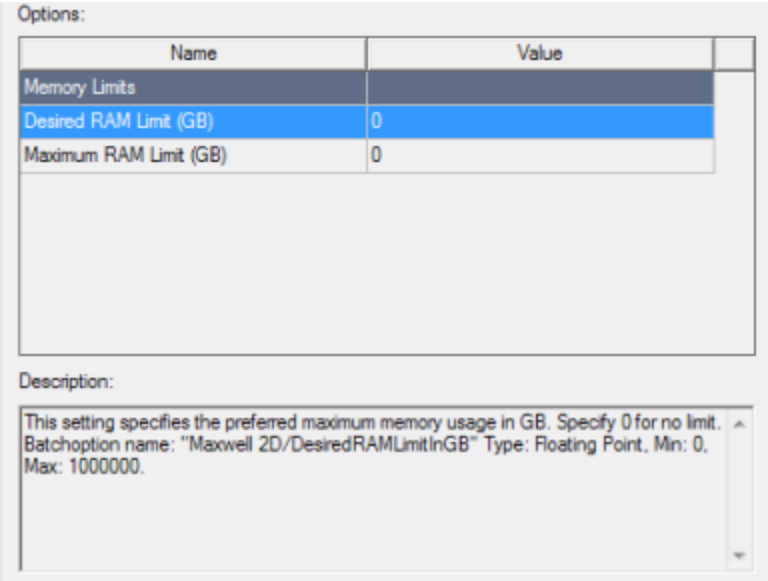


The Options grid contains the available option Names and editable Values.

These options settings will be in effect only when all the following are true:

- A design is being solved whose design type matches this analysis configuration's
- This analysis configuration is the active configuration for its design type
- You have not specified corresponding batch options on the command line. Command line batchoptions can be used to override the options specified by the active configuration.

Selecting an available option causes a display of a description of the option.



Relation to Batchoptions

Analysis configuration option settings can be overwritten by specifying the option name and value inside a -batchoption string. See -batchoptionhelp for a list of batchoption names and possible values. You can also view all available and frequently used batchoptions in the Job Management **Submit Job To:** dialog box, by clicking the **Add...** button under Analysis Options. This opens the **Add Batchoption** dialog box, which gives access to all batchoptions.

Adding Configurations or Accepting Edits

Click **OK** to accept the changes and close the **Analysis Configuration** dialog box. Only machines checked as **Enabled** appear on the distributed machines Configuration Details Machine list..

Regardless of the machine(s) on which the analysis is actually run, the number of processors and RAM Limit (%), the Desired and Maximum RAM Limits, and the default process priority settings are now read from the machine from which you launch the analysis. See Setting HPC and Analysis Options.

For more information, see distributed analysis.

Note	The option is only active if there are multiple rows listed in the parametric table, there are multiple frequency sweeps listed under a given analysis setup, and the number of distributed analysis machines is two or greater.

Time Decomposition Method for Maxwell Transient Designs

Model Setting Tab

Selecting an Optimal Configuration for Distributed Analysis

With the distributed solve option (DSO) it is possible to assign more than one machine in the DSO setup panel to a single computer - assuming the computer has multiple cores. For example, a quad core computer can be listed 4 times in the DSO machine list and each CPU will run a separate simulation in the sweep. This raises the question of how to configure a distributed solution option (DSO) in combination with the multiprocessing option to take optimal advantage of the available hardware. The simplest answer is that for the overwhelming majority of situations the speed improvement will be greater if additional machines are added to a DSO than if the same CPU's are added as multiple processors. That simple answer assumes that there is enough memory for the DSO simulations.

For multiple DSO simulations on a single machine the total memory needed is the sum of the memory used by each simulation. For example, assume we are running discrete frequency sweep and each frequency point needs 3.5GB. Our computer has only 8GB of RAM but is a quad core system. To keep the computer from going heavily into swap, which is highly inefficient, we would only want to assign this computer twice to the list of machines in the DSO setup. To take advantage of the remaining 2 CPU's then it would make sense to set the number of distributed processors to 2. This would be the optimum for this setup. In addition one would need to be sure that the amount of disk space available is also sufficient to fit all the requested simulations - typically hard drive space is not the limiting factor.

Large Scale DSO for Parametric Analysis

Large Scale DSO for parametric analysis operates through a non-graphical batch application called desktopjob. You can run the desktopjob command-line to perform parametric analysis DSO. The command-line interface supported by this batch program is similar to the command-line used for regular DSO jobs.

Large Scale DSO is used for 'large scale parallel' jobs, which either fail or scale poorly as Regular DSO jobs. A Large Scale DSO job does not support the output of full parametric results, but produces "reduced" datasets corresponding to predefined Rectangular plots. The extracted columns of data are saved as .csv files. Typically, there is one .csv file per-trace, per-variation. These .csv outputs can be used directly in downstream applications (for example, Excel, or custom programs that parse .csv files). They can also be Imported as Dataset Solutions for post processing. Non-Rectangular plots of the design (such as statistical eye or digital plot) are not extracted). In order to produce a new output you must re-run the analysis.

The basic process involves:

1. Prepare the project for Large Scale DSO Analysis
2. Submit the Large Scale DSO Job through the Tools>Job Management menu, or via a command line.
3. Monitor the job's progress
4. Post process the results

For details, refer to the following sections:

- Prerequisites for Large Scale DSO
- Job Management Interface for Large Scale DSO
- Large Scale DSO Example
- Command Line Syntax
- Deployment/Configuration
- Results Database Organization
- Job outputs
- Job Monitoring
- Known Issues for Large Scale DSO
- Troubleshooting for Large Scale DSO

Large Scale Distributed Solve Operation could submit a parametric setup to be solved in multiple machines, each machine may launch multiple EM-Desktop processes to solve the assigned variations (Design Points). Variations are distributed to each task (EM-Desktop process) equally, regardless of the machine hardware and each variation's complexity. In practice, some tasks may finish earlier than others, in some extreme case some tasks may hours behind fastest task. DSO can redistribute tasks when a task finishes before other task. Variations are removed from slow tasks and reassigned to fast tasks. If you abort a task, they can be re-assigned to the running task, when the running task finish its original assignment. For more information, see Large Scale DSO theory.

Large Scale DSO offers two new batchoptions related to the redistribution ability.

LargeScaleDSO/VarRedistribution, where 0 disables redistribution (default), and 1 enables it.

LargeScaleDSO/RedistributionLimit, is a positive integer specifying the minimum estimated remaining time (in minutes) for variations to redistribute to another task. The default is 3.

Aborting a Large Scale DSO Simulation

To abort the whole Job, select the **Abort** button on the Job Monitor dialog.

To abort using the Job progress bar, click the button next to the Job progress bar, Click the **Abort** menu item in the popup.

To abort all tasks in a Node(host), click the button next to the node progress bar., and click the **Abort** menu item in the popup. Aborted Variations will be redistributed to other running Nodes, if redistribution is turned on.

To abort an individual task, click the button next to the node progress bar, and click the "Detail" menu item in the popup. In the Task status dialog box, click the **Task** button in the grid. In the variation status dialog box, click **Abort** button. Aborted Variations will be redistributed to other running tasks, if redistribution is turned on.

To terminate a hanging EM-Desktop process, the hanging ansysedt.exe process won't respond to the first abort command. Send a second abort command to terminate the hanging process. Remaining variations will be redistributed to other running tasks, if redistribution is turned on.

For an EM-Desktop process crashed or killed by Windows Task manager or other tools, the task status will be shown as aborted, Remaining variations will be redistributed to other running tasks, if redistribution is turned on.

Running Maxwell from a Command Line

Distributed Analysis

High Performance Computing (HPC) Integration

Large Scale DSO Theory

Prerequisites for Large Scale DSO

General Prerequisites

- Ansys Electronics Desktop must be installed on the cluster which runs either a supported scheduler or Ansys RSM.
- The cluster is compatible with large Scale DSO Requirements
- For releases before 19.0, the input projects for Large Scale DSO jobs distributed to multiple hosts are normally required to be on a shared drive. Beginning with the 19.0 release, this requirement is eliminated for most cases. For the RSM scenario, the shared drive requirement is eliminated, but the project must be accessible on the local host, which must be the first host for the job. For the scheduler scenario, because the job can get started on any of the compute nodes based upon what is allocated to the job by scheduler, users may still need to have the project on a shared drive. However some customers have their own job scripts for job spooling, which copy the project from the source location to a local folder on the first execution host of the job. Such customers will no longer need shared drive for their projects.
- Every node of the cluster supports the disk space (in temp directory) and memory requirements of multiple engines that run in parallel.
- All the machines allocated to Large Scale DSO job must all come from the same platform, Windows or LINUX.

RSM Environment

On the Windows platform, RSM (ansoftrsm.exe) is started as an 'admin' account, rather than as a 'system' account.

Note	Large Scale DSO does not support RSM Service running with 'system login' credentials.

- On each machine of the cluster, 'desktopjob' application is registered with RSM service using the command shown below:

  Windows: <installation-directory>/<platform> desktopjob.exe -regserver

Linux: <installation-directory>/<platform>desktopjob -regserver

Note	Detailed cluster configuration instructions are here.

Scheduler Environment

- No extra configuration is needed.

Related Topics

Large Scale DSO for Parametric Analysis

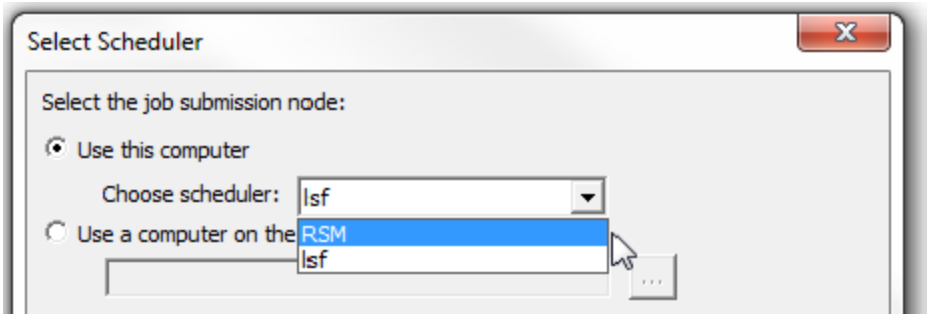
Distributed Analysis

High Performance Computing (HPC) Integration

Job Management Interface for Large Scale DSO

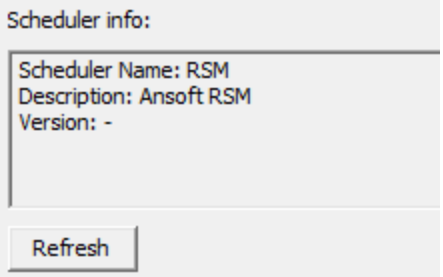
Large Scale DSO jobs run only in non-graphical batch mode, irrespective of the scheduler environment. This is in contrast to a Regular DSO job, which can run in graphical mode. This consideration implies that projects corresponding to Large Scale DSO job must be saved and closed prior to job submission. Secondly, the command to submit a Large Scale DSO job is only available through **Tools** > **Job Management** or via a command window, while a Regular DSO job can be run in an RSM environment by right-clicking directly on the parametric setup. The Job Management window is accessed by running Ansys Electromagnetics product Desktop on the designated Postprocessing Node of the cluster. The Desktop provides UI commands for Scheduler selection, Job submission and Job monitoring/control. You access the Scheduler User Interface by clicking **Tools>Job Management>Select Scheduler...**

Click Select Scheduler to display the selection dialog box. A drop down lists potential schedulers, (which can include RSM, lsf, or sge, depending on the environment).



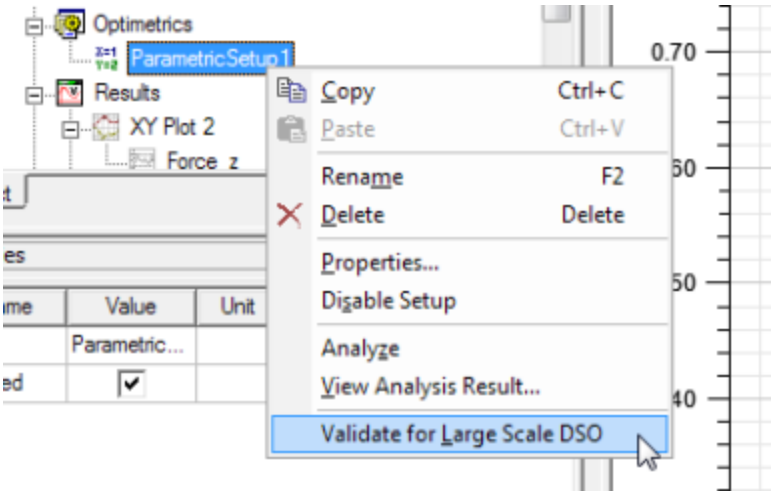
If you select a scheduler that is not supported in your environment, you receive a warning message.

After selecting a scheduler, you can click Refresh to display information for that scheduler.



When you have selected a scheduler supported in your environment, perform the following steps to submit a Large Scale DSO job.

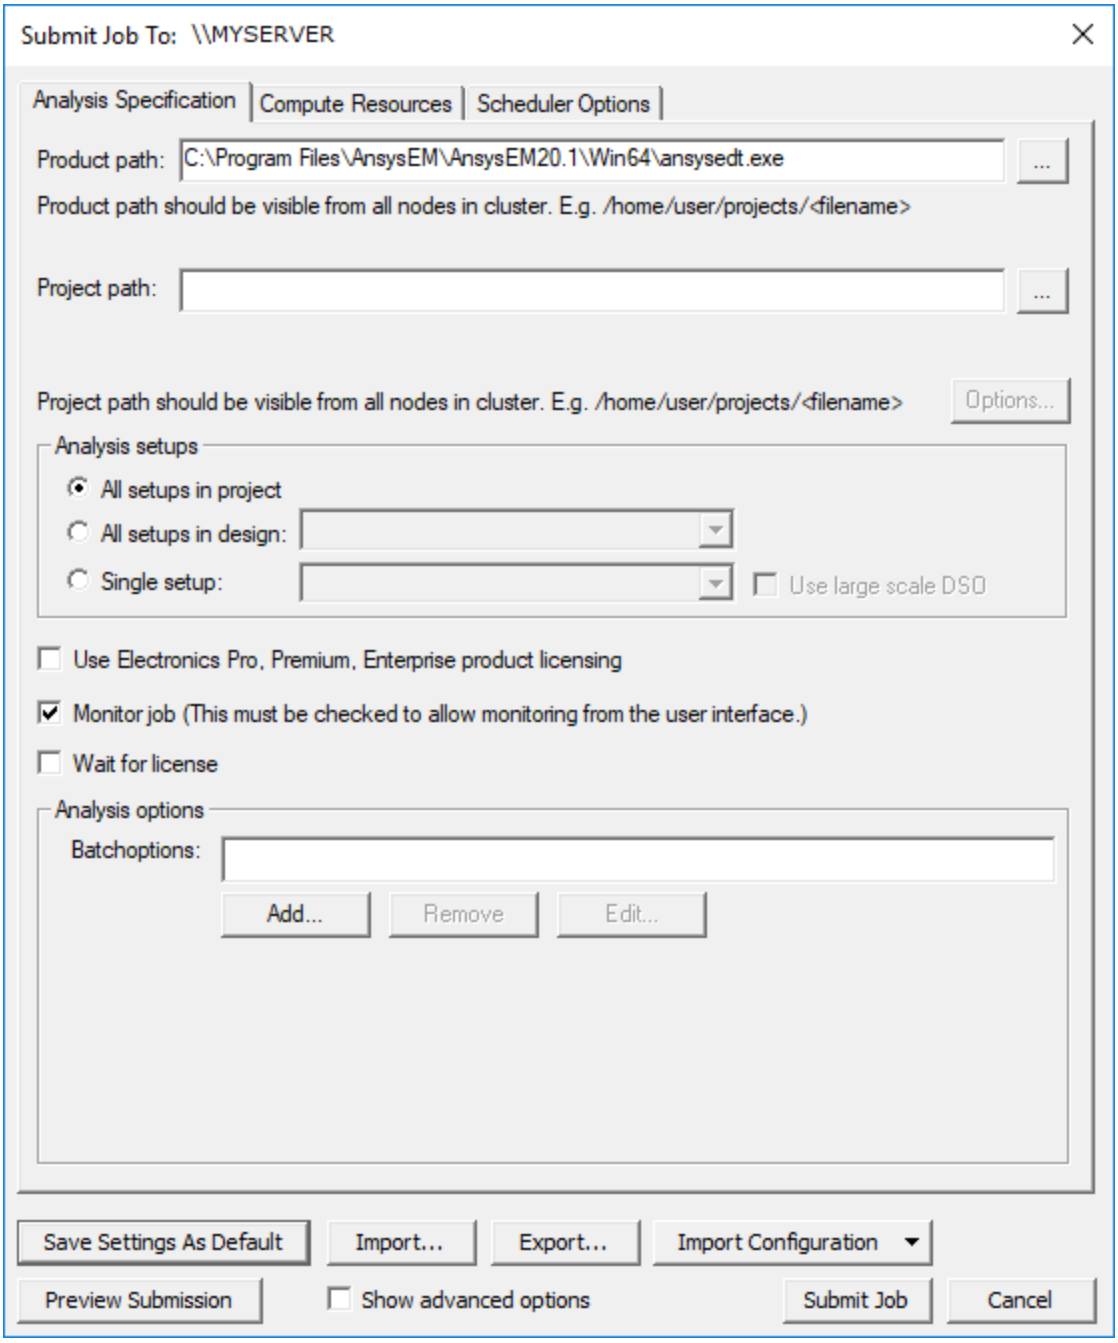
1. Set up and prepare the model on your local workstation. Right-click the desired solution setup and select **Validate for Large Scale DSO**.



2. Correct any errors and save the project.
3. Copy the project (or folder, if the project references external files) from a personal workstation to a shared drive on cluster.
   - In the RSM environment, you must specify a machine list (See Editing Distributed Machine Configurations).
   - In a Linux scheduler environment, a cluster must have a designated 'postprocessing node'.
4. Open a remote desktop session (or equivalent) on the node corresponding to the first machine in the machine list (the designated Postprocessing Node on Linux).
5. Launch Electronics Desktop on that node and open the project.
6. Verify that the model has been prepared correctly.

7. Close the project.
8. Submit the job one of several ways:
    - Click **Tools** > **Job Management** > **Submit Job**.
    - Click **Project** > **Submit Job**.
    - Click <*product_name*> > **Submit Job**.
    - Select the **Simulation** tab and click the **Submit** icon.

   The **Submit Job To** window appears, on the **Analysis Specification** tab.



9. Run **Tools>Job Management>Submit Job...** The standard Job Submission panel pops up.

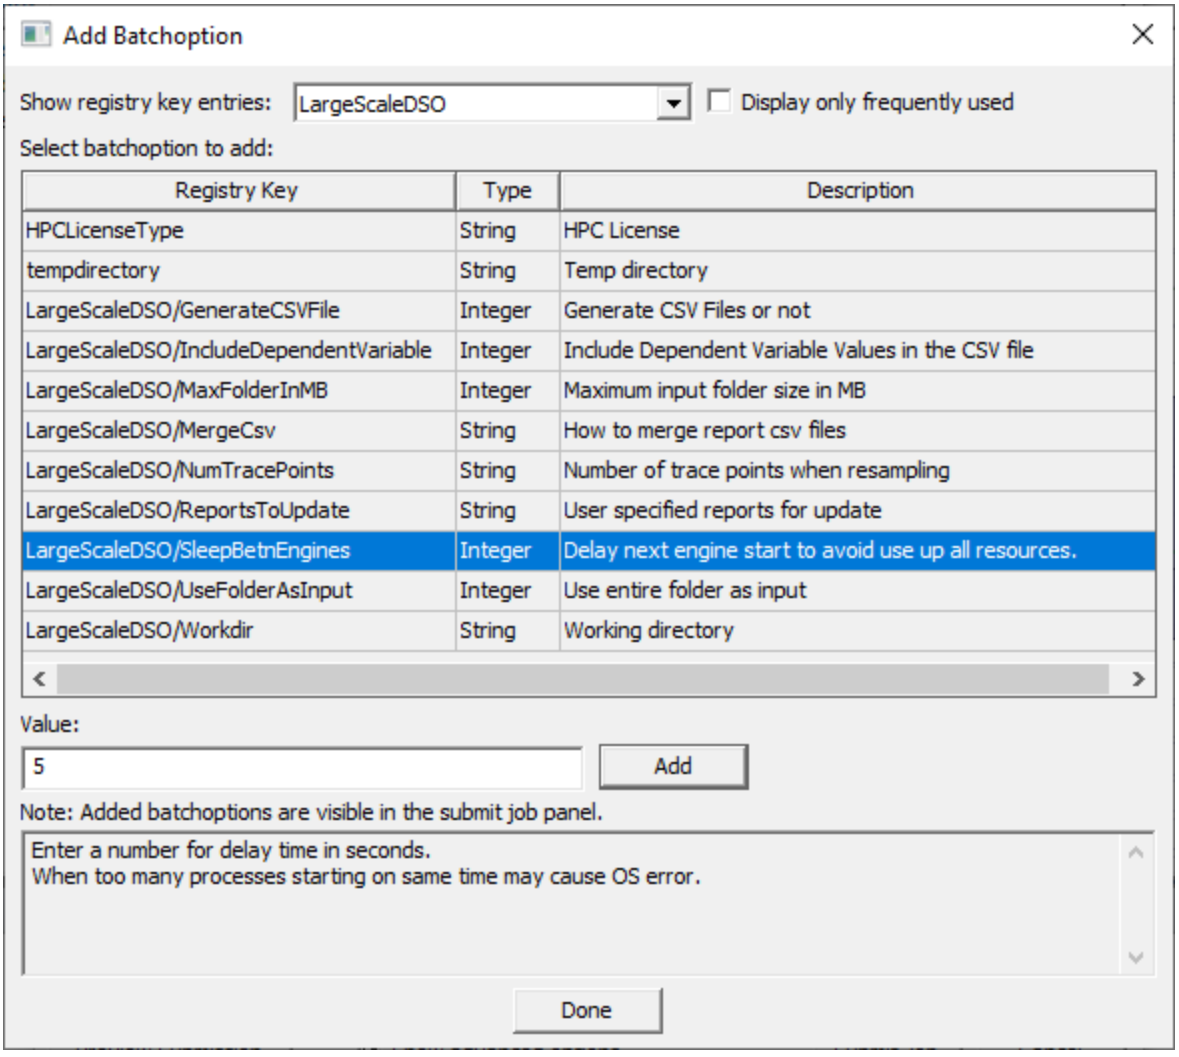
> **Note:** Options vary slightly depending on the selected scheduler.

10. Specify information for all fields:

- Most options will not be enabled until you select a **Project path**.
- Under **Analysis setups**, select setups for analysis.

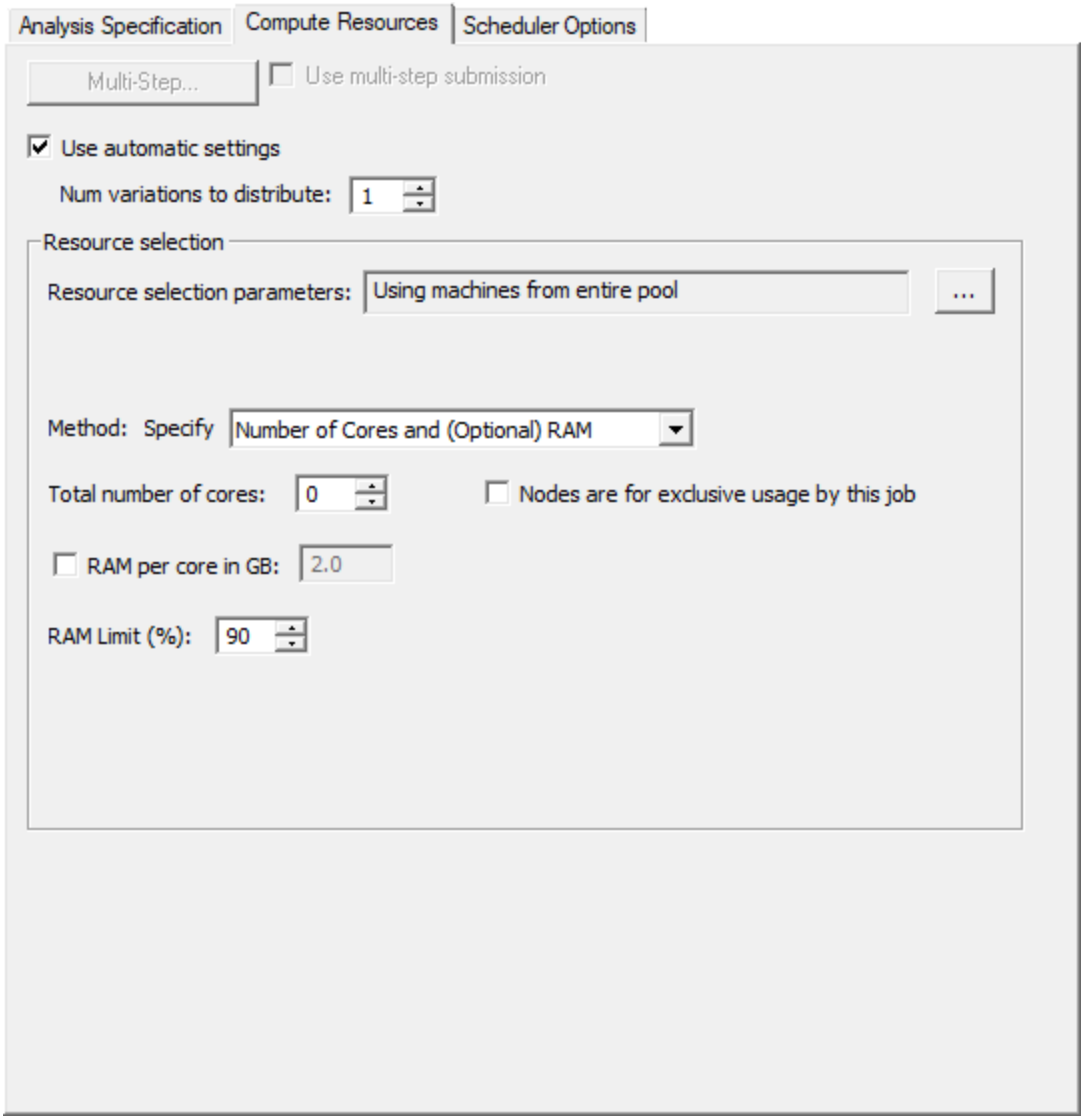
  For Large Scale DSO, select a **Single setup** from the drop-down menu and ensure the **Use large scale DSO** check box is selected.
- Determine whether to **Use Electronics Pro, Premium, Enterprise product licensing**, whether to **Monitor job**, and whether to **Wait for license.** If you wish to monitor jobs through **Tools** > **Job Management**, you must enable job monitoring.
- Add **Batchoptions**, if desired.

  The following shows batchoptions specific to Large Scale DSO.



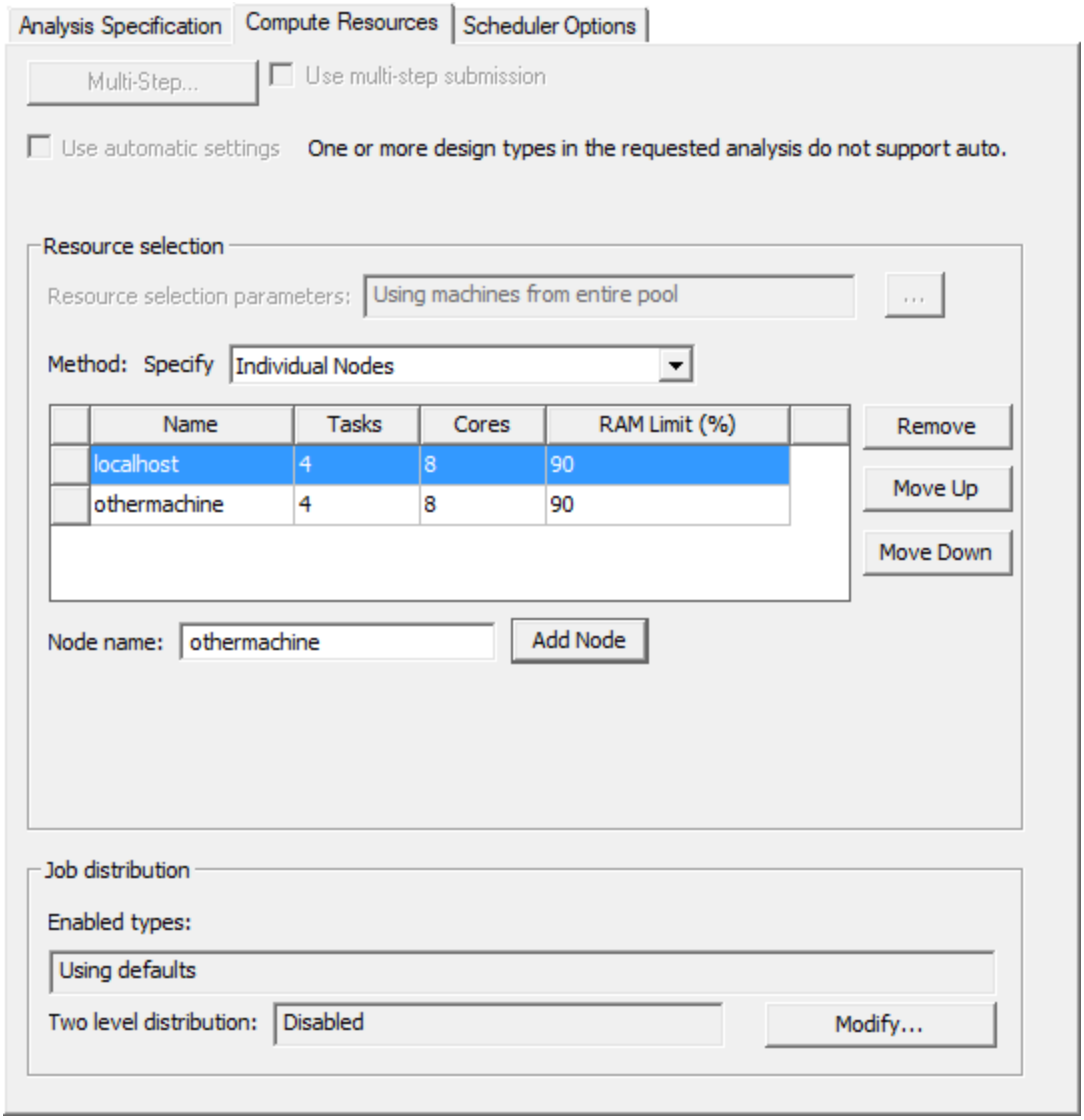
11. Select the **Compute Resources** tab.

    When available, **Use automatic settings** may be selected. If it is selected, also select the Number of variations to distribute.



The values you specify represent minimal requirements for each condition that can interact in leading to the total resources the Scheduler derives from them. A submission preview shows the number of resources assigned.

When automatic settings are not available or are not selected, additional options appear:



For RSM Large Scale DSO jobs submitted from the Job Submission panel, localhost must be the first node in the resource selection panel. Otherwise, the job will fail.

In the **Job distribution** area, you can enable or disable **Two-level distribution** by clicking **Modify**. See: Two-level Distribution Guidelines.

12. If desired, click **Preview Submission** to view a summary of the commands to be sent to the scheduler. The text can be copied to the clipboard.
13. To submit the commands to the scheduler, click **Submit Job**.

Note	The RSM environment does not support queuing, so clicking **Submit Job** starts it immediately.

14. If you enabled job monitoring, you can monitor the job via **Tools**> **Job Management** > **Monitor Jobs**. See: Monitoring Jobs.

Large Scale DSO Command Line Syntax

Large Scale DSO feature operates through a non-graphical batch application called 'desktopjob'. You can run the desktopjob command-line to perform parametric analysis DSO. The command-line interface supported by this batch program is consistent with the command-line used for current DSO jobs. “desktopjob -help” lists all available command-line options as shown below:

Command Line Syntax:

desktopjob.exe `<options> <project-path-on-shared-drive>`

Note that the project path can be to an archive file.

Options:

-help: Print this help text

-cmd: Specify command to run. Available choices: dso

-ng: Run analysis in non-graphical mode

-monitor: Output progress and messages to standard output/error

-waitforlicense: Queue the job until the availability of licenses

-useelectronicsppe: Use Electronics Pro Premium Enterprise licensing to override the Tools/Options entry. For example, -useelectronicsppe 1 to use that license, or -useelectronicsppe 0 to not use that license.

-preserve: Preserves the local storage space of the distributed job for investigation into the job's run. If local storage directory (for example, the temp directory) is provisioned by scheduler, ensure it is also configured to preserve the job's local storage. *This storage should be deleted manually*.

-batchoptions: Override the Tools/Option entries through either a batchoptions file or batchoptions string.

Example:

```
-batchoptions <config-file-on-shared-drive>
-batchoptions "'name1'='val1' 'n2'='v2'"
```

-jobid: Specify a custom job ID for the job. The job's output is organized into a folder with job ID name. This parameter is ignored when run under a scheduler.

-machinelist:

- In the context of **RSM**:

  Specify machines for distributed analysis. Machine list is specified either inline (as a comma separated machine names) or through a file. Multiple cores are specified by repeating the name of machine or by embedding number of cores in the machine name, using a colon separator.

  Example 1:

  ```
  -machinelist "list=m1,m1,m1,m2,m2,m3"
  ```

  Example 2:

```
-machinelist "list=m1:3,m2:2,m3"
```

Example 2:

```
-machinelist "file=machines.txt"
```

- In the context of **a scheduler such as LSF**:

  Specify the portion of total machines for distributed analysis. Use remaining for overhead or shared memory multiprocessing.

  Example:

  ```
  -machinelist "Num=10"
  ```

-auto: Run the leaf jobs in auto mode.

-usefolderasinput: Choose this option if the job's input represents the entire folder rather than just the project file.

-maxfolderInMB: Specify the maximum size (MBytes) of input folder that is allowed for a valid job. By default, the maximumsize allowed for input is 10MB. Specify a value of 0 to remove this size restriction and enable inputs of any size. Note: this option applies when '-usefolderasinput' is used.

-workdir: Specify the shared drive folder for status and result files generated by analysis. By default, the results folder of input project is used as the work directory.

-meregecsv: [acrossDPs | singleDP | both]:

across DPs: Merge report csv files for all design-points (variations). One file is created per trace, across all variations.
singleDP: Merge csv files within a single design-point (variation). One file is created per variation, per a set of traces that can be merged.
both: Merge all traces that have the same primary sweep for all design-points (variations) into one csv file.
Interpolation note: If primary sweep values are not uniformly spaced, mergecsv is enabled with traed values are re-sampled uniformly using '-batchoptions' syntax as shown below:

```
-batchoptions "'LargeScaleDSO/NumTracePoints'=500"
-batchoptions "'LargeScaleDSO/NumTracePoints'='PrimarySweepName:200'""
-batchoptions
"'LargeScaleDSO/NumTracePoints'='ReportName1:Trace1:100;ReportName1:Tr
ace1:100;ReportName1:TraceName2:200'"
```

-abort: Abort a running job identified through the job's working directory. Example: `-abort <projectresultsfolder-path>/>jobid>`. For a complete discussion of methods for aborting jobs or specific tasks, see the discussion of Aborting a Large Scale DSO Simulation under Large Scale DSO for Parametric Analysis.

-repackageresults: Choose this option to add simulations results to the input archive file. Note: this option only applies if an archive file is provided as input.

-batchsolve: Solve the specified parametric setup. Syntax for the setup:

```
<design-name>:Optimetrics:<parametric-setup>
```

Large Scale DSO for Parametric Analysis

Running Maxwell from a Command Line

Large Scale DSO Job outputs

A large-scale-dso analysis does not support the output of full parametric results. Instead, it extracts 'subset' results using predefined Rectangular plots, which are created by user before job is run. The extracted columns of data are saved as CSV files. Typically, there is one CSV file per-trace, per-variation. (Note: Non-Rectangular plots of the design (for e.g. statistical eye, digital plot) are not extracted). The outputs can be either imported as datasets for post-processing in the desktop also as function of parametric variations, or used directly in downstream applications (for example, Excel, or custom programs that parse .csv files).

CSV File contents

The initial header rows of CSV file define the solved variation. For each such row, the first column has variable name and the second column has variable's value. The row following variation rows has the name of primary sweep and the name(s) of extracted quantities. Subsequent rows contain 'data' - quantity values as a function of primary sweep. Below examples provide a context for the CSV file contents:

- Traces of S-parameter report: The data portion of CSV file has 2 columns of data: first column has Freq values and the second column has values for trace's s-parameter component
- Trace of a far field report: Suppose there is a farfield report with a trace ('magrE'), whose primary sweep is 'phi' and secondary sweep is 'theta'. Further suppose that two values of 'theta' are chosen and 'all' values of 'phi' are chosen. For this trace, the data portion of CSV file contains three columns of data: the first column has phi values, the second column has magrE values for the first value of theta, the third column has magrE values for second value of theta. The magrE output columns are titled as 'magrE_crv1', 'magrE_crv2' respectively
- (Advanced) 'Special' sweeps: In the case of a trace with 'special' primary sweep (such as the trace of a time domain quantity), one CSV file is created per curve of trace, per variation. These CSV files always have two columns, irrespective of the number of values chosen for secondary/higher sweeps.

Large Scale DSO for Parametric Analysis

Import Large Scale DSO Dataset Solution

Large Scale DSO Example

This section provides an example of the use of Large Scale DSO to distribute parametric variations of a Maxwell model across the nodes of a cluster or to multiple cores of a single machine.

This example presumes that your configuration satisfies the Prerequisites for Large Scale DSO. For this example, pre-suppose that we have a Windows cluster. Further suppose that the shared drive folder, which contains the input projects and computed results is at the location

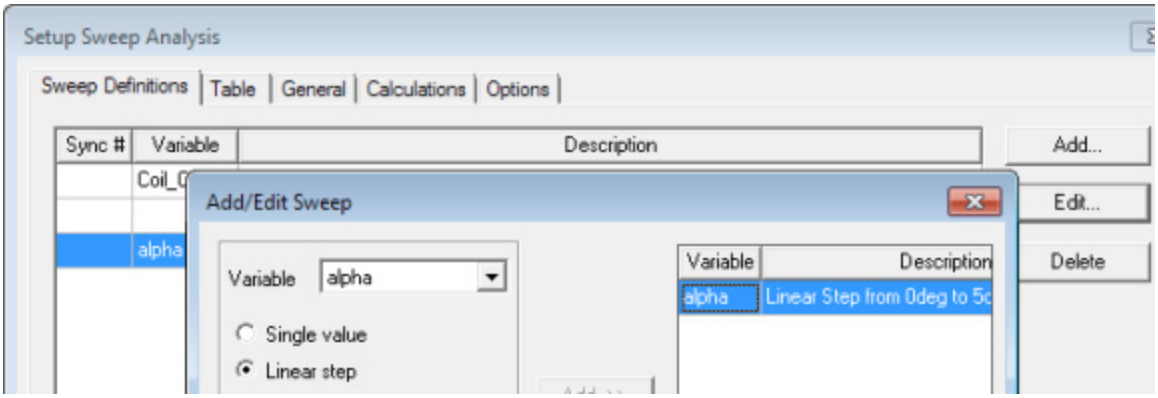
\\sjo7na1\mxwlprojs

Major steps for Large Scale DSO Example

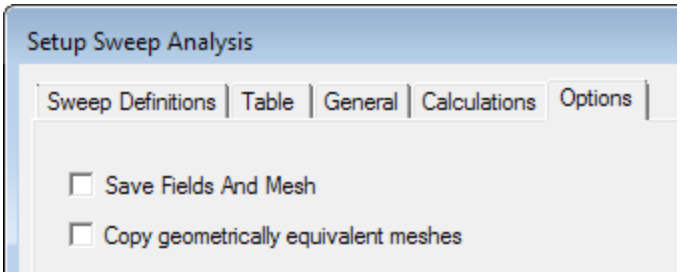
1. Prepare the model for Large Scale DSO Analysis
2. Submit the Large Scale DSO Job
3. Post process the results

Preparing a Project for Large Scale DSO Analysis

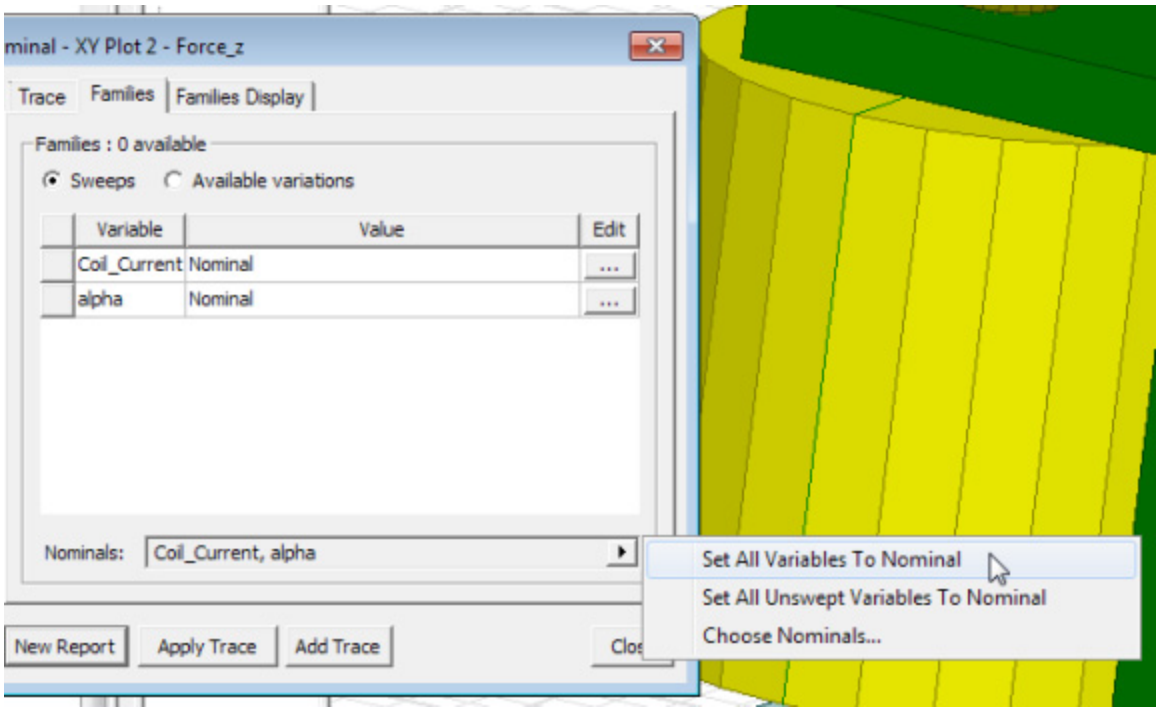
1. Ensure that the Maxwell project is on the shared drive. For this example, the **relay_nominal.aedt** file is on "\\sjo7na1\mxwlprojs\relay_nominal.aedt"
2. Set up a parametric table you wish to use.



3. On the **Options** tab, ensure that **Save Fields and Mesh** is unchecked.



4. Outputs from Large Scale DSO come from predefined rectangular plots that are created *before* the Analysis command is issued. Non-rectangular plots of the design (digital plots, for example) are not extracted. Follow the steps below:
   a. Because these DSO outputs come solely from Rectangular Plots, delete all other postprocessing setups.
   b. Use the **Report** window to define outputs for the desired rectangular plots.
   c. Click on the **Families** tab and ensure that all variables are set to **Nominal**, as shown below.



Note	For Large Scale DSO, outputs are not extracted correctly unless all variables on the **Families** tab are set to nominal.

   d. Click the **New Report** button to create the report.
5. Right-click on the parametric sweep, and select **Validate for Large Scale DSO**.

   A dialog reports any errors. The following are some typical messages:

```
[error] Please remove all the calculations in Parametric
Setup/Calculation page.
[error] Please turn off "Save Fields And Mesh" in Parametric
Setup/Options page.
[error] No rectangular plot exist in the design. Please create
a rectangular report.
```

6. Correct any errors, if necessary to pass validation.
7. Save and Close the project.

Submit the Large Scale DSO Job: Examples

This section includes examples of submitting a Large Scale DSO job using RSM and a Scheduler.

> **Note:** Functionality featured in the example(s) in this section applies to multiple design types.

Using the RSM Environment

1. Before submitting the job make sure that the input project is not open in any Desktop window.
2. For this example, suppose that there are two quad-core machines on your cluster with the names "m1" and "m2". Further suppose that there are two engines per machine, for a total of four parallel engines. Let the number of processors allocated to each engine be 1.
3. From a command prompt, issue the following command:

```
<installation-
directory>\v<version>\<platform>\desktopjob.exe -cmd dso -
machinelist "list=m1:2,m2:2" -batchoptions
\\sjo7na\mxwlprojs\mxwloptions.txt -batchsolve "relay_
nominal"Optimetrics:ParametricSetup1"
\\sjo7na\mxwlprojs\relay_nominal.aedt
```

   where the file \\sjo7na\mxwlproj\mxwloptions.txt has the following contents:

```
   $begin Config
'Desktop/Settings/ProjectOptions/NumberOfProcessors'=1
'Maxwell3D/Preferences/SaveBeforeSolving'=0
'Maxwell/Preferences/HPCLicenceType'='pack'
   #end 'Config'
```

4. Assume the above job is assigned ID "jobID".

Using a Scheduler Environment (such as LSF)

1. Suppose you want to solve variations using four parallel engines, each engine being assigned a single core.

2. From a command prompt, run the following command:

```
bsub -n 4 <installation-
directory>\v<version>\<platform>\desktopjob.exe -cmd dso -
batchoptions \\sjo7na\mxwlprojs\mxwloptions.txt -batchsolve
 "relay_
nominal:Optimetrics:ParametricSetup1"\\sjo7na\mxwlprojs\re
lay_nominal.aedt
```

   where the file \\sjo7na\mxwlproj\mxwlptions.txt has the same contents as the RSM example above.

3. Assume the above job is assigned an ID "jobid"

For example with 2 nodes of 44 cores each (with multiple distributed variations per machine):

MANUAL: `bsub -n 88 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist num=8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/NumCoresPerDistributedTask'=11 'Maxwell 3D/RAMLimitPercent'=90 'HPCLicenseType'='Pack'" -batchsolve TeeModel:Optimetrics:ParametricSetup1 OptimTee-v231-1.aedt`

AUTO: `bsub -n 88 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist numcores=88 -auto -NumDistributedVariations 8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/RAMLimitPercent'=90 'HPCLicenseType'='Pack'" -batchsolve TeeModel:Optimetrics:ParametricSetup1 OptimTee-v231-1.aedt`

For example, with 16 nodes of 44 cores each (note each distributed variation will span 2 machines):

AUTO: `bsub -n 704 <installation-directory>\v<version>\<platform>\desktopjob -cmd dso -machinelist numcores=704 -auto -NumDistributedVariations 8 -monitor -useelectronicsppe=1 -ng -batchoptions " 'Maxwell 3D/RAMLimitPercent'=90 'HPCLicenseType'='Pack'" -batchsolve TeeModel:Optimetrics:ParametricSetup1 OptimTee-v231-1.aedt`

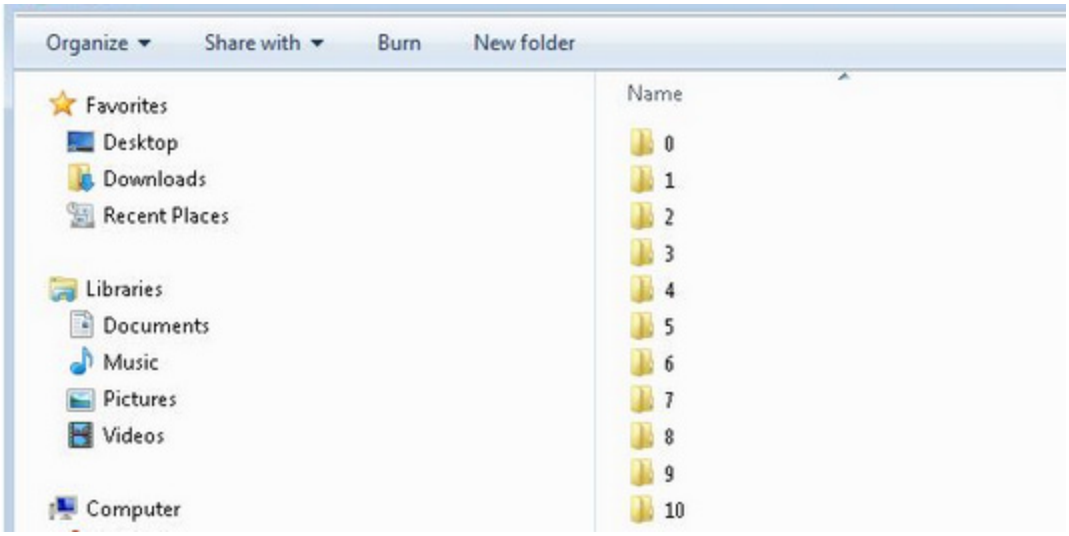
Related Topics

Large Scale DSO for Parametric Analysis

Large Scale DSO Example: Post Process the Results

Once the job is done, output is available in the ~\relay_nominal.aedt\jobid\results folder. Each variation creates a subfolder, which in turn has one csv file per trace of each report. See the detailed information regarding job monitoring and the location of the analysis logs.

The following figure shows the results for 10 variations as located in 10 folders.



Within each folder will be csv files corresponding to the traces for each variation.

You have three options for post-processing csv files.

- Import Large Scale DSO Dataset Solution
- Use Microsoft Excel or any other application that has csv post processing functionality.
- Parse the csv output into your custom program, for any downstream flow.

Related Topics

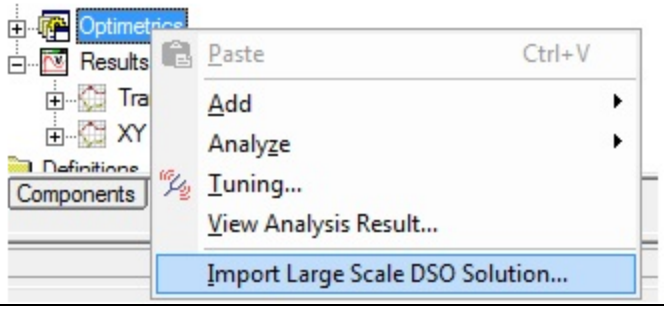
Large Scale DSO for Parametric Analysis

Import Large Scale DSO Dataset Solution

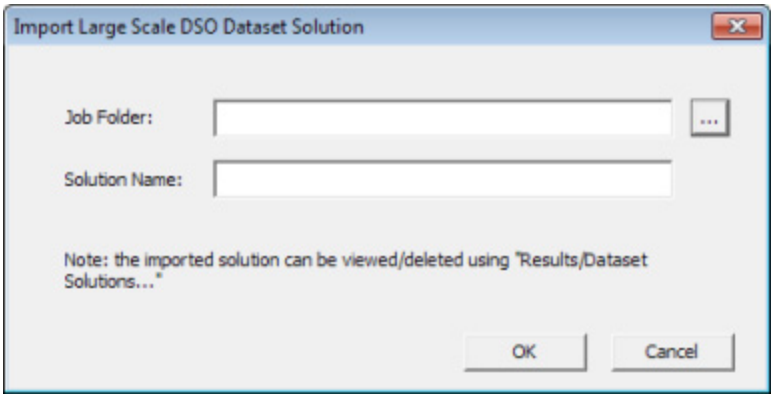
For post-processing Large Scale DSO dataset solutions in the desktop, you create a dataset solution through the **Import Large Scale DSO Solution** command and pointing to Large Scale DSO job's top level results folder.

1. Import solved large scale DSO solution. You can do this in two ways.

   In the Project tree. right click on Optimetrics and from the menu click **Import Large Scale DSO Solution**.



This opens the **Import Large Scale DSO Dataset Solution** dialog.

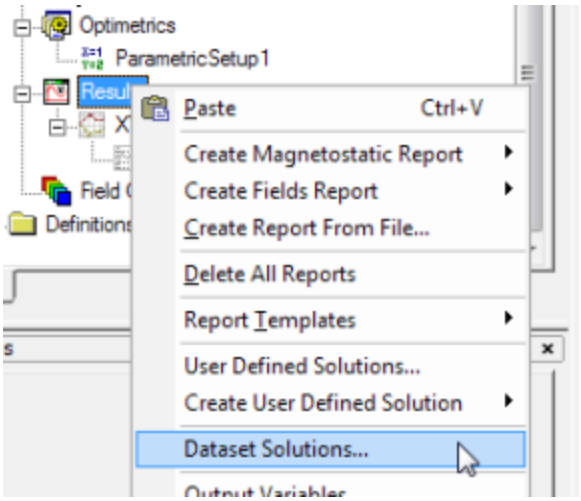


From here you can browse to the results of a Large Scale DSO job and select a job folder. Click the ellipsis button [...] to open the browser window. Navigate to the results directory to see the results, organized by the scheduler prefix and job ID number. To select a results dataset, double-click on the results folder name. See Large Scale DSO Results Database Organization.

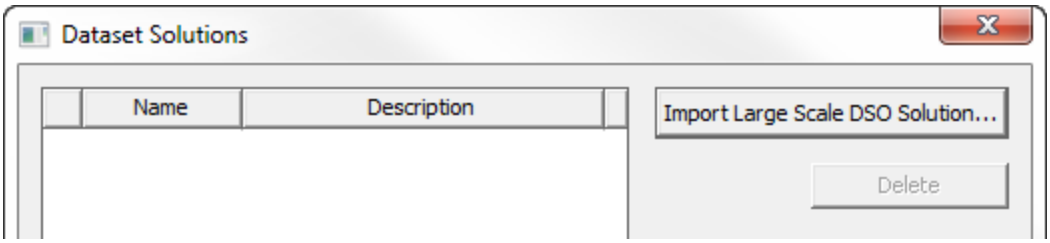
Click, **OK** to import the Dataset. If you have selected the solution folder correctly the dialog closes. If not, an error dialog opens.

2. To View/Delete created dataset solutions:

   In the Project tree, right click on Results and from the menu click **Dataset Solutions....**



This displays the Dataset Solutions dialog.



The dialog lists any existing datasets. You can delete one or more by selecting from the list and selecting **Delete**. The **ImportLarge Scale DSO Solution** button opens the dialog for importing a dataset solution.

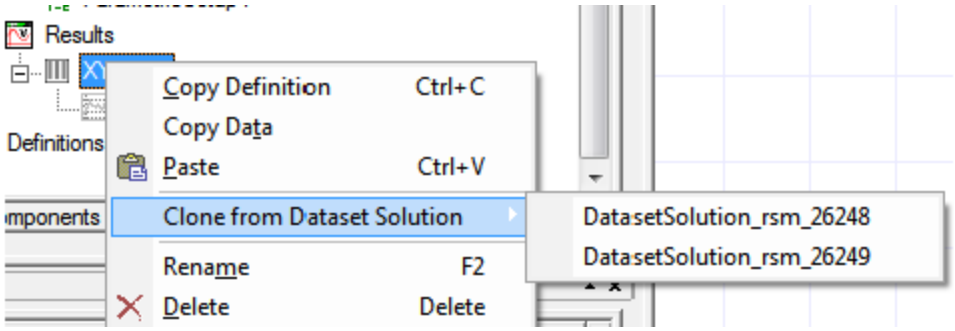
3. To create a Dataset Report

   After you have imported one or more DSO solutions, you can create a Dataset Report. Right click on Results and from the menu select **Create Dataset Report**, and the type of report.

   This opens a reporter window from which you can create a report. If you have previously created an eye diagram report and it is included in the DSO solution data extraction, you can use **Create Dataset Report > Eye Diagram** to recreate this report.

4. Cloning from a Dataset Solution

   If you re-open a project that was solved using large scale DSO, you can quickly clone a report for a solved large scale DSO solution by right-clicking in the Project tree on the report, and choosing Clone from Dataset Solution..., provided this report is qualified for Large Scale DSO data extraction. The provides a way that you can reuse the existing report definition and save the work of creating new report.



Large Scale DSO Results Database Organization

A Large Scale DSO analysis does not support the output of full parametric results. Instead, it extracts 'subset' results using predefined Rectangular plots, which are created by the user before the job is run. The extracted columns of data are saved as CSV files. Typically, there is one CSV file per-trace, per-variation. (Note: Non-Rectangular plots of the design (for e.g. statistical eye, digital plot) are not extracted)

The results of a Large Scale DSO job are located in the '<workdir>/<jobid>/results' folder. If 'workdir' is not specified on the job command-line, it is same as the input project's results folder. For example the default 'workdir' corresponding to '\\shared\projects\relay.aedt' is '\\shared\projects\relay.aedtresults'. Within this results folder, there is one folder per variation. The name of the variation's folder is an integer number corresponding to variation's index in the parametric table. For example, a variation-folder named '4' has results for the fifth row of parametric table, while a variation-folder named '0' has results for the first row of the table.

Below is a sample results folder showing the contents corresponding to results of first variation. There are ten CSV files corresponding to ten predefined traces.

Large Scale DSO for Parametric Analysis

Large Scale DSO Job Monitoring

Large Scale DSO avoids detailed intra-variation monitoring is avoided as it increases network traffic for large-scale jobs. Large Scale DSO jobs are monitored as below:

- **Cluster Monitoring Tools**: The resource usage (CPU, Memory, Network) of Large Scale DSO jobs is monitored using standard cluster monitoring tools. Such job-neutral resource monitoring is ideal as it uses negligible network bandwidth, CPU/Memory.
- **Detailed Monitoring of Analysis of a Variation**: For any detailed monitoring you must examine the information provided in the job's log files. Specifically, the large-scale-dso job writes detailed logs conveying information regarding the machines where engines are running and the local storage location of per-engine distributed database. With such information, you can login to individual machines for deeper probing of each distributed engine.

The following logs are available:

- **Per-node Logs**:

  There is one 'desktopjob.log' file per node assigned to the job. This log contains information regarding the node such as name, local storage folder, number of engines started on this node, etc. It is located in <workdir>/<jobid>/r<nodeIndex>. E.g. "<workdir>/<jobid>/r0" has desktopjob.log corresponding to the engines running on the first node of job, while "<workdir>/<jobid>/r2" has logs corresponding to engines running on third node
- **Per-engine Logs**:

  There is one desktopjob.log file per distributed engine. It is located in <workdir>/<jobid>/r<nodeIndex>/r<taskIndex>. For example, "<workdir>/<jobid>/r0/r0" has logs corresponding to first engine running on first node, while "<workdir>/<jobid>/r1/r2" has logs corresponding to third engine running on second node. Engine unique information (such as local storage of this engine) is logged here
- **Parametric Analysis Log**:

  This log file is located in '<workdir>/<jobid>/r<nodeIndex>/r<taskIndex>' folder and corresponds to Desktop's local-machine parametric 'batchsolve'. It is available only at the end of analysis and contains information regarding the variations solved by this engine and any info/warning/error messages.
- **Root Log**:

  This is the top-level log that logs job distribution information such as hierarchical activation and the list of nodes assigned to this job

For a complete discussion of methods for aborting jobs or specific tasks, see the discussion of Aborting a Large Scale DSO Simulation under Large Scale DSO for Parametric Analysis.

Large Scale DSO for Parametric Analysis

Large Scale DSO Deployment/Configuration

Linux Cluster configuration

- Shared drive for projects: Cluster must provide a shared drive that hosts job inputs - the submitted project must be located on a shared drive (for example, a sub-folder of user's home directory). The shared-drive must accessible using the same path on every node of cluster
- 'Temp directory' configuration

  Temp directory is either on 'local storage' or on storage that has equivalent speed characteristics i.e. the I/O rates of the storage should be invariant to network traffic

  Temp directory on a host has sufficient space to hold results database for the variations that are solved on it. Note:

  This storage is freed at the end of the analysis

  The amount of required space depends on the number of engines per node and the cumulative variations solved on this node

  The amount of required space depends on the project's compression-options. For e.g. if 'Save Fields' of a parametric setup is OFF, the space requirement is smaller by the amount of space taken up by field solution data
- Ansys Electromagnetics RSM environment: In the case of supported scheduler environments, there is no extra configuration needed. In the case of RSM environment, following additional steps are needed:

  RSM must be running on all the nodes of cluster. The credentials of 'RSM service' allow read/write to shared drive. Reason: the remote engine processes are launched using the credentials of RSM service

  Registration of 'desktopjob.exe' with RSM service: 'desktopjob' program must be registered with Ansys Electromagnetics RSM using 'desktopjob -regserver". To ensure that the registration is successful, check that the 'desktopjob' entry in '<RSM-installation-folder>/AnsoftRSMService.cfg' file is valid.

Note	Linux-specific critical note: Edit AnsoftRSMService.cfg and replace 'desktopjob.bin' with 'desktopjob'

Major limitation: In the RSM environment, Large Scale DSO can only be enabled for one product.

Troubleshooting hints (RSM environment only): "shared drive read/write" requirement is a new constraint introduced in Large Scale DSO. So if a user runs into a situation where Regular DSO jobs run and Large Scale DSO jobs fail, one possible cause for the failure: RSM service does not have privileges to read and write to project folder located on shared-drive.

Windows Cluster configuration

All the above steps apply, except for steps that are stated as Linux-specific. Additional instructions:

- RSM and Ansys Electromagnetics products are either installed locally on each node of cluster (i.e. local installation) OR installed on a single shared-drive available to all nodes of

cluster (i.e. network installation)

- Registration of 'desktopjob.exe' with RSM service:
- Network installation: desktopjob.exe is registered with RSM service once, on any of the nodes of cluster
- Local installation: Since each node has it's own RSM installation, desktopjob.exe must be registered with RSM on each node.

Note	IMPORTANT! RSM service must be started using the credentials of a non-system 'admin' account, which has read/write permissions to project's shared drive. If RSM service runs as 'system' user, large-scale-dso jobs will fail

Heterogeneous Cluster configuration

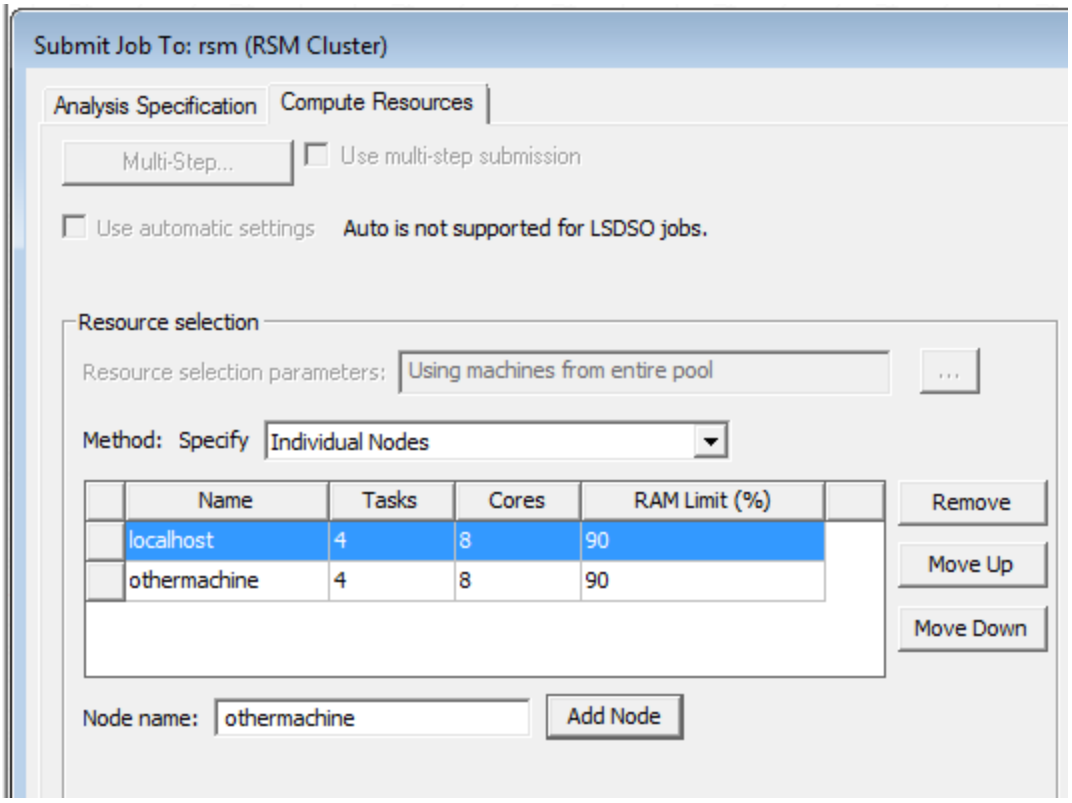
Limitation: Currently heterogeneous cluster (with both linux and windows nodes) is not supported. This is due to the shared drive requirement.

Related Topics

Large Scale DSO for Parametric Analysis

Known Issues for Large Scale DSO

For Large Scale DSO jobs that are submitted from job submission panel using RSM, localhost must be the first node in the resource selection node list, other wise Large Scale DSO solve with RSM will fail.



Cluster configuration (shared drive requirement): The input files (project, etc.) must be present on a shared drive that is accessible from every node of the cluster.

Note: this item is actually listed as a requirement.

Related Topics

Large Scale DSO for Parametric Analysis

Troubleshooting for Large Scale DSO

(Linux only) Deployment/Installation errors (such as mainsoft related or related to deployment configuration) are not captured. If there is such an issue, Large Scale DSO job will fail without useful messages in the logs

Report-based extraction fails mysteriously if traces and parametric-setup are not 'prepared' as per the Getting Started guides.

Job monitoring and control

Job re-start: There is no provision for stopping and re-starting a job. A new job does not reuse solved results - always solves all rows in the table. So an abort or failure of a job re-starts from the

beginning, unless a new parametric table with the unsolved rows is created

Job outcome

Job status: The exit code of job doesn't indicate success or failure correctly. The error messages from multiple log files needs to be combined to determine the reason for failure. In many situations, the reason for a failure is apparent only after re-running the job after turning ON the 'debug logging'

In some Linux scenarios, the analysis appears to finish successfully with valid results, except that the exit code is '134'. In this case, although the exit is abnormal, the failed exit code can be ignored

Load Balancing: For models with 'unbalanced variations table' (i.e. variations that take considerably different amount of time to solve are clustered in few regions of table), job will take longer time to solve than a Regular DSO as the job's overall completion time is determined by the slowest solving region.

Workaround: rearrange the rows in the parametric table so that each region takes a similar time to solve

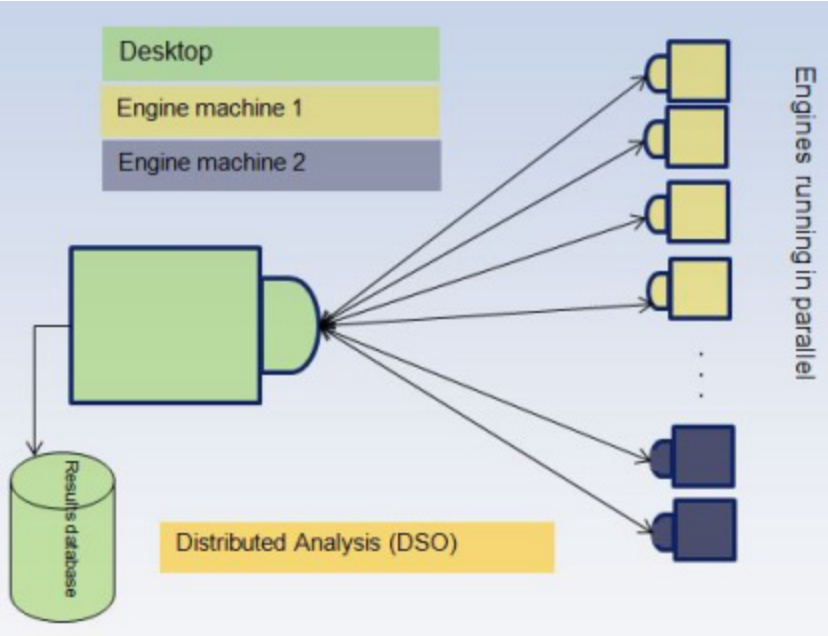
GM Specifics: the model used for 'Report-based extractor' jobs is NOT compatible with the 'ANSYS-extractor-for-GM' jobs. A valid model for ANSYS-extractor-for-GM cannot contain any of: reports, overlay plots, optimetrics calculations.

Related Topics

Large Scale DSO for Parametric Analysis

Large Scale DSO Theory

The parametric analysis command in Desktop computes simulation results as a function of model parameters, such as geometry dimensions, material properties and excitations. The parametric analysis is either performed on a local machine, where each variation is analyzed serially by a single engine, or distributed across machines through a DSO license. Desktop's DSO analysis runs multiple engines in parallel, thus generating results in a shorter time. In the Regular DSO algorithm, the parametric analysis job (Desktop) runs on master node, which in turn launches one or more distributed-parallel engines on each machine allocated to the job. Desktop distributes parametric variations among these engines running in parallel. As variations are solved, the progress/messages and variation results are sent back to Desktop, where they are persisted into the common results database on master node, as illustrated below:



A single engine can now span multiple machines with auto multi-level DSO.

Regular DSO Bottleneck

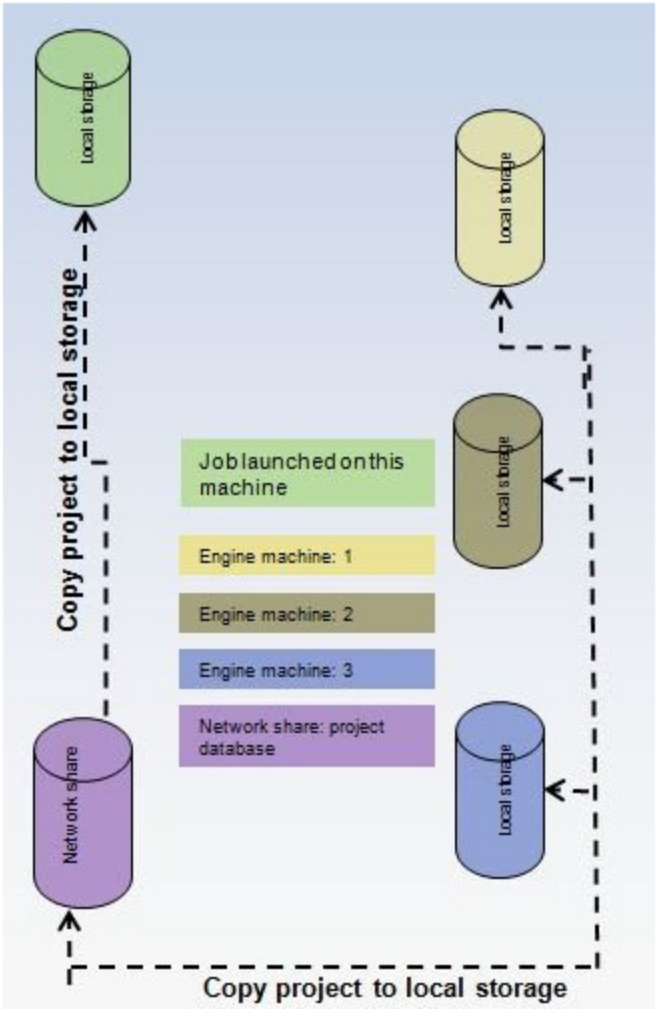
As per above illustration, Regular DSO's speedup is limited by the resources of the centralized 'Desktop' bottleneck. It's been observed that DSO becomes unreliable at a certain point, as the number of engines and number of variations is increased. The term ‘large scale parallel’ can be used to define this tipping point. For a given model, a ‘large-scale parallel’ job denotes scenarios, in terms of the number of distributed-parallel engines and the number of parametric variations, where the Regular DSO runs into centralized bottlenecks that result in one or both of: progressively smaller speedups, unreliability.

With the advent of economical availability and timely provisioning of compute resources, product designers have access to large compute clusters to run their simulations. And they are throwing larger and larger number of compute resources at simulation jobs, in order to obtain results faster. The parametric DSO needs to meet this challenge and target linear speedup for 'large-scale parallel' jobs. The Large Scale DSO feature is targeted toward 100% reliability and linear speedup of large-scale parallel DSO jobs.

Key Algorithms/Concepts for Large Scale DSO

- **Embarrassingly Parallel algorithm**: Large Scale DSO exploits the embarrassingly parallel nature of parametric runs. The solve of each variation is made fully independent of another variation, by replacing Regular DSO's centralized database with per-engine distributed databases
- **Distributed databases**: For each distributed-parallel engine, the database of the input model is cloned to local storage of engine's compute node (as illustrated in the following picture). Parallel analysis is performed on these cloned models and the analysis results also

go the corresponding location on local storage. As each engine has its own database, there is no ‘shared database’ contention between any two engines. There is negligible network traffic as analysis/computations are contained in a single machine and use just the ‘local resources’.



- **Hierarchical activation of engines**: In the Large Scale DSO algorithm, engine activation is done hierarchically, where the overhead of launching of engines is also shared across the nodes. Such hierarchical activation improves reliability of the activation phase of large-scale parallel jobs. A new 'desktopjob' program encapsulates hierarchical activation, as illustrated in the following pictures. In this approach, the 'root' desktopjob (Root DJ) activates a 'level-one' child desktopjob (DJ(L1)) for each unique node allocated to the DSO job. Each level-one desktopjob activates one or more 'leaf' desktopjobs (DJ(L2)) equal to the number of distributed engines per node. A leaf desktopjob in turn runs Desktop in batch mode, to perform local-machine parametric analysis to solve the variations assigned to this engine.
- **Decentralized Load balancing:** A parametric table is divided into regions of equal number of variations, with the number of regions equal to the number of engines. In the following illustration, the analysis of 30 parametric variations is distributed among 5 engines. Each

engine solves it's assigned region as a ‘local machine’ parametric analysis. Large Scale DSO job is considered done once all engines are done with their assigned variations.

- **Distributed results postprocessing**: As engine is done with the solve of a variation, it extracts results for the solved variation before progressing to the analysis of next variation. The extracted results are saved to the local storage. When the engine is done with analysis of all variations, the extracted results are transferred from local storage to the results folder of the input project.

Redistribution Feature

- Large Scale Distributed Solve Operation could submit a parametric setup to be solved in multiple machines, each machine may launch multiple EM-Desktop processes to solve the assigned variations(Design Points). Variations are distributed to each task(EM-Desktop process) equally, regardless of the machine hardware and each variation’s complexity. That may resultin some tasks finishing earlier than others, in some extreme case some tasks may hours behind fastest task.
- Now, redistribution occurs when a task finished its own assignment, it calls back to the L2 to ask for new assignment, L2 forward the request to L1, L1 forward it to L0, L0 may pick one of the slow task to remove some variations or return with no more assignment. When a task is picked to remove unsolved variation, L0 calls L1(may be different L1), L1 forward it to the selected L2, L2 makes a request to the EM-Desktop to remove some variations from its queue. EM-Desktop returns the removed variation indexes, or error code if it fails. In L0 if error is returned, it marks the selected task failed to respond the remove request, to void picking it again. L0 returns the result through L1-L2 back the EM-Desktop.
- The Ansys Electronics Desktop will enqueue the new assignment and then start solving those new variations. If the return data indicates error, it makes another call to L2 to get new assignment. If no more variations return, the Ansys Electronics Desktop finishs the simulation and exit.

Interactive Scheduler Jobs

This section includes information and guidelines for users running interactive scheduler jobs on Linux.

In most cases jobs run under a scheduler run as a batch job. These jobs may be submitted using the Ansys Electromagnetics Desktop job submission GUI, using cluster job submission commands on a command line or using a cluster GUI, if available.

An alternative method for submission of scheduler jobs can be used. For convenience, such jobs are referred to as “interactive scheduler jobs”. In this approach, the user submits an interactive job to the scheduler. From the interactive job prompt, the user launches an Ansys Electromagnetics Desktop product, which starts in interactive (GUI) mode, not batch mode. The user then selects a project and runs one or more analysis commands using the GUI. The intent is that these analysis commands should use all resources allocated to the job, whether on the same host as the GUI or on other hosts.

This approach is supported on Linux, where the user may set up an X Window System server for interacting with the Ansys Electromagnetics Desktop product GUI. The user needs to configure

the cluster environment and/or the interactive environment so that the user may view and interact with the product GUI. This approach is not supported on Microsoft Windows.

DSO Configuration for Interactive Scheduler Jobs
Design Type Options for Interactive Scheduler Jobs

Specifying Options for Interactive Scheduler Jobs

Batch scheduler jobs use command line options for specifying options rather than GUI controls. For interactive scheduler jobs, options may be specified on the command line, using GUI controls, or obtained from the registry. The machines specified in the **Configurations** tab of the **HPC and Analysis Options** dialog will be ignored for interactive scheduler jobs. If the command line used to launch the product contains a list of specific machines (using option -machinelist list=...), then the job will use the specified machines and cores. If the command line used to launch the product does not contain a specific machine list, then the machines and cores allocated to the job by the scheduler will be used for the job. In general, the job distribution settings for interactive scheduler jobs should be specified on the command line, instead of using the **HPC and Analysis Options** dialog box.

- The UI shows the settings that will be used for analysis, even if they come from the command line, not the registry.
- If you make changes to the settings in the UI, and the changed settings will be used for the analysis, even if the changed settings conflict with the command line (including batchoptions).
- If you makes no changes to the settings in the UI, then the command line settings (including batchoptions) will be used for analysis.

Batchoptions settings which are automatically generated for batch jobs submitted using the Ansys Electromagnetics job submission GUI will need to be manually included in the product command line. Some use cases require that certain settings be made on the command line when the product is launched, rather than using the GUI.

Batchoptions for Interactive Scheduler Jobs

For interactive scheduler jobs, only a limited set of batchoptions are supported. These batchoptions include the DSO configuration options, the design-type-specific options, and the following additional design-type-specific options that are not currently listed in the user interface or command line help windows:

- **CreateStartingMesh:** Create the starting mesh only. Do not solve any other steps. Often used for multi-step jobs where the mesh creation is solved in a separate step using fewer resources than the rest of the analysis.
- **NumCoresPerDistributedTask:** Specifies the number of cores that are allocated to the job to use for each distributed task, used when running jobs under a scheduler. The scheduler

communicates the number of cores allocated to the job on each host. This setting is used to determine how to allocate the cores to each task.

- **RAMLimitPercent:** Specifies the percentage of system RAM that the analysis is expected to use on each host. Running out of memory can cause processes to be killed by the Operating System or other failures. The analysis will be gracefully terminated if it requires more than this limit. Typical limits are about 90%, to allow some RAM for the Operating System and other services. If there are multiple jobs running on a single host, then the RAM limit should be reduced accordingly. For example, if there are two jobs running on a host, then the limit could be 45%, which would allow 10% of the RAM for the Operating System and other services.
- **RAMLimitPerCoreInGB:** This is an alternative way to specify the RAM limit, instead of using the RAMLimitPercent. In this case, the RAM limit is the limit per core multiplied by the number of cores allocated to the job on each host. Typically used for jobs running under a scheduler to ensure that the scheduler memory limit and the ansysedt memory limit are consistent.
- **SolveAdaptiveOnly:** Solve adaptive passes only. Do not solve any other steps. Often used for multi-step jobs where the adaptive passes are solved in a separate step using fewer resources than the rest of the analysis.
- **TotalNumOfCores:** The total number of cores for the job. This option is only used for EKM (Engineering Knowledge Manager).
- **ValidateOnly:** Only validate the specified setup, design, or project. Do not analyze the specified setup, design or project.

Any other batchoptions will result in a warning message and will be ignored.

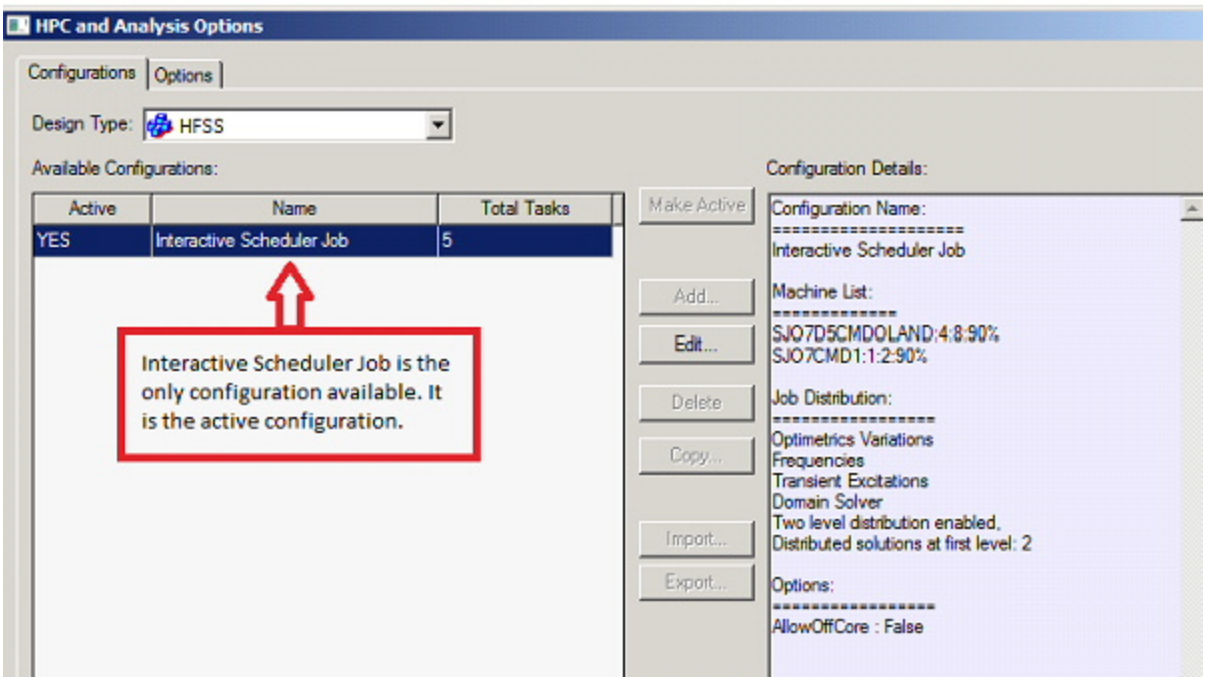
Command Line Example:

```
desktopjob.exe" -cmd dso -jobid RSM_27086 -machinelist
list=localHost:2:2:90%
-monitor -ng -batchoptions "
'LargeScaleDSO/MergeCsv'='acrossDPsAndTraces'"
-batchsolve TeeModel:Optimetrics:ParametricSetup2
E:\work\2018\LS_DSO\OptimTee.aedt
desktopjob.exe" -cmd dso -jobid RSM_25248 -machinelist
list=localHost:2:2:90%
-monitor -ng -batchoptions "
'LargeScaleDSO/MergeCsv'='acrossDPsByRow'"
-batchsolve TeeModel:Optimetrics:ParametricSetup2
E:\work\2018\LS_DSO\OptimTee.aedt
ansysedt -batchoptions " 'TempDirectory'='C:\\TEMP'
'HFSS/SelectedDSOConfiguration'='Local'
'Desktop/Settings/ProjectOptions/DoAutoSave'=1
'LargeScaleDSO/MaxFolderInMB'=100"
```

DSO Configuration for Interactive Scheduler Jobs

When running an interactive scheduler job, there is only one DSO configuration available for each design type. Each configuration is named “Interactive Scheduler Job”. This configuration is always the active configuration for an interactive scheduler job. and it is the only configuration displayed in the list of available configurations shown in the **HPC and Analysis Options** dialog box. No configurations can be added or removed, but the "Interactive Scheduler Job" configuration may be modified using the "Edit" button, which pops up the **Analysis Configuration** dialog.

Because the “Interactive Scheduler Job” configuration is the only configuration accessible for interactive scheduler jobs and it is not accessible in other modes, there is no sharing of the "Interactive Scheduler Job" configuration settings with other modes.



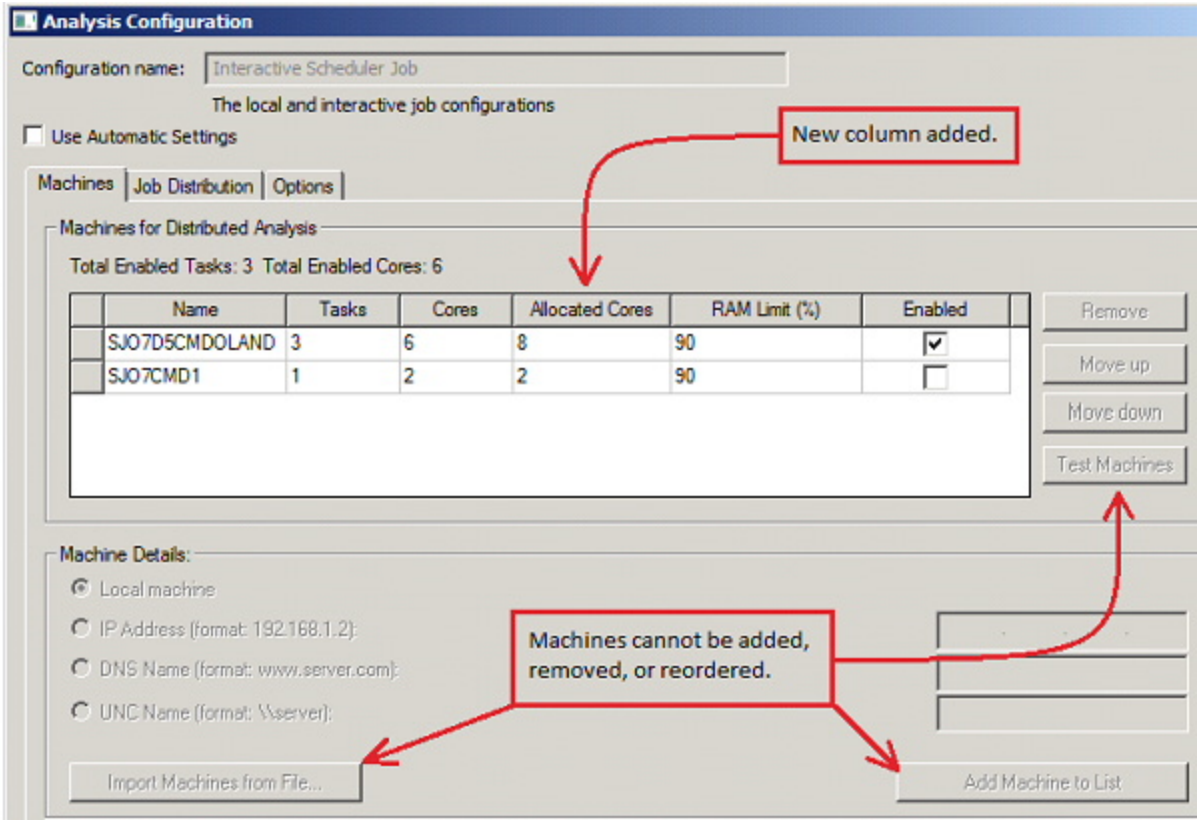
Major differences between interactive scheduler mode and batch mode or normal interactive mode are:

- In interactive scheduler mode, DSO configuration settings and design type options in the UI override command line options and batchoptions.
- When not in interactive scheduler mode, DSO configuration settings and design type options specified on the command line (including batchoptions) override UI settings.

Analysis Configuration - Machines Tab

The most obvious changes for interactive scheduler jobs are visible in the **Machines** tab of the **Analysis Configuration** dialog box. The grid of machine information is pre-populated with the list of machines allocated to the job. It also contains an additional column in interactive scheduler mode. This column, "Allocated Cores", indicates the number of cores allocated to the job by the scheduler on each host. You cannot add or remove machines from the list, or modify the allocated

cores for any machines. You can modify the tasks, cores or RAM limit for any machine, or specify that a machine is enabled or disabled.



Analysis Configuration - Job Distribution Tab

The **Job Distribution** tab of the **Analysis Configuration** dialog only appears if the "Use Automatic Settings" checkbox is not checked. The state of this checkbox, and the settings shown on this tab are initialized from the command line or from the registry. The command line options that affect the "Use Automatic Settings" checkbox or the job distribution settings are:

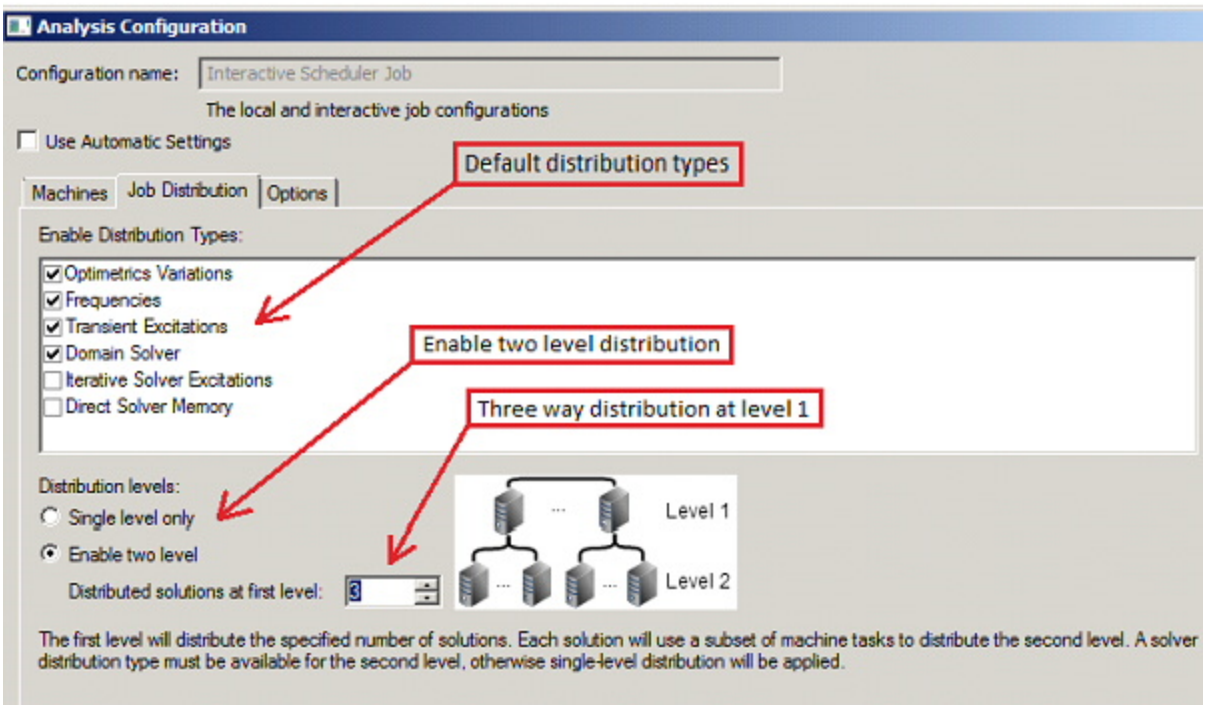
- -distributed
- -local
- -auto
- -machinelist

The registry contains the last value of these settings for an interactive scheduler job for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings are from the command line. Any changes in the GUI also update the registry settings for the "Interactive Scheduler Job" configuration for the current design type.

Example

```
ansysedt -distributed includetypes=default maxlevels=2 numlevel1=3
```

Initial "Job Distribution" settings:



Analysis Configuration - Options Tab

You can use the **Options** tab of the **Analysis Configuration** dialog to examine or modify the DSO configuration options. The DSO configuration options are handled like the design type options, except that the **Interactive Scheduler Job** configuration settings are not shared with other modes.

The settings on this tab are initialized from the command line (using the `-batchoptions` command line option) or from the registry. The registry contains the last value of these settings for an interactive scheduler job for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings are from the command line. Any changes in the GUI also update the registry settings for the "Interactive Scheduler Job" configuration for the current design type.

Example

```
ansysedt -batchoptions 'HFSS/AllowOffCore'=0
```

Design Type Options for Interactive Scheduler Jobs

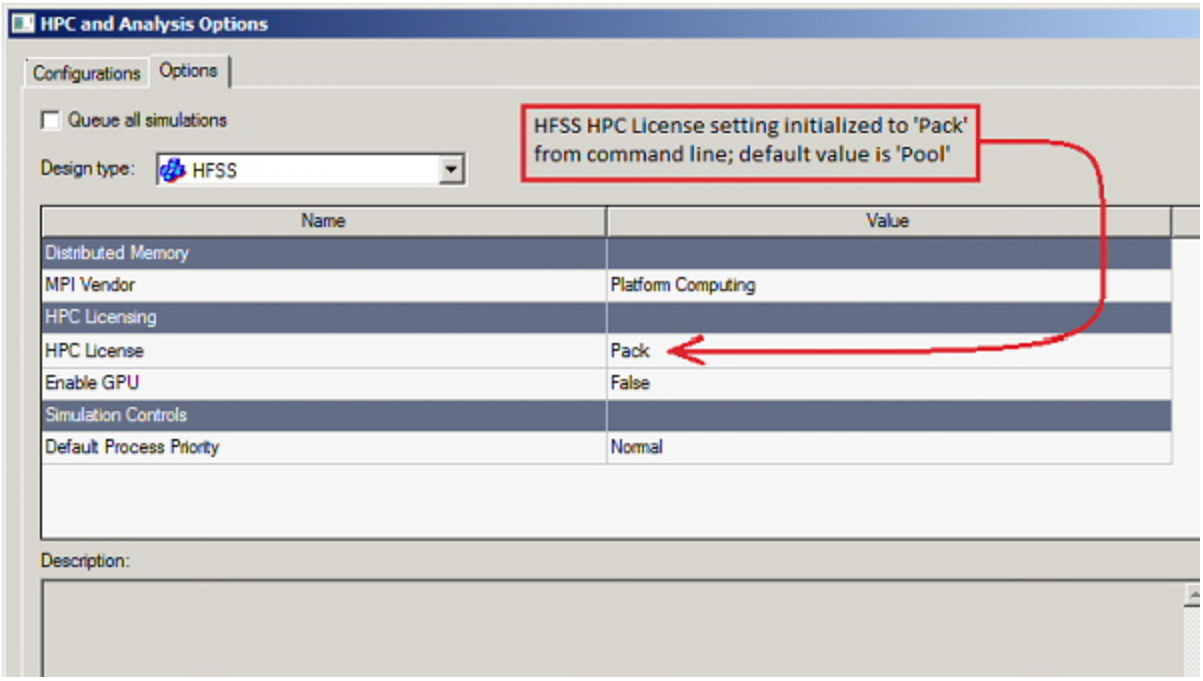
You can use the Options tab of the HPC and Analysis Options dialog to examine or modify the design type options. The settings on this tab are initialized from the command line (using the -batchoptions command line option) or from the registry. The registry contains the last value of these settings for the same user on the same host. Settings on the command line override settings from the registry. Any changes in the GUI will override the initial settings, even if the initial settings

are from the command line. Any changes in the GUI also update the registry settings for the current design type.

These settings are shared between interactive scheduler mode and other modes.

Example:

```
-batchoptions 'HFSS/HPCLicenseType'='Pack'
```



Distribution Command Line Options

The user should include options specifying how the job should be distributed in the command line. These command line options will override options specified using the **HPC and Analysis Options** dialog box or obtained from the registry. Refer to Running Maxwell From a Command Line for more information on command line options.

For both scheduler batch jobs and interactive scheduler jobs, the -MachineList num=<num distributed tasks> format is the most common way to specify the number of tasks for the job. The other formats (-MachineList list=... or -MachineList file=...) allow the user to specify the number of tasks and cores to use on each host. These formats may be useful with clusters of heterogeneous machines, by allowing the user to specify different numbers of tasks or cores for different hosts. If either of the latter two formats is used, the user must ensure that the hosts and cores specified on the product command line are compatible with the hosts and cores allocated to the job.

Batchoptions for Interactive Scheduler Jobs

For interactive scheduler jobs, only a limited set of batchoptions are supported. These batchoptions include the DSO configuration options, the design-type-specific options, and the

following additional design-type-specific options that are not currently listed in th user interface or command line help windows:

- **CreateStartingMesh:** Create the starting mesh only. Do not solve any other steps. Often used for multi-step jobs where the mesh creation is solved in a separate step using fewer resources than the rest of the analysis.
- **NumCoresPerDistributedTask:** Specifies the number of cores that are allocated to the job to use for each distributed task, used when running jobs under a scheduler. The scheduler communicates the number of cores allocated to the job on each host. This setting is used to determine how to allocate the cores to each task.
- **RAMLimitPercent:** Specifies the percentage of system RAM that the analysis is expected to use on each host. Running out of memory can cause processes to be killed by the Operating System or other failures. The analysis will be gracefully terminated if it requires more than this limit. Typical limits are about 90%, to allow some RAM for the Operating System and other services. If there are multiple jobs running on a single host, then the RAM limit should be reduced accordingly. For example, if there are two jobs running on a host, then the limit could be 45%, which would allow 10% of the RAM for the Operating System and other services.
- **RAMLimitPerCoreInGB:** This is an alternative way to specify the RAM limit, instead of using the RAMLimitPercent. In this case, the RAM limit is the limit per core multiplied by the number of cores allocated to the job on each host. Typically used for jobs running under a scheduler to ensure that the scheduler memory limit and the ansysedt memory limit are consistent.
- **SolveAdaptiveOnly:** Solve adaptive passes only. Do not solve any other steps. Often used for multi-step jobs where the adaptive passes are solved in a separate step using fewer resources than the rest of the analysis.
- **TotalNumOfCores:** The total number of cores for the job. This option is only used for EKM (Engineering Knowledge Manager).
- **ValidateOnly:** Only validate the specified setup, design, or project. Do not analyze the specified setup, design or project.

Any other batchoptions will result in a warning message and will be ignored.

Example:

```
ansysedt -batchoptions " 'TempDirectory'='C:\\TEMP'
'HFSS/SelectedDSOConfiguration'='Local'
'Desktop/Settings/ProjectOptions/DoAutoSave'=1
'LargeScaleDSO/MaxFolderInMB'=100 "
```

Batchoptions

Batchoptions may be specified in the command line used to launch the product. Any batchoptions specified in the command line will override the associated registry settings. Batchoptions will also override options specified using **HPC and Analysis Options** window or other dialog boxes used to specify options.

Setting the Number of Cores per Distributed Task

When submitting a job using the Ansys Electromagnetics job submission GUI, the number of cores per distributed task for a job is specified using the batchoption with pathname '<*DesignType*>/NumCoresPerDistributedTask', where <*DesignType* is the design type to analyze. The batchoption setting is automatically included in the product command line when the job is submitted to the scheduler.

For interactive scheduler jobs, the user must include the associated batchoption setting or settings in the product command line when the product is launched. Multiple batchoption settings are required if the user analyzes multiple design types using the same product process. Batchoptions are the only way to specify this setting for batch jobs. There is an alternative to using the NumCoresPerDistributedTask batchoption for Interactive Scheduler Jobs. The user may specify the total number of tasks and the total number of cores for each machine using the **Machines** tab of the **Analysis Configuration** window. You may use **Edit** in the **HPC and Analysis Options** to open the **Analysis Configuration** window for the "Interactive Scheduler Job" configuration.

Setting the Ram Limit Per Core in GB

When cores and RAM per core are requested, the cores could be allocated in an arbitrary/non-uniform way across nodes that themselves could be non-uniform/heterogeneous. For example, nodes could range from 4 cores to 20 cores and from 64 GB to 384 GB. In such environments, the RAM percentage set in the HPC configuration, Job Submission Compute Resources, or batch option may not be appropriate. In such cases, you can use the batchoption for RAMLimitPerCoreInGB. This setting specifies the Maximum amount of RAM used for each core allocated by the scheduler in GB. This batchoption cannot b e combined with RAM limit percent and is only valid when solving in a Linux scheduler environment.

The scheduler GUI automatically passes this new batch option instead of percent limit. From a scheduler GUI, such a request is available only for auto.

You can also use this new batch option for command line submission. The desktop does the computations and passes the percent limit to product/solver.

Setting the Remote Spawn Command Option to Scheduler

The Remote Spawn Command setting is only meaningful when running on the Linux Operating System. The value 'Scheduler' is valid if the job is a scheduler job running under an LSF or SGE scheduler, and only if the MPI Vendor is 'Intel'.

When submitting a job using the Ansys Electromagnetics job submission GUI, the Remote Spawn Command for an analysis may be specified using the batchoption with pathname *DesignType/RemoteSpawnCommand*, where *DesignType* is the Design Type to analyze. The Remote Spawn Command setting is only meaningful when running on the Linux Operating System. The value “Scheduler” is valid if the job is a scheduler job running under an LSF or SGE scheduler, and only if the MPI Vendor is “Intel". To specify the value “Scheduler” for this option for an interactive scheduler job, the Remote Spawn Command must be specified using the

DesignType/RemoteSpawnCommand batchoption in the product command line when the product is launched. In addition, the *DesignType/MPIVendor* batchoption must be specified with value “Intel” in the product command line when the product is launched. For interactive scheduler jobs, the Remote Spawn Command and the MPI Vendor may be specified with batchoptions or as design type options in the **HPC and Analysis Options** dialog box.

Setting MPI Version

When submitting a job using the Ansys Electromagnetics job submission GUI, the MPI Version may be specified using the batchoption with pathname DesignType/MPIVersion, where DesignType is the type of design to analyze (e.g. HFSS). It allows selection of which Intel MPI version to use, for both Windows and Linux. Valid values are "Default", "2018", and "2021".

For interactive solves, the MPI version may be specified with the batchoption in the command line used to launch the product, or as a design type option in the HPC and Analysis Options dialog box.

High Performance Computing (HPC) Integration

Ansys Electromagnetics products offer a direct integration with a number of High Performance Computing (HPC) software programs. This direct integration does not require Ansys Electromagnetics RSM Service. The list of currently-supported HPC software includes:

- Ansys Cloud
- Platform’s Load Sharing Facility (LSF)
- Microsoft Windows® HPC Server
- PBS Pro or PBS Torque
- Grid Engine (GE)

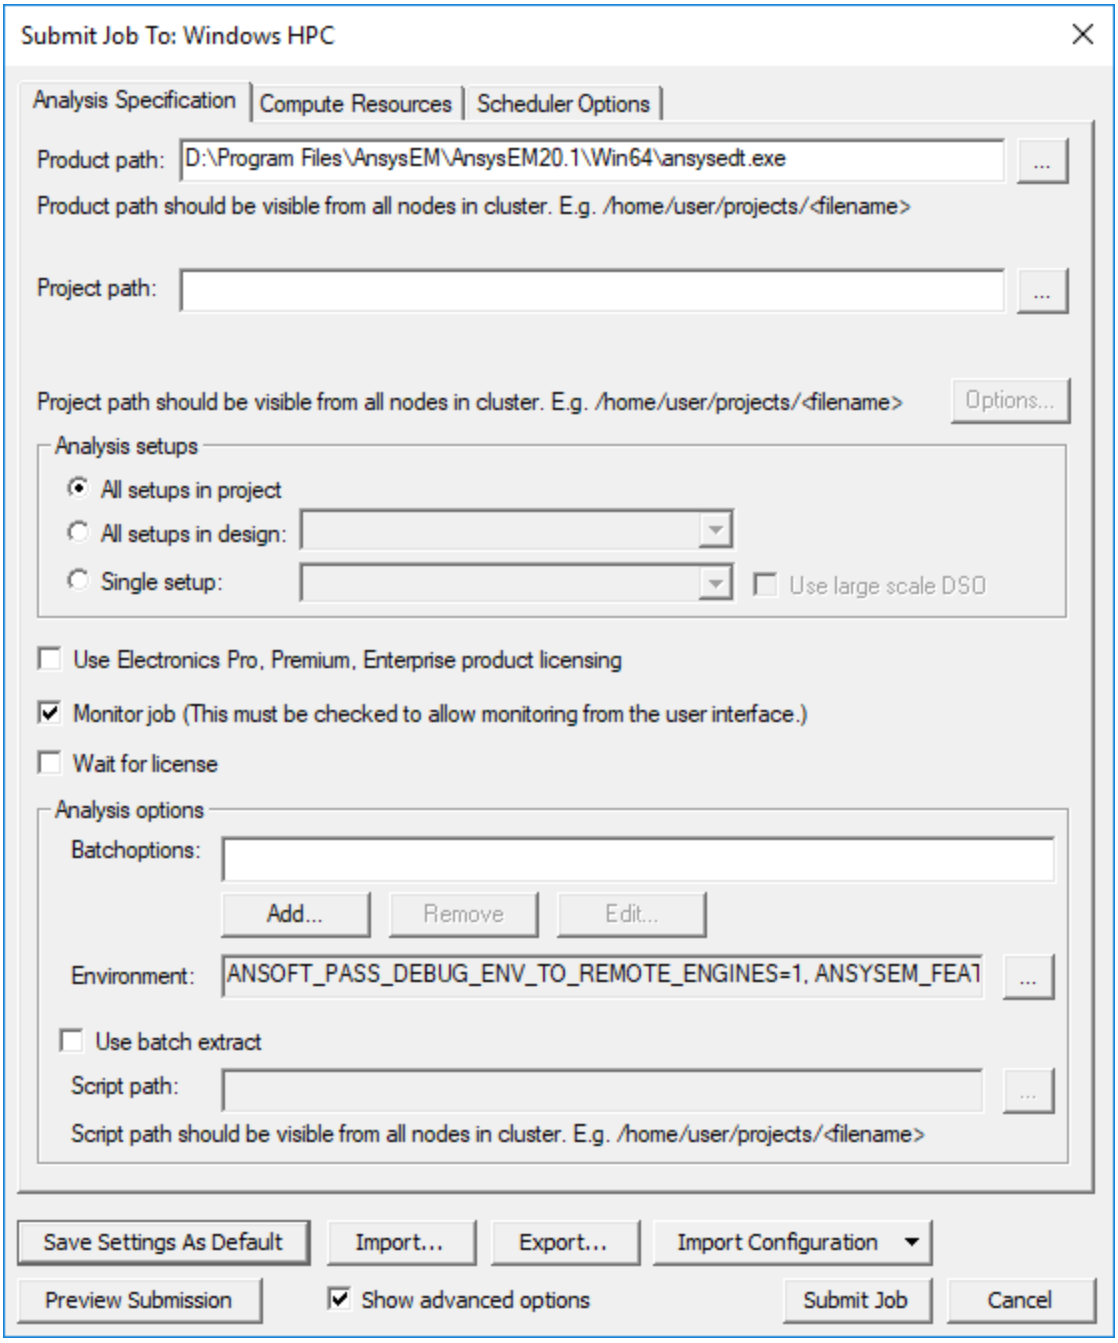
You can also do custom integration.

Note	For additional information about high performance computing not in this guide, see the *Ansys Electromagnetics HPC Administrator's Guide* in the help.

A job scheduler may also be described as a batch system, a Distributed Resource Management System (DRMS) or Distributed Resource Manager (DRM). The features supported on each scheduler are included in the documents for each. For each job scheduler, the versions or revisions that have been tested are included.

HPC Computing integration for Ansys Electronics Desktop supports Lustre FS. However, Ansys doesn't support having Linux home directories stored on Lustre FS. (This is a limitation due to the way MainWin writes temporary/config files into the home directory.)

A user may submit jobs using the command line tools or other tools provided by the scheduler. The Desktop includes a GUI to help the user submit jobs to a job scheduler. This generic Job Submission GUI is shared across the Ansys Electromagnetics products.



The general procedure is to specify the scheduler and head node, describe and submit the job, and monitor the results.

The **Submit Job To** dialog contains three tabs:

- **Analysis Specification**--specify the Product path, Project name, the setups, and analysis options such as batchoptions, or, for advanced users, Environment variables. The Project can be an archive. The project file pathname must be a UNC path that is accessible from

each compute host used for Ansys Electromagnetics jobs.

The Product path and Project fields support mapped drives. This is done through a checkbox in the Specify Product Path dialog displayed when you click the ellipsis [...] button. A checkbox lets you "Use converted UNC path if mapped drive specified." If you select a project or product on a mapped drive, and check the option, the converted UNC path equivalent to the mapped drive pathname is used.

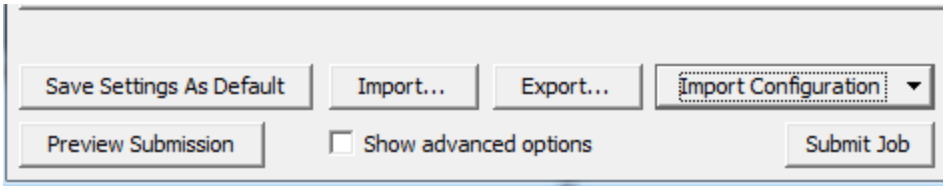
- **Compute Resources**--specify whether to use automatic settings, resource selection parameters, and if, you do not use automatic settings, job distribution parameters.
- **Scheduler Options**--specify for Job name and priority.

There are two ways that the GUI may be used to submit jobs.

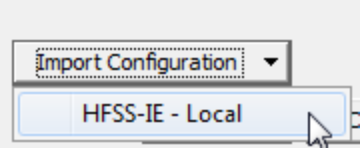
- The first mode requires that the Desktop (UI) process run on a host which is also a submission host for the job scheduler. This mode is called local mode or working mode.
- The second mode is useful for cases in which the submission hosts are not able to run graphical processes, such as the Desktop. The second mode is only supported on Linux in the Ansys Electromagnetics Suite 2023 R1 release. In the second mode, an administrator configures the RSM Service to act as an interface to the job scheduler, and starts the RSM Service on a submission host for the cluster. The user runs the Desktop (UI) process on another host (which may be called the postprocessing host). To submit a job, the user specifies the host where the RSM Service is running, and the Desktop process connects to the RSM Service over the network to submit the job. In this mode, some configuration is required, and the RSM Service typically must run as a privileged user (e.g., root), so that it can launch processes as any user.

Import and Export Configurations

The bottom of the Job Submission GUI has buttons for Import..., Export..., and Import Configuration let you save a configuration for each solver type.



- The **Export** button exports most of the settings of this dialog (all tabs) to a file.
- The **Import** button updates most of the settings in this dialog (all tabs) from a file.
- The **Import Configuration** button updates the DSO settings in this dialog from any DSO configuration as shown in the **Configurations** tab of the **HPC and Analysis Options** dialog box. The **Design Type** of the DSO configuration must match the design type of one of the designs in the project, so the "Project" must be specified before using the **Import Configuration** button. The batchoptions are also set from the specified DSO configuration or from the Design Type options settings, which are shown in the **Options** tab of the **HPC and Analysis Options** dialog.



The **Export** and **Import** buttons may be used to save and then restore a frequently used collection of job submission settings. The **Save Settings as Default** button may also be used to save the current settings, but it always overwrites any previously saved settings. Using the **Export** button, the user may save multiple sets of settings, or may transfer the settings to another machine.

The **Select Scheduler** dialog also has **Export** and **Import** buttons. These buttons may be used to save the settings in this dialog to a file or restore them from a file.

An Exported configuration is named **Submit_Job_Settings** by default and has an **.areg** suffix. A file browser window opens in the project folder and lets you name an exported file and location, and select an **.areg** file to import.

Scheduler Terminology

- Core: unit of processing
- Processor: consists of one or more cores
- Machine/Host/Node: consists of one or more processors, memory, disk, etc.
- Resource: Machines, licenses, etc. that are used by a Job
- Job: Application (also called: program, executable), with command line options, that uses resources to produce useful results. For example, maxwell.exe –ng –BatchSolve …
- Serial Job: job that runs on a single core
- Parallel Job: job that runs on multiple cores (belonging to same or different machines)
- Compute Cluster: network of machines on which Jobs run. Typically, consists of head node (s) and many compute nodes
- Service: Program that runs in the background (e.g., RSM Service). ‘Listens’ on a ‘port’. OS provides programming interface by which Applications communicate with service, once machine and port number are known. Launching an executable on remote machine, requires a service to run on remote machine.

Ansys Electromagnetics Suite Terminology

- Desktop: The main application used to accomplish a task, such as Maxwell. The desktop may run as a GUI or it may run as a batch command.
- Engine: Application (the executable) that is launched by analysis commands, to generate analysis results.
- Multi-processing: A single engine uses multiple cores on the **same** machine.
- Distributed-processing: Multiple engines are launched simultaneously (on same machine **or** different machines). Uses ansoft_distrib (and related) license.

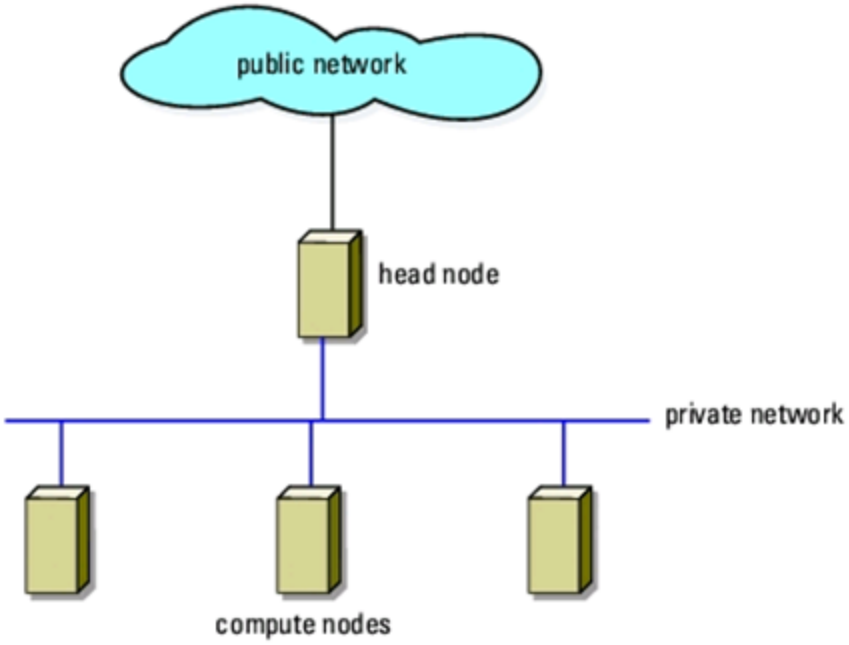
High Performance Computing (HPC) Integration

What a Scheduler Does

- Enables effective/efficient utilization of cluster's resources consistent with organization's goals
- Maintains queue(s) of jobs
- Maximizes throughput of the jobs by processing all jobs as fast as possible
- Typically, one job per cpu policy
- Allows choice of various scheduling policies (e.g. First Come First Serve, Priority Based, Preemption)
- Provides a suite of tools or utilities (graphical or command line) for end user to submit jobs, monitor jobs, abort jobs, suspend jobs, …
- Manages a compute cluster by running various interacting 'services' on head nodes and compute nodes
- Provides a programming interface to access 'services'

Scheduler Managed Compute Cluster



Head node(s) typically maintains queues. Compute nodes are typically on a high speed network, to improve scalability of parallel jobs. Services running on nodes interact with each other to manage resources. End user tools communicate with services to submit/abort/suspend/etc. jobs.

Installation of Ansys Electromagnetics Suite

Ansys Electromagnetics Suite must be available on each cluster host where jobs may be run.

- On a LINUX platform, Ansys Electromagnetics Suite may be installed on a shared drive, that is accessible to all machines in the cluster.
- On a Windows platform, Ansys Electromagnetics Suite must be installed separately on each host of the cluster.

The Ansys Electromagnetics Suite must be accessible using the same path on each host. All cluster users running Ansys Electromagnetics jobs must have permission to read and execute the files in the installation directory and its subdirectories.

The Temp directory selected during installation must be readable and writable by all user accounts used to run the Ansys Elctromagnetics Suite. This temp directory path should be the same on all machines of the cluster and should be local to every machine. For example, c:\temp on Windows, /tmp on LINUX

Because HPC is offered as a direct integration, you need only install the Ansys Electromagnetic Suite software. No additional configuration is required.

Example

Install the Ansys Electromagnetics Suite in directory C:\Program Files\AnsysEM\ on each node of the cluster. The same directory pathname must be used on all hosts.

Firewall Configuration

Installation Directory Examples

Firewall Configuration

If firewall is turned OFF between the machines of the cluster, there is no need for any configuration. If firewall is turned ON, you, or a system administrator, should perform the steps below.

- Windows cluster: Configure firewall by adding exceptions that allow Ansys Electromagnetics Suite programs and services to communicate with each other. If you are using standard Windows Firewall, this is automatically done for you, by the Ansys Electromagnetics installation program. On the other hand, if you are using a 3rd-party firewall software, it needs to be configured in a similar manner.
- Linux cluster: Open up the firewall for range of ports denoting ephemeral (or dynamic) ports. Check with your system administrator on how this can be done on each machine of cluster.

Ansys Electromagnetics Jobs

Using Ansys EM HPC Diagnostics tool

Integration with Microsoft Windows® HPC Scheduler

The Windows HPC scheduler is only supported on Windows. Jobs may be submitted in any of the following ways:

- Using the Windows HPC GUIs from Microsoft: Job Manager or Cluster Manager
- Using the Windows HPC command line tools (job, etc.)
- Using the Desktop UI commands for Scheduler selection, Job submission and Job monitoring/control. You specify the Windows HPC Scheduler User Interface for Submit Job by clicking **Tools>Job Management>Select Scheduler...**

You can also select the **Simulation** tab of the ribbon, and click the **Scheduler** icon.

Select the scheduler from the drop-down menu on the **Select Scheduler** window. Once you select a scheduler, you can access the interface for job submission, monitoring and control.

See the Ansys Electromagnetics Suite Windows Installation Guide for additional information on supported schedulers.

General Guidelines for Submitting Ansys Electromagnetics Jobs

A Job submitted to Windows HPC Cluster is defined by Job properties, Task List and Task properties. Priority, resource requirements, node preferences, etc. come from Job properties. In the case of Ansys Electromagnetics jobs, Task List consists of a single task. Properties of this task specify command line that runs Ansys Electromagnetics Desktop in non-graphical mode to perform analysis of an Ansys Electromagnetics project.

Specifying the Number of Compute Resource Units for HPC Jobs

In the old setup you had to list machines multiple times, and figure out how many cores per task on each machine in order to set Number of Processors Distributed to the smallest of these. In the new setup, you just enter the number of tasks and total cores per machine.

Ansys Electromagnetics Project File and Project Directory for use with Windows HPC Scheduler

Ansys Electromagnetics Suite tools write their results to a subdirectory of the directory containing the Ansys Electromagnetics project file. The Project Directory (the directory containing the project file) must be accessible to all of the cluster hosts that may run Ansys Electromagnetics jobs. The user account for the job must have permission to read the project directory, and to create and modify files and subdirectories of this directory. The pathname of the project file must be

accessible to all cluster hosts using the same path name, which is generally expressed as a UNC pathname.

Example:

The project file is on the user's workstation (with hostname user1_PC) in directory C:\user1\projects\new\project1.aedt, and the directory C:\user1\projects is shared with sharename projects.

Correct

When submitting the job, you should use the following pathname to specify the project file:

```
\\user1_PC\projects\new\project1.aedt
```

Incorrect

If a local pathname is used, the cluster hosts will not be able to find the user's project on the workstation

```
user1_PC: ' C:\user1\projects\new\project1.aedt'
```

Submitting and Monitoring Ansys Electromagnetics HPC Jobs

Jobs may be submitted to the Windows HPC Scheduler using any of the following methods:

- Using the **Submit HPC Job** dialog
- Using the Windows HPC Job Manager GUI
- Using the Windows HPC Command Line Tools
- Using the Windows PowerShell

Client Utilities from the Microsoft HPC Pack, must be installed on the submit host to use any of these methods to submit a job to a cluster. The **Submit HPC Job** dialog will be unable to contact the cluster head node if the client utilities are not installed.

This document covers the first method. See the Microsoft documentation for information on the other three methods.

- Submitting and Monitoring Jobs for Windows HPC
- Specifying the Number of Compute Resource Units for HPC Jobs

Jobs may be submitted from any Microsoft Windows host meeting the following requirements:

- For submitting jobs to the Windows HPC scheduler, the Desktop process must run on a node that is configured for submission of jobs to the Windows HPC cluster. That is, the Windows HPC Client Utilities must be installed on the node, and network communication from the Desktop node to the head node of the cluster must be allowed. For Ansys Electromagnetics Suite 2023 R1, Windows HPC Server 2008 R2 (or later) client utilities are required. Using a computer on the network is not supported for submission of jobs to the Windows HPC cluster.

- When submitting jobs to a Windows HPC cluster, the user must also specify the head node of the cluster to which the jobs will be submitted. When the user selects the "Windows HPC" scheduler in the "Choose scheduler" list, the Head Node edit control is enabled. The user may enter the Windows HPC cluster head node name into the edit box. Alternatively, the head node may be selected using a "Browse for Computer" browser by pressing the "..." button.
- The Windows HPC Pack client utilities are installed on the submission host.
- Network communication between the submission host and the Windows HPC Cluster head node is permitted; there is a network connection between these hosts that is not blocked by any firewall or the like.
- The submission user is permitted to submit jobs to the Windows HPC Cluster.

Job Monitoring

Windows HPC Jobs may be monitored using the **Monitor Job** dialog which is brought up by the **Tools > Job Management > Monitor Jobs...** command. This dialog may also be brought up by checking the **Begin monitoring this job now** checkbox when a job is successfully submitting using the job submission dialog box. In addition to the above requirements to allow job monitoring the following is also necessary:

- Network communication between the submission host and all Windows HPC Cluster nodes where the job may run is permitted; there is a network connection between these hosts that is not blocked by any firewall or the like

Cluster Configuration

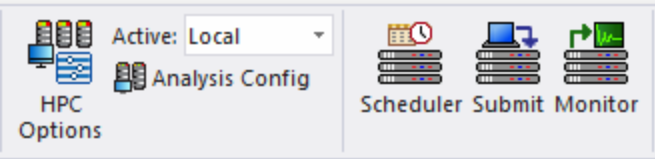
Any job running on a Windows HPC Cluster that is distributed over multiple compute hosts requires network communication between processes running on these hosts. The cluster must be configured to allow this communication. Any firewall or other security software must be disabled or configured to allow communication between any of the compute hosts were a job could run.

Job Submission User Profile on Cluster Compute Nodes

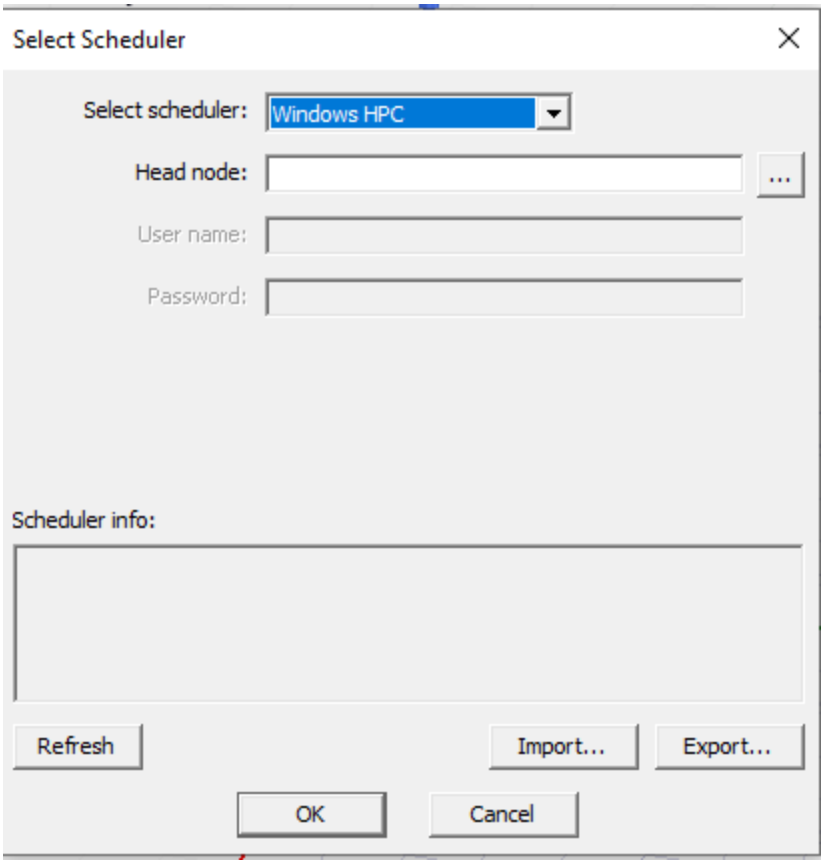
In order for a job to run correctly, the submission user's profile must be accessible and properly initialized on the cluster compute nodes where the job runs. If the Ansoft/temp subdirectory of the user's "My Documents" directory does not exist or is not accessible on the compute cluster nodes where a job runs, the batchoptions for the job will not be processed correctly, resulting in job failure. One way to ensure that this directory is created on each compute host is for the submission user to login to each compute host and run the product GUI one time.

Submitting and Monitoring Jobs for Windows HPC

In order to submit jobs using **Windows HPC**, you must click **Tools>Job Management> Select Scheduler** or you select the **Simulation** tab of the ribbon, and click the **Scheduler** icon.



This opens the **Select Scheduler** dialog box. Specify Windows HPC as the scheduler.



For Windows HPC, specify the head node of the cluster.

After specifying the cluster head node, you can click **Refresh**. This verifies that the head node may be contacted, and displays the scheduler name, a brief description (including the head node name), and the version of the Windows HPC head node.

Pressing **Cancel** discards changes made in this dialog box. Pressing **OK** verifies that the head node can be contacted before accepting the changes. If no problem occurs, the dialog will be closed. If there is a problem contacting the head node, the dialog will not be closed and the changes are not accepted.

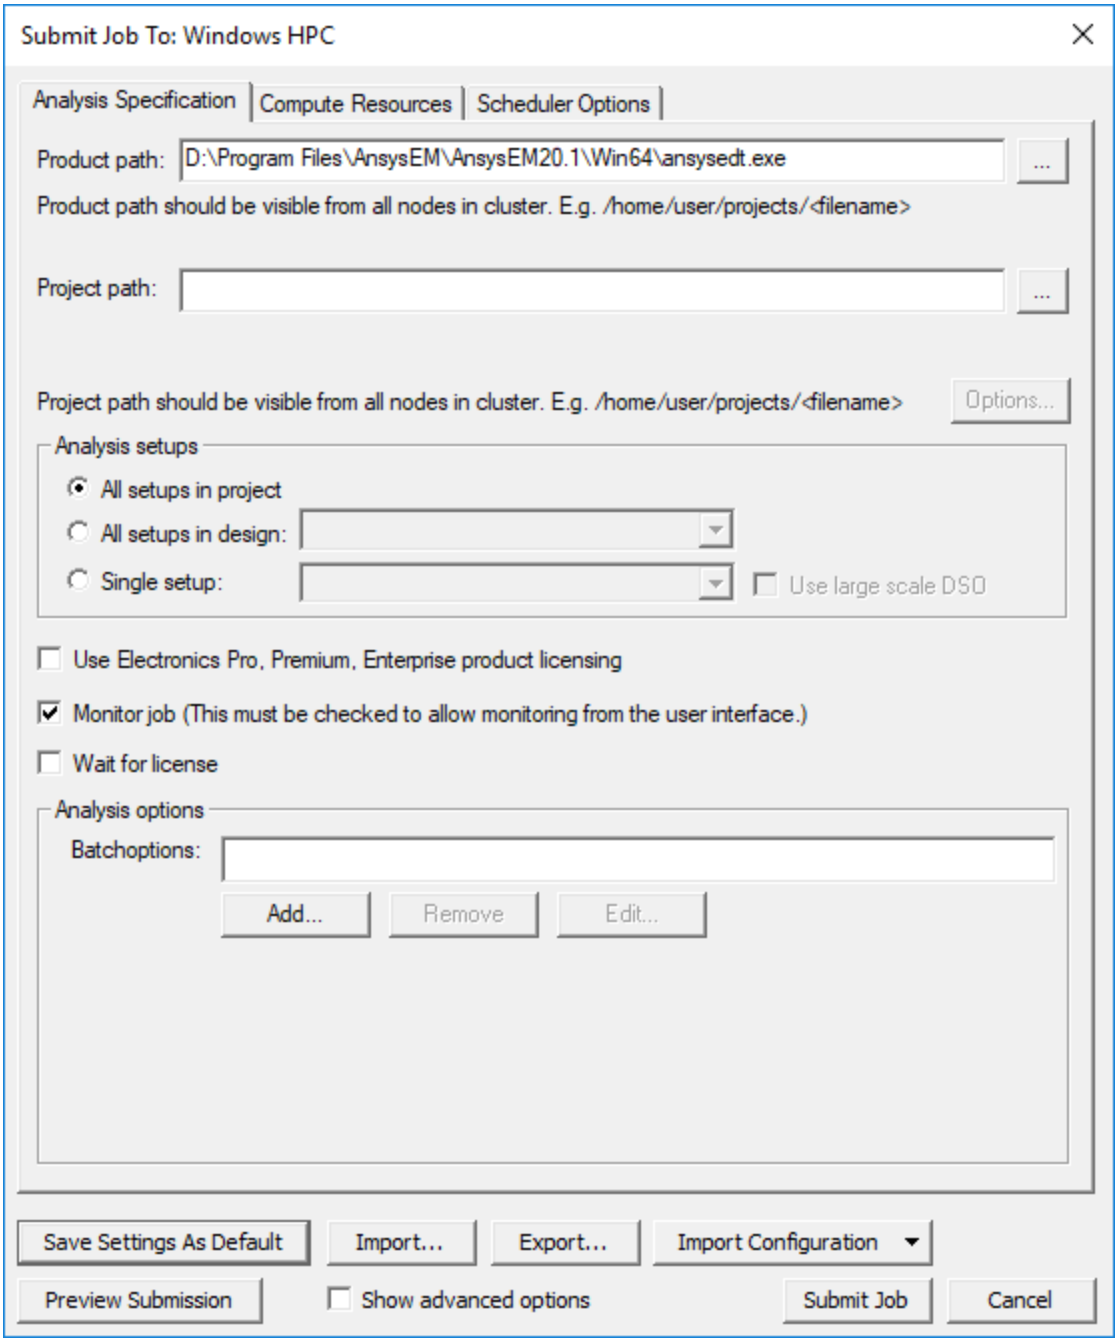
After setting the job submission node, select **Tools> Job Management> Submit Job...** or **Project> Submit Job...** or [ProductName]**> Submit Job...** to open the *Submit Job To:* dialog box. You can also select the **Simulation** tab of the ribbon and click the **Submit** icon. You can also

access **Submit Job** from the shortcut menus for the Project Name, Design name, Analysis Setup, or Optimetrics Setup.

The Submit Job To: dialog: contains three tabs:

- **Analysis Specification**--specify the Product path, Project name, the setups, and analysis options such as batchoptions, or, for advanced users, Environment variables. If you select the Analysis or Optimetrics setup, the Analysis Specification is pre-populated.
- **Compute Resources**--this tab can be populated either by automatic settings, by predefined Analysis Configuration, or specifying parameters in the fields for resource selection, for job parallelization and enabled forms of parallelization.
- **Scheduler Options**--contains fields for Job name and priority. The customization options shown by checking advanced are not used for Windows HPC.

In the **Analysis Specification** tab, enter the pathnames of the product path and of the project file in the “Project” edit box. These must be UNC paths that are accessible from each compute host used for Ansys Electromagnetics jobs. The Project can be an archive. The submission user must have permission to write to the directory containing the project file.



You can select which setups are analyzed in the Analyze Setups section of this dialog box. There are radio buttons to select:

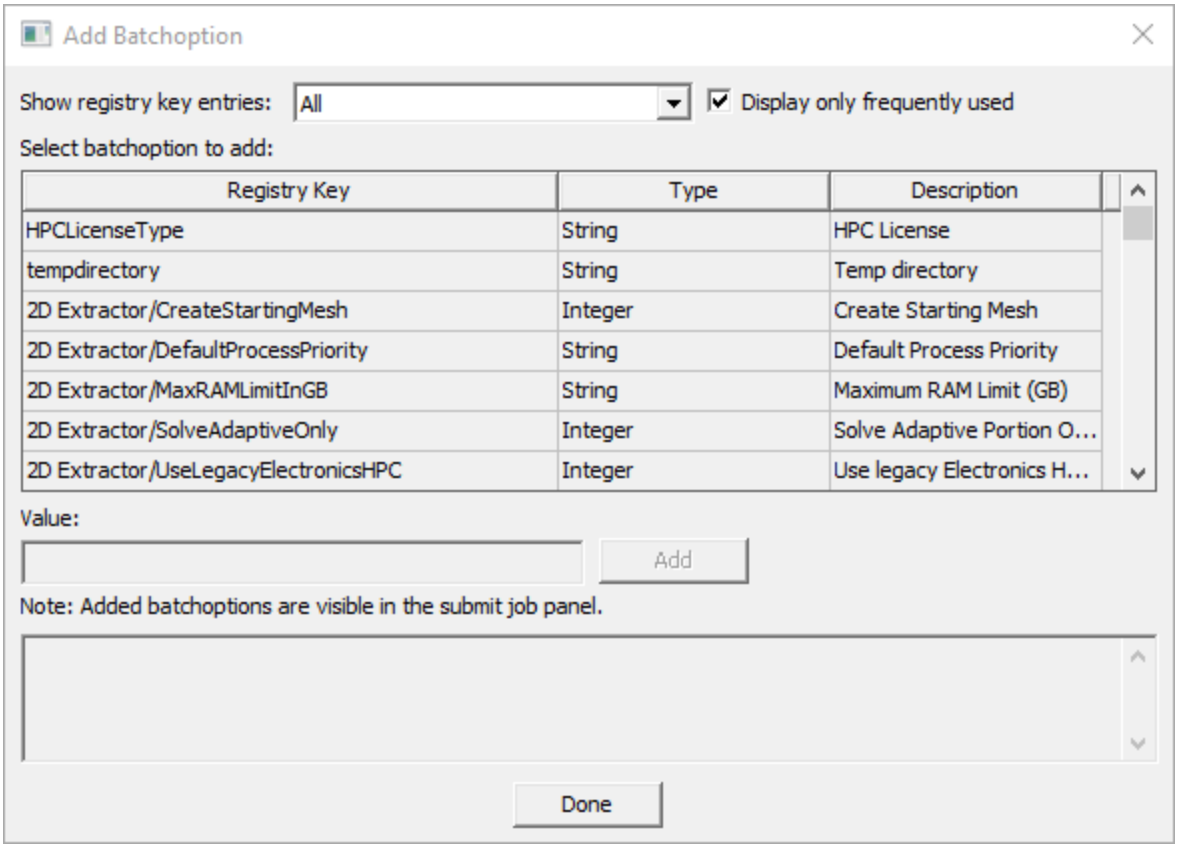
- All setups in the project
- All setups in a specified design: you select the design from the drop-down menu
- Single setup. If you select the Submit Job command from the shortcut menu, the setup name populates the field.

If you specify multiple setups, they will be processed sequentially in the order displayed in the edit box.

The Analysis options include:

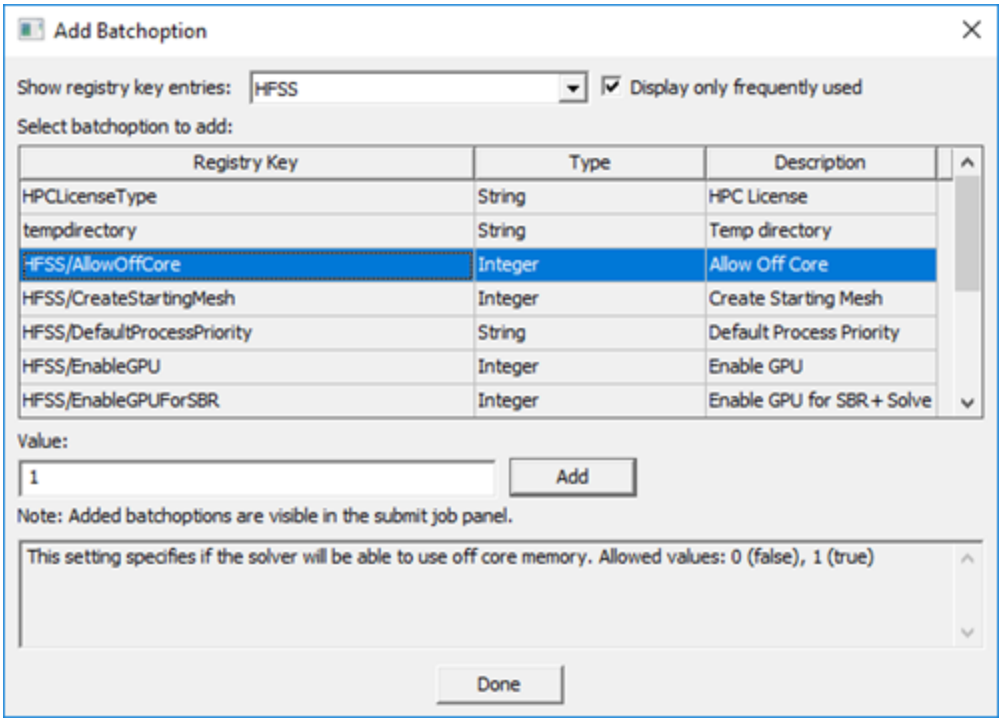
- Monitor job. You must enable this option to monitor the job from the user interface.
- Wait for license- whether to wait until a license if available before starting a simulation.
- Batch options. You can optionally specify -batchoptions in the text field. See detailed discussion of -batchoptions beginning under Running Maxwell from a Command Line.

The **Add...** button opens the *Add Batchoption* dialog box.

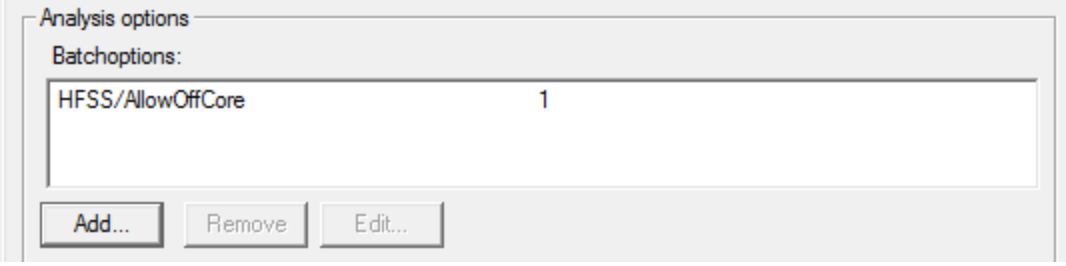


This dialog box provides access to all -batchoption commands. The drop-down menu lets you select specific categories, and you can choose to display only frequently used commands. You can edit and remove any batch options you specify.

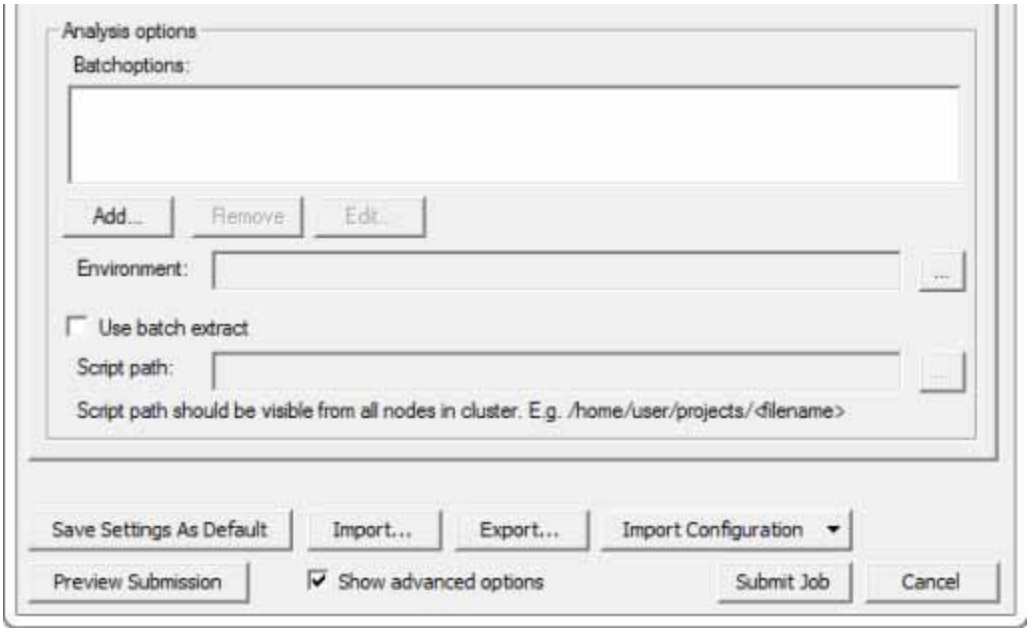
Select a Registry Key in order to show the current Value for the type. The lower field explains the meaning of the Type Value.



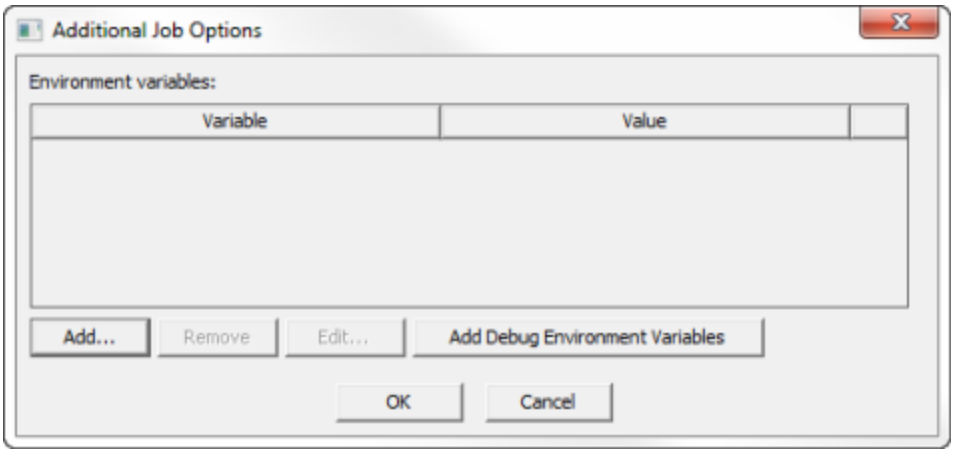
Any batchoptions for which you select **Add** will be visible in the *Submit Job* dialog box.



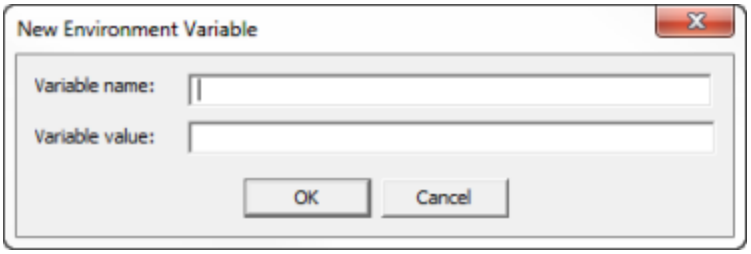
If you have the Show advanced options box checked in the *Submit Job* dialog box, the Environment field and the Use batch extract fields display.



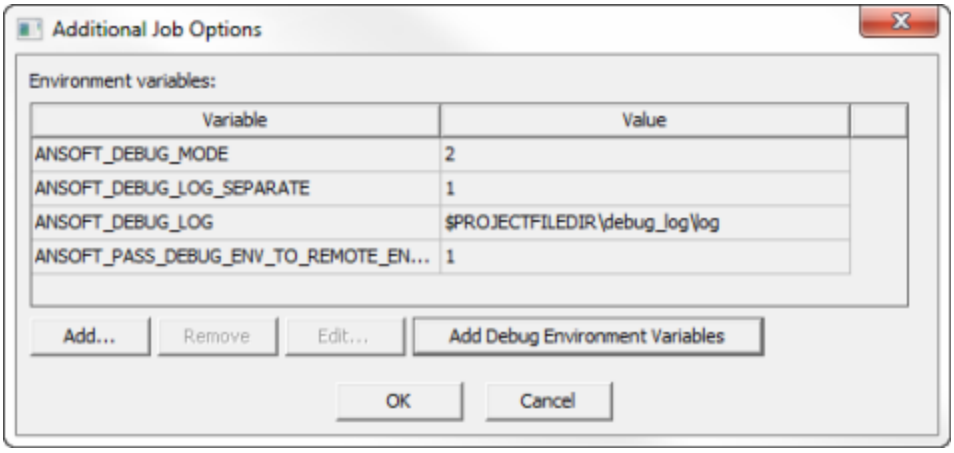
The Environment field lets you specify any Environment variables. Click the ellipsis button [...] to display the *Additional Job Options* dialog box.



Click the **Add...** button to open the *New Environment Variable* dialog box.



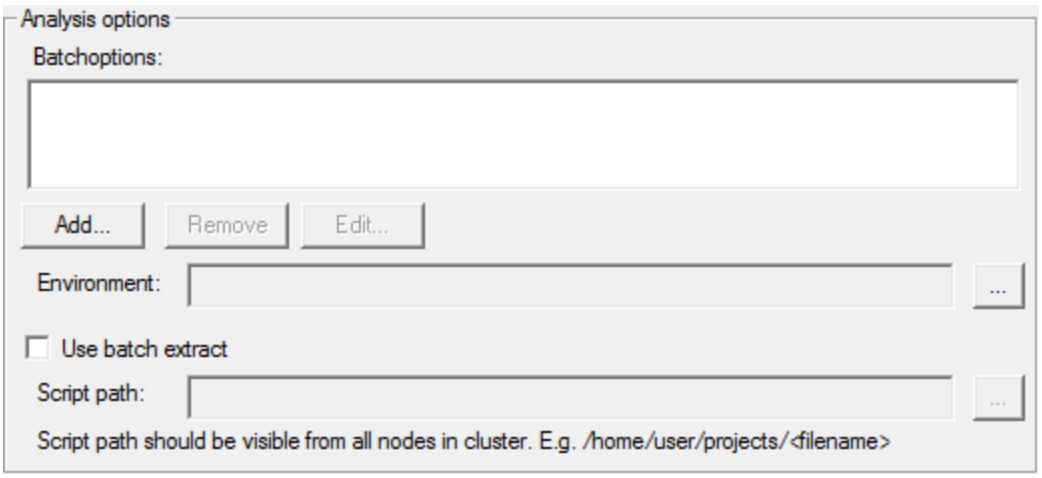
Here you can provide a Variable name and Variable value. Click OK to display the Variable in the Additional Job Options dialog box. Select a Variable to enables the **Remove** and **Edit...** buttons. You can also click **Add Debug Environment Variables**.



Any Variables that you add will be displayed in the Environment field of the *Submit Job* dialog box, if you have also enabled Show Advanced options.

Use Batch Extract for Windows HPC

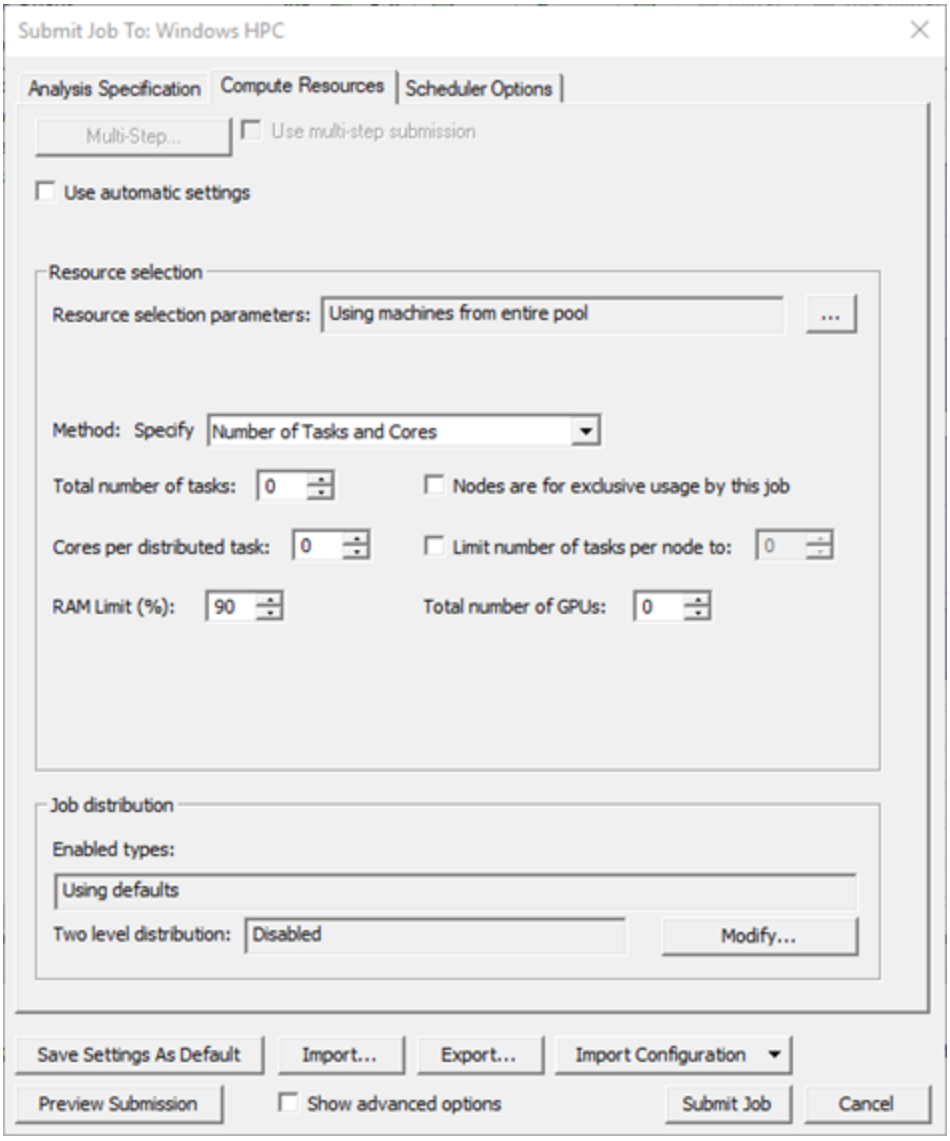
Selecting Show advanced options for Windows HPC also show the Use batch extract fields.



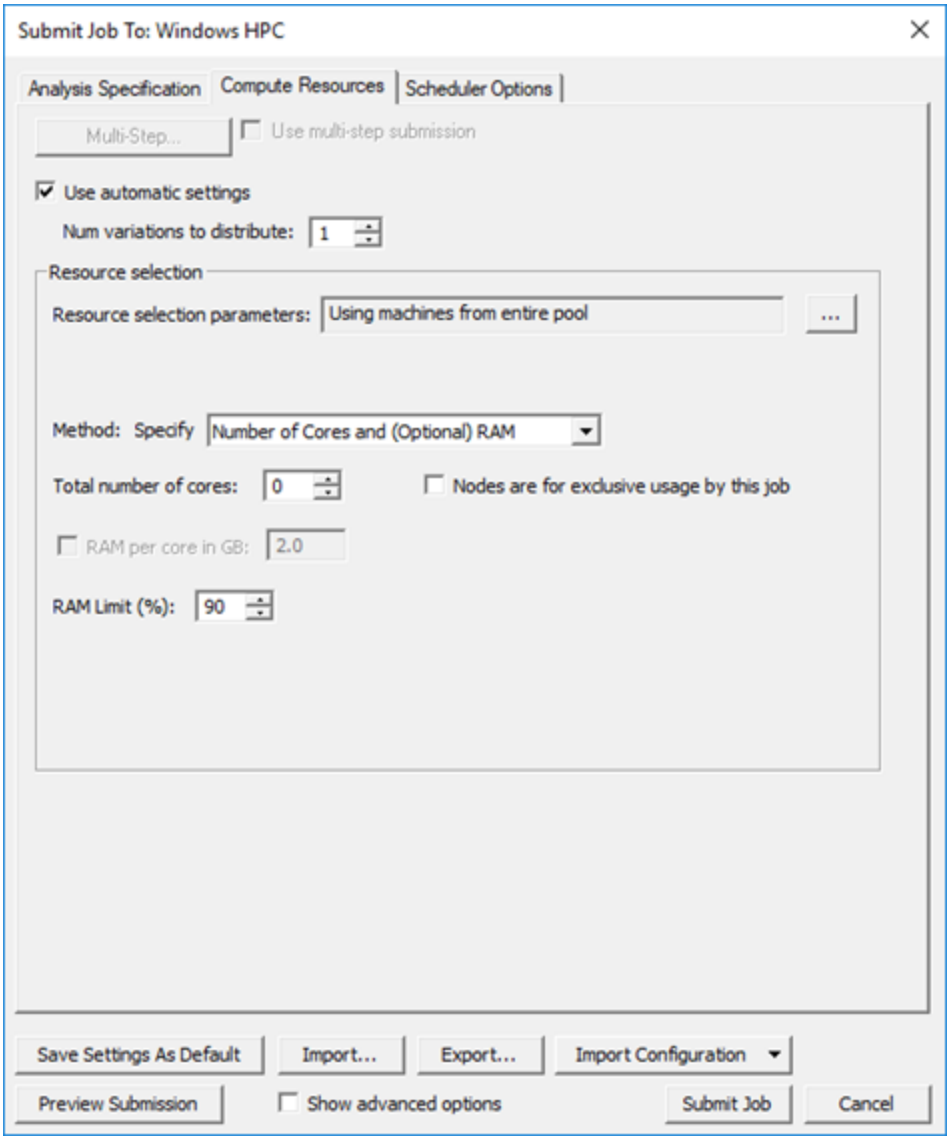
See the discussion on Running Maxwell from a Command line for a discussion of the solve information available through batch extract.

The **Preview Submission** button opens a window that shows the text commands that will be sent to the scheduler.

The following figure shows the *Compute Resources* tab of the *Submit Job To* dialog box.

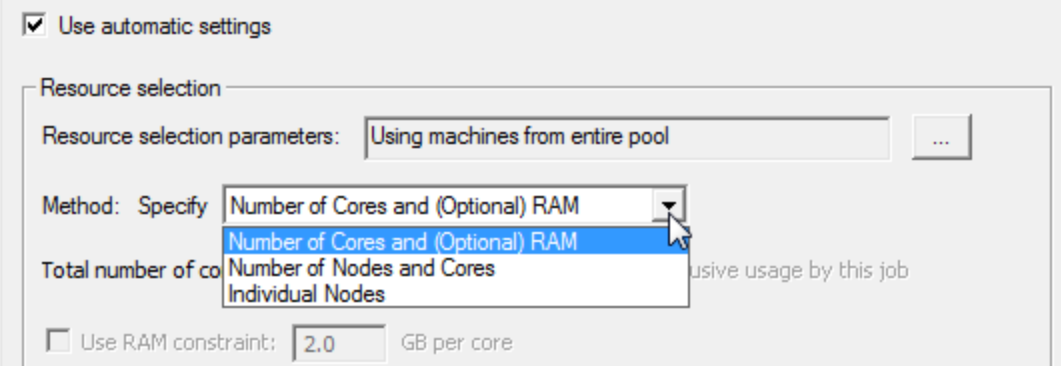


For Ansys Electronics Desktop configurations, the *Submit Job* dialog box includes a **Use automatic settings** check box that simplifies the *Compute Resources* tab.



HFSS, HFSS-3D Layout, and Icepak have **Use automatic settings** selected by default. With Use automatic settings selected, the Job distribution field is removed. For Use automatic settings, you can specify Resource selection parameters. The ellipsis button [...] opens the Compute Resource Selection Parameters dialog box. If you do not specify any parameters, the default is Using machines from the entire pool.

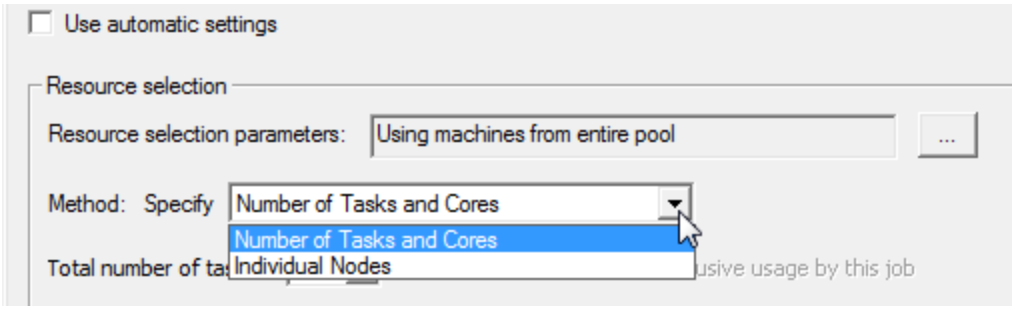
The Method field of the *Submit Job To* dialog box has a drop-down menu with two or three selections, depending on whether you select **Use automatic settings**.



Note:

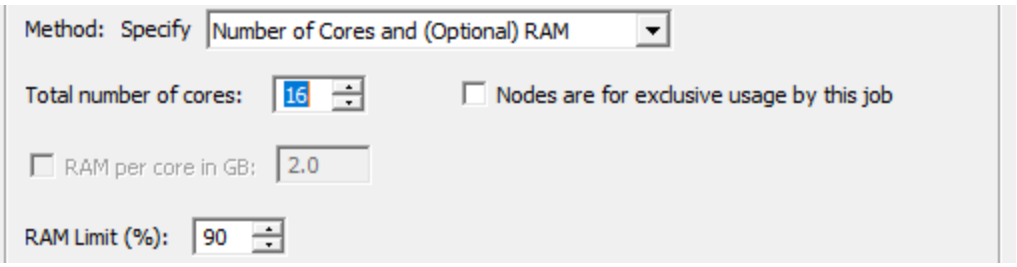
If you select Use automatic settings, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. It does distribute frequencies, domains, and use of multiple level domains.

If you uncheck or cannot access Use automatic settings, these two Methods are listed:

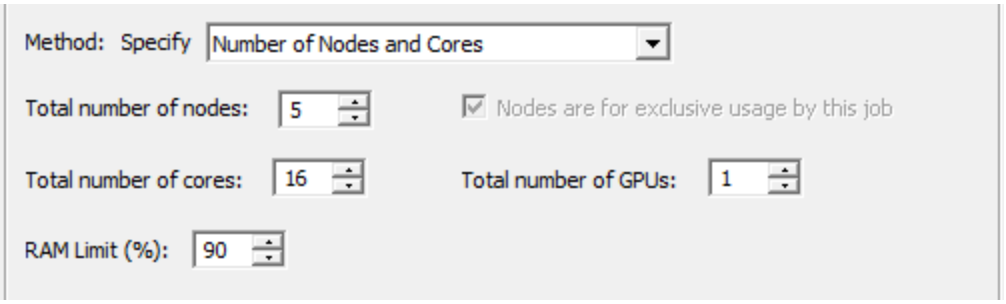


Each Method selection changes the available options listed:

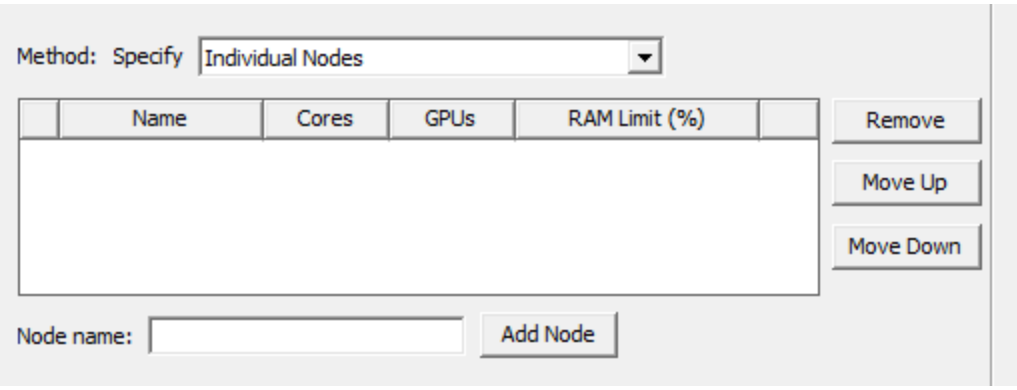
- Specify Number of Cores and (Optional) RAM



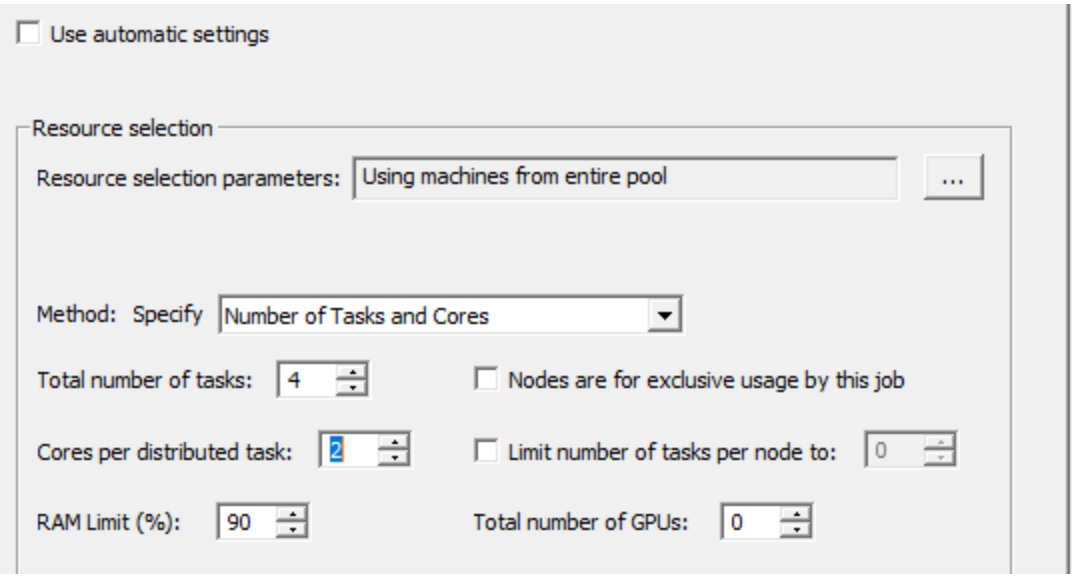
- Number of Nodes and Cores



- Individual Nodes



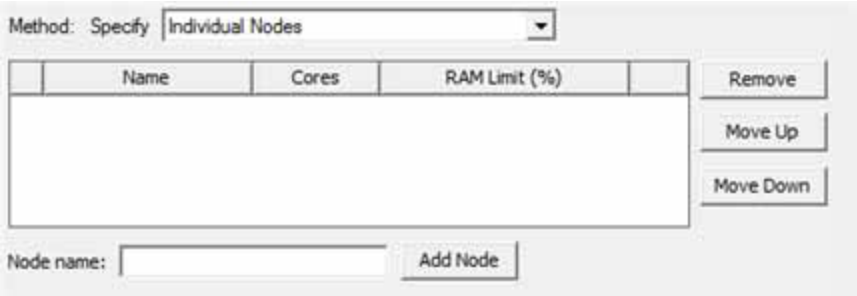
- Number of Tasks and Cores ("Use automatic settings" is unchecked for this option. Checking "Use automatic settings" means that you do not have to specify tasks or core parameters):



Individual Node List

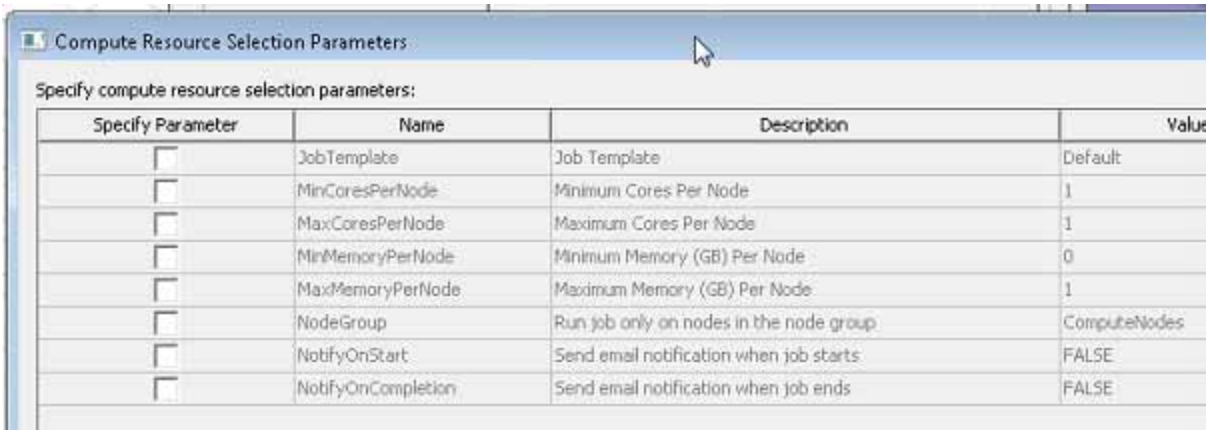
For Windows HPC jobs, you may either specify a node list, or specify job parallelization parameters, but not both.

If you select the Individual Nodes Method, you may specify a node list, and the Job parallelization controls are disabled. In this case, the node list should only include cluster nodes that are valid for the job. For each node, you enter the node name and add the node. In the table, you can specify the number of cores and the RAM limit as a percentage. You can use the Remove, Move Up and Move Down buttons to edit and order the list.



Compute Resource Selection Dialog

By default, you can draw from the entire pool. You can also click the ellipsis button [...] to open a *Compute Resource Selection* dialog box.



The resource selection parameters for Windows HPC jobs are:

- JobTemplate: Job Template - The JobTemplate may limit the job parameters or specify defaults values for job parameters
- MinCoresPerNode: Minimum Cores Per Node
- MaxCoresPerNode: Maximum Cores Per Node
- MinMemoryPerNode: Minimum Memory (GB) Per Node
- MaxMemoryPerNode: Minimum Memory (GB) Per Node
- NodeGroup: Run job only on nodes in the node group

- NotifyOnStart: If True, send email notification when job starts. Email notifications must be configured and enabled for the cluster by the administrator. (The cluster head node must run Windows HPC Server 2008 or above.)
- NotifyOnCompletion: If True, send email notification when job ends. Email notifications must be configured and enabled for the cluster by the administrator. (The cluster head node must run Windows HPC Server 2008 or above.)

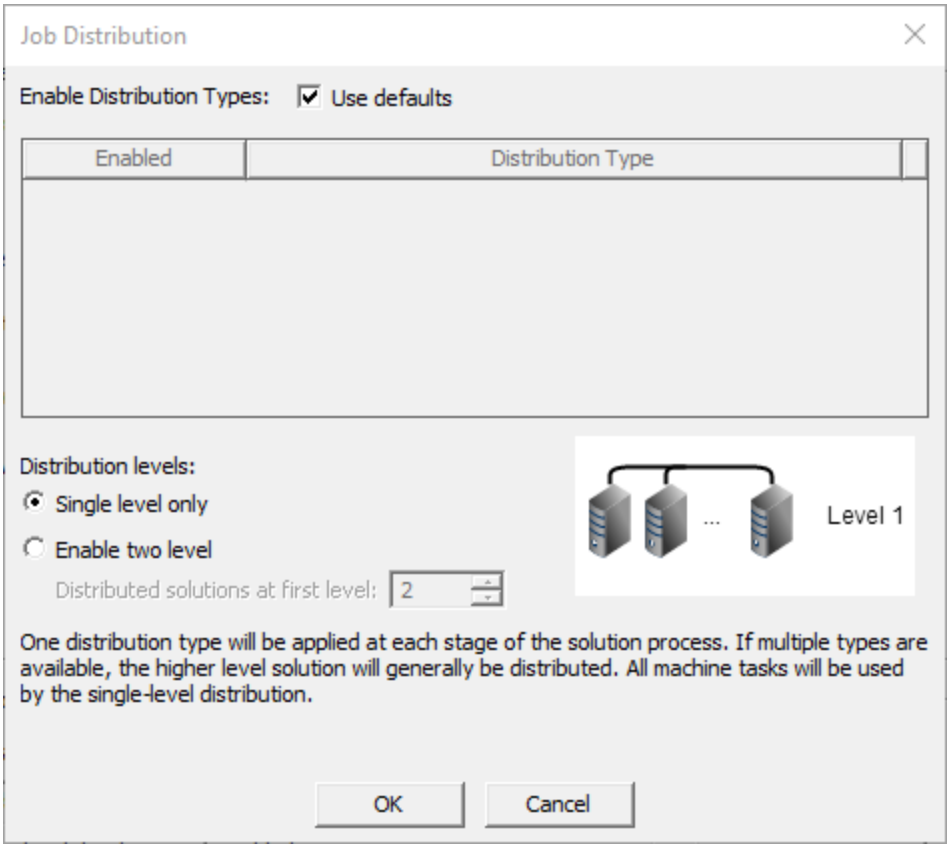
Job Parallelization

For Windows HPC jobs, you may either specify a node list, or specify the job parallelization parameters, but not both. The Job parallelization fields let you specify

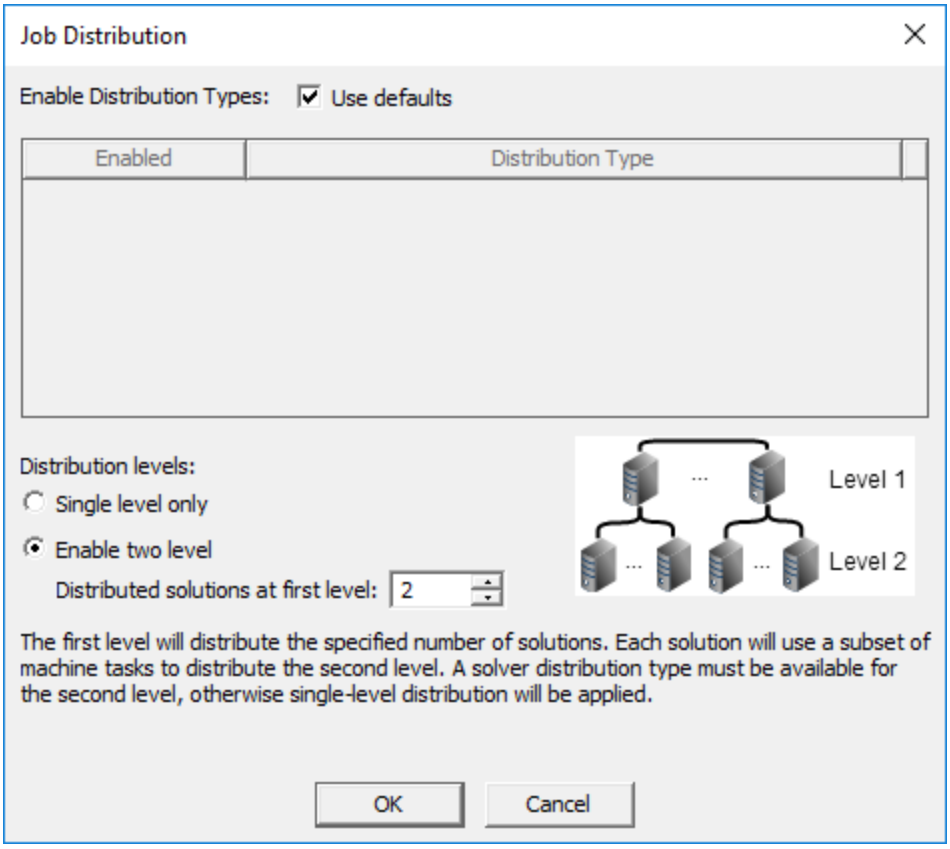
- Total number of tasks: The number of nodes requested for the job is the total number of tasks divided by limit on the number of tasks per node, rounded up if it is not an integer.
- Cores per distributed task. This determines the amount of multiprocessing per task.
- Whether nodes are for exclusive usage by this job
- Whether to limit the number of tasks per node to a value. If the "Limit number of tasks per node" check box is not checked, then the job is submitted with a job unit type of "Core".

Job Distribution

- Single level or two level distribution (*single level* is the default). Click **Modify** to display the *Job Distribution* dialog box and select the **Enable two level** option if applicable and desired.



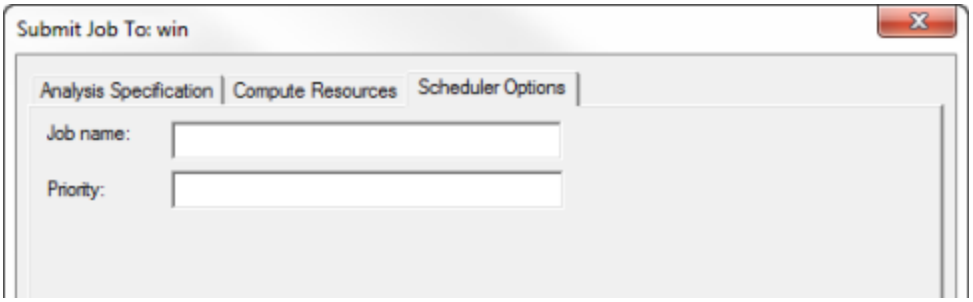
- Second level distribution operates within DSO. If available and enabled you can specify the number distributed solutions for level 1.



In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines, with two processors per engine, and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.

Scheduler Options

The *Scheduler Options* tab provides for specifying the job name and/or the job priority. While the **Show advanced options** check box enables the display of Job submission options, no job submission options should be specified for Windows HPC.



Preview Submission

The Preview Submission button opens a window that shows a text description of the job to be submitted and the task used to start the product on one of the nodes.

The JOB PARAMETERS section contains information on parameter that apply to the job as a whole.

- The "Job resource parameters" section indicates whether the job has exclusive use of nodes, the job unit type, and the minimum and maximum number of units requested for the job, node group, and email notifications.
- The "Job attributes" section displays the job name and job priority.
- The "User Specified Compute Resource Attributes" displays the Resource selection settings.

The TASK PARAMETERS section contains information on parameters that apply to the Desktop task, which is the main task of the job.

- The "Desktop task resource parameters" section indicates the job unit type (which is the same as in the JOB PARAMETERS), and the minimum and maximum number of units requested for the Desktop task.
- The "Command Line section" displays the desktop task command line, including all arguments.
- The "Environment variables" section displays the environment variables that are set for the Desktop task; the same environment variables will also apply to all other tasks of the job.
- The "Working directory" section indicates the working directory in which the Desktop task will run.

Monitor Job

If you have checked the Monitor Job option on the *Submit Job To* dialog box, **AnalysisSpecification** tab, you can invoke the *Monitor Job* window by clicking **Tools> Job Management> Monitor Jobs...** This dialog box may also be brought up by checking the **Begin monitoring this job now** check box when a job is successfully submitting using the job submission dialog box. For more details, see Monitor Jobs window.

Specifying the Number of Compute Resource Units for HPC Jobs

Windows® HPC Job Templates

The job templates are managed by the Windows HPC cluster administrator. Every cluster has at least one job template, the "Default" job template. Every job has an associated job template. If no job template is specified, then the "Default" job template is used. The job template controls two related aspects of the job submission process. When a job is submitted, there are a number of job parameters which may be specified. Each parameter has a set of valid values. For example, the Priority parameter has five valid values, Highest, AboveNormal, Normal, BelowNormal, and Lowest. The job template controls the default value of each parameter; this is the value that the parameter has if it is not specifically overridden by the submitter. For example, in the Default job template, the default value of the Priority parameter is Normal. The job template may also limit the allowed values of each parameter to a subset of the valid values. For example, a job template for privileged users could allow all five Priority values, which a job template for unprivileged users could limit the allowed Priority values to Normal, BelowNormal and Lowest.

Each job template is a Windows object with access controlled by an ACL (access control list). Instead of the usual "Read" or "Read & Execute" permissions, there is a "Submit Job" permission which corresponds to the right to submit a job with this job template. The cluster administrator may create job templates to limit or control access to cluster resources. For example, a job template with limited allowed job run times, or access to a limited set of compute nodes could be created by the cluster administrator. Specific users or user groups could be forced to use this limited job template by omitting access to the other job templates or by adding a deny access entry for the specified user or group to the other job templates. See the *Windows HPC Server 2008 Job Templates* white paper from Microsoft for additional details:

http://www.microsoft.com/en-us/download/confirmation.aspx?id=5659

Job templates may also be created to allow users to run jobs with limited knowledge of the appropriate job parameters. The cluster administrator creates a job template which has reasonable default values for the type of job to be run, and informs users which job template to use for each type of job. The template could also limit some parameters to only the subset of all values that are useful for the type of job associated with the template.

Selecting Computation Resource Units (Job Unit Type)

Windows® HPC Job Credentials

High Performance Computing (HPC) Integration

Selecting Computation Resource Units (Job Unit Type)

The Job Unit Type is the smallest unit of processing resources used to schedule the job. This is one of the most important job properties. There are three options for the Job Unit Type: cores, nodes or sockets.

- **Cores**: Jobs are scheduled in units of cores, which may be also described as a CPU cores, logical processors, or CPUs. This is the smallest unit of granularity available. This selection allows the scheduler to start multiple tasks on a processor, if the total number of cores needed by the tasks is less than or equal to the number of cores on the processor. This selection may also allow the scheduler to distribute more of the computational load to processors with more cores than to processors with fewer cores.
- **Nodes**: Jobs are scheduled in units of nodes, hosts or machines. This is the coarsest level of granularity that may be selected. When this option is selected, only one task will run on any give node at any given time. This is useful in cases where it is not desirable to run multiple tasks on a single host. For example, if each task is multi-threaded, running multiple tasks on the same node may not be needed to fully utilize the computing resources on the node. This may also be preferred if the tasks are memory intensive, and multiple tasks would be competing for the limited memory resources.
- **Sockets**: A socket (which may also be called a NUMA node) is a collection of cores sharing a direct connection to memory. A socket will contain at least one core, and it may contain several cores. The socket concept may not necessarily correspond to a physical socket. Scheduling at the socket level may be useful in cases in which each task requires extensive use of the memory bus, and scheduling multiple tasks on the same socket would result in excessive bus contention.

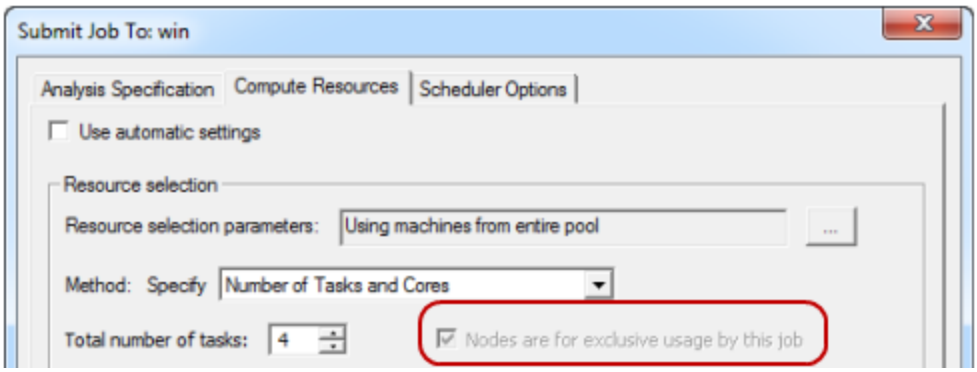
Windows® HPC Job Templates

Selecting Computation Resource Units (Job Unit Type)

Windows® HPC Job Credentials

Windows® HPC Non-Exclusive Jobs

In previous releases, when submitting jobs to a Windows HPC cluster using the **Submit Job To** dialog box, the exclusive node usage property of the job is on the **Compute Resources** tab always set to “true”.



For many cases, this requirement prevents problems. One type of problem that can occur is related to processor affinity. In general, EBU jobs manage processor affinity on their own, and request a single core for each Windows HPC task. If the cluster does set the affinity for the job, then the EBU job cannot use all of the resources allocated to the job because the cluster sets the affinity to allow only a single processor for each Windows HPC task.

Recent versions of Windows HPC allow three choices for the Cluster AffinityType setting:

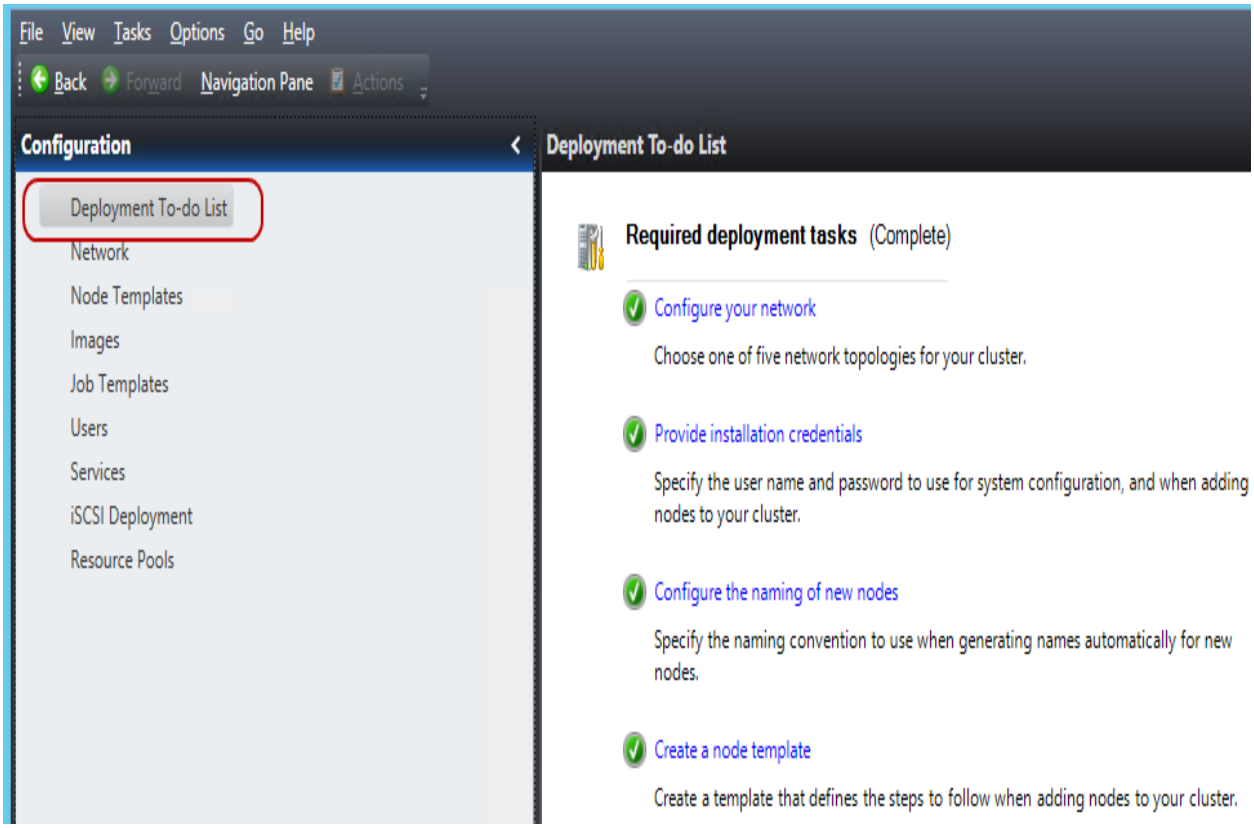
- No Jobs: Affinity is not set for any jobs
- Non Exclusive Jobs (default): Affinity is not set for exclusive jobs
- All Jobs: Affinity is set for all jobs

If the AffinityType is set to “No Jobs”, then we can allow non-exclusive jobs in many cases, but non-exclusive jobs will be disallowed if you specify an explicit host list (because all resources on all specified hosts are used), if you specify nodes and cores (to ensure that the job has exclusive access to the specified number of nodes), or if you specify multi-threading (to prevent a single task from being split across hosts). If the AffinityType is set to “Non Exclusive Jobs”, then exclusive jobs will be disallowed for all cases, the same as the restrictions for the previous release.

The previous job submission dialog always has the “exclusive” checkbox disabled for Windows HPC jobs, so that “exclusive” jobs cannot be submitted to a Windows HPC cluster. The “exclusive” checkbox is now enabled for Windows HPC jobs. This allows you to submit exclusive jobs to a Windows HPC cluster. If this checkbox is checked, but the submission parameters and Windows HPC cluster AffinityType do not allow submission of an exclusive job, then an error message is displayed when you submit or preview the job.

Setting the Windows HPC Cluster Affinity Type

A Windows HPC Cluster administrator is able to modify the Affinity Type setting for the cluster. The administrator should start the Windows HPC Cluster Manager. The first step is to select the Configuration button on the lower left pane, then select the Deployment To-do List in the upper left pane. Then, the upper right pane displays the Deployment To-do List, as shown below.



Next, the "Configure job scheduler policies and settings" should be selected. This is under the heading "Optional deployment tasks".

Optional deployment tasks

Validate your environment before deploying nodes

Run a set of short diagnostic tests to find common problems that can affect node deployment.

Go online to get the latest set of tests

Add an operating system image

Create a new image or load an existing image to use with your node templates when deploying nodes.

Add or remove users

Add or remove users or administrators for your cluster.

Add nodes to your cluster

Deploy nodes, import a node XML file, or add preconfigured nodes to your cluster.

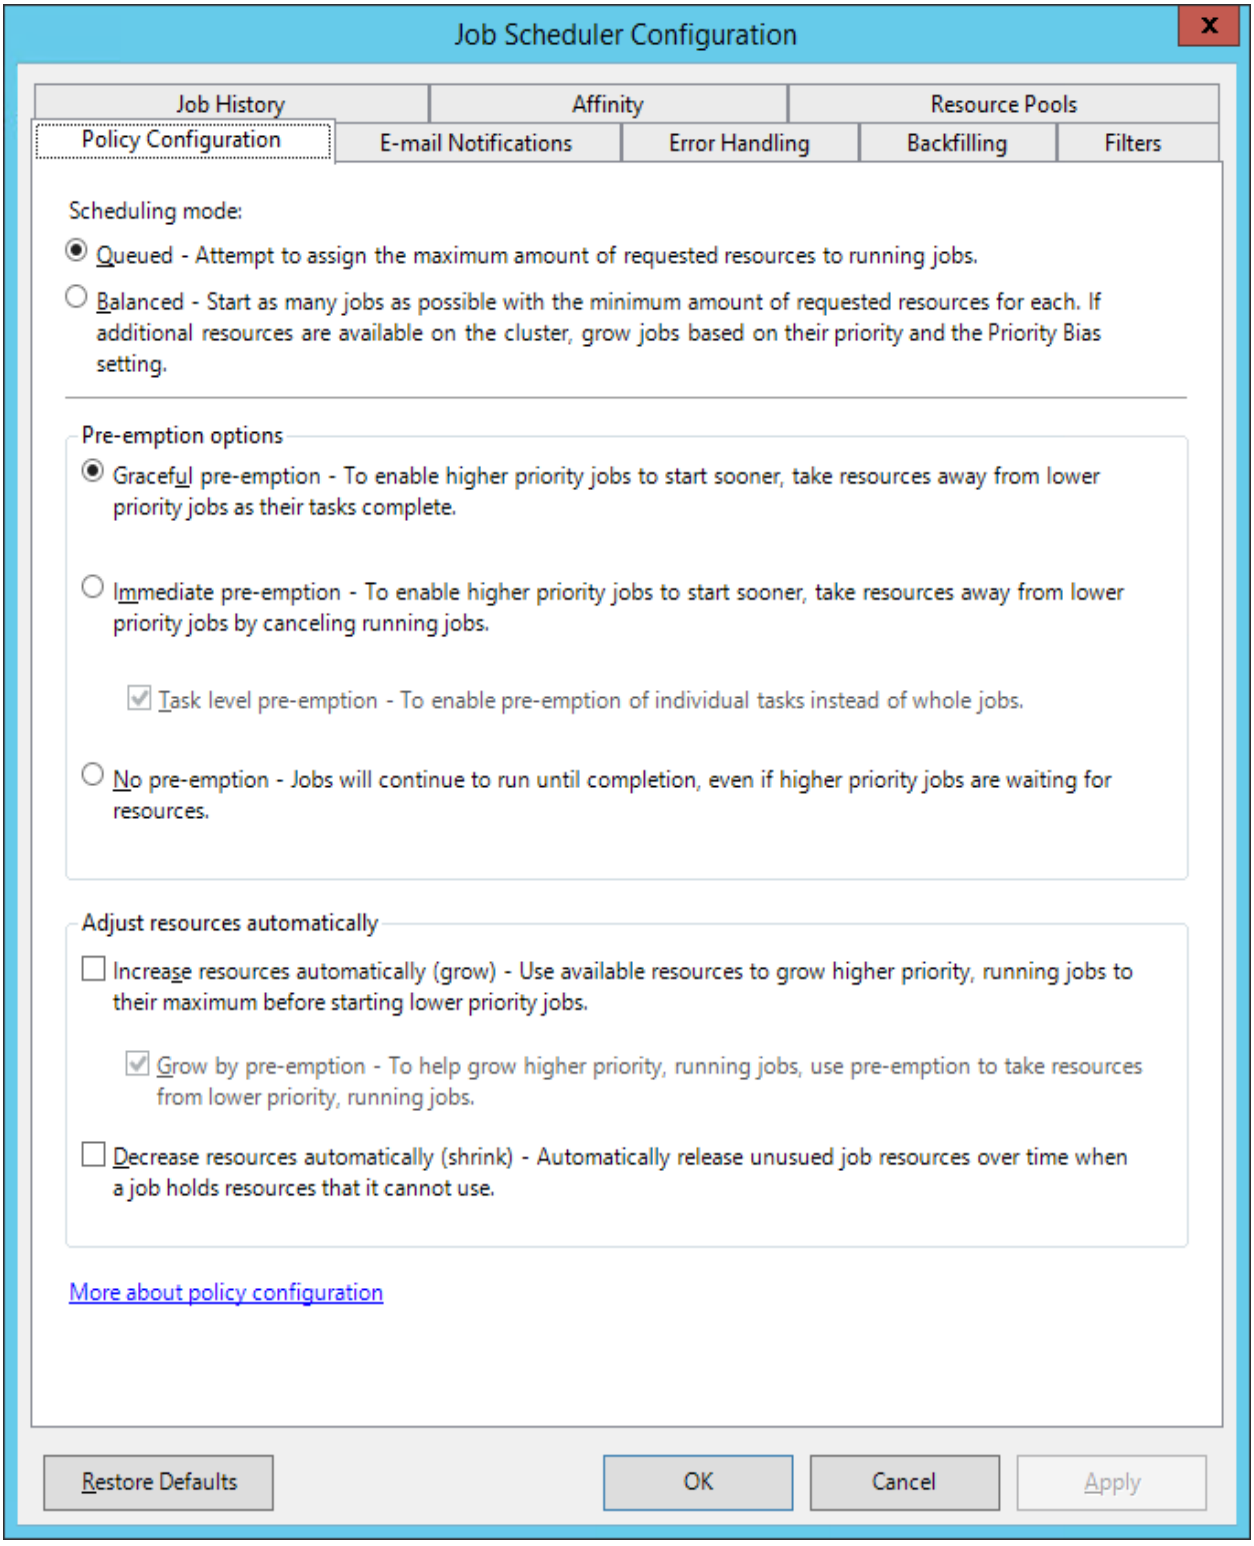
Manage drivers

Add device drivers to the operating system images.

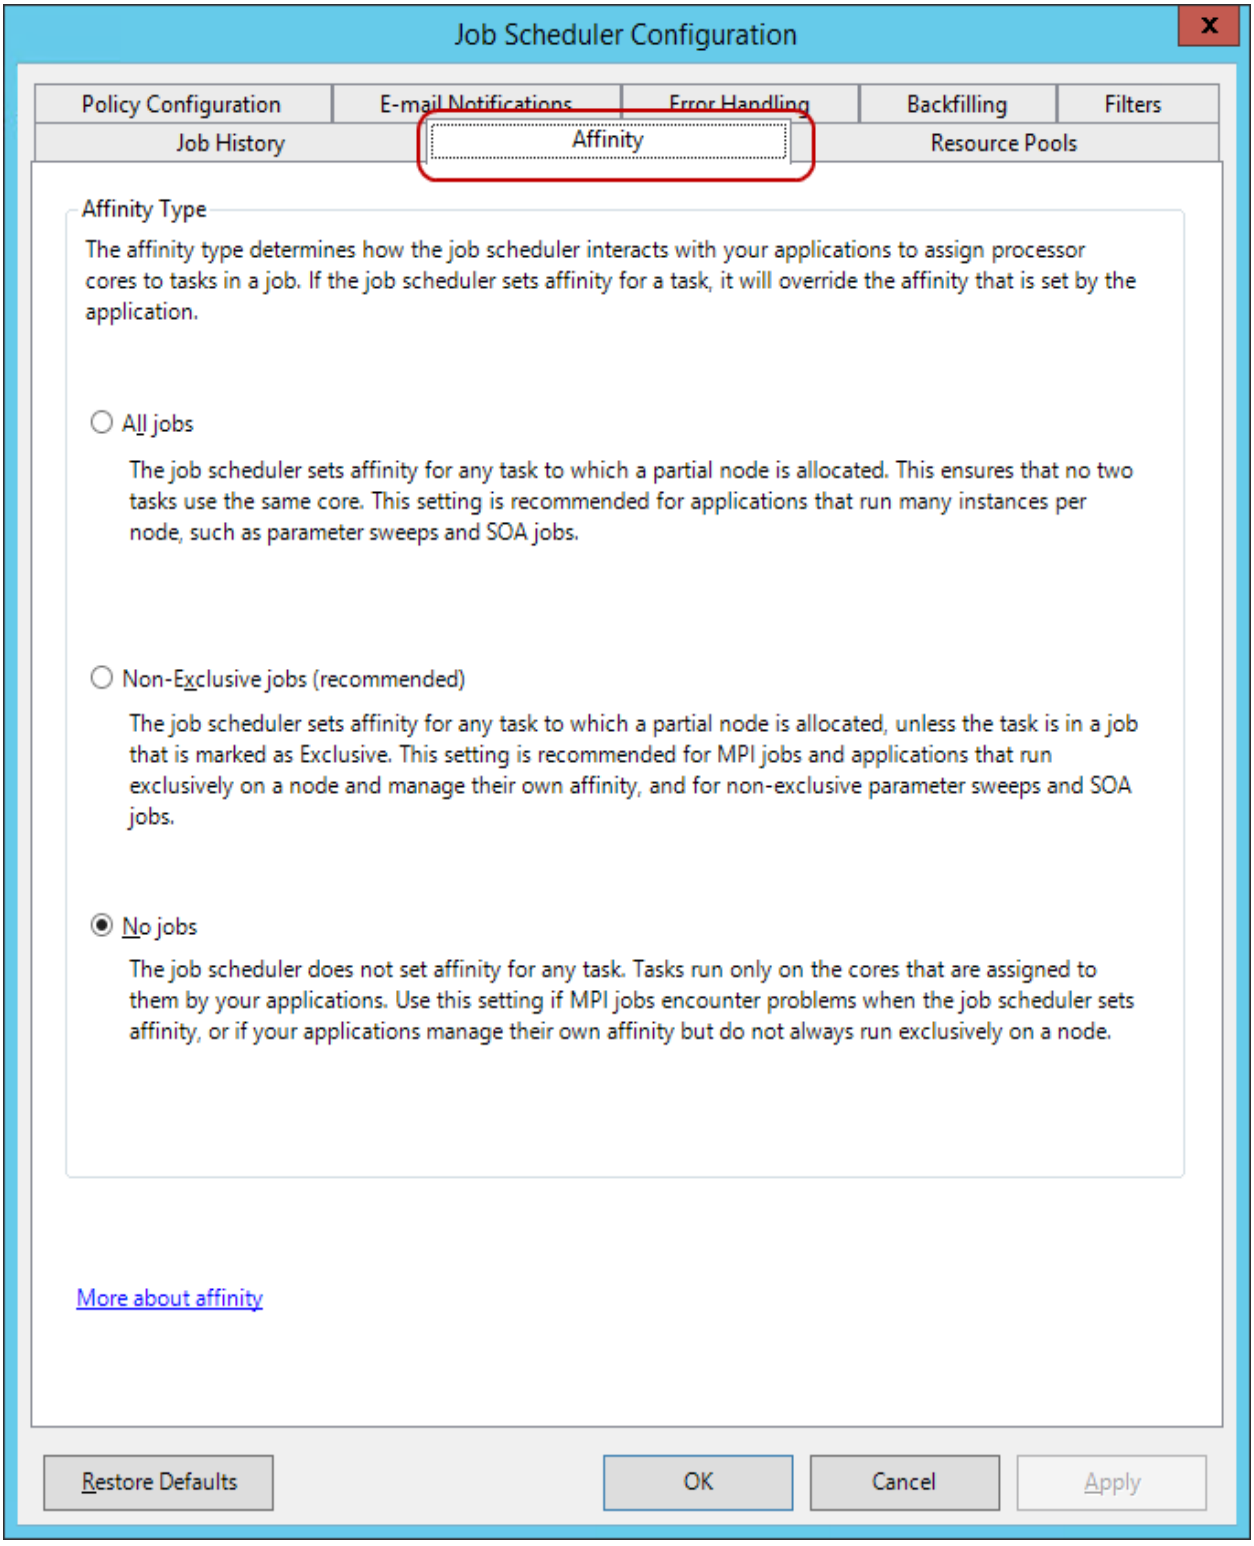
Configure job scheduler policies and settings

Customize policies, error handling, filters, and e-mail notifications for your cluster.

The "Job Scheduler Configuration" dialog pops up, as shown below.



Next, select the "Affinity" tab should be selected.



The cluster administrator may now select a radio button to select the desired Affinity Type:

- All jobs
- Non-Exclusive jobs
- No jobs

In order to submit non-exclusive jobs, the "No jobs" option should be selected. The "Non-Exclusive jobs" option may be selected, but this will not allow non-exclusive Ansys Electromagnetics jobs to be submitted to the cluster. The "All jobs" option is not supported for Ansys Electromagnetics jobs. The OK or Apply buttons may be used to apply the selected option to the cluster.

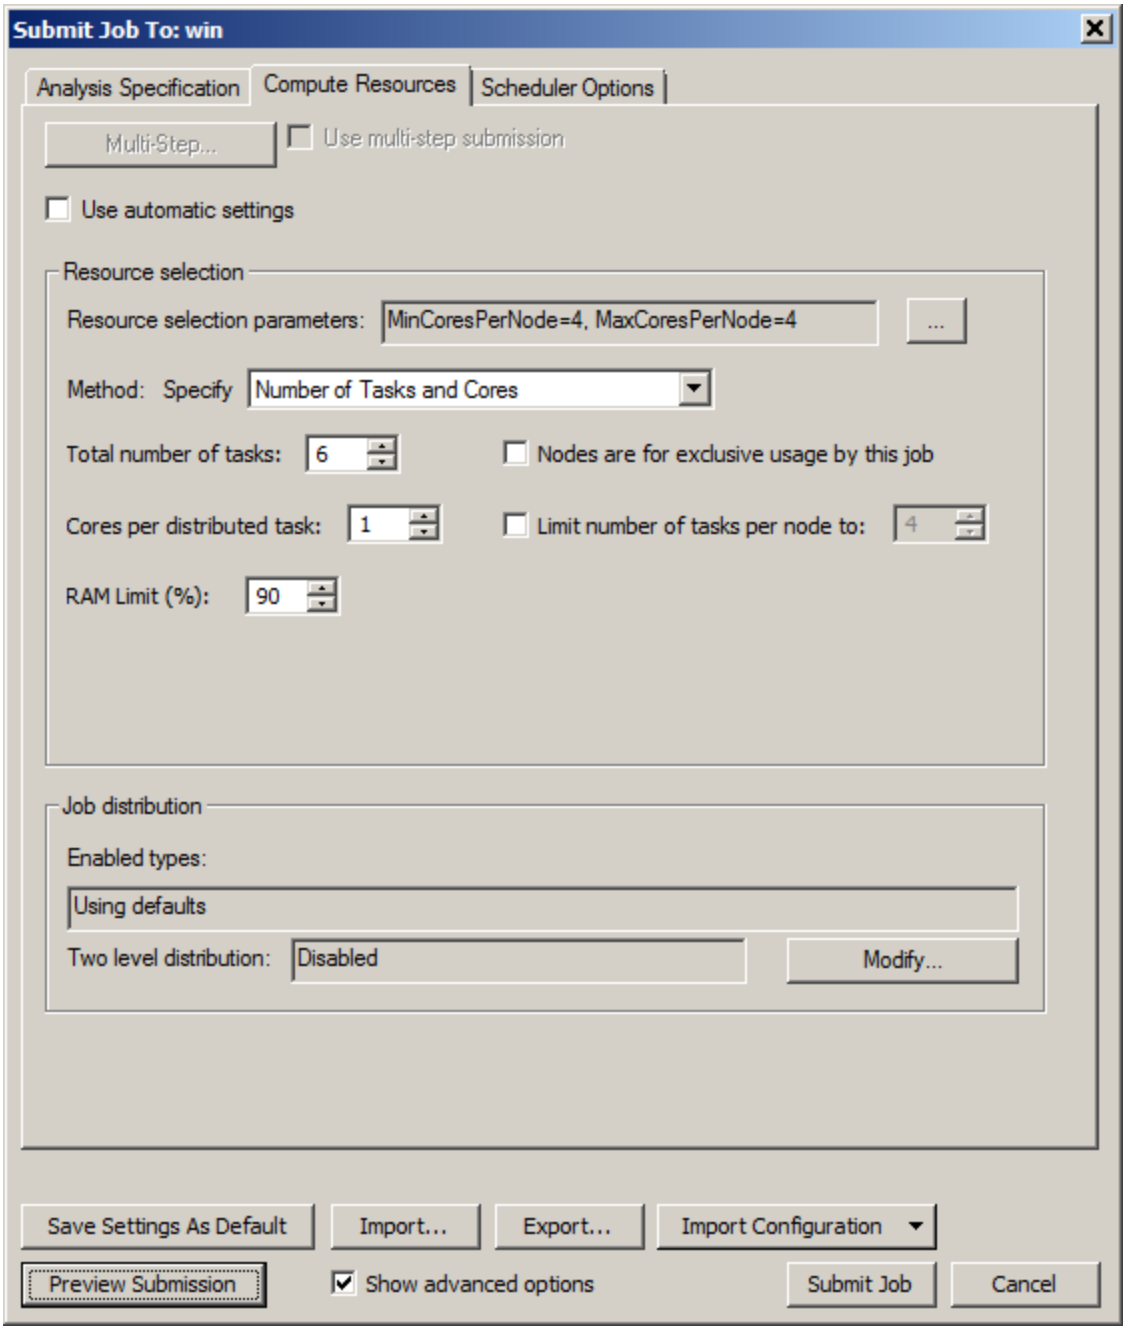
Examples with "Submissions with Nodes are for exclusive usage by this job" Unchecked and Checked

Most of the following screen shots are for the same project file submitted to a Windows HPC cluster with the AffinityType set to "No Jobs". The scheduler resource selection parameters are the same for all of these screen shots:

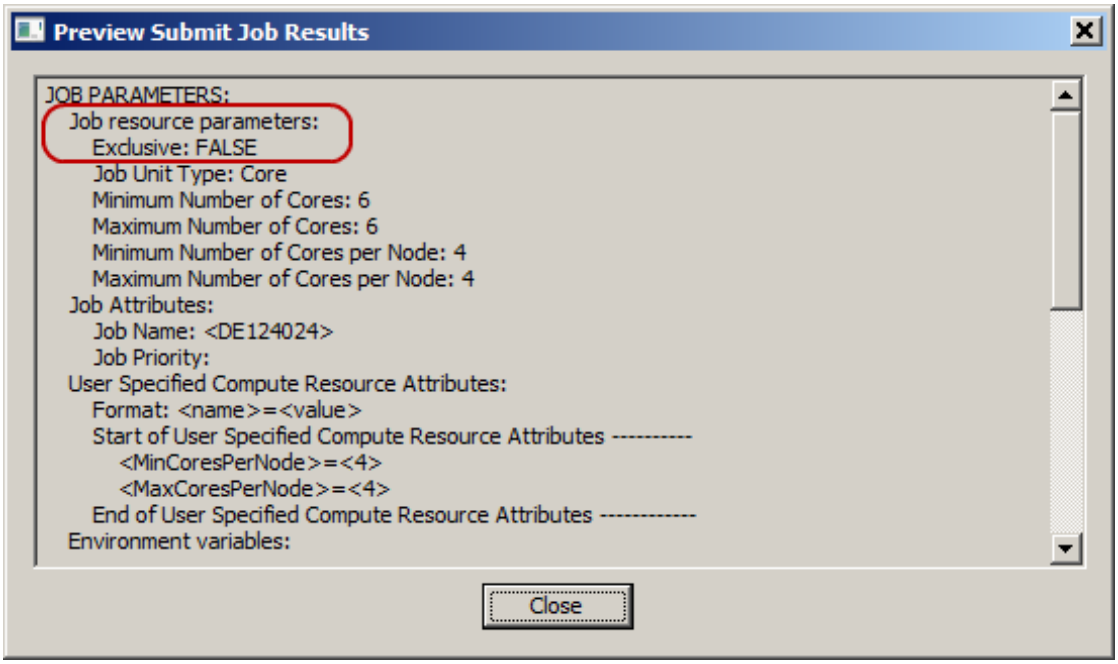
- MinCoresPerNode=4
- MaxCoresPerNode=4

The first set of screen shots show submission of a job to a Windows HPC cluster in which the "Use automatic settings" checkbox is not checked, and the resource selection method is "Specify Number of Tasks and Cores". The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" checkbox. In previous releases, this checkbox was always disabled and checked for Windows HPC jobs. Now, it is enabled, and the user may select whether it is checked or unchecked. If it is checked, then the behavior is the same as previous releases. If it is unchecked, then the job is submitted with the exclusive parameter for the job set to false.

The following screen shot shows this configuration with a Submit Job with Task and Cores specified and nodes as non-exclusive



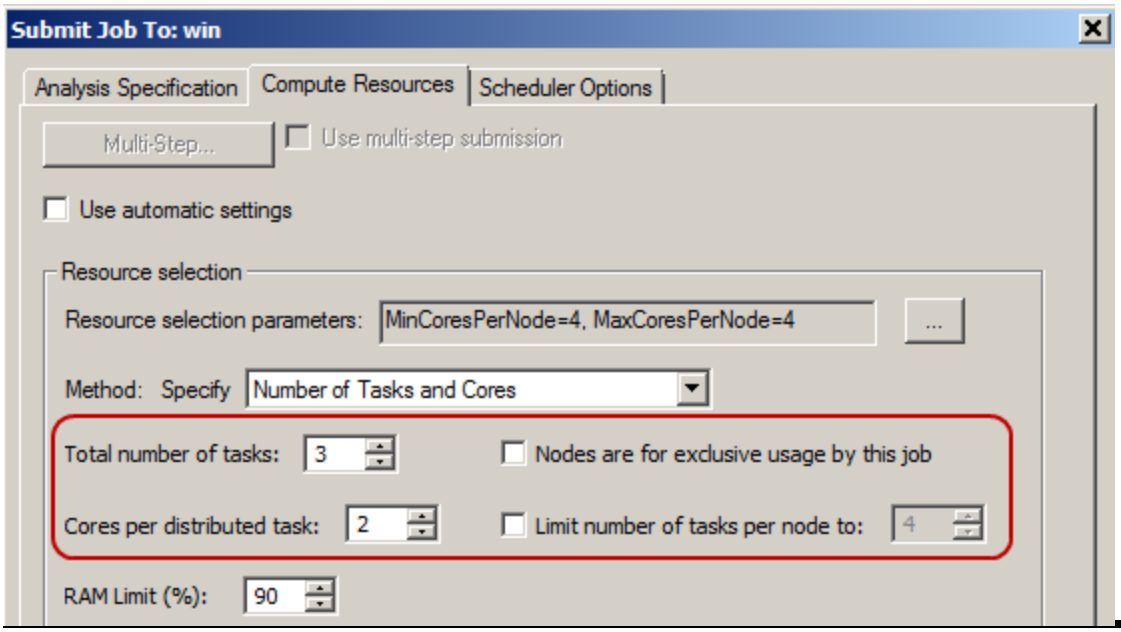
The next figure shows Preview for the job submission indicating that the exclusive parameter for the job is false.



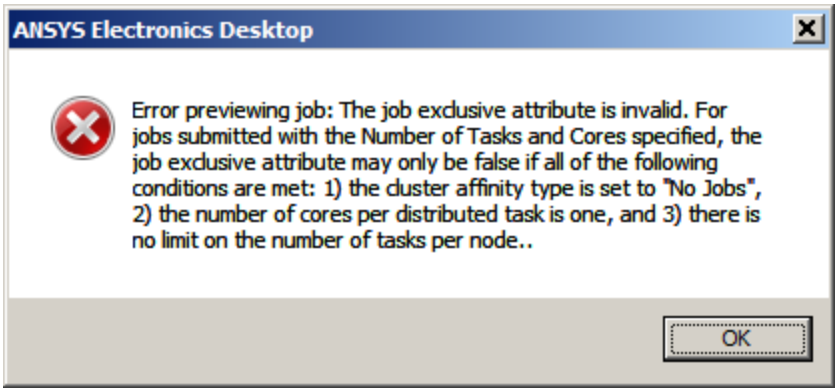
Jobs may only be submitted using this resource selection method with the exclusive parameter set to false if all three of the following conditions are met:

1. The cluster AffinityType is "No Jobs",
2. There is no multiprocessing (i.e., the number of cores per task is one), and
3. There is no limit on the number of tasks per node.

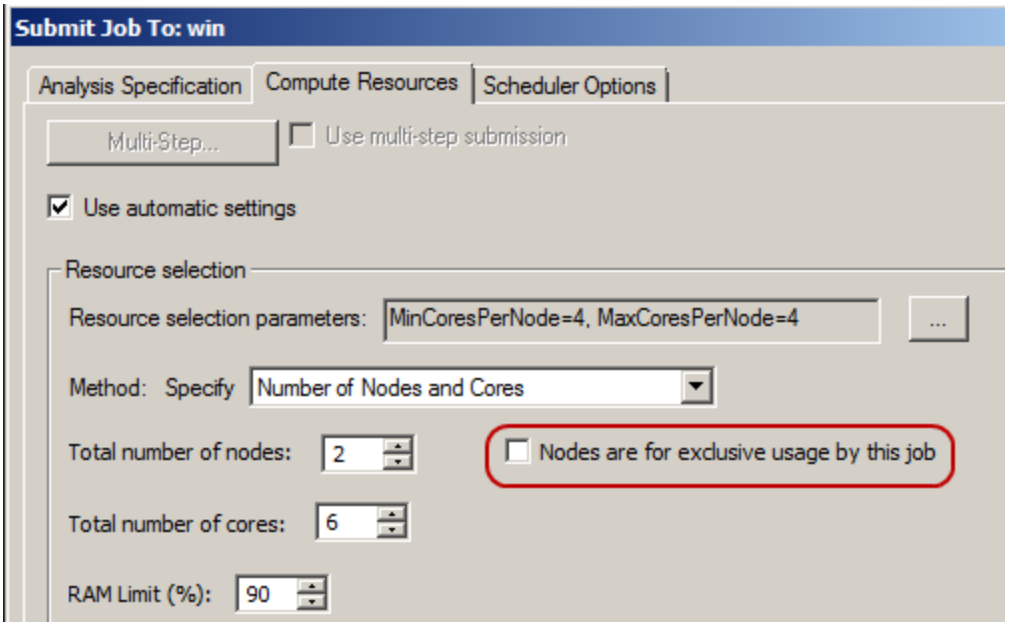
If any of these requirements are not met, then the job is not submitted or previewed, and an error message appears. The following figure shows this configuration.



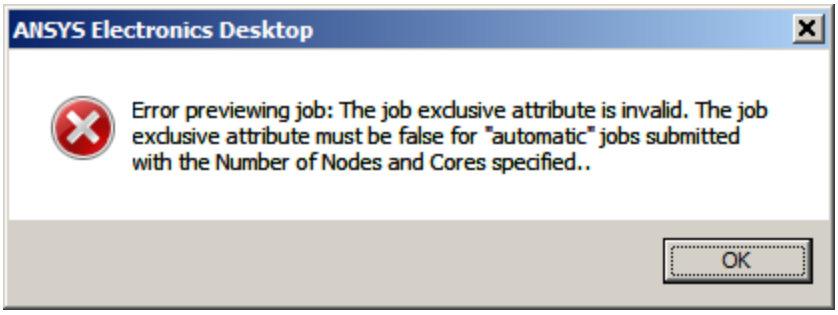
The following figure and screen shot ErrorMsgTasksAndCoresNonExMP.png shows the error message box shown to the user.



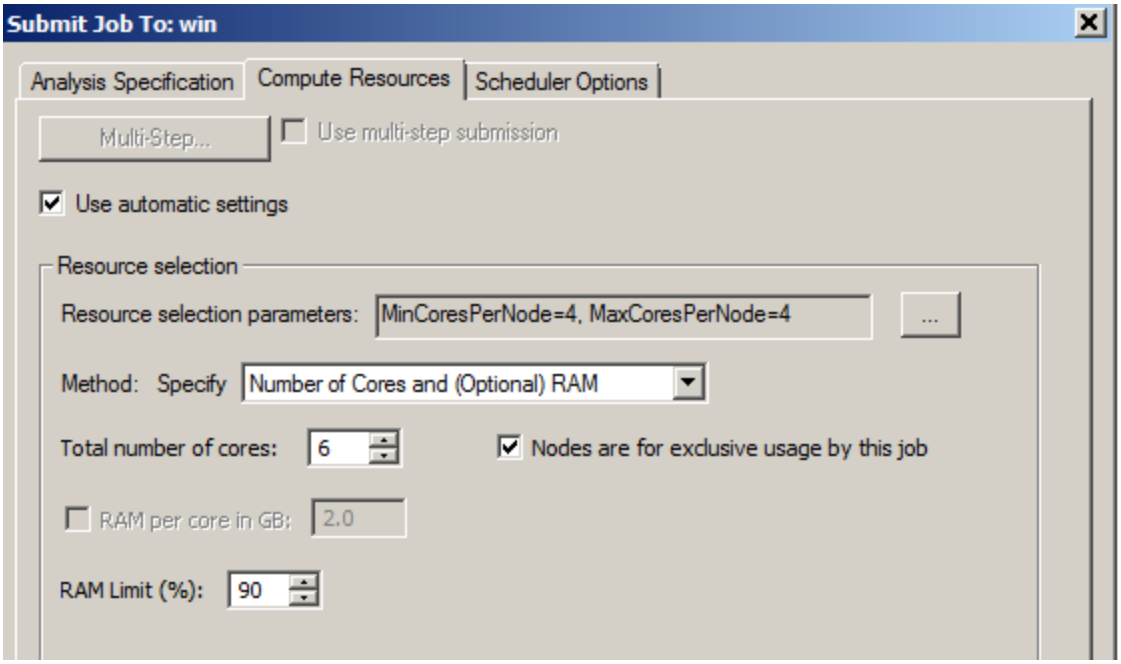
The next example shows submission of a job to a Windows HPC cluster in which the "Use automatic settings" checkbox is checked, and the resource selection method is "Specify Number of Nodes and Cores". The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" checkbox. In previous releases, this checkbox was always disabled and checked for Windows HPC jobs. Now, it is enabled, and the user may select whether it is checked or unchecked. If it is checked, then the behavior is the same as previous releases. If it is unchecked, then the job is not submitted or previewed because only exclusive jobs are allowed when using this resource selection method, and an error message box is shown to the user in this case. The following figure shows this configuration:



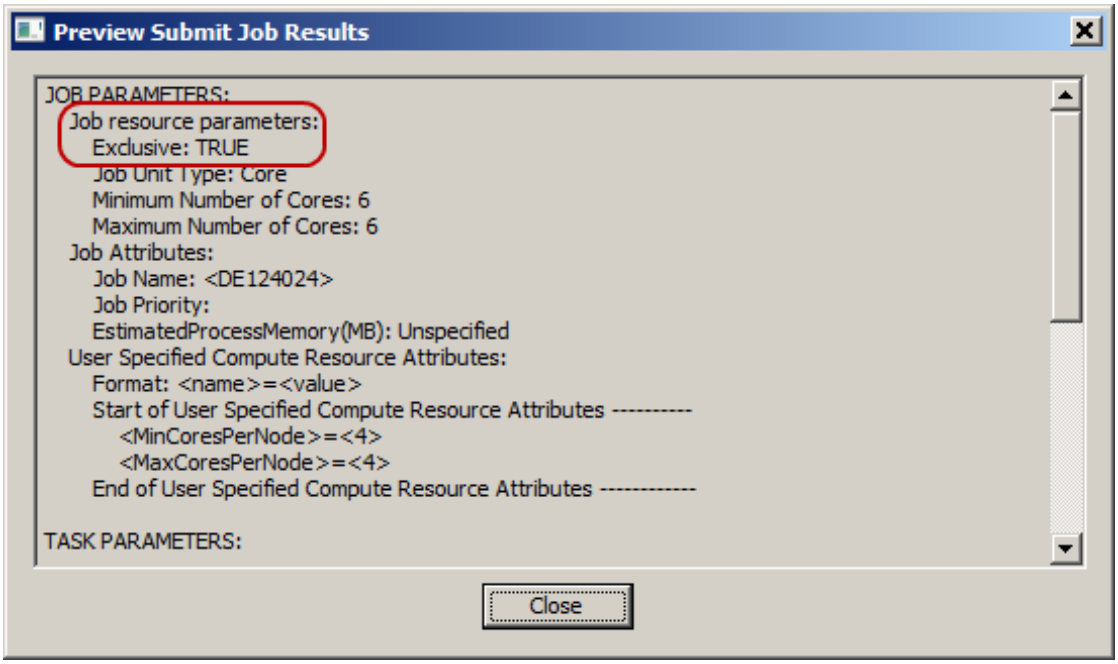
The following figure shows the error message.



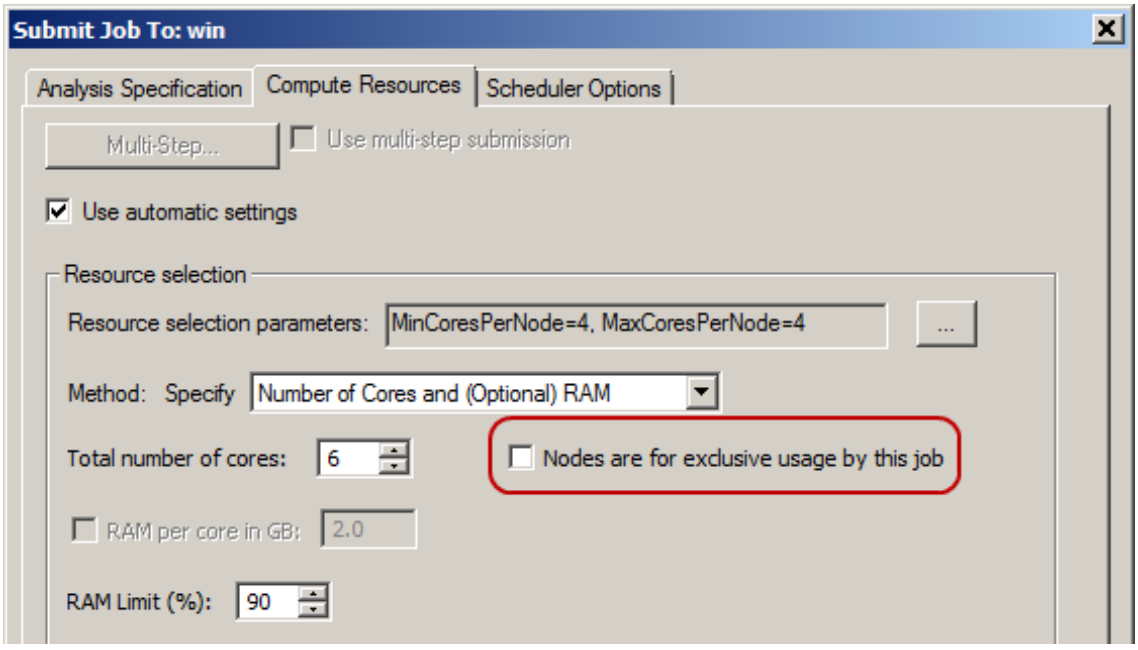
The next example show submission of a job to a Windows HPC cluster in which the "Use automatic settings" checkbox is checked, and the resource selection method is "Specify Number of Cores and (Optional) RAM". The exclusive setting for the job is controlled by the "Nodes are for exclusive usage by this job" checkbox. In previous releases, this checkbox was always disabled and checked for Windows HPC jobs. Now, it is enabled, and you may select whether it is checked or unchecked. If it is checked, then the behavior is the same as previous releases. The following figure shows this configuration.



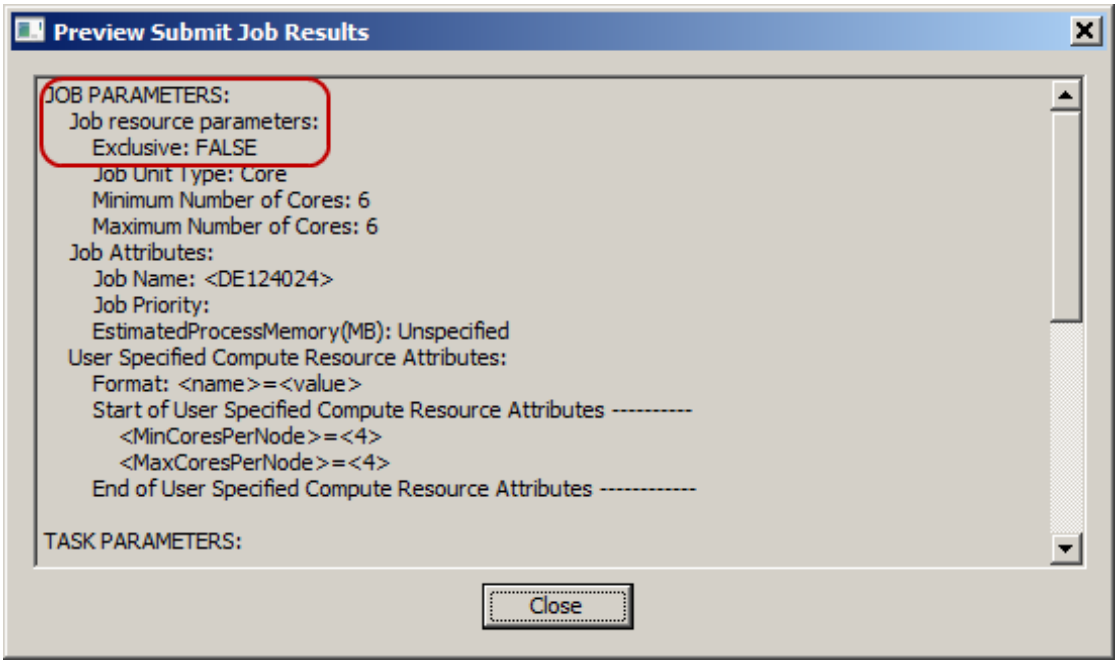
The following figure shows the Job Preview for this case, indicating that the exclusive parameter for the job is true.



If the exclusive checkbox is unchecked, then the job is submitted with the exclusive parameter set to false. The following figure shows this configuration.

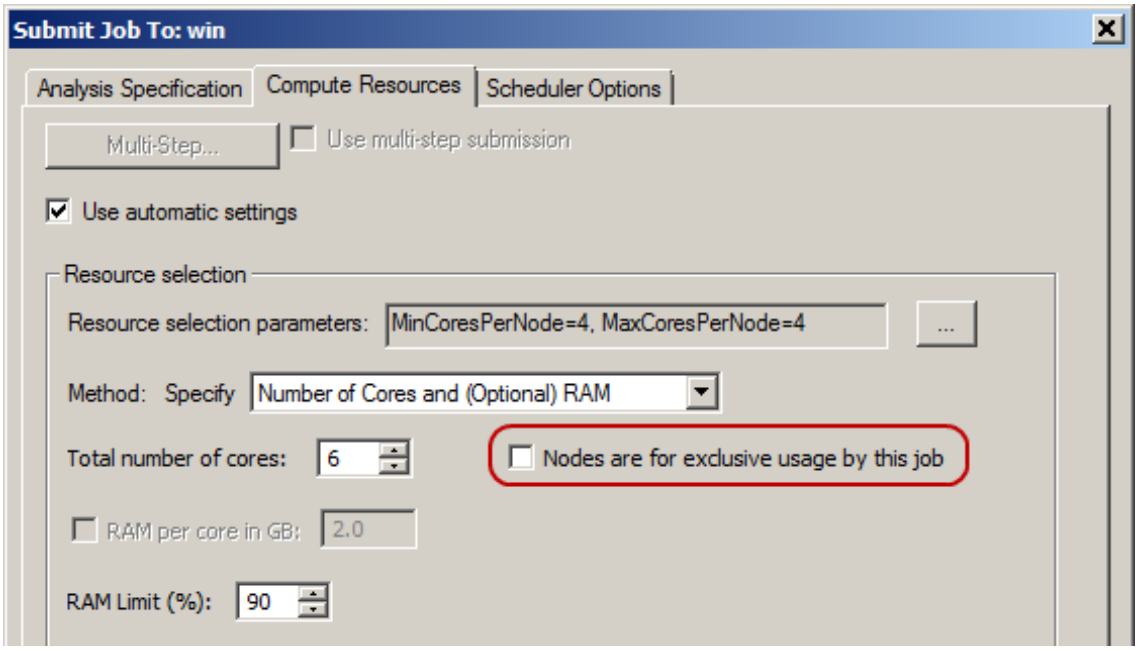


The following figurescreen shot PreviewCoresAndRAMNonEx.png shows the Job Preview for this case, indicating that the exclusive parameter for the job is false.



The last example resembles the previous one, except that the Windows HPC cluster AffinityType is set to "Non Exclusive Jobs" in this case. The job is submitted with the "Use automatic settings" checkbox in the checked state, and the resource selection method set to "Specify Number of Cores and (Optional) RAM". Because the AffinityType is not "No Jobs", only exclusive jobs may be submitted to this cluster. If the exclusive checkbox is not checked, then the job is not submitted or previewed, and an error message box is displayed to the user. The following figure shows this

configuration.



The following figure shows the error message.

High Performance Computing (HPC) Integration

Windows® HPC Job Credentials

Normally, a user will be prompted for the credentials used to submit a job. One way to simplify this process is to use the "cluscfg setcreds" command to set the user's credentials in the credentials

cache. If this is done, then no password needs to be supplied for a job submitted for the specified user. Here is a cluscfg command that may be used to set the user credentials in the credentials cache:

```
cluscfg setcreds /password:* /scheduler:cluster_name
/user:domain\user_name
```

Here:

- cluster_name = the name of the cluster (hostname of the head node)
- domain = optional domain name; if omitted, the following \ should also be omitted
- user = user name

When this form of the command is used, the user is prompted for the password and also asked if the password should be remembered (cached).

See the following web page for more information on the cluscfg setcreds command:

http://technet.microsoft.com/en-us/library/cc947669(WS.10).aspx

Windows® HPC Job Credentials

High Performance Computing (HPC) Integration

Integration with Grid Engine (GE)

Before Sun was acquired by Oracle, this job scheduler was an open source product, and it was known as Sun Grid Engine (GE). Since the acquisition, the product has been renamed Oracle Grid Engine (OGE), and new versions are expected to be closed source versions. The Open Grid Scheduler project hosted on SourceForge plans to continue maintaining an open source version. Univa has taken over support of Oracle Grid Engine, and it is now called Univa Grid Engine. Any of the versions may also be called **Grid Engine** (**GE**).

The Grid Engine scheduler is only supported on Linux. With GE, jobs may be submitted in any of the following ways:

- Using GE commands (qsub, etc.) or the GE gui (qmon)
- Using the generic scheduler GUI in local mode
- Using the generic scheduler GUI in service mode

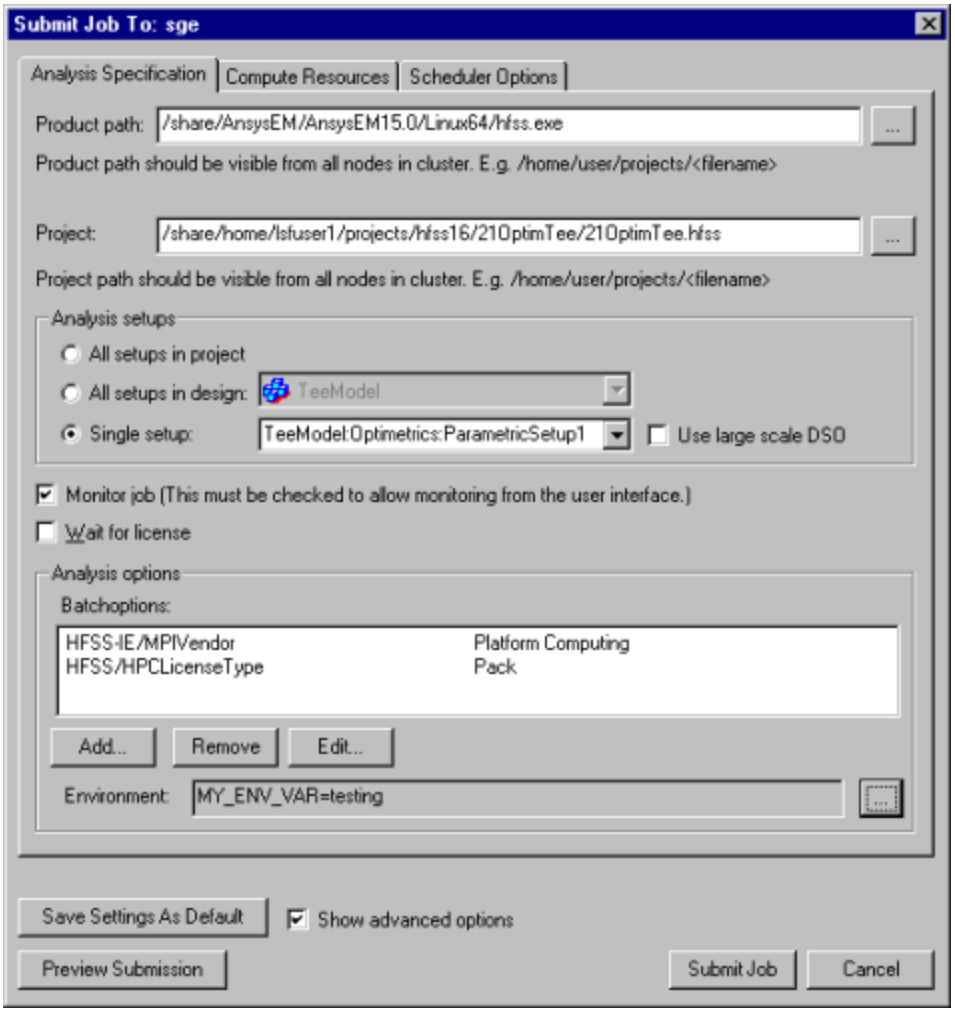
This release has been tested with the following versions of GE:

- SGE (Sun) 6.2u6
- OGS (Oracle) 2011.11
- Univa: 8.1.3

Ansys Electromagnetics products support Grid Engine (GE) for Serial analysis, Multi Processing and Distributed Analysis. Models with parametric sweeps can use Large Scale DSO. With GE, the

Ansys Electromagnetics job doesn't require graphics. Ansys Electromagnetics job progress can be monitored through GE(SGE) commands or in the dialog opened through **Tools>Job Management>Monitor Jobs...**.

In addition to the command line interface, you can also use a Job Management user interface to submit jobs.



Related Topics

Job Management User Interface for GE

Command Line Enhancements for Ansys Electromagnetics Desktop Products

Installation of Ansys Electromagnetics Tools on GE

Windows:

Install on every node of cluster

Setup ‘temp directory’ to a path that is same on all nodes. For example, c:\temp

Linux:

Install on a single node, on a shared drive.

Setup ‘temp directory’ to a path that is same on all nodes. For example, /tmp

Ensure that the product is available using the same path on all nodes

Permissions:

All users of the cluster should have read/write permissions to temp directory

All users should have read/execute permissions to installation directory

When a desktop scheduler GUI is run the same node as the job submission node, no other configuration is necessary: installation is sufficient. You select the scheduler through the desktop GUI. You need to ensure that scheduler commands are available in the path before you launch desktop.

Note	There is no need to install RSM unless the you are using the scheduler GUI on a post processing node that is different from the job submission node. In this case, RSM must be configured with the scheduler type and path. A post processing nodes is a node in the cluster that can run the Ansys Electromagnetics desktop in graphical mode. A job submission node is a node in the cluster in which job submission commands are available.

Turn OFF firewall between cluster nodes.

Scenario 1: The post-processing node and job-submission node roles are served by distinct machines.

In this case, perform the following configuration:

The job-submission node should be configured to run the RSM service, which serves as a proxy to scheduler. The RSM Service should be running as 'root' in order to facilitate jobs running using the credentials of the job's owner. A **configuration file in the RSM installation folder should be edited** to specify information regarding the scheduler that manages jobs on this cluster. A block labeled 'Scheduler' must be included within the 'AnsoftCOMDaemon' block. This block contains two string entries:

- SchedulerName: this contains the unique part of the scheduler proxy library name
- ConfigString: this contains a scheduler specific configuration string

The case of the SchedulerName string is significant on Linux because Linux file names are case sensitive. The case of the SchedulerName string is not significant on Microsoft Windows. In Ansys Electromagnetics Suite, the possible scheduler names are: lsf and sge. The ConfigString entry is a scheduler specific configuration string, described below.

In addition, the AnsoftRSMService must be started with appropriate environment variables set. Generally, the environment variables must be set the same as they would be set for using the scheduler via command lines.

SGE Details

For SGE, the ConfigString entry must contain the search path for the SGE commands. It may contain a single directory, the directory containing the SGE commands. Alternatively, it may be a

path, with directories separated by the colon character ":", where the SGE command directory appears before any other directory containing files with the same name as any SGE commands.

Example ansoftrsmservice.cfg configuration file:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='sge'
'ConfigString'='/opt/sge6.2u4/bin/lx24-amd64'
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Scenario 2: The post-processing node and job-submission node roles are served by the same machine.

The **Select Scheduler...** command (as described in the Job Management User Interface for SGE section) is used to gather details about the scheduler. In this case, the Desktop process should be started in an environment suitable for submitting jobs to the scheduler.

The environment should be configured so that all SGE commands are found using the standard search path. In particular, search for the following commands in the search path should result in the SGE command being found: "qsub", "qdel", "qstat", and "qconf". No other command with the same name should appear before the SGE command in the search path.

Related Topic

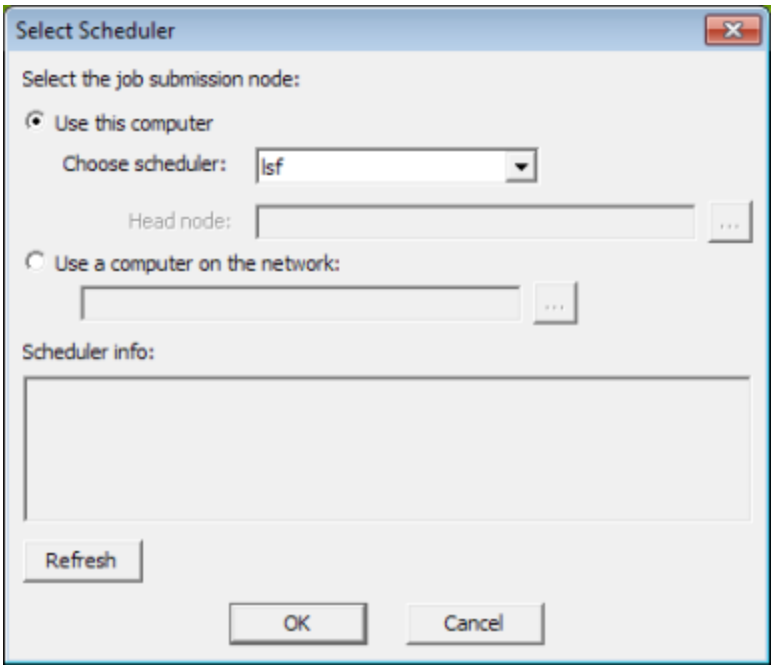
Job Management User Interface for GE

Command Line Enhancements for Ansys Electromagnetics Desktop Products

Job Management User Interface for SGE

The Job Management UI is accessed by running Ansys Electromagnetics product Desktop on the designated 'Postprocessing node' of the cluster. The Desktop provides UI commands for Scheduler selection, Job submission and Job monitoring/control. You access the Scheduler User Interface by clicking **Tools>Job Management>Select Scheduler.**

Before you can use **Submit Job**, you must click **Select Scheduler** as the one-time initial step. This opens the **Select Scheduler** dialog.



Specify the following parameters:

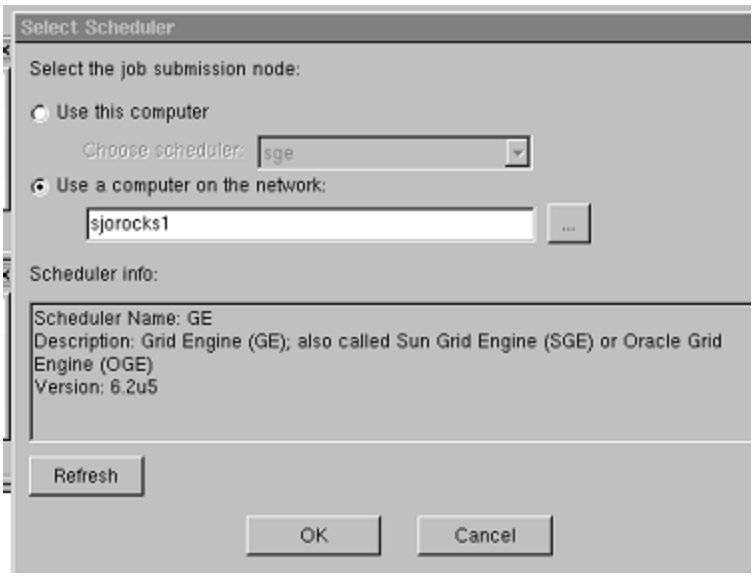
- Job submission node: this is the node on the cluster where scheduler commands (such as SGE's qsub) are allowed to run.

  Choose **Use this computer** if scheduler commands are enabled on the post-processing node.

  Choose **Use a computer on network** if the cluster is configured in a manner as to disallow job-submission from the post-processing node. Specify node name appropriately.

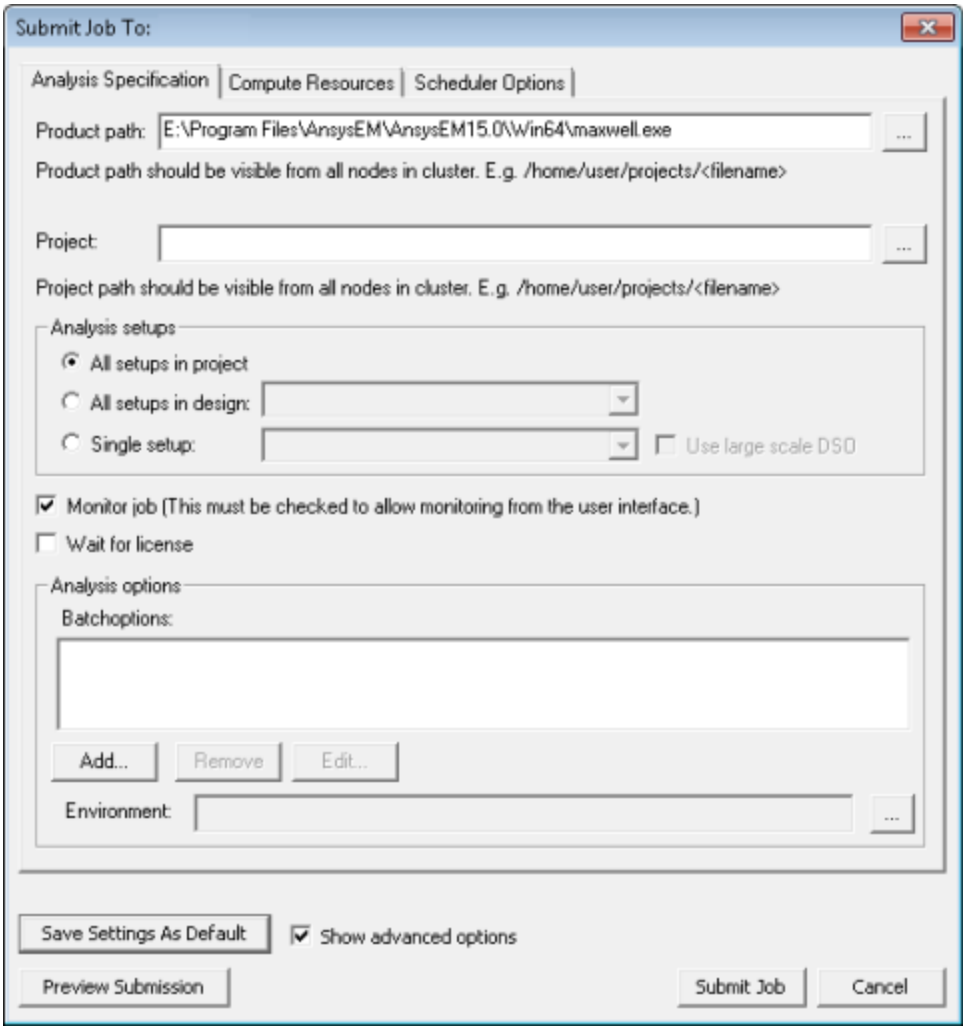
  Pre-requisites: For this choice to work, the job-submission node must already be configured with a running RSM service, as documented in Installation of Ansys Electromagnetics Tools on GE.
- Scheduler: Available choices, depending on your installations, are: RSM, lsf, Windows HPC, and SGE. It is also possible for you to integrate a custom scheduler into this UI, through a scheduler proxy. When this is done, more choices will be available in the combo-box, one per custom scheduler proxy that is deployed in the installation.

After specifying the job submission node, you can click **Refresh**. The scheduler information is then listed in the Scheduler info text field.



Once you select a scheduler, you can access the interface for job submission, monitoring and control. Click OK to close the dialog.

You access the Job submission UI by clicking **Tools>Job Management>Other Schedulers>Submit Job...**. This command launches a multi-tab Submit Job To: dialog similar to the one shown below.



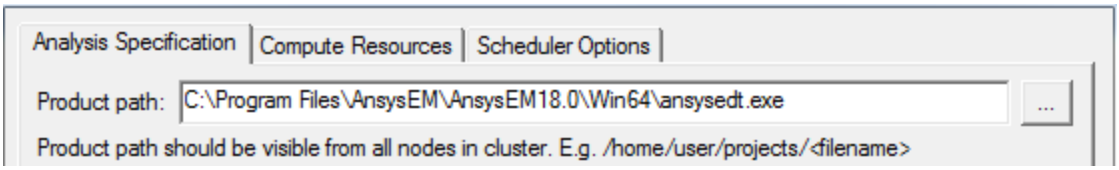
- **Analysis Specification--**specify the Product path, Project name, the setups, and analysis options such as batchoptions, or, for advanced users, Environment variables. If you select the Analysis or Optimetrics setup, the Analysis Specification is pre-populated.
- The **Compute Resources** tab specifies whether to use automatic settings (if available for the design type), and how to select specific resources from the available pool (for example, ParallelEnvironment is an SGE parameter).
- The **Scheduler Options** tab has analysis-independent parameters specific to the job, such as name, priority.

Analysis Specification tab for GE

This tab lets you specify the following:

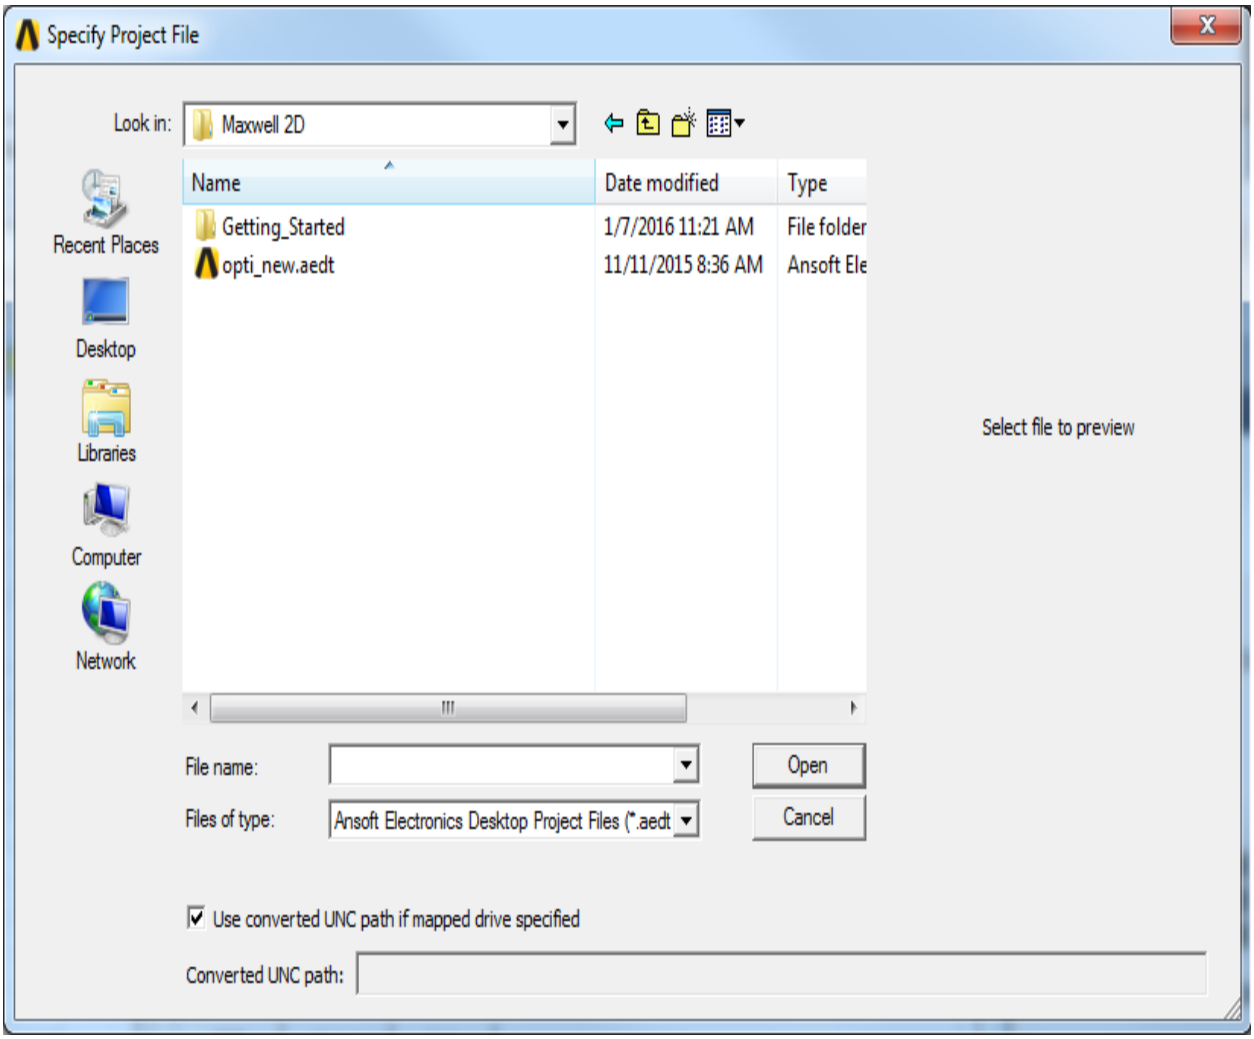
Product Path:

You can specify the product path.



Project:

You can use the ellipsis button [...] to use a navigation window to browse. The path should be visible to all nodes in the cluster. The Project can be an archive.

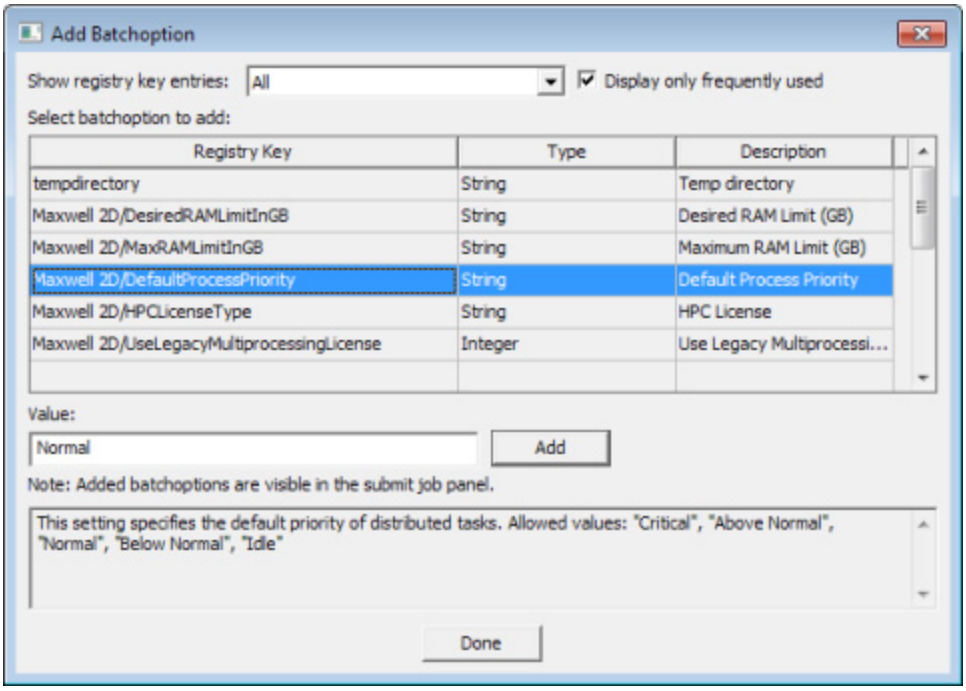


Analysis Setups:

Specify All setups in the project, all in a design, or a single setup. If the setup includes a parametric sweep, the **Use large scale DSO** check box is enabled.

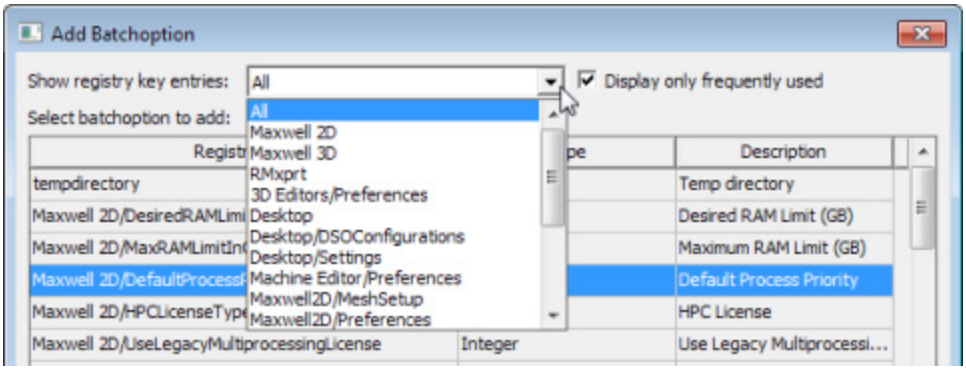
Analysis Options:

- You have check boxes for whether to Monitor Job through the GUI, and whether to Wait for license.
- You can also specify Batchoptions. Click the **Add...** button to open a dialog for selecting the Batchoptions.



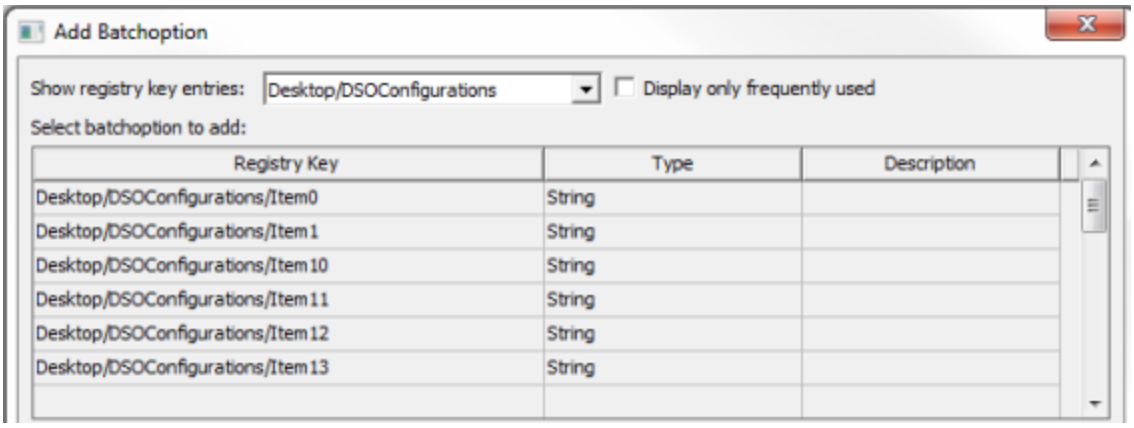
The lower Value field shows the legal values for the selected registry key. You can type the desired value into the upper text field under value. Click the **Add** button to accept the selection of the registry key with the specified value. Click **Done** close the **Add Batchoption** dialog.

At the upper left, a drop down menu lets you specify which registry key categories to display, whether All, or selected category.

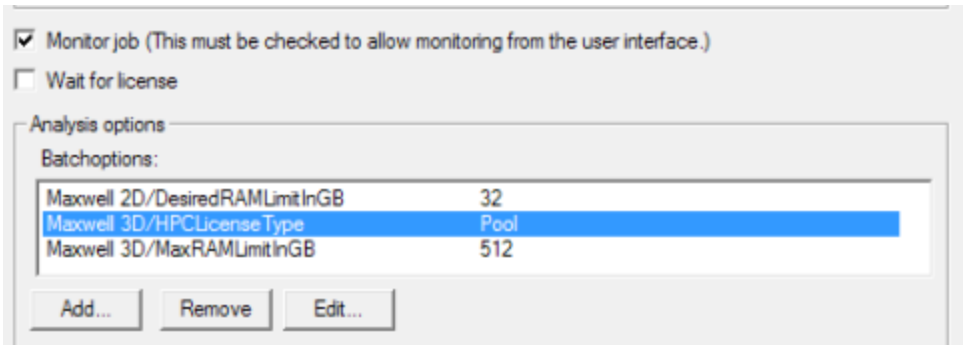


A check box lets you choose between displaying only frequently used entries (the default), or by unchecking, all options available for the selected group.

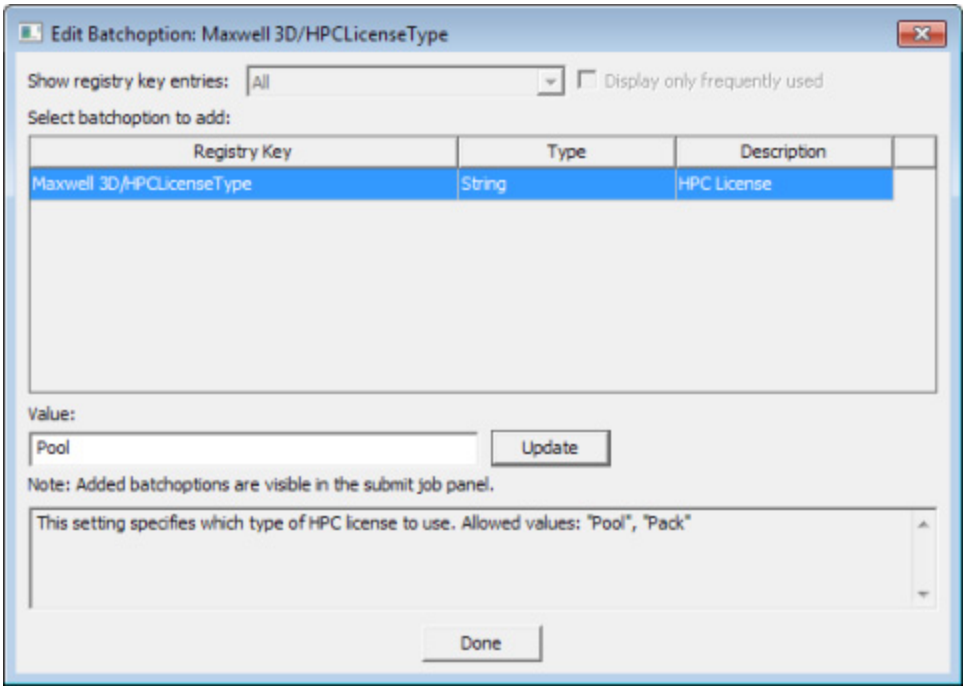
Note that for Large Scale DSO problems, you also have the option to specify predefined configurations.



The added registry keys and values are listed in the Batchoptions field of the **Submit Job** dialog.



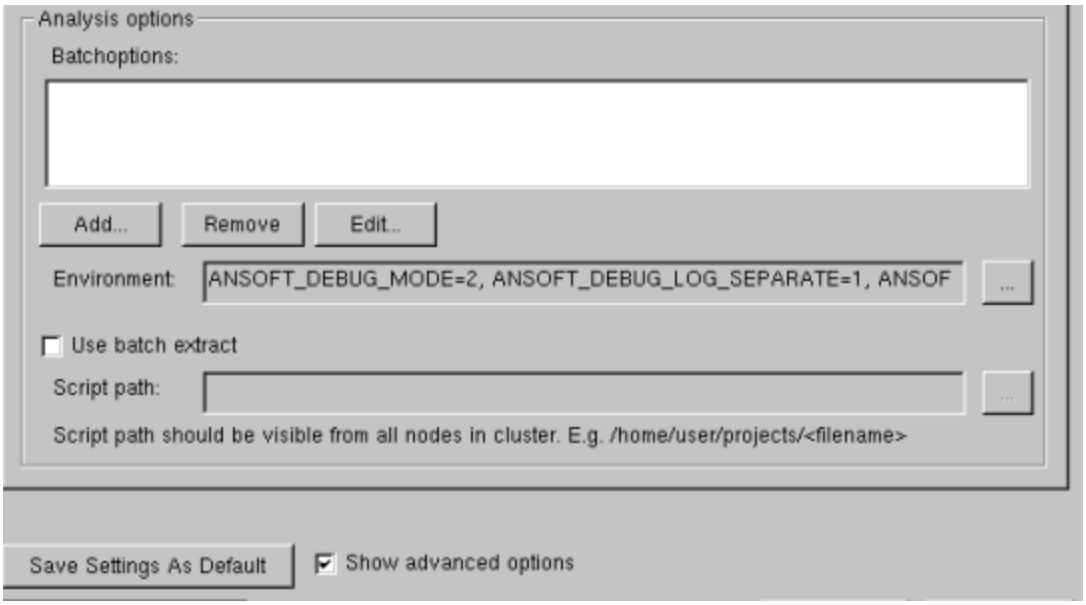
Selecting from the list enables buttons for removing or editing registry key values. Selecting a registry key and clicking **Edit...** opens the **Edit Batchoptions** dialog.



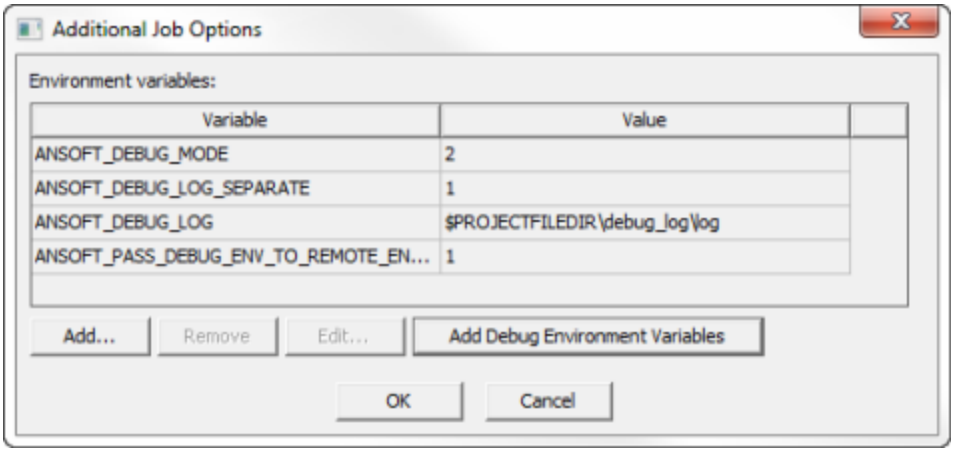
Here you can edit the Value field and update the value for the selected registry key.

Environment:

If you check the **Show advanced options** check box, you can see the Environment field.



This permits specifying Environment Variables. Click the ellipsis button [...] to open the **Additional Job Options** dialog box.

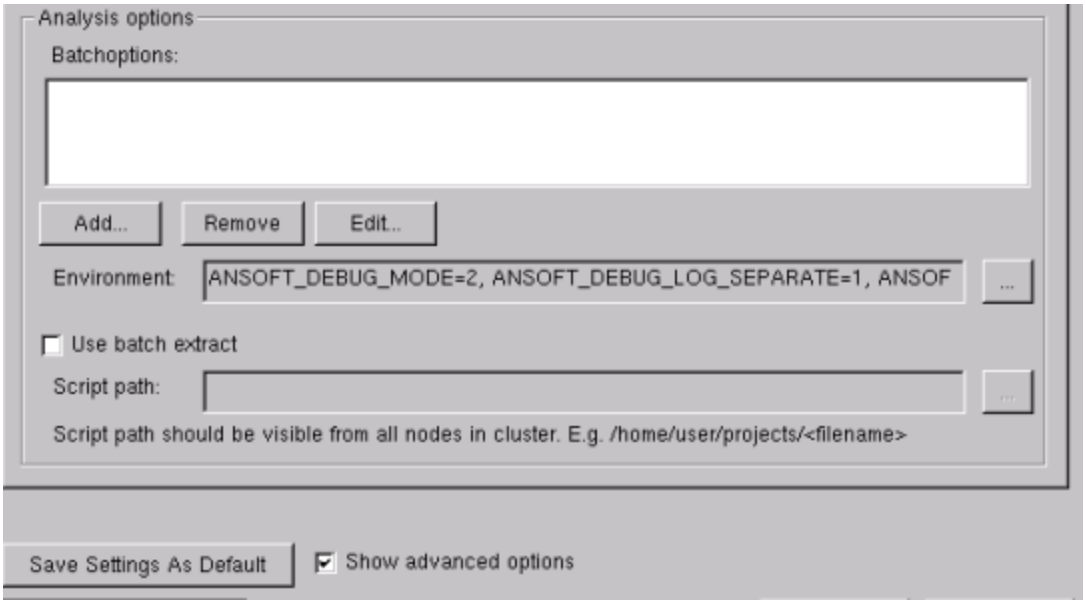


The **Add** button permits you to specify your environment variables. Once, added, you can select **Remove** or **Edit**. The **Add Debug Environment Variables** button adds variables of use in working with support.

- The **Save Settings as Default** button lets you save a current set of values as defaults the next time you invoke the Scheduler GUI. This can simply subsequent job submissions.

Use Batch Extract for Grid Engine

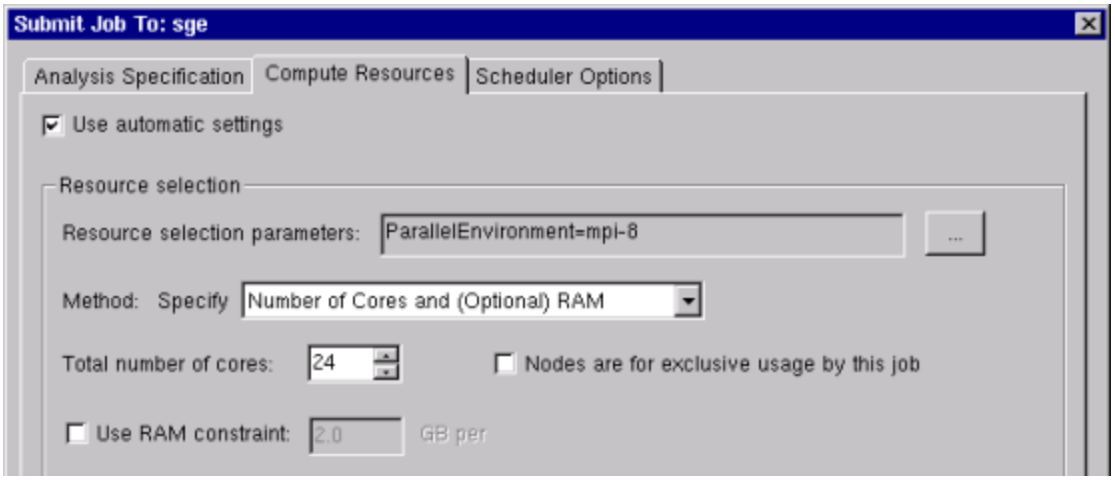
Selecting **Show advanced options** for Grid Engine also show the **Use batch extract** fields.



See the discussion on Running Maxwell from a Command line for a discussion of the solve information available through batch extract.

Compute Resources Specification Tab

This tab lets you provide Resource selection and Job parallelization parameters. Once you have specified parameters, you can Save Settings as Defaults, Preview a Submission, and Submit a job.

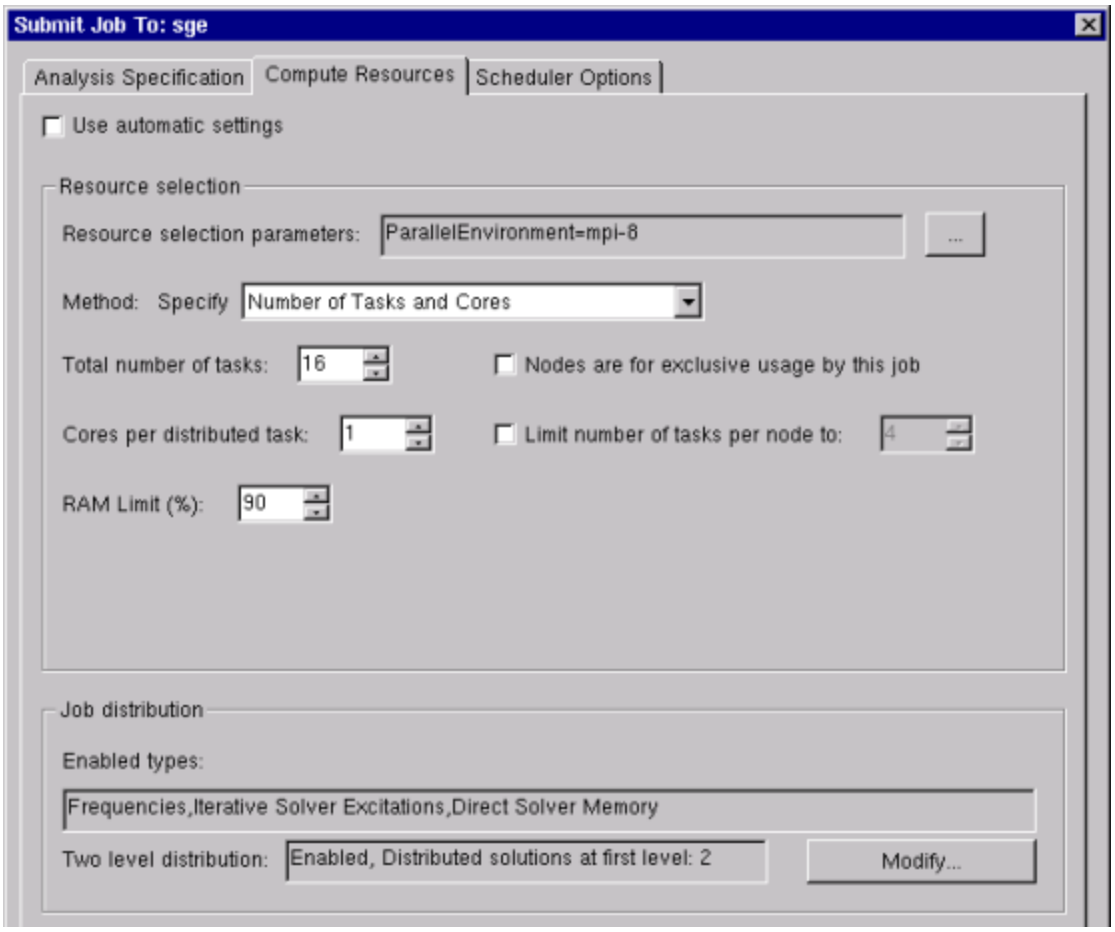


You can also populate this page yourself by specifying Resource selection, Job Parallelization parameters, and Job distribution parameters.

This tab lets you provide Resource selection and Job parallelization parameters. You can elect to **User automatic settings** for job distribution, specify a Method and resource selection parameters, or job distribution parameters.

Note	If you select Use automatic settings, the solver does not support automatic distribution of variations. The Use automatic settings option does not support Optimetrics variations. It does distribute frequencies, domains, and use of multiple level domains.

You can also uncheck **Use automatic settings**. Doing so requires you to also specify Cores per distributed task and enables the Job distribution fields.

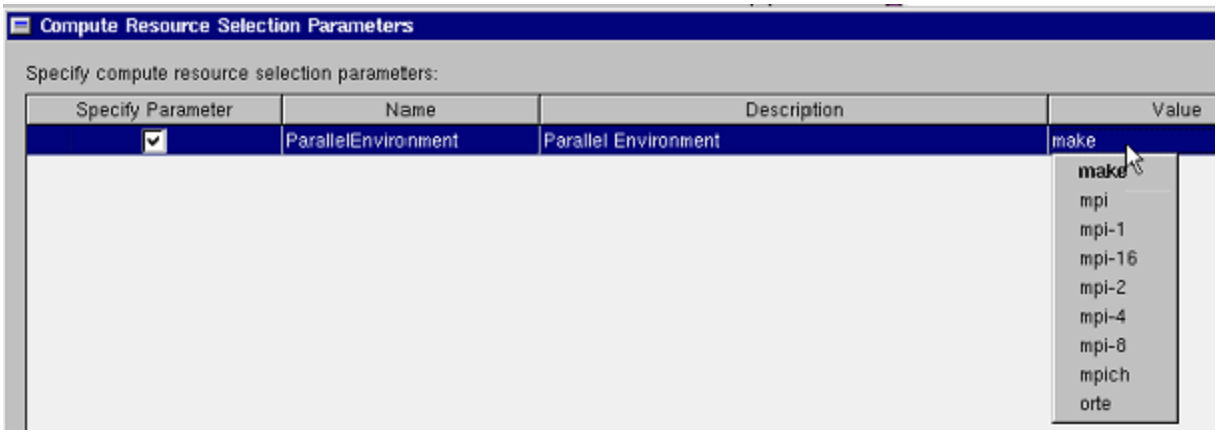


Resource Selection:

If you do not specify parameters for resource selection, SGE may submit jobs to any machine in the entire pool that is available.

- Resource selection parameters.

  Clicking the ellipsis button [...] opens a dialog for parameters specific to SGE, in this case **ParallelEnvironment**. The Specify Parameter check box in the dialog enables a parameter, and you can select the Value for the ParallelEnvironment parameter from a drop down menu.



If you don't specify a parameter, the scheduler handles the situation.

- Specify node list

  Checking Specify node list enables the field for specifying a node list. In a computing environment where the available cores are not uniform, you can use this to have control over which resources your job will use. If your Analysis configuration contains a node list, you can use Populate this Page from Analysis Configuration.

Memory resource behavior is dependent on the Grid Engine version as well as the particular scheduler settings. The output of the "qconf -sc" command shows all of the complexes available to the Grid Engine schedulers. For a complex to be considered valid for memory resource selection, it must be of type "MEMORY", have relop "<=", be request-able (could be "forced" as well, instead of "YES"), and be consumable. At least one valid memory complex must be available to submit jobs using the Automatic Cores and RAM method.

Univa 8.3 introduced a new column to the complexes listing. For Univa 8.3 and later, there is an additional column for whether resources are available to a preempting job after preemption of a running job. It is up to the cluster administrator to determine the appropriate Available After Pre-Emption (aapre) setting for memory complexes. This setting is ignored for memory complex validation.

Determining the correct memory complex by default is error-prone. Because the correct choice of memory complex can vary from cluster to cluster, the memory complex selection is now exposed by default under the compute resource selection parameters, allowing the user to make the selection without having to set an environment variable. Only complexes that have been validated (meeting the requirements specified above) can be selected. The cluster administrator (or someone who has knowledge of the specifics of the cluster in use) should be able to determine the correct memory complex to use for Ansys Electronics jobs. To disable exposure of this selection option, the following environment variable can be set to "0":

ANSOFT_SGE_ENABLE_MEM_RES_ATTRIB

Method

For the Method, use the drop down to select Number of Cores and (Optional RAM) or Number of Nodes and Cores.

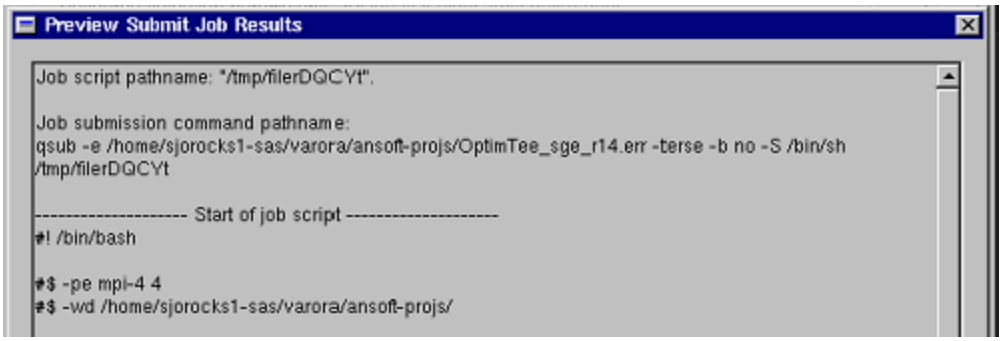
Total Number of Cores

You can specify a Total number of cores, and whether the Nodes are exclusive to the job.

RAM Constraint and RAM Limit

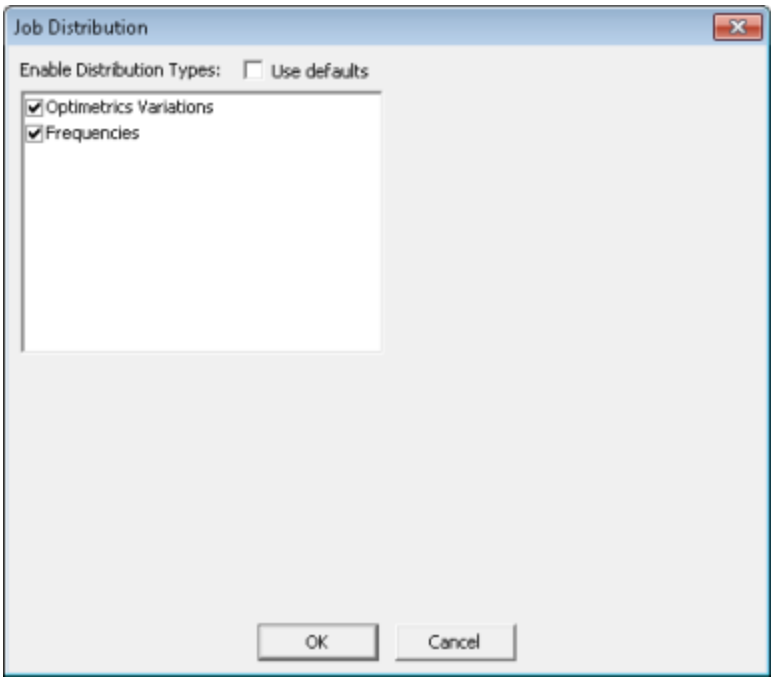
If you check Use RAM Constraint, you can specify a GB RAM constraint. You can also specify a RAM Limit as a percent.

In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.



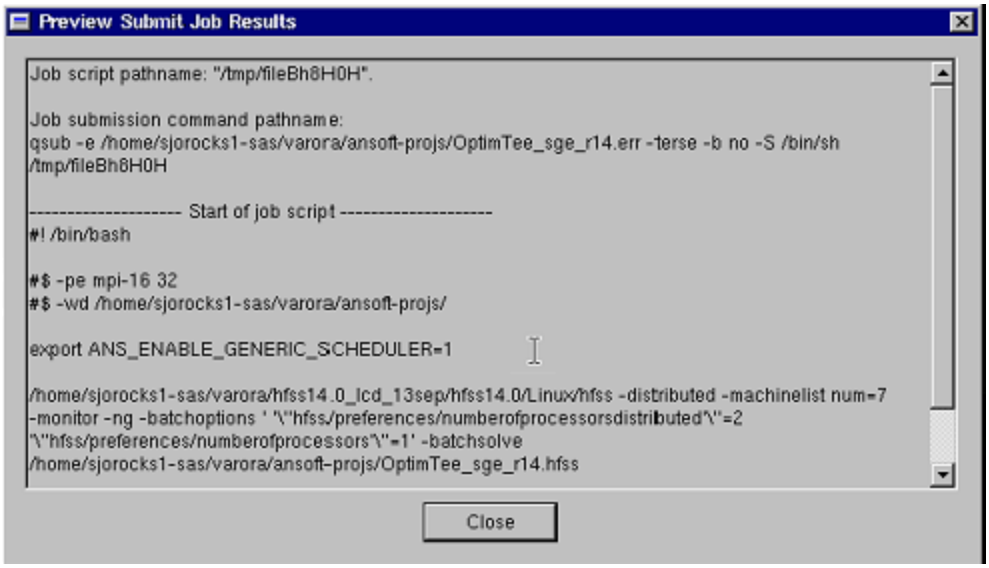
Job Distribution

- Enabled types, such as Optimetrics Variations, Frequencies, etc.

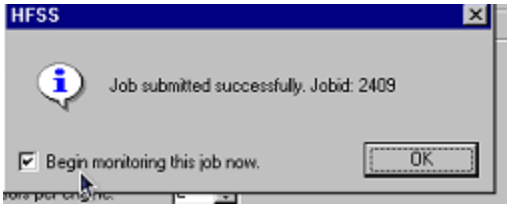


Preview submission

This opens a screen showing the qsub command to be used to submit the job.



Submit job actually sends the batch command to the SGE cluster.A dialog reports a successful submit and presents a check box for monitoring.

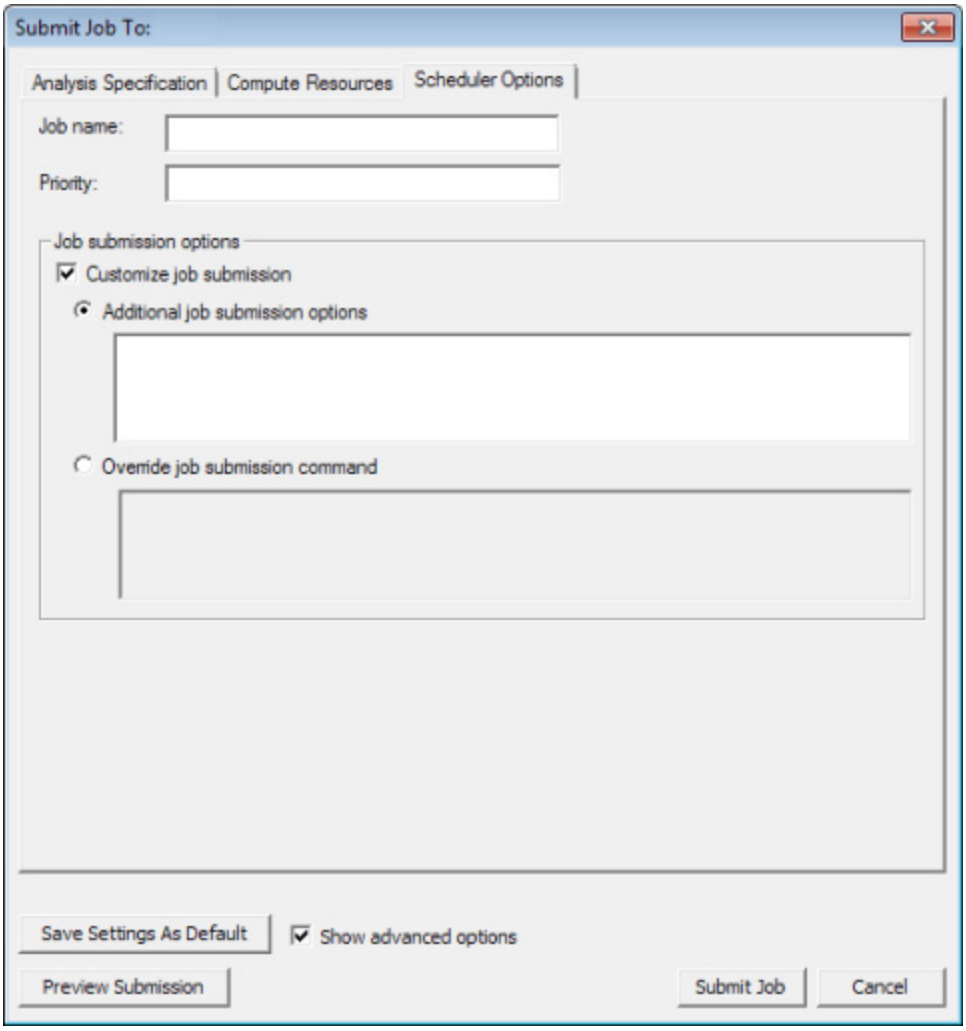


Scheduler Options Tab

This tab lets you give Job name and Priority

If you check **Show advanced options**, you can also specify **Job submission options**.

The Job submission options permit you to customize a job submission in terms of addition job submission options, or override a job submission command.



When the "Override job submission" radio button is checked, the user specified options replace most of the job submission options, whereas when the "Additional job submission options" radio button is checked, the user specified options are appended to the bsub command.

Text in the enabled field is appended to the bsub command. You can see the effects of any custom additions by clicking **Preview Submission**.

SGE Commands for Information About Jobs and Cluster Configuration

The following SGE commands are especially useful for getting information about the cluster configuration or for getting information about running or completed jobs. This list only contains a few of the most common commands. Consult the SGE man pages for a complete list and more details.

`qconf -help`: The first line displays the SGE version

`qacct -j` *job-id*: Displays a log of the completed job with id job-id (if accounting is enabled)

`qstat -j` *job-id*: Displays a log of the running job with id job-id

`qconf -sc`: Show all complex attributes

`qconf -spl`: Show a list of all parallel environments

`qconf -sp` *pe-name*: Show details of parallel environment named pe-name

`qconf -sql`: Show a list of all queues

`qconf -sq` *queue-name*: Show details of queue named queue-name

`qconf -sconf`: Show configurations

Submitting Ansys Electromagnetics SGE Batch Jobs

The SGE qsub command may be used to submit Ansys Electromagnetics jobs. Typical command formats are:

```
qsub qsub_argsansysEM_exeansys_args
qsub qsub_argsjob_script
qsub qsub_args[ -]
```

where:

- *qsub_args* are the options of the qsub command,
- *ansysEM_exe* is the pathname of the Ansys Electromagnetics tool executable to launch,
- *ansys_args* are the arguments to the Ansys Electromagnetics tool command, and
- *job_script* is a shell script containing the Ansys Electromagnetics desktop command to run.

In the first format, the Ansys Electromagnetics desktop command and its arguments are specified on the **qsub** command line. In the second format, the pathname of a shell script containing the Ansys Electromagnetics desktop command and its arguments is specified on the **qsub** command line. In the third format, the command is omitted or replaced with a hyphen; this indicates that the command or script will be taken from stdin.

Quoting Ansys Electromagnetics Command or Arguments for SGE

If the Ansys Electromagnetics tool executable pathname (*ansys_exe*) or any of the arguments of the Ansys Electromagnetics tool command (*ansys_args*) contain characters which are interpreted by the command shell, then these special characters must be properly quoted to ensure that the correct command is launched by SGE. This is especially important when using the first form of the **qsub** command, as the Ansys Electromagnetics desktop command is processed by the shell twice in this case. It is processed by the shell when the **qsub** command is processed, and again when the job is started.

Serial SGE Batch Jobs

In general, Ansys Electromagnetics batch jobs may be submitted as SGE serial jobs without any special considerations.

See Monitoring Ansys Electromagnetics SGE Batch Jobs for options for monitoring Ansys Electromagnetics batch jobs.

Parallel SGE Batch Jobs

When an Ansys Electromagnetics batch job is run as an SGE parallel job, the SGE scheduler will select the hosts for the distributed analysis job, and start the desktop process on one of these hosts. The desktop process will obtain the list of hosts from the SGE scheduler, and start analysis

processes, as needed, using the SGE scheduler facilities. To run an SGE parallel job, the job must be submitted to an SGE parallel environment (PE).

If the qmaster tcp port is not configured as a service, but rather via the environment variable SGE_QMASTER_PORT, this variable must be set in the Ansys Electromagnetics batch job environment. This is needed because the Ansys Electromagnetics desktop uses the "qrsh -inherit" command to launch engine processes.

See Monitoring Ansys Electromagnetics SGE Batch Jobs for options for monitoring Ansys Electromagnetics batch jobs.

Setting Up an SGE Parallel Environment (PE)

To allow Ansys Electromagnetics batch jobs to distribute analysis engines to multiple hosts, the job must be run in a parallel environment (PE) in which the control_slaves parameter is set to TRUE. This setting is required to allow the Ansys Electromagnetics desktop to start analysis engines on hosts other than the local host, i.e., the host where the Ansys Electromagnetics desktop is running.

Here is a sample parallel environment configuration:

```
pe_name ans_test1
slots 999
user_lists NONE
xuser_lists NONE
start_proc_args /bin/true
stop_proc_args /bin/true
allocation_rule $round_robin
control_slaves TRUE
job_is_first_task FALSE
urgency_slots min
accounting_summary TRUE
```

The user_lists and xuser_lists parameters are ACLs (access control lists) used to control which users have permission to use the parallel environment. The user_lists setting gives permission to use the PE. The xuser_lists setting denies permission to use the parallel environment. The xuser_lists settings override the user_lists settings.

The start_proc_args and stop_proc_args parameters contain the pathname and arguments for the parallel environment startup and shutdown scripts. No startup or shutdown scripts are needed for parallel Ansys Electromagnetics batch jobs. The setting /bin/true may be used as the value for these scripts; this utility does nothing and returns an exit code indicating success (0).

The parallel environment allocation_rule parameter will affect how the analysis engine tasks are distributed across the hosts allocated to the job. The $round_robin setting distributes the tasks across the hosts in a round robin fashion, resulting in the load being relatively evenly distributed over all of the hosts. The $fill_up setting allocates all slots on a host before distributing the tasks to

another host; the result is that most hosts are either fully utilized or completely unused. See the sge_pe man page for other settings for this parameter.

The control_slaves parameter must be set to TRUE, as described above.

The job_is_first_task parameter also affects how tasks are allocated. When submitting a job to run in a parallel environment, the number of parallel tasks, n, is specified on the command line. If this setting is TRUE, then the job process is considered one of the tasks, and only (n-1) additional tasks are allocated to the job. If the setting is FALSE, then the job process is not considered to be one of the tasks, and n additional tasks are allocated for the job.

See the sge_pe man page for more information about these and other PE parameters.

A parallel environment does not run tasks directly. Instead, the tasks are distributed to queues associated with the parallel environment. In order to complete the setup of a parallel environment, one or more queues need to be associated with the parallel environment. The queue pe_list parameter is used to specify the parallel environments (PEs) supported by the queue. This is an important step; **if no queues support a given PE, then jobs submitted to that PE will not run**.

Parallel Batch Job Command Line Considerations

The number of engines run on a host will depend on the total number of distributed engines, and the number of hosts allocated to the job. The memory required on a host depends on the number of engines running on the host and on the memory needed for each engine. The **qsub** command **-l resource=***value*,... or **-q** *queue_list* command line options specify that the parallel batch job run on machines with sufficient memory and other resources.

What a Scheduler Does

Recommended Practices for SGE Clusters

Monitoring Ansys Electromagnetics SGE Batch Jobs

The suggestions below may be used for SGE serial jobs and for SGE parallel jobs.

SGE qstat Command

The SGE **qstat** command may be used to display information on jobs and queues. If the **-j [***job_list***]** option is included, then information on jobs is displayed. If the **-j [***job_list***]** option includes a job list, then the displayed information is limited to the jobs in the job list.

The **-u***user*,... option limits the output to jobs associated with users in the user list. If the **-u***user*,... option is not specified, then information on queues or jobs of the current user are displayed.

The **-t** option displays extended information about the subtasks of each displayed job. This is equivalent to the **-g t** option. The **-r** option displays extended information about the resource requirements of the displayed jobs.

See the SGE manual pages for more information.

Ansys Electromagnetics desktop -monitor Command Line Option for SGE

Example SGE qsub Command Lines

Issue with qrsh (SGE)

Issue with MainWin Core Services for SGE

Ansys Electromagnetics Desktop -monitor Command Line Option for SGE

The **-monitor** command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

The SGE scheduler redirects the standard output and standard error streams of batch jobs to files specified in the **qsub -o [[***hostname***]:]***path*,... and the **-e [[***hostname***]:]***path*,... command line options, respectively. If either option is not specified, then the associated stream is redirected to the default file pathname.

The **qsub -j y[es] | n[o]** controls whether the standard output and standard error streams are merged. If the y or yes value is specified, then the standard error stream is merged into the standard output stream. If the **-e** *host_and_path* option is also specified in this case, the *host_and_path* setting is ignored. If the n or no value is specified, or if this option is not specified, then the standard error stream and standard output stream are not merged.

You can monitor the progress of a job by checking the standard output file for progress, info and warning messages, and checking the standard error file for error and fatal messages.

Monitoring Ansys Electromagnetics SGE Batch Jobs

Example SGE qsub Command Lines

Recommended Practices for SGE Clusters

Issue with qrsh (SGE)

Issue with MainWin Core Services for SGE

Example SGE qsub Command Lines

All of the following examples show how to submit Linux Maxwell jobs on SGE, but similar command lines will work for other Ansys Electromagnetics products.

Serial job using command line:

```
qsub -b y /AnsysEM/v231/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

- The **-b y** option indicates that electronics desktop is launched directly from the command line, instead of using a script.
- No queue is specified, so the default queue will be used

Serial job with a hard runtime limit of 15 minutes:

```
qsub -b y -l h_rt=00:15:00 /opt/AnsysEM/v231/ansysedt
-ng -BatchSolve ~/projects/OptimTee.aedt
```

- The -l h_rt=00:15:00 option indicates that this job has a "hard" runtime limit of 15 minutes.

Serial job using a script, with a runtime limit specified in the script:

```
qsub ~/sge/scripts/OptimTee.csh
```

- The **-b y** option is absent, so the script ~/sge/scripts/OptimTee.csh will be run when the job starts.
- The script file OptimTee.csh may contain SGE directives in addition to the command(s) to run. In this example, a directive with a hard runtime limit if 15 minutes is included in the script.

Script file contents:

```
#!/bin/csh
#$ -l h_rt=00:15:00
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

- The SGE directive #$ -l h_rt=00:15:00 is equivalent to including -l h_rt=00:15:00 on the qsub command line.

Distributed processing job using 4 engines:

```
qsub -b y -pe pe1 4 /opt/AnsysEM/v231/ansysedt
-ng -BatchSolve -Distributed -machinelist num=4
~/projects/OptimTee.aedt
```

- The **-b y** option indicates that maxwell is launched directly from the command line, instead of using a script.

- The **-pe pe1 4** command_line option indicates that this is a parallel job running under the pe1 parallel environment, and that 4 cores or processors are allocated to this parallel job.
- The "-machinelist num=n" option is now required for batch jobs.
- The **-Distributed** option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines.

Recommended Practices for SGE Clusters

Issue with qrsh (SGE)

Issue with MainWin Core Services for SGE

Recommended Practices for SGE Clusters

The following subsections contain recommendations on how to set up an SGE cluster for efficiently running Ansys Electromagnetics serial and parallel jobs. These recommendations require the cluster administrator to make configuration changes.

Submitting Exclusive Jobs

Consumable Memory Limits

Serial Jobs in SGE

Parallel Jobs in SGE

Using Multithreading with Parallel Jobs

Submitting Exclusive Jobs

In many cases, clusters are used to run "large" Ansys Electromagnetics batch jobs. That is, these are jobs that may require a large quantity of resources, such as processors, memory, disk space, or run time. One way to ensure that the resources needed by the batch job are available to the job is to run the job in an "exclusive" mode. That is, any host running the job is not available for use by any other jobs. There is no SGE built in mechanism for specifying that a job is "exclusive". SGE is extensible, and it is not difficult to configure the cluster to allow exclusive jobs. The steps below show one way to do this. This example requires SGE 6.2u3 or later. Note that specifying a job as "exclusive" may delay the start of the job if there are not enough hosts available to run the job exclusively.

1. Use the command qconf -mcto add a new complex to the table of complexes. Recommended attributes are:
   - name : exclusive
   - shortcut : excl
   - type : BOOL
   - relop : EXCL

- requestable : YES
- consumable : YES
- default : 0
- urgency : 0

2. Set the value of "exclusive" to TRUE for each execution host using the command qconf -me hostname, where hostname is the name of the host. The values of all host configuration parameters may be displayed using the command qconf -se hostname. The "complex_ values" line should look similar to:

   complex_values exclusive=TRUE, but other values may also be included.

3. When submitting a job, the job will be "exclusive" if the value "excl" is included in the resource list specified by the qsub -l option. If the resource list does not include "excl" then the job will not be exclusive, and other jobs may run on the same host or hosts as this job.
4. Example qsub command line for exclusive serial job:

   ```
   qsub -b y -l excl /opt/AnsysEM/v231/ansysedt -ng
   -BatchSolve ~/projects/OptimTee.aedt.
   ```

   Although serial jobs use only one slot, no other jobs will run on the host where this job is running, even if additional slots are present.

5. Example qsub command line for exclusive parallel job using eight engines, each using a single thread of execution:

   ```
   qsub -b y -l excl -pe pe1 8 /opt/AnsysEM/v231/ansysedt -ng -
   BatchSolve -Distributed -machinelist num=8
   ~/projects/OptimTee.aedt
   ```

   None of the hosts used for this job will be allowed to run other jobs while this job is running.

Consumable Memory Limits

SGE contains several built-in complexes related to memory, including mem_total, for example, but none of these are "consumable". If a job is submitted with resource list including one of these non-consumable memory complexes (such as mem_total), then the job will run on a host or hosts only if sufficient memory is available. If a second job is submitted, the memory request for the second job is compared to the original total when determining if the job may run on a host. This may result in both jobs running out of memory. For example, if host A has mem_total=16G of memory, and two jobs are submitting with option "-l mt=16G", then both jobs could run on host A, if sufficient slots are available on host A.

SGE allows complexes to be "consumable" to avoid this type of problem. If a complex is consumable and a job requests x amount of the complex in the -l resource list, then the available amount of the resource is decreased by x for subsequent jobs. For the same example as above, if the mem_total complex was consumable, then the first job would run on host A. This would decrease the available mem_total from 16G to 16G-16G = 0. The second job could not run on host A because there is no memory available for this job.

The steps below show how to set up a consumable resource called physical_memory to accomplish the same thing. We do not recommend changing the behavior of the built-in

complexes (such as mem_total) because other scripts may expect normal behavior of the built-in complexes.

1. Use the command qconf -mcto add a new complex to the table of complexes. Recommended attributes are:
   - name : physical_memory
   - shortcut : phys_mem
   - type : MEMORY
   - relop : <=
   - requestable : YES
   - consumable : YES
   - default : 0
   - urgency : 0
2. Set the value of "physical_memory" to an appropriate value for each execution host using the command qconf -me hostname, where hostname is the name of the host. The appropriate value is the actual physical memory on each host. Because the type is MEMORY, the K, M, and G suffixes may be used to represent kilobytes, megabytes and gigabytes. The values of all host configuration parameters may be displayed using the command qconf -se hostname. The "complex_values" line should look similar to:

   complex_values physical_memory=16G,

   but other values may also be included, and the memory value should be appropriate for the host.
3. When submitting a job, the physical memory requirement per slot may be specified in the resource list as follows: -l phys_mem=mem_needed. The number of slots assigned to the job on a specific host will be limited by the number of slots available on the host, and also by the physical_memory available on the host.

Serial Jobs in SGE

If a serial job is submitted with the option -l phys_mem=mem_neededincluded, then the job may only run on a host in which the remaining physical_memory is equal to or greater than the mem_ neededvalue.

Example 1: Host A has physical_memory=16G, and host B has physical_memory=8G. If mem_ neededis 8G, the job may run on either host A or host B. If mem_neededis 16G, then the job may only run on host A.

Example 2: Host A has physical_memory=16G, and host B has physical_memory=8G. Job 1 is already running on host A, and it was submitted with option -l phys_mem=8G. If job 2 is submitted with option -l phys_mem=16G, then job 2 cannot start until job 1 finishes, because only host A has 16GB of physical_memory. If job 2 is submitted with option -l phys_mem=8G, then job 2 may start immediately, and run on either host A or host B, because both hosts have 8G of physical_memory remaining.

Parallel Jobs in SGE

Because the consumable setting for physical_memory is YES (and not JOB), each slot of the job requires a physical_memory of mem_needed. The number of slots on a host assigned to the job is limited by the number of available slots on the host. It is also limited by the physical_memory available on the host; the number of slots assigned to the job cannot exceed the available physical_memory on the host divided by the mem_neededspecification.

Example 1: Execution host A and execution host B both have 4 slots per host (configured in the queue associated with the parallel environment). Host A has physical_memory=16G and host B has physical_memory=8G (shown by commands qconf -se Aand qconf -se B). If a job is submitted that requires 6 slots and 4G per slot, it will be able to run, with 4 slots on host A and 2 slots on host B. The qsub command might look like: qsub -l phys_mem=4G -pe pe_name 6 command args

Example 2: Same as example 1, except that 7 slots are requested. In this case, the job will never run. Although there are 8 slots available on hosts A and B, only two of the slots on host B are usable by this job because it only has physical_memory of 8G. With only 6 slots total available to this job (4 on host A and 2 on host B), the job can not start. In this case the command might look like: qsub -l phys_mem=4G -pe pe_name 7 command args

Using Multithreading with Parallel Jobs

For large jobs it may be useful to combine multiprocessing with distributed processing. Distributed processing refers to starting multiple processes, in which each process performs a portion of the analysis. These processes may run on the same host or on different hosts. The number of processes running at the same time is known as the number of "analysis engines". Multiprocessing refers to using multiple threads within a single process to decrease the run time of the process. Multiprocessing may also be called multi-threaded processing.

As a concrete example of combining multiprocessing with distributed processing, an analysis could run with four engines, where each engine uses two threads. In order to distribute the processing load so that no processor is overloaded, one slot is generally allocated per thread, so 8 slots would be needed for this example (4 engines * 2 threads per engine = 8 threads). The four engines could all run on a single host, or they could be distributed across 2, 3 or 4 hosts, depending on available slots. Each engine represents a single process, so the two slots for each engine must be allocated on the same host.

This section describes how to set up an SGE cluster so that a specified number of slots per host may be requested when a job is submitted. This procedure will require the cluster administrator privileges. This capability may be used to submit parallel jobs in which one engine runs on each host, and the number of slots per host matches the number of threads used by each engine.

1. Let n be the largest number of slots available on any host used for the jobs. Create a separate parallel environment for each value of the number of slots per host from 1 to n. For example, pe_sph1 is a parallel environment in which one slot is allocated to the job per host, pe_sph2 is a parallel environment in which two slots are allocated to the job per host, etc. The command qconf -ap pe_namemay be used to create each new parallel environment. The allocation_rule parameter should be set to the number of slots per host, an integer from 1 to n. The control_slaves parameter should be set to TRUE, as described above. The slots parameter should be set to the maximum number of slots managed by this parallel_ environment, which is typically set to a large number, such as 999. The other parameters

should be set to values appropriate for the cluster. For example, the pe_sph2 parallel environment might have the following parameters:

- pe_name : pe_sph2
- slots : 999
- user_lists : NONE
- xuser_lists : NONE
- start_proc_args : /bin/true
- stop_proc_args : /bin/true
- allocation_rule : 2
- control_slaves : TRUE
- job_is_first_task : FALSE
- urgency_slots : min
- accounting_summary : TRUE

2. When submitting a job, use the parallel environment where the slots per host matches the number of threads per engine.

The batchoptions setting -machinelist num=n is required. This should be set to match the number of slots per host. With any analysis, a portion of the analysis may not be distributed across multiple engines.

Example qsub command line for running distributed processing with four engines and multiprocessing with two threads per engine:

```
qsub -V -b y -pe pe_sph2 8 "/opt/AnsysEM/v231/ansysedt
-ng -BatchSolve -Distributed -machinelist num=4 -batchoptions
"projects/OptimTee.aedt"
```

The -Voption indicates that the all environment variables in the submission environment should be copied to the job environment.

- The -b y option indicates that Maxwell is launched directly from the command line, instead of using a script.
- The -pe sph2 8 command_line option indicates that this is a parallel job running under the pe_sph2parallel environment so that two slots are allocated to this job from each host, and that 8 slots in total are allocated to this parallel job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".
- The -machinelist num=4option indicates that a total of four engines will be started.
- The entire Maxwell command is in double quotes, and the double quotes enclosing the -batchoptions value are escaped. Each of these double quotes is replaced by the sequence "\"".

Integration with Sun Grid Engine (SGE)

Monitoring Ansys Electromagnetics SGE Batch Jobs

Issue with qrsh (SGE)

Ansys Electromagnetics parallel batch jobs use the SGE **qrsh** command to launch engine processes on remote hosts. If the **qrsh** command is not working correctly, then the parallel job is unable to launch engine processes on remote hosts. If this problem occurs, the batch log for the job typically includes one or more error messages indicating that a COM engine was unable to be started on a remote host. If this occurs, the user or cluster administrator should verify that the SGE qrsh command is working correctly, and correct the problem if the SGE **qrsh** command is not working correctly.

The **qrsh** command may be tested by running a simple command on a specified host, such as **qrsh -l hostname=host1 hostname** or **qrsh -l hostname=host1 ls /tmp**, where host1 is the remote host name. The first test should simply echo back the hostname of the remote machine. The second test should list the contents of the /tmp directory on the remote machine.

The failures of the SGE qrsh command are associated with the following global sge configuration parameters, listed below with values that may cause the failures:

```
qrsh_command /usr/bin/ssh -t
rsh_command /usr/bin/ssh -t
rlogin_command /usr/bin/ssh -t
```

If these parameter settings are removed, then the SGE built-in mechanisms are used for qrsh, rsh, and rlogin. No problems with the built-in versions have been reported. The SGE qconf -sconf global command may be used to view these parameter settings. The SGE qconf -mconf global command may be used to modify or remove these parameter settings.

Issue with MainWin Core Services for SGE

By default, SGE creates a temporary directory for each SGE batch job, and deletes this temporary directory and its contents when the job finishes. SGE sets the TMP and TMPDIR environment variables of the job environment to point to this temporary directory. Ansys Electromagnetics desktop software starts the MainWin Core Services on startup, if they are not already running. After the Ansys Electromagnetics desktop software finishes, the MainWin Core Services time out and automatically shut down. The MainWin Core Services use the TMP and/or TMPDIR directories to store temporary data. If this temporary data is removed before the services shut down, then the services do not shut down automatically. Normally, SGE will remove the temporary directory and its contents before the services time out. The result is that these extraneous service processes run forever. If this problem occurs, each Ansys Electromagnetics batch job starts an additional set of these services that never shut down. This can result in an excessive number of processes running on the host where the Ansys Electromagnetics desktop is started. The names of the service processes are:

- watchdog
- regss
- mwrpcss

Workaround for Issue with MainWin Core Services

One way to avoid this problem is to modify the environment in which the Ansys Electromagnetics desktop runs so that the TMP and TMPDIR environment variables do not point to the directory which will be immediately removed by SGE when the job finishes. This can be done by copying the value of the TMPDIR environment variable to the ANS_SGE_TMPDIR environment variable, and unsetting the TMPDIR and TMP environment variables. The services ignore the ANS_SGE_TMPDIR environment variable, but if this variable is set, then it will be used as the temporary directory for the rest of the Ansys Electromagnetics software.

Here is an example bash wrapper script that may be used to work around this issue. In this example, the product is maxwell, but the same approach will work for any Ansys Electromagnetics product. In this example, the script is named sge_maxwell and is in the AnsysEM software installation directory. When an Ansys Electromagnetics desktop job is submitted to the SGE scheduler, the script (sge_maxwell, in this example) should be submitted instead of maxwell. The script will modify the environment, as needed, then start maxwell. When the analysis finishes, the script returns the exit status of maxwell.

An alternative is to place the script in an arbitrary directory, and modify the script to include an absolute path to the product (maxwell in this example).

Script contents:

```
#! /bin/bash

# This script will not correctly process arguments containing
# spaces or other characters special to the shell.

# Create maxwell command line
# In this example, sge_maxwell and maxwell are in the same
directory
# An alternative is to use an absolute path for the maxwell
command
cmd0=$0
cmd="${cmd0/%sge_maxwell/maxwell} $@"

# Fix environment variables
export ANS_SGE_TMPDIR=${TMPDIR}
unset TMPDIR
unset TMP
```

```
# Run the maxwell command and return the exit status
${cmd}
exit $?
```

Issue with MainWin Core Services for SGE
Recommended Practices for SGE Clusters

Integration with Platform's Load Sharing Facility (LSF)

The Load Sharing Facility (LSF) scheduler is only supported on Linux. Jobs may be submitted in any of the following ways:

- Job Submission GUI
- Using LSF commands (qsub, etc.)

See the Ansys Electromagnetics Suite 2023 R1 Unix/Linux Installation Guide for additional information on supported schedulers.

> **Note:**
>
> If a temp directory is setup by the LSF cluster administrator, analysis engines use this temp directory, overriding the setting in the Ansys EM product.

LSF Job Management

You can use Ansys Electronics Desktop to submit batch jobs to LSF and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select LSF as the scheduler.
2. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to LSF.

   LSF-specific Settings:

   - On the **Compute Resources** tab, click the **Resource Selection Parameters** ellipses button (**...**) to specify the following:
     - **Queue** – a drop-down menu lets you select Normal, chkpn_rerun_queue, idle, license, night, normal_allow_excl, owners, priorityu, or short.

- **MinCoresPerNode** – the minimum number of cores allowed on a node to be eligible for selection; translates to bsub -R select[ncpus>=N]
- **MaxCoresPerNode** – the maximum number of cores allowed on a node to be eligible for selection; translates to bsub -R select[ncpus<=N]
- **MinMemoryPerNode** – the minimum amount of physical memory (specified in integer GigaBytes) allowed on a node to be eligible for selection; translates to bsub -R select[maxmem>=M]
- **MaxMemoryPerNode** – the maximum amount of physical memory (specified in integer GigaBytes) allowed on a node to be eligible for selection; translates to bsub -R select[maxmem<=M]

If you do not specify parameters, the scheduler does so.

- For LSF, the only non-automatic method of **Resource Selection** is **Number of Tasks and Cores**. You can specify the number of tasks, whether they are for exclusive use by the job, cores per distributed task, a limit number of tasks per node, and RAM limit as percent.

3. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

LSF Job Submission Guidelines

Before submitting an LSF job, ensure the following are true:

- The project is available in a shared drive that is accessible to all machines in the cluster.
- The project is available using the same path on all machines of cluster.
- There is sufficient space in the project directory and temp directories.
- There is sufficient memory per engine.
- The number of compute resources (Distributed Analysis machines and Multi Processing cores) will achieve the desired scale factor and effective resource utilization.

Integration of Ansys EM Products with LSF

With LSF you do not need to set 'Distributed Analysis Machines' or 'Remote Machine' options. Instead, you submit a job to LSF, requesting the appropriate resources for the job (number of processors, memory per processor, etc.).

For example:

```
bsub -n 1 ansysedt.exe -Batchsolve -ng -local -machinelist num=1
OptimTee.aedt
bsub -n 4 ansysedt.exe -Batchsolve -ng -Distributed -machinelist
num=4 OptimTee.adsn
```

The job is queued by LSF until the requested resources are available. Upon resource availability, LSF starts Electronics Desktop with the specified command line on one of the allocated machines. During analysis, Electronics Desktop dynamically obtains the allocated 'Distributed Analysis

Machines' from LSF. Electronics Desktop interfaces with LSF to launch engines on remote machines without going through Ansys RSM.

Installing Ansys EM Tools on LSF Cluster

The LSF scheduler is supported on Linux only.

lsf.conf should contain this line:

```
LSF_UNIT_FOR_LIMITS=MB
```

The administrator should have this line in the lsb.params file to ensure that memory reservations are per-slot (per-core):

```
RESOURCE_RESERVE_PER_SLOT=Y
```

Jobs may be submitted in any of the following ways:

- Using LSF commands (bsub, etc.)
- Using the generic scheduler GUI in local mode
- Using the generic scheduler GUI in service mode

See the Ansys Electromagnetics Suite 2023 R1 Unix/Linux Installation Guide for additional information on supported schedulers.

Setup:

1. Install on a single node, on a shared drive.
2. Setup 'temp directory' to a path that is same on all nodes (for example, /tmp).
3. Ensure that the product is available using the same path on all nodes.

Permissions:

- All users of the cluster should have read/write permissions to temp directory.
- All users should have read/execute permissions to installation directory.
- Turn OFF firewall between cluster nodes.

When a desktop scheduler GUI is run the same node as the job submission node, no other configuration is necessary; installation is sufficient. Select the scheduler through the Electronics Desktop GUI. Ensure that scheduler commands are available in the path before you launch Electronics Desktop.

Note:

There is no need to install RSM unless you are using the scheduler GUI on a post-processing node that is different from the job submission node. In this case, RSM must be configured with the scheduler type and path.

A post-processing node is a node in the cluster that can run Electronics Desktop in graphical mode. A job submission node is a node in the cluster in which job submission commands are available.

Per-slot Resource Reservation

Set the cluster for per-slot resource allocation if the automatic cores and RAM resource selection method is to be used. You can check the cluster to see if per-slot resource allocation is configured by using the "bparams -a" command. Search the output for "RESOURCE_RESERVE_PER_ SLOT" to determine the setting (either "Y" or "N"). If set to "N" then consult the LSF administration guide on how to change this to "Y".

Scenario 1: The post-processing node and job-submission node roles are served by distinct machines.

In this case, perform the following configuration:

The job-submission node should be configured to run RSM service, which serves as a proxy to scheduler. The RSM Service should be running as 'root' in order to facilitate jobs running using the credentials of the job's owner. A **configuration file in the RSM installation folder should be edited** to specify information regarding the scheduler that manages jobs on this cluster. A block labeled 'Scheduler' must be included within the 'AnsoftCOMDaemon' block. This block contains two string entries:

- SchedulerName: this contains the unique part of the scheduler proxy library name
- ConfigString: this contains a scheduler specific configuration string

The case of the SchedulerName string is significant on Linux because Linux file names are case sensitive. In Ansys Electromagnetics Suite 2023 R1, possible scheduler names are: lsf and sge. The ConfigString entry is a scheduler specific configuration string, described below.

In addition, the AnsoftRSMService must be started with appropriate environment variables set. Generally, the environment variables must be set the same as they would be set for using the scheduler via command lines.

LSF Details

For the LSF scheduler proxy library, the ConfigString entry in the ansoftrsmservice.cfg configuration file is ignored. It may be empty or omitted entirely.

The AnsoftRSMService must be started with the environment set as it would be set for submitting jobs to the LSF cluster.

- For Linux, the cshrc.lsf or the profile.lsf file may be sourced to set up the environment, depending on the shell.

Example ansoftrsmservice.cfg configuration file:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='lsf'
'ConfigString'=''
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Scenario 2: The post-processing node and job-submission node roles are served by the same machine.

The **Select Scheduler...** command (as described in the Job Management User Interface for LSF section) is used to gather details about the scheduler. In this case, the Desktop process should be started in an environment suitable for submitting jobs to the scheduler. See below for details.

The environment should be configured so that the following LSF environment variables are set appropriately for the LSF cluster in use: LSF_BINDIR, LSF_SERVERDIR, LSF_LIBDIR, and LSF_ENVDIR. In addition, the following LSF commands should be found in the LSF_BINDIR directory: "bsub", "bjobs", "bkill", "lsid", "lsrun", "lshosts", "bmgroup", "bparams" and "bqueues".

Using the bsub Command to Submit Batch Jobs

The LSF bsub command may be used to submit jobs. The typical command format is:

`bsub` *`bsub_args ansys_exe ansys_args`*

where:

- *bsub_args* are the options of the `bsub` command,
- *ansysEM_exe* is the pathname of the Ansys Electromagnetics desktop executable to launch, and
- *ansys_args* are the arguments to the Ansys Electromagnetics desktop executable.

bsub Arguments

The **bsub** command has a large number of options that may be used to control the submission process. Only a few options that are often used with Ansys Electromagnetics jobs are listed here. The following options may be used to submit serial or parallel LSF jobs.

-n*`min_proc, max_proc`* or **-n***`min_proc`*

Submits a parallel job, specifying the number of processors (or slots) required for the job. Here, *min_proc* is the minimum number of processors, and *max_proc* is the maximum number of processors. If no maximum is specified, then exactly *min_proc* processors are requested. If

PARALLEL_SCHED_BY_SLOT=Y in lsb.params, this option specifies the number of slots required to run the job, not the number of processors. If the **-n** command line option is not specified, then the job is submitted as a serial batch job.

-R "span[ptile=n]"

There are many ways to use the -R "res_req" option to the bsub command. We only cover -R "span[ptile=n]" here, because this option is very useful for Ansys Electromagnetics jobs. When this option is specified, the LSF scheduler will allocate n processors (or slots) on each host to this job, even if more processors are available on the host.

-x

All hosts running this job operate in exclusive execution mode. The job will only run on a host having no other jobs running on that host. No other batch jobs will be started on a host while this job is running on that host.

See LSF documentation for a complete list of options for the **bsub** command.

> **Important:**
>
> If the Ansys EM tool executable pathname (*ansys_exe*) or any of the arguments of the Ansys tool command (*anssys_args*) contain characters which are interpreted by the command shell, these special characters must be properly quoted to ensure that the correct command is launched by LSF. A similar problem may occur if any of the *ansoft_args* require single quote, double quote or space characters. Note that the Ansys Electronics Desktop command is processed by the shell twice: once when the **bsub** command is processed, and again when the job starts.

Example LSF bsub Command Lines (Linux Only)

> **Note:**
>
> The following examples use HFSS as the product, but similar command lines will work for all Ansys EM products.

Serial Job

```
bsub -n 1 /Program Files/AnsysEM/v231/Win64/ansysedt -ng
-BatchSolve -machinelist num=4 ~/projects/OptimTee.aedt
```

The -n 1 option indicates that this job runs on one core.

Serial Job Requiring a Minimum of 4GB

```
bsub -n 1 -R "select[mem>4000]"
/Program Files/AnsysEM/v231/Win64/ansysedt -ng
-BatchSolve -machinelist num=4 ~/projects/OptimTee.aedt
```

The -R "select[mem>4000]" option indicates that this needs a minimum of 4 GB memory.

Multi-processing Job using 4 Cores

```
bsub -n 4 -R "span[ptile=4]"
"/Program Files/AnsysEM/v231/Win64/ansysedt -ng -BatchSolve
-batchoptions -machinelist num=4 ~/projects/OptimTee.aedt"
```

- The -R "span[ptile=4]" option indicates that the four cores need to be on the same machine.
- The -batchoptions option indicates that HFSS should use four cores for multi-processing.
- The entire hfss command is in double quotes, and the double quotes enclosing the -batchoptions value are escaped. Each of these double quotes is replaced by the sequence "\"".

Distributed Processing Job using 4 Engines

```
bsub -n 4 /Program Files/AnsysEM/v231/Win64/ansysedt -ng -
BatchSolve -Distributed ~/projects/OptimTee.aedt
```

- The -n 4 option indicates that the four cores are needed for the job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines. The -Distributed option can have additional options, such as includetypes=xxx, excludetyeps=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".

Distributed Processing and Multi-processing Job using 4 Cores, with 2 Cores for Multi-processing

```
bsub -n 4 -R "span[ptile=2]" ~/projects/OptimTee.csh
```

Shell Script (~/projects/OptimTee.csh):

If a command is included in the **bsub** command line, the entire command will be processed by the command shell two times. The command is processed when the **bsub** command is processed by the shell and is processed again when the command is started by the scheduler. This example shows how to use a shell script so that the command line will be processed only once. The command is placed in the shell script, and then the shell script pathname is placed in the **bsub** command line. Then, the command is only processed by the command processor when the job is started. When using this approach, the shell script should be accessible from all of the cluster hosts.

```
#!/bin/csh
/Program Files/AnsysEM/v231/Win64/ansysedt -ng -BatchSolve
-Distributed -machinelist num=2 -batchoptions
~/projects/OptimTee.aedt
```

- The **-n 4** option indicates that the four cores are needed for the job.
- The **-R "span[ptile=2]"** option indicates that the cores must be allocated in groups of two cores on the same machine.
- The **-machinelist num=2** option indicates that this is a DSO job and that a total of two engines will be started.
- The **hfss** command is placed in the shell script (~/projects/OptimTee.csh). In the **bsub** command line, the **hfss** command is replaced by the shell script pathname.
-

Monitoring LSF Batch Jobs

You can monitor jobs through the Electronics Desktop user interface, or through the command line.

The suggestions below are for batch jobs run under LSF.

Ansys Electronics Desktop -monitor Command Line Option

The -monitor command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

LSF bpeek Command

The LSF bpeek command may be used to monitor job progress. The command **pbeek [-f]** *job_id* displays the standard output and standard error produced by the job with id *job_id* from the job start to the current time (the time when the command is executed). This command is only valid for jobs that have not yet finished. When used with the **-f** option on Linux, the output of the job is displayed using the command tail **-f**, so that ongoing progress may be monitored.

In order to display messages to standard output and standard error, specify the **-monitor** command line option on the Ansys EM tool command line. Then, these messages can be seen using the LSF bpeek command.

Terminating LSF Batch Jobs

To cancel or terminate an Ansys EM LSF batch job, we recommend using the job monitoring UI to terminate jobs cleanly, rather than using the bkill commands. Using this approach will allow the batch job to shut down in an orderly fashion.

Using the LSF **bkill** command without the **-s SIGTERM** option or simply terminating the job processes may cause some of the following problems:

- Some engine processes are not shut down and continue to run.
- LSF job is not fully removed.

- Project .lock file is not removed.
- MainWin core service processes (watchdog, mwrpcss and/or regss) are not stopped.

Some of these may interfere with submission of additional LSF batch jobs. For example, it may be necessary to manually remove the project lock file to submit another batch job for the same project. MainWin core service processes may also interfere with starting subsequent Ansoft batch jobs. Normally, these processes should timeout and end 15 seconds after the Ansys Electromagnetics product shuts down. Any MainWin core service processes (watchdog, mwrpcss and/or regss) that continue to run for more than 15 seconds after the product has stopped may be hung. The hung processes may need to be manually killed, after ensuring that these processes are associated with an Ansys EM job that has finished or terminated.

Stop a job cleanly - ensures that the results obtained until now are preserved:

```
bkill -s TERM <jobid>.
```

Stop an job abruptly - results are most likely lost. You have to manually remove the project lock file:

```
bkill <jobid>
```

LSF Known Issues and Workarounds

The following are known issues. Workarounds are noted when available:

- Desktop or remote machine cannot have multiple IP addresses. This is unsupported.
- Core dump files may appear when a job has finished running. Results are still computed correctly. Workaround: Limit size of core dumps to 0 through the following job submit option: `bsub -C 0 -n <number-of-cores> -q <queue-name>`
- Firewall should be turned off on all machines in the cluster.
- Sometimes LSF ends a job (for example, a job may be preempted due to a high priority job). This may result in the presence of a .lock file in the project directory. You must manually delete the .lock file before continuing with further analysis.
- When an LSF job is ended, MainWin services (watchdog, regss, and mwrcpss) could keep running. The result is that later jobs cannot start on the machine. The fix is to end these processes before starting a new job.
- Analysis fails abruptly when running out of resources (cpu/memory/disk). Ensure sufficient resources are provided.

LSF Troubleshooting

The following are general troubleshooting steps:

1. Ensure the LSF `lsrun` command is enabled.
2. Look for user errors.

   For example:

- Are the executable path and project path correct and complete?
- Are there sufficient resources (CPU/Memory/Disk) allocated to the job?
- Is the project available on the execution host?
- Does the job submitter have read/writer permissions on the project directory and read/execute permissions on the installation directory?
- Is the project locked?

3. Determine whether this is a standalone product issue.
   - Run Electronics Desktop on the machine outside of the scheduler and see if it opens and analyzes.
4. Examine outputs and logs.
   - Output of the LSF batch job. Obtain this using LSF commands: "`bacct -l <jobid>`"
   - Batch log (typically <projectname>.log, located in the project directory.
5. Enable additional debug logs using the steps below.

   In the job submission window, set the following environment variables:
   - ANSOFT_DEBUG_MODE = 1
   - ANSOFT_DEBUG_LOG = <*path to directory accessible by all machines in the cluster*>
   - ANSOFT_DEBUG_LOG_SEPARATE = 1
   - ANSOFT_LSF_LOG = <*path to a specific .log file in the directory set under ANSOFT_DEBUG_LOG*>
6. For each pair of machines between which remote analysis fails, run `ping remote-machine` and note the output.
7. For each machine in the network, dump network interfaces (for example, run `ifconfig -a`) and note the output.

Integration with PBS (Portable Batch System)

The PBS Pro and PBS/Torque schedulers are only supported on Linux. Jobs may be submitted in any of the following ways :

- Job Submission GUI
- Using PBS commands (qsub, etc.) or the PBS gui (xpbs)

See the Ansys Electromagnetics Suite 2023 R1 Unix/Linux Installation Guide for additional information on supported schedulers.

PBS Job Management

You can use Ansys Electronics Desktop to submit batch jobs to PBS and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select PBS as the scheduler.
2. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to PBS.

   PBS-specific Settings:

   - On the **Compute Resources** tab, click the **Resource Selection Parameters** ellipses button (**...**) to specify either the **Queue** or **QueueAtServer** parameter.

     For **Queue**, you may select a queue for the job from the list of queues configured for the default server. Only queues that are enabled and that do not have the from_ route_only attribute set to true are listed.

     For **QueueAtServer**, you may specify a queue at the default server or at another server by entering text into this field in one of three formats:

     - queue_name
     - @server_name
     - queue_name@server_name

     The queue_name format submits with the name queue_name. The other formats submit with the name server_name. The *destination* value of the -q *destination* option on the qsub command line is the user-specified string. *This string will not be validated by the scheduler proxy library*.

     Either **Queue** or **QueueAtServer** may be specified, but both may not be specified. If neither **Queue** nor **QueueAtServer** is specified, the job is submitted to the default queue at the default server.
3. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

Monitoring Jobs

Running Ansys Electronics Desktop from the Command Line

Command Line Information for HPC

Non Standard Installations for PBS

PBSPro

If the environment variable PBS_DEFAULT is set, the value of this environment variable will be used as the name of the default server, instead of obtaining the default server name from the PBSPro configuration file. The default pathname of the PBSPro configuration file is: `/etc/pbs.conf`. The environment variable PBS_CONF may be used to specify a different pathname for the PBSPro configuration file.

PBS/Torque

If the environment variable PBS_DEFAULT is set, the value of this environment variable will be used as the name of the default server, instead of obtaining the default server name from the PBS/Torque server file. The name of the PBS/Torque server file is server_name, and it is installed in the TORQUEHOME directory. By default, TORQUEHOME is `/var/spool/torque`. To specify a different TORQUEHOME directory, the environment variable ANSOFT_ TORQUEHOME should be set to the pathname of the desired directory.

Related Topics

Integration with PBS (Portable Batch System)

PBS Limitations

General Limitations

- There is no support for GPUs when submitting jobs via the GUI.
- Support for PBSPro and PBS/Torque is only available on Linux; Windows is not supported.
- Staging of input or output files is not supported for jobs submitted using the GUI.
- All jobs submitted via the GUI are independent jobs. Neither job dependencies nor job arrays are supported.
- If the user -specified server is not the default server, there is no check for sufficient resources before submitting the job.
- If the user specified server is not the default server, the limit on the number of tasks per node is ignored for both PBSPro and PBS/Torque. For PBS/Torque, only one task will be allocated for each node. For PBSPro, the scheduler may allocate any number of tasks to a node, provided that the node has sufficient cores for all of the tasks.
- For jobs submitted to a routing queue, the check for sufficient nodes and cores by the scheduler proxy only verifies that there are sufficient nodes and cores associated with the server.
- The queue attributes “resources_max” and “resources_min” are not checked when determining whether there are adequate resources to run the job.

PBSPro Limitations

- The PATH in the submission user’s default environment must include the directory containing the PBSPro commands.
- Failover is not supported.
- HPC Basic Profile Jobs are not supported.
- Globus vnodes are not supported. When checking for sufficient nodes and cores for the job, only nodes of type PBS are considered.
- For jobs submitted to an execution queue, the only vnode attribute used to determine if a vnode is available to the job is the “queue” attribute.

PBS/Torque Limitations

- When checking for sufficient nodes and cores for the job, only nodes of type cluster are considered.
- The “exclusive” check box has no effect for PBS/Torque.
- For PBS/Torque, even if a job is submitted to an execution queue at the default server, there is no check for sufficient nodes and cores available to the queue. All of the server’s execution nodes are assumed to be available for the job.
- For PBS/Torque, there are significant limitations when submitting a job in which the number of tasks and number of cores per task are specified. Unlike PBSPro, there is no capability to specify that the cores should be allocated in “chunks”. Instead, the submission command includes the number of groups of nodes and the number of processors per node (ppn) for each node in the group. To determine the size of each group and the ppn setting for each group, the server nodes are examined from largest number of cores to smallest. This may not be optimal because some of these nodes may not be usable by the queue specified for the job, or because the nodes with the largest number of cores may be busy. Similar issues could occur for PBSPro, but they should be less likely, because only the nodes usable by the queue are considered.

Submitting Jobs Via Ansoftrsmservice on a Different Host

Before starting the ansoftrsmsevice as a daemon on a job submission host, the 'Scheduler' section of the ansoftrsmservice.cfg must be specified.

This section contains two settings, 'SchedulerName', which must be set the string 'pbs', and 'ConfigString', which must be set to the pathname of the directory containing the PBSPro or PBS/Torque commands.

Here is an example ansoftrsmservice.cfg file, showing the format of this file and an example 'ConfigString' setting:

```
$begin 'AnsoftCOMDaemon'
$begin 'Managed COM Servers'
$end 'Managed COM Servers'
$begin 'Scheduler'
'SchedulerName'='pbs'
'ConfigString'='/share/pbs/default/bin'
$end 'Scheduler'
$end 'AnsoftCOMDaemon'
```

Integration with PBS

Submitting Ansys EM PBS Batch Jobs

The PBS qsub command may be used to submit Ansys EM batch jobs. The typical command format is:

```
qsub qsub_args script
```

where:

- *qsub_args* are the options of the **qsub** command,
- *script* is the pathname of the job script.

The job script is a shell script containing the Ansys batch command or commands to be run. If a batch command line contains any characters that are special to the shell running the script, then these special characters should be quoted, as needed. The job script may also contain PBS directives on lines before the first executable line of the script. Any **qsub** options on the command line will take precedence over the PBS directives in the job script.

When a PBS batch job is started, the job script runs as the job user in a new shell. In this shell environment, the path must include the directory containing the PBS commands.

> **Note:**
>
> You should ensure that the PATH variable set in the shell startup script (e.g., .cshrc, .profile, .bashrc) includes the directory containing the PBS commands. For example:
>
> ```
> export PATH=/opt/pbs/default/bin:$PATH
> ```
>
> If the PATH variable is not set correctly, the job runs only locally, the batch log file shows the list of allocated hosts as empty, and the error file shows an error (sh: qstat: command not found.)

Further PBS directives need to be on top of the job script file. This is discussed in the PBS documentation.

Serial PBS Batch Jobs

In the PBS documentation, serial batch jobs are also called single-node jobs. In general, any job submitted without specifying the -l nodes=value command line argument, will run as a serial or single-node job.

See Monitoring PBS Batch Jobs for options that can facilitate monitoring of Ansys Electromagnetics batch jobs.

Parallel PBS Batch Jobs

In the PBS documentation, parallel batch jobs are also called multi-node jobs. When an Ansys Electromagnetics batch job is run as an PBS parallel job, the PBS scheduler will select the hosts for the distributed analysis job based on the qsub command line arguments, the PBS resource directives from the job script, and the status of the hosts when the job is run. The desktop process will be started on one of these hosts. The desktop process will obtain the list of hosts allocated to the job from the PBS scheduler, and start analysis processes on these hosts, as needed, using the PBS scheduler facilities. To run a PBS parallel job, the job must be submitted with a -l nodes=value **qsub** command line argument or with a -l nodes=value PBS directive in the job script.

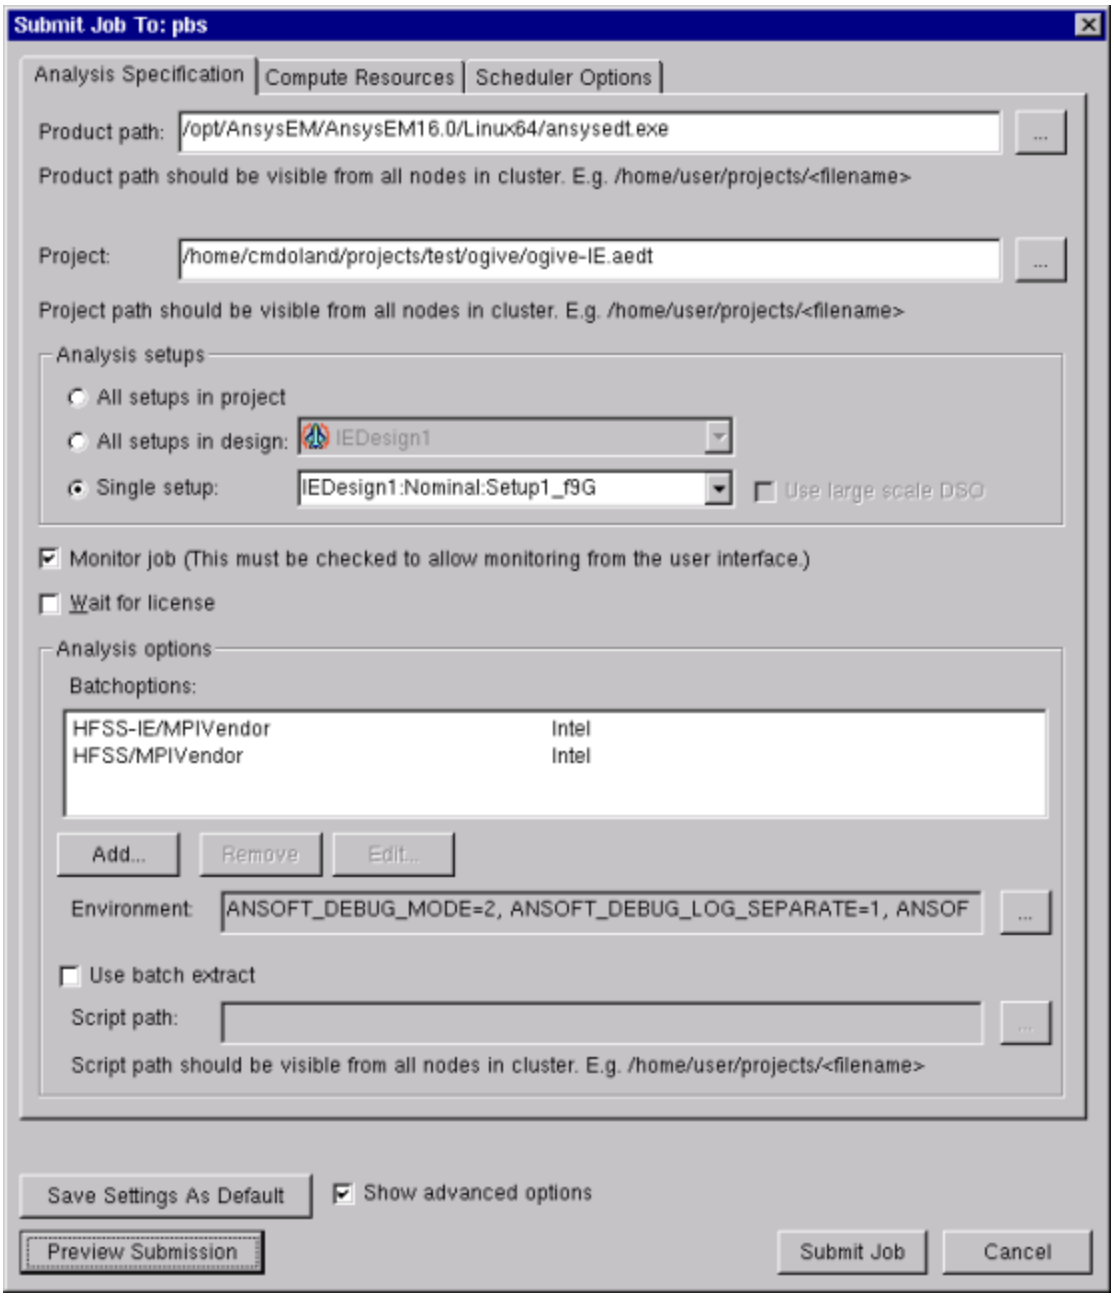
Example PBS qsub Command Lines

What a Scheduler Does

Job Management User Interface for PBS

After setting the job submission node, select **Tools>Job Management>Submit Job...** to open the **Submit Job To:** dialog box. This contains three tabs:

- **Analysis Specification**--specify the Product path, Project name, the setups, job monitoring, and analysis options such as batchoptions, or, for advanced users, Environment variables.
- **Compute Resources**--this tab can be populated either by automatic settings, by predefined Analysis Configuration, or specifying parameters in the fields for resource selection, for job parallelization and enabled forms of parallelization.
- **Scheduler Options**--contains fields for Job name and priority. The customization options shown by checking advanced are not used for Windows HPC.



In the **Analysis Specification** tab, enter the pathnames of the product path and of the project file in the “Project” edit box. These must be UNC paths that are accessible from each compute host used for Ansys Electromagnetics jobs. The submission user must have permission to write to the directory containing the project file. The Project can be an archive.

You can select which setups are analyzed in the Analyze Setups section of this dialog box. There are radio buttons to select:

- All setups in the project
- All setups in a specified design: you selects the design from the dropdown list

- Single setup:

If you specify multiple setups, they will be processed sequentially in the order displayed in the edit box.

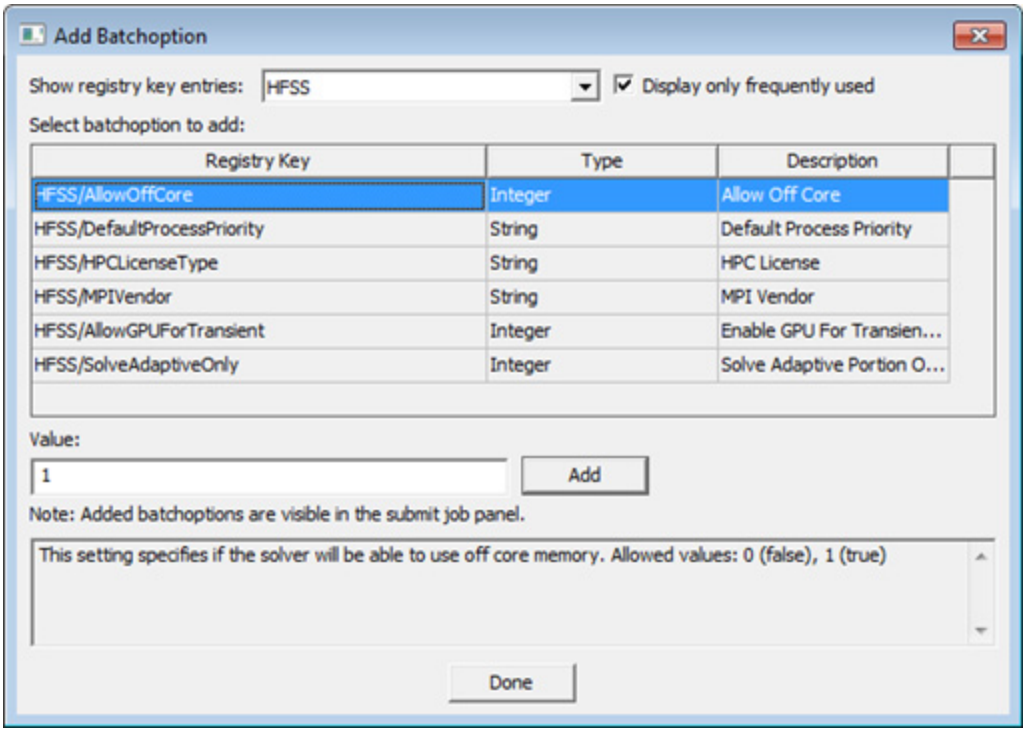
The Analysis options include:

- Monitor job. You must enable this option to monitor the job from the user interface.
- Wait for license- whether to wait until a license if available before starting a simulation.
- Batch options. You can optionally specify -Batchoptions in the text field. See detailed discussion of -Batch Options beginning under Running Maxwell from a Command Line.

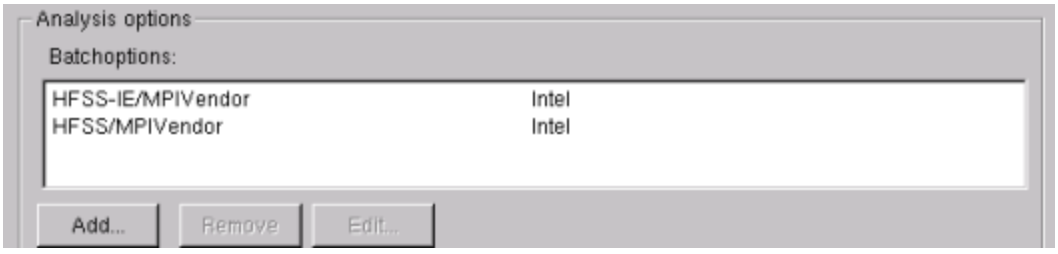
The **Add...** button opens the **Add Batchoption** dialog.

This dialog provides access to all -Batchoption commands. The drop down menu lets you select specific categories, and you can choose to display only frequently used commands. You can edit and remove any batch options you specify.

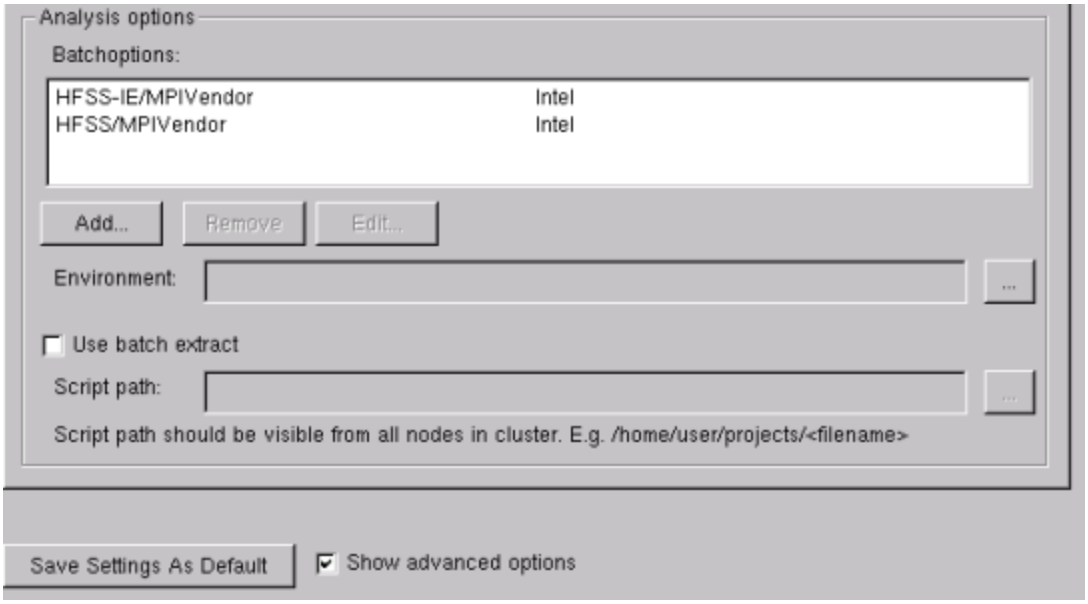
Select a Registry Key. in order to show the current Value for the type. The lower field explains the meaning of the Type Value.



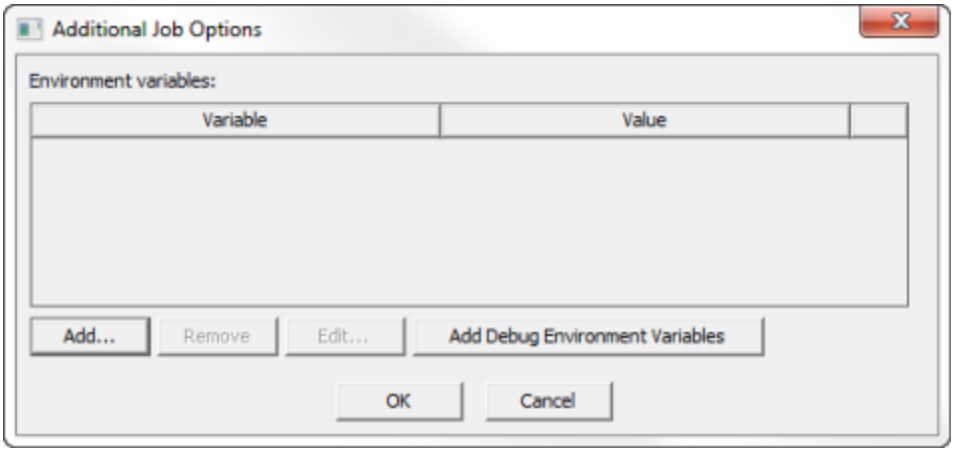
Any batchoptions for which you select **Add** will be visible in the **Submit Job** dialog.



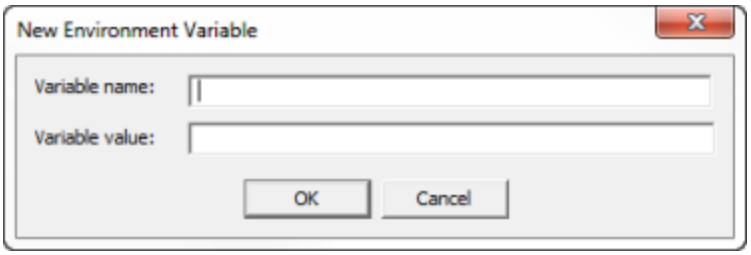
If you have the Show advanced options box checked in the **Submit Job** dialog box, the Environment field and the Use batch extract fields display.



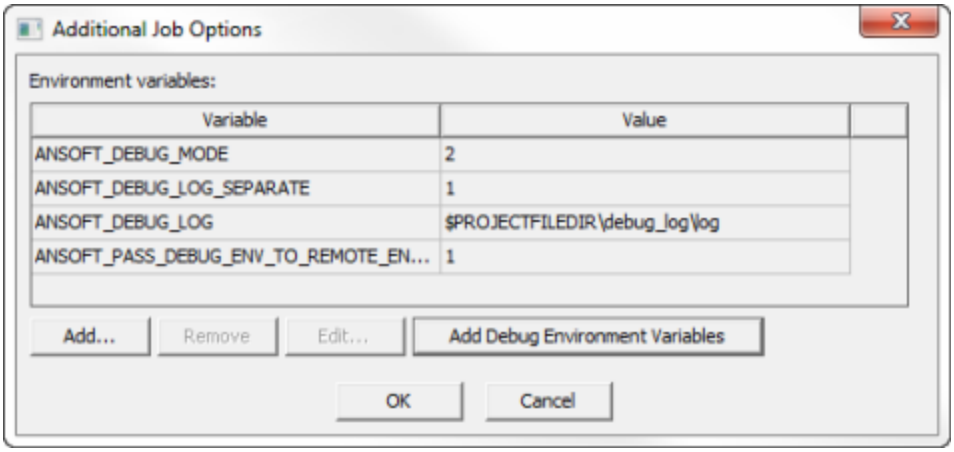
The Environment field lets you specify any Environment variables. Click the ellipsis button [...] to display the **Additional Job Options** dialog.



Click the **Add...** button to open the **New Environment Variable** dialog.



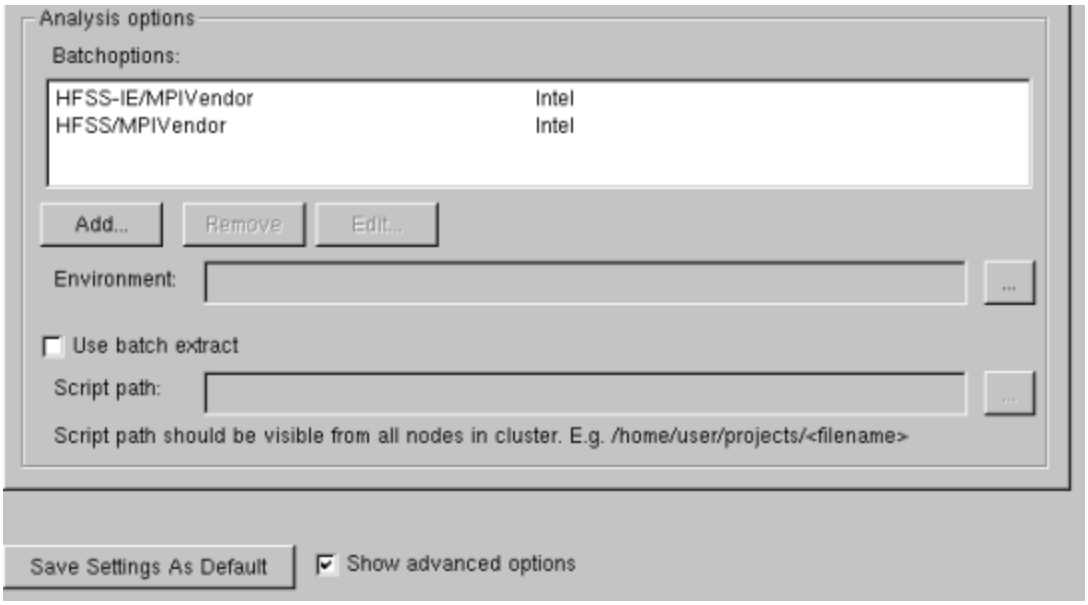
Here you can provide a Variable name and Variable value. Click OK to display the Variable in the Additional Job Options dialog box. Select a Variable to enables the **Remove** and **Edit...** buttons. You can also click **Add Debug Environment Variables**.



Any Variables that you add will be displayed in the Environment field of the **Submit Job** dialog box, if you have also enabled Show Advanced options.

Use Batch Extract for PBS

Selecting Show advanced options for PBS also show the Use batch extract fields.



See the discussion on Running Maxwell from a Command line for a discussion of the solve information available through batch extract.

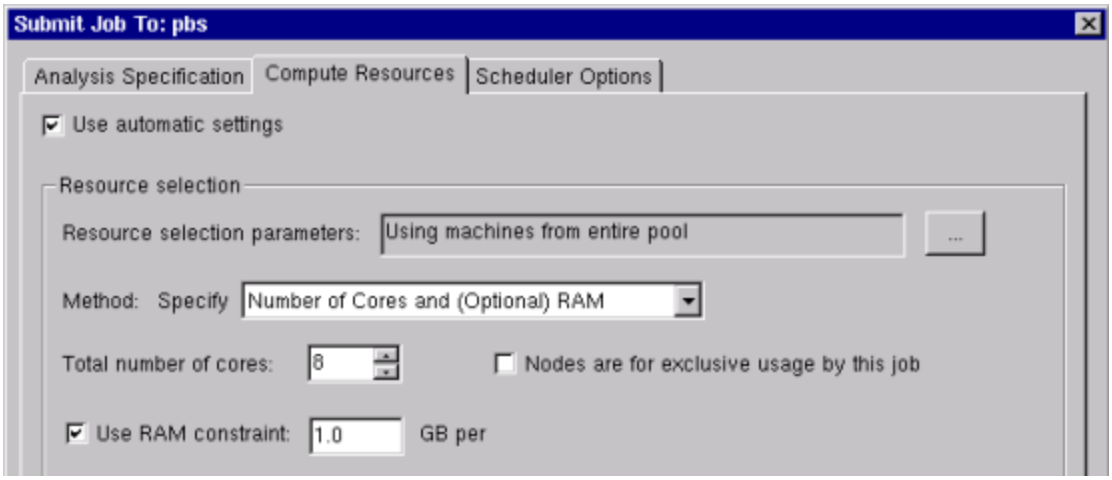
The **Preview Submission** button opens a window that shows the text commands that will be sent to the scheduler.

Compute Resource Selection for PBSPro and PBS/Torque

This section outlines how users will be able select compute resources for PBSPro and PBS/Torque jobs using the GUI. Selections include:

- Use automatic settings. If you do not select this, you specify task and/or core parameters. If you do, these task/core assignments are made automatically.
- Resource selection parameters.
- Method - drop down list with selections for Number of tasks and cores, or Number of cores and (optional) RAM, or Node List. Each method has a different set of associated parameters.
- Task and Core parameters. The parameters offered depend on Method selection.
- RAM parameters
- Job distribution.

If you select Use automatic settings with the Number of Cores and (Optional) RAM, the parameters include Total number of cores, exclusive usage option, and RAM parameters. .



Note	If you select Use automatic settings, the solver does not support automatic distribution of variations. The Use automatic settings option does not support Optimetrics variations. It does distribute frequencies, domains, and use of multiple level domains.

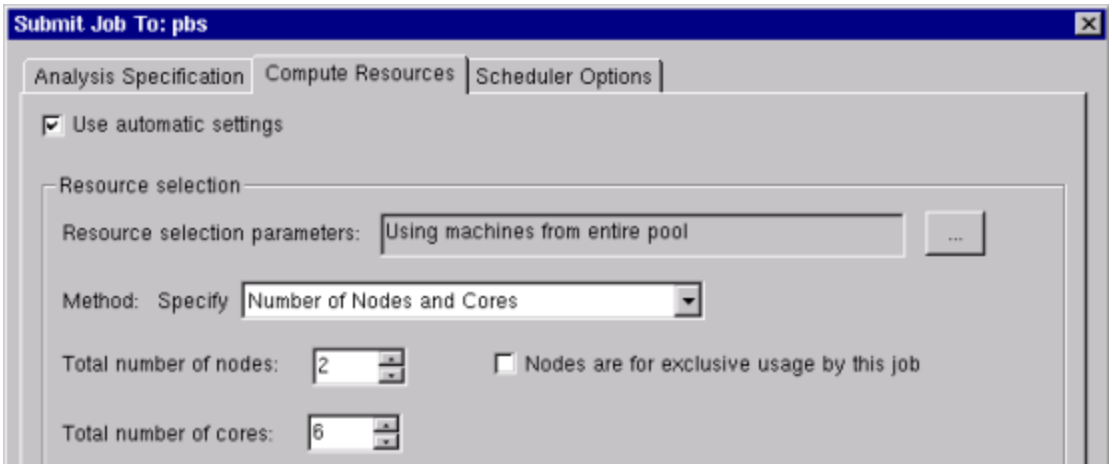
If you select Use automatic settings and Number of Cores and (Optional) RAM, and do not select Use RAM constraint, the text field is disabled

RAM Constraint

If you check **Use RAM Constraint**, you can specify a GB RAM constraint.

In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.

If you select Use automatic settings and Number of Nodes and Cores as the Method, the choices are for Number of Nodes and Cores.

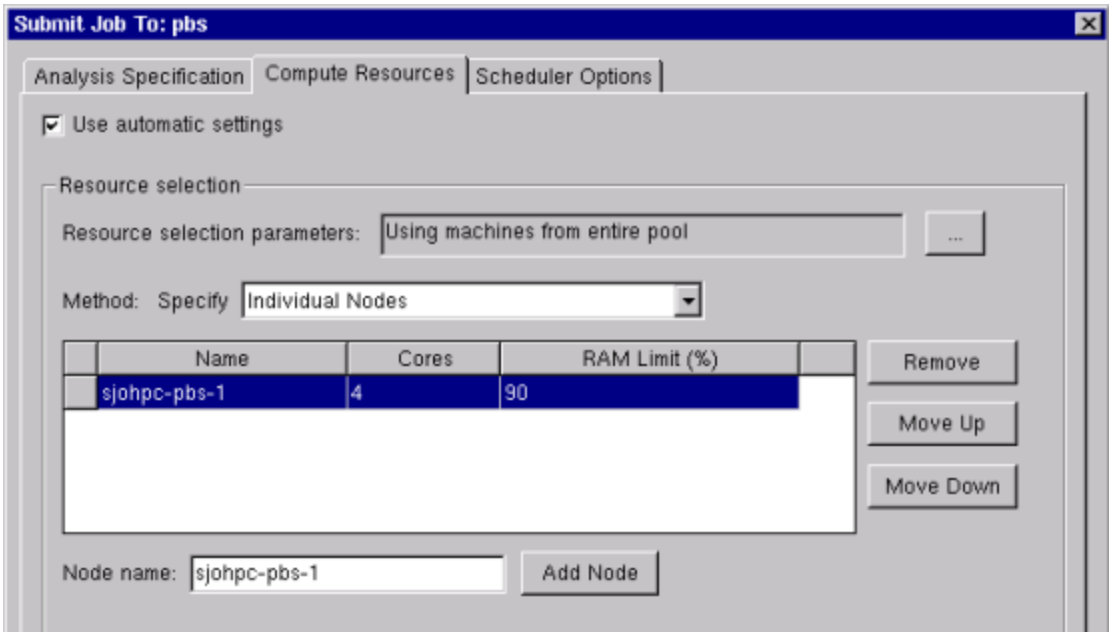


No User Specified Node List

If you do not specify the "Individual nodes" method, then the node list edit control is disabled. The user must specify resource selection parameters for nodes, cores, and tasks, depending on the method selected. If the server is the default server, then an attempt is made to determine if sufficient resources to run the job are up and available to the job on the server before it is submitted. If the server is the default server, and the queue is an execution queue, then an attempt is made to determine if sufficient resources to run the job are up and available to the job in the queue before the job is submitted. If either check fails, the job is not submitted and an error message is returned. If the server is not the default server, then there are no checks for sufficient resources before attempting to submit the job.

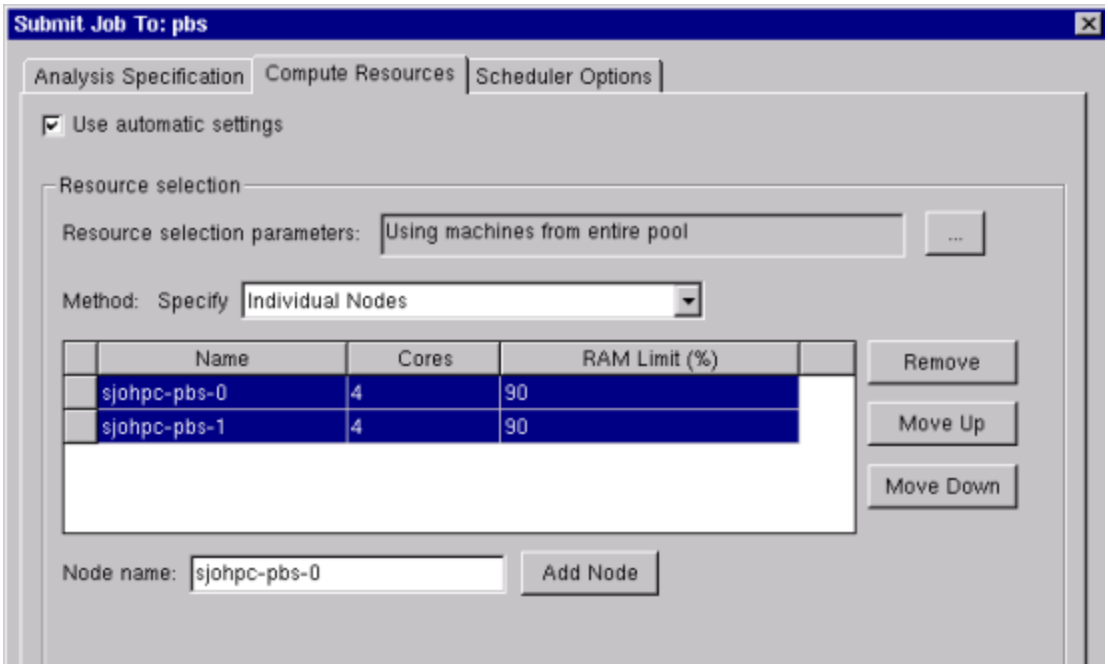
User Specified Node List for PBS

For PBSPro and PBS/Torque, a user specified explicit node list is supported when you select Individual nodes method.



With Individual nodes selected, then you may enter a list of nodes with the number of cores and RAM limit percentage. In this case, the qsub command requests exclusive access to each of these nodes for the job. If the server for the job is the default server, then the node names are validated against the execution nodes for the default server. If any of the requested nodes are not available for new jobs, then the job is not submitted and an error message is returned. If the specified (or default) queue is an execution queue, and any of the requested nodes are not available to this queue, then the job is not submitted and an error message is returned. If the server is not the default server, then the node names are not validated by the scheduler proxy. The total number of tasks and the cores per distributed task may not be specified in this case.

If you specify multiple individual nodes, you can use the Move Up and Move Down buttons to control the order. Use the Remove button to delete the selected node.



Scheduler Options tab for PBS

On the Scheduler options tab, you can specify a job name, and set a priority.

Integration with PBS (Portable Batch System) Professional from Altair Engineering

Compute Resource Selection Parameters for PBS

The user may specify the following compute resource selection parameters using the grid control in the GUI:

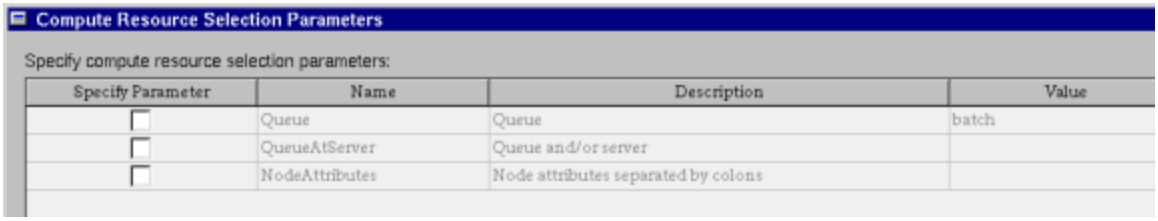
- Queue
- QueueAtServer
- NodeAttributes

These parameters are described in more detail below.

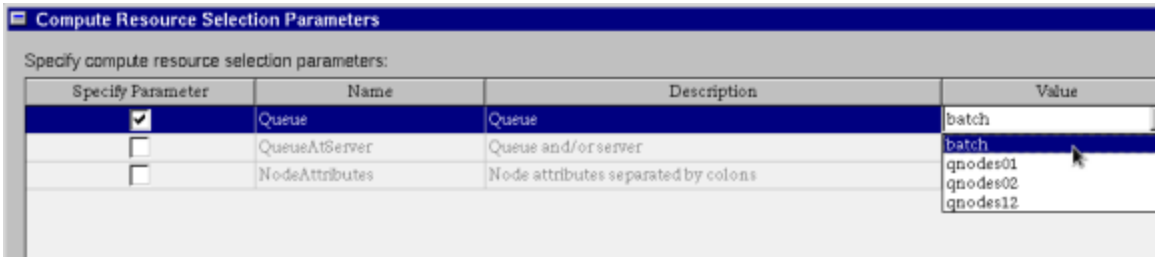
Queue

The user can select a queue for the job from the list of queues configured for the default server. Only queues that are enabled and that do not have the `from_route_only` attribute set to `true` are listed.

The following image shows the **Compute Resource Selection Parameters** dialog with no parameters specified:



The example below shows the user selecting the queue **workq** from a dropdown list containing all of the queues available at the default server.



Either the Queue or the QueueAtServer parameter may be specified, but both may not be specified. If neither the Queue parameter nor the QueueAtServer parameter is specified, then the job is submitted to the default queue at the default server.

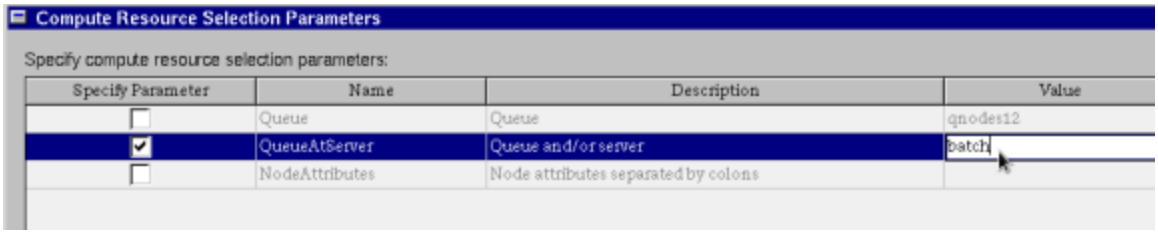
QueueAtServer

The user may specify a queue at the default server or at another server. The user may enter any text into this field. The user may enter a string in one of the following forms:

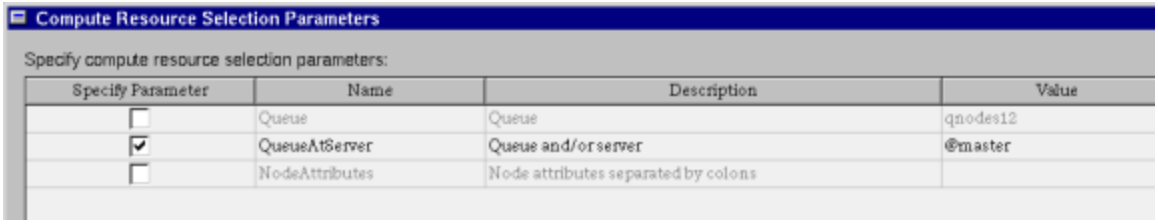
1. queue_name
2. @server_name
3. queue_name@server_name.

Using the first form, the job is submitted to the queue with name queue_name at the default server. Using the second form, the job is submitted to the default queue at the server with name server_name. Using the third form, the job is submitted to the queue with name queue_name at the server with name server_name. The *destination* value of the `-q` *destination* option on the `qsub` command line is the user specified string. This string will not be validated by the scheduler proxy library.

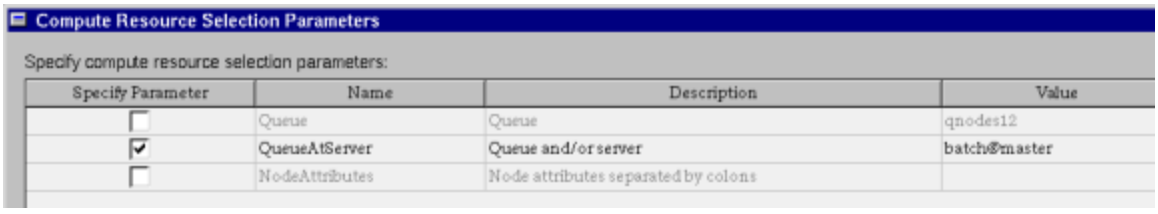
The following example shows how to enter a destination in which only a queue is specified:



The example below shows how to enter a destination in which only a server is specified:



Finally, the following example shows how to enter a destination in which both the queue and server are specified:



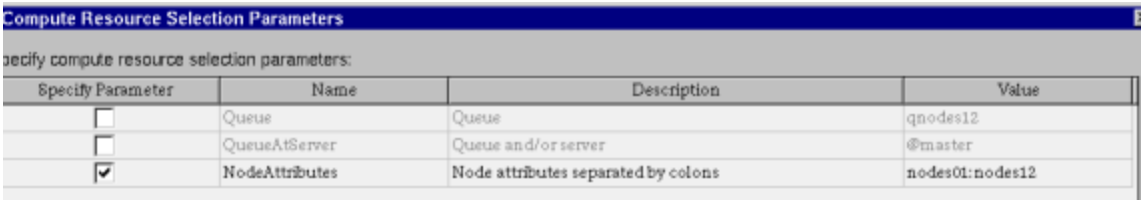
Either the **Queue** or the **QueueAtServer** parameter may be specified, but both may not be specified. If neither the **Queue** parameter nor the **QueueAtServer** parameter is specified, then the job is submitted to the default queue at the default server.

NodeAttributes

You can specify additional node attributes for the job using the **NodeAttributes** parameter. Any text can be entered into this field. If you specify multiple attribute, they should be separated by the colon character.

- For PBSPro, the contents of this field are appended to each chunk in the select resource specification of the job submission command. You can specify any resources that are valid for chunks inside a select resource specification.
- For PBS/Torque, the contents of this field are appended to each chunk in a nodes resource specification of the job submission command. In addition, only nodes that match all node features (or properties) included in the **NodeAttributes** string can be used by this job.

These are the only nodes considered when the software distributes cores to nodes. The following image shows how to specify two node attributes separated by a colon character.



The following image shows Job Preview output, which indicates how the node attributes appear in the job submission command for a PBS/Torque cluster.

Integration with PBS (Portable Batch System) Professional from Altair Engineering

Monitoring PBS Batch Jobs

You can monitor jobs through the Electronics Desktop user interface, or through the command line.

The suggestions below are for batch jobs run under PBS.

PBS qstat Command

The PBS **qstat** command may be used to display information on jobs and queues. In this section, several qstat command line options that may be used to monitor job progress are described.

- The **qstat -a** command displays information about all jobs in the system.
- The **qstat -r** command displays information about all running jobs in the system.
- The **qstat -s** command resembles the **qstat -r** command; the only difference is that a comment from the scheduler or batch administrator is also shown for each job.
- The **qstat -au** *userid* command displays information about all jobs owned by user userid.
- The **qstat -f** *jobid* command displays all available information about the job with id *jobid*.

See the PBS manual pages for more information.

Ansys Electromagnetics -monitor Command Line Option for PBS

The Ansys Electromagnetics **-monitor** command line option enables batch job output to the standard output and standard error streams. The warning, info, and progress messages are sent to the standard output stream. The error and fatal messages are sent to the standard error stream.

The PBS scheduler redirects the standard output and standard error streams of batch jobs to files specified in the **qsub -o** [*hostname*:]*pathname* and the **-e** [*hostname*:]*pathname*command line options, respectively. If either option is not specified, then the associated stream is redirected to the default file pathname for that stream.

The **qsub -j join** option controls whether the standard error stream for the job will be merged with the standard output stream for the job. A join value of **oe** indicates that the interleaved standard output and standard error will be sent to the standard output file or stream. A join value of **oe** indicates that the interleaved standard output and standard error will be sent to the standard error file or stream. A join value of n indicates that the standard output and standard error streams will not be joined. If the **qsub -j join** option is not specified, then the standard error and standard output streams will not be joined.

A user can monitor the progress of a job by checking the standard output file for progress, info and warning messages, and checking the standard error file for error and fatal messages.

Integration with PBS (Portable Batch System)

qsub Arguments

Example PBS qsub Command Lines

qsub Arguments

The PBS **qsub** command has a large number of options for control of the submission process. In this section, we review the -l nodes=*value*command line option with Ansys Electromagnetics parallel batch jobs.

This option or directive has the following format:

```
-l nodes=node_spec[+node_spec...][#suffix]
```

where *node_spec* is one of the following

```
nodename[:pc_spec[:pc_spec...]]
```

Host name of the specified node, followed by optional **ppn** or **cpp** specifiers.

```
[N][:property[:property...]][:pc_spec[:pc_spec...]]
```

Optional number of nodes, followed by optional node properties, followed by optional **ppn** or **cpp** specifiers. If the number *N* is omitted, then the default value of 1 host is used.

Here, the optional **ppn** or **cpp** specifiers *pc_spec* are of form:

```
ppn=X
```

Number of processes (tasks) per node. Default is 1 if not specified.

```
cpp=Y
```

Number of CPUs (threads) per process. Default is 1 if not specified.

The optional global suffix, #suffix, which applies to all hosts has one of the following values:

```
#excl
```

This suffix requests exclusive access to the allocated nodes.

```
#shared
```

This suffix requests shared (i.e., non-exclusive) access to the allocated nodes.

The total number of requested processes is determined by adding up the product of the number of nodes and the number of processes per node for each *node_spec*. In general, this should match the number of distributed engines specified in the Ansys Electromagnetics desktop -Machinelist num=*num_distributed_engines*command line option.

The number of CPUs per process (**cpp**) specified in the PBS **qsub** command line or in the PBS directives in the script file should generally match the number of processors per engine specified in the Desktop **-batchoptions** value.

See the PBS documentation for a complete list of options for the **bsub** command, and further information on running multi-node jobs.

Related Topics

Integration with PBS (Portable Batch System) Professional from Altair Engineering

Monitoring Ansys Electromagnetics PBS Batch Jobs

Example PBS qsub Command Lines

Example PBS qsub Command Lines

All of the following examples show how to submit Linux maxwell jobs on PBS, but similar command lines and job scripts will work for all Ansys Electromagnetics products. Most of the following examples are PBS "Single-node jobs." The last example is a PBS "multi-node jobs"; this examples demonstrate how to specify the allocation of threads, tasks and nodes to a job.

Serial job:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

Serial job that needs a minimum of 4GB memory and two hours of real (wallclock) time:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l walltime=2:00:00
#PBS -l mem=4gb
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve
~/projects/OptimTee.aedt
```

Multi-processing job using 4 cores:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l ncpus=4
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve -batchoptions
"'Maxwell3D/Preferences/NumberOfProcessors'=4"
~/projects/OptimTee.aedt
```

- The #PBS -l ncpus=4 directive indicates that four cores or CPUs are allocated to this job.
- The -batchoptions option indicates that Maxwell should use four cores for multi-processing.

Distributed processing job using 4 engines on a single host:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l ncpus=4
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve -Distributed
-machinelist num=4
~/projects/OptimTee.aedt
```

- The #PBS -l ncpus=4 directive indicates that four cores or CPUs are allocated to this job.
- The -Distributed option indicates that this is a DSO job, so that multiple engines will be started. Because 4 cores are allocated to the job, the job will run 4 engines. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".

Distributed processing and multi-processing job using 8 cores on two nodes, running 4 engines (two per node) with 2 cores for multi-processing:

```
qsub ~/pbs_scripts/OptimTee.sh
```

Job Script File:

```
#!/bin/sh
#PBS -l nodes=2:ppn=2:cpp=2#excl
/opt/AnsysEM/v231/ansysedt -ng -BatchSolve -Distributed
-machinelist num=4 -batchoptions
~/projects/OptimTee.aedt
```

- The PBS directive **#PBS -l nodes=2:ppn=1:cpp=2#shared** indicates that two nodes are requested [2], two processes (engines) run on each node [ppn=2], and each process will use two cores [cpp=2]. The hosts allocated to this job may not be used for any other jobs while this job is running [#excl].
- The **-machinelist num=4** option indicates that this is a DSO job and that a total of four engines will be started.

qsub Arguments

Monitoring Ansys Electromagnetics PBS Batch Jobs

Example PBS qsub Command Lines

Integration with SLURM Scheduler (Linux Utility)

For Linux customers, this release supports the SLURM (Simple Linux Utility for Resource Management) scheduler for job submission, monitoring, and control (abort). In addition, this provides Windows-to-Linux support for the same functionality, that is submit, monitor, and control. Using SLURM as a starting point, customers should be able to develop their own integrations for other schedulers. Ansys Electronics Desktop GUI can also check job states in the SLURM scheduler within current job monitoring. Persistence mode provides more efficient management between Desktop and scheduler proxies. Windows to Linux submission also provides convenient access to generic scheduler in Linux environments through Remote RSM Service.

When you submit a job to the SLURM scheduler or Remote RSM to a SLURM cluster, you can use their own job options to override job options in the **Scheduler Options** tab. If you want to do that, the override job options must have "--export=None".

Consult the *Linux Installation Guide* for additional information on supported schedulers.

See Integrating Ansys EM Tools with Third Party Schedulers for more information.

Configuration of the generic scheduler with SLURM

Requirements

Files must be under ${ANSYS_EM_INSTALL_DIR}/schedulers directory. Desktop and RSM service use the same required file list below.

The required files are listed here:

- ${NSTALL_DIR}/schedulers/libgeneric_scheduler.so
- ${NSTALL_DIR}/schedulers/proxies.cfg
- ${NSTALL_DIR}/schedulers/scripts/persistence.py
- ${NSTALL_DIR}/schedulers/scripts/SLURM_GetInfo_linux.py
- ${NSTALL_DIR}/schedulers/scripts/SLURM_GetRunInfo_linux.py
- ${NSTALL_DIR}/schedulers/scripts/SLURM_SubmitJob_linux.py

- ${NSTALL_DIR}/schedulers/scripts/SLURM_ControlJob_linux.py
- ${NSTALL_DIR}/schedulers/scripts/SLURM_GetJobState_linux.py
- ${NSTALL_DIR}/schedulers/scripts/SLURM_LaunchProcess_linux.py
- ${NSTALL_DIR}/schedulers/scripts/utils/ComputeResourceList.py
- ${NSTALL_DIR}/schedulers/scripts/utils/ErrorCode.py
- ${NSTALL_DIR}/schedulers/scripts/utils/__init__.py
- ${NSTALL_DIR}/schedulers/scripts/utils/RunCommand.py
- ${NSTALL_DIR}/schedulers/scripts/utils/slurm-intelMPI-integration.sh

Environment Variables

There are some environment variables for the Generic Scheduler proxy. All environment variables apply on both Desktop and RSM Service.

ANSYSEM_HPC_MPI_USE_SSH

MPI tight integration is disabled if this variable is set. If this environment variable not set, the proxy will use tight integration to run jobs. If MPI tight integration needs to be disabled, set this environment variable before launching Ansys Electronics Desktop to submit jobs, and submit this environment variable to job execution nodes with job configuration.

ANSYSEM_GENERIC_SCRIPT_DIR

This variable adds a customized directory to be searched for proxy scripts. The path can be any form of following addresses. Persistence script path will not change.

- absolute address to any folder with read access
- relative address to folder under the Electronics Desktop installation directory
- relative address to folder under the schedulers directory
- relative address to folder under the schedulers/scripts directory

ANSYSEM_GENERIC_EXEC_PATH

This variable adds customized directories to be searched for proxy executables. Mono executable and IronPython executable should be specified when they are not in the Ansys Electronics Desktop installation. This environment variable must be set for RSM Service.

ANSYSEM_GENERIC_PROXY_PERSISTENCE

If set, this variable redirects the persistence script location to be used; otherwise, the default persistence script path is used.

Configuration File

The configuration file "proxies.cfg" is located at ${ANSYS_EM_INSTALL_DIR}/schedulers/. The file can have multiple scheduler configurations. The file content and explanation are below.

[slurm] ***# Unique scheduler name***

DisplayName=SLURM ***# Display name in GUI***

 # Proxy Scripts

SubmitJob=scripts/SLURM_SubmitJob_linux.py

ControlJob=scripts/SLURM_ControlJob_linux.py
GetSchedInfo=scripts/SLURM_GetInfo_linux.py
GetJobState=scripts/SLURM_GetJobState_linux.py
GetRunInfo=scripts/SLURM_GetRunInfo_linux.py
LaunchProcess=scripts/SLURM_LaunchProcess_linux.py
 # Persistence Mode
Persistence=Yes

Persistence Mode

Persistence mode uses a persistent process to communicate with Ansys Electronics Desktop and proxy scripts. If persistence mode is disabled, Ansys Electronics Desktop uses proxy scripts directly. Enabling persistence mode may help speed up communication with proxy scripts.

> **Note:** Disabling persistence will cause large delays in GUI functionality. The primary use case of disabling persistence is to support troubleshooting.

- To enable persistence mode, make sure "Persistence=Yes" is in configuration file before launching Ansys Electronics Desktop.
- To disable persistence mode, make sure "Persistence=No" is in configuration file before launching Ansys Electronics Desktop.

Remote RSM Service Support

In ansoftrsmservice.cfg, fill your scheduler information from configuration file proxies.cfg as below. SchedulerName must be generic. Change "Proxy" as needed.

```
$begin 'Scheduler'
'SchedulerName'='generic'
'ConfigString'='{"Proxy":"slurm"}'
$end 'Scheduler'
```

Then, set the environment variable “ANSYSEM_GENERIC_EXEC_PATH” with Mono and IronPython path. Multiple paths can be filled with delimiter “:”. Ansys Electronics Desktop has built-in components in AnsysEM installation path, and you can replace the installation path like:

```
ANSYSEM_GENERIC_EXEC_PATH= <AnsysEM
Installation>/Linux64/common/mono/Linux64/bin:<AnsysEM
Installation>/Linux64/common/IronPython
```

Also set environment variable “ANSYS_EM_GENERIC_COMMON_TEMP” to a directory widely accessible to users using Remote RSM Service on the cluster. This environment variable specifies a temporary folder to use. Thus, it must be accessible for most users.

```
ANSYS_EM_GENERIC_COMMON_TEMP=/tmp
```

Then, launch **ansoftrsmservice** in the AnsysEM RSM installation folder. (Be sure not to confuse AnsysEM (Ansoft) RSM with ANSYS RSM since these are two very different things.) It is

recommended that the user for **ansoftrsmservice** should be a dedicated service user account for only running **ansoftrsmservice**. This account should have limited permissions for security reasons. The service user should not have a login. It is recommended to disable login, so that the only way to run as the user is to “su” to that user from the root (or other accounts with sudo permissions). Other users can use any account credentials in the Desktop Select Scheduler GUI to submit jobs as the requested user.

Using the generic scheduler with SLURM

To select scheduler and get scheduler information:

1. Click **Tools** > **Job Management** > **Select Scheduler...**, or select the **Simulation** tab on the ribbon, and click the **Scheduler** icon.

   This opens the **Select Scheduler** dialog box.
2. Select **SLURM** from the drop-down menu; or, if the Remote RSM service is used, fill in scheduler master node address, and use valid account credentials.
3. Click **Refresh**.

   Scheduler Information should show.
4. Click **OK** to select the scheduler.

   Submit Jobs and Monitor Jobs with SLURM

   Job submission and monitoring follow the same process and method as using other schedulers. Currently, submission using a node-list is not supported.
5. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.

Using MPI Tight Integration

By default, jobs would be submitted with SSH as remote spawn command method. If MPI tight integration preferred, you should submit the job with an additional batch option setting in the Submit Job Browser:

Enable MPI Tight Integration:

```
<design-type>/RemoteSpawnCommand = “Scheduler”
```

Enable SSH:

```
<design-type>/RemoteSpawnCommand = “SSH”
```

Selecting a Scheduler

Submitting a Job

Monitoring Jobs

Running Ansys Electronics Desktop from the Command Line

Command Line Information for HPC

Ansys Electromagnetics Jobs

For most cluster environments, an Ansys Electromagnetics job will consist of an Ansys Electromagnetics Desktop running in non-graphical mode, performing a batch solve. The user will submit the job to the scheduler, specifying an Ansys Electromagnetics Desktop command line to be executed on the cluster. For some schedulers, the user may or must specify a script to run instead of specifying the Ansys Electromagnetics Desktop command line; in these cases, the script will contain the corresponding Ansys Electromagnetics Desktop command line. When the resources requested for the job are available to the job, the scheduler will start the job. In many cases, the user submitting the job will not know which host or hosts are allocated to the job. With direct integration, if the Ansys Electromagnetics job is a distributed job, the Ansys Electromagnetics Desktop will query the scheduler for the hosts allocated to the job, and it will use the scheduler facilities to launch the distributed engines.

Related Topics

High Performance Computing (HPC) Integration

Running Maxwell from a Command Line

Command Line Information for Ansys Electromagnetics Suite Desktop Products

Any **Tools>Options** setting can be specified via command line, using corresponding registry keys.

This feature is available in all desktop products.

Examples

```
ansysedt.exe -batchsolve
-batchoptions -machinelist num=2
"'Maxwell/HPCLicenseType'=pool
projectname.aedt
```

This example demonstrates how to set the same options as the previous example, but here using a registry.txt file:

```
ansysedt.exe -batchsolve -batchoptions registry.txt
projectname.aedt
```

Registry.txt contains:

```
$begin 'Config'-machinelist num=2
'Maxwell/HPCLicenseType'=pool
$end 'Config'
```

Distributed Jobs

An Ansys Electromagnetics batch job which distributes the analysis over several hosts may also be called a distributed job. To submit a distributed job, the following Ansys Electromagnetics desktop command line options should be used:

- The -Distributed option should be present, and the -Local option should be absent. When running as a batch job under one of the schedulers with direct integration, this option is a directive to the job to 1) obtain the list of hosts allocated to the job, directly from the scheduler, and to 2) use the scheduler to launch the analysis engines on the hosts allocated to the job.
- The -Machinelist num=*num_distributed_engines*option should be included, where *num_distributed_engines*is the total number of analysis engines to be started on the hosts assigned to the job.

Other examples:

- Serial Job on a Single Processor
- Distributed Job using Four Processors
- Multiprocessing Job Using Four Cores
- Distributed Analysis and Multi-Processing in the Same Job

Serial Job on a Single Processor

Suppose Maxwell is installed at “C:\Program Files\AnsysEM\v231\Win64\” and you are using AnsoftRSMService for remote-analysis/DSO:

```
C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng
-BatchSolve -machinelist num=2
-monitor \\shared_drive\projs\OptimTee.aedt
```

User is using LSF for remote-analysis/DSO

```
bsub -n 1 C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng
-BatchSolve -machinelist num=3 -monitor -local \\shared_
drive\projs\OptimTee.aedt
```

Distributed Job using Four Processors

RSM Service

```
C:\Program Files\AnsysEM\v231\win64\ansysedt.exe-ng -Batchsolve
-monitor -Distributed
-machinelist list="10.1.1.221, 10.1.1.222, 10.1.1.223,
10.1.1.224" \\shared_drive\projs\OptimTee.aedt
```

LSF

```
bsub -n 4 C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng
-Batchsolve -monitor
-Distributed -machinelist num=4
\\shared_drive\projs\OptimTee.aedt
```

Multiprocessing Job Using Four Cores

Multi-processing job using 4 cores

```
bsub -n 4 -R "span[ptile=4]" C:\Program
Files\AnsysEM\v231\win64\ansysedt.exe -ng -monitor
-Local -BatchSolve -machinelist num=4 -batchoptions \\shared_
drive\registry.txt \\shared_drive\projs\OptimTee.aedt
```

This requests 4 cores to come from the same machine, as multi-processing needs cores to be on the same machine

Distributed Analysis and Multi-Processing in the Same Job

Distributed-processing using 4 engines and multi-processing using 4 cores, using a total of 16 cores

```
bsub -n 16 -R "span[ptile=4]" C:\Program
Files\AnsysEM\v231\win64\ansysedt.exe -ng
-BatchSolve -Distributed -machinelist num=4
-batchoptions \\shared_drive\registry.txt
\\shared_drive\projs\OptimTee.aedt
```

Integrating Ansys Electromagnetics Tools with Third Party Schedulers

This section indicates how to create a dynamically linked library to allow integration of Ansys Electromagnetics tools with an arbitrary scheduler environment. Each scheduler proxy library is used for a single specific scheduler environment. If the library is installed with a valid name and in the correct location, then it will automatically be loaded and used by Ansys Electromagnetics tools.

- Introduction
- Common Requirements for Running Jobs
- Using a Shared Library (Linux) or a DLL (Microsoft Windows)

- Scheduler Proxy Interfaces
- Using an IronPython Program for Scheduler Integration

Introduction

Ansys Electromagnetics Software Tools may be run as serial or parallel jobs on a cluster under control of a scheduler. Serial jobs are run using a single analysis engine at any one time on a single host. If the tool performs multiple analyses (for a frequency sweep or a parametric analysis, for example), the analyses are performed one after the other. Parallel jobs are run using multiple analysis engines running in parallel on the same host or on separate hosts. For parts of the analysis (such as meshing), the parallel job may use only a single analysis engine on a single host. Other parts of the analysis (such as a frequency sweep, parametric analysis or DDM, for example) may be distributed to multiple analysis engines running in parallel.

- Serial Jobs
- Parallel Jobs

Serial Jobs

When an Ansys Electromagnetics batch analysis runs as a serial job, the analysis engines run on the same host as the desktop process. The desktop process does not need to interact with the scheduler to get the names of hosts allocated to the job or to start processes on other hosts.

Parallel Jobs

For a parallel job, the desktop process starts multiple analysis engines that run in parallel. These engines may be started on the host where the desktop process is running, or on other hosts allocated to the job. The desktop process interacts with the scheduler to obtain information on the hosts that are allocated to the job, and to start engines on the local host or on other hosts allocated to the job. This document provides information on how to facilitate this interaction between the desktop process and the scheduler controlling the cluster.

For some popular job schedulers in a standard configuration, Ansys Electromagnetics provides an "out of the box" integrated solution that will work with the scheduler. In this case, the Ansys Electromagnetics installation includes code that will determine if the analysis is running as a scheduler job and communicate with the scheduler when needed. For other schedulers, the code to obtain information about the hosts allocated to a job and to distribute portions of the job to hosts assigned to the job is not provided in the installation. In order to facilitate using Ansys Electromagnetics software tools with other schedulers, the user may provide a way for Ansys Electromagnetics tools to interact with the scheduler. Currently, two general approaches are available to users.

In the first approach, the user creates a shared library (on Linux) or a dynamically linked library (on Microsoft Windows) to provide communication between the Ansys Electromagnetics tool and the scheduler. This library is loaded by the Ansys Electromagnetics tool at runtime, and if the Ansys Electromagnetics tool is running as part of a scheduler job, the Ansys Electromagnetics tool interacts with the library to get information from the scheduler, and to start additional processes on specified hosts. Each such library implements the same set of extern "C" functions needed to

mediate the interactions between the Ansys Electromagnetics tool and the scheduler. The details of these functions are described below.

In the second approach, the user creates an IronPython program to provide communication between the Ansys Electromagnetics tool and the scheduler. This program is loaded by the Ansys Electromagnetics tool at runtime, and if the Ansys Electromagnetics tool is running as part of a scheduler job, the Ansys Electromagnetics tool uses the IronPython program to get information from the scheduler, and to start additional processes on specified hosts. Each python script contains a class implementing a specified interface, which contains functions needed to mediate the interactions between the Ansys Electromagnetics tool and the scheduler. The details of the interface are described below. The IronPython interface is equivalent to the extern "C" functions used in the first approach.

Common Requirements for Running Jobs

The following requirements must be met for serial and parallel jobs to run successfully. They apply whether using "out of the box" scheduler integration or scheduler integration using a library or using an IronPython program. When we refer to host requirements, the requirements apply to all hosts that may be allocated to an Ansys Electromagnetics serial or parallel batch job.

Installation Requirements

The Ansys Electromagnetics installation directory tree must be accessible from all cluster hosts using the same path. One way to achieve this is to place the Ansys Electromagnetics installation on a shared drive that is accessible to the cluster hosts using the same pathname. On Windows, this may require the use of UNC names to refer to the installation directory. Another option is to install the Ansys Electromagnetics tool locally on each cluster host using the same local directory pathname.

Project File and Directory Requirements

The directory containing the project file must also be available from all cluster hosts using the same path. The project file and the containing directory must be readable and writable by the user account used to run the job. The controlling process for a distributed job is called the Desktop process, and it reads from and writes to the project file and other files in the same directory and its subdirectories. Although only the Desktop process reads from and writes to this directory, the Desktop process may be started on any of the hosts allocated to the job, so all hosts should have access to this directory using the same pathname.

Using a Shared Library (Linux) or a DLL (Microsoft Windows)

This section describes how to create a dynamically linked library to allow integration of Ansoft tools with an arbitrary scheduler environment. Each scheduler proxy library is used for a single specific scheduler environment. If the library is installed with a valid name and in the correct location, then it will automatically be loaded and used by Ansys Electromagnetics tools.

Installation Details

The scheduler proxy library must be installed in the schedulers subdirectory of the Ansys Electromagnetics installation directory. For example, if the Ansys Electromagnetics installation directory is C:\Program Files\AnsysEM\v231\Win64, then the scheduler proxy library must be installed in directory C:\Program Files\AnsysEM\v231\Win64\schedulers.

The scheduler proxy library base name must match "libprefix_scheduler" on Windows and "liblibprefix_scheduler" on Linux. The extension must be a valid extension for a dynamically loaded library on the platform where it is used. The scheduler proxy library name prefix libprefix shall be unique, so it does not conflict with other scheduler proxy libraries in the same directory. To avoid confusion, the scheduler proxy library name should be all lower case on OSs where file names are case sensitive.

Build Information for Scheduler Proxy Library

This section contains the recommended compiler and linker settings for building a scheduler proxy library.

- 32 Bit Microsoft Windows
- 64 Bit Microsoft Windows
- Linux

32 Bit Microsoft Windows

The proxy library should be compiled and linked as a 32 bit DLL, using the following recommended compiler and linker options:

Compiler Options

- Use of MFC: Use Standard Windows Libraries
- Character Set: Use Multi-Byte Character Set [/D "_MBCS"]
- Runtime Library: Multi-threaded DLL [/MD]
- Calling Convention: __cdecl [/Gd (default)]

Linker Options:

- Create a DLL [/DLL]
- 32 bit code [MACHINE:X86]

64 Bit Microsoft Windows

The proxy library should be compiled and linked as a 64 bit DLL, using the following recommended compiler and linker options:

Compiler Options

- Use of MFC: Use Standard Windows Libraries
- Character Set: Use Multi-Byte Character Set [/D "_MBCS"]
- Runtime Library: Multi-threaded DLL [/MD]
- Calling Convention: __cdecl [/Gd (default)]

Linker Options:

- Create a DLL [/DLL]
- 32 bit code [MACHINE:X64]

Linux

The proxy library should be compiled and linked as shared library (*.so) file. The following compiler and linker options are recommended when building using gcc/g++:

Compiler Options

- Generate 32 bit code: [-m32]
- Generate position independent code, suitable for use in a shared library: [-fpic]
- Generate code compatible with pthreads library: [-pthread]

Linker Options:

- Create a shared object file: [-shared]
- Generate 32 bit code: [-m32]
- Generate position independent code, suitable for use in a shared library: [-fpic]
- Generate code compatible with pthreads library: [-pthread]

Implementation Details for Custom Scheduler Integration

Function Name Prefix

Each exported function will have a scheduler specific function name prefix. The function name prefix will be the same as the library name prefix, except that it is converted to upper case. For example, if the library name prefix is "lsf", then the function name prefix is "LSF". In the examples below, we use FN_PREFIX to denote the function name prefix.

The scheduler proxy library must provide implementations of the following extern "C" functions:

- IsProductLaunchedInYourEnvironment
- GetTempDirectory
- GetMachineListAvailableForDistribution
- LaunchProcess
- GetUseRsmForEngineLaunch

- GetThisJobID
- GetSchedulerDisplayName

IsProductLaunchedInYourEnvironment

Purpose

Determine if the program is running in the context of the scheduler for which this library was written.

Signature

```
extern "C" bool FN_PREFIX_IsProductLaunchedInYourEnvironment();
```

Arguments

None.

Return Value

Returns true if the current process is running as a job of the scheduler. Otherwise, false is returned.

Notes

For many schedulers, the presence of certain environment variables or their values may be checked to determine if the current process is running as a job of the scheduler.

GetTempDirectory

Purpose

Get the pathname of the temporary directory provided by the scheduler for the current job. The pathname is an empty string if the scheduler does not provide a temporary directory for the current job.

Signature

```
extern "C" bool FN_PREFIX_GetTempDirectory(char * buffer,
unsigned int* length);
```

Arguments

`buffer`: Pointer to a character buffer to contain the temporary directory path name or NULL.

`length`: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the pathname of the temporary directory, including the terminal null byte, then the pathname is copied to the buffer and true is

returned. If the buffer length is insufficient for the pathname of the temporary directory, then the buffer is unchanged, and false is returned.

Notes

To get the pathname of the temporary directory, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the pathname. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

GetMachineListAvailableForDistribution

Purpose

Get the list of hosts allocated to the current job. A host will appear in the list multiple times if the scheduler has allocated multiple processors or cores on the host to the job. The number of times the host appears in the list is equal to the number of processors or cores of the host that are allocated to the current job. The list is a text string containing a space separated list of hostnames.

Signature

```
extern "C" bool FN_PREFIX_
GetMachineListAvailableForDistribution(char * buffer, unsigned
int* length);
```

Arguments

`buffer`: Pointer to a character buffer to contain the list of machines available for distribution or NULL.

`length`: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the lists of hosts, including the terminal null byte, then the list is copied to the buffer and true is returned. If the buffer length is insufficient for the list of hosts, then the buffer is unchanged, and false is returned.

Notes

To get the list of hosts for distribution, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the list. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

The hostnames in the list provided by this function shall be used in calls to LaunchProcess(). These host names must be in a format that is accepted by that function. See the section below on LaunchProcess.

LaunchProcess

Purpose

Launch a local or remote process to run an analysis engine. This function is called by the Ansys Electromagnetics desktop application to launch an engine process on a specified host. The hostname is one of the names in the list provided by the GetMachineListAvailableForDistribution function. See the GetMachineListAvailableForDistribution section above. If the hostname does not refer to the local host, then this function shall use the scheduler to launch the engine on the specified host. If the hostname refers to the local host, then the engine may be started as a child process, or it may be started using the scheduler.

Signature

```
extern "C" int FN_PREFIX_LaunchProcess(const char* hostName,
const char* exePathName, const char* arg1, const char* arg2);
```

Arguments

`hostName`: The name of the host where the process is to be launched.

`exePathName`: The pathname of the analysis engine executable to be started.

`arg1`: The first argument of the analysis engine command line.

`arg2`: The second argument of the analysis engine command line.

Return Value

Returns 0 on success. Returns a non-zero value if an error occurs.

Notes

The hostName argument will be one of the hostnames provided by the function `GetMachineListAvailableForDistribution()`.

If the hostName argument is the same as the current host, then the analysis engine process may be started as a child process. If the hostName argument is not the same as the current host, then the analysis engine process will be started on the remote host using the facilities available in the scheduler environment. The command line of the analysis engine process is `exePathName arg1 arg2`. The command line arguments `arg1` and `arg2` may contain newlines, tabs, spaces or other characters that are interpreted by the command processor, such as single quote (') or double quote (") characters, or dollar signs ($). Newlines or tabs may be replaced by spaces, if the newline or tab characters cannot be easily handled. If the analysis engine command is processed by a shell, then it may be necessary to quote any special characters in the `exePathName` or in the arguments so that the special meaning is removed. If a scheduler command is used to request the scheduler to launch the command to start the engine process, the analysis engine command may be processed by the shell twice: once when the scheduler command is processed, and a second time when the analysis engine process is started. If this is the case, then the quoting of special characters needs to account for two passes through the command processor.

GetUseRsmForEngineLaunch

Purpose

This function is optional. If this feature is not needed, then the function need not be implemented. Most schedulers should not need this feature.

For some schedulers, it may be desirable for the Ansys Electromagnetics RSM service to launch the engine processes instead of using the scheduler proxy library. For example, if the scheduler proxy library is limited to launching one process per host, then the scheduler proxy library may be used to launch one Ansys Electromagnetics RSM service executable per host, and the Ansys Electromagnetics RSM executable will launch all of the engine processes.

If the Ansys Electromagnetics RSM service should be used to launch engine processes for this scheduler, then this function shall be implemented and it shall return true.

If the Ansys Electromagnetics RSM service should not be used to launch engine processes for this scheduler, then this function is not required. If it is implemented, it should return false. If it is not implemented, it will be treated the same as if it was implemented and returns false.

Signature

```
extern "C" bool FN_PREFIX_GetUseRsmForEngineLaunch(void)
```

Arguments

None.

Return Value

Returns true if the Ansys Electromagnetics RSM service should be used to launch engine processes for this scheduler. Returns false if the Ansys Electromagnetics RSM service should not be used to launch engine processes for this scheduler.

Notes

This function is optional. If not implemented, then it is treated the same as if it was implemented and returns false.

GetThisJobID

Purpose

Get a string identifying the job currently running in the scheduler environment. This string is displayed to the end user to identify the job.

Signature

```
extern "C" bool FN_PREFIX_GetThisJobID(char * buffer, unsigned
int* length);
```

Arguments

`buffer`: Pointer to a character buffer to contain the Job ID or NULL.

`length`: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the string identifying the current job, including the terminal null byte, then the job ID is copied to the buffer and true is returned. If the buffer length is insufficient for the job ID, then the buffer is unchanged, and false is returned.

Notes

To get the job ID, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the job ID. After creating a buffer of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

For many schedulers, the job ID may be obtained from the value of an environment variable.

GetSchedulerDisplayName

Purpose

Get a string identifying the scheduler associated with the current scheduler proxy library. This string is displayed to the end user to identify the scheduler.

Signature

```
extern "C" bool FN_PREFIX_GetSchedulerDisplayName(char *
buffer, unsigned int* length);
```

Arguments

buffer: Pointer to a character buffer to contain the scheduler display name or NULL.

length: Pointer to a location to contain the length of the buffer. Must be a valid pointer to an unsigned int.

Return Value

If argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned.

If argument buffer is not NULL, then the value to which argument length points (the buffer length) is checked. If it is large enough to contain the scheduler display name, including the terminal null byte, then the scheduler display name is copied to the buffer and true is returned. If the buffer length is insufficient for the scheduler display name, then the buffer is unchanged, and false is returned.

Notes

To get the scheduler display name, the infrastructure first calls this function with a NULL buffer, and obtains the required length of the buffer for the scheduler display name. After creating a buffer

of the appropriate size, the infrastructure calls this function again, passing the pointer to the buffer in the buffer argument and a pointer to the size of the buffer in the length argument.

The scheduler display name is generally a fixed string.

Scheduler Proxy Interfaces

Scheduler proxy supports the following new graphical interface functions. The scheduler specific prefix of each function is not shown in this listing.

void Initialize(const std::string& config):

Initialize the proxy library for scheduler interaction. The **config** argument contains scheduler specific initialization information.

int CheckEnvironment(std::string& msg):

Check the environment in which the proxy library is running.

- Returns 0 (success) if the environment is appropriate for submitting jobs to the scheduler.
- Returns a non-zero error code if the environment is incorrect. If a non-zero error code is returned, an error message to display to the user is written to the msg argument.

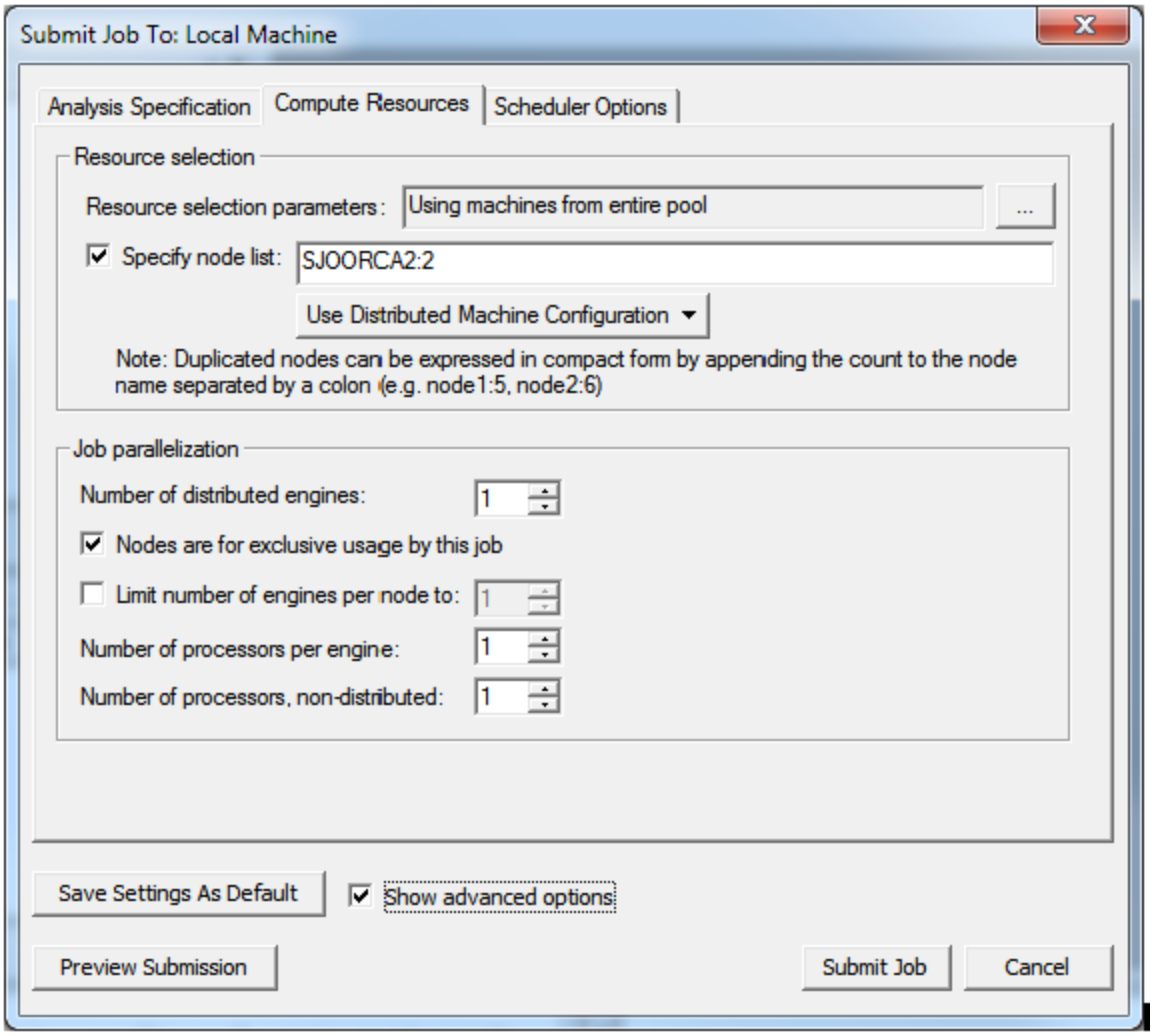
int GetSchedulerInfo(std::string& msg, std::string& schedulerName, std::string& schedulerDescription, std::string& schedulerVersion):

This function returns some basic information about the scheduler with which the scheduler proxy library interacts.

- On success, 0 is returned, and the scheduler name, scheduler description, and scheduler version are written to the **schedulerName**, **schedulerDescription** and **schedulerVersion** arguments.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

int GetComputeResourceAttributes(std::string& msg, AttributeDefinitionsStruct& attributeDefs):

The **Compute Resource Selection Parameters** dialog allows the user to specify scheduler specific resources. This function returns the information used to create and populate the Compute Resources tab in the Submit Job To: dialog box.



Each line in the dialog is defined by a single attribute definition in the **attributeDefs** argument. An attribute definition defines the name and description of an attribute, as well as information about the allowed values and the default value. In general, only the most commonly specified job attributes are included in the **attributeDefs** argument.

- On success, 0 is returned, and the attribute definitions are written to the **attributeDefs** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.
- If the scheduler proxy library does not support any attributes using this approach, the **attributeDefs** argument will contain no attribute definitions, and 0 will be returned.

int AbortJob(std::string& msg, const std::string& jobID, bool force, const SubmissionUserStruct& submissionUser):

This function requests the scheduler to abort a job identified by the **jobID** argument. If the force argument is true, then errors should be ignored (the exact behavior is scheduler specific). The **submissionUser** argument contains information about the client user (the

user running the Desktop process). The request to abort the job should run in the context of this user. If no user is specified, then the request to abort the job runs as the user of the process or thread running the function.

- If the request is successfully submitted, then 0 is returned.
- If there is an error, then a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

int SubmitUniformJob(std::string& msg, std::string& jobID, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const UniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser,const IJobParameters* jobParametersCB):

This function submits a job to the scheduler.

- On success, 0 is returned, and the job identifier of the newly submitted job is written to the **jobID** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

This function is used to submit jobs to the scheduler in which the resources allocated to the job are uniformly distributed across the nodes allocated to the job. All other arguments are input arguments, and they are described below:

The **cmdLineInfo** argument contains the command line arguments. The first argument is the command name.

The **jobParallelization** argument contains information on how the job should be parallelized. It contains the following integral parameters:

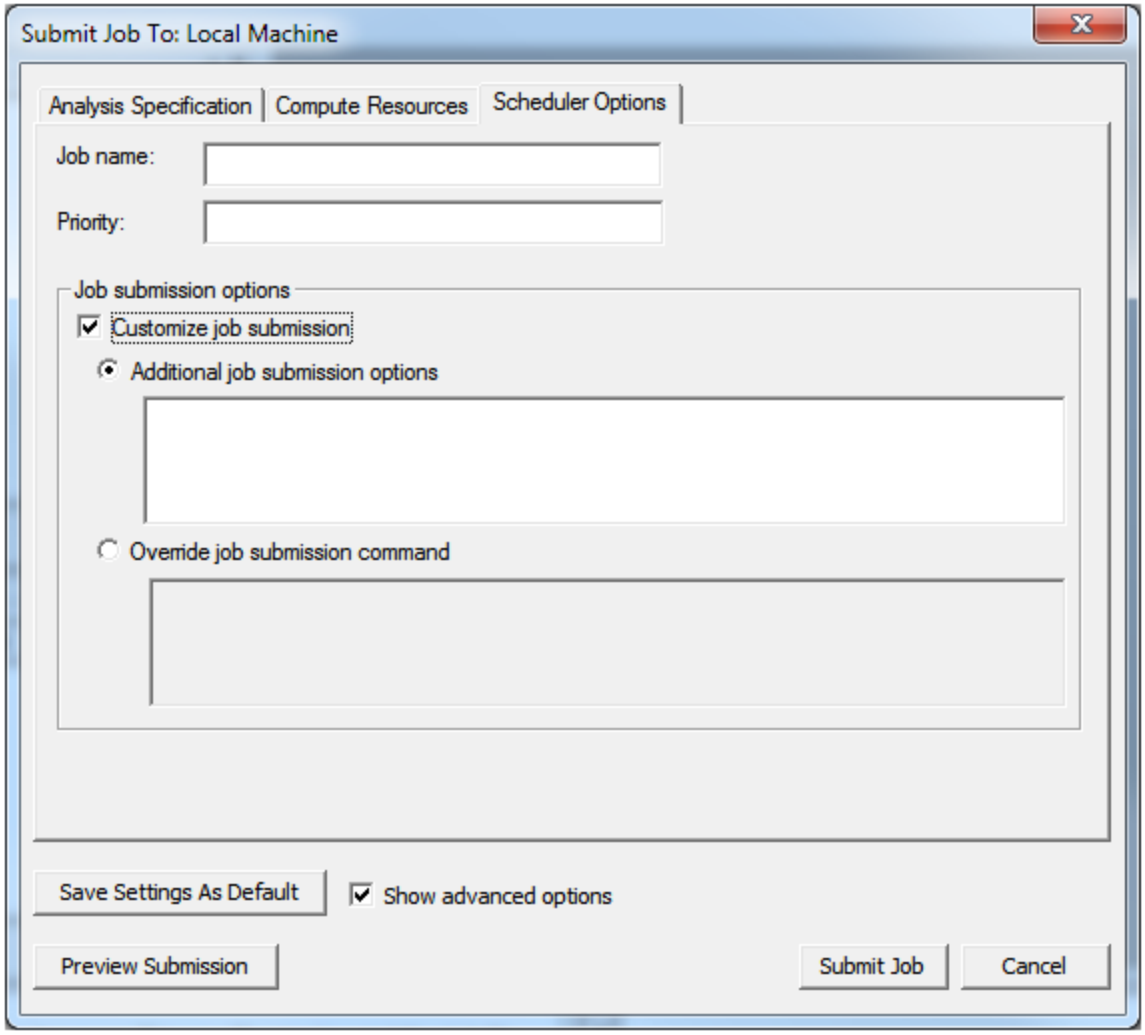
- the total number of distributed engines,
- the number of cores to allocate for each distributed engine,
- the maximum number of engines to allocate to a single node (optional), and
- the number of cores to allocated for the non-distributed portion of the analysis.
- It also contains a boolean parameter indicating whether nodes used for this job should be exclusively allocated to this job.

The **computeResources** argument is a reference to an object of type **UniformComputeResourcesStruct**. This **struct** contains zero or more resource attribute settings for the job. Each resource attribute setting consists or a resource name and a resource value. The resource name is the name of one of the resources defined in the **AttributeDefinitionsStruct** filled in by the **GetComputeResourceAttributes()** function. The resource attribute value is the value specified for the resource attribute by the user using the **Compute Resource Selection Parameters** dialog box. If no resource attributes are specified by the user in this dialog box, then the **computeResources** argument will contain no resource attribute settings.

The **jobOptions** argument contains the environment variable settings for the job.

The **jobAttributes** argument contains job submission attributes which are not necessarily related to the compute resources allocated to the job. The job name and the requested job priority are included in this data structure. The **SchedulerOptions** tab of the **Job Submission** dialog allows

the user to either specify additional job submission options or to specify all submission options, replacing the settings from the other **Job Submission** dialog controls.



The user specified submission options are included in this data structure, as well as a boolean setting indicating whether the user specified options are in addition to the automatically generated options, or whether they replace the automatically generated submission options.

The **submissionUser** argument contains information about the client user (the user running the Desktop process). The job is submitted to the scheduler to run as this user.

The **jobParametersCB** argument is a pointer to an object that implements the **IJobParameters** interface. This interface allows the scheduler proxy library to get additional information about the job. Specifically, the **GetWorkingDirectory()** interface function returns the working directory to be used for the job.

The **cmdLineInfo** argument contains the command line arguments. The first argument is the command name.

int SubmitNonUniformJob(std::string& msg, std::string& jobID, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const NonUniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser,const IJobParameters* jobParametersCB):

This function submits a job to the scheduler.

- On success, 0 is returned, and the job identifier of the newly submitted job is written to the **jobID** argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

This function is used to submit jobs to the scheduler in which the nodes to use and the number of engines to run on each node are specified by the user. All other arguments are input arguments, as for the **SubmitUniformJob()** function. These input arguments are the same as for the **SubmitUniformJob()** function, except that the **computeResources** argument is a reference to a **NonUniformComputeResourcesStruct**, as described below:

The **computeResources** argument is a reference to an object of type **NonUniformComputeResourcesStruct**. This object contains a vector of pairs, where each pair consists of the name of a node in the cluster, and the number of engines to run on the node.

int PreviewUniformJob(std::string& msg, std::string& preview, const CmdLineStruct& cmdLineInfo, const JobParallelizationStruct& jobParallelization, const UniformComputeResourcesStruct& computeResources, const JobOptionsStruct& jobOptions, const JobAtributesStruct& jobAttributes, const SubmissionUserStruct& submissionUser, const IJobParameters* jobParametersCB):

This function is similar to the **SubmitUniformJob()** function, but instead of submitting the job, text representing how the job will be submitted is written to the preview argument. Typically the preview text includes the job submission command and the contents of the job script created for the job. For some schedulers, this content may not be meaningful, so the text returned could be different.

- On success, 0 is returned, and the job preview text is written to the preview argument.
- On failure, a non-zero error code is returned, and an error message to display to the user is written to the msg argument.

The other arguments are input arguments with the same meaning as for the **SubmitUniformJob()** function. The **submissionUser** argument is ignored for this function.

Testing Your Scheduler Integration

One way to test these functions is to run the analysis for an Ansys Electromagnetics product in batch mode. When running in batch mode, a batch log file is created in the same directory as the project file. The batch log file has the same base name is the project file, with an extension of ".log". For example, if the project file is TestProject123.aedt, then the batch file is TestProject123.log. The batch log file contains useful information about the analysis run.

See the product specific help for details on running the product in batch mode, and for the command line options to use for distributed analysis.

- Testing IsProductLaunchedInYourEnvironment
- Testing GetSchedulerDisplayName and GetThisJobID
- Testing GetTempDirectory
- Testing GetMachineListAvailableForDistribution
- Testing LaunchProcess
- Testing GetUseRsmForEngineLaunch

Testing IsProductLaunchedInYourEnvironment

This function should be tested first. If the Ansys Electromagnetics application is not able to load and run this function, or if it returns false, then none of the other functions will be called. If the batch analysis is running in a scheduler environment, and this function returns true, then there will be an "info" message near the beginning of the batch log indicating that the analysis is running as a scheduler job. This message will include the scheduler display name returned by the function GetSchedulerDisplayName, and it will also include the job ID returned by the function GetThisJobID. If the batch analysis is not running in a scheduler environment, then none of the messages will include a scheduler display name or job ID.

If this message does not appear when running in a scheduler environment, ensure that the scheduler proxy library is named correctly, that it is built correctly, that it is installed in the correct directory, and that the function name prefix is the same is the library prefix converted to upper case.

Testing GetSchedulerDisplayName and GetThisJobID

As described above, when running a batch job in a scheduler environment, the scheduler display name and the job ID will appear in an "info" message near the beginning of the batch log. The values returned by these functions are copied to this message verbatim, so they can be directly compared to the expected values.

Testing GetTempDirectory

Unfinished. The temp directory displayed in the batch log is the default installation setting, not the one from the scheduler. The scheduler temp directory is set in AnsoftCOMApplication::MainFunction(), so it happens for COM engines, but not for the desktop.

Testing GetMachineListAvailableForDistribution

This function is used for distributed analysis. The analysis may be distributed across several machines if portions of the analysis are independent. For example, frequency sweeps, parametric analysis and domain decomposition allow different portions of the analysis to be

distributed across machines. The analysis in a batch job will be distributed to multiple processors or hosts if the analysis includes a setup that may be distributed (e.g., a frequency sweep or parametric analysis) and the **-Distributed** option is included in the desktop command line. The list of machines is displayed in an "info" message near the beginning of the batch log. The list in the info message can be directly compared to the expected list of machines.

To verify that the machine list is constructed correctly for a variety of cases, it may be necessary to test several jobs with different resource requirements and verify that the machine list is correct in each case. For example, one may run batch analyses with the following resource requirements:

- One processor on one host
- Several processors on one host
- One processor on each of several hosts
- Several processors on each of several hosts

Testing LaunchProcess

This function is used to launch analysis engines in the case where the analysis is distributed across multiple hosts. The analysis may be distributed across several machines if portions of the analysis are independent. For example, frequency sweeps, parametric analysis and domain decomposition allow different portions of the analysis to be distributed across machines. The analysis in a batch job will be distributed to multiple processors or hosts if the analysis includes a setup that may be distributed (e.g., a frequency sweep or parametric analysis) and the **-Distributed** option is included in the desktop command line. The list of machines is displayed in an "info" message near the beginning of the batch log. The batch log may also contain info messages when portions of the analysis distributed to different machines start or finish. These messages usually include the name of the host when the analysis ran or will run. One can verify that the analysis is actually running on the expected host or hosts using the Linux ps command or the Windows Task Manager.

In general, one analysis engine is started for each occurrence of each host in the list of machines available for distribution. For example, if the list of hosts is "hostA hostA hostA hostB hostB", then a total of 5 engines would be started, three on hostA and two on hostB. In some cases, an additional engine is started to perform the portion of the analysis which is not distributed; if this is the case, the non-distributed engine is idle during the portion of the analysis which is distributed. If this occurs in the case where the list of hosts is "hostA hostA hostA hostB hostB", then a total of 6 engines would be started, but at most 5 engines would be active at any given time. When each analysis engine is running, it may start additional child processes to do a portion of the analysis, but these are not counted as additional analysis engines because the parent of the sub-engine is inactive (waiting for the sub-engine results) when the sub-engine is active.

Testing should be sufficient to demonstrate that the scheduler proxy library can start multiple engine processes on the desktop host, and can also start multiple engine processes on other hosts.

Testing GetUseRsmForEngineLaunch

In most cases, this function will not be implemented or tested. If this function is implemented and returns true, then the Ansys Electromagnetics desktop application will not start the analysis engines using the LaunchProcess function directly. Instead, the Ansys Electromagnetics desktop application will start one AnsoftRSMService process on each host using the `LaunchProcess` function, and the engine processes will be started by these AnsoftRSMService processes. One may check for these processes using the Linux ps command or the Windows Task Manager. One AnsoftRSMService process should run on each host. These processes will be named ansoftrsmservice.exe or AnsoftRSMService.exe. These processes will be started on each host before any analysis engine is started on the host, and will remain running until the job is complete.

Troubleshooting Custom Scheduler Integration

None of the Proxy Functions are Called

There are several problems which could result in none of the proxy functions being called.

The scheduler proxy library must be installed in the schedulers subdirectory of the Ansys Electromagnetics installation directory. The installation directory is set in the registry entry `HKEY_CURRENT_USER/Software/Ansoft/Product/Version/Desktop/InstallationDirectory`, where “Product” is the Ansys Electromagnetics product name (for example, Maxwell) and “Version” is the Ansys Electromagnetics product version (for example, 14.0).

The scheduler proxy library name must match "*_scheduler.dll" on Windows and "lib*_scheduler.so" on Linux. If the library name does not match this format, then the library will not be loaded. In addition, the function name prefix must be the same as the library name prefix converted to upper case. For example, if the library name prefix is "abc", then the function name prefix is "ABC". In this example, the library name is "abc_scheduler.dll" on Windows, and "libabc_scheduler.so" on Linux. In this example, the full name of the IsProductLaunchedInYourEnvironment function is ABC_IsProductLaunchedInYourEnvironment on Windows and Linux, and it must have extern "C" linkage.

Verify that the compile and link flags follow the guidelines in the section "Build Information", above. Incorrect compile or link flags may prevent the library from being loaded by the Ansys Electromagnetics product.

If there is a problem with calling the `IsProductLaunchedInYourEnvironment` function, then none of the other functions will be called. The other functions are only called if the `IsProductLaunchedInYourEnvironment` function is successfully called and returns true.

Troubleshooting IsProductLaunchedInYourEnvironment Function

Verify that the conditions specified in the section "None of the Proxy Functions are Called" are met.

Verify that this function returns true when called in an environment running under the scheduler, and that it returns false when called in an environment not running under the scheduler.

Troubleshooting GetSchedulerDisplayName

Verify that the `IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

Verify that the scheduler display name is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the display name, including the terminal null byte, then the display name is copied to the buffer and true is returned.

Troubleshooting GetThisJobID

Verify that the `IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

Verify that the job ID is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the job ID, including the terminal null byte, then the job ID is copied to the buffer and true is returned.

Troubleshooting GetTempDirectory

Verify that the `IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

Verify that the temporary directory name is a valid ASCII string.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the temporary directory pathname, including the terminal null byte, then the temporary directory pathname is copied to the buffer and true is returned.

Troubleshooting GetMachineListAvailableForDistribution

Verify that the `IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

Verify that the list of hosts is a valid ASCII string containing a space separated list of host names. A host name will appear in the list a number of times equal to the number of processors or cores available to the job on that host.

Verify that, if argument buffer is NULL, then the required length of the buffer is stored in the location to which argument length points, and true is returned. The required buffer length must include space for the string null terminator.

Verify that, if argument buffer is not NULL and the value to which argument length points (the buffer length) is large enough to contain the list of hosts, including the terminal null byte, then the list of hosts is copied to the buffer and true is returned.

Troubleshooting LaunchProcess

Verify that the `IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

The hostName argument is a host name from the list returned by the GetMachineListAvailableForDistribution function. Verify that the LaunchProcess function can accept host names in the format returned by the GetMachineListAvailableForDistribution function.

The exePathName argument is the pathname of the analysis engine executable to be started. This pathname may contain spaces or other characters special to the shell. Ensure that the LaunchProcess function is able to handle such cases.

The arg1 and arg2 arguments may contain newlines, tabs, single quotes, spaces, dollar signs, and other characters which may be special to the shell. Ensure that the LaunchProcess function is able to handle such cases. If needed, the newline characters may be replaced by other whitespace characters. One or both of these arguments could also be an empty string; verify that the empty string is correctly passed to the engine process command line.

If a scheduler command is used to launch the engine process on a remote machine, the engine command line may be processed by the shell twice, once when the scheduler command is processed by the shell, and again when the engine command is processed by the shell. In such cases, the quoting of characters special to the shell will need to be take these two passes through the shell into account. In some implementations, it may be necessary or convenient to use different approaches for launching engine processes on the local machine and on remote machines; if this is done, verify that the approach used to determine whether the hostName argument represents the local machine is correct.

Troubleshooting GetUseRsmForEngineLaunch

In most cases, this function will not be implemented. If it is implemented, then follow the suggestions below.

`Verify that the IsProductLaunchedInYourEnvironment` function returns true when running in the scheduler environment.

If the RSM should be used for launching engines, verify that this function returns true. Otherwise, verify that this function returns false.

Using an IronPython Program for Integration with a Scheduler

This section describes how to create an IronPython program for integration with a scheduler. Each such program is used for a single specific scheduler environment. If the program is installed with a valid name and in the correct location, then it will automatically be loaded and used by Ansys Electromagnetics tools.

Installation Details

The IronPython program must be installed in the schedulers subdirectory of the Ansys Electromagnetics installation directory. For example, if the installation directory is C:\Program Files\AnsysEM\v231\Win64\, then the IronPython program must be installed in directory C:\Program Files\AnsysEM\v231\Win64\schedulers.

The program file extension must be ".py". Select the program name so that it does not conflict with other IronPython programs in the same directory. If the Operating System or file system treat file names in a case sensitive manner, the file extension ".py" must be lower case.

Python Programming Notes

The scheduler program will be run in the IronPython environment both on Microsoft Windows and on Linux. There are some differences between IronPython and CPython. The version of IronPython in use as of June 9, 2011 is 2.6.1.

Implementation Details

The program must contain the following:

Import the ISchedulerPluginExtension interface as follows:

```
from Ansys.Ansoft.SchedulerPluginDotNet import
ISchedulerPluginExtension
```

Define a class which implements the ISchedulerPluginExtension interface. In this document, this class is named SamplePluginExtension, but any class name may be used. The class member functions are described in the next section. The class definition will look similar to the following:

```
class SamplePluginExtension(ISchedulerPluginExtension):

def GetName(self):
return "SamplePluginExtension"

def GetDescription(self):
return "Example python script plugin extension"
. . .
```

Include the following line in the program so that the class that you have defined, SamplePluginExtension, is loaded by the infrastructure:

```
ExtensionRegistrar.RegisterPluginExtension
(SamplePluginExtension())
```

The infrastructure will make the EntensionRegistrar object available in the environment where the program is loaded.

Each of the functions to be implemented in the SamplePluginExtension class is described below.

- GetName
- GetDescription
- IsProductLaunchedInYourEnvironment
- GetSchedulerDisplayName
- GetThisJobID
- GetUseRsmForEngineLaunch
- GetTempDirectory
- GetMessageStringToRegisterForSigTerm
- GetMachineListAvailableForDistribution
- LaunchProcess

GetName [IronPython]

Purpose

Return a short string containing the name of the plugin extension. This string is used to identify the scheduler plugin extension in logs or program output.

Signature

```
GetName(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the name of the plugin extension.

Notes

The plugin extension name is generally a fixed string.

GetDescription [IronPython]

Purpose

Return a string containing the description of the plugin extension. This string is used to identify the scheduler plugin extension in logs or program output.

Signature

```
GetDescription(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the description of the plugin extension.

Notes

The plugin extension description is generally a fixed string.

IsProductLaunchedInYourEnvironment [IronPython]

Purpose

Determine if the program is running in the context of the scheduler for which this program was written.

Signature

```
IsProductLaunchedInYourEnvironment(self)
```

Arguments (excluding self)

None.

Return Value

Returns True if the current process is running as a job of the scheduler. Otherwise, False is returned.

Notes

For many schedulers, the presence of certain environment variables or their values may be checked to determine if the current process is running as a job of the scheduler.

GetSchedulerDisplayName [IronPython]

Purpose

Get a string identifying the scheduler associated with the current plugin extension. This string is used to identify the scheduler.

Signature

```
GetSchedulerDisplayName(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the description of the scheduler for which this plugin extension was written.

Notes

The scheduler display name is generally a fixed string.

GetThisJobID [IronPython]

Purpose

Get a string identifying the job currently running in the scheduler environment. This string is displayed to the end user to identify the job.

Signature

```
GetThisJobID(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the Job ID for the current job.

Notes

For many schedulers, the job ID may be obtained from the value of an environment variable.

GetUseRsmForEngineLaunch [IronPython]

Purpose

For some schedulers, it may be desirable for the AnsoftRSM program to launch the engine processes instead of using the scheduler plugin extension directly. For example, if the plugin extension is limited to launching one process per host, then the plugin extension may be used to launch one AnsoftRSM executable per host, and the AnsoftRSM executable will launch all of the engine processes.

If AnsoftRSM should be used to launch engine processes for this scheduler, then this function shall return True.

If AnsoftRSM should not be used to launch engine processes for this scheduler, then this function shall return False.

Signature

```
GetUseRsmForEngineLaunch(self)
```

Arguments (excluding self)

None.

Return Value

Returns True if AnsoftRSM should be used to launch engine processes for this scheduler. Returns False if the plugin extension should be used to directly launch engine processes for this scheduler.

Notes

If this function returns True, then the plugin extension will directly launch only one process on each host.

GetTempDirectory [IronPython]

Purpose

Get the pathname of the temporary directory provided by the scheduler for the current job. The pathname is an empty string if the scheduler does not provide a temporary directory for the current job.

Signature

```
GetTempDirectory(self)
```

Arguments (excluding self)

None.

Return Value

Returns a string containing the pathname of the temporary directory provided by the scheduler for the current job. Returns an empty string if no temporary directory is provided by the scheduler for the current job.

Notes

If the return value is an empty string, then the temporary directory specified on the command line or in the registry will be used.

GetMessageStringToRegisterForSigTerm [IronPython]

Purpose

Obsolete. This function should return an empty string.

Signature

```
GetMessageStringToRegisterForSigTerm(self)
```

Arguments (excluding self)

None.

Return Value

Returns an empty string.

Notes

This function should always return an empty string.

GetMachineListAvailableForDistribution [IronPython]

Purpose

Get the names of the hosts allocated to the current job. A host name will appear in the output string multiple times if the scheduler has allocated multiple processors or cores on the host to the job. The number of times the host name appears in the string is equal to the number of processors or cores of the host that are allocated to the current job. The output is a text string containing the host names separated by space characters.

Signature

```
GetMachineListAvailableForDistribution(self)
```

Arguments (excluding self)

None.

Return Value

A string containing the names of the hosts allocated to the job, separated by space characterss. The number of times the host appears in the string is equal to the number of processors or cores of the host that are allocated to the current job.

Notes

The hostnames in the string provided by this function shall be used in calls to LaunchProcess(). The host names must be in a format that is accepted by that function. See the section below on LaunchProcess.

LaunchProcess [IronPython]

Purpose

Launch a local or remote process to run an analysis engine. This function is called by the Ansys Electromagnetics desktop application to launch an engine process on a specified host. The hostname is one of the names provided by the GetMachineListAvailableForDistribution function. See the GetMachineListAvailableForDistribution section above. If the hostname does not refer to the local host, then this function shall use the scheduler to launch the engine on the specified host. If the hostname refers to the local host, then the engine may be started as a child process, or it may be started using the scheduler.

Signature

```
LaunchProcess(self, hostName, exePathName, arg1, arg2)
```

Arguments (excluding self)

hostName: The name of the host where the process is to be launched.

exePathName: The pathname of the analysis engine executable to be started.

arg1: The first argument of the analysis engine command line.

arg2: The second argument of the analysis engine command line.

Return Value

Returns 0 on success. Returns a non-zero value if an error occurs.

Notes

The hostName argument will be one of the hostnames provided by the function GetMachineListAvailableForDistribution().

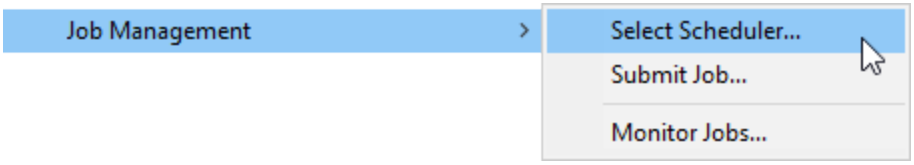
If the hostName argument is the same as the current host, then the analysis engine process may be started as a child process. If the hostName argument is not the same as the current host, then the analysis engine process will be started on the remote host using the facilities available in the scheduler environment. The command line of the analysis engine process is exePathName arg1 arg2. The command line arguments arg1 and arg2 may contain spaces or other characters that are interpreted by the command processor, such as backslash (\), single quote (') or double quote (") characters, or dollar signs ($). If the analysis engine command is processed by a shell, then it may be necessary to quote any special characters in the exePathName or in the arguments so that the special meaning is removed. If a scheduler command is used to request the scheduler to launch the command to start the engine process, and that command is processed by a command shell, then the analysis engine command may be processed by the shell twice: once when the scheduler command is processed, and a second time when the analysis engine process is started. If this is the case, then the quoting of special characters needs to account for two passes through the command processor.

The command line arguments arg1 and arg2 may be empty strings. These arguments must be preserved, even if they are empty strings. In some versions of the IronPython subprocess module, empty argument strings are discarded, resulting in an incorrect number of command line arguments. A workaround for this issue is to replace an empty string argument by a string consisting of a single space character.

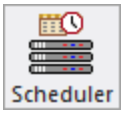
Selecting a Scheduler

Access the **Select Scheduler** window one of three ways:

- Click **Tools** > **Job Management** > **Select Scheduler...**

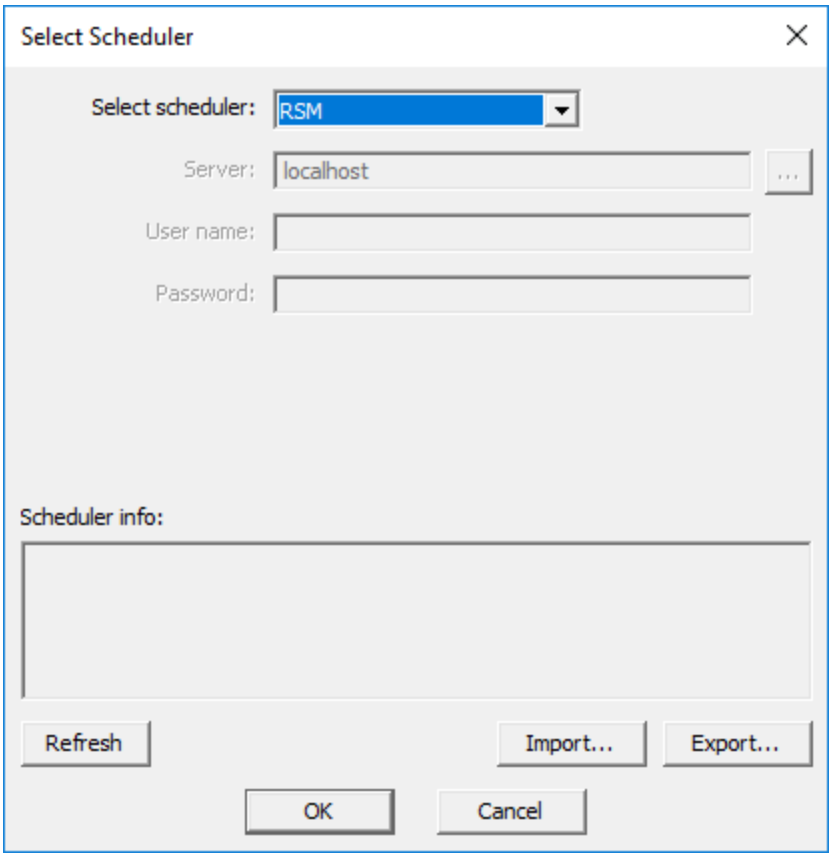


- Select the **Simulation** tab and click the **Scheduler** icon.



- From a command window, use the -showselectscheduler command.

The **Select Scheduler** window appears:



From the **Select Scheduler** window:

- Use the **Select scheduler** drop-down menu to select a scheduler.

> **Note:**
>
> If you select a scheduler that is unsupported in your environment, you will receive a warning message.
>
> See HPC Integration for a list of currently supported schedulers.

- If applicable for the scheduler type, enter server and user information.

- Information about the selected scheduler appears in the **Scheduler info** field.
- Click **OK** to complete your selection.

Submitting a Job

Ansys Electromagnetics Desktop supports its own Remote Simulation Management (RSM) and Ansys Cloud software along with other High Performance Computing (HPC) software management programs (See: HPC Integration). The **Simulation** tab of the ribbon includes icons for setting HPC Options, creating and selecting analysis configuration, selecting the scheduler, submitting jobs, and monitoring jobs.

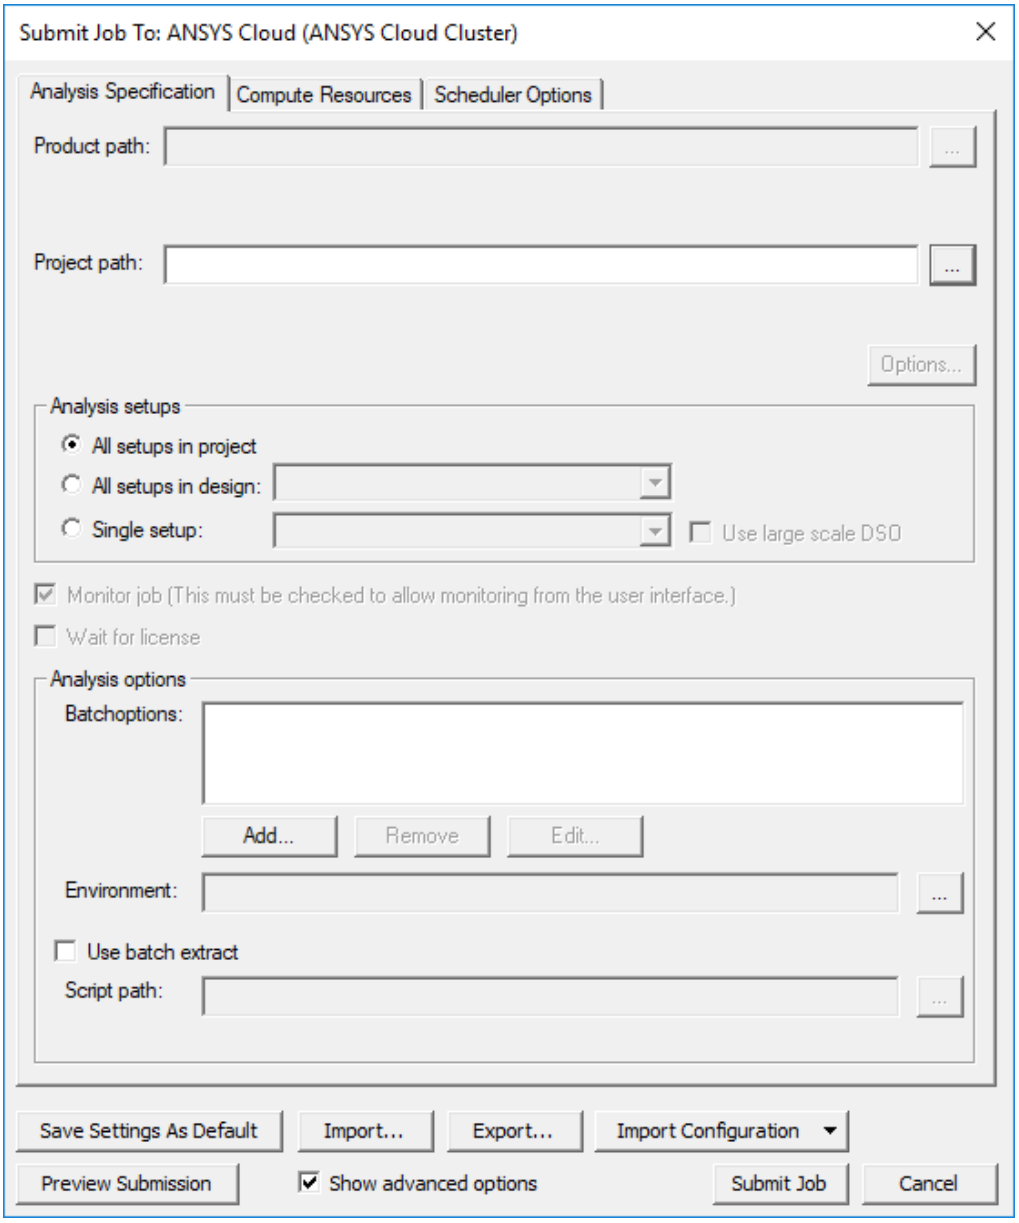
There are two ways that the GUI may be used to submit jobs. The first (and most common) mode requires that the Desktop (UI) process run on a host which is also a submission host for the job scheduler. This mode is called local mode or working mode.

The second mode is only supported on Linux in the Ansys Electromagnetics Suite. In the second mode, an administrator configures the RSM Service to act as an interface to the job scheduler, and starts the RSM Service on a submission host for the cluster. The user runs the Desktop (UI) process on another host (which may be called the post-processing host). To submit a job, the user specifies the host where the RSM Service is running, and the Desktop process connects to the RSM Service over the network to submit the job. In this mode, some configuration is required, and the RSM Service typically must run as a privileged user (for example, root), so that it can launch processes as any user. This mode is useful for cases in which the submission hosts are not able to run graphical processes.

To submit a job:

1. Prepare your design.
2. Open the **Submit Job To** window one of the following ways:
    - On the **Simulation** tab, click the **Submit** icon.
    - Select **Tools** > **Job Management** > **Submit Job**.
    - Select **Maxwell 2D** or **Maxwell 3D** > **Submit Job**.
    - Right-click a solution setup and select **Submit Job**. *In this case, the information in the **Submit Job To** window will be pre-populated from the setup*.
    - From a Command window, use the -showsubmitjob command.

    The **Submit Job To** window appears. The window header indicates your selected scheduler.



This window contains up to three tabs:

- **Analysis Specification** – allows you to specify the product path, project name, setup and analysis options, batchoptions, and environment variables (for advanced users).
- **Compute Resources** – allows you to specify whether to use automatic settings, and to set resource selection and job distribution parameters.
- **Scheduler Options** – allows you to specify the job name and priority. *This tab does not appear if you have selected local RSM as the scheduler*.

3. On the **Analysis Specification** tab, specify your desired options.

   The **Product path** and **Project** fields support mapped drives. Click the ellipses (**...**) to select files.

   The project can be an archive. The project file pathname must be a UNC path that is accessible from each compute host used for Ansys Electromagnetics jobs. After clicking the **Project path** field's ellipsis button (**...**), a check box allows you to **Use converted UNC path if mapped drive specified**. If you select a project or product on a mapped drive, and check the option, the converted UNC path equivalent to the mapped drive pathname is used.

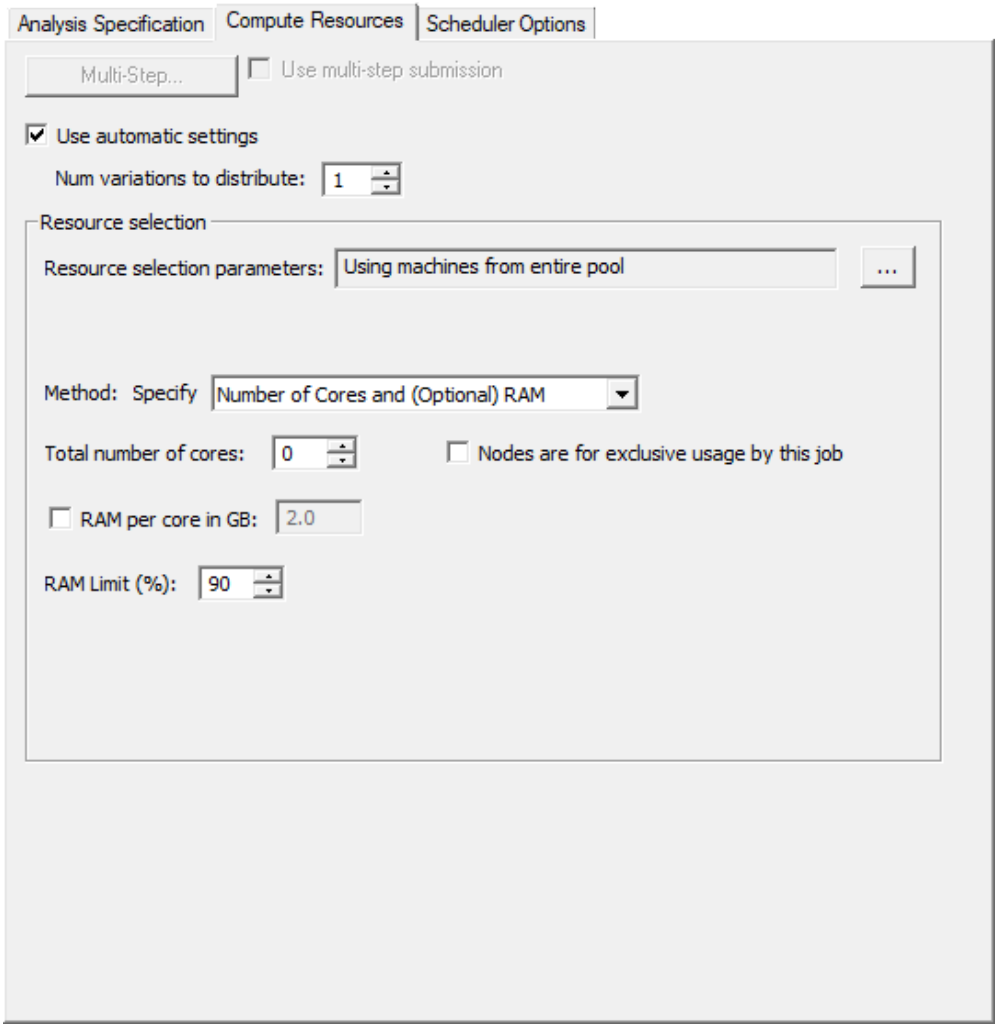
   Note:

   If you select Ansys Cloud as your scheduler for a design type that is in Beta, you will receive a warning:

   
   In the **Analysis Setups** area, select the radio button for **All setups in project**, **All setups in design**, or a **single setup**.

   For Parametric setups, you have the option to select **Use Large Scale DSO**. See: Large Scale DSO for Parametric Analysis.

4. Select the **Compute Resources** tab.



Options may vary slightly depending on your selected scheduler.

5. If applicable, determine whether or not to **Use multi-step submission**.
6. Determine whether or not to **Use automatic settings**.
7. Use the buttons in the **Resource selection** area to allocate resources. See: Job Management for Large Scale DSO.
8. If you opted not to use automatic settings, you can also set **Job distribution** parameters. See: Distributed Analysis.
9. If applicable, select the **Scheduler Options** tab and set the **Job name** and **Priority**.

10. If desired, import or export job configurations.
11. If desired, click **Save Settings as Default** to save the current settings and overwrite defaults. These settings are saved on a per-scheduler basis.
12. If desired, click **Show advanced options** to see options for advanced users. See: Running Electronics Desktop from a Command Line.
13. If desired, click **Preview Submission** to view the commands to be sent to the scheduler. Ansys Cloud submissions contain queue (pool) configuration details, including the job's hourly cost in Ansys Elastic Units (AEUs).

    The preview text can be copied to the clipboard.
14. Click **Submit Job** to submit the job to your selected scheduler.

Selecting a Scheduler

Monitoring Jobs

Using Advanced Job Submission Options

Using Advanced Job Submission Options

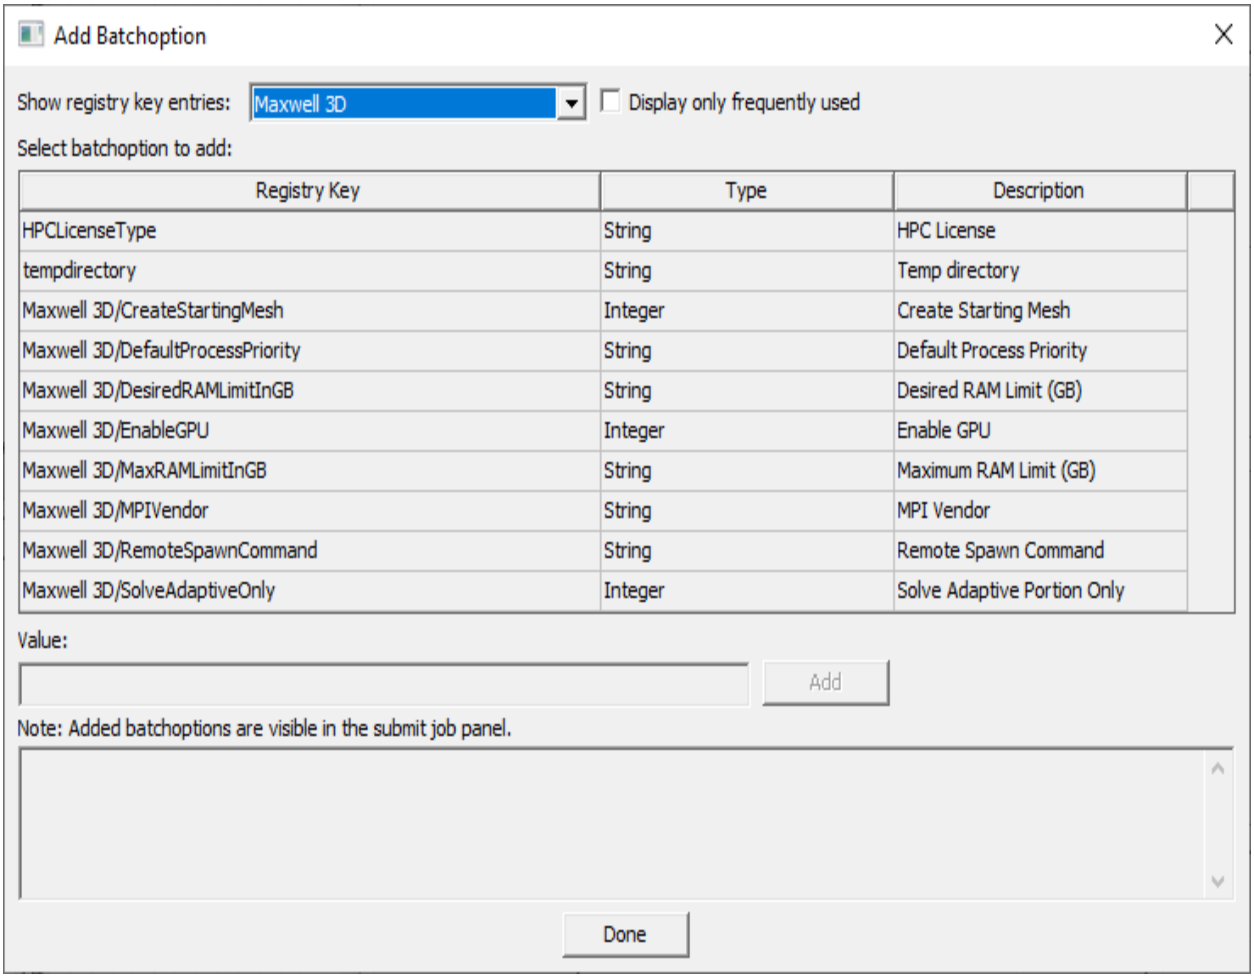
From the job submission window, you can select **Show advanced options** to enable additional analysis options and job submission options.

This topic covers the following:

- Batchoptions
- Environment Variables
- Batch Extract
- Customize Job Submission

Batchoptions

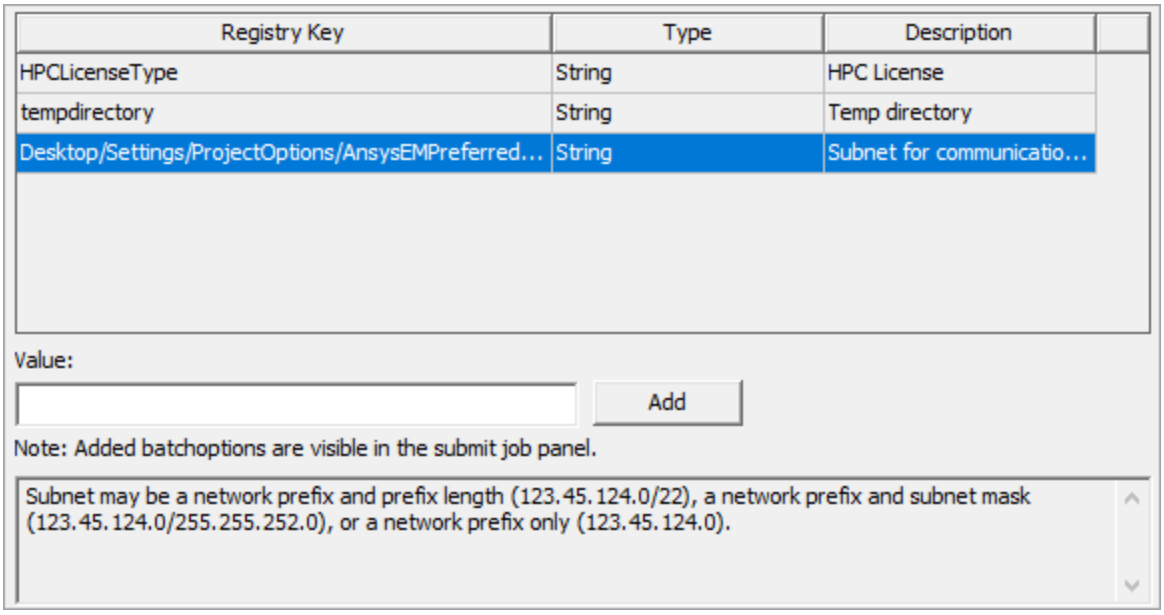
In the **Submit Job To** window, under **Batchoptions**, click **Add** to open the **Add Batchoption** window.



The **Show registry key entries** drop-down menu allows you to select categories of registry keys to display.

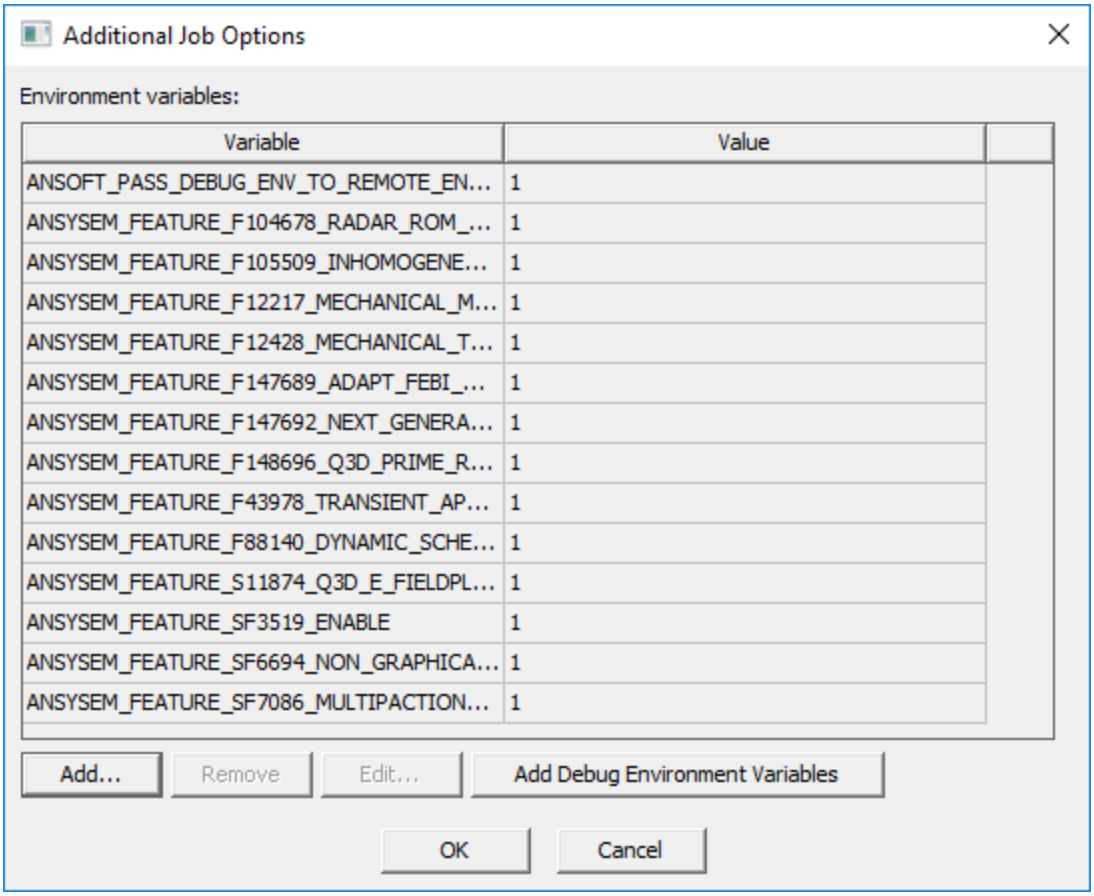
Note that **Display only frequently used** is selected by default. Deselect this to view all options for the selected category.

Select a registry key to activate the **Value** field, where you can enter a value. Selecting a key also populates the bottom of the window with a description of that key:



Environment Variables

In the **Submit Job To** window, under **Environment**, click the ellipses (**...**) to open the **Additional Job Options** window.



This window lists all currently activated environment variables.

Active variables display a value of 1. Inactive variables display a value of 0. Non-binary variables may contain project paths, integer values, etc.

You can perform the following actions:

- **Add** – Add an environment variable. You will be prompted to enter the variable name and value.
- **Remove** – Select and remove an environment variable from the list.
- **Edit** – Select an environment variable and enter a new value.
- **Add Debug Environment Variables** – Activates a selection of debugging variables and adds them to the list. The log files created are only useful to development and if a customer or an application engineer needs to set these environment variables they should be working with a developer directly or indirectly who will know what needs to be set.

Batch Extract

In the **Submit Job To** window, select **Use batch extract** to enable the **Script path** field. Click the ellipses (**...**) to browse and select a VBscript or Python script to execute along with the job.
See: Running Ansys Electronics Desktop from the Command Line for a description of Batch Extract.

Customize Job Submission

In the **Submit Job To** window's **Scheduler Options** tab, advanced options for some schedulers allow you to **Customize job submission**. When the **Override job submission** radio button is selected, user-specified options replace most of the job submission options. When the **Additional job submission options** radio button is selected, user-specified options are appended to the bsub command.

Submitting a Job

Monitoring Jobs

Running Ansys Electronics Desktop from the Command Line

Using the Command Line to Submit HPC Jobs

Ansys Electronics Desktop can be run from the command line. When using the command line to perform HPC jobs, take the following into consideration.

Distributed Jobs

An Ansys EM batch job which distributes the analysis over several hosts may also be called a distributed job. To submit a distributed job, the following Ansys EM desktop command line options should be used:

- The -Distributed option should be present, and the -Local option should be absent. When running as a batch job under one of the schedulers with direct integration, this option is a directive to the job to 1) obtain the list of hosts allocated to the job, directly from the scheduler, and to 2) use the scheduler to launch the analysis engines on the hosts allocated to the job. The -Distributed option may now have additional options, such as includetypes=xxx, excludetypes=xxx, maxlevels=n, and numlevel1=n, where n indicates and integer, and xxx indicates a list of distribution types or "default".
- The -Machinelist num=*num_distributed_engines* option must be included, where *num_distributed_engines* is the total number of analysis engines to be started on the hosts assigned to the job.

Other examples:

- "Serial Job on a Single Processor" below
- "Distributed Job Using Four Processors" on the facing page
- "Multiprocessing Job Using Four Cores" on the facing page
- "Distributed Analysis and Multi-Processing in the Same Job" on the facing page

Serial Job on a Single Processor

Suppose Ansys Electronics Desktop is installed at "C:\Program Files\AnsysEM\v231\Win64\ and you are using RSM for DSO:

```
C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng -
BatchSolve -machinelist num=2
-monitor \\shared_drive\projs\OptimTee.aedt
```

User is using LSF for remote-analysis/DSO

```
bsub -n 1 C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng
-BatchSolve -machinelist num=3 -monitor -local \\shared_
drive\projs\OptimTee.aedt
```

Distributed Job Using Four Processors

Ansoft RSM

```
C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng -
Batchsolve -monitor -Distributed
-machinelist list="10.1.1.221, 10.1.1.222, 10.1.1.223,
10.1.1.224" \\shared_drive\projs\OptimTee.aedt
```

LSF

```
bsub -n 4 C:\Program Files\AnsysEM\v231\win64\ansysedt.exe -ng
-Batchsolve -monitor
-Distributed -machinelist num=4
\\shared_drive\projs\OptimTee.aedt
```

Multiprocessing Job Using Four Cores

Multi-processing job using 4 cores

```
bsub -n 4 -R "span[ptile=4]" C:\Program
Files\AnsysEM\v231\win64\ansysedt.exe -ng -monitor
-Local -BatchSolve -machinelist num=4 -batchoptions \\shared_
drive\registry.txt \\shared_drive\projs\OptimTee.aedt
```

This requests 4 cores to come from the same machine, as multi-processing needs cores to be on the same machine

Distributed Analysis and Multi-Processing in the Same Job

Distributed-processing using 4 engines and multi-processing using 4 cores, using a total of 16 cores

```
bsub -n 16 -R "span[ptile=4]" c:Program
Files\AnsysEM\v231\win64\ansysedt.exe -ng
-BatchSolve -Distributed -machinelist num=4
-batchoptions \\shared_drive\registry.txt
\\shared_drive\projs\OptimTee.aedt
```

Job Import and Export

The bottoms of the scheduler selection and job submission window contain buttons for **Import...**, **Export...**, and **Import Configuration**. Import and Export may be used to save and then restore a frequently used collection of job submission settings, to save multiple sets of settings, or to transfer settings from one machine to another. Electronics Desktop uses Ansoft Electronics Registry Settings (*.areg) files for these purposes:

- **Export...** – exports most of the settings of this window (all tabs) to an *.areg file.
- **Import...** – updates most of the settings in this window (all tabs) from an *.areg file.
- **Import Configuration** – updates DSO settings in this window from any DSO configuration, as shown in the **Configurations** and **Options** tabs of **HPC and Analysis Options**.

> **Important:**
>
> The Design Type of the DSO configuration must match the design type of one of the designs in the project, so the **Project path** must be specified before using the **Import Configuration** button.

Scripting

The SubmitJob scripting command uses job submission settings that have been exported from the **Submit Job** window to an *.areg file. The path to this *.areg file is the first argument to the SubmitJob scripting command. See: Job Submission Scripting.

Multi-Step Job Submission

Multi-step job submission allows you to divide the simulation of a project on a cluster as two or more jobs, each of which has unique resource specifications. For example, creating the initial mesh and doing adaptive refinement can use a single machine, while frequency sweeps can easily be distributed over many machines. Breaking up the simulation into multiple steps allows the first job to do initial meshing and adaptive passes, only reserving a single compute node, or maybe even reserving just a partial node. The second job can then do the frequency sweep(s),

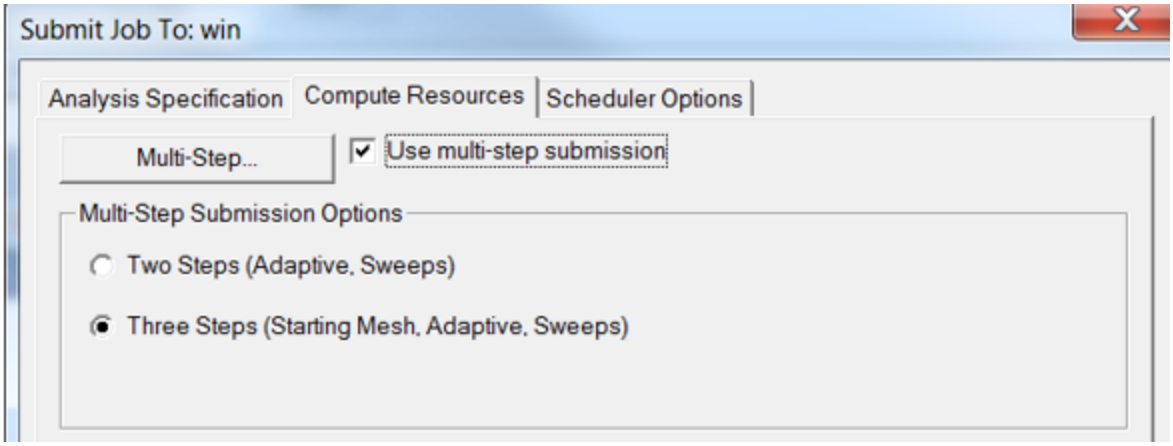
reserving and using multiple nodes. Note that while the first job runs, because it may only be using one node, other nodes are available for other jobs. The Ansys Electronics Desktop job submission GUI allows you to submit multi-step jobs, and specify compute resources individually for each step. Electronics Desktop can also be used to monitor the execution of multi-step jobs.

Limitations

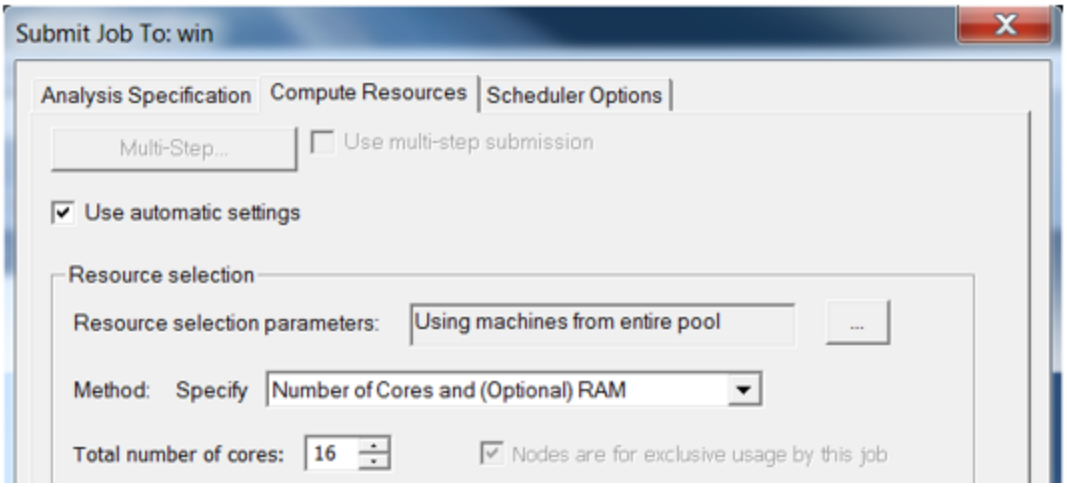
Multi-step job submission is only allowed for a single setup of a project. Only certain design types (or setup types for a given design type) offer this functionality. Ansoft RSM does not support multi-step jobs because it does not have queuing capabilities.

How-to Specify Multi-Step Job Submission

From an open project, right-click a setup in the project tree, and select **Submit Job...** on the shortcut menu. This pre-populates the **Submit Job To** window's **Analysis Specification** tab for the selected setup. Select the **Compute Resources** tab. If the design setup and selected scheduler allow for multi-step submission, and your computing resource supports it, the **Compute Resources** tab shows the **Multi-Step...** button and the **Use multi-step submission** check box is enabled.



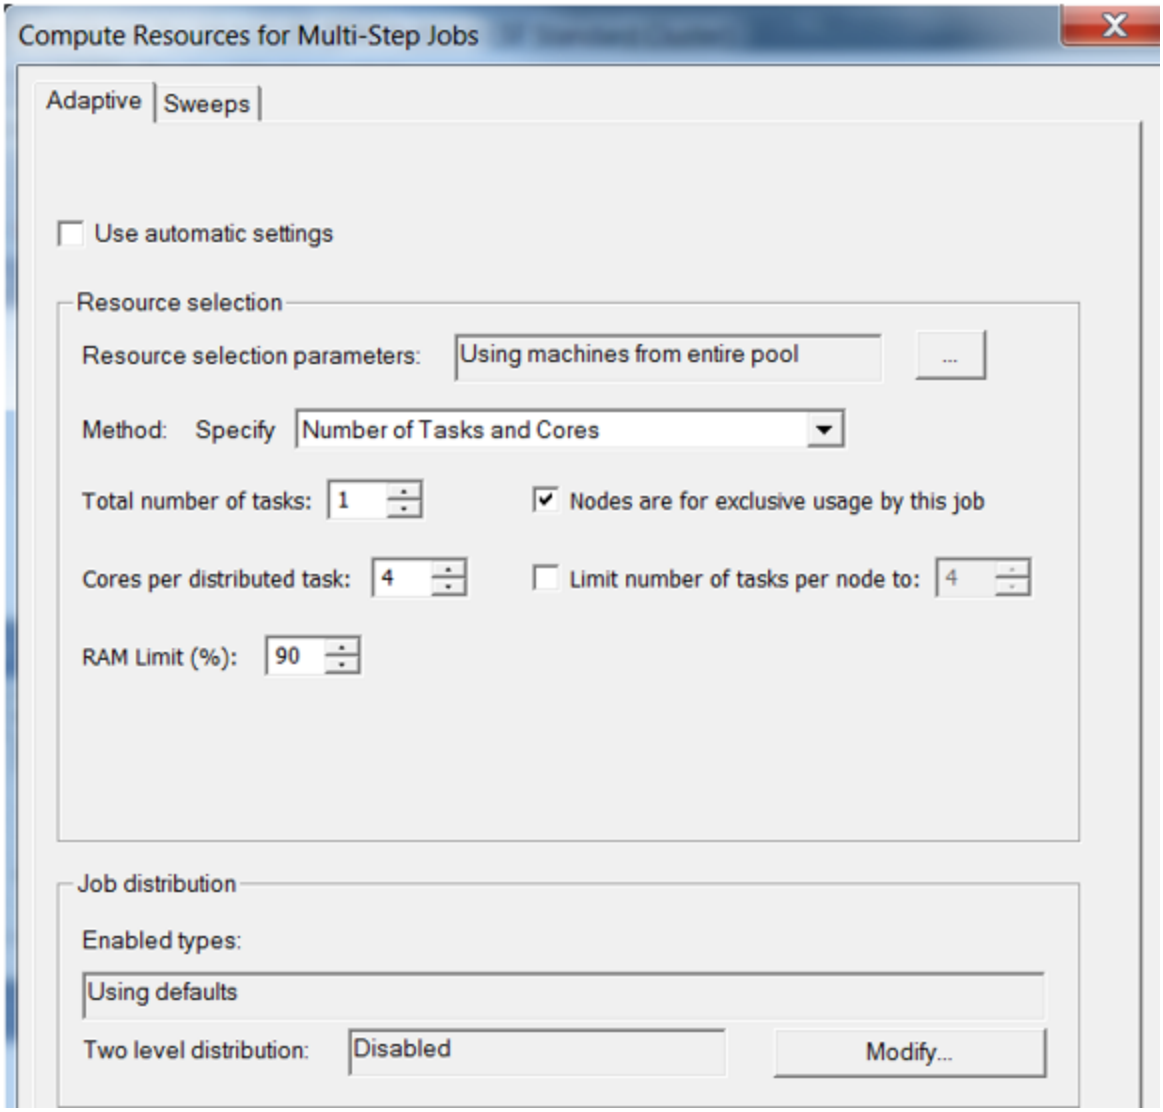
If the Multi-Step button and check box are not enabled it could be because you have not selected a single setup, the design type of the setup does not support Multi-Step, or the scheduler type (e.g., RSM) does not support it.



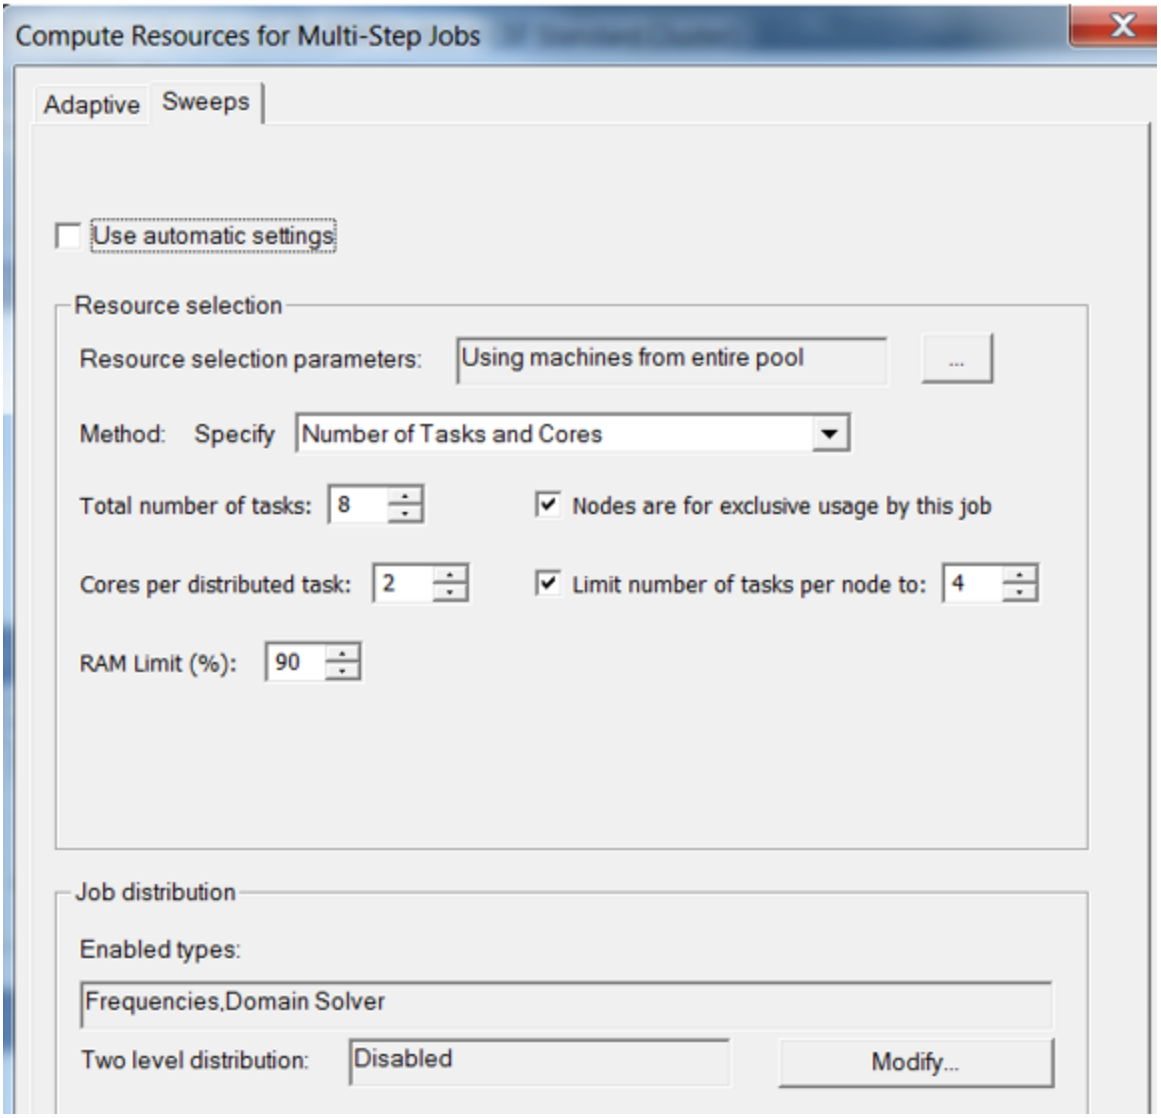
On the **Compute Resources** tab, check the **Use multi-step submission** box and select the appropriate submission option, that is:

- Two Steps for Adaptive and Sweeps
- Three Steps for Mesh, Adaptive, and Sweeps

Then click **Multi-Step…**, which will bring up a **Compute Resources for Multi-Step Jobs** dialog box where there is a tab for each step used, that is for potential for Mesh, Adaptive, and Sweeps.

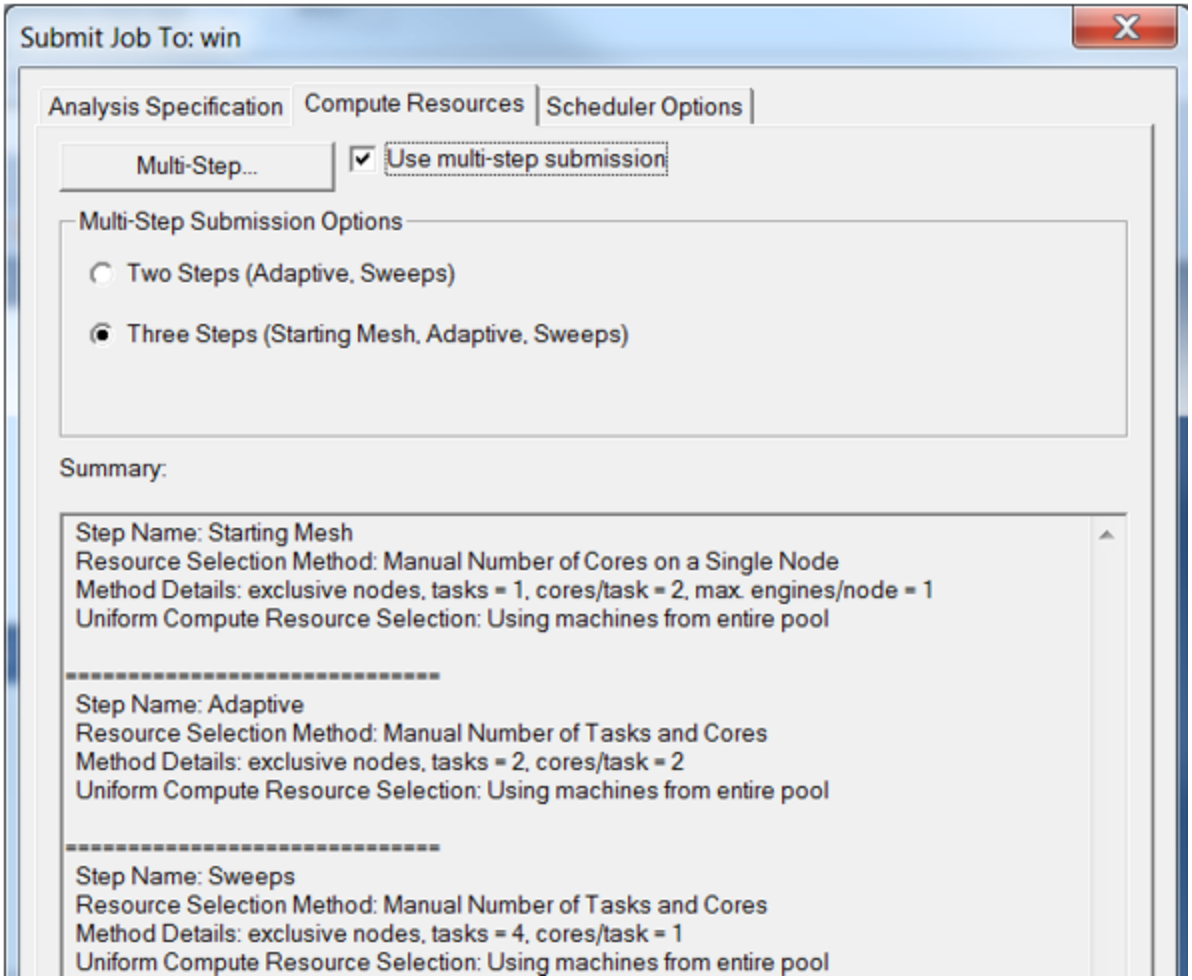


Notice, for example, that the **Sweeps** tab lists the same resources choices but they can be assigned differently.

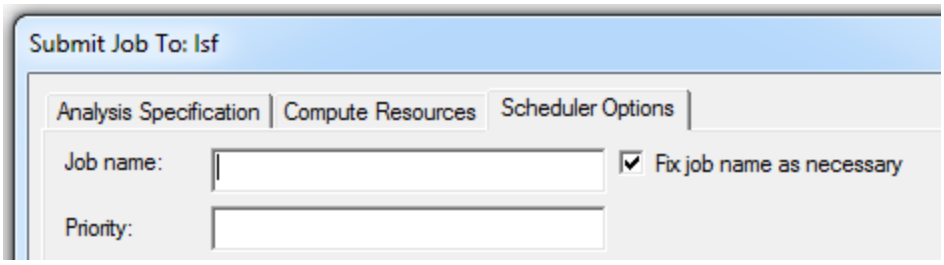


Set the desired compute resources for each step and click **OK**.

The Summary field of the **Compute Resources** tab shows a text summary of resource specifications used for each step.

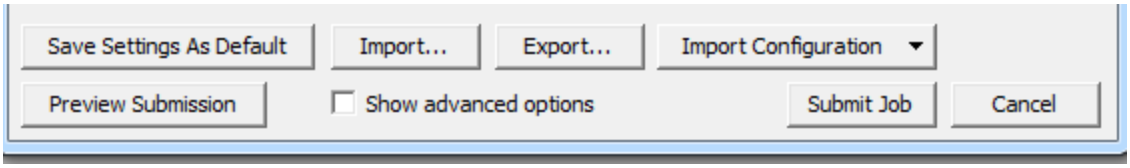


If desired, set the job name on the **Scheduler Options** tab. When the jobs are submitted, each will have a name given by job name (if any) appended with the name of the step for the job. For example, if the job name entered is “MultiStep”, then the individual jobs might be named “MultiStep-Adaptive” and “MultiStep-Sweeps”.



There is a new **Fix job name as necessary** check box for the job name. This applies only to certain schedulers where there are constraints on the job name. It is useful to ensure proper submission in the case where appending the step name results in an invalid job name.

When you click **Preview Submission**, you see a preview for each step, all in the same output window. Any errors or warnings for a step, generated during preview validation, are displayed with the text for the preview of that step.



When you click **Submit Job**, each job is submitted individually, and dependencies are set with the scheduler so that subsequent jobs wait for the prior step's job to complete before starting. Any errors in job submission for any step prevent further steps from being submitted.

The dialog reporting successful submission has been modified slightly for multi-step jobs. It will show the jobs IDs of all jobs that are part of the multi-step job sequence.

Multi-Step Job Monitoring

You can monitor the job step in progress. When one job completes, the status shows "Completed", but monitoring restarts once the next job step is running.

Aborting a Job Step

You can also abort the job step in progress. With multi-step jobs submitted from the Electronics Desktop GUI, this will also cause remaining jobs (which would otherwise remain queued in the scheduler) to be canceled.

Archive Projects for Multi-Step Job Submission

Note that you can submit archive projects. Monitoring is based on the archive for the first step, then on the extracted project for subsequent steps.

Submitting a Job without Opening the Project

You can also submit a job without opening the project. This can be done by choosing **Tools** > **Job Management** > **Submit Job…** and then manually entering the project path (You can also use **Browse** can to select the project.) Note that you must also select a single nominal setup before the **Use multi-step submission** check box is enabled on the **Compute Resources** tab.

Windows to Linux Job Submission

Given a set of prerequisites, Ansys Electronics Desktop can permit Windows to Linux job submission as part of HPC.

Prerequisites for Job Submission

Directory Shared between Windows and Linux

For all jobs submitted to a Linux cluster, the project file is required to be in a directory that is accessible from all execution hosts used by the job. For submission of jobs from a Windows host to a Linux cluster, the project file must also be accessible from the Windows host where the GUI runs. There must be a directory shared with both Windows and Linux hosts, and the project file may be in a subdirectory (at any level) of the shared directory.

Network Access from Windows Host to Linux Job Management Host

The job is submitted to the cluster from a Linux host configured for submission of jobs to the Linux cluster. We call this Linux host the “Job Management” host. The information about the job to be submitted is transmitted to the Job Management host over the network. As a result, the Windows host where the GUI runs must have network access to the Job Management host. If this communication is blocked, then job submission from a Windows host to the Linux cluster will not be possible. Communication could be blocked if there is a firewall or if the Linux cluster is only on a private network, for example.

RSM Service Running on Job Management Host

The ansoftrsmservice must be running on the Linux Job Management host. Before the ansoftrsmservice is started, it must be configured for submission of jobs to the cluster. The SchedulerName and ConfigString fields in the Scheduler block of the ansoftrsmservice.cfg configuration file must be specified. The contents of these fields are described in the following table:

Field Name	Contents	Examples
SchedulerName	Identifier of Scheduler	IBM Spectrum LSF: ’`lsf`’ PBSPro or Torque: ’`pbs`’ Univa, SGE, etc.: ’`sge`’ SLURM: 'generic'
ConfigString	Directory containing scheduler commands	IBM Spectrum LSF: ’’ (not required) PBSPro or Torque: ’`/opt/pbspro/PBSPro_13.0.0/default/bin`’ Unive, SGE, etc.: ’`/opt/univa/bin/lx-amd64`’ SLURM:'{"Proxy":"slurm"}'

The environment should be configured for job submission before starting the ansoftrsmservice. The ansoftrsmservice should be run as a non-privileged user; no special privileges are required. It should be run as a user without login privileges, so that only privileged users have access to this process.

Prerequisites for Job Monitoring

For job monitoring, all prerequisites for job submission are required. One additional requirement, described below, is also required for job monitoring.

Network Access from Windows Host to Linux Cluster Hosts

In order to obtain full monitoring information from a job, the Windows host needs access to some of the job processes. That is, the Windows monitoring host requires network access to the

processes running on the Linux cluster execution hosts. If this communication is blocked, then only limited monitoring information is available.

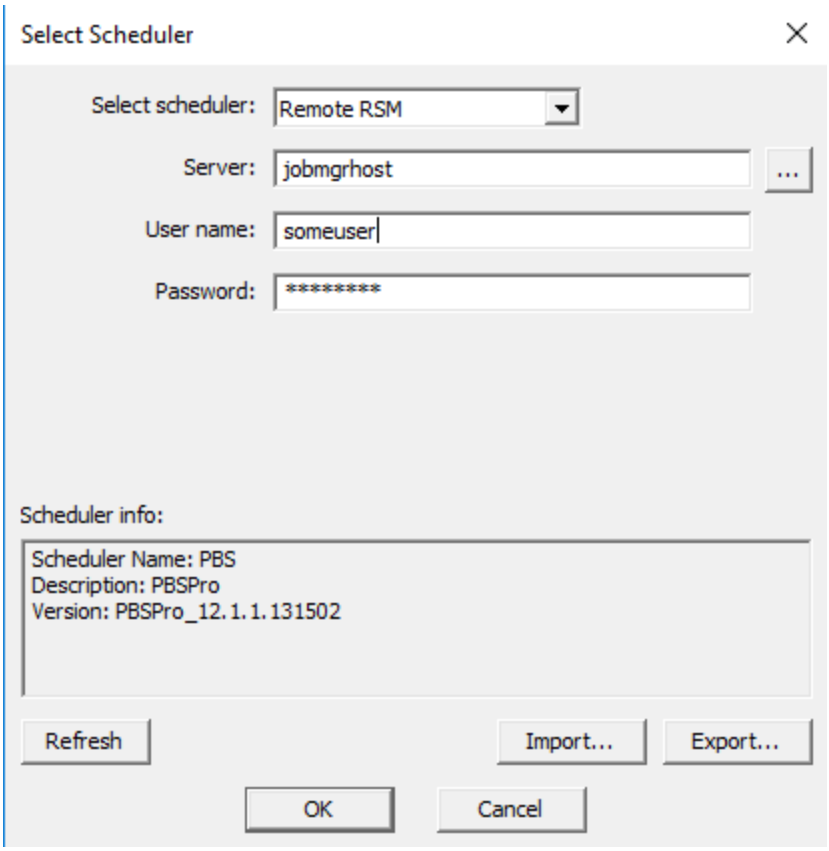
Supported Schedulers

This feature may be used with all Linux schedulers for which job submission from the GUI is supported:

- IBM Spectrum LSF
- Univa Grid Engine (formerly Sun Grid Engine, Oracle Grid Engine)
- PBSPro
- Torque

Select Scheduler Dialog

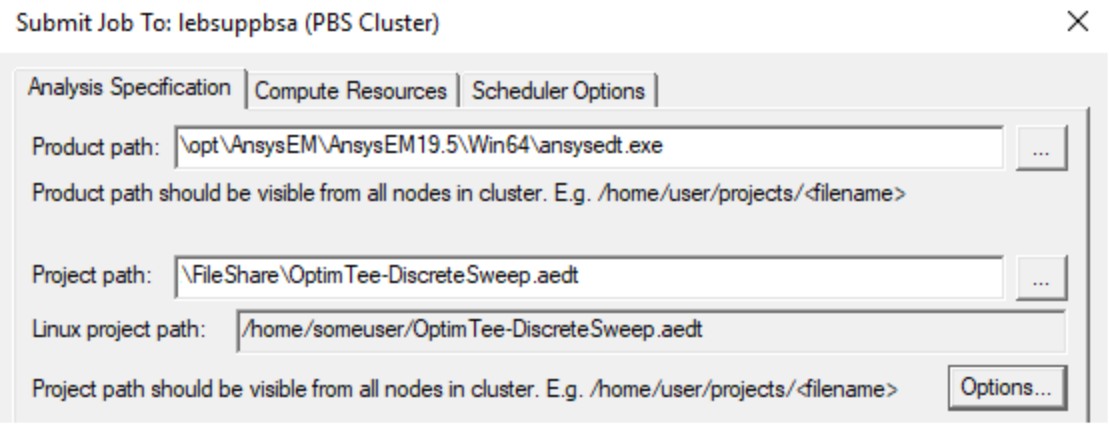
If you select the **Use a computer on the network** option, you can enter a username and password. This username and password are used when the job is submitted to the Linux scheduler.



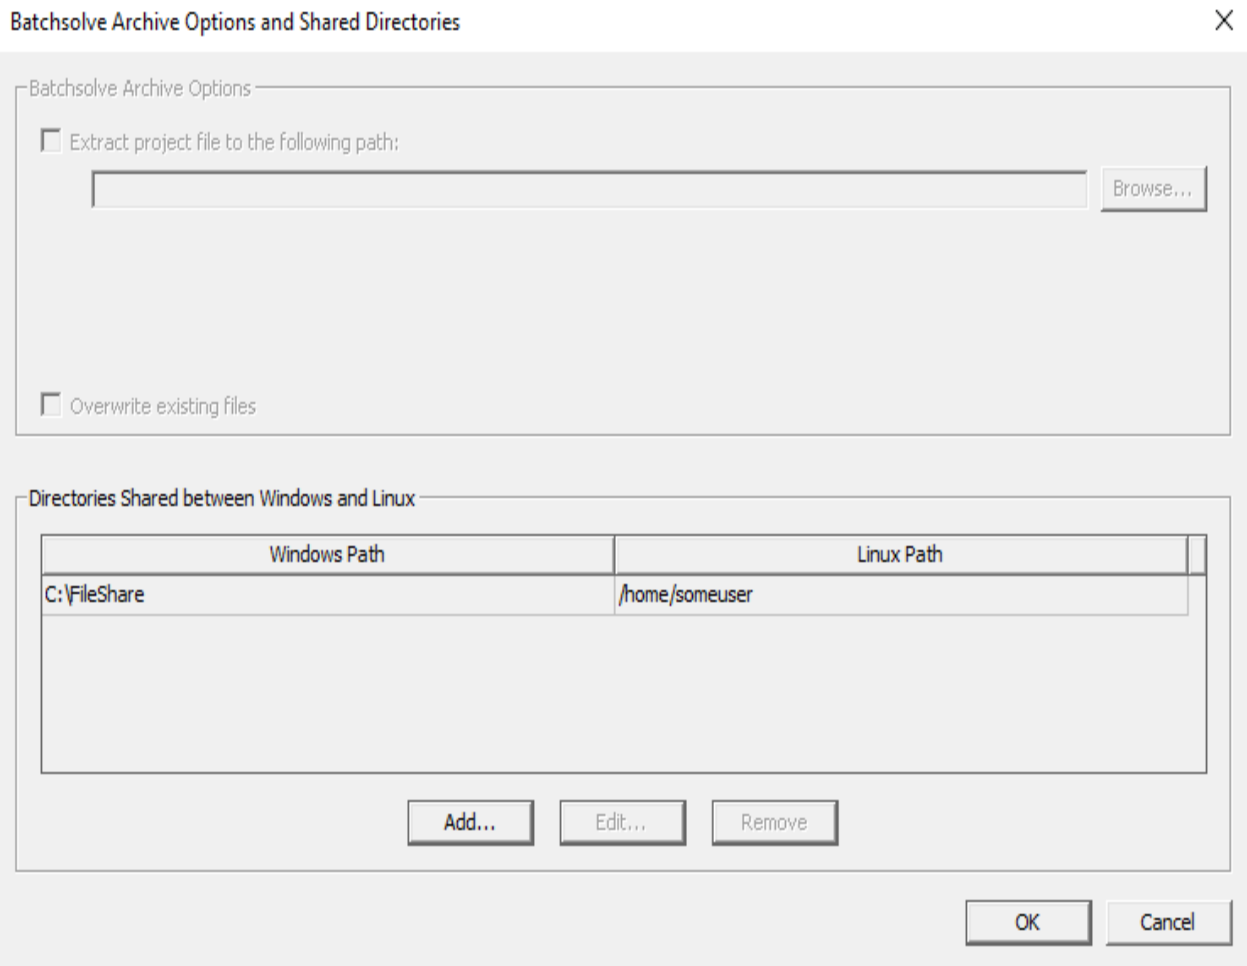
Submit Job Dialog

In the **Submit Job** dialog box, you must enter the Linux path to the product in the Product path edit control. The browse button (labeled "...") may not be used to browse for the product. There is no requirement for the product installation directory to be accessible from the Windows GUI host.

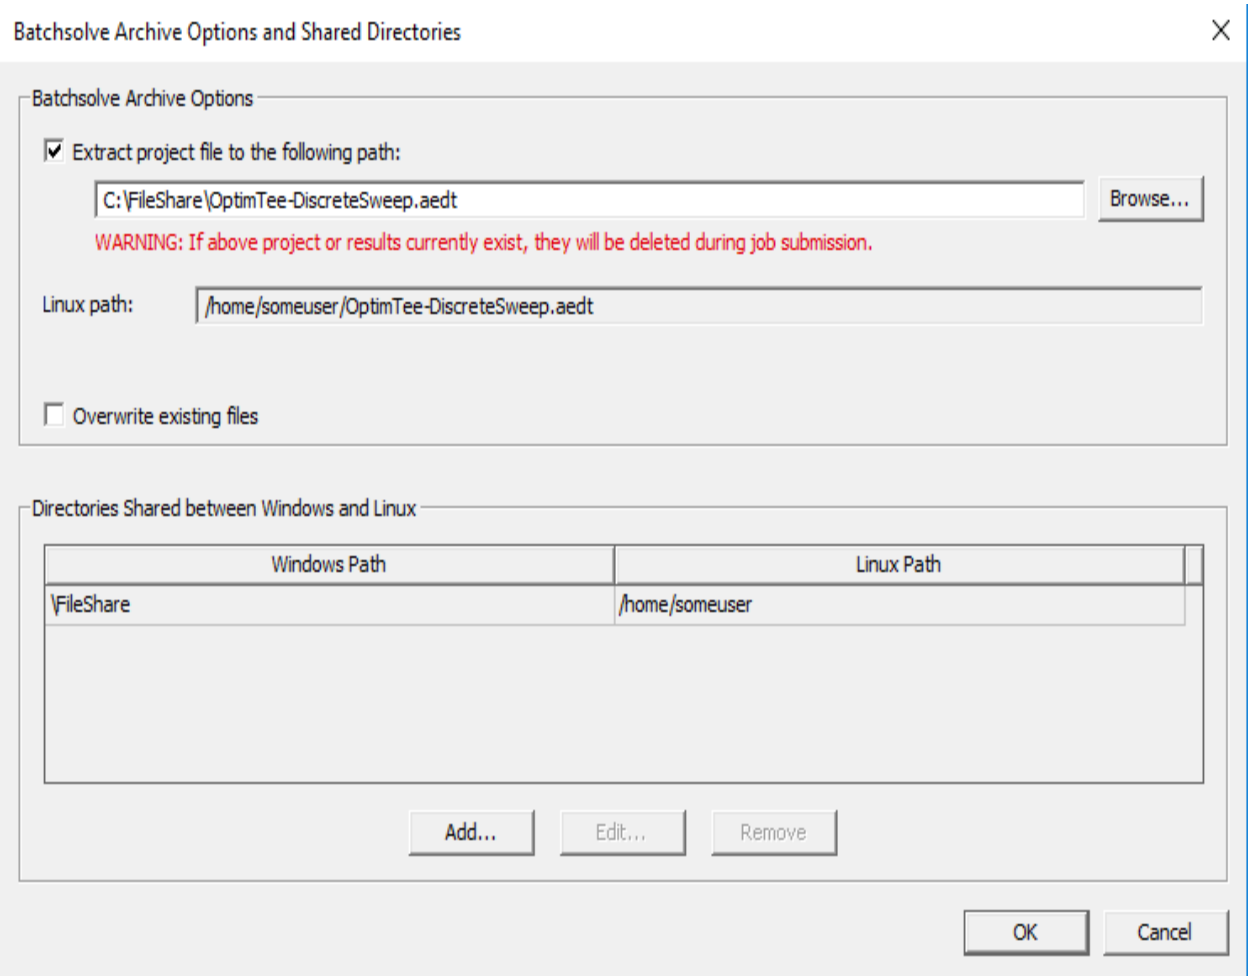
You must enter the Windows path of the project file in the Product path edit control or use the browse button (labeled "...") to select the Windows path of the project file. If the Linux path of the project file can be determined from the specified Windows path and the directories shared between Windows and Linux, then the Linux path of the project file is shown in the Linux project path edit control. This edit control cannot be edited directly.



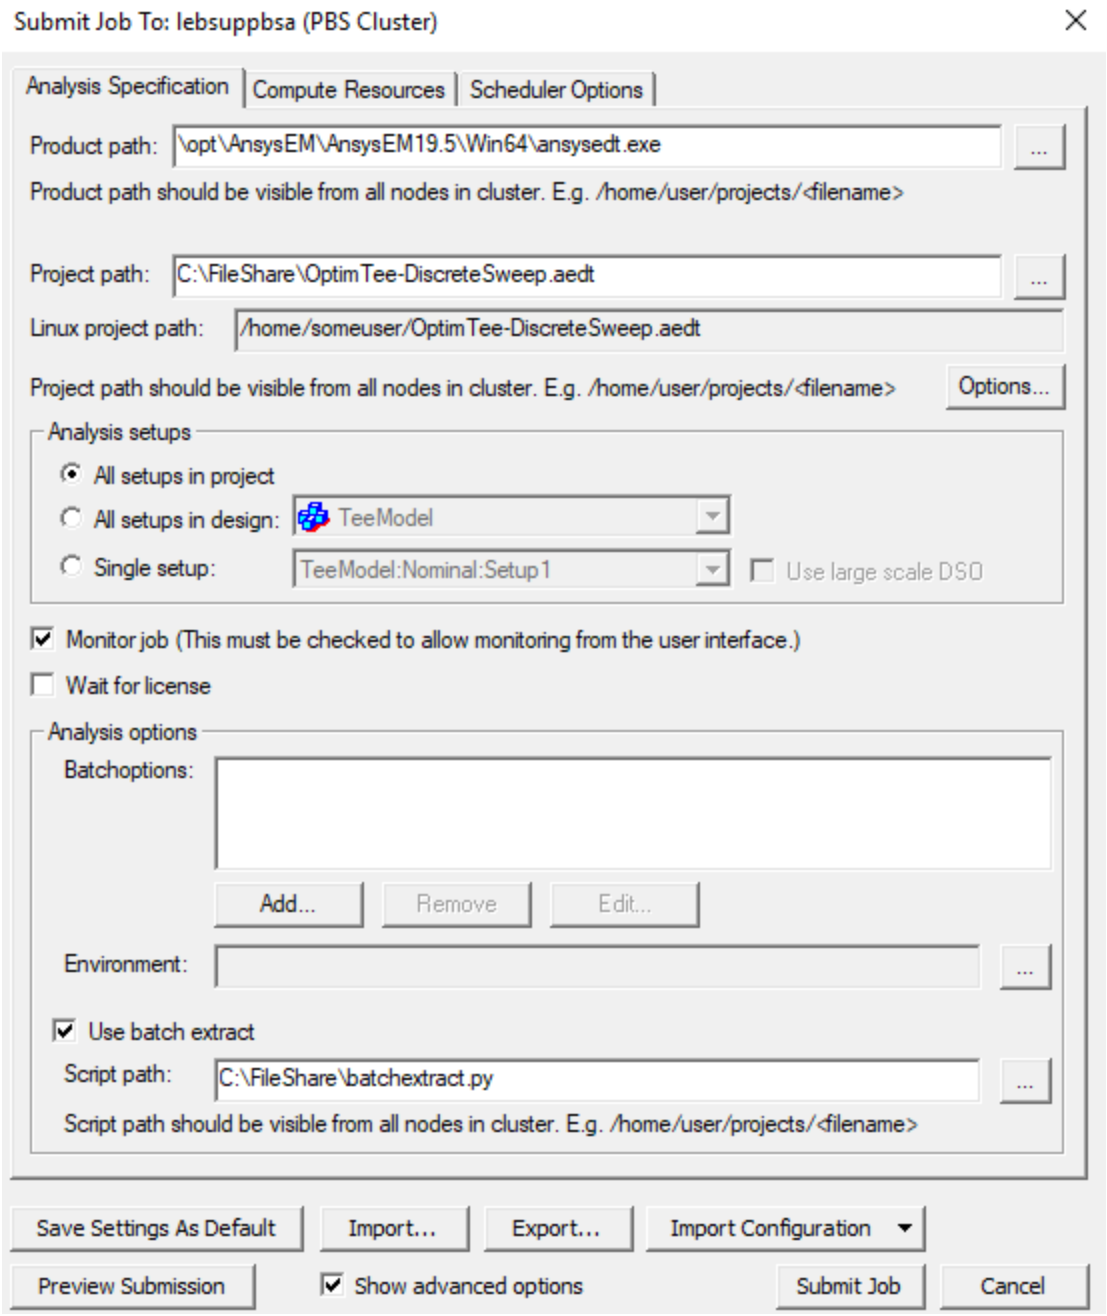
The **Options** button activates a dialog that you can use to specify archive options for a job. The lower portion of this dialog allows you to specify one or more directories shared between Windows and Linux. The mapping of directories between Windows and Linux is shown in a grid which displays the Windows path and the Linux path for each shared directory. There are also buttons to add a new shared directory, to edit an existing shared directory, or to delete one or more shared directories. The Windows path or the Linux path of any shared directory may be selected in the grid and directly edited, as well.



If you specify a project in an archive, the dialog activated by the **Options** button may be used to specify the Windows pathname of the project to be extracted from the archive. If this is done, the Linux pathname of the target project is determined from the directories shared between Windows and Linux and shown in the upper portion of this dialog.



If you specify a batchextract script, the Linux path of the batchextract script is determined from the Windows path of the batchextract script and the directories shared between Windows and Linux.



User Passwords are Encrypted

Jobs are submitted to the Linux cluster using the user name and password entered in the **Select Scheduler** dialog box. These settings are persistent; in general, these settings need to be entered only if they change. To ensure security, user passwords are stored in an encrypted format. When a job is submitted from a Windows host using the ansoftrsmservice running on a Linux submission host, the user credentials are sent over the network in an encrypted format.

Job Submission Scripting

To help with automation, you can submit batch jobs can through script commands of the **oDesktop** object. The **SubmitJob** script command uses job submission settings that have been exported from the **Submit Job** dialog box to a .areg file. The path to this .areg file is thus the first argument to the SubmitJob command. Additional arguments include the path to the project file, the design name (if restricting the solve to a particular design), and the setup name (if further restricting the solve to a single setup within a design).

For further automation, you can use the SelectScheduler scripting command to determine what scheduler to use for submission, to include options for head node, username, and whether to require password entry from the user. (If the username differs from the cached username, or the force password flag is set, then the **Select Scheduler** dialog box appears.) If there are any issues with the scheduler selection (for example, a password is required or the requested host wasn't found), then the **Select Scheduler** dialog box appears. This is the only part of job submission scripting that may required user intervention. This same mechanism is used if, from within the SubmitJob command, there is failure to connect to the scheduler. Even though there are allowances for graphical user intervention if something goes wrong, if the password (if required) is cached and all settings are correct, the entire submission process can run non-graphically and fully automated.

Limitations

All settings besides the arguments passed to the **SubmitJob** command must be stored in the .areg file containing settings exported from the **Submit Job** dialog box. These include (but aren't limited to) batch options, environment variables, batch extract settings, and compute resource selections. To run many job submission scripts with variation of these settings, there must be multiple .areg files available.

Note that the same project can be submitted multiple times with a single script. Care must be taken in this situation because each time a project is submitted, the state-keeping files used for monitoring are removed so that the job can create them from scratch to ensure consistency. While this ensures proper monitoring for a job that is just being submitted, it could interfere with monitoring (or even correct solving if a lock file is deleted) of a job that is already in progress. Because of this, if the same project is to be re-submitted from within a single script, the job should be monitored (waiting for completion) before trying to submit it again. This monitoring/waiting can be done with a combination of a single **LaunchJobMonitor** command followed by a loop that checks the result of a **RefreshJobMonitor** command.

How to do Job Submission Scripting

The typical scenario for job submission scripting would be to do the following:

1. Manually select the scheduler. Use the **Select Scheduler** dialog box to open the **Submit Job** dialog box.
2. Choose a representative project (with the desired design type), and select appropriate analysis settings.
3. Make the required compute resource selections and try to preview the job.
4. If preview is successful, export the dialog settings and record the path to the new .areg file.
5. Create a script containing at a minimum a **SubmitJob** command with the path to the .areg file, and the path to the project file. Note that there must be double backslashes for each backslash of a path, since the backslash is an escape character. When the script is run, and all is successful, there should be a message in the message windows stating that the job was submitted, including the job ID(s). There could be multiple job IDs if multi-step submission is used.

See the Scripting help (click **Help>Maxwell Scripting Help**) for details on the **SelectScheduler**, **SubmitJob**, **LaunchJobMonitor** and **RefreshJobMonitor** commands.

High Performance Computing (HPC) Integration

Running Ansys Electronics Desktop from a Command Line

Monitoring Jobs

There are a number of tools that allow you to monitor jobs, including the **Monitor Job** window and detailed .log files.

- Monitor Job Window
- Monitoring Ansys Cloud Jobs
- Monitoring Large Scale DSO Jobs

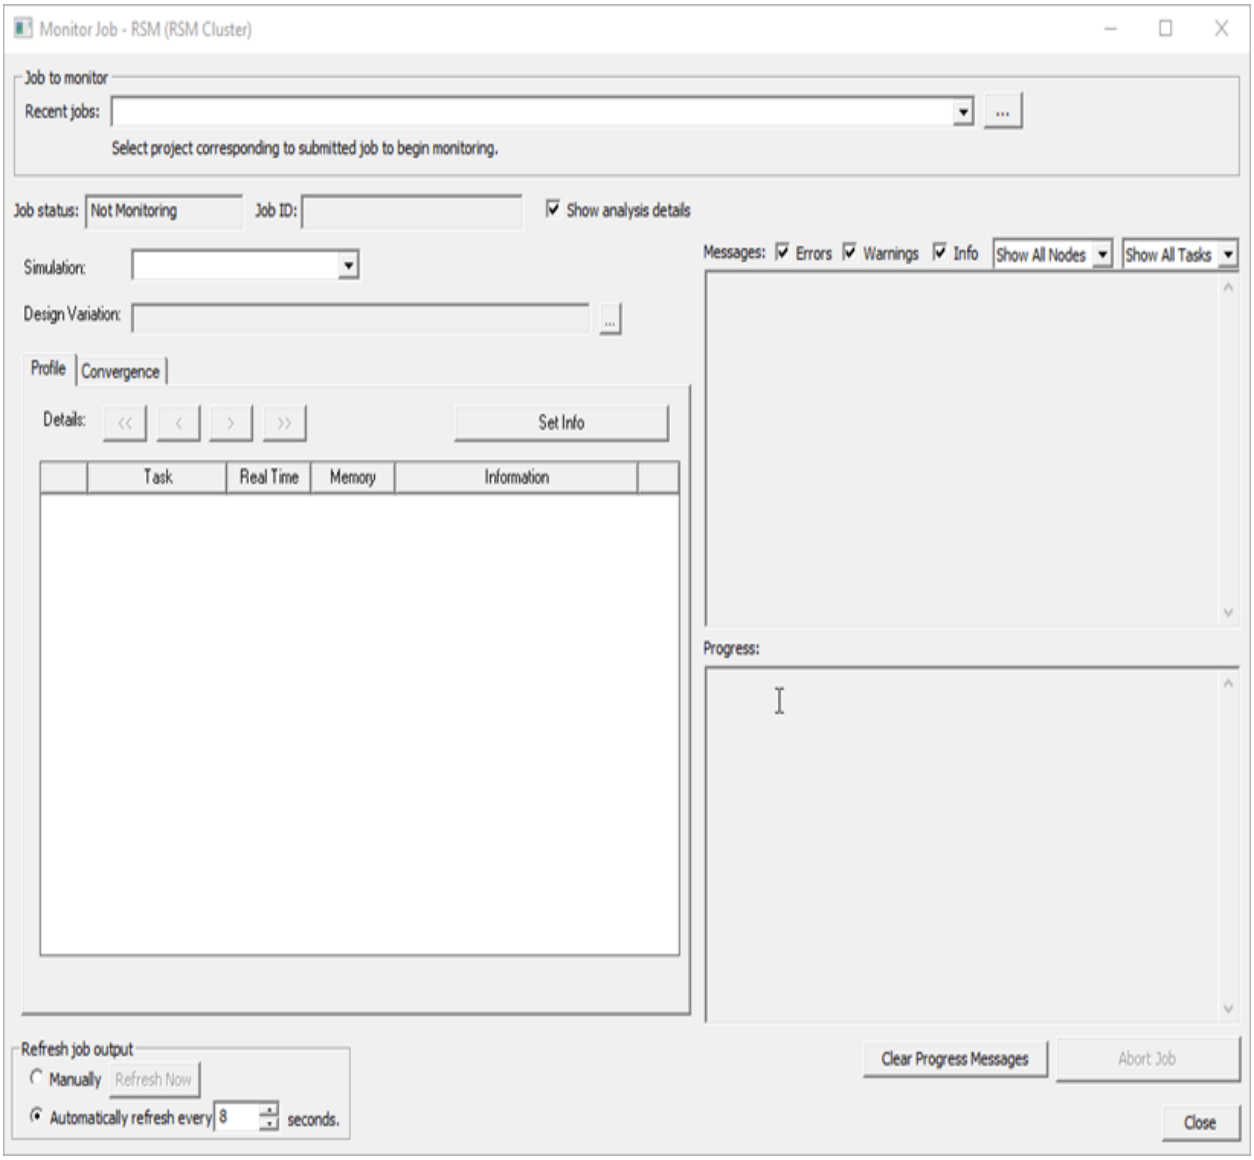
Monitor Job Window

The **Monitor Job** window allows you to monitor the progress and status of jobs, including information on variations solved so far, variations currently solving, and the number of variations remaining.

To monitor jobs:

1. Click **Tools** > **Job Management** > **Monitor Jobs**, or:
   select the **Simulation** tab and click the **Monitor** icon, or
   from a Command window, use the -showmonitorjobs command.

   The **Monitor Job** window appears.



Note:

The window may look slightly different, depending on your selected scheduler.

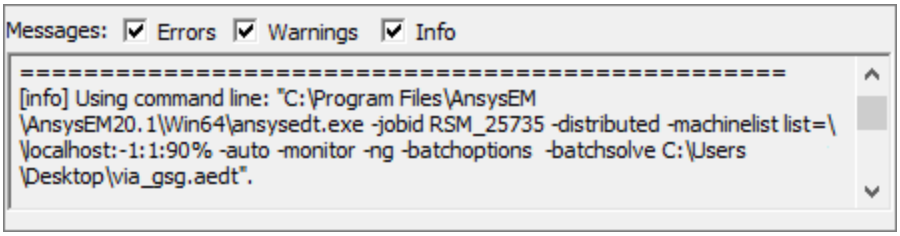
The **Monitor Job** window contains the following areas:

- **Job to Monitor** – Allows you to select either a recent job, or a project containing the job you want to monitor. You can select an archive.
- **Job Status** – The current job status. The normal progression is: Starting Monitoring, Queued, Running, Shutting Down, Completed. A status of Unknown may indicate a connection problem.
- **Job ID** – Identified by the scheduler prefix and job number.

- **Simulation** – Drop-down menu that allows you to select an individual simulation setup.
- **Design Variation** – Click the ellipses button (**...**) to select or deselect design variations.
- **Profile Tab** – Displays detailed information about completed tasks, including execution time and memory usage.

Task	Real Time	CPU Time	Memory	Information
Start				Time: 10/16/2019 14:17:38; Host:: Processor: 12;
				Executing from C:\Program Files\AnsysEM\AnsysEM20.1\Win64\Q
				Performing minimal design validations
InitMesh	00:00:08	00:00:07	106 M	70131 triangles
PreProc	00:00:00	00:00:00	106 M	70131 triangles
AdaptMesh_1	00:00:01	00:00:00	107 M	78514 triangles
Solve(1p)_1	00:00:00	00:00:00	126 M	51207 unknowns
ErrorCalc_1	00:00:00	00:00:00	126 M	78514 triangles
PostProc	00:00:01	00:00:00	126 M	995 elements
Solution Process				Elapsed Time: 00:02:15
Stop				Time: 10/16/2019 15:15:30; Status: Normal Completion

- **Convergence Tab** – Displays the completed, maximum, and minimum **Number of Passes**.
- **Messages** – Displays errors, warnings, and job information. Use the check boxes to choose which of these to display.



- **Progress** – Displays progress bars when tasks are currently in progress.

  The arrow button opens a menu that allows you to either **Abort** that analysis, or perform a **Clean Stop**.
- **Refresh Job Output** – Allows you to select either manual or automatic refresh for the **Monitor Job** window.

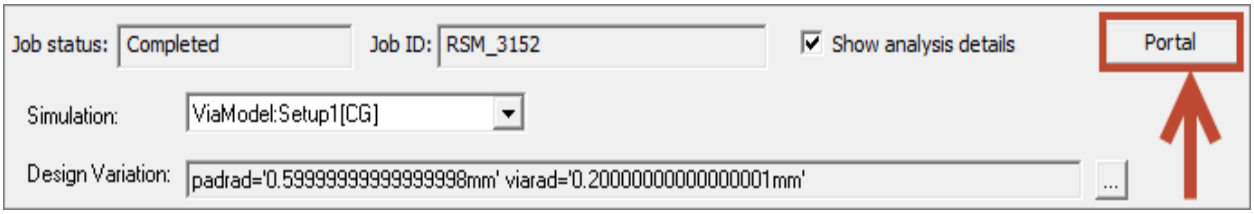
To display less information, deselect **Show analysis details**. This removes the **Simulation**, **Design Variation**, **Profile**, and **Convergence** information, instead displaying only **Messages** and **Progress**.

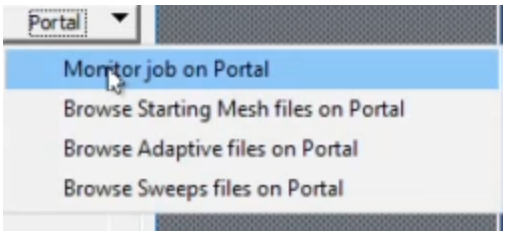
1. Click **Close** when you are done monitoring.

Monitoring Ansys Cloud Jobs

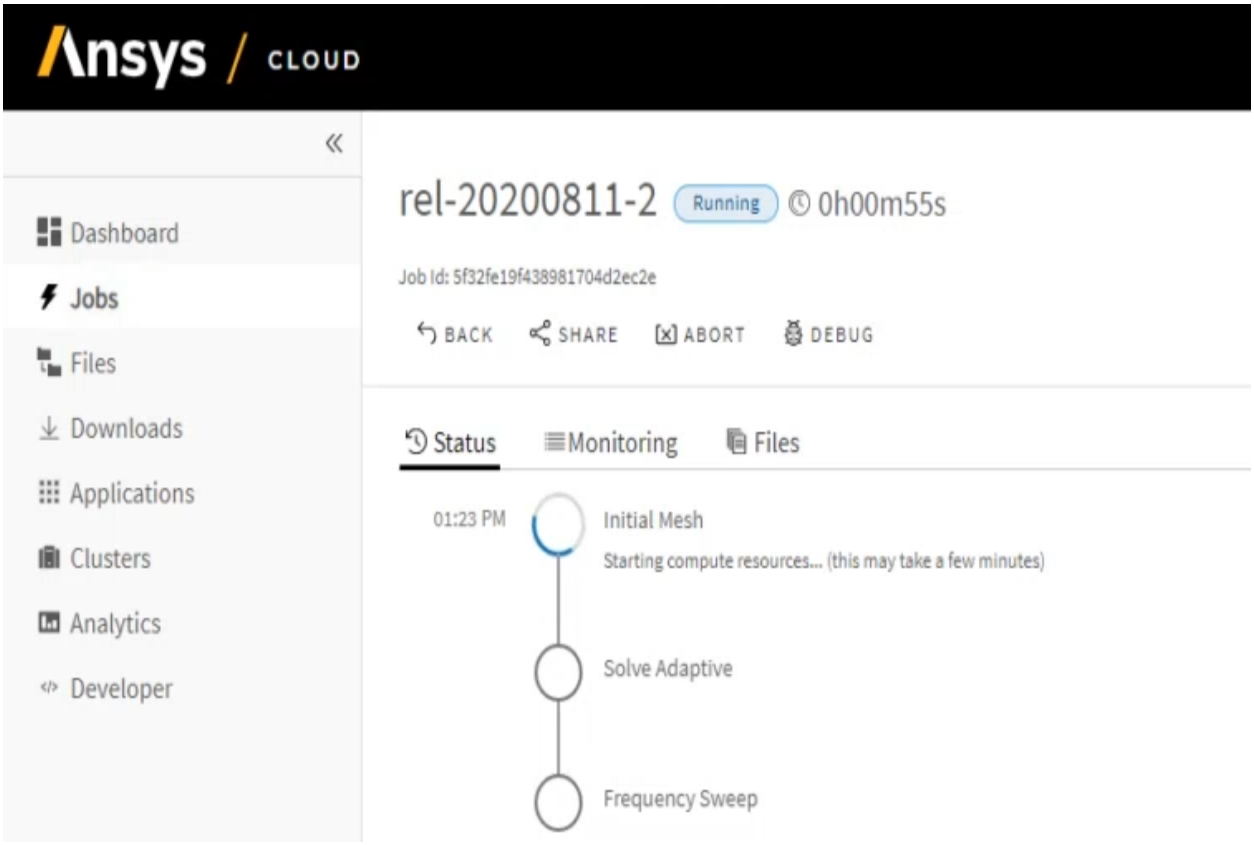
For Ansys Cloud submissions, the **Monitor Job** window includes two additional items:

- **Portal** – link to the Ansys Cloud Portal, where job details and additional monitoring information are available.

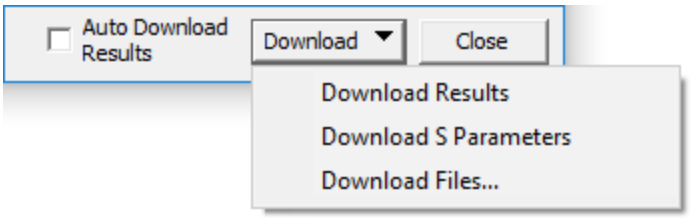




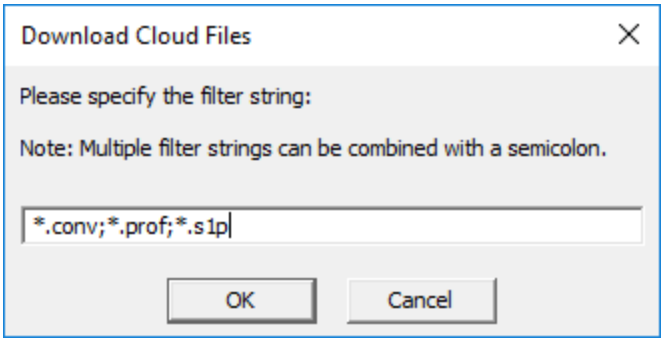
Monitor job on Portal Opens a Portal Web interface that lets you monitor an Ansys Cloud job. The additional menu options for **Portal** are for multi-step submissions, opening the Portal Web interface directly to folders with Starting Mesh Files, Adaptive Files, or Sweeps files.



- **Download** – button that allows you to download the results, s-parameters, or specified files. These are saved in a folder with same name as the job ID inside the `/<project-name>.aedtdownload` folder (or `/<project-name>.aedtzdownload` folder, if the submission was based on an archive). You can also select the **Auto Download Results** check box to have the results downloaded to this location automatically.



If you choose to **Download Files**, the **Download Cloud Files** dialog box appears:



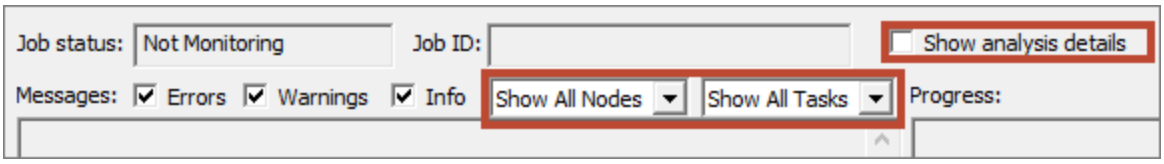
Specify the types of files you want to download (separated by semicolons) and click **OK**.

Monitoring Large Scale DSO Jobs

For Large Scale DSO submissions, the Monitor Job window includes the following items:

- **Show Messages in Node Tree** – Instead of viewing job details, you can select this option to view nodes and tasks in a tree format.

Drop-down boxes allow you to filter which Nodes and Tasks to display in the tree.



To leave this mode, select **Show analysis details**.

Ansys Cloud Support for HPC Job Management

Ansys Electromagnetics Desktop supports the Ansys Cloud service that allows quick and easy access to cloud-based HPC resources. The service is accessible through both the Simulation Ribbon and **Tools** > **Job Management**.

Note	For this release you can submit HFSS, HFSS 3D Layout, Icepak, Maxwell 3D, Maxwell 2D, Mechanical, Q3D Extractor, and 2D Extractor jobs, monitor their progress, and download and post process the results. Other solvers are either in Beta or are not yet supported for Ansys Cloud.

Uploads to and downloads from Ansys Cloud use archives to improve speed. The Project browser shows both .aedt and .aedtz (archive) files. If you submit an unarchived project, an archive will be automatically created for upload. When the job completes, the results are packaged into an archive. When the download is initiated, the repackaged archive file is transferred to the download folder along with the other job-related files, such as the log.

For single setups, you can use Multi-step submission. This separates the resource specification and reporting as appropriate for each stage of the solve.

Prerequisites for Using Ansys Cloud with Ansys Electronics Desktop

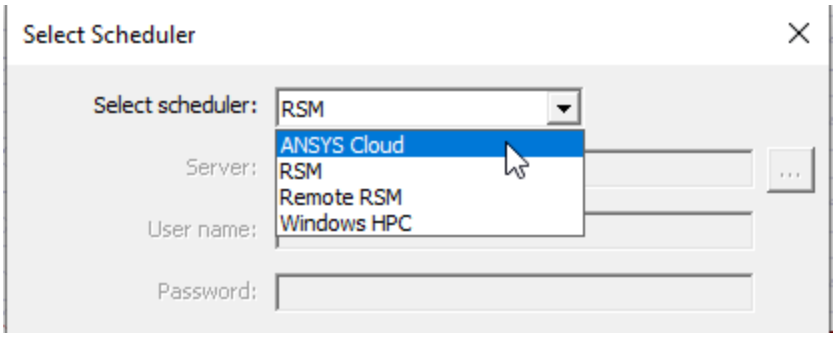
- You will need an "Ansys Cloud Compute Essentials" subscription associated with your Ansys Account. The Ansys Account is an extension of the Ansys Discovery account that includes those products and services that require sign-in, such as the AppStore, Cloud Compute and others. Contact your account manager or service representative to obtain a subscription invitation.
- You must select Ansys Cloud as your Job Management Scheduler, and, if necessary, log in to the Ansys Cloud Service using the Ansys Discovery Account and associated password.

Job Management UI for Ansys Cloud

You can use Ansys Electronics Desktop to submit batch jobs to Ansys Cloud and monitor those jobs.

This involves the following steps:

1. Use **Tools** > **Job Management** > **Select Scheduler** to select Ansys Cloud as the scheduler.



2. Click **Log in** to launch a login window for the Ansys Cloud.

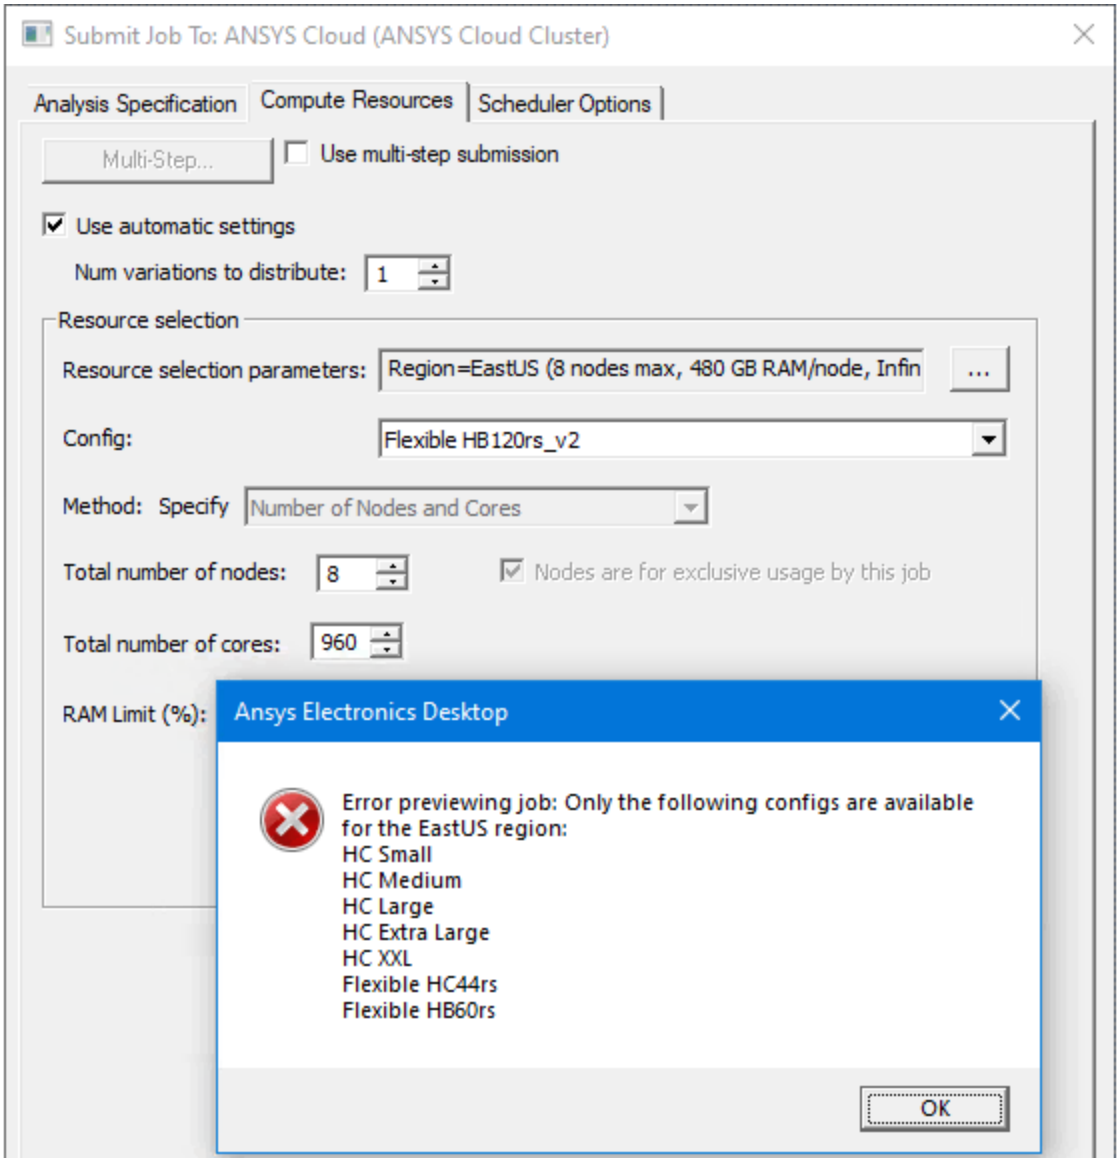
   After a successful login, you may not need to log in again for several days if you do not log out.

   If you wish to log out, click **Log out** from the **Select Scheduler** window.
3. Use **Tools** > **Job Management** > **Submit Job** to submit a batch job to Ansys Cloud.

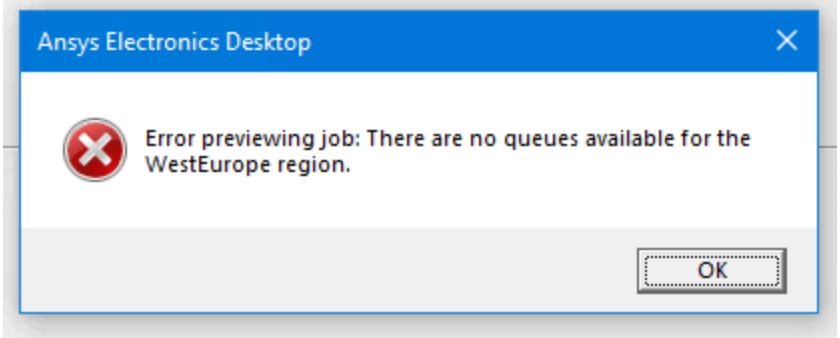
   Ansys Cloud-specific Settings:

   - On the **Compute Resources** tab, **Resource Selection Parameters** will allow you to select a **Region** (for example, EastUS, JapanEast, WestEurope). The **Config** drop-down does not display configurations that are not available in any of the selectable

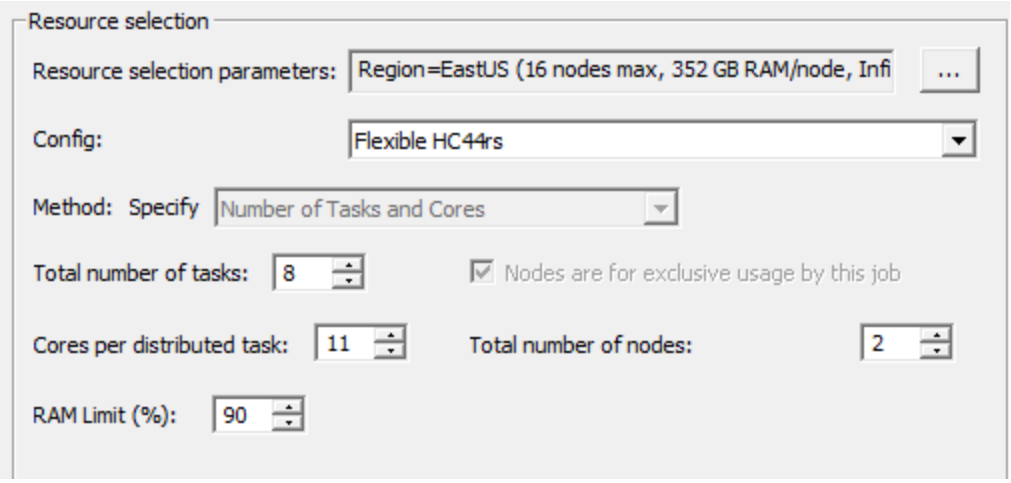
regions. That is, if the regions are EastUS, WestEurope, and SouthwestUS, and none of these regions have the smallhc-based queues, then the "HC Small" configuration does not show up in the **Config** drop-down. If you select a resource that is not available in the specific region you select, an error messages shows the available choices for that region.



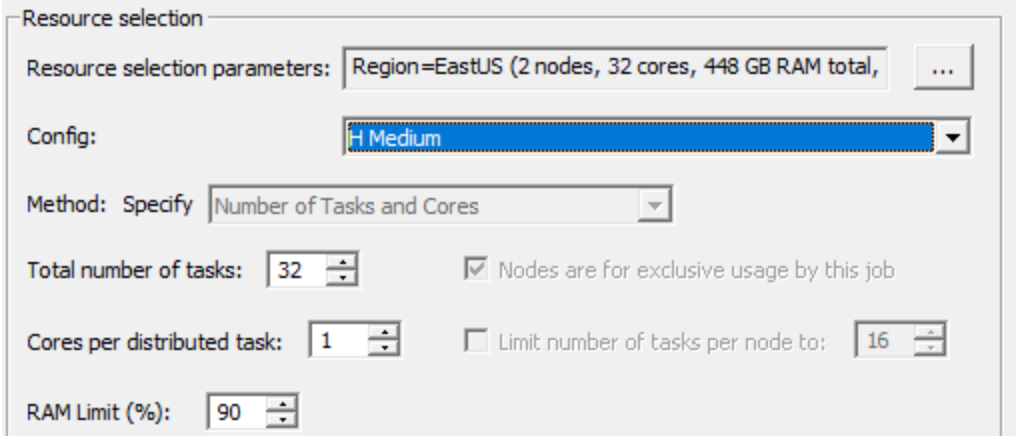
If no queues are available, an error message provides a message:



- On the **Compute Resources** tab, select a **Config** size and style (Flexible or fixed) based on the following:
-
  - **Small:** 16 cores, 1 node, 224 GB RAM total
  - **Medium:** 32 cores, 2 nodes, 448 GB RAM total, Infiniband
  - **Large:** 128 cores, 8 nodes, 1792 GB RAM total, Infiniband
  - **Extra Large:** 256 cores, 16 nodes, 3584 GB RAM total, Infiniband
  - **XXL:** Even larger.
  - **Flexible**: Flexible queues permit the following resource selection methods: Automatic Number of Nodes and Cores, Manual Number of Tasks and Cores. If you select a Flexible queue for manual Number of Tasks and Cores, you will see a new item in **Resource Selection** for "Total number of nodes" replacing the "Limit number of tasks per node to" option that appears for fixed queues.

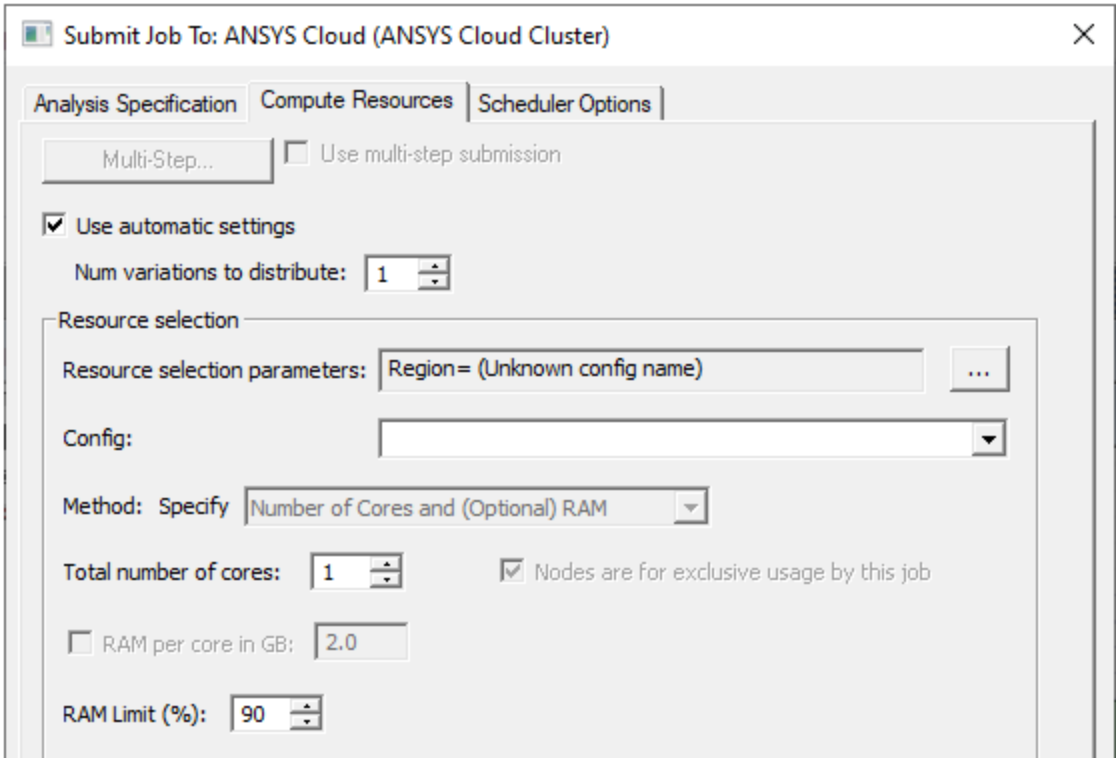


In comparison, if you selected a fixed configuration, the Resource selection panel appeals like this:

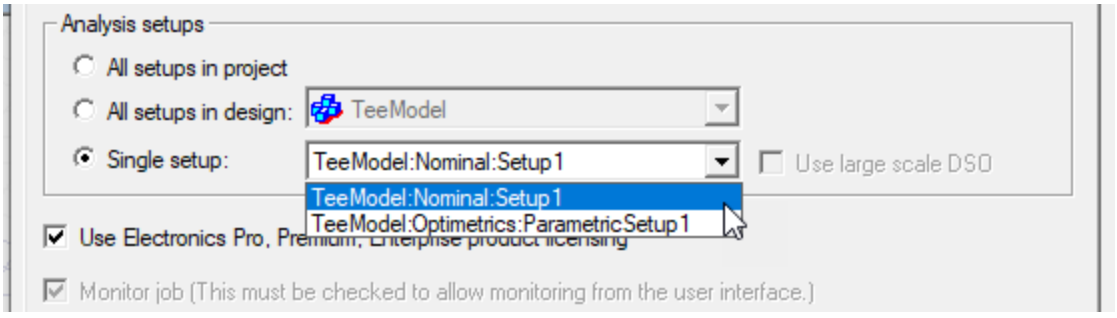


> **Important:**
>
> Attempts to use more for submission will result in error messages.

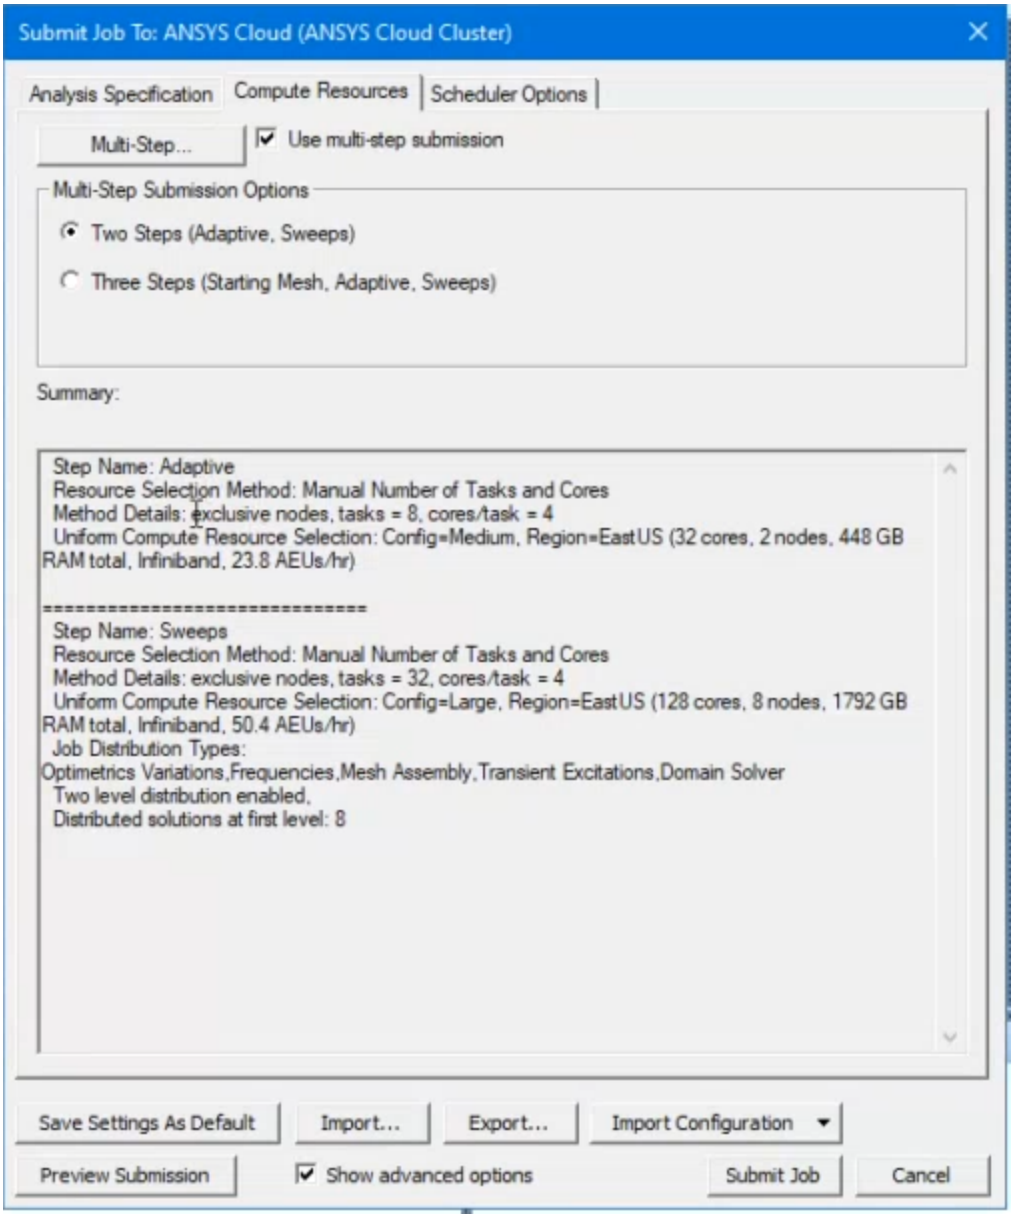
- On the **Compute Resources** tab, if you select **Use automatic settings** with **Num variations to distribute** set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. If you set **Num variations to distribute** to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically.



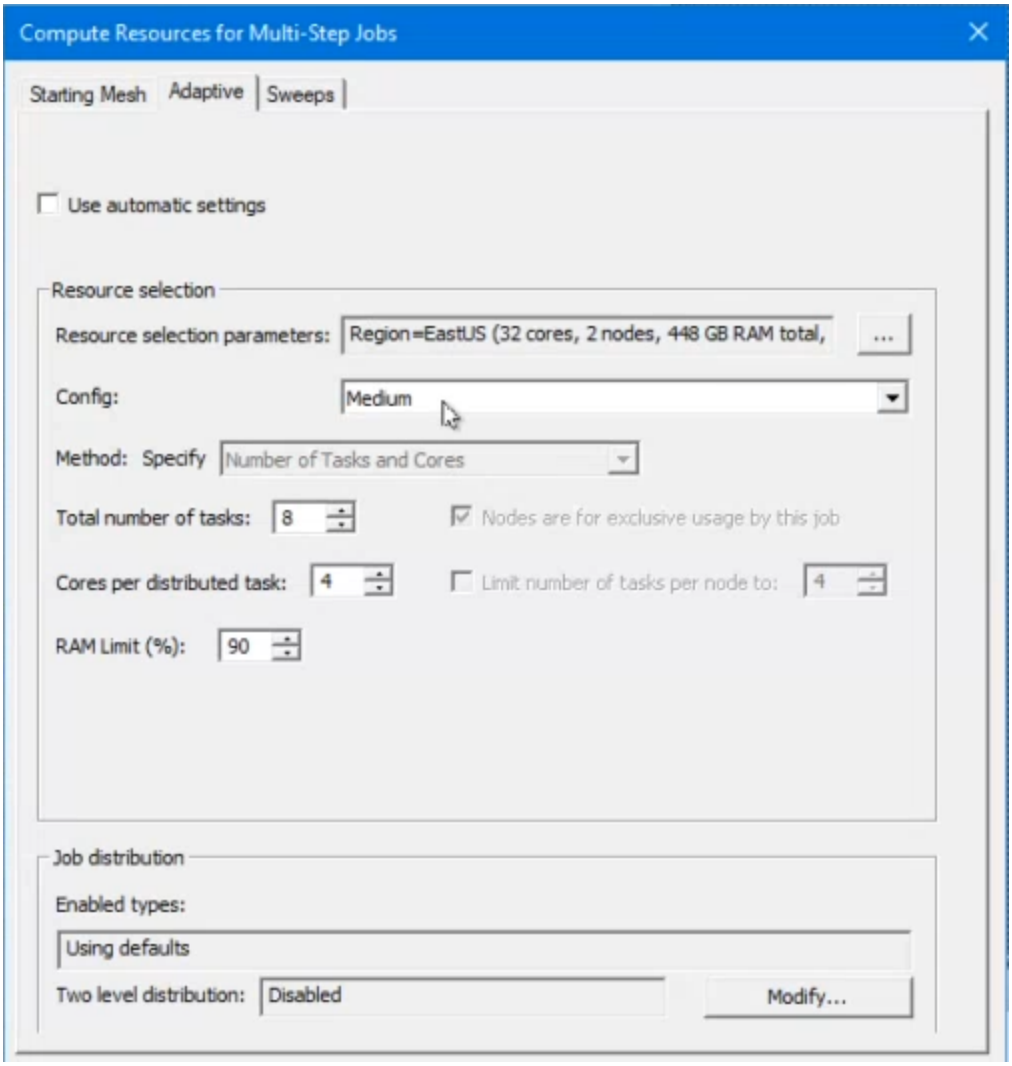
- In response to a set of minimal constraints, Ansys Cloud scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines with two processors per engine and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Click **Preview Submission** to see the number of resources assigned, and that the scheduler-generated code includes an MPI specification.
- To use **Multi-Step Submission** on Ansys Cloud, you must specify a single setup on the **Analysis Specification** tab.



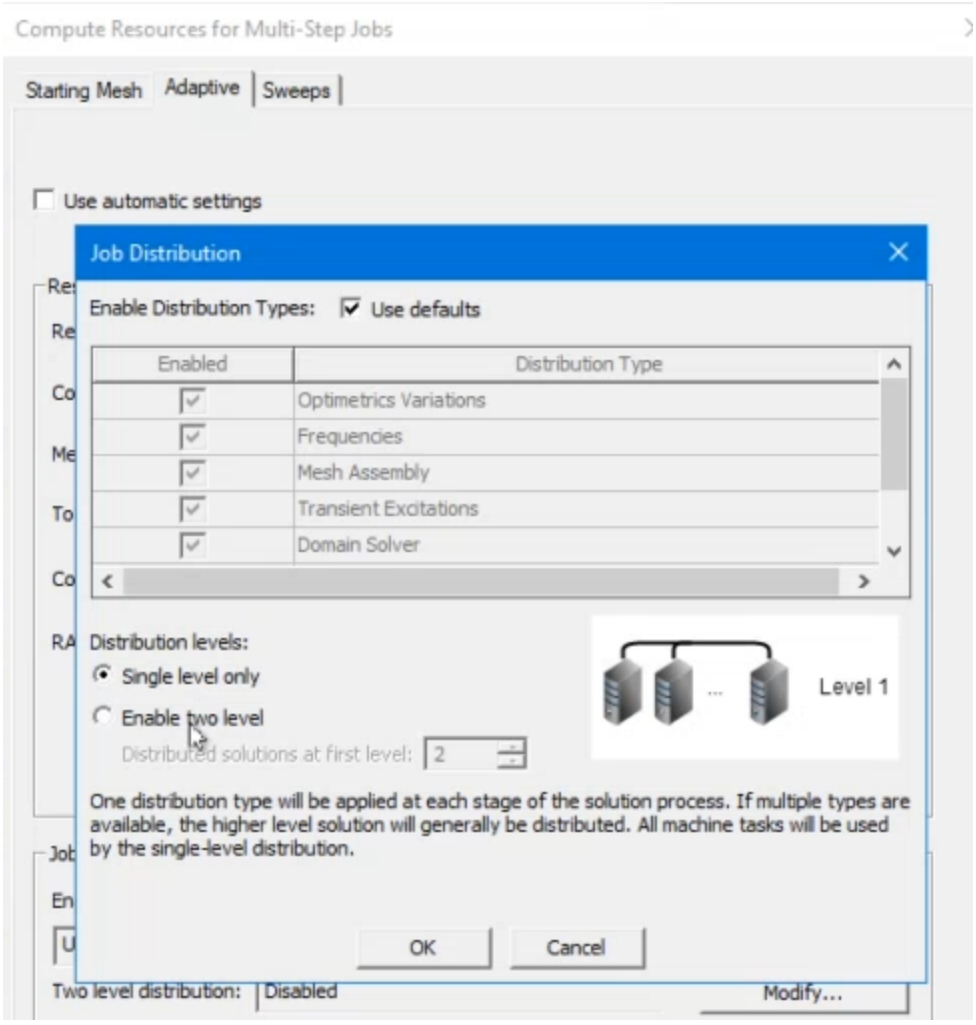
This enables **Multi-Step** options on the **Compute Resources** tab.



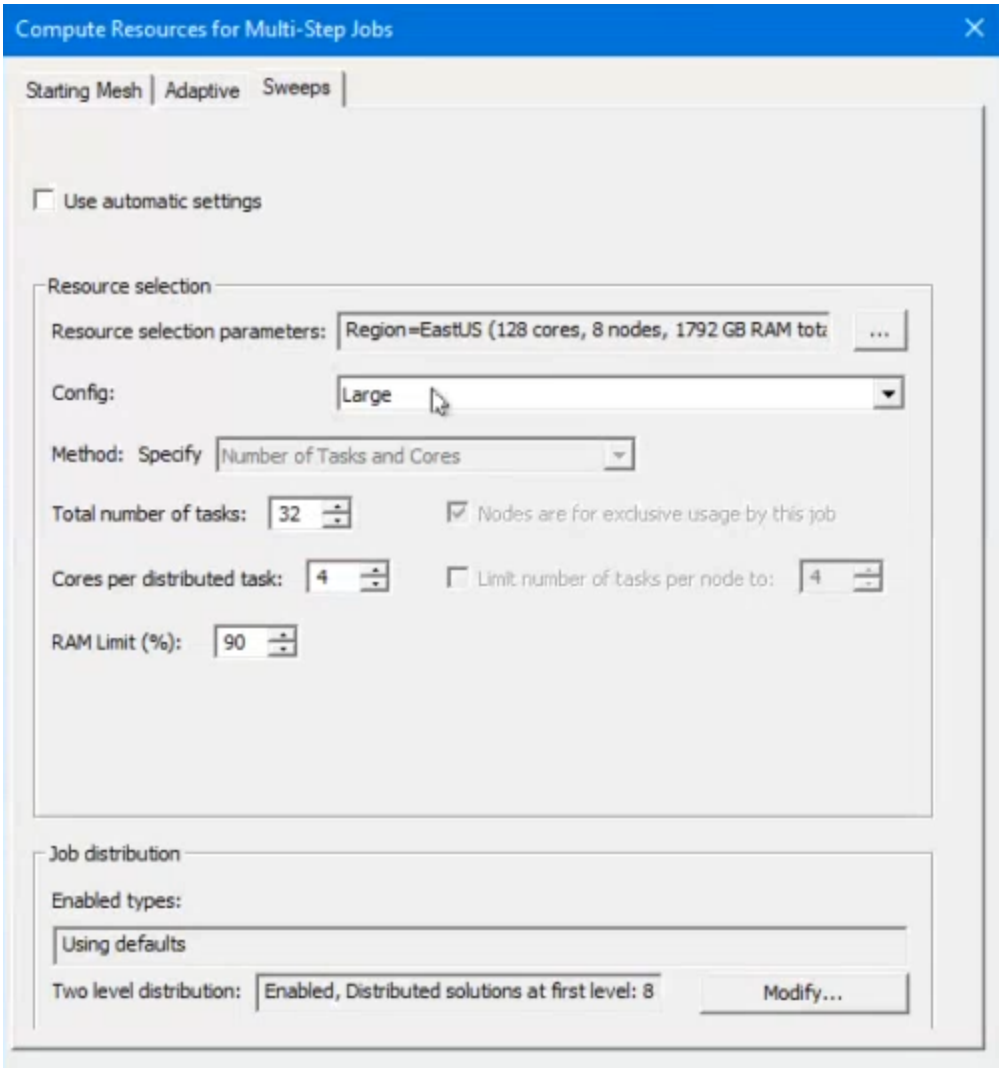
Click the **Multi-Step** button to open the **Compute Resources for Mult-Step Jobs** dialog box. It has tabs for **Starting Mesh**, **Adaptive**, and **Sweeps**.
On the **Adaptive** tab, you can **Use automatic settings**, or specify **Resource Selection**



Click the **Modify...** button on the **Adaptive** tab to open the **Job Distribution** dialog box.

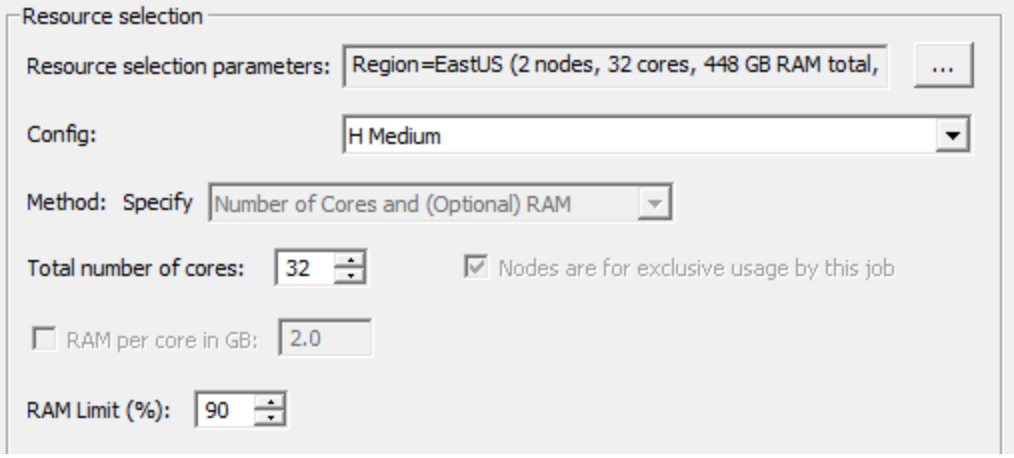


The **Sweeps** tab lets you specify resources or **Use automatic settings**.

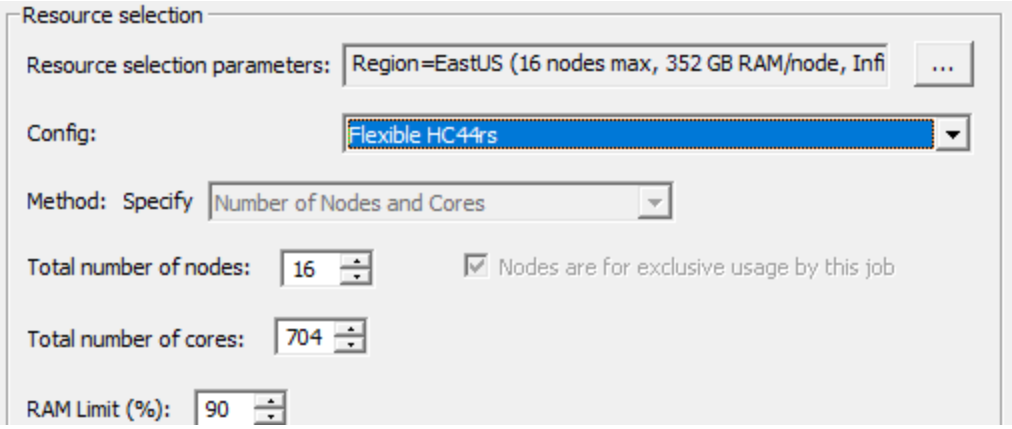


The **Sweeps** tab includes an independent **Modify..** button to specify **Job Distribution**.

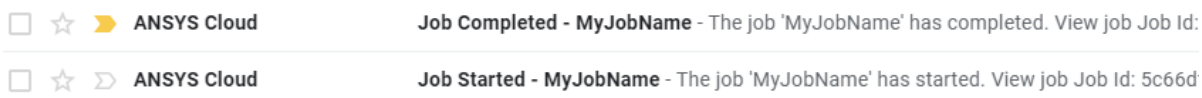
Select automatic settings, or specify different resources for each step. When a job is finished, that is, on the last step, reports update and traces are extracted into CSV files. If select fixed queue for automatic sections, the Resource selection panel only allows cores and has RAM with RAM disabled:



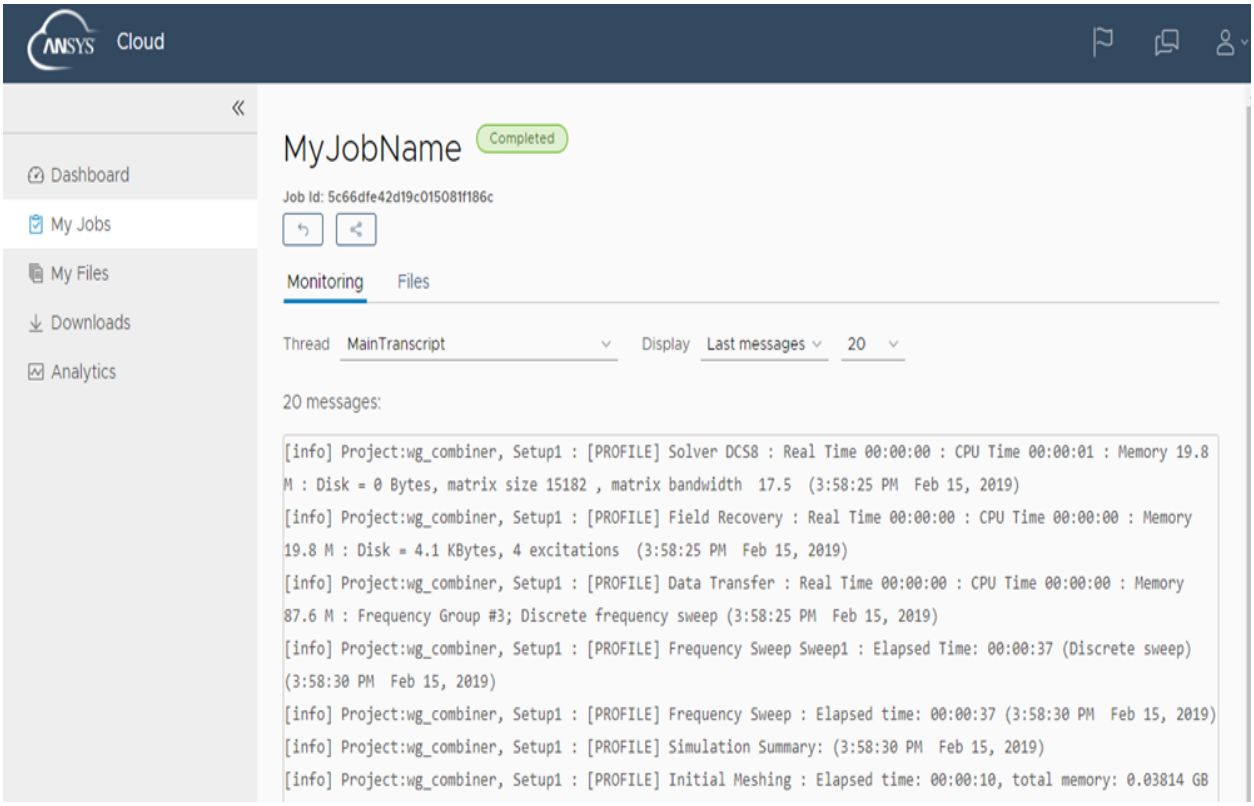
If you select flexible queue for automatic settings, The Resource selection panel only allows nodes and cores for a flexible queue:



4. Use **Tools** > **Job Management** > **Monitor Job** to monitor the job's progress.
5. You will receive an email when the job has started, and another when it has finished.



6. Use the link in the email (or the **Portal** button on the job monitoring window) to launch the Ansys Cloud Portal and view detailed results:



Environment Variable Settings for Ansys Cloud

When submitting jobs to Ansys Cloud from Electronics Desktop, certain environment variable and batchoption settings must be made to ensure proper operation on the cloud. These settings are done automatically through the job submission window.

These environment variable settings will override any attempts from the user to set the same environment variables:

- ANS_NODEPCHECK=1
- ANSYSEM_FIX_REVERSE_LOOKUP=1
- ANSYSEM_DESKTOP_SUBNET_FROM_COMENGINE_ADDR=1

The environment variable ANSYSEM_ENV_VARS_TO_PASS contains a semicolon-separated list of filters for environment variables to be passed from ansysedt.exe to COM engines. You are allowed to set this environment variable. After being prepared for the job it will have the following filters set at minimum (with the user-requested filters following these):

```
ANSOFT_*;ANS_*;ANSYSEM_*;ANSYSLMD_LICENSE_*;I_MPI*
```

Troubleshooting and Debugging Environment Variables

To keep downloaded files that help with troubleshooting, enable the environment variable ANSYS_EM_PRESERVE_DOWNLOAD_FILES.

Debug logs (and other files generated in the working directory) from remote nodes are automatically collected.

Option Settings for Ansys Cloud

The following option is automatically added for Ansys Cloud jobs:

- -autoextract
- For single step jobs it will include "-autoextract reports".
- For multi-step jobs, the last step will include "-autoextract reports" but the first steps will only include "-autoextract" (no reports). Reports are only extracted on the last step.

See: Running Electronics Desktop from a Command Line.

Automatic Batchoption Settings

The license type batch option ("HPCLicenseType") is forced to be "Pack" because Cloud is configured to only work with pack licensing. The following MPI batchoptions are automatically set as "Intel" because Ansys Cloud is configured to only work with Intel MPI.

- HFSS 3D Layout Design/MPIVendor
- HFSS/MPIVendor
- Icepak/MPIVendor
- Maxwell 2D/MPIVendor
- Maxwell 3D/MPIVendor
- Q3D Extractor/MPIVendor

RSM Integration with Job Management UI

Ansys Electromagnetics supports its own Remote Simulation Management (RSM) software, along with other High Performance Computing (HPC) software management programs (see High Performance Computing (HPC) Integration).

When do you need RSM?

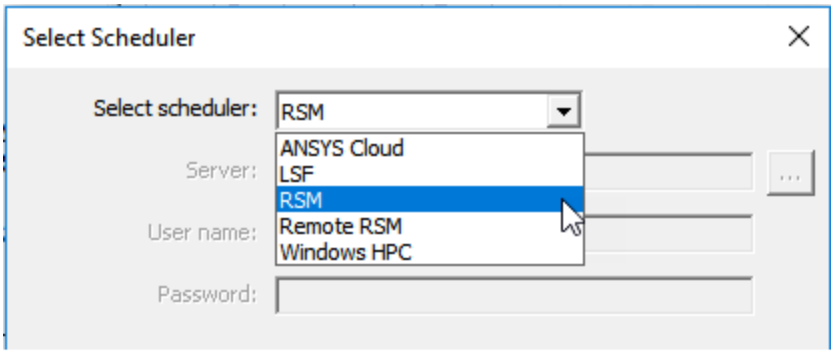
RSM is in general required if you want to run remote or distributed simulations. However, if you have a separate scheduling system that Ansys Electromagnetics supports, and you plan to run batchsolve simulations only, then you may not need to install RSM. For details of installation and configuration of RSM, see the *Ansys Electromagnetics Installation Guides*.

Job Management UI for RSM

You can use the Job Management UI to submit batch jobs to RSM. The Job Management UI is accessed by running Ansys Electromagnetics product Desktop on the designated 'Postprocessing node' of the cluster. The Desktop provides UI commands for Scheduler selection, Job submission and Job monitoring/control. You access the Scheduler User Interface by clicking **Tools>Job Management>Select Scheduler...**

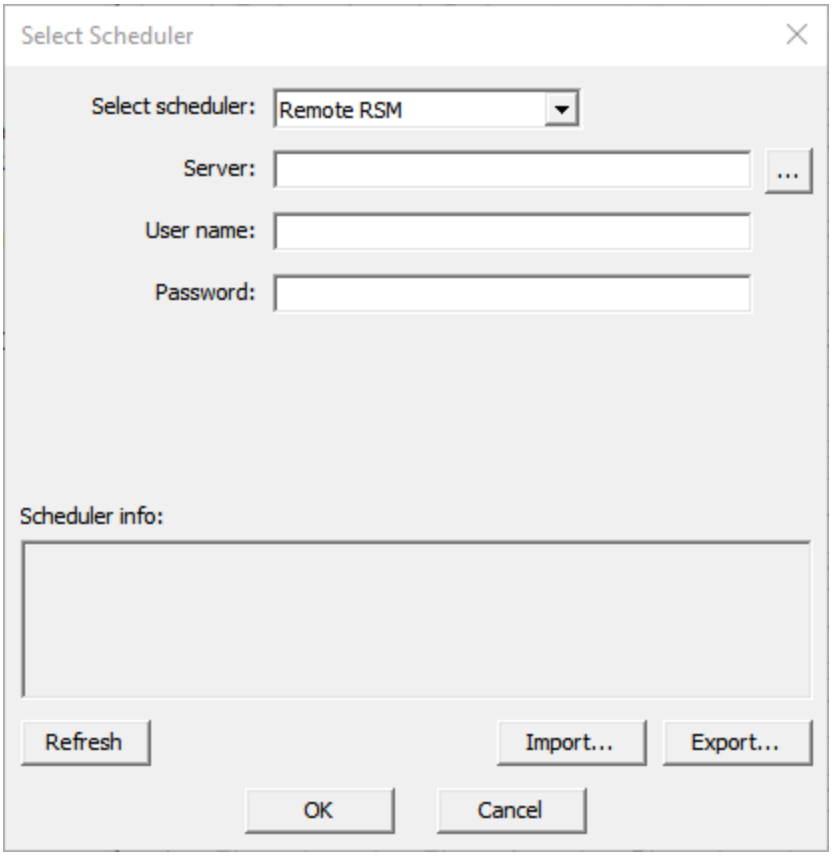
You can also select the **Simulation** tab of the ribbon, and click the **Scheduler** icon.

This displays the selection dialog box. The **Select scheduler** drop-down menu lists potential schedulers (which can include RSM, LSF, Windows HPC, or sge, depending on the environment).

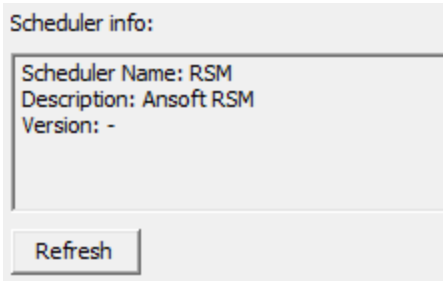


If you select a scheduler that is not supported in your environment, you receive a warning message.

If you select Remote RSM and your environment has been configured , you can select a computer, user name, and password.



After selecting a scheduler, you can click **Refresh** to display information for that scheduler.



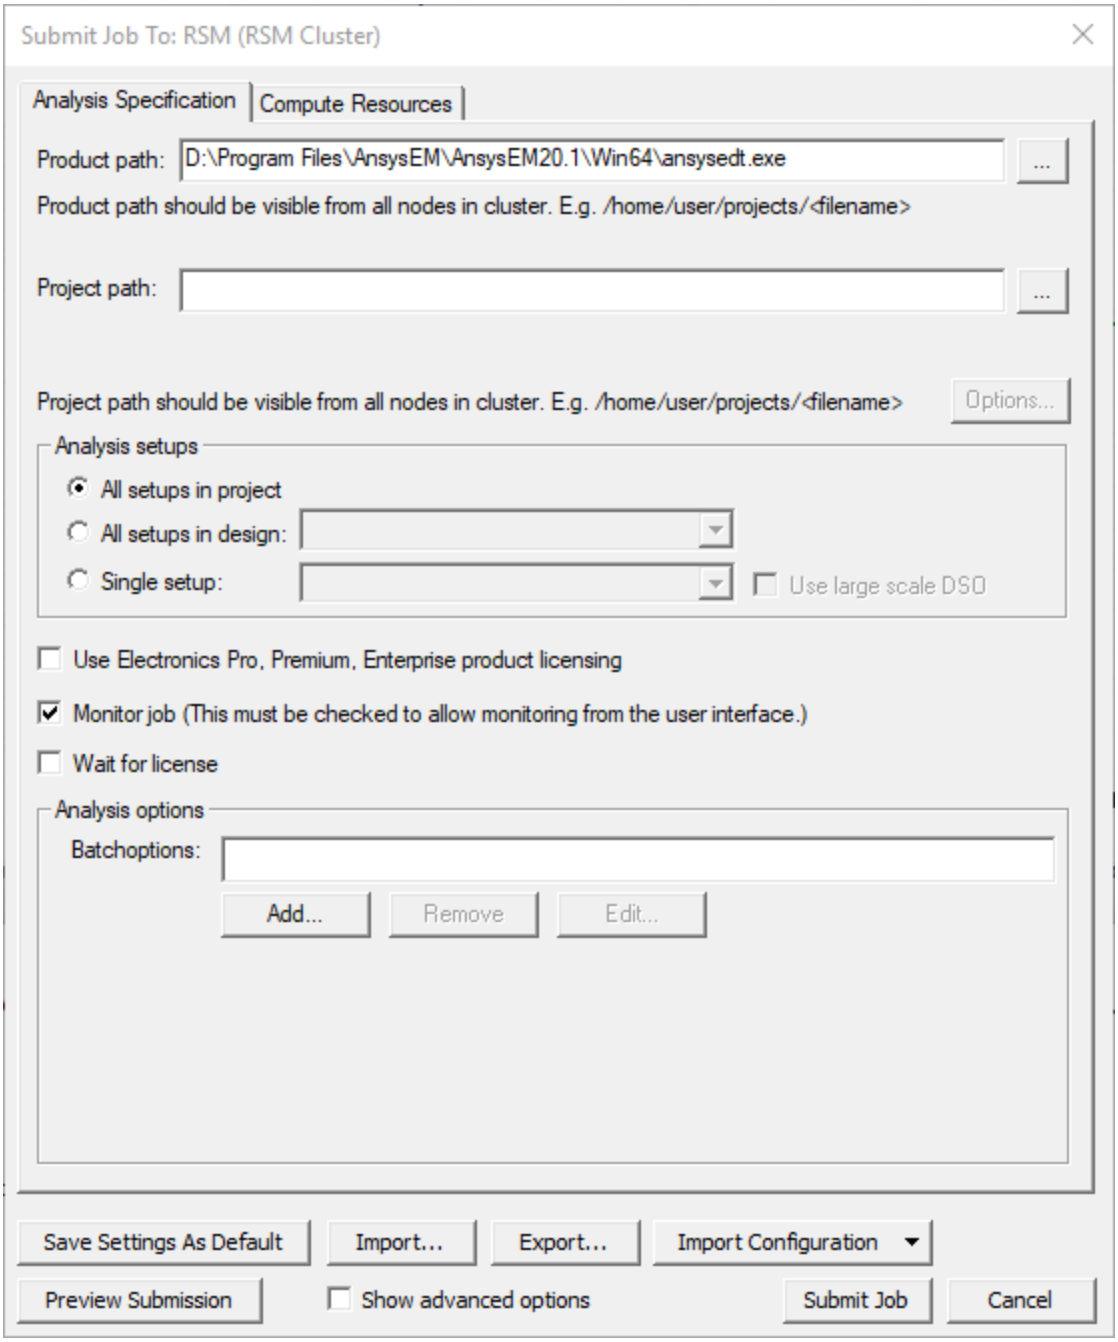
Once you have selected a scheduler supported in your environment, you can go through the following steps to submit a batch job.

1. Setup and prepare the model on local workstation.
2. Copy the input project (or folder, if the project references external files) from a personal workstation to a shared-drive on cluster (for example, project is copied to /home/projects/spool/test.aedt).
   - In the RSM environment, you are required to specify a machine-list. (See the Remote Analysis options panel.) For example, say the machine-list is: 3 cores from 'm1' and 3

cores from 'm2', for a total of 6 engines. You select the list on the **Compute Resources** tab of the **Submit Job to RSM** dialog box, as described below.

3. Open a remote-desktop session (or equivalent such as vnc session) on the node corresponding to the first machine of job's machine-list, 'm1' in this case. Launch Desktop graphically on 'm1'.
4. Select **Tools>Job Management>Submit Job...** or **Project> Submit Job...** or [ProductName]> **Submit Job...** to open the **Submit Job To** dialog box. You can also access **Submit Job** from the shortcut menus for the Project Name, Design name, Analysis

Setup, or Optimetrics Setup.



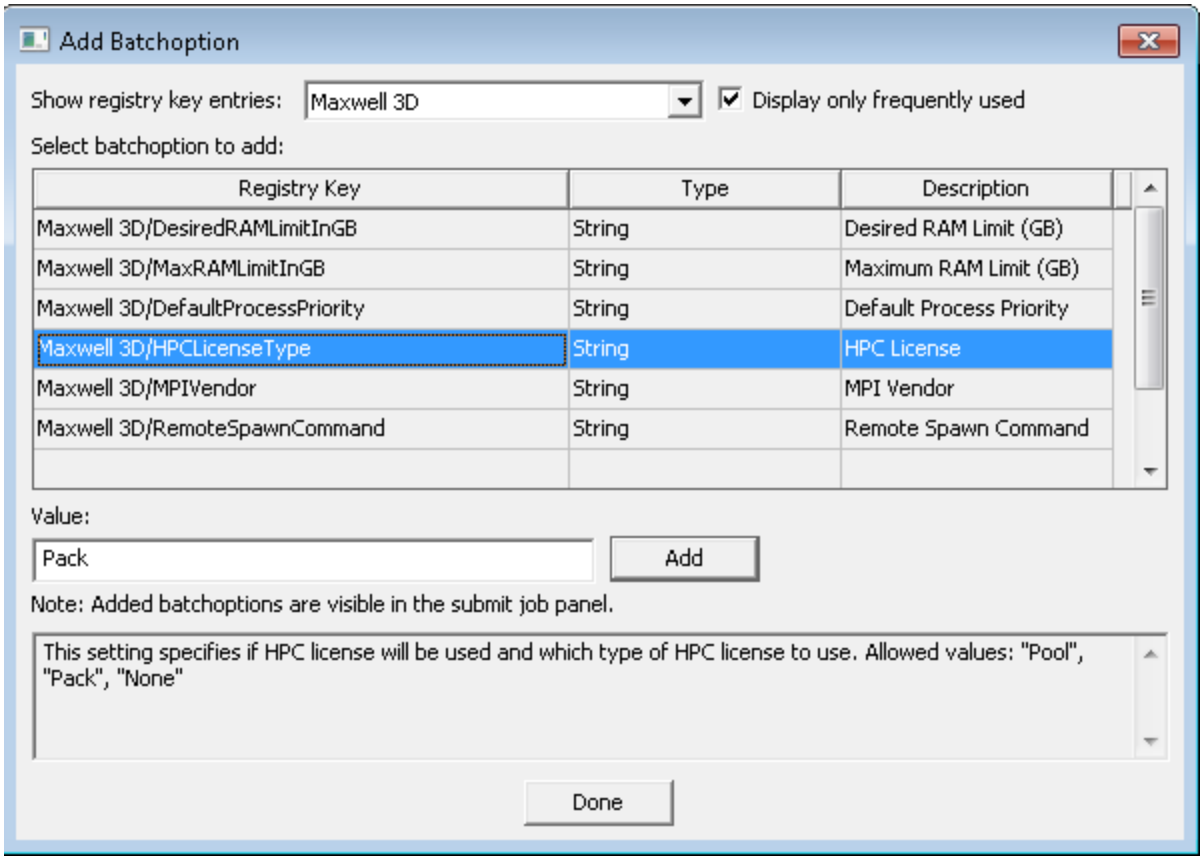
- The **Analysis Specification** tab has parameters to specify the input project model, the analysis setup and analysis options (including batchoptions) that affect analysis algorithms.
- The **Compute Resources** tab specifies the amount of compute resources and how to select specific resources from the available pool.

5. Use the ellipsis button [...] to open a browser to select the project. The Project can be an archive.

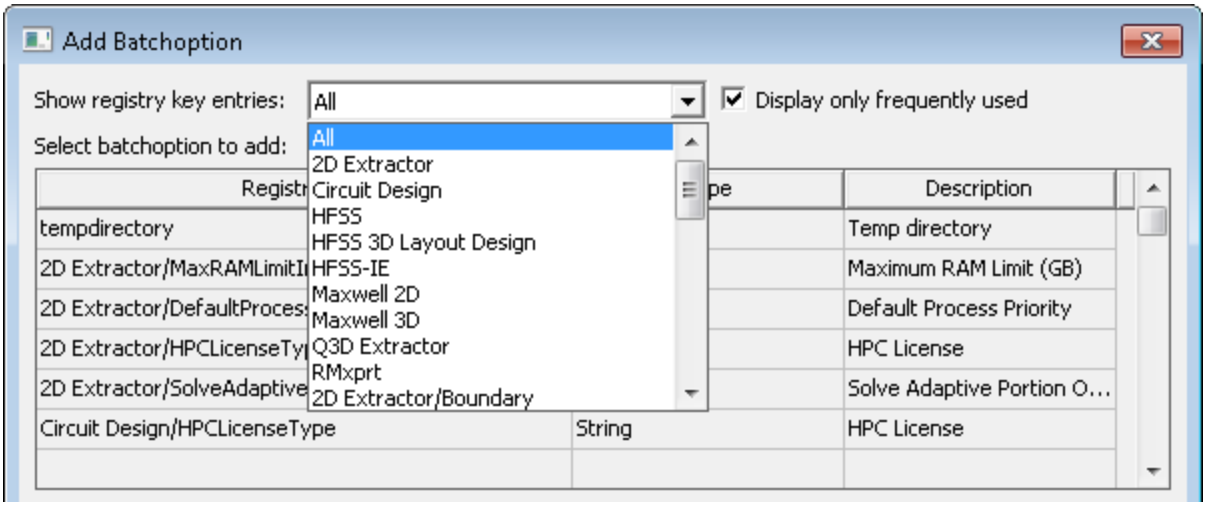
6. In the Analysis setups field, you can select radio buttons for All setups in the project, All setups in the design, or a Single setup. For instance, the Rotational_actuator.aedt example includes setups for Nominal, Parametric, and Optimization.

   For Parametric setups, you have the option to select Use Large Scale DSO. For details on how and when you use this feature, see Job Management Interface for Large Scale DSO.

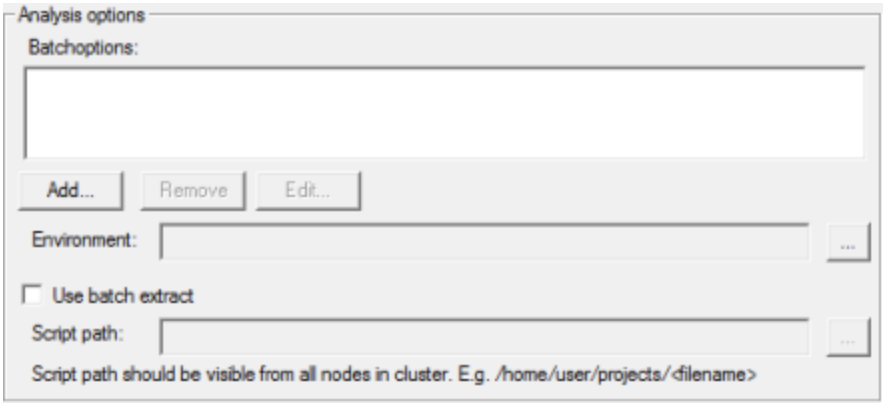
7. The Analysis options includes checkboxes for Monitoring the job, whether to wait for a license, and a field for adding Batchoptions. via a graphical interface, or as text.
   - If you intend to Monitor the job through a user interface, you must check Monitor job. You can then monitor this job through the **Tools>Job Management>Monitor Jobs...** command or by checking the dialog that opens when you submit the job.
   - The Batchoptions field allows you to add additional -batchoptions parameters, either as text, or by using a dialog with selection menus. Click the **Add** button to view the **Add Batchoption** dialog box.



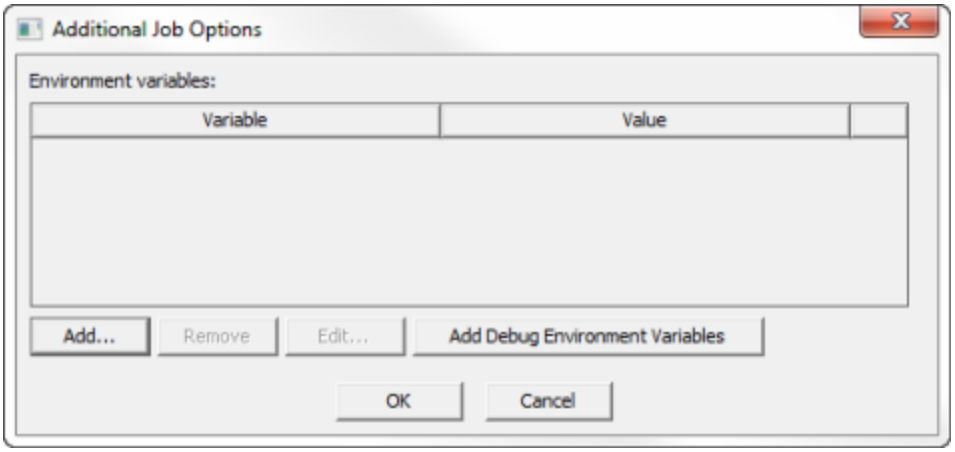
The Show registry key entries field lets you filter the entries displayed, by means of drop down menu selection, and a check box to Display only frequently used entries.



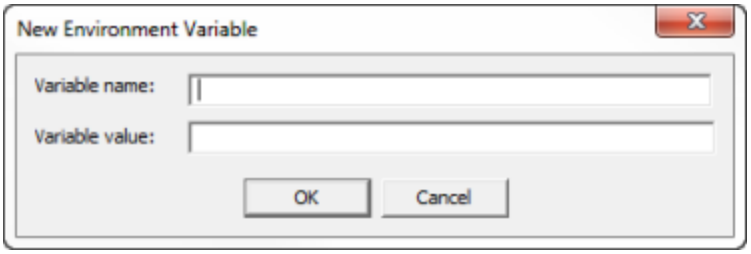
- When you have selected a batchoption, you can type the value in the field, and click the **Add** button to add the option to the batchcommand.
- In the **Submit Job To:** dialog box, you can enable Show advanced options to display additional fields for Environment variables, and whether to Use batch extract.



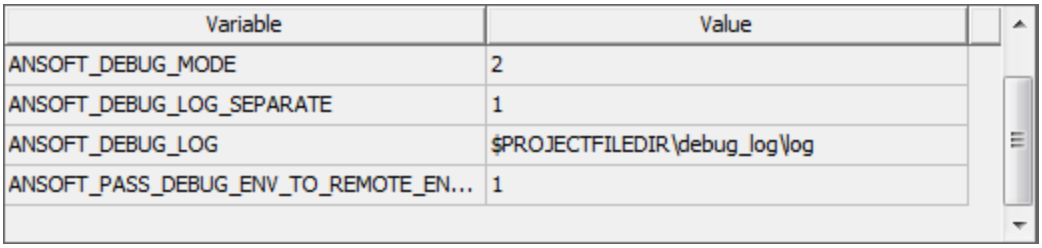
This field is for environment variables, for instance, for debugging features or other variable controlled features. Click the ellipsis [...] button to open a dialog for **Additional Job Options**.



The **Add...** button opens a New Environment Variable dialog in which you can include a variable name and value.



Clicking the **Add Debug Environment Variables** button automatically adds a set of debug variables. This can be useful in working with Ansys Application Engineering support.



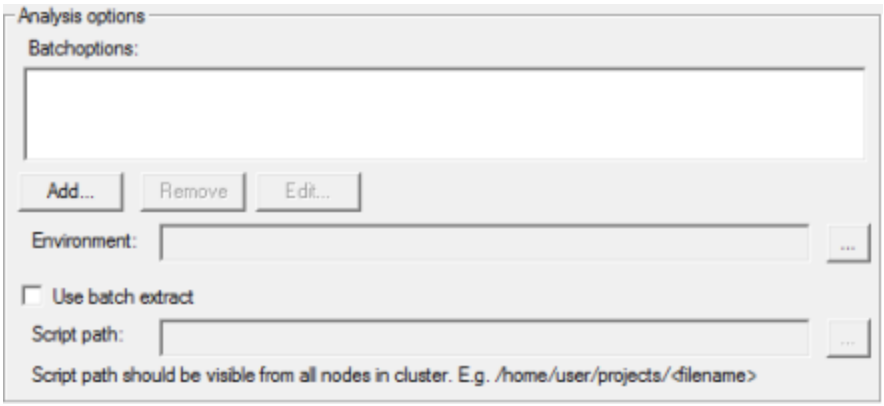
Selecting a variable in the dialog enables the Remove and Edit buttons. The Edit button opens a dialog where you can change the variable and value.

8. To see the command-line to be submitted to the scheduler, click **Preview Submission.** This opens a dialog showing the command to be sent to the scheduler.

The text can be copied to the clipboard, if desired.

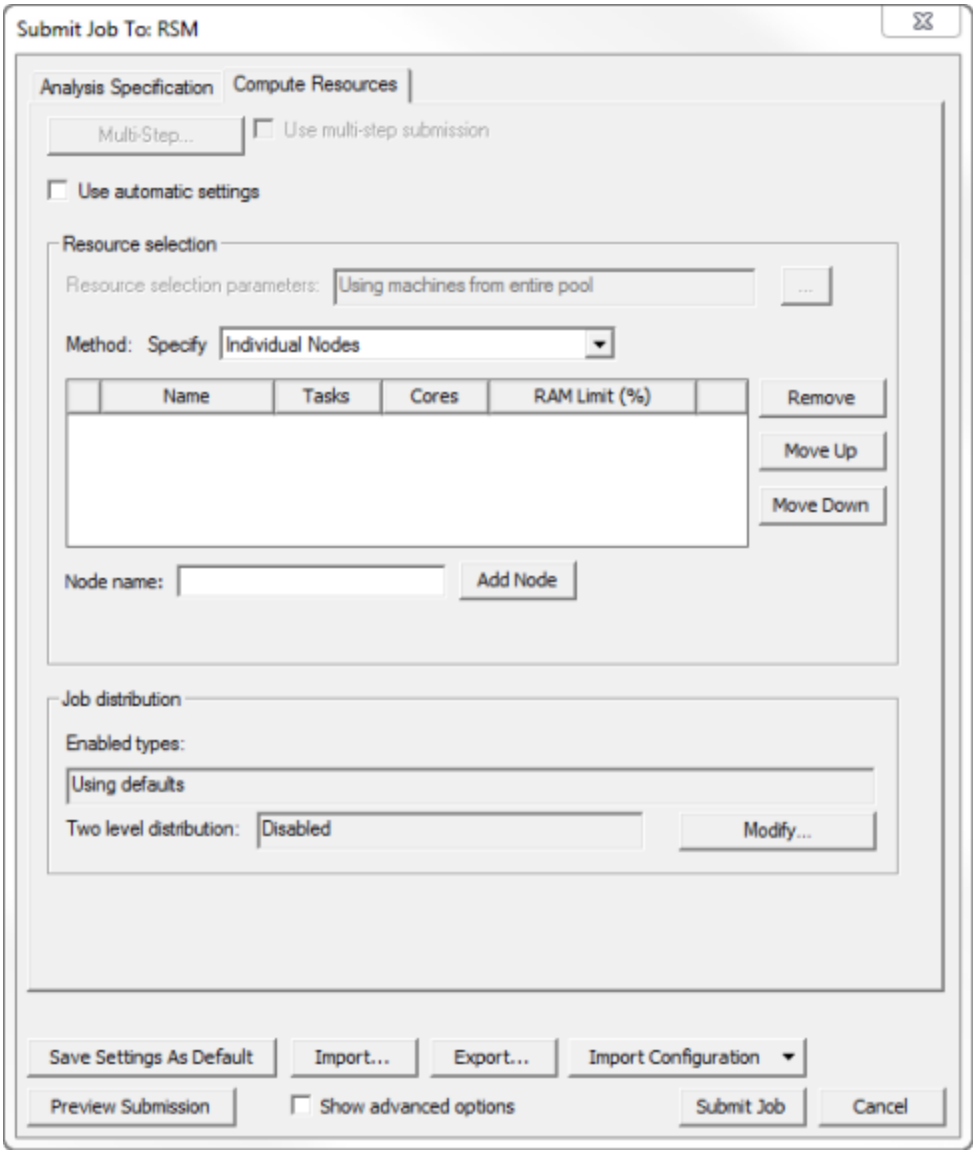
Use Batch Extract for RSM

Selecting Show advanced options for RSM also shows the Use batch extract fields.

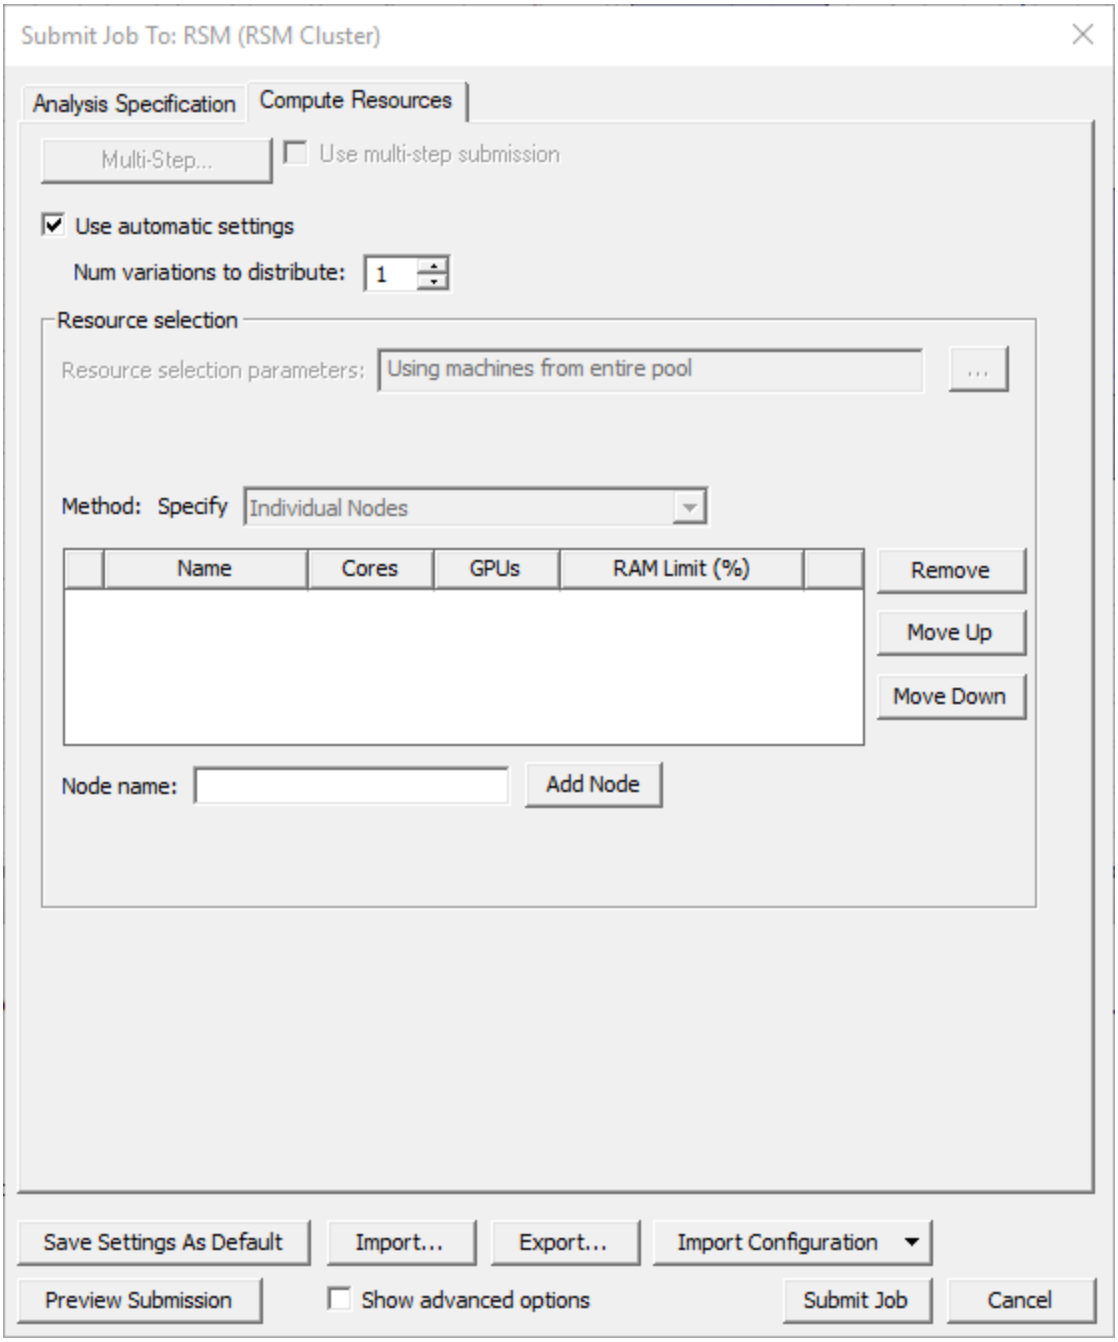


See the discussion on Running Maxwell from a Command line for a discussion of the solve information available through batch extract.

9. The **Compute Resources** tab of the **Submit Job to: RSM** dialog displays other parameters. Depending on the resources available for a scheduler environment, some of the fields may be disabled.



With **Use automatic settings** selected, the Job distribution field is removed and the Use automatic settings checkbox and Num variations to distribute field appears.

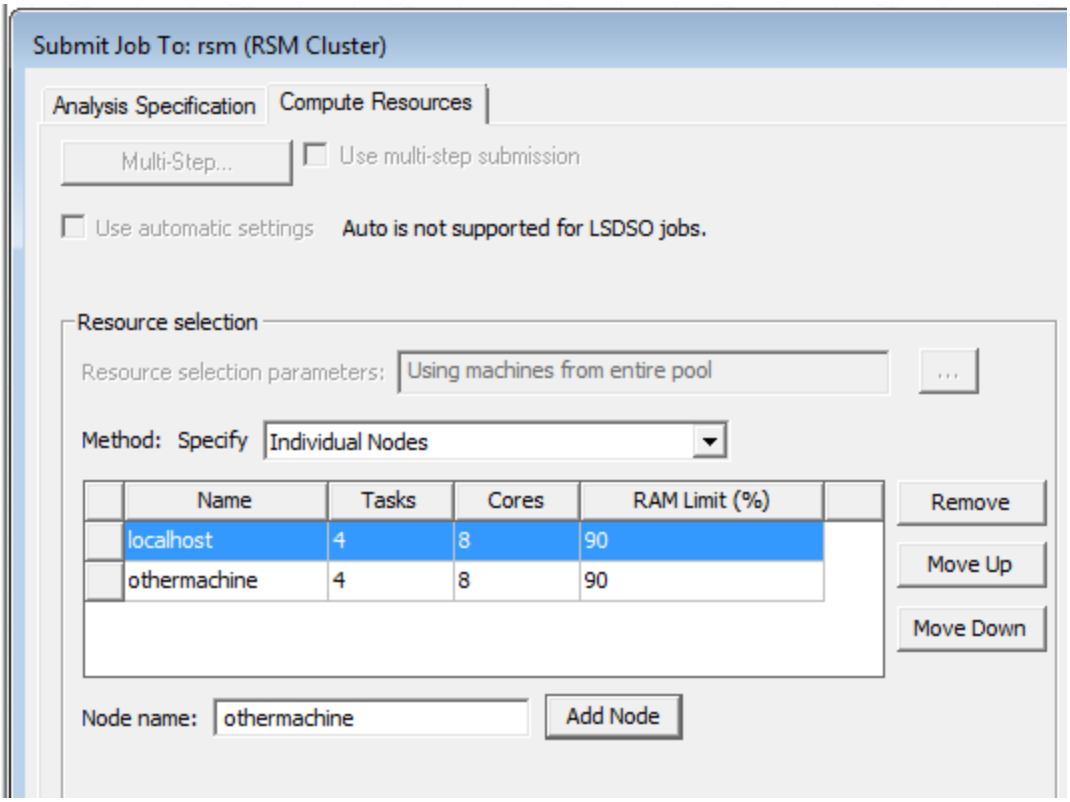


Note	If you select Use automatic settings with Num variations to distribute set to 1, Optimetrics variations will be solved sequentially. Other distribution types will be distributed automatically. It does distribute frequencies, domains, and use of multiple level domains. If you set Num variations to distribute to 2 or more, Optimetrics variations will be solved in parallel. Other distribution types will be distributed automatically.

Otherwise:

- Specify node list

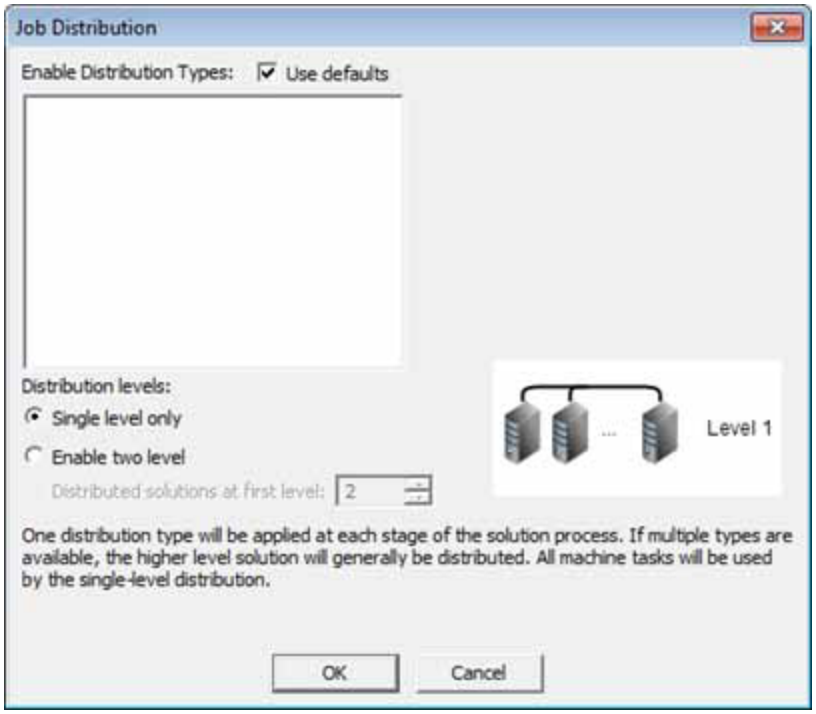
  Here you can specify a node list. In a computing environment where the available cores are not uniform, you can use this to control which resources your job will use. For use with Large Scale DSO for RSM, for jobs that are submitted from job submission panel, localhost must be the first node in the resource selection node list, other wise LSDSO solve with RSM will fail.



Job Distribution

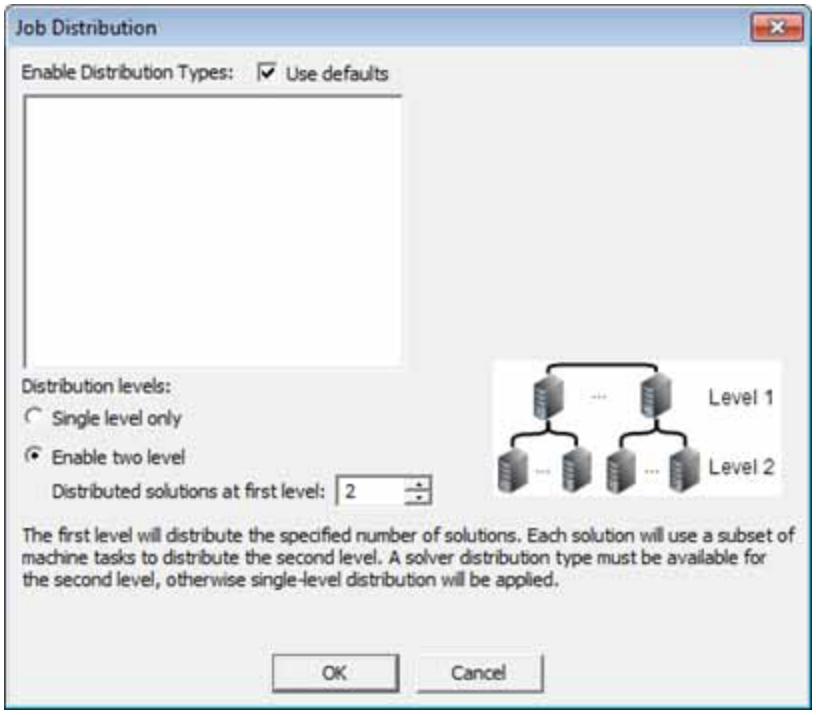
If you disable User automatic selection, you can modify the Job distribution settings.

Two level distribution, which may be disabled. Click the **Modify** button to display the **Job Distribution** dialog.



Enabled Distribution types can be modified here.

Second level distribution operates within DSO. If available and enabled you can specify a number of engines for level 1.

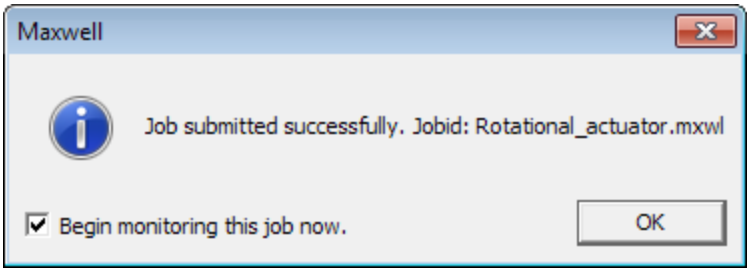


In response to a set of minimal constraints, the Scheduler may increase the resources assigned beyond the minimal values in order to meet the full set of requirements. For example, if you specify 7 distributed engines, with two processors per engine, and also limit the number of engines per node to 4, the scheduler may increase the number of cores used in order to meet the limit specified for engines per node. Notice that a preview of the Submit Job Results shows the number of resources assigned, and that the scheduler generated code includes an MPI specification.

10. To submit the command with the specified parameters, click **Submit Job**.

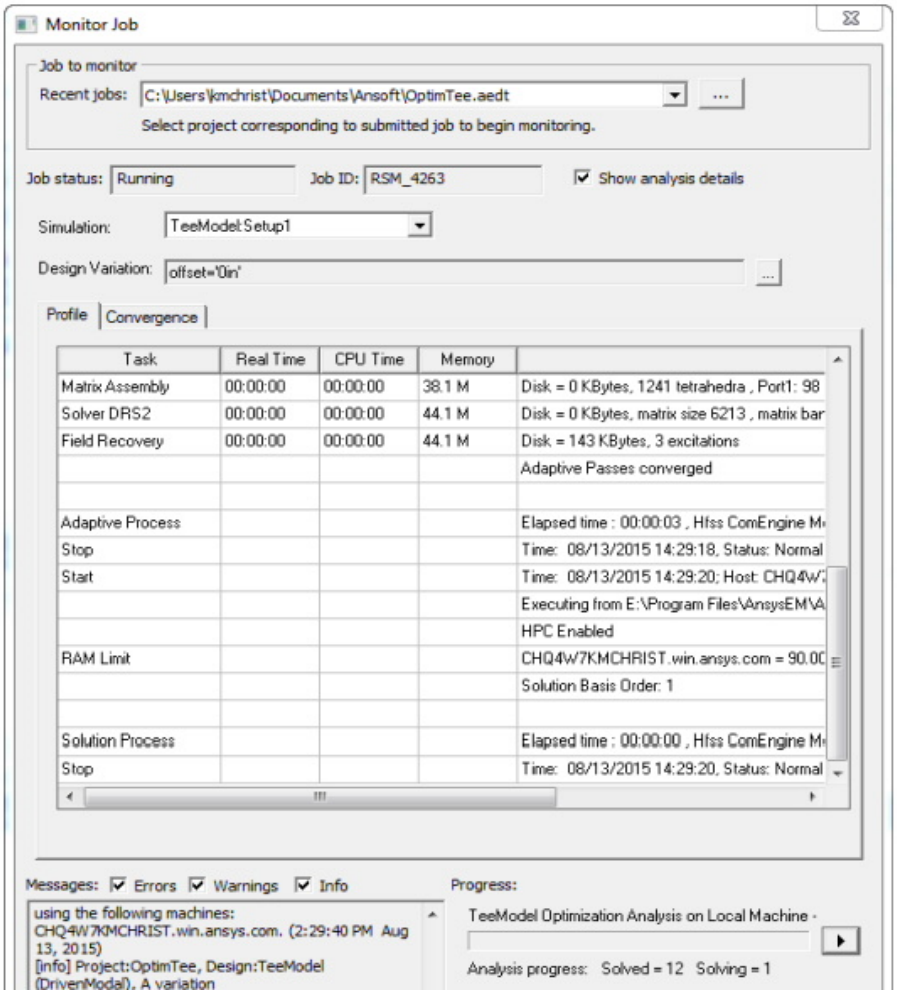
Note	The RSM environment does not support for queuing, so 'Submit Job' will immediately start running the job.

A dialog displays in which you can check "Begin monitoring this job now."



11. You can monitor this job either automatically (by checking the option) or through the **Tools>Job Management>Monitor Jobs...** command. For more details, see Monitor Job

window.

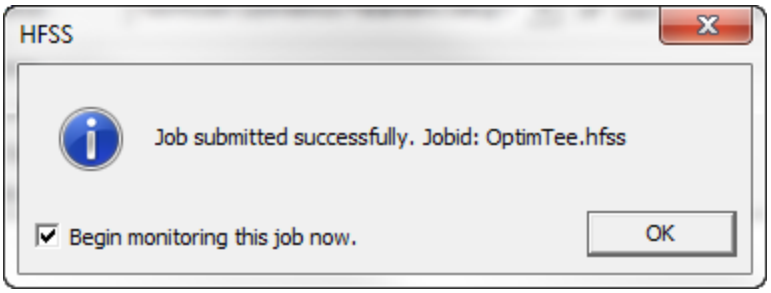


The dialog contains fields reporting the job status, job ID, messages issues, and progress. You can filter the messages for Errors, Warnings, and Info. By option you refresh the job manually or automatically at specified intervals.

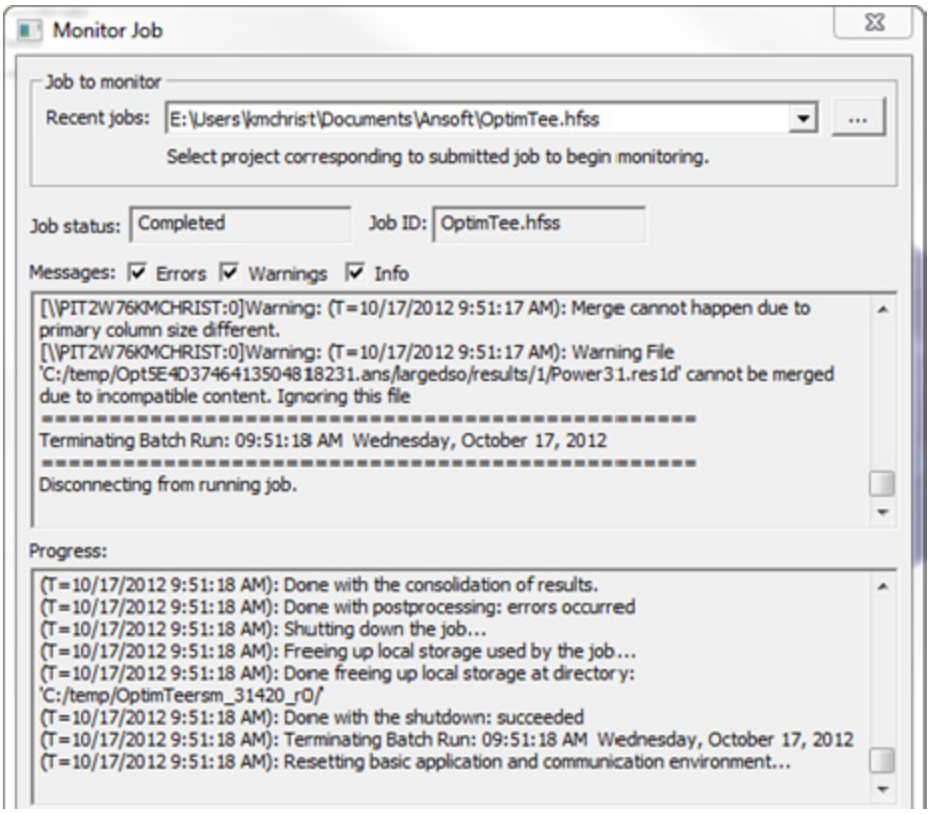
12. To submit the command with the specified parameters, click **Submit Job**.

Note	The RSM environment does not support for queuing, so 'Submit Job' will immediately start running the job.

A dialog displays in which you can check "Begin monitoring this job now."

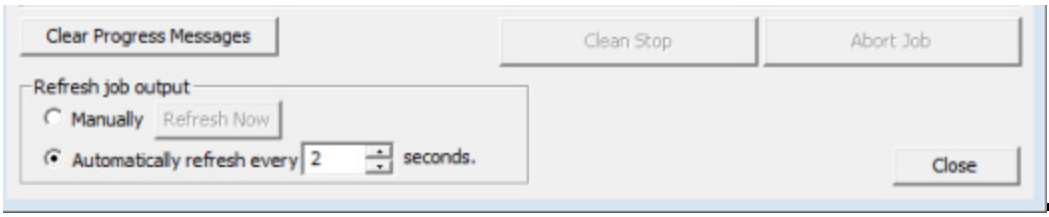


13. You can monitor this job either automatically (by checking the option) or through the **Tools>Job Management>Monitor Jobs...** command.



The dialog contains fields reporting the job status, job ID, messages issues, and progress. You can filter the messages for Errors, Warnings, and Info.

By option you refresh the job manually or automatically at specified intervals. You can choose to **Clear Progress Messages**.



You also have command buttons to perform a **Clean Stop** of a simulation between time steps, or to **Abort** a simulation.

Process for Changing the Listening Port used by AnsoftRSM Service

To change the listening port used by the AnsoftRSMService, you need to change the configuration file, ansoftrsmservice.cfg, as follows:

You must specify the ListenPort within a 'CommDetails' block, which must be within a 'Default:CommDetails' block, which must be within the top level block of the file, the 'AnsoftCOMDaemon' block. The following example shows the listen port changed from 32958 to 32957, with these blocks at the beginning of the file:

```
    $begin 'AnsoftCOMDaemon'
$begin 'Default:CommDetails'
  $begin 'CommDetails'
ListenPort='32957'
  $end 'CommDetails'
$end 'Default:CommDetails'
. . . .
    $end 'AnsoftCOMDaemon'
```

For the second level block, ensure that there is a single colon character and no spaces or tabs separating the two parts of the block name 'Default:CommDetails'. The third level block, with name 'CommDetails' is also required. Use caution when editing this file by hand, because any typos in the block or value names may cause the data to be ignored.

Using the Ansys EM HPC Diagnostics Tool

The Ansys EM HPC diagnostics tool simplifies HPC troubleshooting by automating diagnosis of routine issues. The diagnostics tool is run on the cluster as a scheduler managed job. Using its HTML-based diagnostics report, the cluster administrator or Ansys support staff can either resolve the issue, or guide the user with steps for further troubleshooting. In some cases, Ansys support staff may request to rerun the diagnostics with additional diagnostics tests. The user may extend the diagnostic scripts to suite their HPC environment.

The following sections describe how to use the diagnostics tool.

- Supported schedulers
- Running the diagnostics job
- Basic diagnostic job
- Using diagnostics scripts on Linux clusters
- Using Windows HPC job file
- Diagnostic report
- Site-specific diagnostics job
- Environment variables
- ANSYSEM_DIAG_PROD_DIR contents

- ANSYSEM_DIAG_RESULTS_DIR contents
- How does the diagnostic tool work

Supported schedulers

The tool supports diagnosis of issues on Linux and windows clusters managed by the following schedulers:

- LSF
- SGE
- PBS/Torque
- Windows HPC

For the above schedulers, the tool includes standard diagnostic scripts. Further, if password-ssh has been enabled, it also supports generic Linux clusters using ssh. Please note that currently diagnostics tool does not support PBSPro and LSF/Windows.

Running the diagnostics job

The diagnostics are run as a scheduler managed job. Once the job finishes, you locate the resulting HTML file and provide it to the cluster administrator or to Ansys support staff. If there are any job or test failures, please also provide the networking*.json files from the Hosts subdirectory as well.

Basic diagnostic job

To run the basic diagnostics, submit a diagnostic job to the scheduler using a provided job submission script. Each standard diagnostic job is a 12 core job with 4 cores per host. On Linux, running this script submits a scheduler job to run the diagnostic tool on the cluster. On Windows, you need to submit a job using a job file.

Basic scripts for each supported scheduler are available in the diagnostics subdirectory of the schedulers directory.

Linux:

```
.../Linux64/schedulers/diagnostics
```

Windows:

```
.../Win64/schedulers/diagnostics
```

Using diagnostics scripts on Linux clusters

The following standard scripts are provided in the diagnostics directory:

```
.../Linux64/schedulers/diagnostics.
```

These job submission scripts are scheduler specific.

Scheduler	Standard job submission script	Comment
LSF	test_lsf	Supports both lsrun and blaunch
SGE	test_sge	Supports both qrsh and rsh
PBS/Torque	test_torque	Requires changing the PATH and PBS_BINARY_PATH environment variable
Generic Linux cluster	test_ssh	Supports only ssh. Requires password-less ssh. Requires creating a file with the names of hosts and saving it in ${HOME}/ansysem_hostfile

Using Windows HPC job file

A sample job file **winhpctest.xml** is available in the diagnostics directory:

```
.../Win64/schedulers/diagnostics
```

To submit this diagnostic job, you must change the job description to suite your environment as following:

1. Select a directory for saving the diagnostic results. This directory must be accessible at the same path from all the hosts of the cluster.
2. Locate the directory for Ansys EM installation. This directory also must be accessible at the same path from all the hosts of the cluster.
3. Locate the **winhpctest.xml** in the diagnostics subdirectory of schedulers directory in the Ansys EM installation.
4. Start Windows HPC job manager, and choose “New job from XML File…” action.
5. Select the **winhpctest.xml** job file.
6. Change the value of both the following environment variables with the directories located in the first two steps:

   ANSYSEM_DIAG_PROD_DIR

   ANSYSEM_DIAG_RESULTS_DIR
7. Now submit the job.

Note	After making the above changes, you can also save the resulting XML file using "Submit Job XML File…". Then you can submit the job using the job command as following: `job submit /jobfile: XMLfileName`

Diagnostic report

The diagnostic report is an HTML file which (along with other related diagnostics results) is placed in the following directory

Linux:

```
${HOME}/Ansoft/HPCDiag/Results/JOBID
```

Windows:

```
%ANSYSEM_DIAG_DIR%\Results\JOBID
```

Report file:

```
.../HTML/report.html
```

where JOBID is the job ID assigned by the scheduler. On Windows, the user must specify ANSSEM_DIAG_DIR directory.

Site-specific diagnostics job

To run a diagnostic job with job submission parameters of your choice, you need to create your own job submission script. For example, you may want to specify a different LSF queue, or select a different SGE parallel environment. To run such a job, you need to create your own job submission script starting from the standard diagnostic scripts with the following steps:

1. Locate the relevant standard diagnostic script in the diagnostics subdirectory of schedulers directory in Ansys EM installation.
2. Make a copy of the diagnostics script into a directory that is accessible from a submit host for the cluster.
3. Edit the script file to change the value of ANSYSEM_DIAG_PROD_DIR environment variable to point it to the installation directory (See below).
4. Modify the job submission parameters as needed.
5. Optionally, copy any site-specific diagnostic tests provided by Ansys support staff in the ../Custom directory of ANSYSEM_DIAG_RESULTS_DIR directory.
6. Run the diagnostics script from a submit host for the cluster

Environment variables

The following environment variables are applicable for both Linux and Windows environment.

ANSYSEM_DIAG_PROD_DIR

Environment variable	ANSYSEM_DIAG_PROD_DIR
Description	Location of the Ansys EM installation. This must be available at the same path from all the hosts of the cluster.
Windows example	`\\filer\AnsysEM\v231\Win64`
Linux example	`/shared/ansysem/v231/Linux64`
Comments	Windows: Required. Linux: Optional. Export this environment variable if you make a copy of the diagnostic script.

ANSYSEM_DIAG_RESULTS_DIR

Environment variable	ANSYSEM_DIAG_RESULTS_DIR
Description	Location of the diagnostic report and other results on a shared drive. This must be available at the same path from all the hosts of the cluster
Example	`\\filer\Home\User\Ansoft\HPCDiag`
Linux example	`/shared/home/user/Ansoft/HPCDiag`
Comments	Windows: Required. Linux: Optional. Export this environment variable if the home directory for the user is not accessible from the cluster.

ANSYSEM_DIAG_CUSTOM_DIR

Environment variable	ANSYSEM_DIAG_RESULTS_DIR
Description	Location of the configuration of product tests and other custom site-specific tests. This location must be on a shared drive that is available at the same path from all the hosts of the cluster
Example	`\\filer\Home\User\Ansoft\HPCDiag\Custom`
Linux example	`/shared/home/user/Ansoft/HPCDiag/Custom`
Comments	Windows: Optional. You may want to specify it if the path %ANSYSEM_DIAG_RESULTS_DIR%\..\Custom is not suitable Linux: Optional. Export this environment variable if the home directory for the user is not accessible from the cluster.

How the diagnostic tool works

The diagnostics are run as a scheduler managed job. Running the diagnostic script submits a scheduler job that runs the diagnostic tool on the hosts allocated to the job. Once the diagnostic job starts, the tool executes a set of diagnostic tests. These tests run on each host allocated to the job, collecting diagnostic information relevant for running HPC jobs. The tool combines the diagnostic information to produce an HTML report. The tool saves the HTML diagnostic report and other results in a shared drive, which must be available at the same path from all the hosts of the cluster. On Linux, the default is Ansoft/HPCDiag subdirectory under the user's home directory. On Windows, the user must specify this location using the ANSYSEM_DIAG_RESULTS_DIR environment variable.

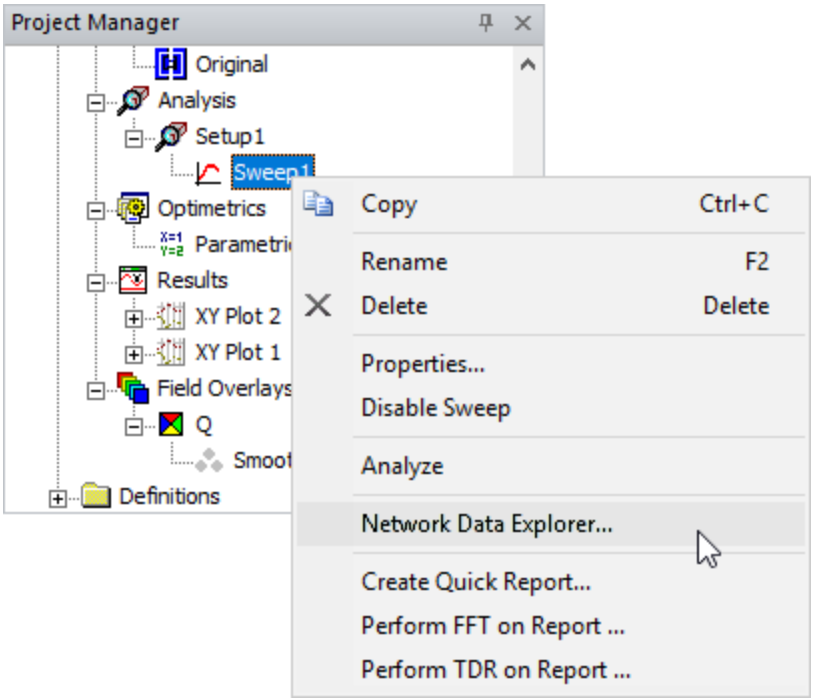
22 - Network Data Explorer

The Network Data Explorer provides visualization, analysis, and manipulation tools for network data of 3D and 2D Eddy Current solutions.

To access Network Data Explorer, click **Tools>Network Data Explorer**.

If you have run a simulation with data that can be converted into network data, you can also access Network Data Explorer through the shortcut menu in the Project Manager.

Note: Accessing Network Data Explorer from this menu automatically loads simulation data.



The **Network Data Explorer** window appears.

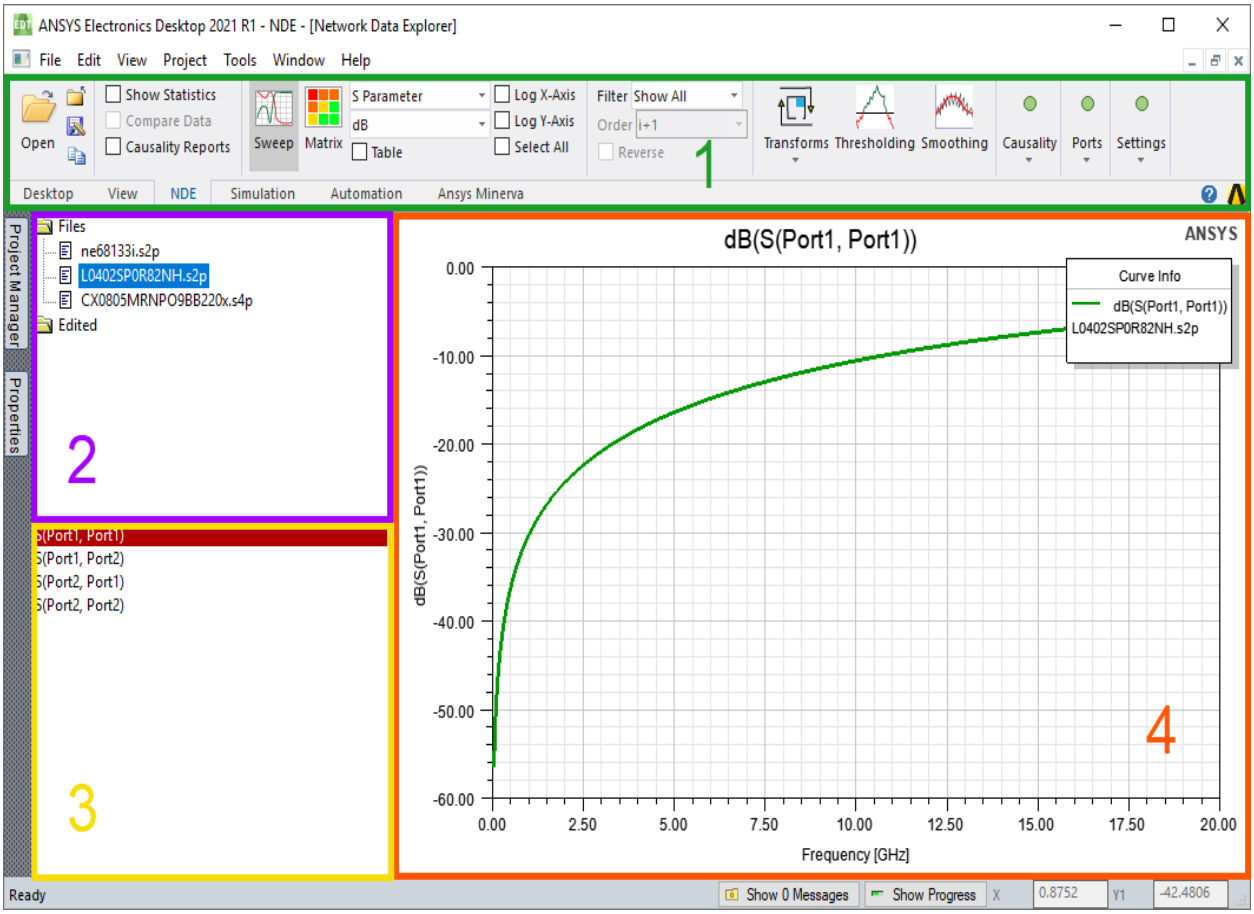
Multithreading

Network Data Explorer Overview

The Network Data Explorer window is divided into the following panes:

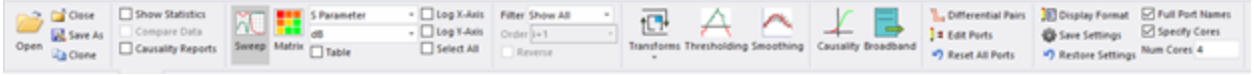
1. **NDE ribbon** – allows you to perform many functions of the Network Data Explorer.
2. **Network Data Selection pane** – allows you to select a network data file.
3. **Cell and Frequency Selection pane** – allows you to narrow your selection.
4. **Data View pane** – displays data in table or plot format.

The panes are shown in the following figure. Additional information about each pane follows.



NDE Ribbon

The ribbon provides access to many of the Network Data Explorer's functions and display options.

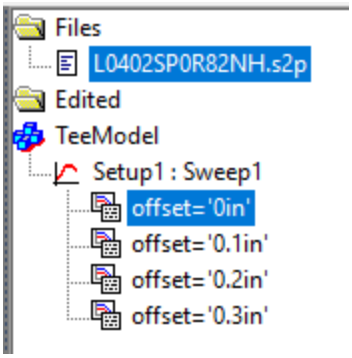


On this ribbon, you can control:

- Plotting - allows you to determine how the data is displayed.
- Quantity – allows you to select the type of quantity to display (parameter values, matrix statistics, or causality plots).
- Parameter Type – allows you to choose the parameter for display (S, Y, or Z parameters, Port Impedance, or Gamma).
- Format – allows you to decide the display function to apply to the data (e.g., magnitude, phase, dB, real, imaginary).
- Export – allows you to export either SYZ data (*.s1p, *.ts, *.nmf, *.tab, *.m, *.cit) or Broadband data (*.sp).
- Check – allows you to check causality.
- Cores – allows you to enable or disable multithreading.
- Post-Process Selection – allows you to choose between Terminal Data and Differential Pairs, if your design includes Differential Pairs

Network Data Selection Pane

This pane allows you to view and compare various data sets. Original data sets appear under Files. Click one of these to see the data set as it was when it was opened. Altered data sets are listed under Edited. These data sets appear here when they have been smoothed, transformed, or changed in some way.



This pane also lists available variations for AEDT design solution data. Variations are listed under a setup name icon (for example “Setup1 : Sweep1”) that is listed under a design icon (“TeeModel”). Variations can be selected and displayed just like other data sets.

Use the **Shift** and **Ctrl** keys to select and display data sets from multiple files simultaneously. Multiple data sets can be selected to display multiple traces in sweep plots, but not in tables. Click the **Files** icon to select all data sets under **Files**. Click the **Edited** icon or a design/setup icon to do the same.

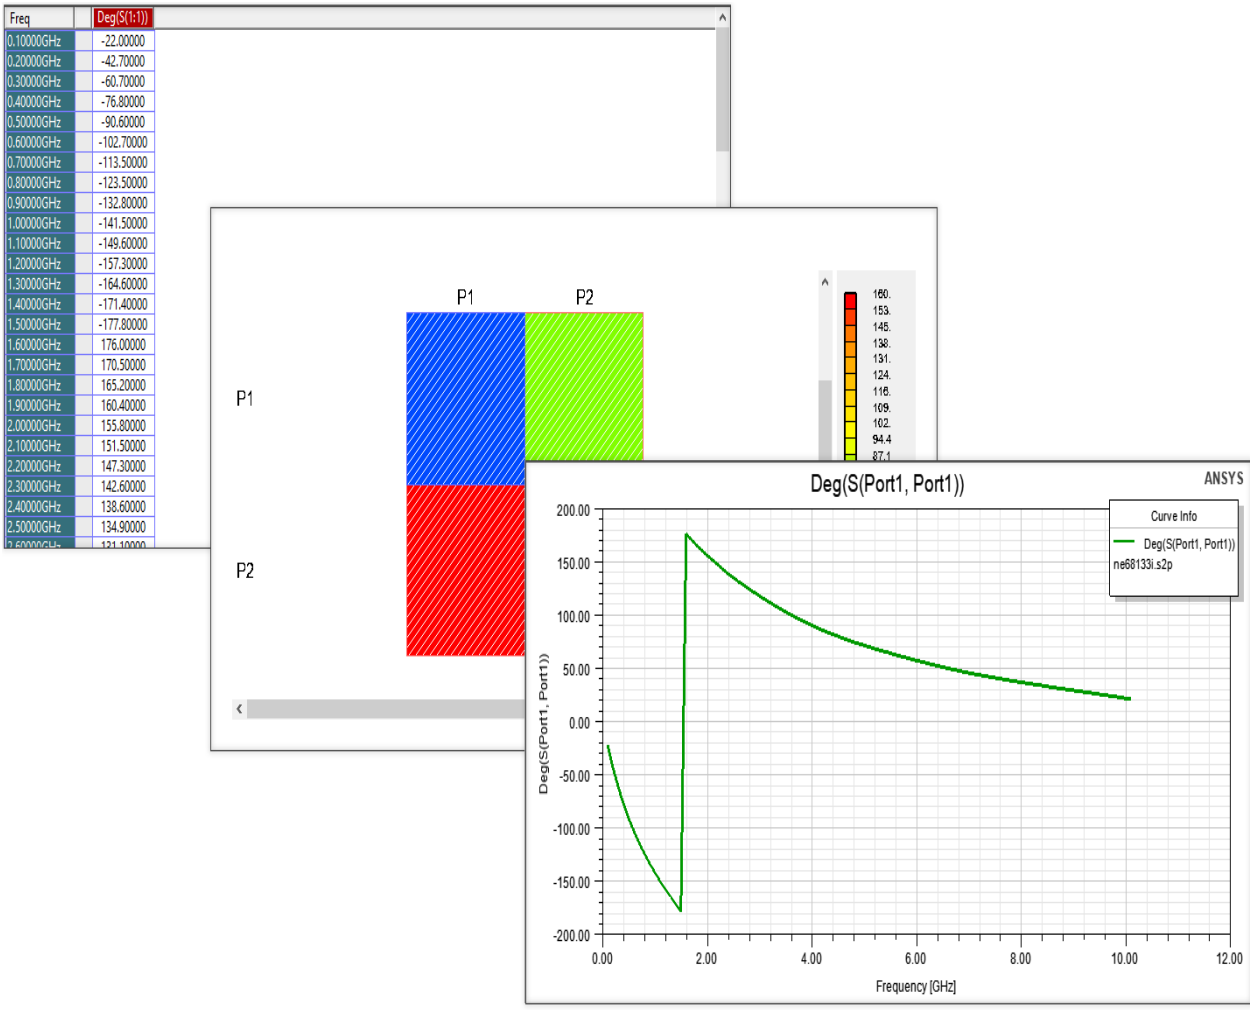
Cell and Frequency Selection Pane

Select the **Sweep** button on the NDE ribbon to display cell entries, for example S(1,1). Select the **Matrix** button to display frequencies. When displayed by frequency, the entire matrix is presented in the Data View pane for each selected frequency. When displayed by matrix cell, the data for the individually chosen cells is shown across all frequencies. Use the **Select All** check box to select all frequencies or cells.

> **Note:** For Maxwell 2D solutions when the geometry is in XY mode, a Model Depth selection is available. The default Matrix selection is the alphabetically first defined matrix parameter. The default Model Scale setting is 1. The default Model Depth setting is 1 meter.

Data View Pane

The Data View Pane displays data for **Sweep** or **Matrix** in either plots or a table, depending on your selection.



Loading Data Into Network Data Explorer

If you launched **Network Data Explorer** using the shortcut menu, the current solution data is automatically loaded and ready for viewing. Otherwise, you must load a data file into Network Data Explorer.

You can import the following file types:

- Touchstone Format (*.s*p)
- Touchstone 2 Format (*.ts)
- Citifile (*.cit)
- Neutral Format (*.nmf)
- State Space File (*.sss)

Note	When this type of file is loaded, Network Data Explorer regenerates s-parameter data based on the file. You can compare the regenerated s-parameters to the original data.

To import a file into Network Data Explorer, either drag and drop an analysis from the Project Manager into Network Data Explorer or:

1. On the **NDE** ribbon, click **Open**. An **Open** window opens.
2. Navigate to and select a file.
3. Click **Open**. The file appears in the **Files** tree.

The file browser allows you to open multiple files at a time. However, the displayed data always corresponds to the data set indicated in the Network Data Selection pane. Click the file you want in that pane to switch between data sets.

Exporting Data from Network Data Explorer

Network Data Explorer allows you to export data to a variety of different file formats.

In this section, you will learn about:

Exporting SYZ Data

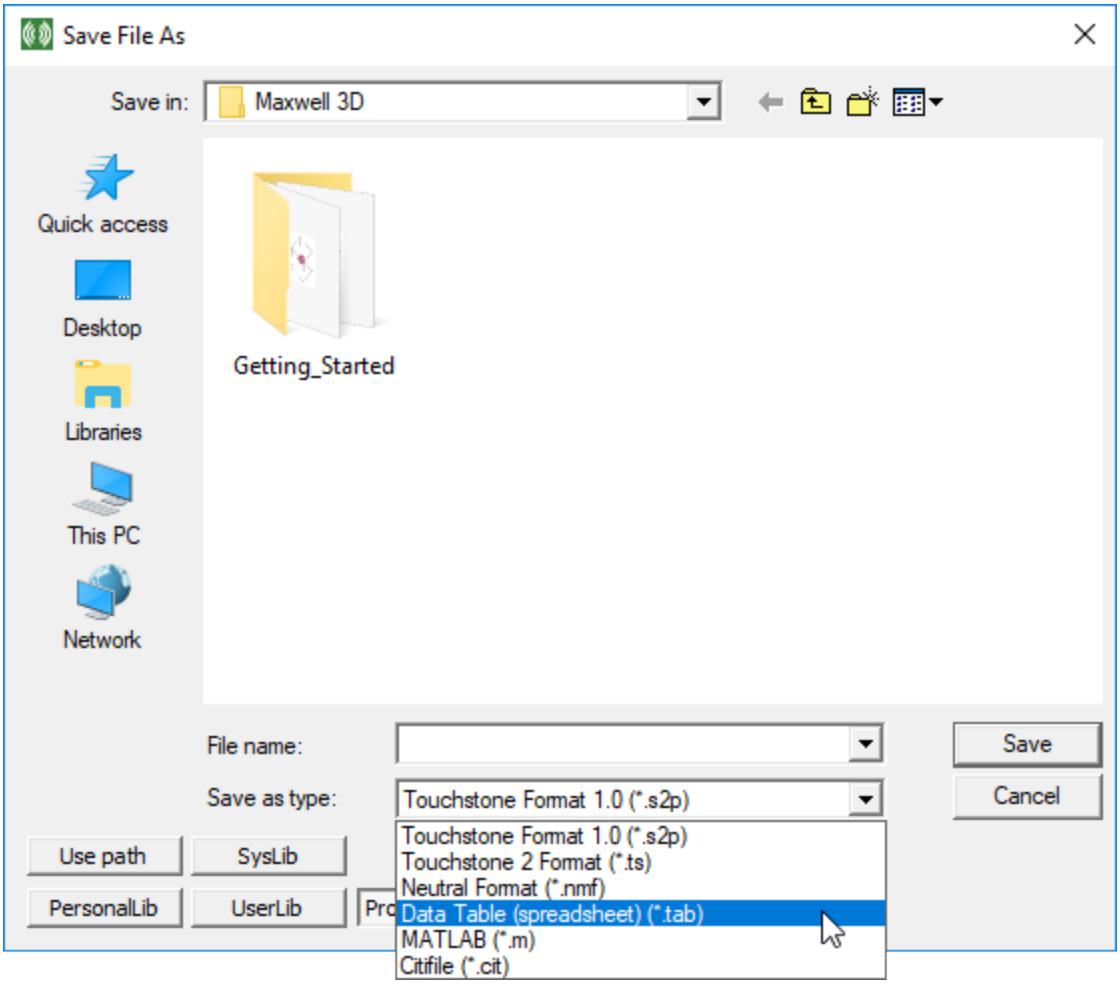
Exporting Macro Model

Creating an NPort Model

Scripting for Network Data Explorer

Export SYZ Data

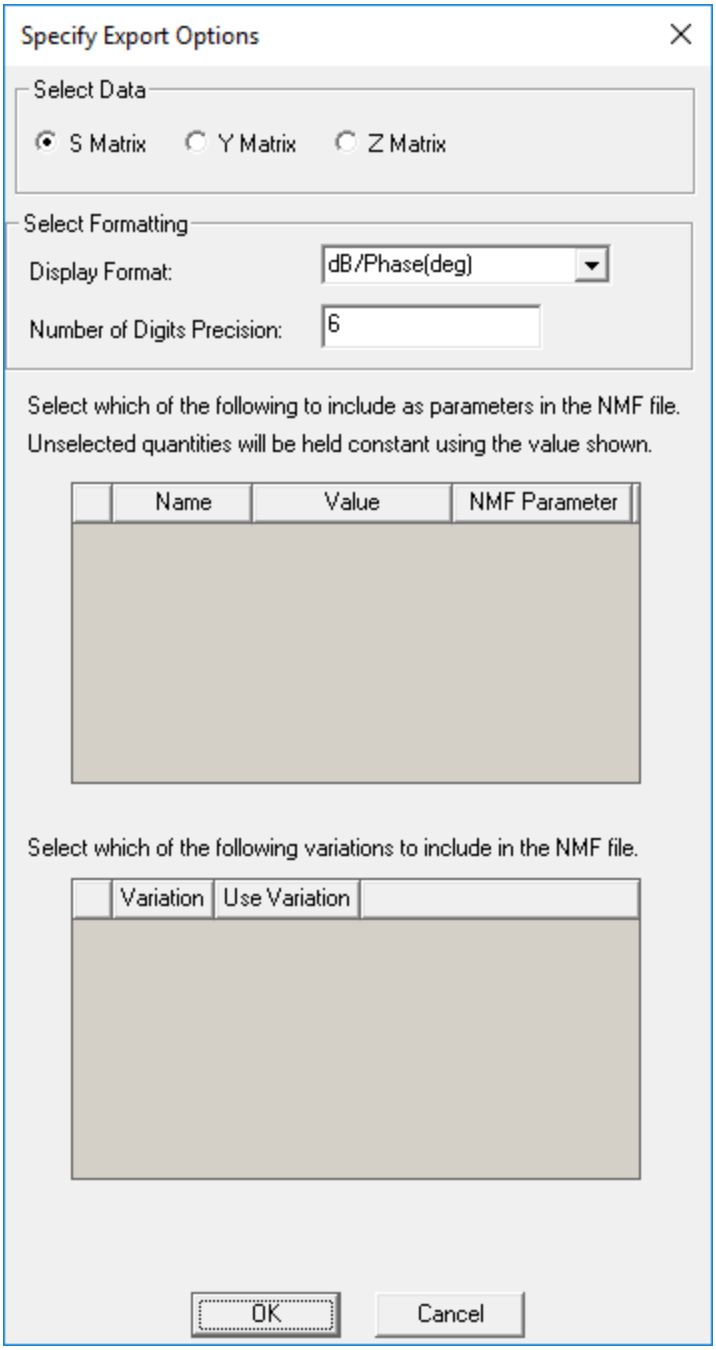
To export SYZ data from within Network Data Explorer, click the **Save As** icon on the **NDE** ribbon. The **Save File As** window appears.

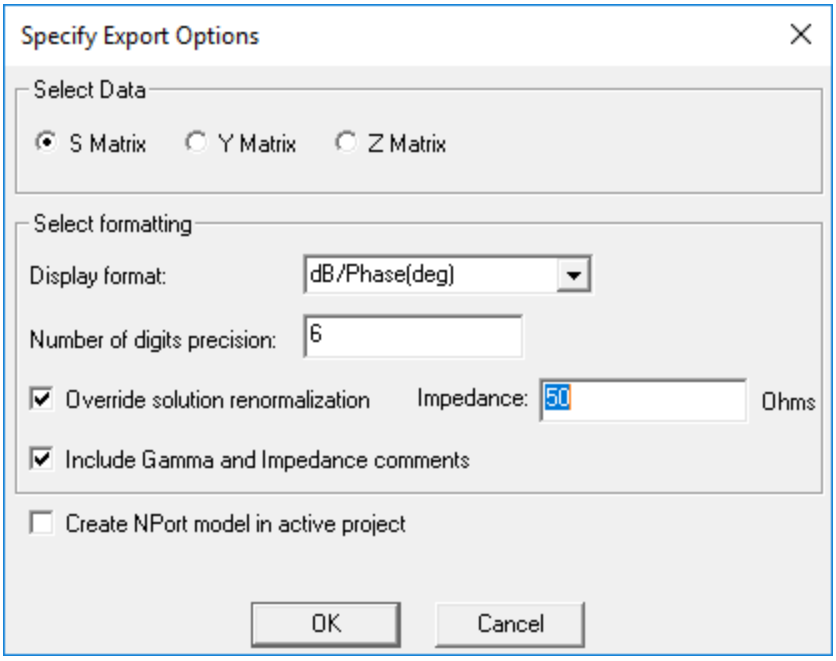


You can export data in any of six file types:

- Touchstone Format 1.0 (*.s*p)
- Touchstone 2 Format (*.ts)
- Neutral Format (*.nmf)
- Data Table Spreadsheet (*.tab)
- MATLAB (*.m)
- Citifile (*.cit)

Select a file type and name for export. A **Specify Export Options** window appears.





Depending on the type of export file, different options appear. However, all file types allow you to:

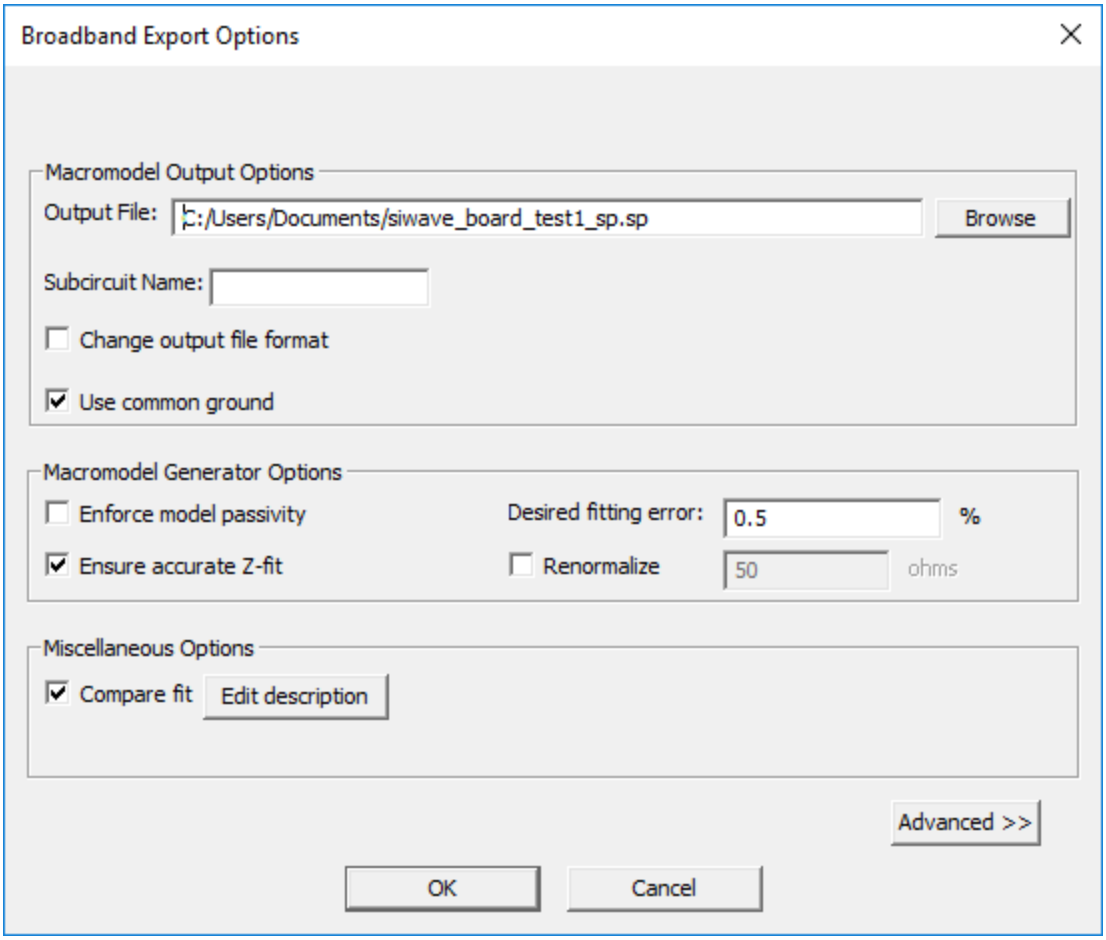
- Select from **S Matrix**, **Y Matrix**, and **Z Matrix** data.
- Select the **Display Format**.

Some types allow you to create an NPort Model in the active project.

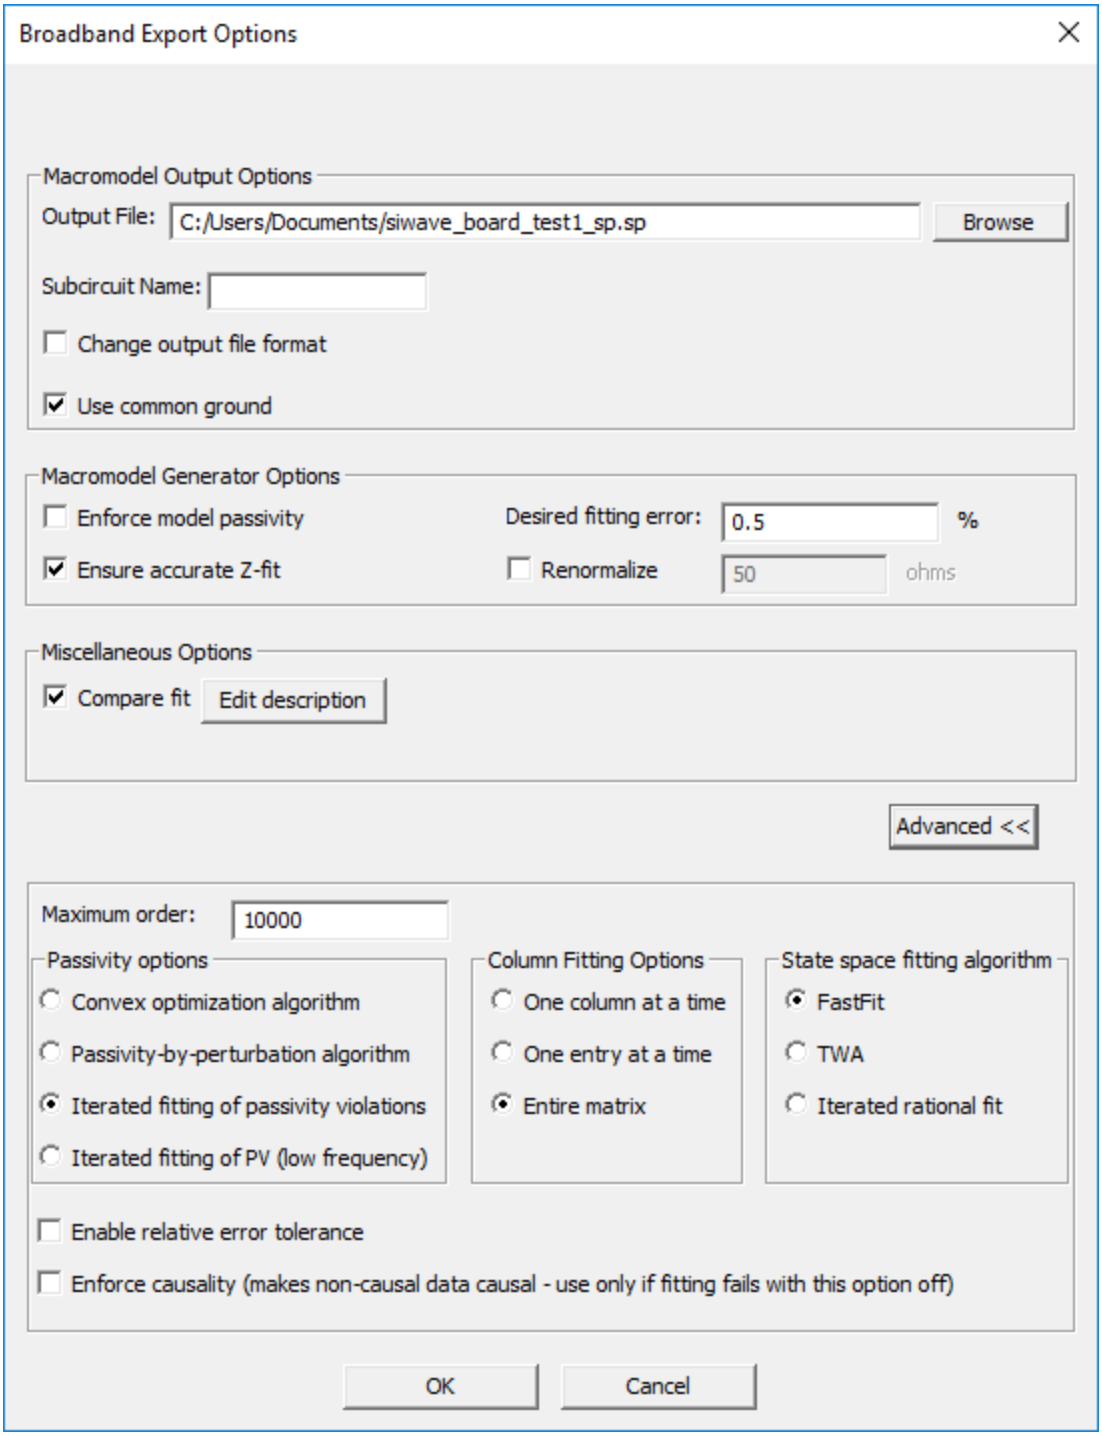
Exporting Macro Model

To export data, click the **Broadband** icon on the **NDE** ribbon.

The **Broadband Export Options** window appears.



Click **Advanced >>** to view all options.



Macromodel Output Options include:

- **Output File** – Allows you to choose the name and location of the file.
- **Subcircuit Name** – Use this field to name the subcircuit.

- **Change Output File Format** – Check this box to open a submenu allowing you to select a new output format.
- **Use Common Ground** – Check this box to use common ground. When this option is on, ports are referenced to ideal ground (node 0). When this option is off, extra ports are generated to provide the reference levels. Common grounding is best when the pins are physically near to each other and ideal ground is suitable. For distant connections and circuits with non-ideal reference levels such as differential pairs, common grounding is not used.

Note	◦ R and L values may be quite sensitive to the values of the S-parameters. This is an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters. ◦ Since resistances of power cables is typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to get multiplied by 5000 times when the R and L values are computed. ◦ As a general rule, for high power applications a reference impedance of 1 ohm is probably a better choice than 50 ohms.

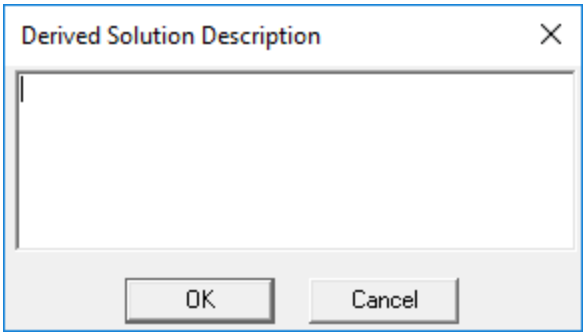
Macromodel Generator Options include:

- **Enforce Model Passivity** – Check this box to enforce passivity.
- **Ensure Accurate Z-fit** – Check this box when state-space fitting of Y-parameters or Z-parameters does not produce an accurate fit.
- **Desired Fitting Error** – Allows you to select the value at which rational fitting fails (if the fitting error exceeds this value).
- **Renormalize** – Check this box to renormalize using the specified impedance item. 50 ohms is the default setting, but you can type a different value.

Note	• R and L values may be sensitive to S-parameter values. This presents an issue if the actual impedance value is much greater than or much less than the reference impedance of the S-parameters. • Since resistances of power cables are typically in the milliohms range at DC, using a reference impedance of 50 ohms is 5000 times higher. This causes any fitting errors in the state space model to be multiplied by 5000 when the R and L values are computed. • For high-power applications, a reference impedance of 1 ohm is generally a better choice than 50 ohms.

Miscellaneous Options include:

- **Compare Fit** – When this box is checked, the original and derived solution will be available for comparison. You can click **Edit Description** to open the **Derived Solution Description** window and add a text description to better identify the export.



Advanced Options include:

- **Maximum Order** – Allows you to specify the number of poles. See Note below.
- **Passivity Options** – If you enabled **Enforce Model Passivity**, this area allows you to select the passivity enforcement method. **Iterated fitting of passivity violations** (IFPV) is the default method. The other options are methods that can be tried if IFPV yields a poor fit. The **Iterated fitting of PV (low frequency)** option builds upon the existing IFPV with the objective of improving the fit to "Z" at DC and low frequencies.
- **Column Fitting Options** – This area allows you to choose how poles are matched to columns:
  - **One Column at a Time** – The set of poles will be shared across all entries of a single column.
  - **One Entry at a Time** – Each entry will be fitted using a separate set of poles.
  - **Entire Matrix** – The set of poles will be shared across all entries of the matrix being fitted.
  -

Notes	• Typically, using the same set for all entries is adequate, and yields the most compact models. However, if all the entries of the matrix have completely unrelated transfer functions, it may be better to fit them using separate pole sets. • The options **One column at a time** and **One entry at a time** do not work when either **Ensure accurate Z-fit** or FastFit is used.

- **State Space Fitting Algorithm** – Allows you to select FastFit, TWA, Iterated rational fitting. See Note below.
  - **FastFit** (default) – FastFit is the Ansys-proprietary method for state-space fitting. Network Data Explorer uses FastFit for calculating the state-space matrices from the network data. The FastFit algorithm for state-space fitting is an alternative to the Tsuk-White algorithm (TWA) and Iterated Rational Fitting (IRF) methods. FastFit is generally as accurate as TWA, but is significantly faster than both TWA and IRF. It also aims to fit the lower frequencies with higher fidelity.

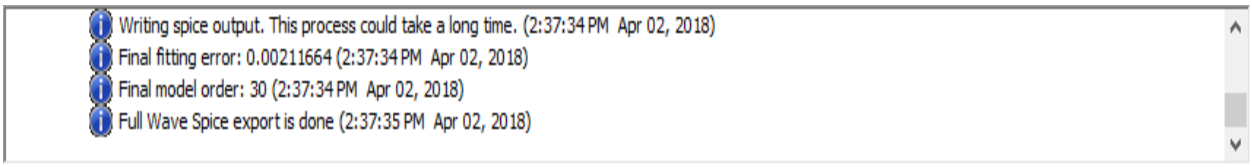
  - **TWA** – The Tsuk-White Algorithm is an Ansys-proprietary method for fitting a state space model to extracted s-parameter data. It uses techniques based on Singular Value Decomposition (SVD) to quickly determine required number of poles for fitting a model.
  - **Iterated Rational Function** – The IRF fitting approach takes a matrix of S-parameter data and, for each matrix entry, tries a succession of different pole-zero approximations (increasing the number of poles used at each iteration) until it can find an acceptable fit to the data. For broad frequency sweeps and large numbers of excitations, this process can be time consuming because of all the iterations and is not guaranteed to produce a good fit to the data. It is retained as a fallback if the TWA algorithm fails.
- **Enable Relative Error Tolerance** – Allows you to enable relative error tolerance, which works best with TWA fitting.

Notes	Note that the **Enable Relative Error Tolerance** option works best with the TWA fitting algorithm, is not recommended for use with iterated rational fitting, and is disabled when either FastFit or **Ensure accurate Z-fit** is used.

- **Enforce Causality** – Allows you to make non-causal data causal. Use this option only if fitting fails without it.

Notes	Broadband models are built from a rational-function approximation to the data. The fidelity of this approximation can be controlled by setting the Maximum order (number of poles).

Click **OK** to begin the export. The **Messages** pane details the export process.



Comparing Original S-Parameters with Exported S-Parameters

If **Compare Fit** was checked during export, the **Data Selection** pane updates to list both the original and exported solution *and* the **Compare** checkbox is checked.

Creating an NPort Model

Touchstone, Neutral Format, and Citifile exports allow you to select an option to **Create NPort Model in active project**.

Creating an NPort Model exports the active data set back to the design, either as a static n-port model or as a parametric n-port model. If there are multiple variations, a parametric n-port model

is automatically created containing all variations. When only a single variation exists, the user can create a static n-port model that either links to a file (the data is exported first) or stores the data itself. Linking to a file reduces the size of the ADSN file. The newly created model can be placed as a component in a circuit. This is particularly useful after reducing the number of ports via termination.

The import of the exported solution is done by reading the exported Touchstone file.

Scripting for Network Data Explorer

Scripting is available for each Network Data Explorer export method, which means a script can be recorded to duplicate the export process.

Network Data Explorer can be invoked in the following contexts, and scripting is available from the Project Context and the Design Instance Context (simulation setup):

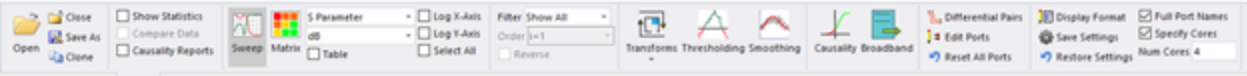
- **Project Context** – In the context of a project, you can open a touchstone file and then export.
- **Design Instance Context** – In the context of a solution (RCM from the simulation setup in a design), you can export the corresponding network data solution.

When there is no design available, export functionality and scripting are not available.

For more information, see Network Data Explorer Script Commands in the *Ansys Electronics Desktop Scripting Guide*.

Network Data Explorer Edit Menu Commands

The **Edit** menu on the **Control** pane includes several commands.



In this section, you will learn about:

Data Sources

Setting Display Format

Displaying Full Port Names

Saving or Resetting Default Settings

Magnitude Thresholding

Smoothing All Frequencies

Cell Filtering

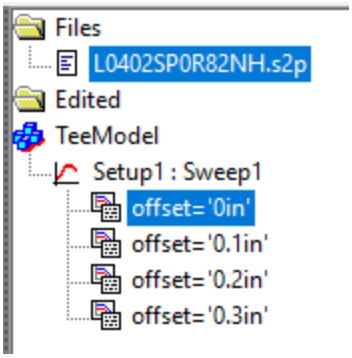
Editing Port Properties

Defining Differential Pairs and Displaying Mixed Mode Parameters

Resetting All Port Properties

Network Data Explorer Data Sources

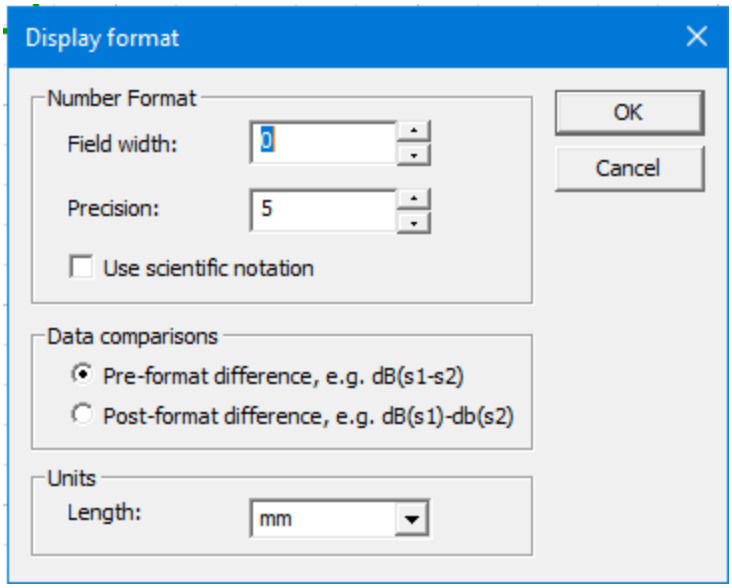
Network Data Explorer allows you to easily view all data sources in the **Network Data Selection** pane.



Network Data Explorer Display Format

The **Display Format** window affords additional control over the display of values in Network Data Explorer.On the **NDE** ribbon, click the **Display Format** icon.

The **Display Format** window appears.

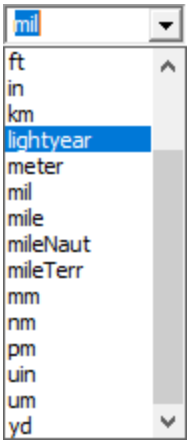


The **Number Format** options allow you to specify **Field Width** (the minimum number of characters used to display a number) and **Precision** (the number of decimals to display). You can also check the **Use scientific notation** checkbox, if desired.

The Data Comparisons options allow you to choose Post-format difference or Pre-format difference.

- **Post-format difference** – when comparing data sets, subtract values after applying the formatting function (e.g. dB, magnitude); the values displayed will be the difference between the magnitude, dB, and so on.
- **Pre-format difference**- when comparing data sets, subtract values before applying the formatting function (e.g. dB, magnitude); the values displayed will be the magnitude, dB, etc., of the complex difference.

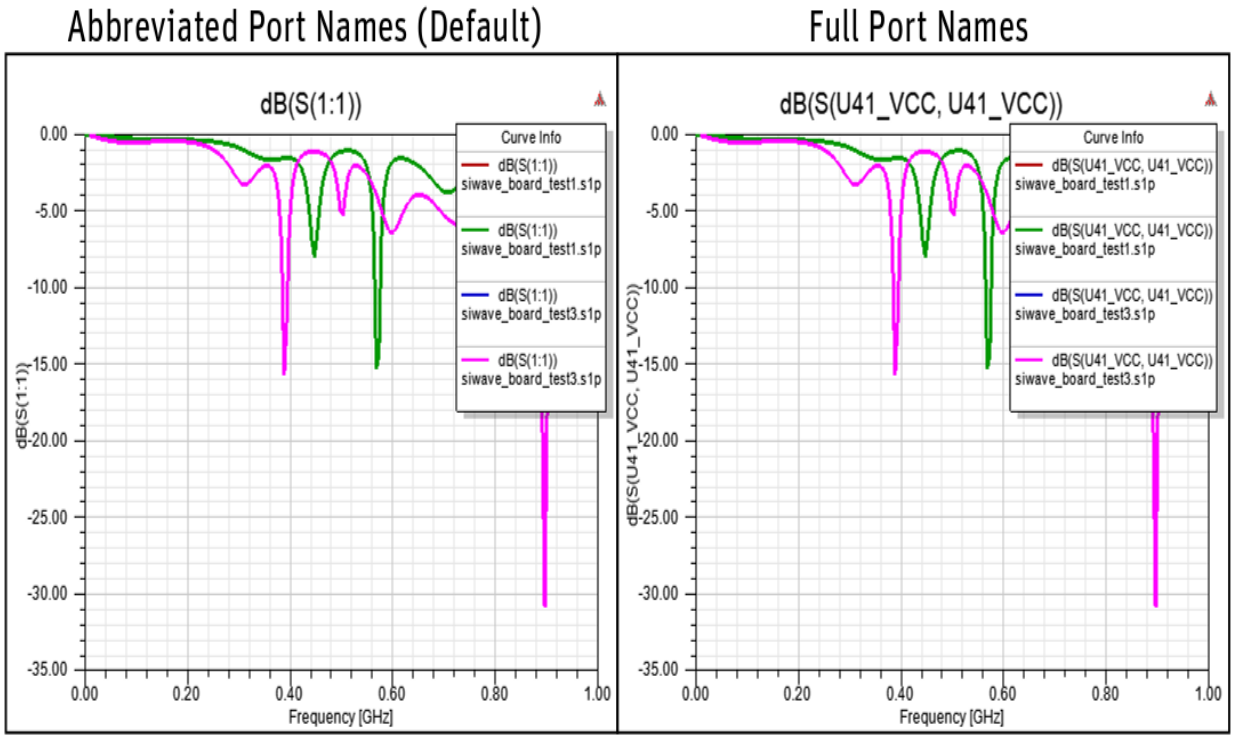
The **Units** option allows you to specify the **Length** unit (the unit used to display and interpret length values). The default is mm.



Network Data Explorer Display Full Port Names

By default, full port names are displayed. This applies to both the Data Selection pane and the Data View pane. To change this so that port names in Network Data Explorer are displayed in an abbreviated form (P1, P2, etc.), click the **Full Port Names** check box on the **NDE** ribbon.

The following figure shows the difference in display for a plot.



Note	Tool-tips always display the full port name.

Network Data Explorer Save or Reset Default Settings

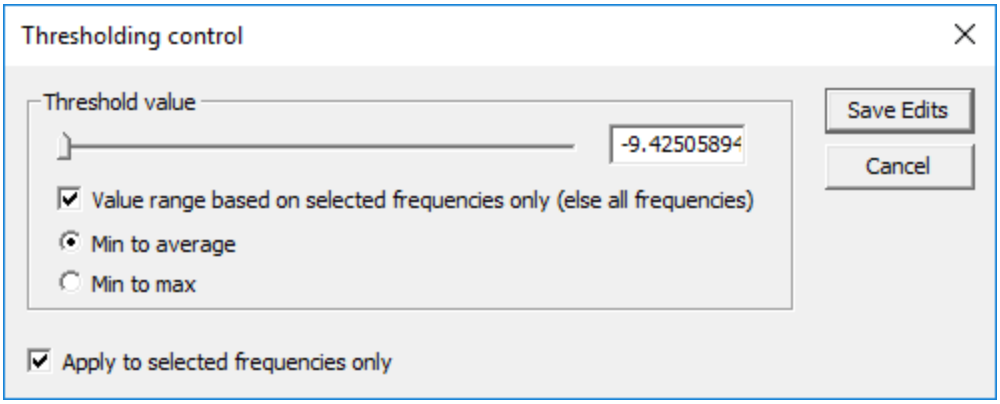
To save field settings as the default, click the **Save Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the chosen settings will be selected by default.

To restore the default settings (i.e. the settings previously saved using the **Save Settings** button), click the **Restore Settings** icon on the **NDE** ribbon. The next time Network Data Explorer is opened, the original settings will be selected by default.

Network Data Explorer Magnitude Thresholding Control

Thresholding is a way of reducing matrix entries to zero based on a value threshold. Thresholding applies to the displayed data (e.g., Magnitude), but the original matrix value is reset to zero. To access threshold settings, click the **Thresholding** icon on the **NDE** ribbon.

The **Thresholding Control** window appears.



Set the threshold value by sliding the control or by entering a value. The data range for the slider is determined by the options below:

- **Value range based on selected frequencies only** – When selected, the slider value range is determined from the selected frequencies only, otherwise, the entire data set is used to determine the range.
    - **Min to average** – When selected, the slider data ranges extends from the data minimum to the mean.
    - **Min to max** – When selected, the slider data range extends over the entire data range, from minimum to maximum data values.
- **Apply to selected frequencies only** – When this box is checked, the **Save Edits** button only modifies the currently selected network data matrices. Otherwise, the matrix data for all frequencies and variations is adjusted.

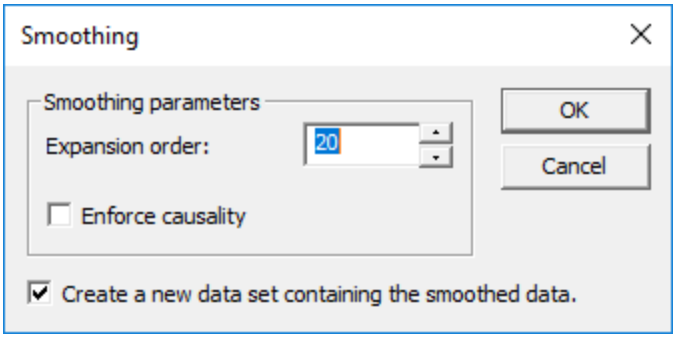
Click **Save Edits** to apply thresholding values.

Smoothing

To access data smoothing options:

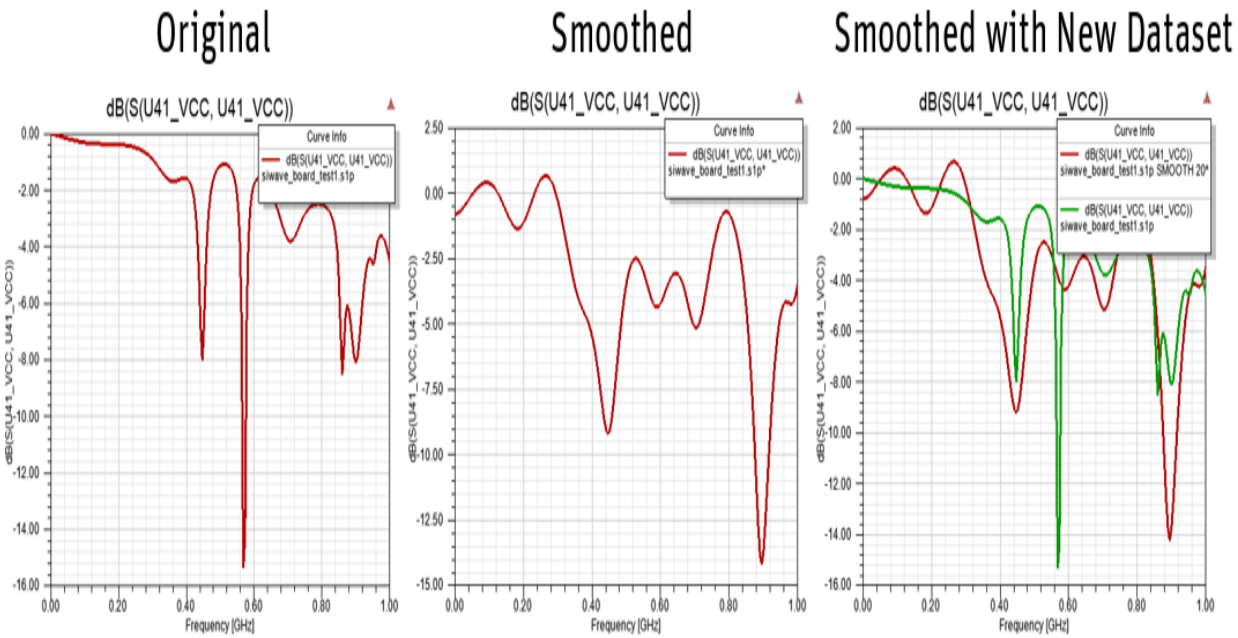
1. Click the **Smoothing** icon on the **NDE** ribbon.

The **Smoothing** window appears.



2. The **Smoothing Parameters** area allows you to choose the **Expansion Order**. This can be any discrete value between 1 and 150.
3. If desired, check the **Enforce Causality** checkbox.
4. If desired, check the **Create a new data set containing the smoothed data** checkbox. If selected, the smoothed data appears alongside the original data.
5. Click **OK**.

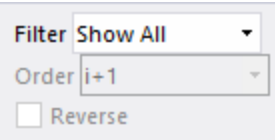
The Data View Pane updates. The following image shows a plotted result with **Create a new data set containing the smoothed data** unchecked and checked.



A least-squares polynomial fit of the specified order is used to interpolate new data points for the magnitude and phase components of the S-parameters.

Cell Filtering

The cells available in the data selection pane may be restricted using cell filtering. The **Cell Filtering** control are located on the **NDE** ribbon.



Cell filtering is modeless, and filters are immediately applied to the cell list. Filtering remains in effect when the window has been closed.

For an n-port model with a total of 2n pins in the standard arrangement, the choices are:

- **Show all** – display all available cells. There are n-squared choices.
- **Return loss** – show S(i, i). There are n choices.
- **Insertion loss** – show S(i, i+1). There are n choices.
- **Lower triangle** – show S(i, j) for all j < i. There are n(n-1)/2 choices.

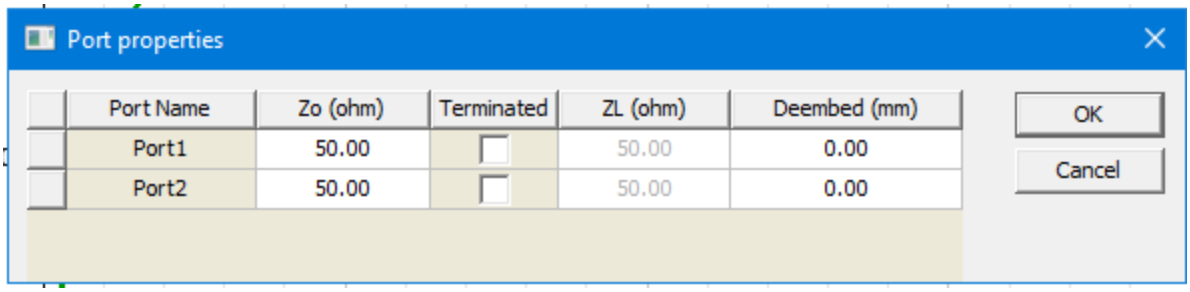
Three pin arrangements are recognized:

- **S(i, i+1)** and its **Reverse order**, S(i, i-1)
- **S(i, i+n)** and its **Reverse order**, S(i, i-n)
- **S(i, 2*n-i+1)** and its **Reverse order**, S(i, 2*n-i-1)

Changing Port Properties and Reducing Matrix Size

The normalization impedance, termination, port order, gamma values, and de-embedding distance may all be edited from the **Port Properties** window.

To access these options, click **Edit Ports** on the **NDE** tab. The **Ports Properties** window opens.



Ports appear in a table. Click a column heading to sort by that column. Click within a cell to edit the port property:

- **Zo (ohm)** and **ZL (ohm)** – specify Impedance values. Accepted syntaxes are:
  - real (e.g., 50)
  - real + imag i (e.g., 50+5i)
  - imag i (e.g., 5i).
- **Terminated** – use the checkbox to terminate a port. Terminated ports are eliminated from the matrix, reducing the matrix size. Existing data sets with mismatching port numbers will no longer be available for data comparisons.
- **De-Embedding** – this column appears only if gamma values are available. Default units can be changed from the Set Display Format window.

To reorder ports, click and drag a row to a new location.

To save changes, click **OK**.

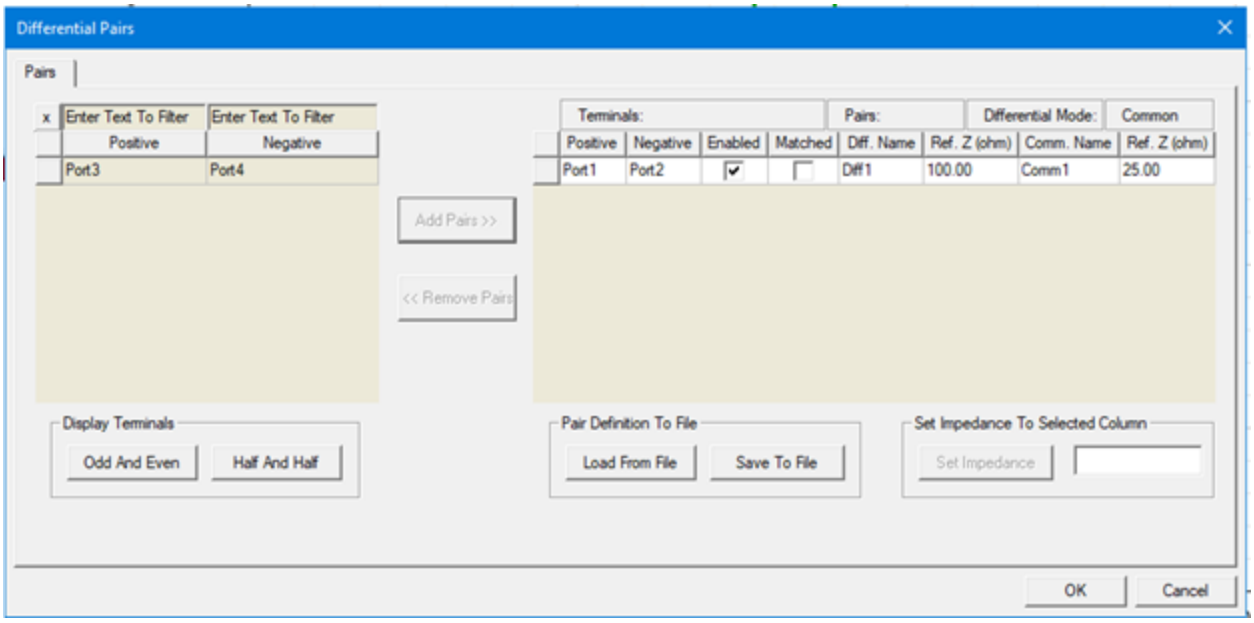
Displaying Mixed-Mode Parameters using Differential Pairs

Network Data Explorer displays mixed-mode parameters when differential pairs are both defined and activated.

To define differential pairs:

1. Select existing ports.
2. Open Network Data Explorer (**Tools>Network Data Explorer**).
3. On the **NDE** ribbon, select **Differential Pairs**.

The **Differential Pairs** window appears.



4. Select a pair from the list on the left and click **Add Pairs**.
5. Click **OK**.
6. To disable all differential pairs, click the **Enabled** column header in the **Differential Pairs** dialog to deselect all pairs.

Note	The Network Data Explorer **Edit** menu option **Reset All Port Properties** deactivates all pairs, but it does not clear the differential pair settings. And since **Reset All Port Properties** also clears reference impedances and terminations, it should not be used when the user simply wishes to disable all differential pairs.

Reset All Port Properties

Reset All Ports resets all changes in the **Edit Ports** window. It also deactivates all differential pairs defined in the **Differential Pairs** window but does not remove the definitions.

Data View Pane Context Menus

The Data Display pane presents different right-click menu options, depending on the context. Some of the commands are the same as those on the NDE ribbon. Others only appear in the context menus.

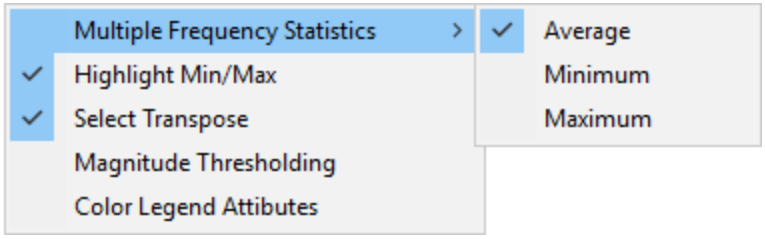
Network Data Explorer commands unique to the context menus are:

- Multiple Frequency Statistics
- Highlight Min/Max
- Select Transpose
- Color Legend Attributes
- Matrix Entries Plot Menu

Multiple Frequency Statistics

The **Multiple Frequency Statistics** menu option determines the statistical composite to display when multiple frequencies have been selected for the matrix display. The statistical data is always the first matrix displayed, followed by matrices for each individual frequency. The **Multiple Frequency Statistics** option also indicates the data used in the colored matrix plot when multiple frequencies have been selected.

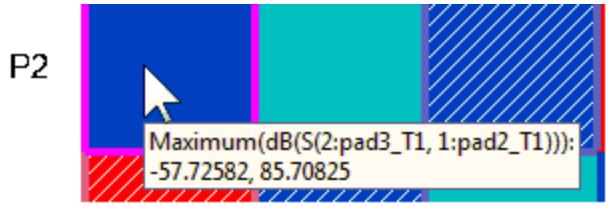
This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



The menu options are:

- **Average** – display the average of the matrix values across selected frequencies.
- **Minimum** – display the minimum matrix values across selected frequencies.
- **Maximum** – display the maximum matrix values across selected frequencies.

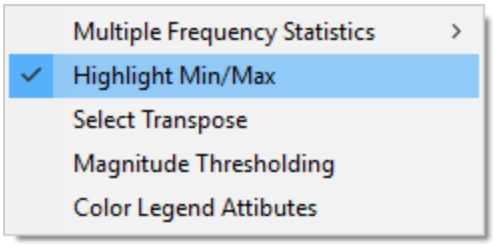
The selected information also appears in a tool-tip when you hover the cursor over a cell.



Highlight Min/Max

The **Highlight Min/Max** menu option determines whether the minimum and maximum matrix entries should be highlighted in the matrix table and color plot view.

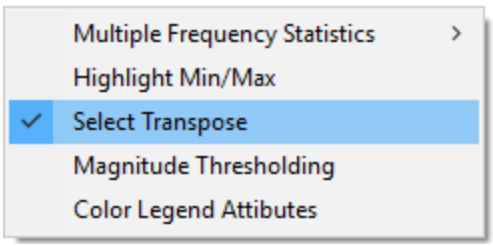
This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



Select Transpose

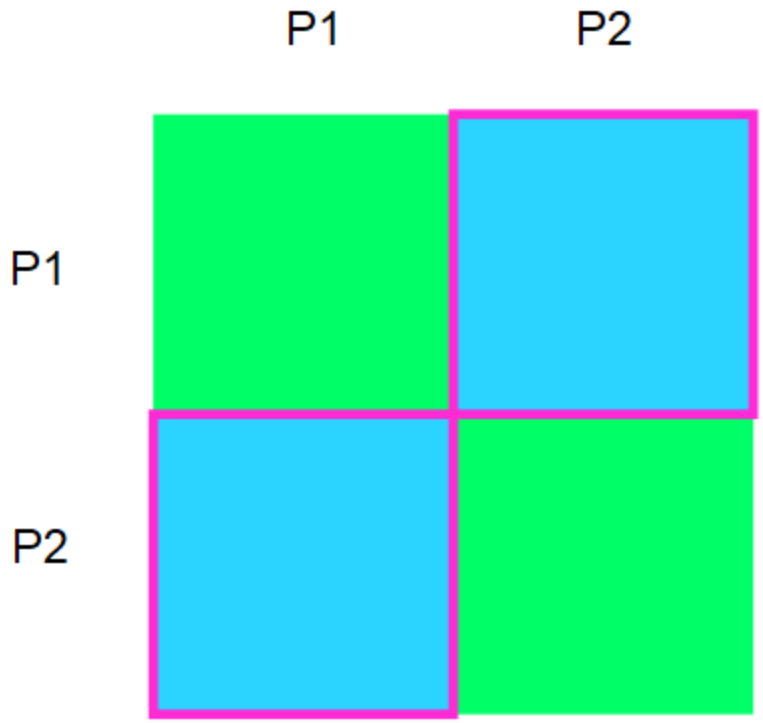
The **Select Transpose** menu option determines whether transpose cells are highlighted along with selected cells.

This right click menu option appears in the **Matrix** plot, regardless of whether you are in Table or Plot view.



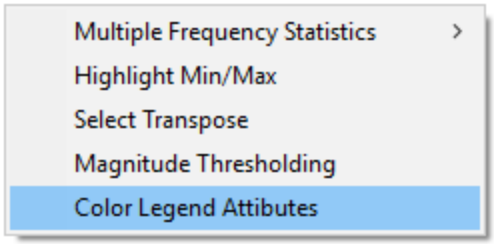
Transpose cells are highlighted in Table or Plot view, as shown below.

0.01000GHz	P1	-57.10340, -81.97841	-57.72581, 85.70836	-0.00213, -0.18916
	P2	-57.72582, 85.70825	-57.09556, -81.98749	-66.27113, 99.16916
	P3	-0.00213, -0.18916	-66.27110, 99.16941	-57.10246, -81.95892
	P4	-66.27112, 99.16942	-0.00213, -0.18929	-57.72556, 85.71465

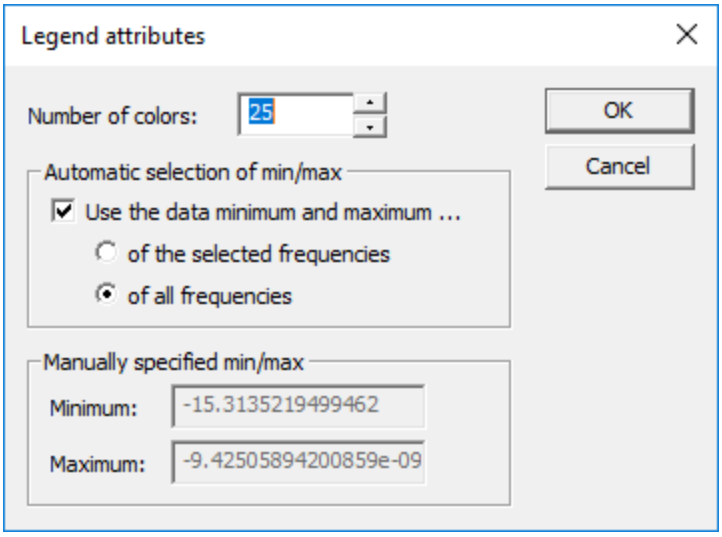


Color Legend Attributes

The **Color Legend Attributes** menu option allows you to change the granularity of the color scheme and the value range for plots. This right click menu option appears in the **Matrix** plot.



Alternatively, double-click the matrix color plot to open the **Legend Attributes** window.



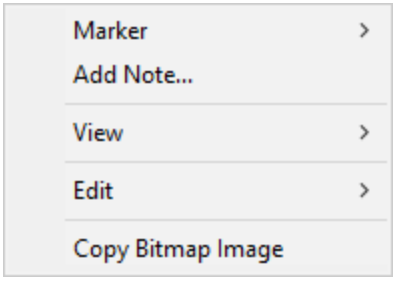
Options include:

- **Number of colors** – allows you to select number of color entries in the legend (the number of divisions between the start/end of the data range). This can be set to any discrete number between 1 and 50.
- **Automatic selection of min/max** – check the **Use the data minimum and maximum** checkbox to automatically select the data range using the minimum and maximum values from either selected frequencies or all frequencies in the data set.
- **Manually specified min/max** – when the when the range is not automatically determined, these fields permit the user to manually enter hard values. For example, for S parameter data magnitude data, you could enter a minimum of 0 and a maximum of 1.

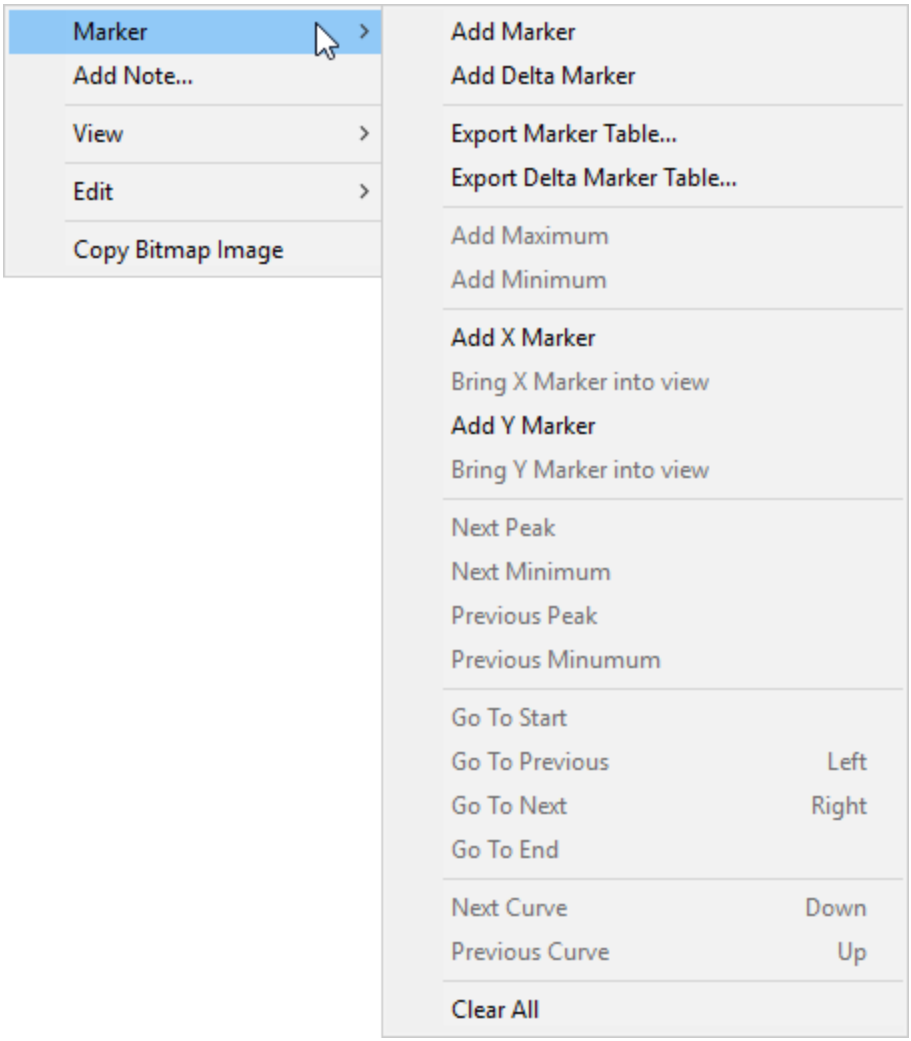
Using a standard range across all frequencies permits you to quantitatively compare plots, and ndExplorer remembers legend settings for each data-type and display-format pair.

Matrix Entries Plot Menu

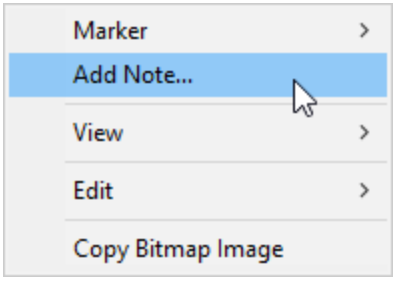
When the **Matrix entries** radio button is selected and you are viewing the data in **Plot** mode, several new right-click menu options appear.



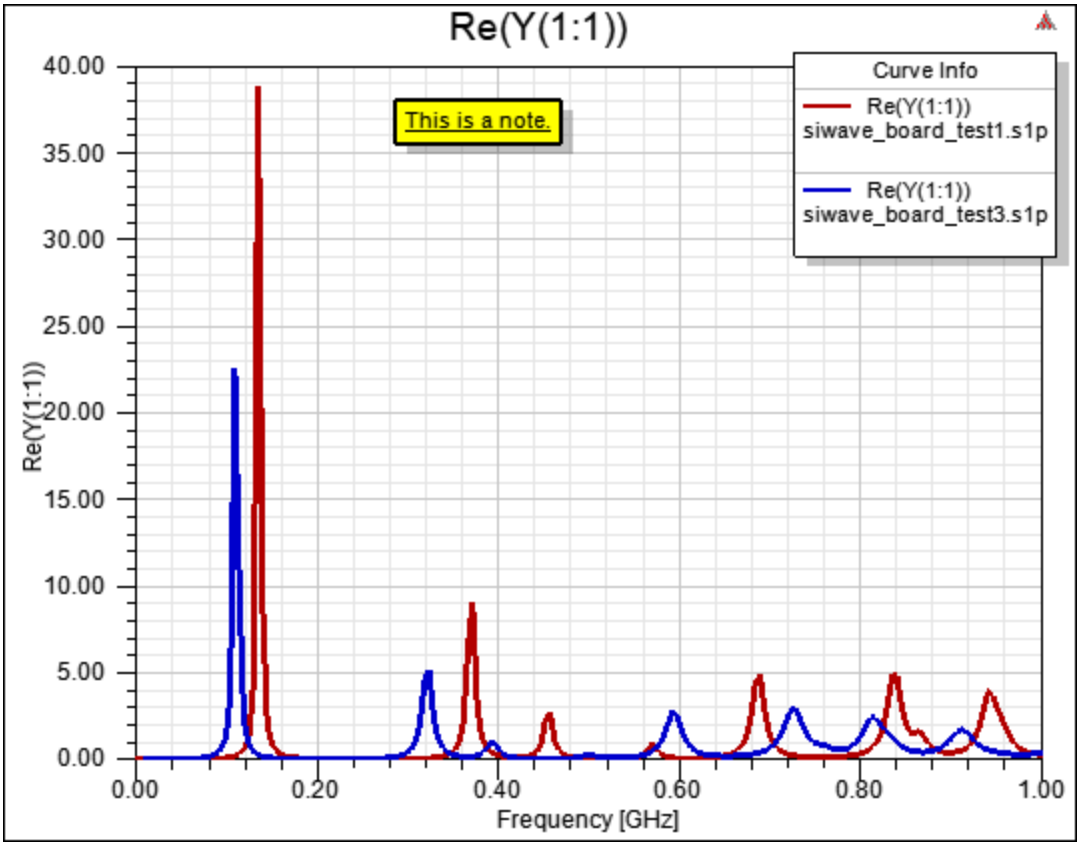
The **Marker** sub-menu provides commands for adding markers to plots.



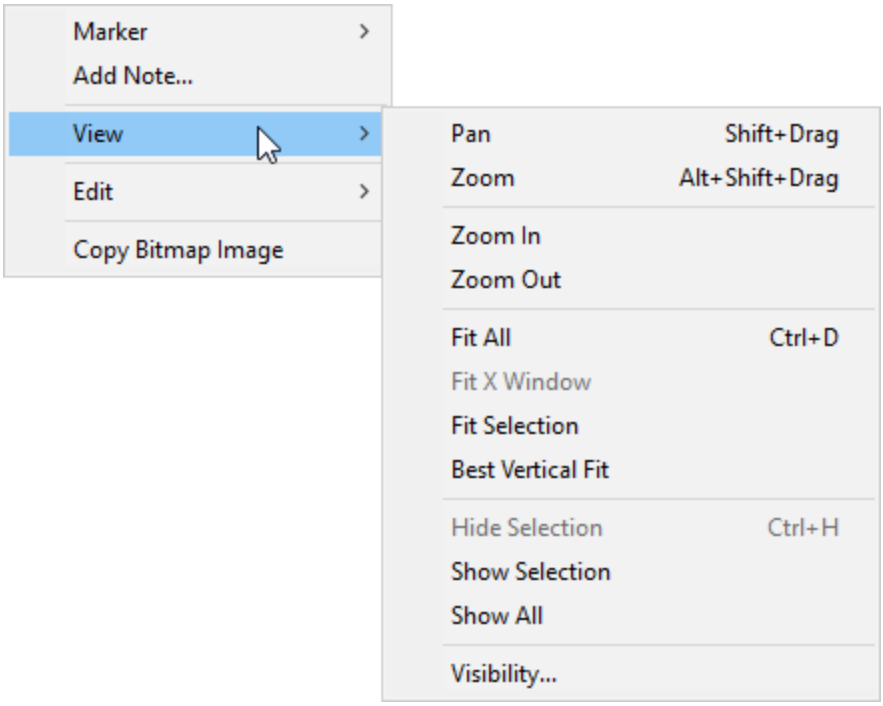
The **Add Note** menu option allows you to add a note to the plot.



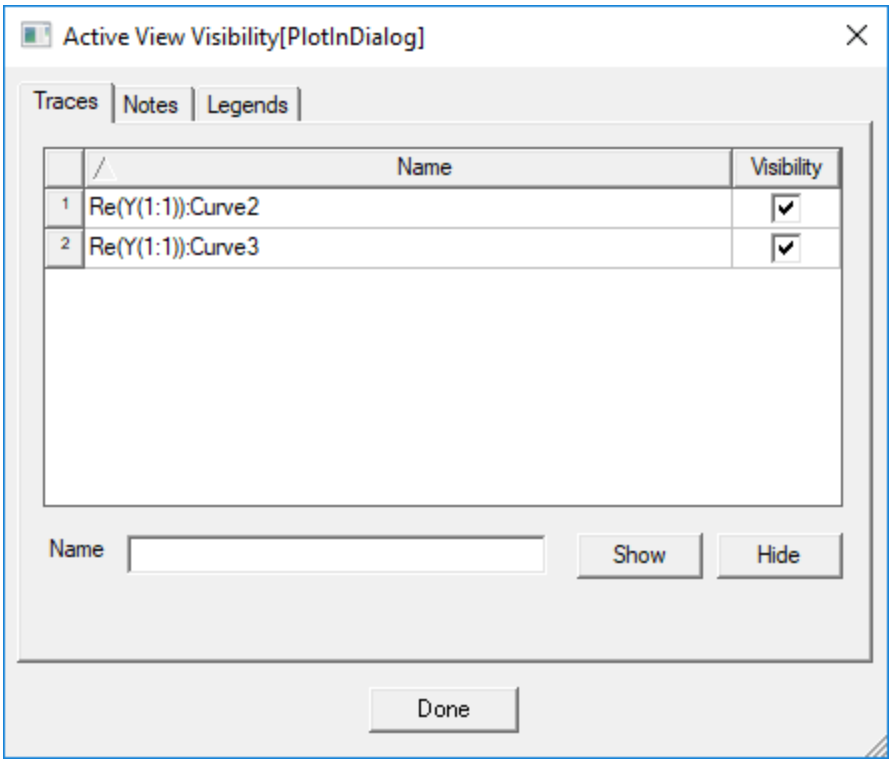
The note appears at the location you right-clicked. You can click and drag the note to a new location, or double-click the note to change its color and font.



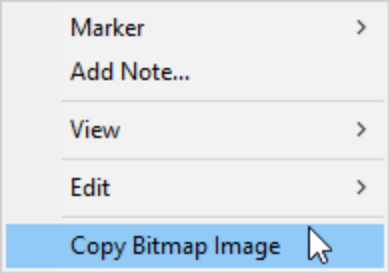
The **View** sub-menu provides commands for viewing, panning, zooming, and fitting elements to your plot.



Click **Visibility** to open the **Active View Visibility** window, where you can select the visibility of traces, notes and legends.



The **Copy Bitmap Image** menu option copies the plot to your clipboard. You can then paste it into a graphics editor.



Exploring Network Data and Modifying the Display

Network Data Explorer allows you to view data and modify various aspects of the display, including color plots, color coding, viewing across frequencies, and displaying individual statistics. This section provides examples of Network Data Explorer capabilities:

This section provides examples of Network Data Explorer capabilities:

- Viewing the S, Y, or Z Matrix for a Frequency
- Viewing a Color-coded Matrix Plot
- Displaying a Cell Graph Across All Frequencies
- Displaying Matrix Statistics by Frequency
- Displaying Individual Statistics for All Frequencies
- Creating a Statistics Plot
- Comparing Network Data

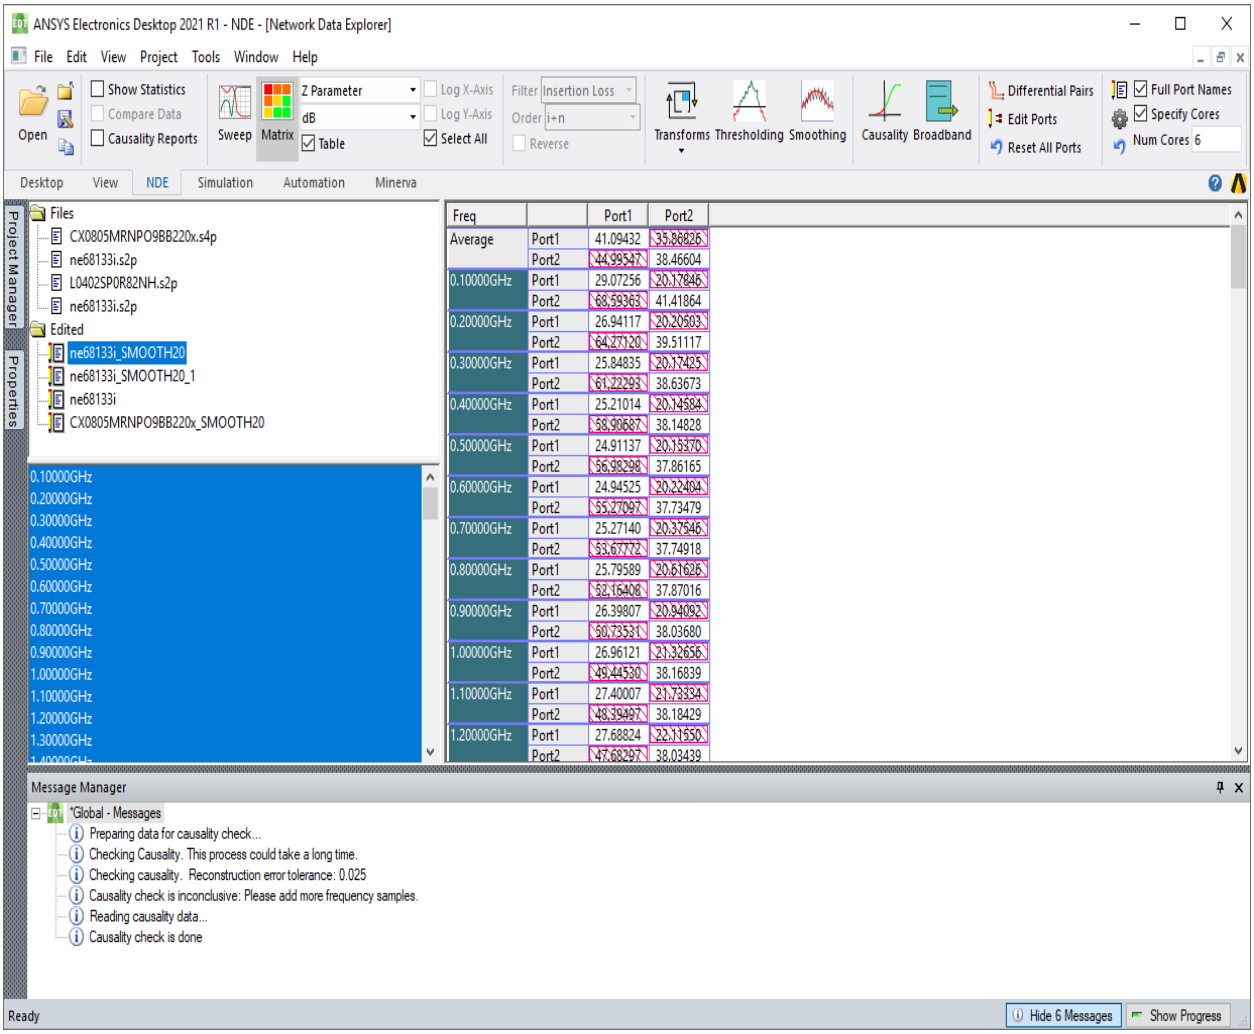
Viewing the S, Y, or Z Matrix for a Selected Frequency

To view the S, Y, or Z matrix:

1. On the **NDE** ribbon, click **Matrix**
2. Click the **Table** check box.
3. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
4. Choose a format from the drop-down menu, for example: dB or Mag.

5. In the Cell and Frequency Selection pane, select frequencies to display or click the **Select All** check box on the **NDE** ribbon to select all frequencies.

   The S, Y, or Z matrix displays.



6. Hover over a cell to see more information in a tool tip.
7. Right click to see a right click menu with other commands.

Maximum values are highlighted in red stripes. If Select Transpose is enabled, transposes are highlighted in red stripes as well.

Minimum values are highlighted in blue stripes.

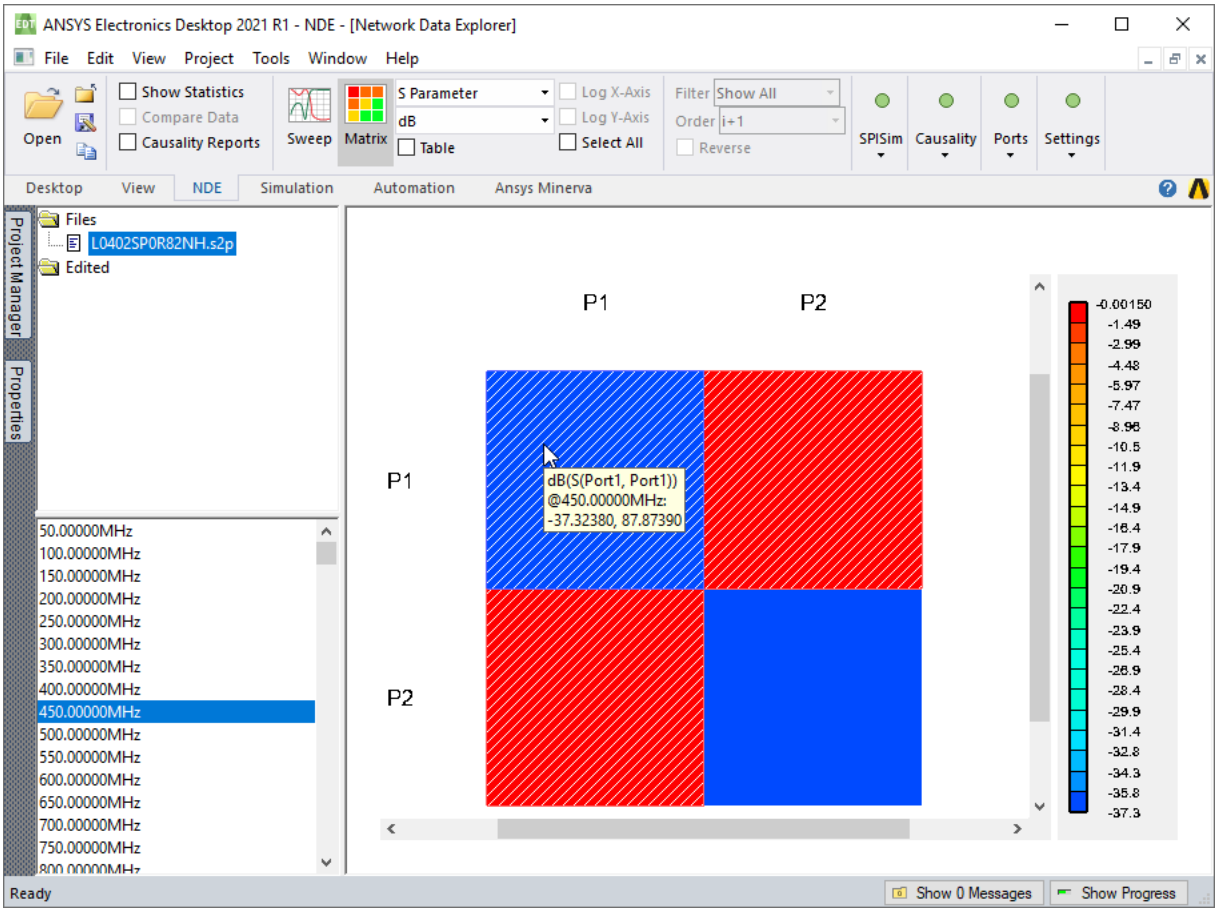
Selected cells appear in solid blue. If Select Transpose is enabled, the transpose is highlighted in blue as well.

Double-clicking a cell switches to a matrix cell view, in which values for all frequencies for that cell are displayed. The double-clicked frequency is highlighted with solid red shading

Complex values are compared using their modulus. When multiple frequencies or variations are selected, the data display depends on the Multiple Frequency Statistics setting.

Viewing a Color-coded Matrix Plot

1. On the **NDE** ribbon, click **Matrix**.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, **Z parameter**, or another choice.
3. In the Cell and Frequency Selection pane, select the frequencies you want to plot or click the **Select All** check box on the **NDE** ribbon to select all frequencies.
4. Hover over a cell to see more information in a tool tip.
5. Right click to see a right click menu with other commands.



Matrix values display in a color-coded grid. If the selected **Format** is a complex value, only the real component is used to determine the display color. When multiple frequencies or variations are selected, the data display depends on the Multiple Frequency Statistics setting. Maximum values are highlighted in red. Minimum values are highlighted in dark blue.

Hover the cursor over any cell to view information about it.

Click any cell to select it. Selected cells appear with a pink outline. If Select Transpose is enabled, the transpose is selected in pink as well.

Double-click any cell to view a matrix cell plot in which all frequency values for that matrix cell are displayed as a graph.

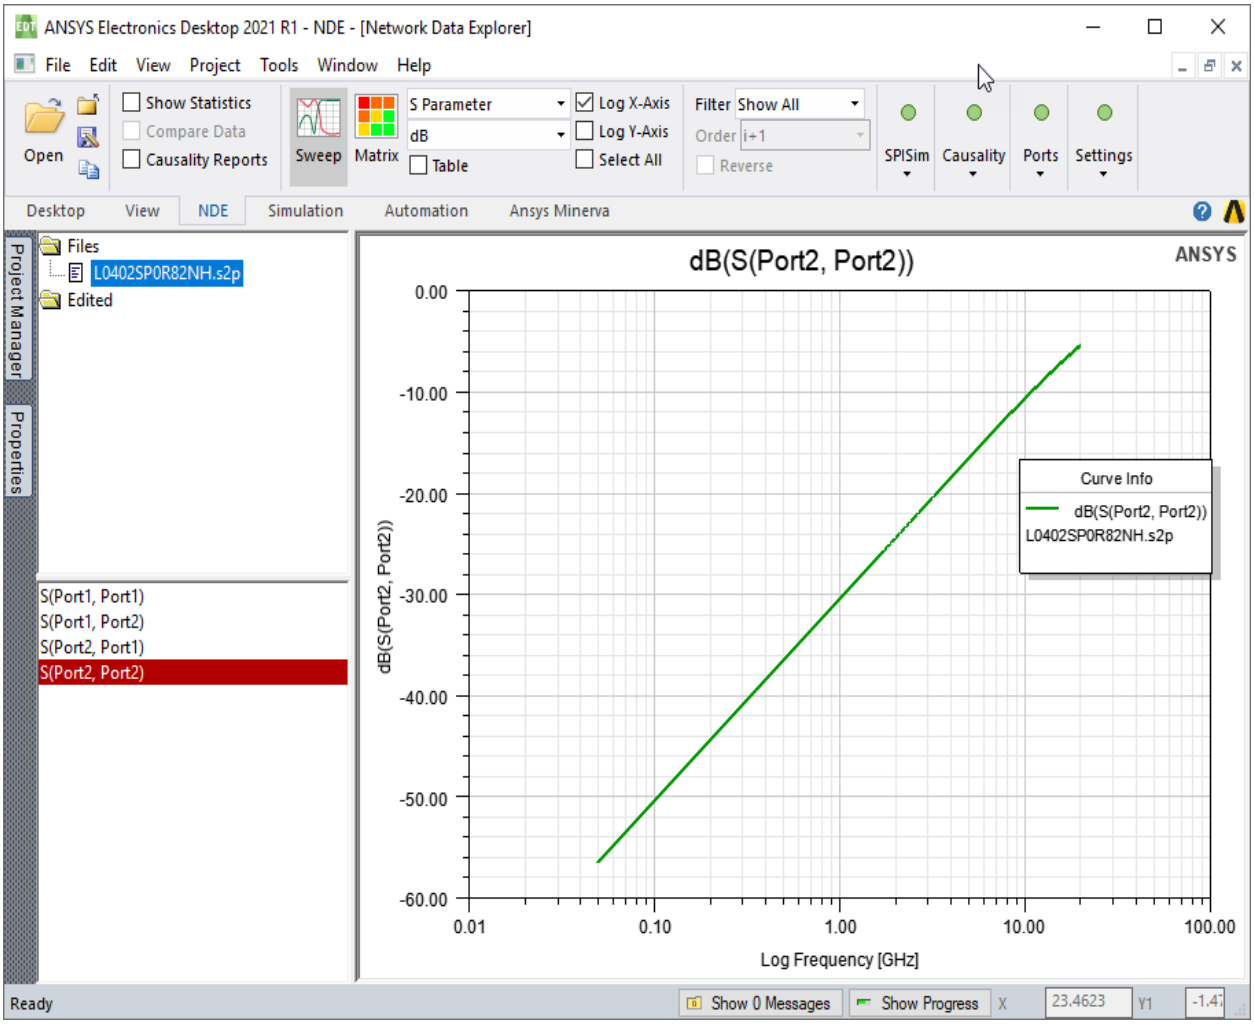
- Setting Multiple Frequency Statistics
- Changing Color Legend Attributes

Displaying a Cell Graph Across All Frequencies

Network Data Explorer can plot a cell across all frequencies.

1. On the **NDE** ribbon, click **Sweep**. The Data View Pane updates if necessary.
2. Use the **Parameter** type drop-down menu to select **S parameter**, **Y parameter**, or **Z parameter**.
3. In the Cell and Frequency Selection pane, select cells to display or click the **Select All** check box on the **NDE** ribbon to select all cells.
4. To add a log scale to the X-axis, click **Log X-Axis** on the **NDE** ribbon.



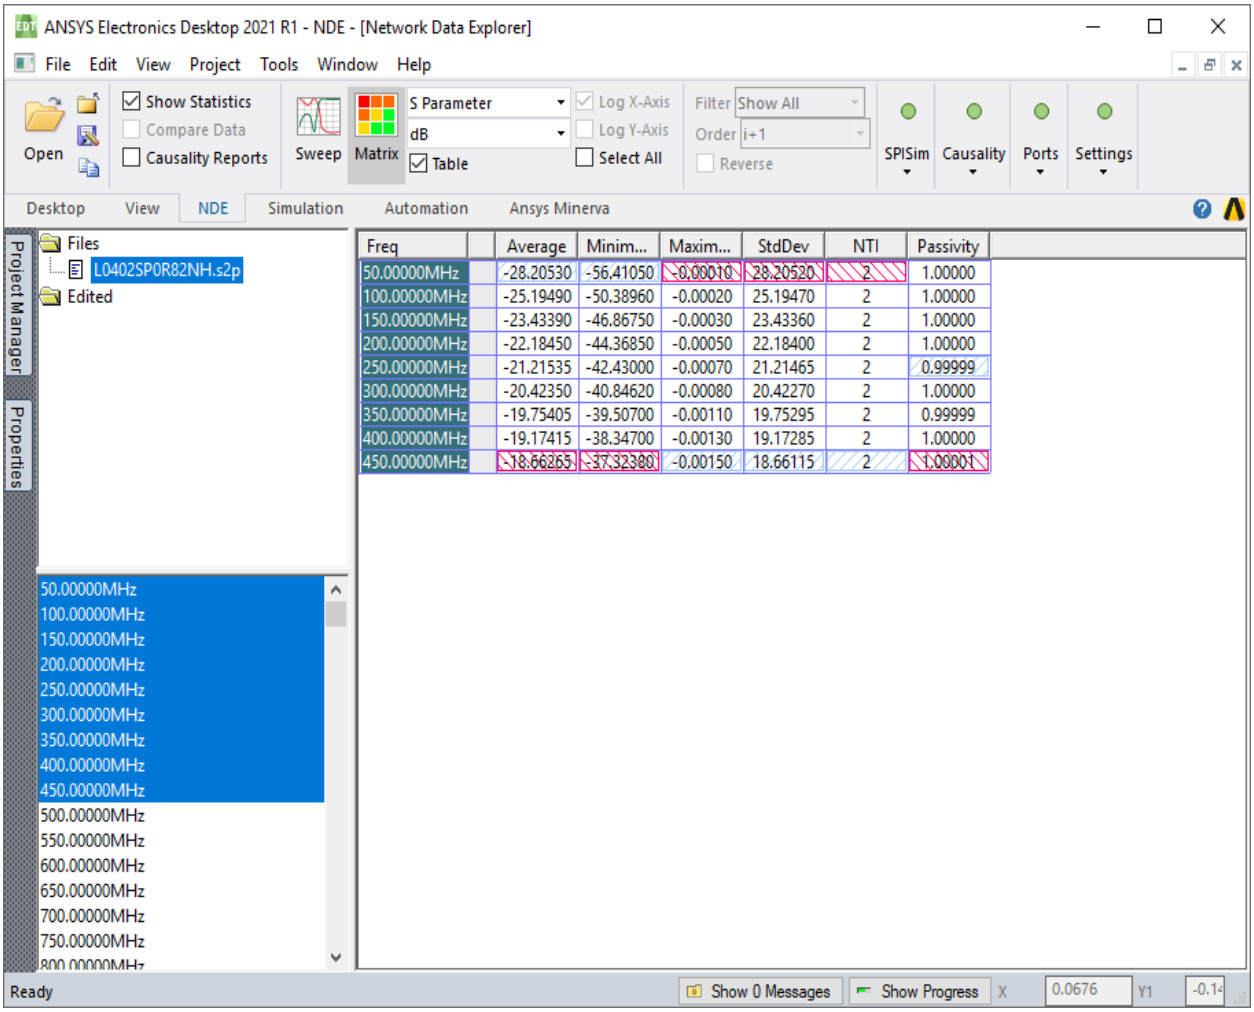
5. To add a log scale to the Y-axis, click **Log Y-Axis** on the **NDE** ribbon.
6. Right click to see a right click menu with other commands.

Displaying Matrix Statistics by Frequency

Network Data Explorer can display various statistical measurements.

1. On the **NDE** ribbon:
    1. Click **Matrix**.
    2. Click **Table**.
    3. Click **Show Statistics**.

2. In the Cell and Frequency Selection pane, select frequencies to display.



Click a column header to sort data by that column.

Hover the cursor over a cell to view information about it.

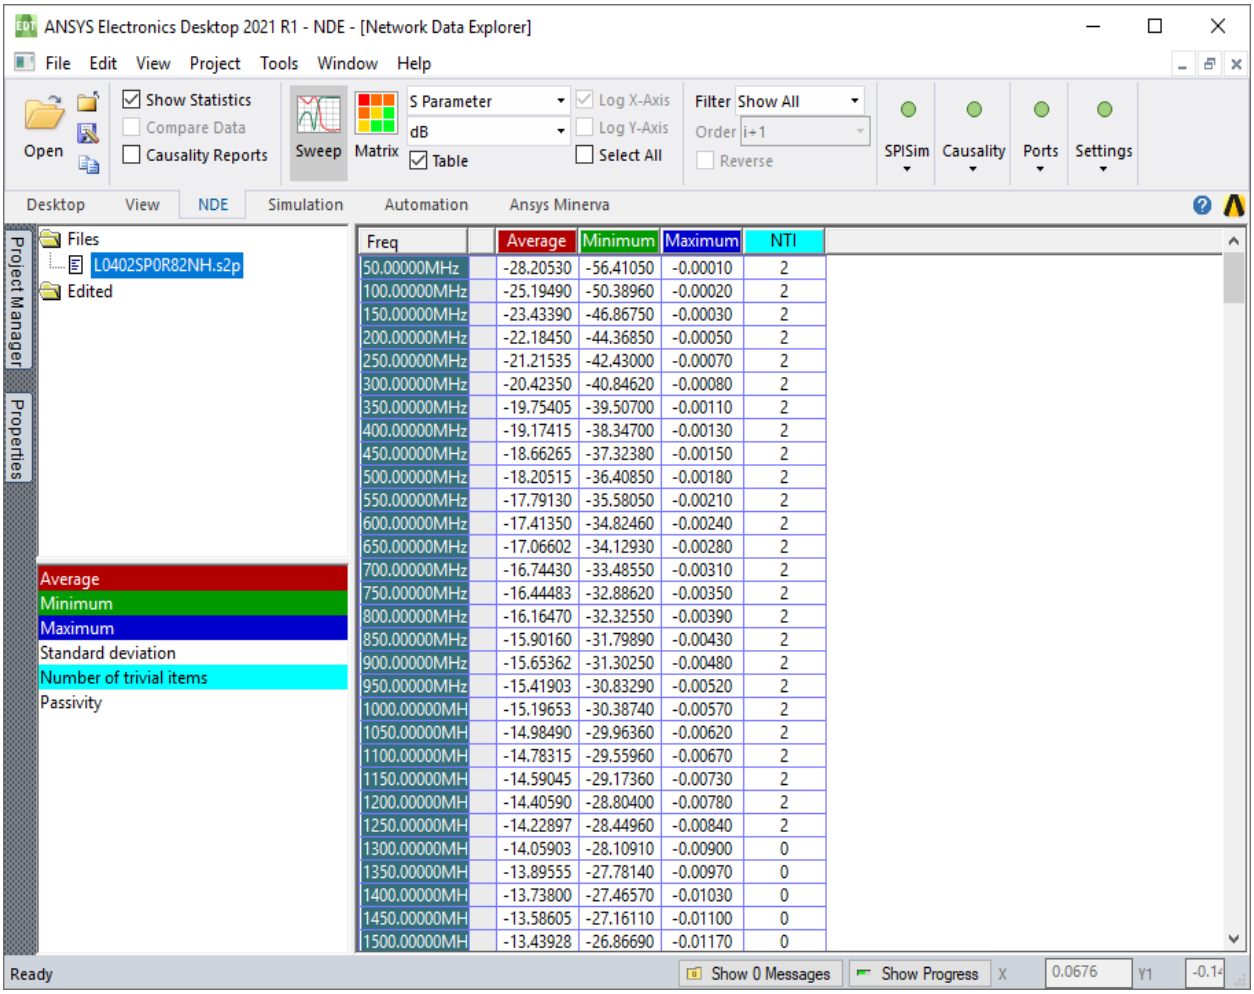
Only real (not complex) data formats are offered for statistical analysis. **Passivity** is only available for S-parameter data (comparisons inactive). **NTI** refers to the number of trivial items; for S-parameters, this includes all zeros and ones; for all other data (and data comparisons), only zeros are counted as trivial. The minimum value for each column is highlighted in blue; the maximum is highlighted in red.

Displaying Individual Statistics for All Frequencies

1. On the **NDE** ribbon:
    1. Click **Sweep**.
    2. Click **Table**.
    3. Click **Show Statistics**.

2. In the Cell and Frequency Selection pane, select statistics to display.

   The information displays in a table in the Data View pane.



Selected statistics are displayed for all frequencies.

Passivity is only available for S-parameters (comparisons inactive).

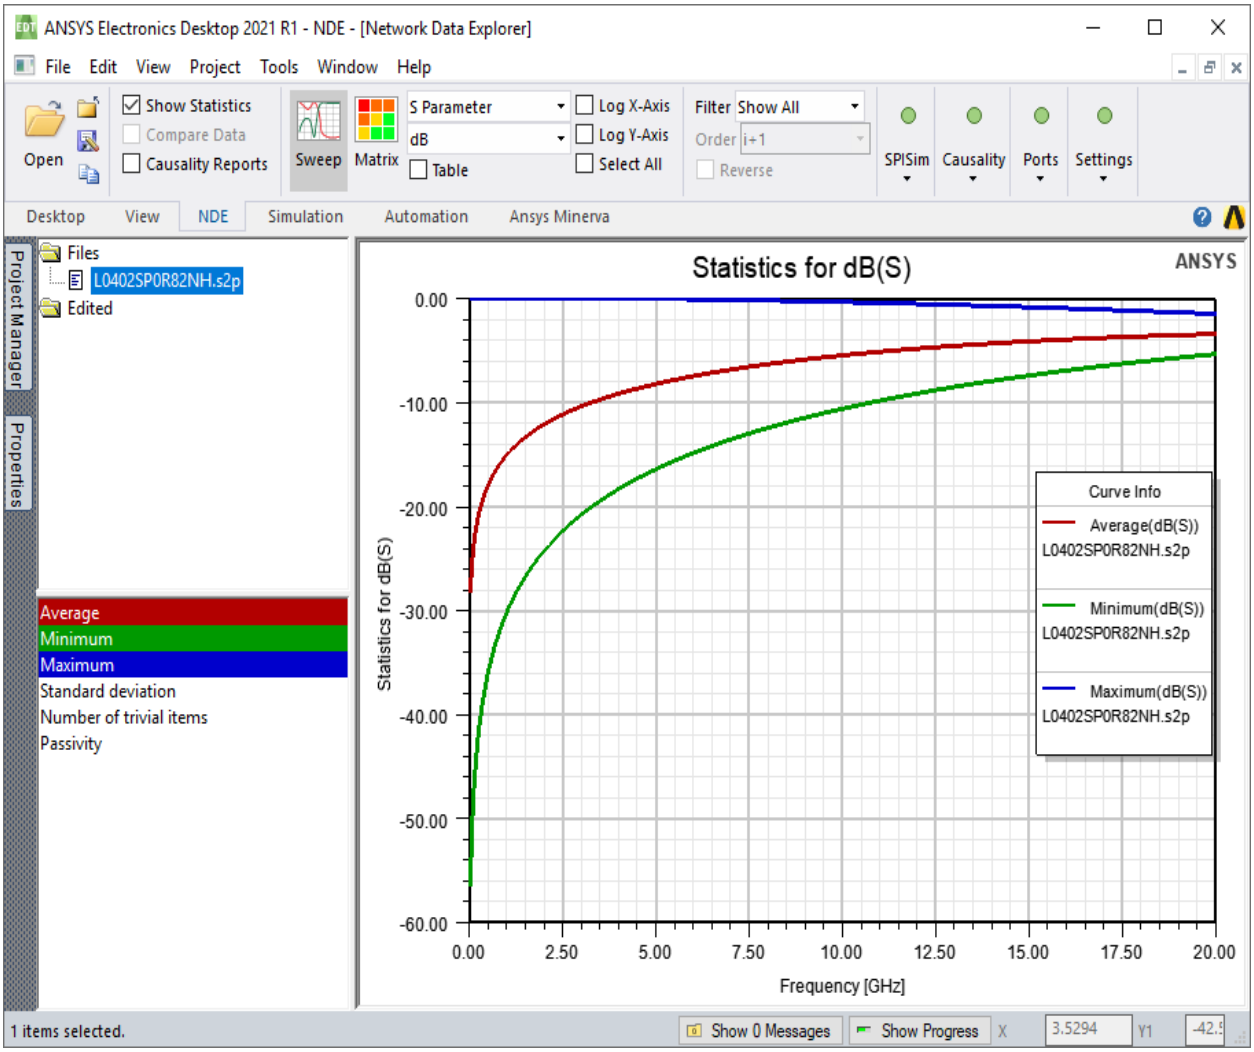
For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

Creating a Statistics Plot

Network Data Explorer can display a graph of selected statistical measures across all frequencies.

1. On the **NDE** ribbon:
   1. Click **Sweep**.
   2. Click **Show Statistics**.
2. In the Cell and Frequency Selection pane, select statistics to display.

The selected statistics are plotted.



Hover the cursor over a statistic to view more information about it.

Passivity is only available for S-parameters (comparisons inactive).

For S-parameters, the **Number of Trivial Items (NTI)** includes all values of 0 and 1. For other data and data comparisons, only values of 0 are counted as trivial.

Comparing Network Data

Network Data Explorer can compare variations for two network data sets that are the same size.

1. On the **NDE** ribbon, click **Sweep**.
2. In the Network Data Selection pane, select exactly two data sets.
3. On the **NDE** ribbon, click **Compare Data**.

4. In the Cell and Frequency Selection pane, select which cells you want to compare . For each value along the X-axis, the Y-axis values are subtracted, one from the other, to create the comparison plot. The second selected data is subtracted from the first selected data.
5. Optionally, check **Show Statistics** to show values applied to all cells and all frequencies

It is not possible to compare a data set against itself *unless the data set has been loaded twice*.

Traces for a given cell or statistical measure are displayed for all data sets; you can use tool tips to distinguish between them.

If a single cell or statistical measure is displayed, different colors are used for each data trace. If multiple cells or statistical measures are selected, a single color is used for all data traces for each cell or statistical measure.

In a data comparison, traces are shown for all selected data sets. This is true for both cell and statistical traces.

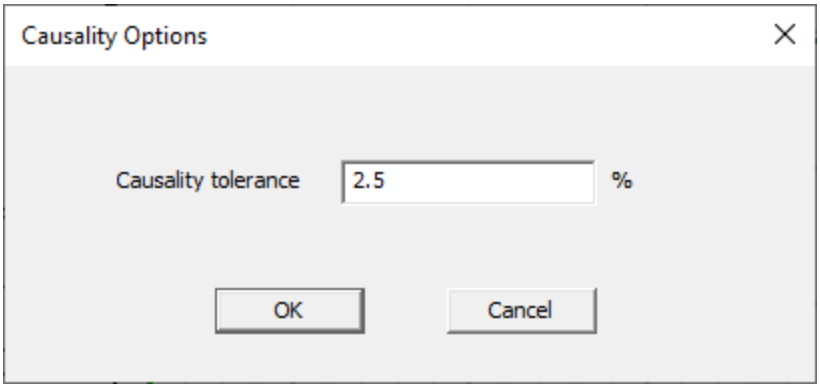
If **dB** format is shown, you can either subtract values before or after applying the dB function. See Display Format to make this choice.

Causality Checking and Plots

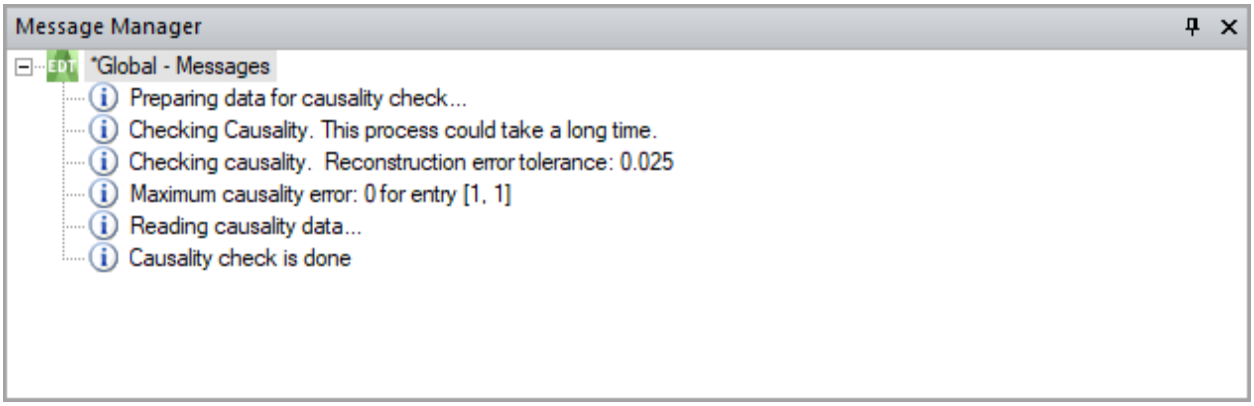
Network Data Explorer can perform a causality check on S-parameter data from any source (solution or file), and provide plots of the results in various formats.

When S-parameter data is loaded into Network Data Explorer, the **Causality** button is enabled.

1. On the **NDE** ribbon, click **Causality**. The **Causality Options** dialog opens.



2. Enter a **Causality tolerance** and click **OK** to start the causality check. Depending on the size of the S-parameter data, the causality check may take several minutes to complete. The check's status displays in the Message Manager.



When the check completes, the Messages Pane updates to display a summary of results.

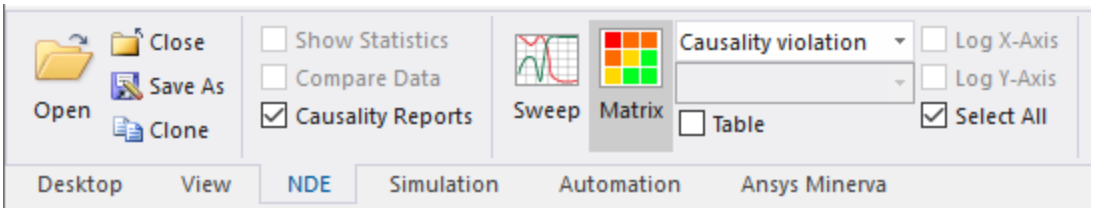
Reconstruction Error Tolerance – Causality of a frequency response is determined by calculating the generalized Hilbert transform of the data at all frequencies. A causal frequency response is equal to its generalized Hilbert transform. The reconstruction error is the difference between the tabulated data and its transform at a given frequency. The message shows the maximum reconstruction error tolerance for a causal frequency response. The default tolerance of 0.01 is equal to the state-space fitting tolerance.

Maximum Causality Error – The maximum causality error for all port pairs and all frequencies, along with the matrix indices (port numbers) where the maximum noncausality occurs. A noncausal response is one where all matrix entries can be conclusively analyzed, and at least one entry exceeds the causality tolerance. The maximum reconstruction appears first, followed by port numbers in brackets (e.g., [port number, port number]). When all results are conclusive but no matrix reconstruction error exceeds the tolerance, the maximum causality error is reported as zero, and no matrix entry is listed.

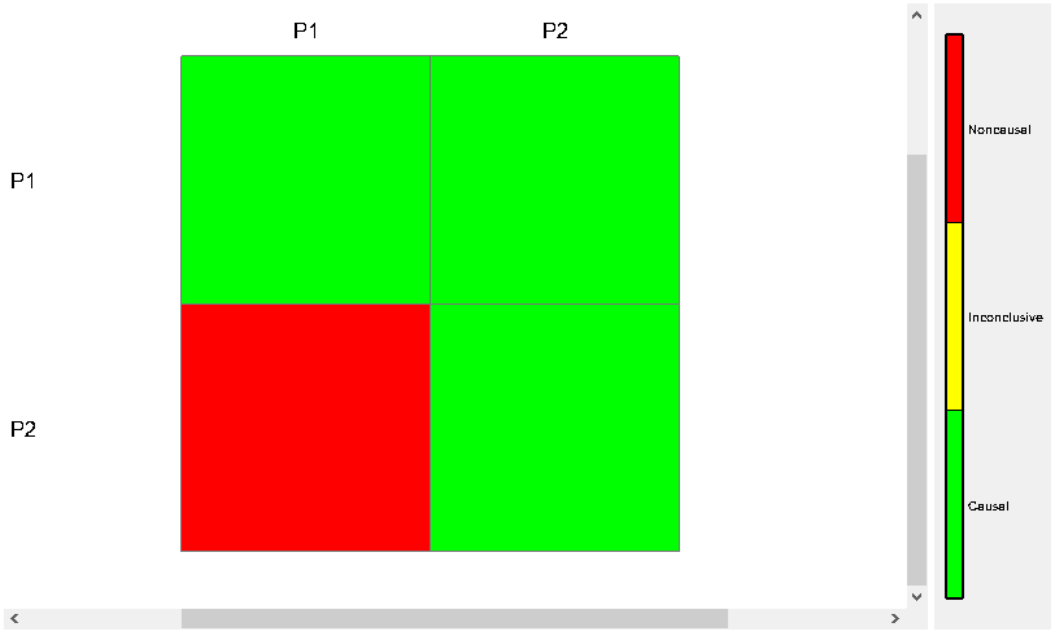
If the data does not contain enough frequency points to determine whether the data is or is not causal, the Messages Pane will note an inconclusive result. ndExplorer will also report the data set as inconclusive if any cells are inconclusive, even if other entries exhibit causality violations.

To see the plotted results of the causality check:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Matrix** icon or select **Causality violation** in the **Parameter** type drop-down menu.



A rectangular plot displays, with dimension N x N and color-coding to indicate the causality status of each port pairing.



In this plot, the cells go from (Port 1, Port 1) at the upper-left area to (Port N, Port N) at the lower-right corner. The result shows the causality over all frequencies in the data. In this example, the matrix is asymmetric, so that S12 is noncausal, while S11, S21, and S22 are causal.

To see the details for each frequency, click the **Table** check button on the **NDE** ribbon.

Freq		Port1	Port2	Port1	Port2

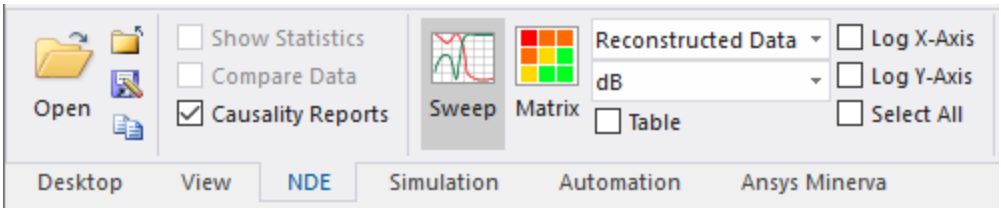
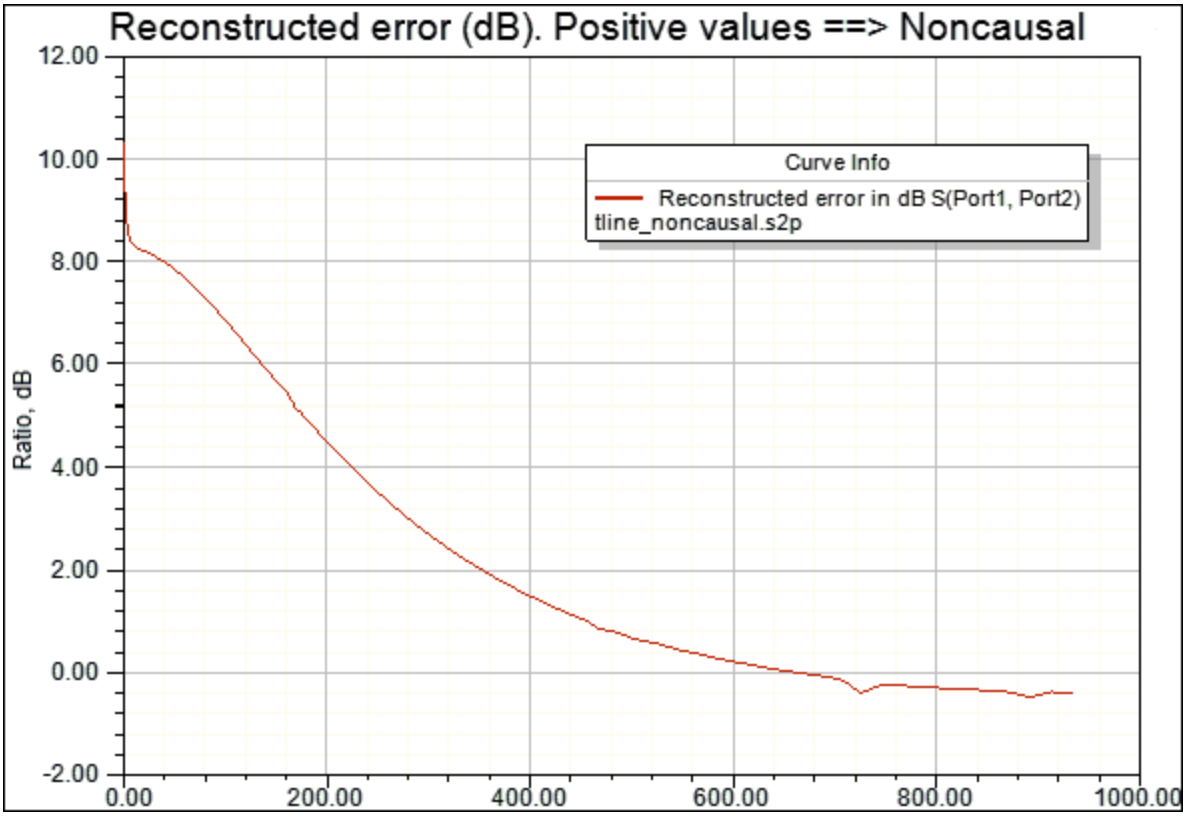
	Port2	0.08091, 0.00000	0.00174, 0.00000	0.00094, 0.00000	0.00021, 0.00000
1.60000GHz	Port1	0.00315, 0.00000	0.00038, 0.00000	0.00006, 0.00000	0.00015, 0.00000
	Port2	0.07512, 0.00000	0.00208, 0.00000	0.00065, 0.00000	0.00011, 0.00000
1.70000GHz	Port1	0.00275, 0.00000	0.00034, 0.00000	0.00006, 0.00000	0.00021, 0.00000
	Port2	0.06069, 0.00000	0.00152, 0.00000	0.00101, 0.00000	0.00021, 0.00000

To plot the reconstructed frequency response generated by the causality checker:

1. On the **NDE** ribbon, click **Causality Reports**.
2. Either click the **Sweep** icon or select **Reconstructed Data** in the **Parameter** type drop-down menu.
3. In the **Format** drop-down menu, select the desired format. **dB** is selected by default.

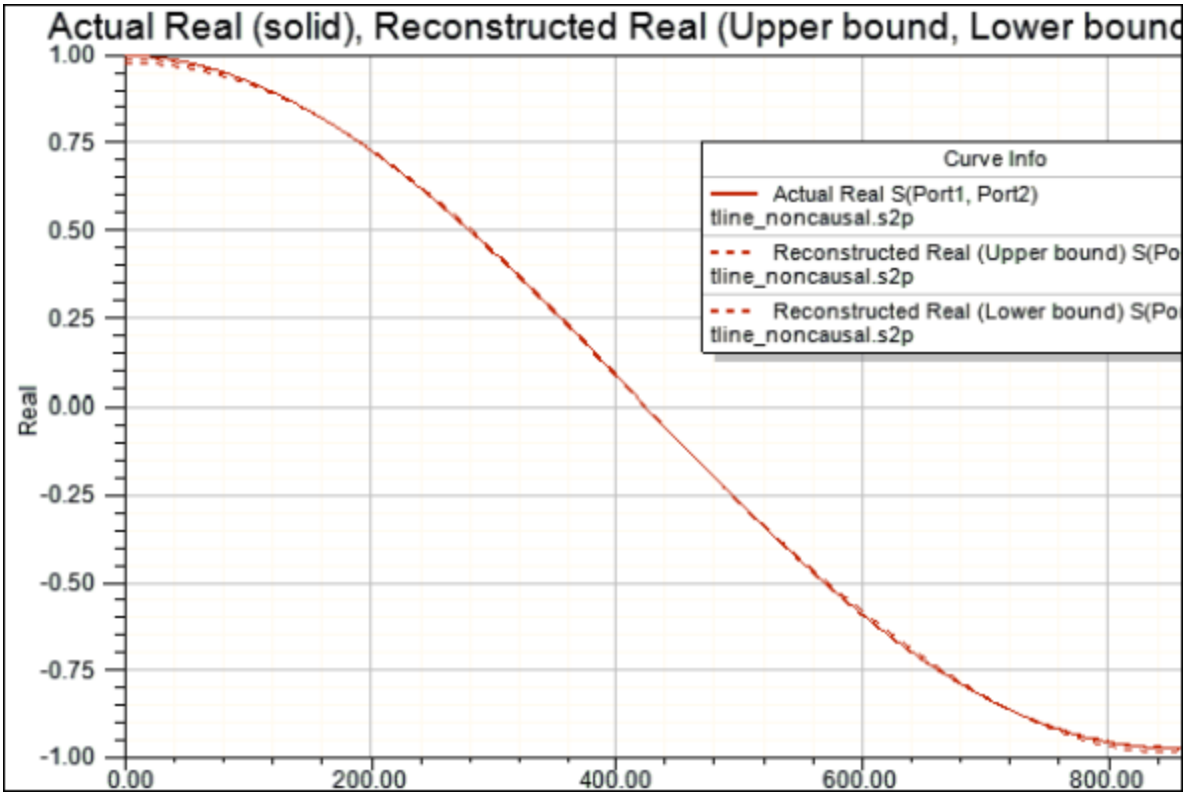


The plot appears, showing the reconstruction error at each frequency divided by the tolerance.



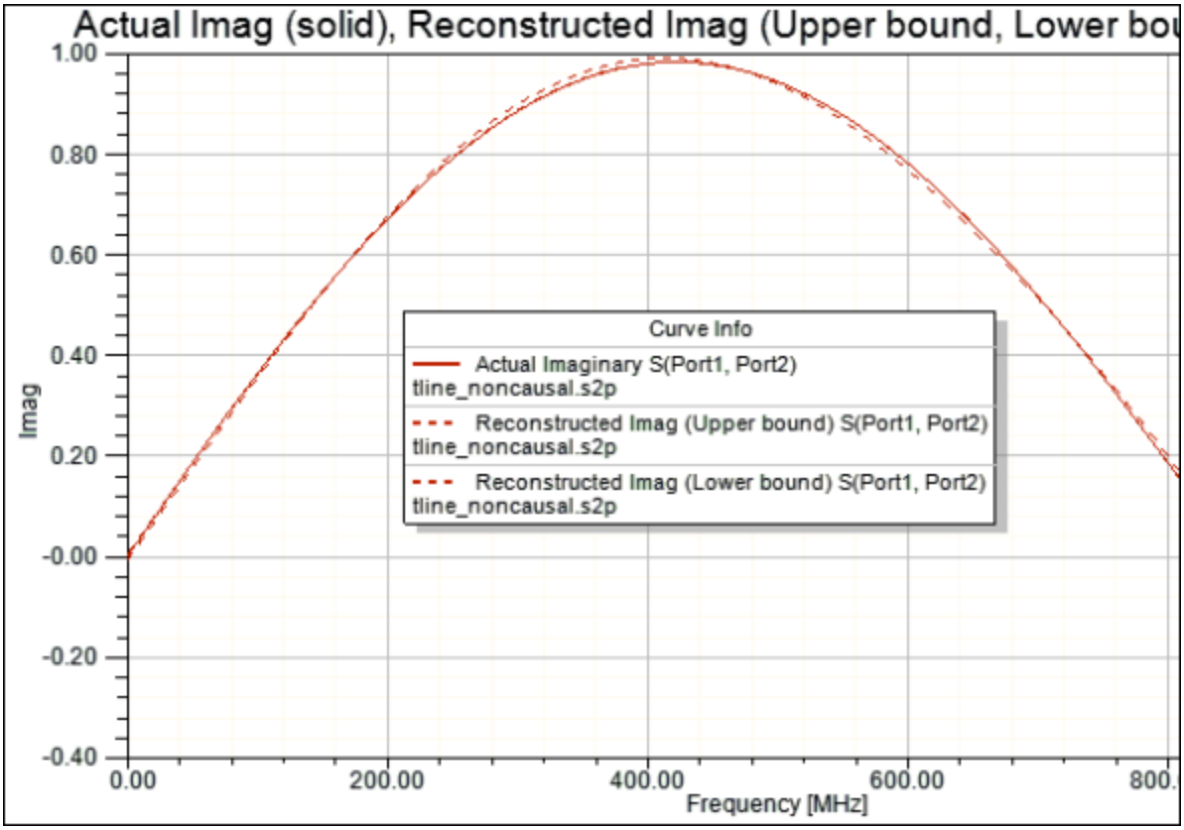
The reconstruction error ratio for parameter S12 is positive for frequencies less than about 680MHz, indicating a broad range of noncausal behavior.

4. To compare the real part of the reconstructed data to the real part of the actual data, set the **Format** to **Real**.



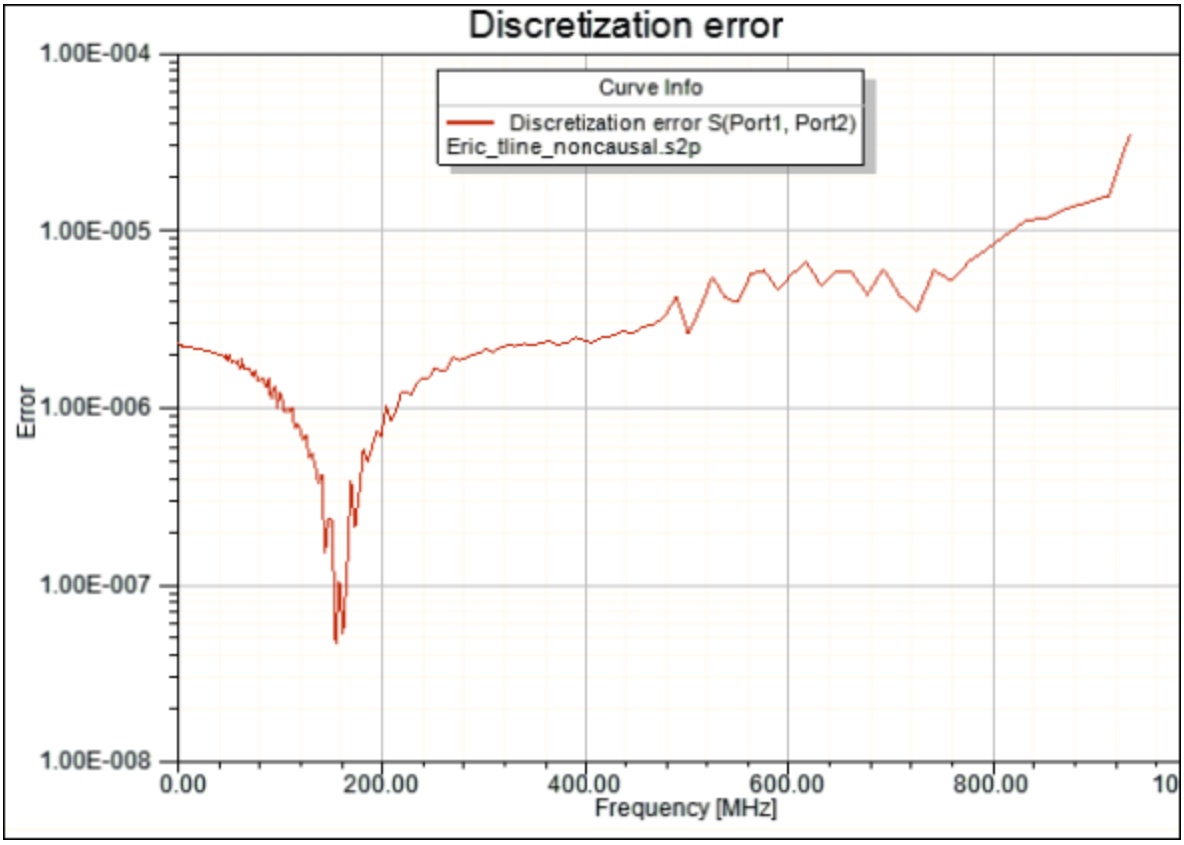
For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

5. To compare the imaginary part of the reconstructed data to the imaginary part of the actual data, set the **Format** to **Imaginary**.



For a causal frequency response, the actual data (solid line) will be within the upper and lower bounds of the reconstruction (dotted lines) at all frequencies.

6. To view the frequency-dependent discretization error, set the **Format** to **Discretization**.



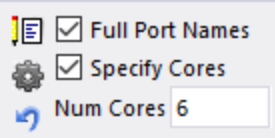
The discretization error is the error that is due to the fact that the data are available only at discrete frequencies rather than for a continuous spectrum. A discretization error near or greater than the causality tolerance renders the causality check inconclusive. Data at more frequencies could reduce the discretization error and render the analysis conclusive. This set of data exhibits low discretization errors (<<0.01) at all frequencies, and the causality check is conclusive (conclusively noncausal in this example).

Network Data Explorer Multithreading

By default, multithreading (execution on multiple cores) is enabled for Causality Checking and Macro Model export. Multithreading saves significant time in the Causality Check calculation, and improves the time for other state-space fitting operations. See Technical Notes.

The **Cores** field in the Network Data Explorer Control Pane defaults to half the number of cores detected on your computer.

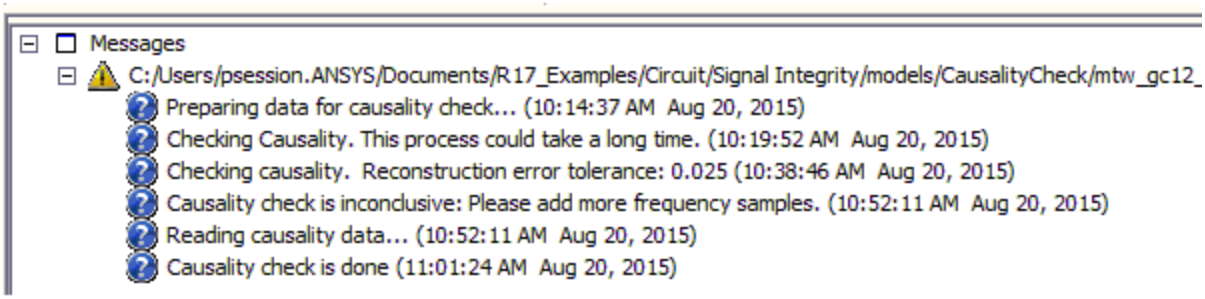
For best performance, disable hyper-threading on your computer. When hyper-threading is enabled, the number of cores includes the physical cores and an equal number of logical cores. With hyper-threading disabled, the display shows only half the number of physical cores.



To disable multithreading, uncheck the checkbox.

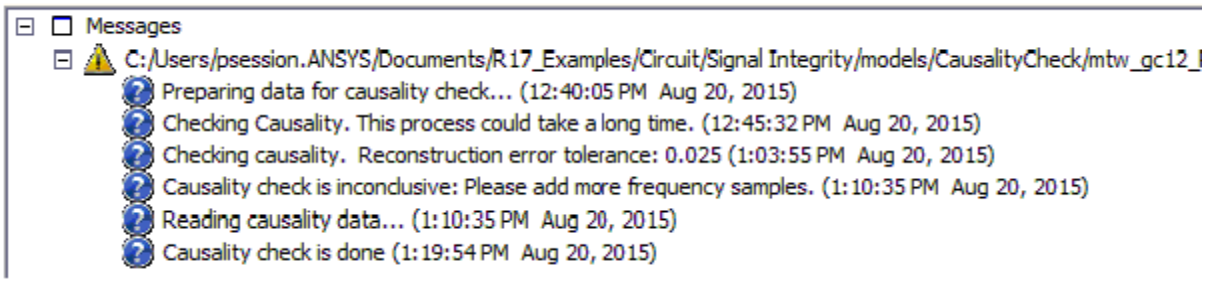
Multithreading Technical Notes

Multithreading can save significant time in the causality check calculation, especially for data sets with large number of ports or a large number of frequencies. The Network Data Explorer contributes a fixed amount of overhead time in preparing the data, and this overhead is not reduced by multithreading. Here are the messages from the causality check of a 278-port Touchstone file using two cores.



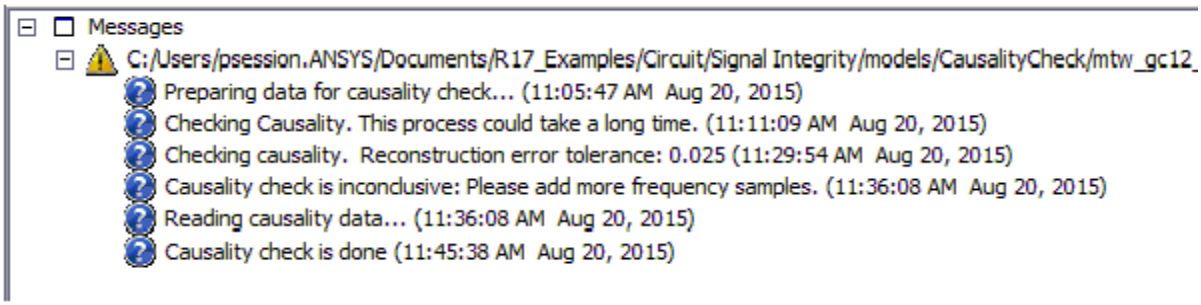
The causality check itself happens between the message `Checking causality. Reconstruction error tolerance: 0.025` (time 10:38:46) and the message `Causality check is inconclusive: Please add more frequency samples` (time 10:52:11). The difference between these two times is the time for the causality check after setup, 13:25 or thirteen minutes and twenty-five seconds. There is a fixed overhead of around 25 minutes involved in the overall time duration for this example.

Here are the causality check messages for the same 278-port file using 8 cores:



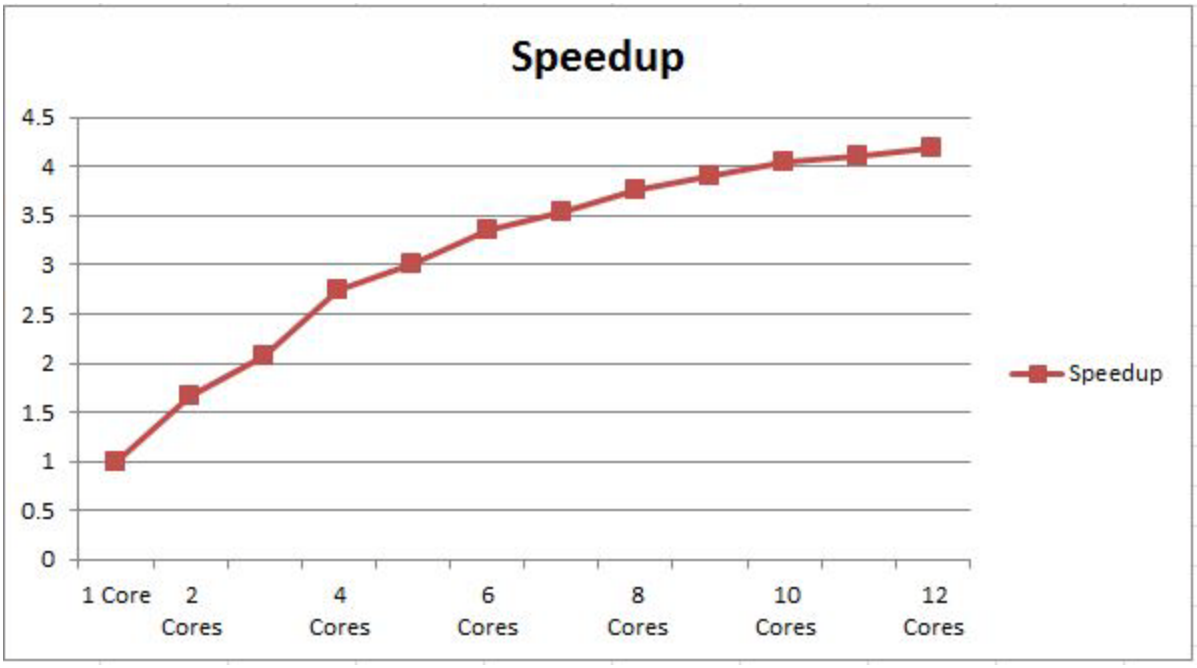
Now the causality check happens between times (1:03:55) and (1:10:35), a difference of (6:40) or six minutes and forty seconds, about half the time for the two-core example.

The speedup from multithreading is not linear in practice. Here are the messages from the same 278-port file using 16 cores:



Now the causality check happens between times (11:29:54) and (11:36:08), a difference of (6:14) or six minutes and fourteen seconds, not significantly better than the eight-core performance.

Here is a graph showing the speedup of the causality checker using multithreading on this 278-port file. The plot is generated using data from runs with 1, 2, 4, 6, 8, 10, and 12 cores, then averaging the known times to approximate the speedup for 3, 5, 7, 9, and 11 cores. The speedup for N cores is the time with one core divided by the time with N cores.



23 - Post Processing and Generating Reports

When Maxwell has completed a solution, you can display and analyze the results in the following ways:

- View solution data including the following: convergence information, computing resources that were used during the solution process, mesh statistics, and matrices computed during each adaptive, non-adaptive, or sweep solution.
- View analysis results for Optimetrics solutions.
- Plot field overlays - representations of basic or derived field quantities on surfaces or objects.
- Overlay Field Plots on Models
- Create 2D or 3D reports of RLC matrices and basic and derived field quantities.
- Plot the finite element mesh on surfaces or within 3D objects.
- Create animations of field quantities, the finite element mesh, and defined project variables.
- Use the Fields Calculator to perform computations using basic field quantities.

Note	Except in the case of non-model boxes drawn in the global coordinate system (CS), non-model objects cannot be used for any fields post processing operation You can use non-model boxes drawn in the global CS for post processing operations, including integration and solution domaining.

Related Topics

Viewing Analysis Results for Optimetrics Solutions

Viewing Solution Data

While Maxwell is generating a solution, or when it is complete, you can view the following types of information about the solution in the **Solutions** dialog box. The information actually available will vary with the solution type and setup of your design.

- Convergence information.

Note	Since adaptive mesh refinement is not performed for transient solutions, convergence data is not available for **Transient** analysis.

- Computing resources, or profile information, that were used during the solution process.
- Output Parameters (for example Force and Torque), and Matrix Data computed during each adaptive, non-adaptive, or sweep solution.
- Mesh data.
- The state of solved solutions.
- Winding results (for eddy current solutions only).
- End Connection results (for eddy current solutions only).
- Loss results (for eddy current solutions only).

To access the **Solutions** dialog box, in which the information above can be viewed, do one of the following:

- Click **Maxwell3D**, **Maxwell2D,** or **RMxprt**, and then select **Results>Solution Data**  .
- Right-click **Results** in the project tree, and then click **Solution Data** on the shortcut menu.

Related Topics

Viewing Solution Data for an Optimetrics Design Variation

Monitoring the Solution Process

Viewing Convergence Data

To view an adaptive solution's convergence information, either during or after the solution process:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

   The **Solutions** dialog box appears with the **Convergence** tab selected.
2. From the **Simulation** pull-down list, select the solution setup for which you want to view convergence data.

   By default, the most recently solved solution is selected.
3. Under the **Convergence** tab, depending on your design setup, you can review the following convergence data:
   - Whether the solution is converged or not converged.
   - Number of adaptive passes completed and remaining.
   - The number of tetrahedra or triangles created at each adaptive pass.
   - Solution type dependent parameters such as Loss, Total Loss, Loss Error.
4. Select **Table** to display the convergence data in table format or **Plot** to plot the convergence data on a rectangular (XY) plot.
5. Optionally you can **Export** the convergence data to a text file.
6. If you select **Save Defaults**, the current selection of either Table or Plot, and for Plot the current X and Y axis selections, will be applied based on the design-type, each time you open the desktop. You can also select **Clear Defaults** to reset to the original settings.

> **Note:** In the case of the 3D AC Conduction solver, even though the convergence columns names refer to the loss as a solution criteria, the convergence parameter considered is the magnitude of the apparent power.

Viewing the Number of Completed Passes

At any time during the solution process, you can view the number of adaptive passes (solve — error analysis — refine cycles) that have been completed as well as the maximum and minimum number of passes. When the solution is complete, you can view the number of adaptive passes that were performed. If the solution converged within the specified stopping criteria, fewer passes than requested may have been performed.

To view the number of passes:

- In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

  The **Solutions** dialog box appears with the **Convergence** tab selected.

  The number of completed passes is listed in the **Number of Passes** area.

Viewing Output Variable Convergence

At any time during or after the solution process, you can view the values of the output variable.

To view the output variable convergence, use the Reporter to create a plot that displays the output variable values.

Related Topics

Plotting Convergence Data

To display convergence data vs. pass on a rectangular (x - y) plot:

1. In the project tree, right-click the solution setup of interest, and then click **Convergence** on the shortcut menu.

   The **Solutions** dialog box appears with the **Convergence** tab selected.
2. In the lower-left corner of the window, select **Plot** as the **View** type.
3. Select the data you want to plot on the x-axis from the **X** pull-down list.
4. Select the data type you want to plot on the y-axis from the **Y** pull-down list.
5. Click **Close**.

The xy plot appears in the view window.

Viewing a Solution Profile

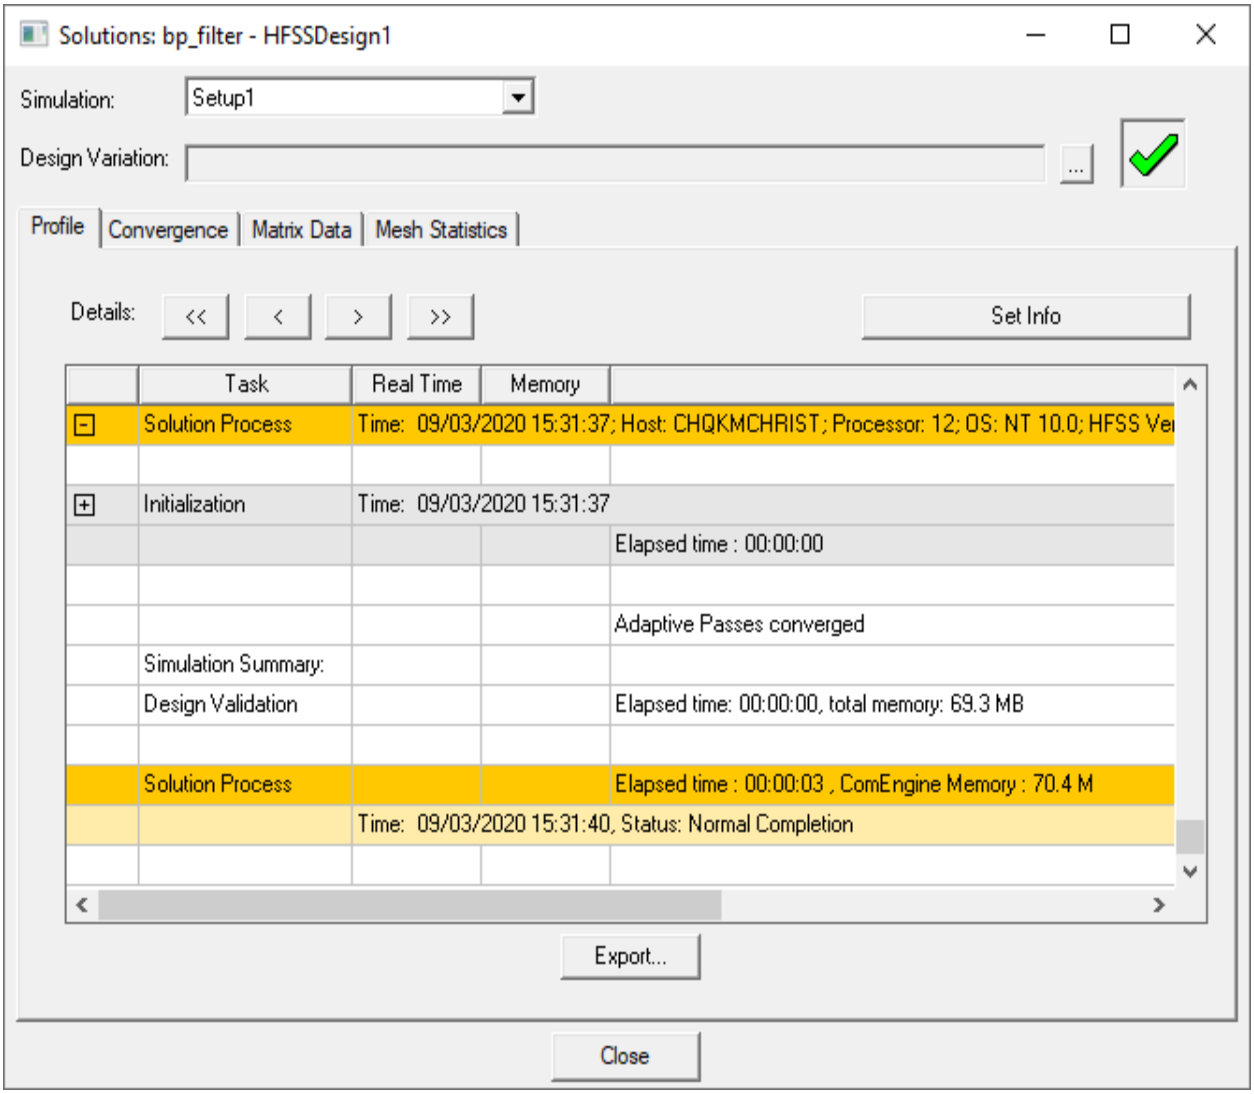
At any time during or after the solution process, you can examine the computing resources or profile data that were used by Ansys Electronics Desktop solvers during the analysis. The profile data is essentially a log of the tasks performed by Ansys Electronics Desktop during analysis. The log indicates the length of time each task took and how much physical and disk memory was required.

1. In the project tree, right-click a solution setup, and select **Profile**.

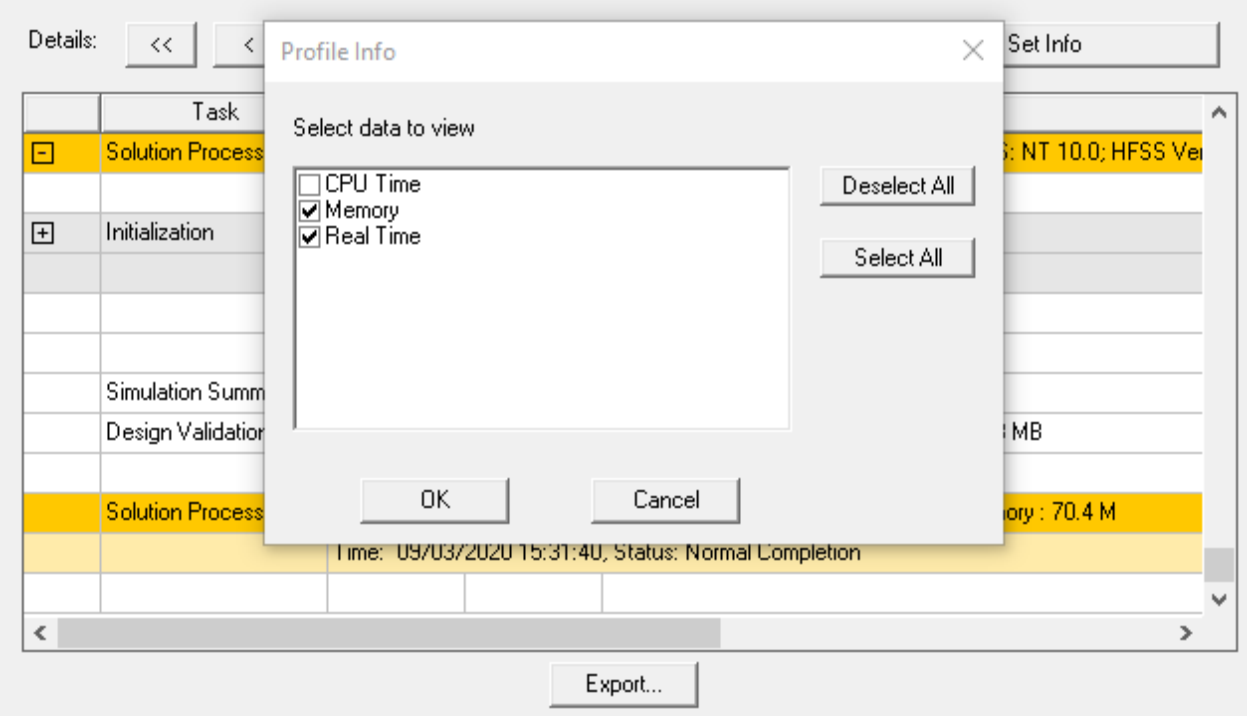
   The **Solutions** dialog box appears, with the **Profile** tab selected. You can also click the **Solution Data** icon on the ribbon to open the **Solutions** dialog box, and then select the **Profile** tab.

   The displayed data depends on the type of problem and solution setup.

   A Beta feature (Enhanced Profile Display] allows you to have the **Profile** data is displayed using nested subgroups. The **Details** buttons compress groups [<<] and [<] and expand them [>] and [>>].



The Profile data is displayed using nested subgroups. The **Details** buttons let you compress groups [<<] and [<] and expand them [>] and [>>]. You can also click the [+] buttons in the first column to open a subgroup, or use a [-] button to close one. The Set Info button lets you select from available Profile information.



2. If one or more setups exist, you can select the desired profile information from the **Simulation** drop-down menu. In general, the information displayed includes:

Task	Lists the type of task that was performed. The Tasks lists included Start, various Mesh tasks, Simulation Setup, Port Adaptation, Adaptive Pass tasks, including simulation setup, Matrix Assembly, Solver tasks, and Field Recovery, Sweep tasks, and Solution Process summary and Totals for time.
Real Time	The difference in time between the start of the task and the end of the task (elapsed time).
CPU Time	The amount of CPU time required to perform the task.
Memory	The peak amount of physical memory (RAM) used by the individual executable running the task. The memory is freed for other uses after each task is complete.
Information	General information about the solution, for example, the number of tetrahedra used in the mesh, disk use, solver information, sweep information, the elapsed time, and the memory used by the MaxwellComEngine, and totals. The elapsed time is the difference between the time in the **Start** line and the time in the **Total** line — how long the task actually took between when **Analyze** was clicked and when the simulation finished. The elapsed time is a little greater than the **Real Time** given in the **Total** line. This is because the **Total** line contains the sum of all of the real times reported by the

	individual processes and does *not* include the typically small amount of time the Maxwell ComEngine uses before, after, and in between calling the other executables.

The matrix solver writes specific information in some of these fields as outlined below:

Task	The matrix solver task reports the type of solution performed by the solver, based on the physics of the problem. It has the form "Solver *pdsn*" (e.g. Solver MRS2 or Solver DCS4-L2), where • *p* , the precision type is: M (mixed for direct solver) or D (double for direct and iterative solver). • *d* , the matrix data type is: R (real) or C (complex) • *s* , the symmetry type is: S (symmetric), A (asymmetric), or H (hermitian) • *n* , the number of processors used. You specify the number of available processors on the local machine in the Maxwell options. If a solve does not use all available processors (local or distributed), the number reported may be less than the number available. If a simulation uses the iterative solver, the Solver designation can include a level indicator appended. to an Iterative solver designation (L2 in the example above). The higher the Level number the lower the memory, you will never see L1 (this would be equivalent to direct solver. And a first order solve will only display L2 since it only has one level of order to go down for preconditioning. A second or mixed order solve may display L3 depending on the mesh quality. If the solver switches from the Iterative Solver to the Matrix solver, you see a Matrix solver warning: Switch from Iterative Solver to Direct Solver.
Information:	The matrix solver information line includes, for example, Disk = 0 KBytes, matrix size 11137 , matrix bandwidth 20.3) • **Disk**: The amount of hard disk space used during the calculation of the matrix solution. If the disk usage for matrix solver is non-zero in profile, it usually indicates off-core matrix solver. If the matrix solver must solve off-core, smaller blocks of the data to be solved are created on disk, each block is then solved in physical memory, and then the matrix solution is reassembled. As a result of this additional processing, the time required to calculate a solution is higher. • **Matrix size**: The size of the matrix that was solved (the number of unknowns)

	• **Matrix bandwidth**: An FEM matrix is a sparse matrix. The solver only stores the non-zero entries. The matrix bandwidth is the average number of non-zeros per row. It gives an idea of the sparsity of a FEM matrix.Storage for the sparse matrix is proportional to the total number of nonzeros = #rows x bandwidth. The higher the bases order, the larger the bandwidth. • In the case of the Iterative Solver, **# Iterations**

To Export the Profile data:

1. Open the **Solutions** dialog box with the **Profile** tab selected.
2. Click the **Export...** button.

   This opens a file save dialog that lets you provide a file name and location.
3. Click **Save**.

   The data is saved in a text file with a **.prof** extension.

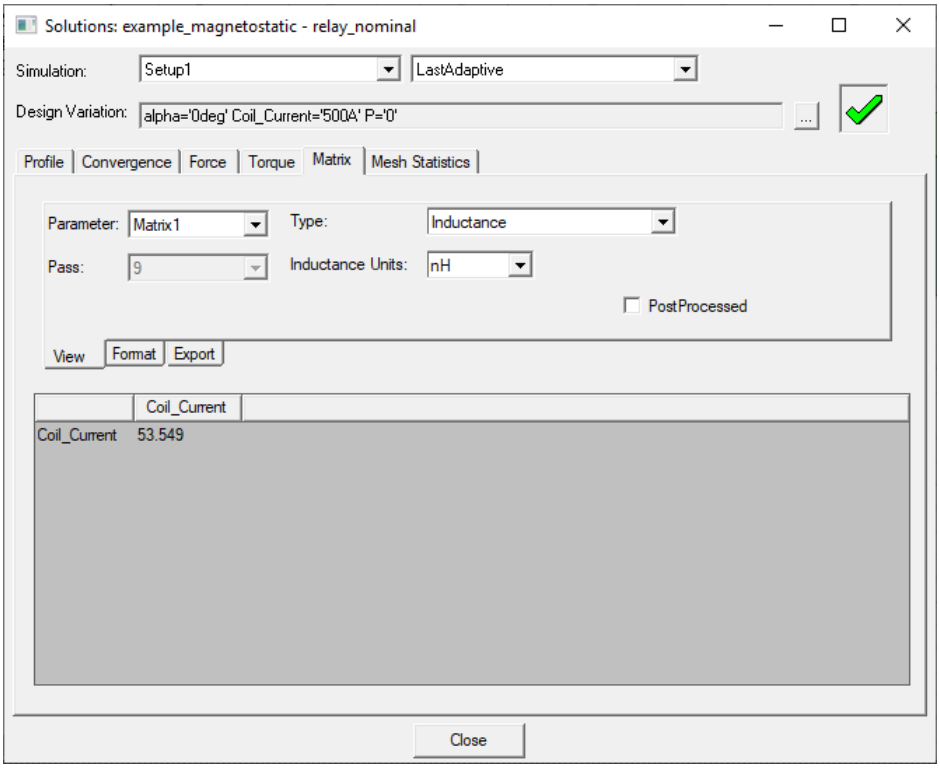
Viewing an Optimetrics Solution's Profile Data

Viewing Matrix Data

To view matrix parameter data:

1. In the project tree, right-click the solution setup of interest, and then click **Solutions** on the shortcut menu.

   The **Solutions** dialog box appears. Select the **Matrix** tab. A typical example is shown below.



2. The **Design Variation** box shows the current design.

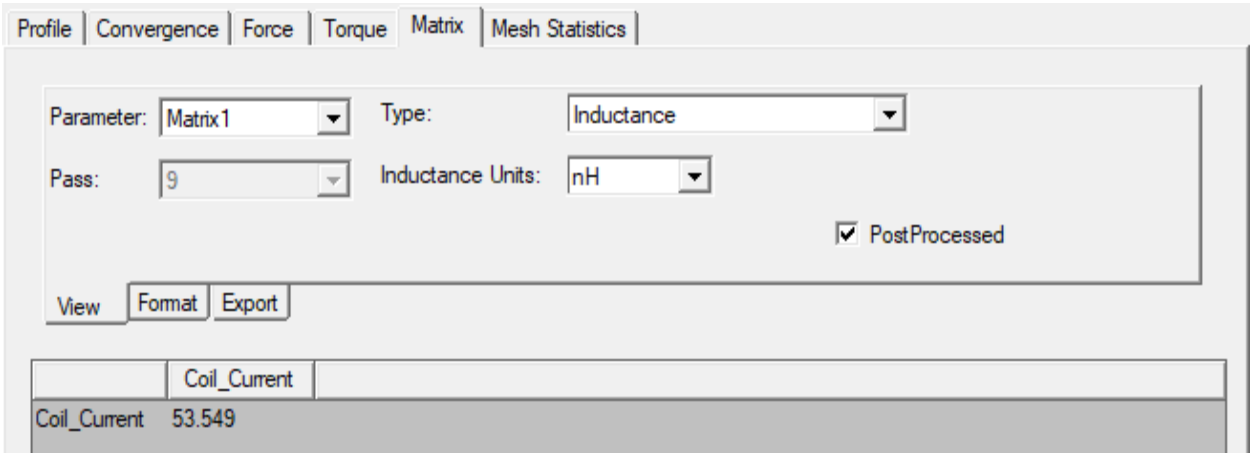
   Optionally, click the **...** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box which lists all the solved variations in the design.
3. In the **Simulation** pull-down lists:
   - Select the solution setup from the left pull-down list.
   - Select the solved pass data you wish to view from the right pull-down list, either the **LastAdaptive** pass or an intermediate **AdaptivePass**. If you select **AdaptivePass** you must also select the desired intermediate pass form the **Pass** pull-down list.
4. Select a **Parameter**.
5. Select one of the items from the **Type** pull-down list. Items available in the **Type** list depend upon the design's solution type setting. For example:
   - **Inductance** (for magnetostatic and 3D transient A-Phi solutions)
   - **Re(Z), Im(Z)** (for eddy current solutions)
   - **R, L** (for eddy current solutions. The extracted resistance values of designs that use Litz wire windings take into consideration the stranded AC loss effects due to skin effect and proximity effects.)
   - **G,C** (for ACConduction solutions)
   - **Capacitance** (for electrostatic and 3D transient A-Phi solutions)

- **Conductance** (for DC Conduction solutions)
- **Flux Linkage** (for magnetostatic and eddy current solutions)
- **Inductive Coupling Coefficient** (for magnetostatic and eddy current solutions)
- **Capacitive Coupling Coefficient** (for electrostatic and ACConduction solutions)
- **Conductive Coupling Coefficient** (for DC Conduction solutions)

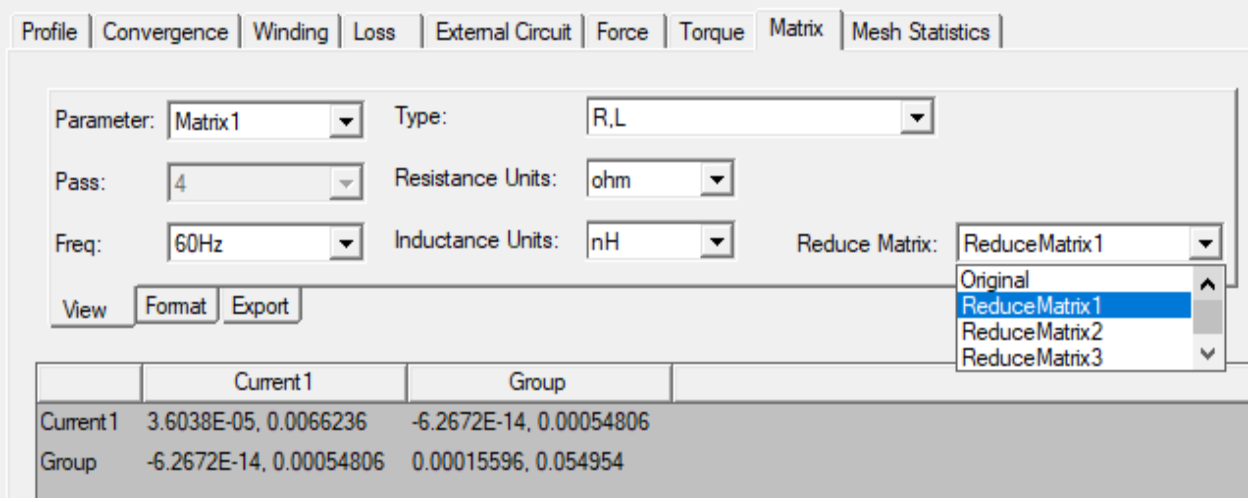
Depending on the solution type you selected, you may have to specify the **Units** in which to display the information. The available units depend on the matrix type being displayed.

The bottom pane displays values for the selected type. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.

6. (Optional) For Magnetostatic designs, the results of the post processing calculation on the matrix, including grouped sources defined on the Matrix dialog Post Processing tab, can be seen by selecting **PostProcessed**.



7. (Optional) For 2D and 3D Eddy Current designs, you can join (group) two or more excitations to one excitation in either a series or a parallel connection. The result of each set of join (group) operation is known as a Reduce Matrix. For Eddy Current designs that include one or more reduce matrices, select the reduce matrix of interest from the **Reduce Matrix** drop down list. For reduce matrix selections, only the **R, L Type** values are available for viewing. (Refer to *Assigning a Reduce Matrix* for information on creating reduce matrices.)



8. (Optional) To export the matrix data (as specified by the **Type** list):
   a. On the **Export** tab, click **Export Solution**.
      The **Export Solution** dialog box appears.
   b. Select a location for the solution data.
   c. Type a filename in which to store the data in the **File name** text box.
   d. Click **Save**. The solution is saved as a data table in the specified file.
9. (Optional) For 2D and 3D Magnetostatic designs only, you may export a circuit based on the matrix parameter type by clicking **Export Circuit** on the Export tab. The **Export Circuit** button appears in the dialog box when a supported type is selected.

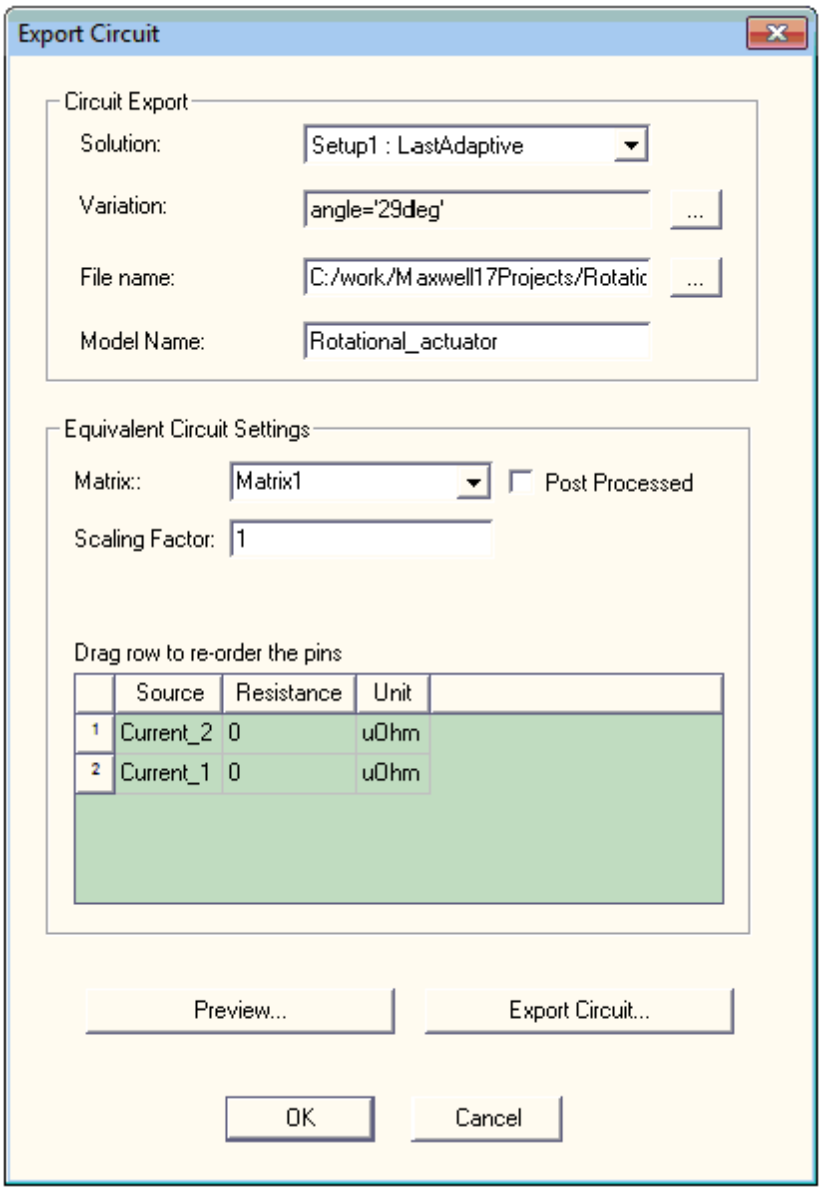
Exporting a Circuit Model

To export the circuit:

1. In the **Solutions** dialog box, click **Export Circuit**.
   The **Export Circuit** dialog box appears.



2. In the **Equivalent Circuit Settings** section, select the matrix you want to export from the **Matrix** pull-down list.
3. (Optional) Type a scaling factor in the **Scaling Factor** text box. You may want to provide a scaling factor if you are using symmetry to analyze a portion of the model.
4. For an induction matrix, type a **Resistance** for each source listed in the table.
5. (Optional) If desired, drag table rows to re-order the circuit pins.
6. (Optional) The results of the post processing calculation (defined on the Matrix dialog Post Processing tab) on the matrix can be included by selecting **PostProcessed.**
7. In the **Circuit Export** section, select a setup from the **Solution Setup** pull-down list.

8. (Optional) Click the **...** button to open the **Set Design Variation** dialog box to choose a **Variation**.
9. Type the path and file name in the **File name** text box, or click the **...** button to select the desired location for the exported circuit.
10. (Optional) To view the netlist:
    a. Click **Preview**.
       The **Circuit Model Preview** dialog box appears. You can also click **Export Circuit** from within this dialog box.
    b. Click **Close** to close the netlist.
11. To export the circuit to the specified file, click **Export Circuit**.
12. Click **OK** to close the **Export Circuit** dialog box.
13. Click **Close** to close the **Solutions** dialog box.

Coupling Coefficient Matrix

For a matrix with entries M_{ij}, i, j = 1,..., N, the coupling coefficient for row i and column j is given by the following equation:

$$k = \frac{M_{ij}}{\sqrt{M_{ii} \times M_{jj}}}$$

This coefficient indicates how much flux in one coil is linked with the other coil.

If all the flux in one coil reaches the other coil, $|k| = 1$ (and coupling is 100%).

Inductors with $|k| > 0.5$ are tightly coupled. Inductors with $|k| < 0.5$ are loosely coupled.

The mutual inductance (*M*) falls between 0 and $\sqrt{M_{ii} \times M_{jj}}$ (the geometric mean of the inductances).

Assigning a Matrix

AC Loss Effects of Litz Wire on Impedance Matrix

The impedance matrix of poly-phase windings is expressed as:

$$[Z] = \begin{pmatrix} R_{11} + jX_{11} & \cdots & R_{1n} + jX_{1n} \\ \vdots & \ddots & \vdots \\ R_{1n} + jX_{1n} & \cdots & R_{nn} + jX_{nn} \end{pmatrix}$$

where *n* is the number of windings.

Litz wire eddy current losses are computed in a post-process. When the total number of windings includes some Litz wire windings, the final AC impedance matrix, including an additional resistance matrix due to Litz wire eddy current losses, is expressed as:

$$[Z'] = \begin{pmatrix} R_{11} + jX_{11} & \cdots & R_{1n} + jX_{1n} \\ \vdots & \ddots & \vdots \\ R_{1n} + jX_{1n} & \cdots & R_{nn} + jX_{nn} \end{pmatrix} + \begin{pmatrix} r_{11} & \cdots & r_{1n} \\ \vdots & \ddots & \vdots \\ r_{1n} & \cdots & r_{nn} \end{pmatrix}$$

where resistances denoted by r_{ij} are additional Litz wire eddy current resistance components.

To compute Litz wire eddy current resistance components, we use a permeability freezing algorithm. After nonlinear iteration is convergent and permeabilities in all mesh components are frozen, the original impedance matrix *[Z]* is derived by injecting 1A exciting current into each phase winding one by one. The self-impedance is obtained from the induced voltage in the excited winding, and all mutual impedances are obtained from the induced voltages in all other windings.

However, the Litz wire eddy current resistance matrix is derived in a different way. When a winding is excited with 1A rms current and all other windings with zero-value currents, the value of the total eddy current loss (no matter in the excited winding, or in other zero current windings), is the value of the self-resistance. That is, if I_1 = 1A rms current in winding 1 produces total eddy current loss P_1, then the self-resistance of winding 1 is:

$$r_{11}{I_1}^2 = r_{11} = P_1$$

Similarly, if I_2 = 1A rms current in winding 2 produces total eddy-current loss P_2, then the self-resistance of winding 2 is:

$$r_{22}{I_2}^2 = r_{22} = P_2$$

To calculate the mutual resistance between winding 1 and winding 2, we need to inject 1A currents in both winding 1 and winding 2. In such a case, the total eddy-current loss is:

$$r_{11}{I_1}^2 + 2r_{12}I_1I_2 + r_2{I_2}^2 = r_{11} + 2r_{12} + r_{22} = P_{12}$$

where P_{12} is the total eddy current loss in all Litz wire windings caused by 1A currents in both winding 1 and winding 2. Therefore,

$$r_{12} = \frac{P_{12} - r_{11} - r_{12}}{2}$$

Viewing Parameter Data

To view parameter solution data such as force and torque:

1. In the project tree, right-click the solution of interest in the **Parameters** folder, and then click **View Solution** on the shortcut menu.

   The **Solutions** dialog box appears.

2. The **Design Variation** box shows the current design.

   Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** pull-down lists:
   - Select the solution setup from the first pull-down list.
   - Select the solved pass data you wish to view from the second pull-down list, either the last adaptive pass or one of the intermediate passes.
4. On the desired parameter tab, such as **Force** or **Torque**, select a **Parameter** and optionally an adaptive **Pass** to view.

   Depending on the solution type you selected, you may have to specify the **Units** in which to display the information. The available units depend on the matrix type being displayed.

   Optionally, to export the parameter solution data:
   a. Click **Export Solution** to open the **Export Solution** dialog box appears.
   b. Select a location for the solution data.
   c. Type a filename in which to store the data in the **File name** text box.
   d. Click **Save**.
5. Click **Close** to close the **Solutions** dialog box.

Related Topics

Adding solution Parameters

Viewing Mesh Statistics

To view an adaptive solution's mesh information, either during or after the solution process:

1. In the project tree, right-click the solution setup of interest, and then click **Mesh Statistics** on the shortcut menu.

   The **Solutions** dialog box appears with the **Mesh Statistics** tab selected.

   The table lists the design elements and depending upon the solution type may include: Num Tets (tetrahedra), Min edge length, Max edge length, RMS edge length, min tet vol., max tet vol., mean tet vol. and standard deviation (min elem area, max elem area, mean elem area and standard deviation for 2D designs).

   If mesh repairs have been performed, two additional columns appear in the table; Recovered % and Reparied %. These columns indicate the fraction of an object that was successfully recovered and the fraction that needed some repair.

To toggle the mesh statistics display from low to high values or visa versa:

1. Click on the column header.

   This displays a shadowed triangle pointing down to indicate a list ordered from highest to lowest, and a triangle pointing up to indicate a list ordered from lowest to highest. Clicking again inverts the current order.

Click on the blank cell above the object list to invert the order of objects, though in this case, the cell does not display a directional triangle.

Viewing Winding Results (Eddy Current)

To view winding results for Eddy current solutions:

1. In the project tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

   The **Solutions** dialog box appears.
2. The **Design Variation** box shows the current design.

   Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** pull-down lists:
   - Select the solution setup from the left pull-down list.
   - Select the solved pass data you wish to view from the right drop-down list – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If LastAdaptive is selected, the **Freq** drop-down list is enabled for you to choose frequency. If AdaptivePass is selected, the **Pass** drop-down list is enabled for you to choose the desired intermediate pass.
4. If the design includes windings, the **Winding** tab displays the following columns: **Flux Linkage[Wb]**, **Induced Voltage[V]**, **Input Current[A]**, **Input Voltage[V]**, and **Current[A]**. Results listed in these columns are complex quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
   - For Current type windings: Flux Linkage, Induced Voltage, and Input Current results are shown. The other quantities are shown as N/A (not applicable).
   - For Voltage type windings: Flux Linkage, Induced Voltage, Input Current, and Current results are shown. The other quantities are shown as N/A (not applicable).
   - For External type windings: Flux Linkage, Induced Voltage, and Current results are shown. The other quantities are shown as N/A (not applicable).
5. Click **Close** to close the **Solutions** dialog box.

Viewing End Connection Results (2D Eddy Current)

To view end connection results for Maxwell 2D Eddy current solutions:

1. In the project tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

The **Solutions** dialog box appears.

2. The **Design Variation** box shows the current design.

   Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** pull-down lists:
   - Select the solution setup from the left pull-down list.
   - Select the solved pass data you wish to view from the right drop-down list – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If LastAdaptive is selected, the **Freq** drop-down list is enabled for you to choose frequency. If AdaptivePass is selected, the **Pass** drop-down list is enabled for you to choose the desired intermediate pass.
4. If the design includes end connections, the **End Connection** tab displays columns for: **Induced Voltage[V]**, and **Current[A]**. Results listed in these columns are complex quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
5. Click **Close** to close the **Solutions** dialog box.

Viewing Loss Results (Eddy Current)

To view loss results for Eddy current solutions:

1. In the project tree, right-click the **Results** folder, and then click **Solution Data** on the shortcut menu.

   The **Solutions** dialog box appears.
2. The **Design Variation** box shows the current design.

   Optionally, click the **[...]** button, and choose a design variation solved during an optimization or parametric analysis from the **Set Design Variation** dialog box.
3. In the **Simulation** pull-down lists:
   - Select the solution setup from the left pull-down list.
   - Select the solved pass data you wish to view from the right drop-down list – either the **LastAdaptive** pass, or an intermediate **AdaptivePass**. If LastAdaptive is selected, the **Freq** drop-down list is enabled for you to choose frequency. If **AdaptivePass** is selected, the **Pass** drop-down list is enabled for you to choose the desired intermediate pass.
4. The **Loss** tab displays the following columns: **Core Loss[W]**, **Solid Loss[W]**, **Stranded Loss[W]**, **Stranded Loss R[W]**and **Stranded Loss AC[W]**. Results listed in these columns are real quantities. The **Format** tab allows you to customize how values are displayed by setting the desired width, precision, and whether to use scientific notation.
5. Click **Close** to close the **Solutions** dialog box.

Cleaning Up Solutions

You can use **Clean Up Solutions** to selectively make deletions, or remove all solutions from the results.

To use **Clean Up Solutions**:

1. Depending upon the project type, click **Maxwell3D, Maxwell2D, or RMxprt and then select Results>Clean Up Solutions**.

   The **Clean Up Solutions** dialog box appears.
2. Under **Solutions**, select whether you want to delete only fields data, only fields and mesh data, only linked data, or all solution data. Deleting all solution data erases all mesh, matrix, and fields data for all adaptive passes and frequency sweeps for the selected **Variations**.

   Optionally, you can **Include Linked Data** in the deletions.

   Linked data can be mesh, field or some other post-processing data that the source design generated. The target design for the link caches these data internally to minimize the need to activate the source design.
3. Under **Variations**, select which solution data you want to delete:
   - Select **All Except Current Variation** to delete all solution data that do not correspond to the current project and design variable values for the current design.
   - Select **All Variations** to delete all solution data for the current design.
   - Select **Select** to specify the variations you wish to delete. Click **Variations** to select the variations for deletion.
4. Click **Do Deletions**.

   The solution data you selected are deleted. Any post processing reports or field overlays you created that included data you deleted will be marked with an X in the project tree. They will be invalid until new solution data are generated.

Creating Animations

An animated plot is a series of frames that displays a field, mesh, or geometry at varying variable values. To create an animated plot, specify the variable values of the plot that you want to include. Each plot associated with a variable value is a frame in the animation. You specify how many frames to include in the animation.

Note	Each animation frame requires memory for storage which depends upon the mesh size and type of plot. Memory usage may become very large during plot animations. To reduce memory usage, specify the minimum number of frames possible. See General Options for more information.

You can export the animation to animated Graphics Interchange Format (GIF), to Audio Video Interleave (AVI) format, or to WebM format.

Creating Geometry Animations

Geometry animations may be created to evaluate the effect of varying geometry variables on the model. You must define at least one variable associated with the geometry prior to creating a geometry animation. Following is the general procedure for creating an animation that varies a part of the model geometry:

1. Right-click in the view window, then click **View>Animate**.
   If multiple geometries can be varied in the design, the **Select Drawing** dialog box appears, proceed to step 2. If only one geometry is variable, proceed to step 3.

   The **Setup Animation** dialog box appears.
2. In the **Select Drawing** dialog box:
   a. Select the geometry variable to vary in the animation.
   b. Select the object you want to animate.

Note	If previous animations have been created for this project, the **Select Animation** dialog will appear. You may choose an animation setup from the list if one is associated with the geometry variable of interest and the animation will start. If no existing animation setup is acceptable, select **New** and continue at Step 3 below.

3. In the **Setup Animation** dialog box:
   a. Type a name for the animation in the **Name** text box or accept the default name.
   b. Optionally, type a description of the animation in the **Description** text box.
   c. Under the **Swept Variable** tab, the **Swept Variable** list includes all of the defined geometric project and design variables. Select the geometry variable that you want to animate from the **Swept Variable** list.
   d. Specify the values of the variable that you want to include in the animation:
4. Type the starting value of the variable in the **Start** text box.
5. Type the stopping value of the variable in the **Stop** text box.
6. Type the number of **Steps** to include in the animation.
   For example, if the **Start** value is **0.15in**, the **Stop** value is **0.45in**, and the number of steps is **15**, the animation will display the geometry at 15 values between 0.15 inches and 0.45 inches. The animation will also include the start value, which will be the first frame displayed, resulting in a total of 16 frames in the animation.

a. If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.

4. Click the **Design Point** tab.
5. Deselect the **Use defaults** check box.
6. In the table, select the row corresponding to the variable setting of interest.
7. Click **OK**.

   The animation begins in the view window, displaying one frame for each variable value.

   The play panel appears in the upper-left corner of the desktop, enabling you to stop, restart, and control the speed and sequence of the frames.

Related Topics

Controlling the Animation's Display

Creating Field Plot Animations

To animate an existing field plot:

1. Right-click on the plot name in the **Project Tree**, and then select **Animate**.
   The **Setup Animation** dialog box appears.

Note	If previous animations have been created for this project, the **Select Animation** dialog will appear. You may choose an animation setup from the list if one is associated with the geometry variable of interest and the animation will start. Otherwise select **New** and continue at Step 2 below.

2. Type a name for the animation in the **Name** box, or accept the default name.
3. Optionally, type a description of the animation in the **Description** box.
4. Under the **Swept Variable** tab, the **Swept Variable** list includes all of the defined project and design variables. Select the variable that you want to animate from the **Swept Variable** pull-down list.
5. The **Select Values** table lists all solved values for the variable selected in **Swept Variable**. Select the values to include in the animation. By default, all solved values will be included.
6. *(For Electric Transient Solver plots only)*
   a. Type the starting value of the variable in the **Start** box.
   b. Type the stopping value of the variable in the **Stop** box.
   c. Type the number of **steps** to include in the animation in the **Steps** box.
      For example, if the **Start** value is **0.15in**, the **Stop** value is **0.45in**, and the step size is **15**, the animation displays the geometry at 15 values between 0.15 inches and 0.45 inches. The animation also includes the start value, which is the first frame displayed, resulting in a total of 16 frames in the animation.
7. If the design has multiple project or intrinsic variables, click the **Design Point** tab to set the values of the non-animated variables.

a. Deselect the **Use defaults** check box.
b. In the table, select the row corresponding to the variable setting of interest.
c. If intrinsic variables are available, select the value of interest in the **Intrinsic variables** section of the dialog.

8. Click **OK**.

   The animation begins in the view window, displaying one frame for each variable value.

   The play panel appears in the upper-left corner of the desktop, enabling you to stop, restart, and control the speed and sequence of the frames.

Controlling the Animation's Display

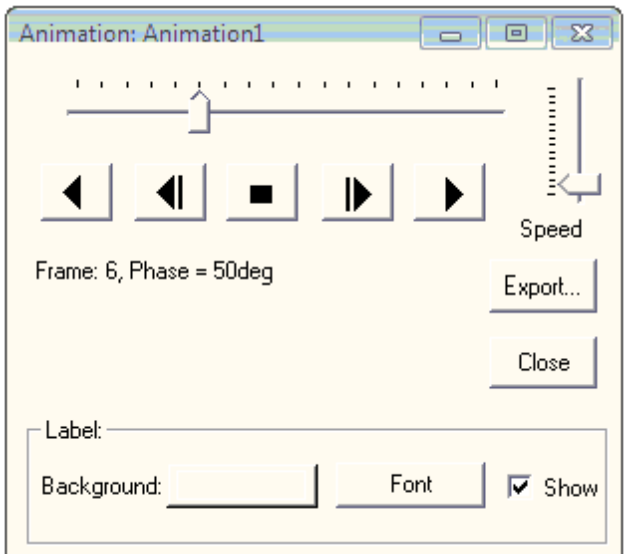
When an animation is displayed in the view window, the **Animation** window, also called the *play panel*, appears in the upper-left corner of the desktop. It has buttons that enable you to control the speed and sequence of the frames, start and stop the animation and export the animation. Click an area of the window below to learn its function.



Animation slider	Each dot on the slider represents a frame in the animation. Drag the slider to the right to display the next frame in the animated plot. Drag the slider to the left to display the previous frame in the animation.
	Plays the plot's animation sequence backwards.

	Steps backward through the animated plot one frame at a time.
	Stops the animation.
	Steps forward through the animated plot one frame at a time.
	Plays the plot's animation sequence forwards.
	Drag the **Speed** slider to the top to increase the speed of the animation. Drag the **Speed** slider to the bottom to decrease its speed.
Frame information	The current frame and phase at which the plot is being displayed is listed below the control buttons.
	Enables you to export the animation to an animated Graphics Interchange Format (GIF) or to Audio Video Interleave (AVI) format.
	Closes the animation window.
Show label checkbox	If you select the Show checkbox, a label showing the swept variable value appears in the animation. You can select the label with the mouse and drag it to another location. Background	Click the background button to open a color palette dialog that lets you set the

	background for the swept variable label. 	The font button opens a font selection dialog that you can use to set the Font, Font Style, and Size for the label. The Default is Arial Narrow 14pt.

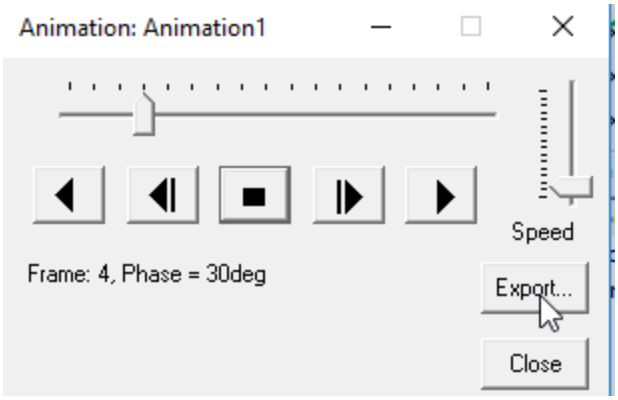
Related Topics

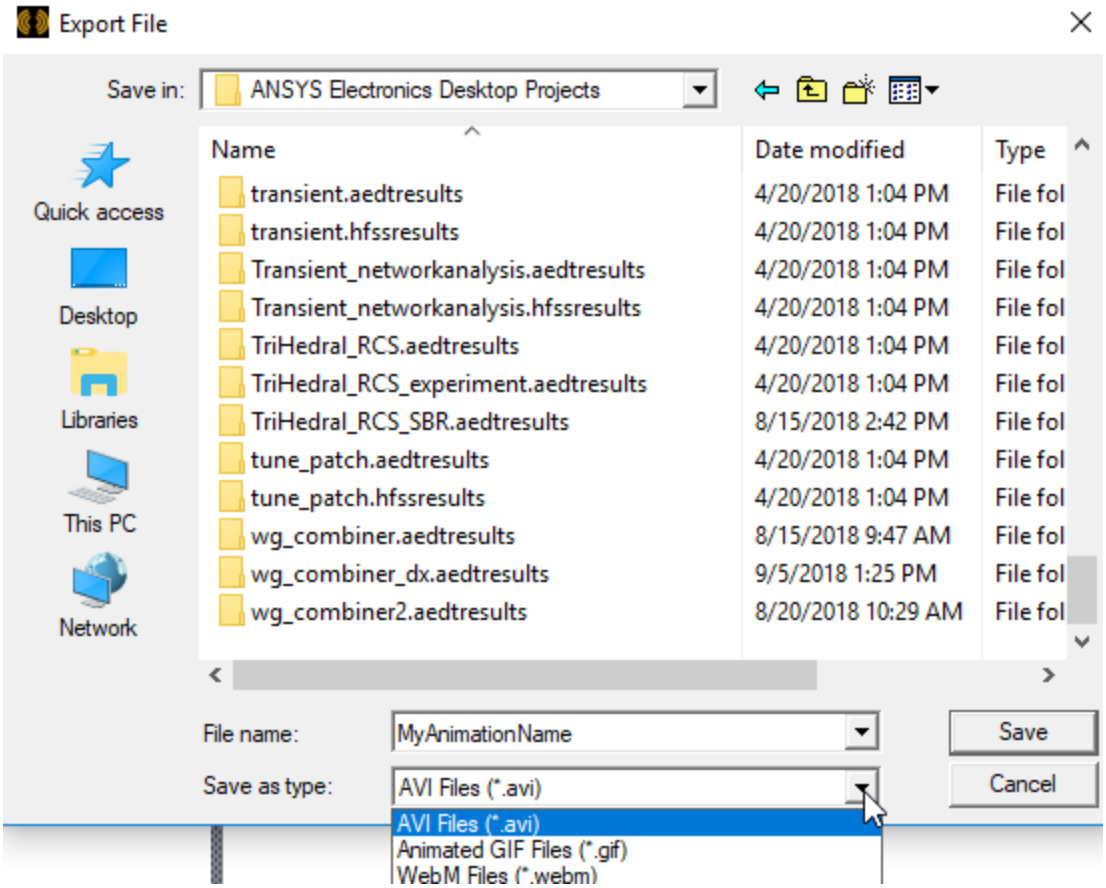
Creating Animations

Exporting Animations

1. Create the animation you want to export.
2. In the play panel, click **Export**.

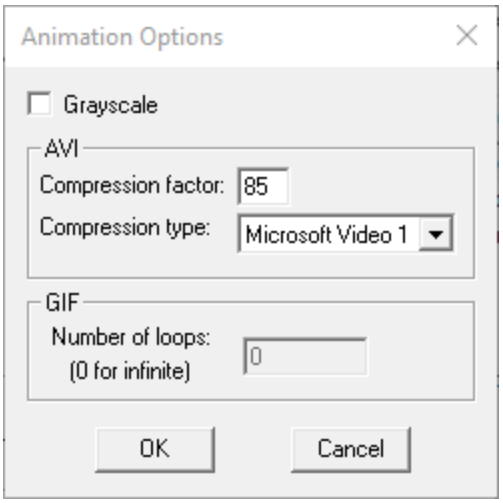


The **Export File** dialog box appears.



3. Specify the directory to **Save in**, the **File name** and use the **Save as type** drop down men to select **Animated GIF File (.gif)** or **AVI File (.avi)** or **WebM File (.webm)**.

   The **Animation Options** dialog box appears.



4. To replace colors in the file with 256 shades of gray, select **Grayscale**.

Grayscale animations tend to use less memory than full color animations.

5. For AVI format export, specify the **Compression factor** (the default is 85) and one of the following **Compression types**:

INTEL Indeo	
Cinepak	
Microsoft Video 1	
None	

6. For GIF format export, specify the number of loops. The default "0" denotes infinite loops.
7. Click **OK** to close the **Animations Options** dialog.

   The animation is exported to the file format you specified.

Creating Reports

After Maxwell has generated a solution, all of the results for that solution are available for analysis. One of the ways you can analyze your solution data is to create a 2D or 3D report, or graphical representation, that displays the relationship between a design's values and the corresponding analysis results. You create reports using either the **Create Quick Report** command, or the **Create<*type*> Report** commands. The **Quick Report** feature lets you select from a list of predefined categories (such as S-parameters) from which to create a rectangular plot.

For each solution type – Electrostatic, Magnetostatic, AC Conduction(2D only), DC Conduction, Eddy Current, Transient, Transient A-Phi Formulation (3D only), or Electric Transient(3D only) – the **Results** menus present a list of **Create <*type*> Report** commands based on the solution data of direct interest for the design. For example, for the Magnetostatic solution type, the **Results** menu contains templates for Magnetostatic parameters and for Fields.These appear on the menus as **Create Magnetostatic Report** and **Create Fields Report**. Each of these **Create <*type*> Report** menu items includes a further cascading menu that lists the Display Types available for that report. For some reports you can modify the Display Type from the Properties for that Report.

If you have created custom report templates (for example, including your company name or other format changes), you can also create a report based on that template by selecting **Maxwell 2D, Maxwell 3D, or RMxprt>Results>Report Templates>**<*templateName*>. You can also access previously defined templates using **Report2D>Report Templates>Apply Settings**. You can save the properties for a modified report to provide the custom default settings for all new reports.

You can also use the **Report2D>Export** feature and select ReportData File (.rdat) format file which you can then select for **Create Report from File**.

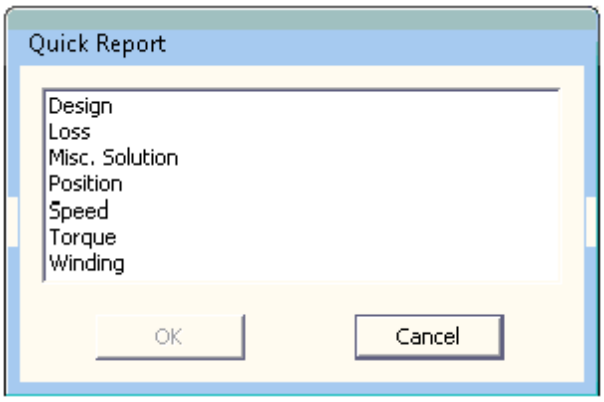
Creating a Quick Report

Creating a New Report

Creating a Quick Report

Following is the procedure for creating a quick report.

1. On the Project tree under "Analysis", select a **setup** or **sweep icon**, or the **Results** icon.
2. Right-click to display the shortcut menu and select **Create Quick Report**.
   The **Quick Report** dialog appears.



3. Select the one or more categories for the report from the list and click OK. The list of categories varies with the solution type.

A rectangular plot for each selected category displays. The new plot or plots appear in the Project tree under the Results icon. The default Report Name that appears is derived from the report category specified in the **Quick Report** dialog box. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

Quick Report Categories

When using the Quick Reports function for Solutions, the following report categories may be available depending upon the solution parameters requested, solution type, etc:

Category	Description
Coupling Coeff	Reports values of the coupling coefficient.
Design	Reports values of design variables.
Force	Reports values of Force parameters such as Force Magnitude and Components, Load Force.
Torque	Reports values of Torque parameters such as Torque Magnitude and Components
L, Lnom	Reports values of Inductance Matrix calculations.
MagFlux, MagFluxNom	Reports values of magnetic flux calculations.
C	Reports values of Capacitance Matrix calculations.
R	Reports values of Resistance Matrix calculations.
Z	Reports values of Impedance Matrix calculations.
Loss	Reports values of Loss parameters such as CoreLoss, EddyCurrentLoss, ExcessLoss, HysteresisLoss, SolidLoss, StrandedLoss, StrandedLossR, and StrandedLossAC.
Misc Solution	Reports values for the solution process such as DeltaT, Energy Error, and Temporal Error
Position	Reports Position of moving objects.
Speed	Reports Speed of moving objects.
Winding	Reports Flux Linkages, currents and voltages in coils.

Creating a New Report

Following is the general procedure for creating a new report:

1. On the **Maxwell3D** or **Maxwell2D** menu or the Project tree, point to **Results**, and then select **Create <*type*> Report** and select **Display Type** for that template. The available **Report Types** depend on the simulation setup.

   If you have created custom report templates (for example, including your company name or other format changes), you can also create a report based on that template by selecting **Maxwell 2D, Maxwell 3D, or RMxprt>Results>Report Templates>PersonalLib>**<*templateName*>. You can also make such changes the default for new reports by right-clicking a modified report and selecting **Report Templates>Save Settings as default**.

   When you have selected the ***<type>*** and display type from the **Results** menu, the **Report** dialog box appears, with the **Trace** tab selected by default.

2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - *For Transient projects only*:

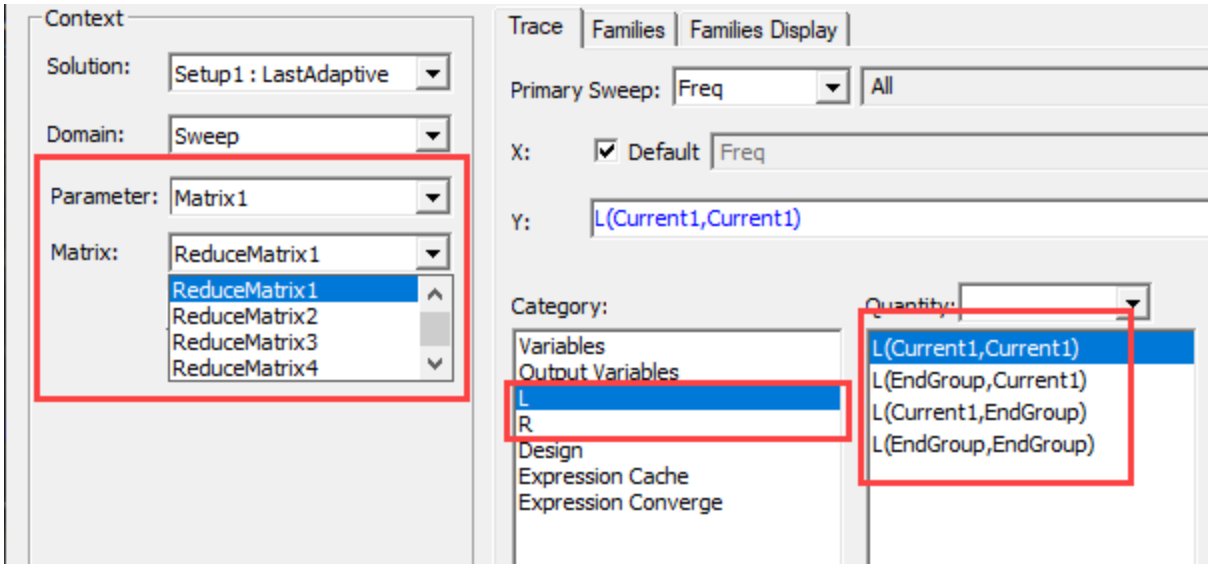
     Domain field with a pull down selection list containing options for plotting vs time (Sweep Domain) or plotting vs frequency (Spectral Domain).
   - *For Transient projects only*:

     Domain field with a pull down selection list containing options for **Average and RMS** and **Transient D-Q** for electric machines. Click **Machine Options** to setup the machine specific parameters.
   - *For Eddy Current projects only*:

     Domain field with a pull down selection list containing options for plotting vs frequency (Sweep Domain) or plotting vs time (Time Domain).

     Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

3. In the **Y** Component section, make selections for the following:
   a. Categories - depend on the Solution type and the design. For example, Magnetostatic categories include: Torque, Output Variables, Inductance, and other user-selectable solution parameters. Transient categories include: Loss, Output Variables, Variables, and others. Eddy current categories include: Loss, Winding, End Connection, L (inductance), R (resistance) Z (impedance), and others.
   b. Quantities for Y are relative to the selected category. For example, Loss quantities include: CoreLoss, EddyCurrentLoss, HysteresisLoss, and others. Winding quantities include: Flux Linkage, Induced Voltage, and others - depending on the winding type.

Note	The Quantity text field can be used to filter the Quantity list by typing in text, or by using the four predefined selections. This is useful if the Category selected produces a lengthy Quantities list. See Filtering Quantity Selections for the Reporter. When the matrix is very large, the number of quantities can be correspondingly huge. Therefore, the Quantities field can optionally use a tree structure to divide matrix quantities into groups by their first element name. The initial display shows groups, without initially listing group members.

   c. **Function** list to apply to the Y quantities.
   d. The Y value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. In the **X (Primary Sweep)** section, make selections for the following:
   a. Select the Primary sweep from the drop down menu. By default **All** of the chosen sweep's values are used. You can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting).
      To select an X component that is different from the Primary Sweep, uncheck the Default field to enable the X field and browse [...] button. Click the browse [...] button to display the **Select X Component** dialog box. This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog to assign the X component.
   b. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.
5. **Update Report** setting
   - **Real Time** checked -- enable real time updates for all reports while the reports are being edited.
   - **Real Time** unchecked -- enables drop down menu to **Update All Reports** or **Update Report**. Reports will only be updated with one of these user selectable update options or upon exiting the report dialog box. This can be useful if you expect a trace to take time to display. You can then add additional traces without having to wait.
6. The **Report** dialog command buttons permit you create a new report with the settings you provide, or to modify an existing report.
   - **Output Variables** – opens the **Output Variables** dialog box.
   - **Add Trace** – this is enabled when you have created or selected a report. Add one or more traces to include in the report.
   - **Update Trace** – updates the selected traces in a report based on further processing or changes.
   - **New Report**. Adds a report to the Project tree under the Results icon. The new Report is displayed in the Project window.
   - **Options** – opens the **Report Setup Options** dialog box. This contains a check box for using the advanced mode for editing and viewing trace components. This mode is automatic if the trace requires it. It also contains a field for setting the maximum number of significant digits to display for numerical quantities.
   - **Close** – closes the **Report** dialog box.
7. Click **New Report** to create a new report in the Project tree.

   The report appears in the view window. It will be listed in the project tree under Results, with the default name based on the Report Category you selected, for example, Force Plot *n* or Output Variables Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes. Traces within the report also appear in the project tree. Some plots may take time to complete. Performing a **File>Save** in such cases after the plot

has been created will permit you to review the plot later without having to repeat the calculation time when you reopen the project later.

8. To speed redraw times for changed plots, perform a **Save**. This saves the data that comprises expressions. If you do not do a save of a changed plot, the changed version is not stored.

Note	Remember the evaluated value of an expression is always interpreted as in SI units. However, when a quantity is plotted in a report, you have the option to plot values in units other than SI. For example, the expression "1+ang_deg(S_{11})" represents an 'angle'' quantity evaluated in radians, though plotted in degree units. To represent an angle quantity in degrees, you would specify units as "1 deg + ang_deg(S_{11})".

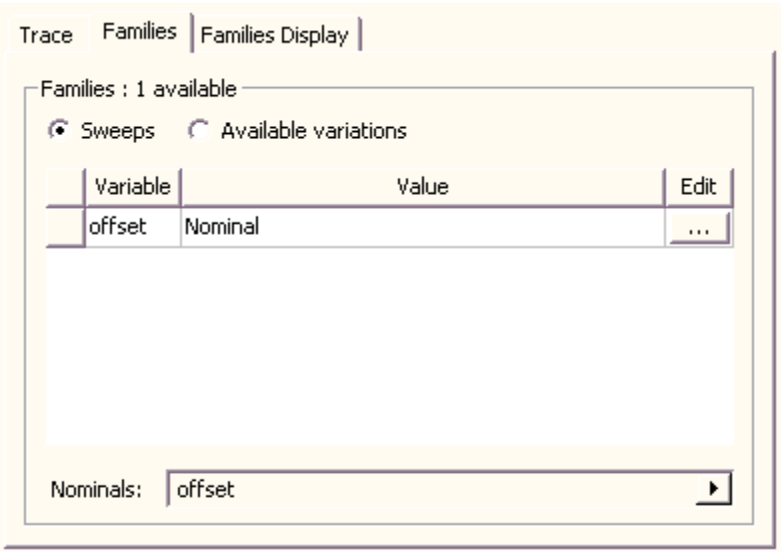
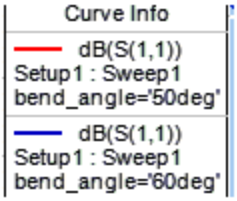
Using Families Tab for Reports

The **Families** tab of the Report dialog provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined and solutions exist for multiple variable values (for example, for a parametric sweep). If no variables are defined, or none have solutions for different values, 0 families will be available. If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the solution value (which may be All, Nominal, or a Specific value), and an Edit column with an ellipsis [**...**] button. Families gives the number available. If an existing variable is specified as Nominal, only that value is currently available. You can set any solved variables as Nominal, All, or select from values provided for Available solutions.



When you select a variable with multiple solved values, a trace for each solved value appears in the Report, with the variable value appended to the trace name in the Report legend.



You can make selections for the following.:

1. Select the **Sweeps** radio button (the default) to list the swept variables you can select.
2. With the **Sweeps** radio button selected, click the ellipsis [**...**] button to display a list of variable values for a particular variable. You can use a scroll bar to navigate the list.
   - To select all values, click the check box for **Use all** values. This writes “All” in the value field for that variable. You can also select individual values by clicking on them.
   - To select a range of values, hold down the shift key, and click again.
   - To select intermittent additional values, hold the CTRL key and click additional. The values you select are highlighted in the list, and are also listed in the Values column for that variable.
   - To select all, use the **Select All** button. This highlights the complete list, as well as listing all values for the variable in the Value field.
   - To clear the selections, use the **Clear All** button.
3. To edit the available list, click the ellipsis [**...**] button to display the **Edit Sweep** dialog. For the selected variable, this lets you specify:

- a single value as value and units
- a linear step with start value, stop value, and step value, and units for each.
- a linear count, with start value, stop value with units, and a count.
- a decade count
- an octave count
- an exponential count.

Once you have specified the changes you want, you can add you change to the list by clicking **Add>>** or replace the current list by clicking **Update>>**.

4. Click **OK** to close the **Edit Sweep** dialog box. You must still select the **Edited** radio button to be able to select the from the edited list, rather than the Default selection. And you must make selections here to move the new values to the variable value list in the **Families** tab.

   .Select the **Available variations** radio button to list the choices that derive from variable combination.

   a. To select individual variations, check the select box.
   b. Click the **Select** button at the top of the column to check or clear all variations at once.
   c. To invert the list order, click the triangle beside the variable name.

   The **Families Displa**y tab has three radio button selections.

   a. **All Families**
   b. **Statistics** which lists a table statistical functions that you can select to apply to the plot. The functions include Min, Max, Avg, Mean, Variance, Std Dev, and Sum. You can use the Select check boxes or the Select All and Clear All button.

   c. **Histogram** which lets you select the number of bins to use for a histogram plot, and the sampling frequency to use.

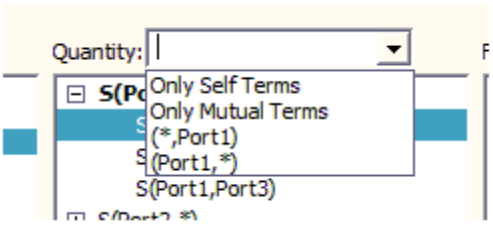
Filtering Quantity Selections for the Reporter

When a two port quantity Category is selected, four predefined filters are added to the combo box. “Port1” is the first matrix element name found in the quantity list.



- Only Self Terms -- Only display quantities when the first and second port are same.
- Only Mutual Terms -- Only display quantities when the first and second port are different.
- (*,Port1) -- Only display quantities when the second element name is “Port1”. You can edit the element name to display quantities for other elements.
- (Port1,*) – Only display quantities when the first element name is “Port1”. You can edit the element name to display quantities for other element.

Creating a Report from a Report Data File

Using the Report Data File format, **.rdat**, a report can be saved (exported) from one design, and subsequently imported into a different design (or even imported into the same design). This allows you to take a static snapshot of a set of simulation data and view it at a later stage of the design process, or view the same data set in one or more different designs.

To save a report to a Report Data File:

1. Create the report that you wish to save.
2. Right-click in the report window (or right-click on the desired report icon in the project tree) and select **Export** to open the **Export Report** dialog.
3. Select the Report Data files option (**.rdat**) in the **Save as type** selection drop down.
4. Navigate to the desired location and either create a file name or select an existing file for the exported report; and then click **Save**.

To create a report from an existing Report Data File:

1. Right-click on the **Results** folder in the project tree and select **Create Report From File**.
2. Browse to select the desired Report Data file (**.rdat**), and then click **Open**.
3. The selected report is added to the design and opens in a new report window.

Modifying Reports

To modify the data that is plotted in a report:

1. In the project tree, click the report you want to modify.
2. Right-click **Modify Report**.

   The **Report** dialog appears.
3. The **Report** dialog command buttons permit you create a new report with the settings you provide, or to modify an existing report.
   - **Output Variables** – opens the **Output Variables** dialog.
   - **Add Trace** – this is enabled when you have created or selected a report. Add one or more traces to include in the report.
   - **Update Trace** – updates the selected traces in a report based on further processing or changes.
   - **New Report**. Adds a report to the Project tree under the Results icon. The new Report is displayed in the main window.
   - **Options** – opens the **Report Setup Options** dialog box. This contains a check box for using the advanced mode for editing and viewing trace components. This mode is automatic if the trace requires it. It also contains a field for setting the maximum number of significant digits to display for numerical quantities.
   - **Close** – closes the **Report** dialog.

   The updated report appears in the view window.
4. **Update Report** setting

- **Real Time** checked -- enable real time updates for all reports while the reports are being edited.
- **Real Time** unchecked -- enables drop down menu to **Update All Reports** or **Update Report**. Reports will only be updated with one of these user selectable update options or upon exiting the report dialog box. This can be useful if you expect a trace to take time to display. You can then add additional traces without having to wait.

5. In the **Context** section you make selections depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - *For Transient projects only*:

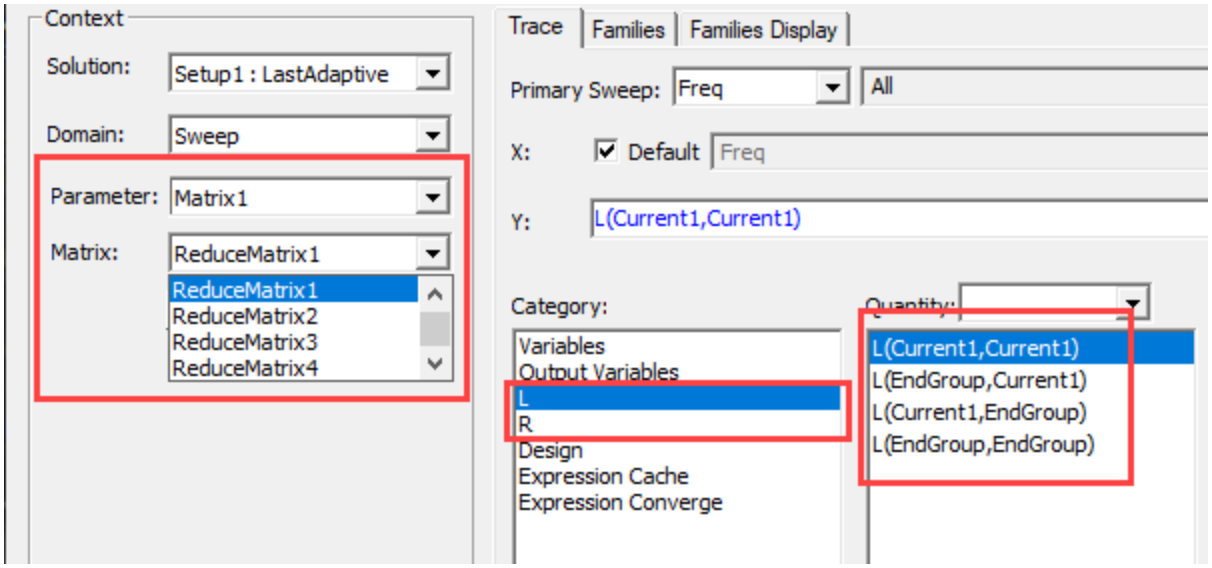
     Domain field with a pull down selection list containing options for plotting vs time (Sweep Domain) or plotting vs frequency (Spectral Domain).
   - *For Transient projects only*:

     Domain field with a pull down selection list containing options for **Average and RMS** and **Transient D-Q** for electric machines. Click **Machine Options** to setup the machine specific parameters.
   - *For Eddy Current projects only*:

     Domain field with a pull down selection list containing options for plotting vs frequency (Sweep Domain) or plotting vs time (Time Domain).

     Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating *matrix* and *reduced* matrix parameters for Eddy Current designs.)



- **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

6. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis **[...]** button. See Using Families tab for Reports.
7. In the **Y** Component section of the dialog make selections for the following:
   a. Categories - those depend on the Solution type and the design. For example, Magnetostatic categories include: Torque, Output Variables, Inductance, and other user-selectable solution parameters. Transient categories include: Loss, Output Variables, Variables, and others. The selected category provides the default name of the plot, for instance Force Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes.
   b. Quantities for Y are relative to the selected category. For example, Loss quantities include: CoreLoss, EddyCurrentLoss, HysteresisLoss, and others.

Note	The Quantity text field can be used to filter the Quantity list by typing in text, or by using the four predefined selections. This is useful if the Category selected produces a lengthy Quantities list. See Filtering Quantity Selections for the Reporter. When the matrix is very large, the number of quantities can be correspondingly huge. Therefore, the Quantities field can optionally use a tree structure to divide matrix quantities into groups by their first element name. The initial display shows groups, without initially listing group members.

c. **Function** list to apply to the Y quantities.

d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

8. In the **X (Primary Sweep)** section, make selections for the following:

a. Select the Primary sweep from the drop down menu. By default **All** of the chosen sweep's values are used. You can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting).

With Use all values unchecked, you can select one or more by clicking an individual value, dragging to select multiple values, or using Alt-Click to specify specific values.

You select either the Sweep radio button for Default or Edited selection.

You can also select the browse [...] button here to display the Edit Sweep dialog for Modify Reports, which includes additional editing features.

To select an X component that is different from the Primary Sweep, uncheck the Default field to enable the X field and browse [...] button. Click the browse [...] button to display the **Select X Component** dialog box. This lets you specify the X component as you do the Y; that is, in terms of Categories which define the selectable Quantities, and Functions to apply. After making selections, **OK** the dialog to assign the X component.

b. The **Families** tab provides a way to select from valid solutions for sweeps where a simulation has multiple variables defined (for example, for a parametric sweep). If so, the variables other than the one chosen as the **X (Primary sweep)**, are listed under the **Families** tab with columns for the variable, the value, and an Edit column with an ellipsis [**...**] button. See Using Families tab for Reports.

You can also view and edit the properties of Reports and their traces via their Properties windows. See Modifying the Background Properties of a Report.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the **Project** tree to display the **Properties** dialog box. Selecting the Display Type field displays a menu with selections available for that plot. Once you make a selection, the plot display updates for the current selection.

Note	Remember that for many excitations of interest for plotting, you can control the default base names through the dialog described here: Setting Default Boundary/Excitation Base Names. This may save you the need to edit individual names in the plots.

Modifying the Background Properties of a Report

Modifying the Background Properties of a Report

To modify the appearance of a report, or the display properties an object in a report:

1. Open the report you want to modify.
2. You must select an editable object in the report to be able to edit its properties. Click on an object to select it and to view its Properties in the docked properties window. To open a floating Properties window, either double click on the selected object, or select **Edit>Properties**.

   The Properties tabs and options displayed for editable plot objects varies depending on the report type (for example, whether 2D rectangular, Stacked, or 3D), and can include the following:

   - **Cartesian** -- this lets you edit the scrollbar and thumb properties for 2D rectangular plots.
   - **Header** – this lets you edit the Properties for the text displayed at the top of the report, including the Title font, Company Name, Show Design Name, Subtitle Font. The plot title is tied to the report's name and is not a Header property. If you change the report name in the Project tree, plot title synchronizes. The Company Name and the Show Design Name check box are grouped in the Properties dialog as Subtitle. Edits to the Subtitle Font Property affects both of them.
   - **General** – this dialog (or General tab for other Report properties windows) lets you edit the background color (the perimeter around the trace display) for the plot, the contrast color (the trace display background), the Field width, the Precision, the Visual Detail level, and whether to use scientific notation for marker and delta marker displays. (X and Y notation display is set separately, in the Axis property tabs.) An Auto Scale property on by default and when enabled scales text in plots and colorkey (contour plot, field plots in 3D modeler) for high resolution screens.
   - **Legend --** this lets you edit the Properties for whether to Show Trace Name, Solution Name, and Variation Key. At least one of these three must be selected. You can also edit the Font, the background color of the Legend box, the Border Color, the Border Width, Grid Color (for the lines between Trace descriptions), and the Grid line width. Also see Modifying the Legend in a Report

- **Color Key** -- for 3D plots, to control the appearance of the color key (colors, transparency, border appearance, fonts, number format, Min and Max, field width and precision.
- **Contour** -- for 3D plots, to control the appearance of the color map, including map type, ramp color, spectrum, IsoValType, levels, number of contours, and values shown.
- **Stacked** -- for stacked plots, properties for X scrollbar, thumb properties, and stack layout, auto fit, and stack height.
- **Traces** – you can select traces either in the Legend or on the plot. The properties for traces include: Color, Line Style, Line Width, Trace Type, whether to Show a symbol, Symbol Frequency, Symbol style, whether to Fill symbol, symbol color, and whether to Show arrows. See Editing the Display Properties of Traces.
- X, Y, or Z **Axis**-- the defaults for most of these values are set in the **Report 2D Options** Axis tab.
  - Display name -- check box for whether to display the axis name.
  - Specify name -- check box for specifying the Axis name.
  - Name -- this describes the axis to which the following properties/options refer. These are selected in the Report dialog.
  - Axis Color -- set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
  - Axis Font -- click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. OK the selections to apply the font edits and to close the dialog.
  - Show Units -- this specifies whether to display units.
  - **Window (section)**
    - Window Mode-- can be Axis range, Continuous moving window, or Step moving window.
    - Window Width (in) -- provide an integer value for the previous selection.
  - **Manual Format** (section)
    - Number format -- select from the drop down menu, Auto, Decimal, or Scientific notation.
    - Field Width -- enter a real value.
    - Field Precision -- enter a real value.
- X, Y, or Z **ScalingTab** – These properties provide control over scaling.
  - Axis Scaling -- use the drop down menu to select scaling as Linear or Log. For the Y axis, all zero or negative values are discarded before log scaling is applied.
  - Specify Min -- check box
  - Min -- text entry in same units as axis units. Saved as SI internally.
  - Specify Max -- check box
  - Max -- text entry in same units as axis units. Saved as SI internally.
  - Specify Spacing -- check box
  - Spacing -- text entry in same units as axis units. Saved as SI internally

- **Manual Units** (section)
  - Auto Units -- use the check box compute the correct units for the axis.
  - Units -- click on the cell to select from a menu of available units if you have not checked Auto Units.
- **Infinity Visualization** (section)
  - Map Infinity Mode -- check box.

  Each axis now can be set to treat infinity values in a user defined way. When you check the Map Infinity Mode, any infinity values in the input data get the infinityMap value (negative infinity get the value*-1 and positive infinity the positive value specified). This can be useful if there are zeros, or very small values that can be treated as zero, in the data, for example, dB Gain.
  - Map Infinity To -- enter a real value for the Map Infinity Mode.
- **Grid** -- properties for grid labels and grid style, appearance, line styles, color, major and minor lines, and scaling. For the 3D rectangular plots, there are separate tabs for the XY, YZ and ZX axes.

3. Edit the properties, and click **OK** to apply the changes.

Modifying the Legend in a Report

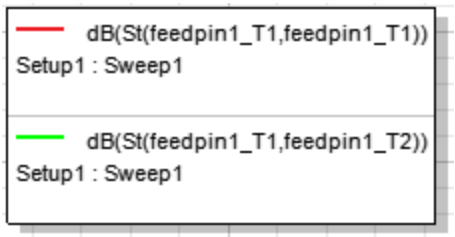
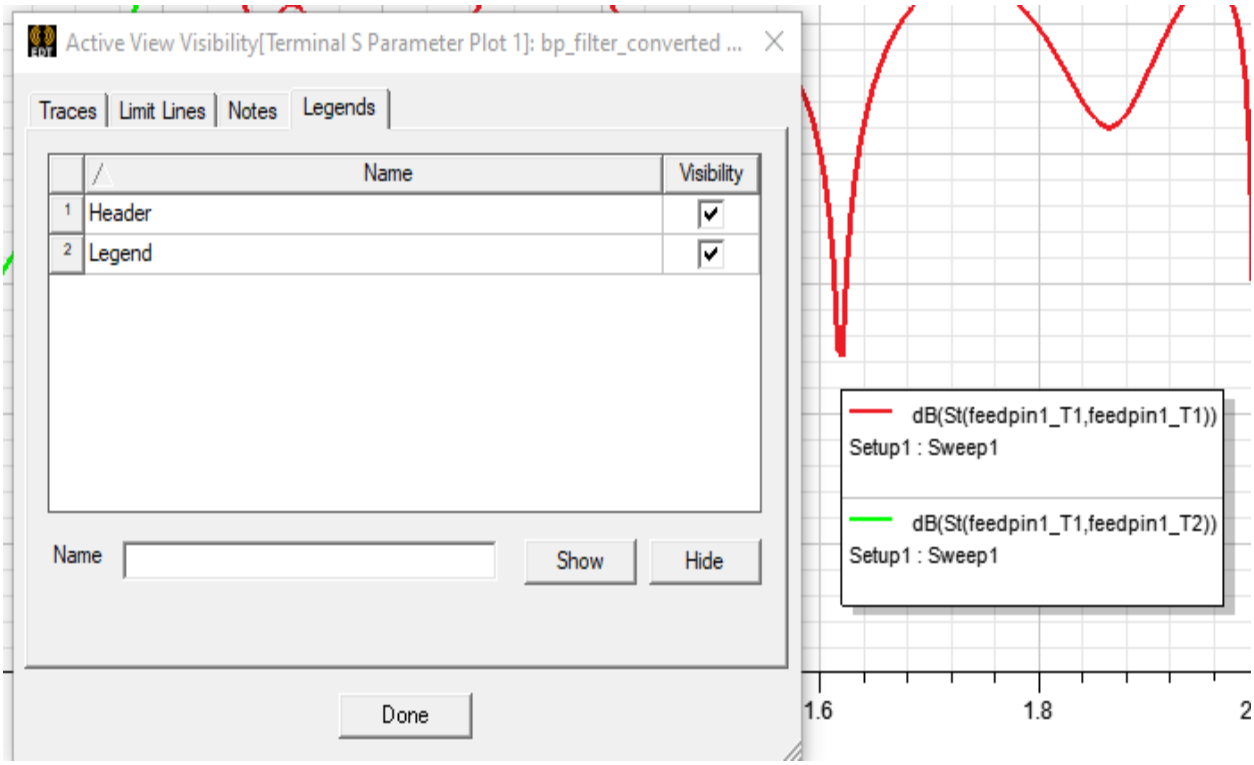
The legend in a report is a list of the curves being plotted. For each curve, the legend gives the name, shows the line color, and lists the setup and the adaptive pass used to generate the curve.



To **show** or **hide** a legend in a report:

1. Make the report the active view.
2. Use **View>Active View Visibility** display or hide the report and display the **Active View Visibility** dialog.
3. Select the **Legends** tab.

   This lists the legend (or legends) in the report.

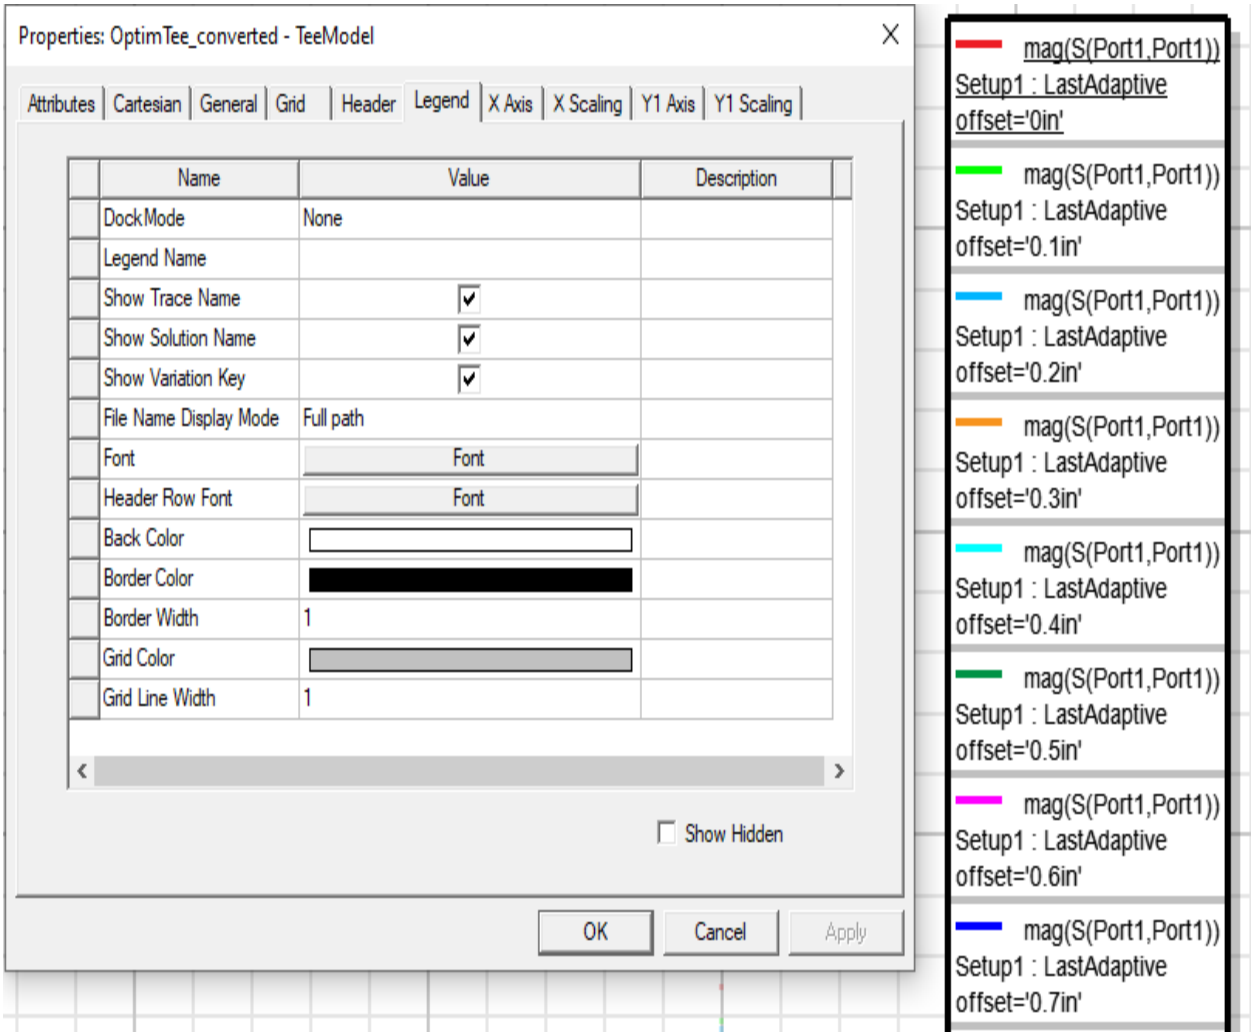


4. Check the visibility check box, and OK the dialog to close it and apply the change.

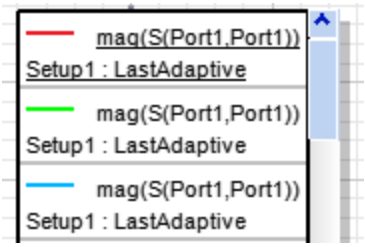
To **edit the display properties** of a legend:

1. Select the legend in a report by clicking on the Curve Info panel to display a docked properties window, or right-click on the legend and select **Edit>Properties** to display the floating properties window.

   This lets you edit the Properties for Dock Mode, Legend Name (default is no name. When non-empty, a header row for the Legend in plot shows up with that string.), whether to Show Trace Name, Solution Name, and Variation Key (which applies to parametric variables, if present). If none of these three are selected, only a trace color shows.



Here is an example with Variation Key off.



You can also edit the Font by clicking the Font cell to display the **Edit Text Font** dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. OK the selections to apply the font edits and to close the dialog box.

You can also edit the background color of the Legend box, the Border Color, the Border Width, Grid Color (for the lines between Trace descriptions), and the Grid line width.

2. Click **OK** to close the Properties window and apply the selections.

To **change the display name** for traces, see Editing Trace Properties.

To **move** a legend in a report:

1. Click and hold on the legend.
   The cursor changes to crossed lines with arrow tips.
2. Still holding, drag the legend to a new location and release.
   The legend is released and the crossed lines change back to a mouse pointer.

To **resize** a legend in a report:

1. Position the mouse tip over the edge you want to resize.
   The mouse pointer changes to a horizontal or vertical line with arrow tips.
2. Click and drag the horizontal or vertical edge to the desire size.
3. Release.

Selecting the Report Type

The **Report Types** available for creating a report depends on the simulation setup. The Report Category provides the default report name for the project tree and the text displayed in the report header. For example, Force as the Category type causes the default report name to be Force Plot *n*. Depending on the design setup, you can make a selection from the following report types.

Select from the following report types:

Magnetostatic	Project variables, user specified Output Variables and Design data are available to plot. Depending upon the solution parameters requested, torque data may be available to plot, as well as Inductance, and magnetic flux. Quantities such as Lnom, and MagFluxNom may also be available for plotting. See Post processed Quantities for more details.
Electrostatic	Project variables, user specified Output Variables and Design data are available to plot. Depending upon the solution parameters requested, torque data may be available to plot, as well as Capacitance.

Eddy Current	Project variables, user specified Output Variables and Design data are available to plot. Depending upon the solution parameters requested, torque data may be available to plot, as well as Inductance, Resistance, Impedance. Quantities such as Lnom, MagFlux, and various Winding, Loss, and End Connection quantities may also be available for plotting, depending on the design. See Post processed Quantities for more details.
DC Conduction	Project variables, Output Variables, and Design data are available for plotting, as well as Resistance matrix data.
AC Conduction (2D Only)	Project variables, Output Variables, and Design data are available for plotting. Depending upon the solution parameters requested, Capacitance, Conductance, and Admittance quantities may also be available for plotting.
Transient	Project variables, Output Variables, and Design data are available for plotting, as well as Force, Torque, Loss, Winding, and solution process data.
Transient A-Phi Formulation (3D only)	Project variables, Output Variables, and Design data are available for plotting, as well as Force, Torque, Loss, Winding, and solution process data. Terminal Voltage, Terminal Current, Inductance, and Capacitance quantities may also be available for plotting, depending on the design.
Electric Transient (3D Only)	Project variables, Output Variables, and Design data are available for plotting, as well as Force, Torque, Loss, and solution process data.
Fields	Project variables, Output Variables, and Design data are available for plotting, as well as calculator expressions.
Noise Vibration	Project variables, Output Variables, and Design data are available for plotting, as well as calculator expressions.
Harmonic Force	Project variables and Output Variables, are available for plotting, as well as harmonic force data (radial, tangential, and axial complex values of harmonic force are available for transient 3D designs – only radial and tangential for transient 2D designs).

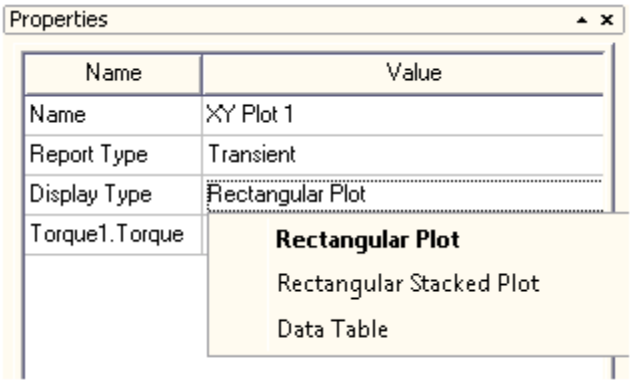
Selecting the Display Type

The information in a report can be displayed in several formats. Select from the following **Display Type** formats in the **Create Report**dialog box:

Rectangular Plot	A 2D rectangular (x-y) graph.
Rectangular Stacked Plot	A series of 2D rectangular (x-y) graphs stacked vertically, sharing a common x-axis scale, but with each trace having its own y-axis scale.
Data Table	A spreadsheet with rows and columns that displays, in numeric form, selected quantities against a swept variable or another quantity.
3D Rectangular	A 3D rectangular (x-y-z) graph.

Plot	
3D Rectangular Bar Plot	A 3D rectangular (x-y-z) bar graph.
Rectangular Contour Plot	A rectangular (x-y-z) graph. Contour plots are useful to visualize surfaces (for e.g. Directivity as a function of phi/theta).

You can also modify the display type of an existing plot from the **Properties** window for that plot. Select the Report icon in the Project tree to display the Properties window. Selecting the **Display Type** field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

Creating 2D Rectangular Plots

A rectangular plot is a 2D, x-y graph of results.

1. On the **Results** menu (Maxwell menu or right-click on **Results** on the Project tree), click **Create <*type*> Report**, and select **Rectangular Plot**.

   The **Report** dialog appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - *For Transient projects only*:

     Domain field with a pull down selection list containing options for plotting vs time (Sweep Domain) or plotting vs frequency (Spectral Domain).

- *For Transient projects only*:

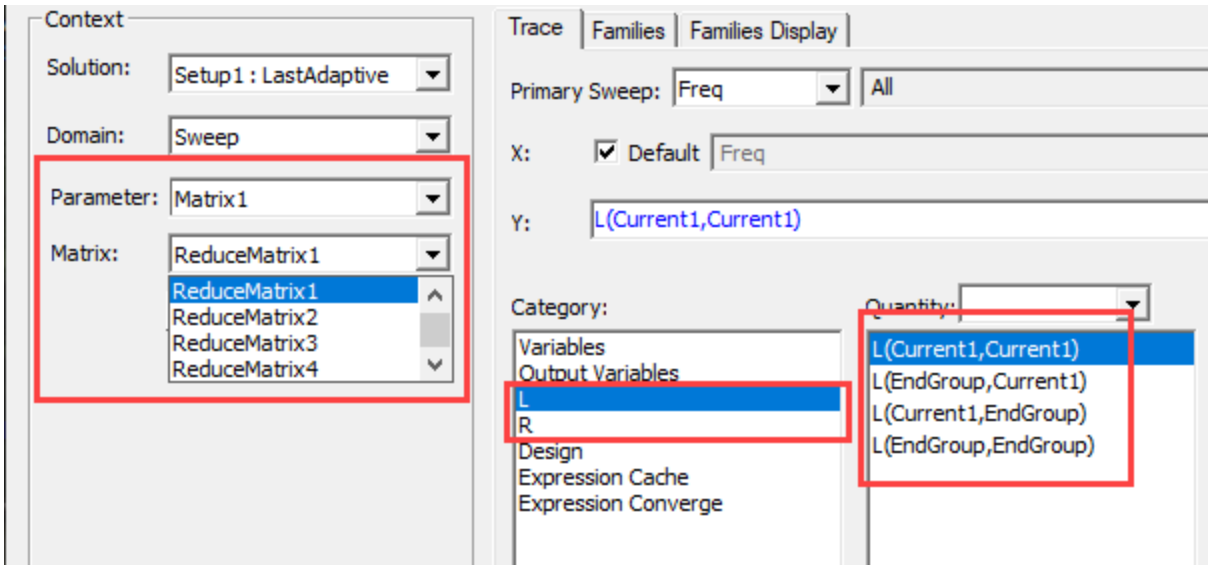
  Domain field with a pull down selection list containing options for **Average and RMS** and **Transient D-Q** for electric machines. Click **Machine Options** to setup the machine specific parameters.

- *For Eddy Current projects only*:

  Domain field with a pull down selection list containing options for plotting vs frequency (Sweep Domain) or plotting vs time (Time Domain).

  Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

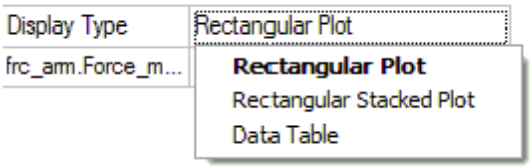
e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. On the **Trace** tab, **X** (Primary sweep) line, specify the quantity to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop down list.
   - If sweeps are available, you can select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.
7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

Plotting a Quantity versus Adaptive Pass

Creating a 2D Rectangular Stacked Plot

A rectangular stacked plot is a 2D, x-y graph of results, with each trace displayed on a separate plot.

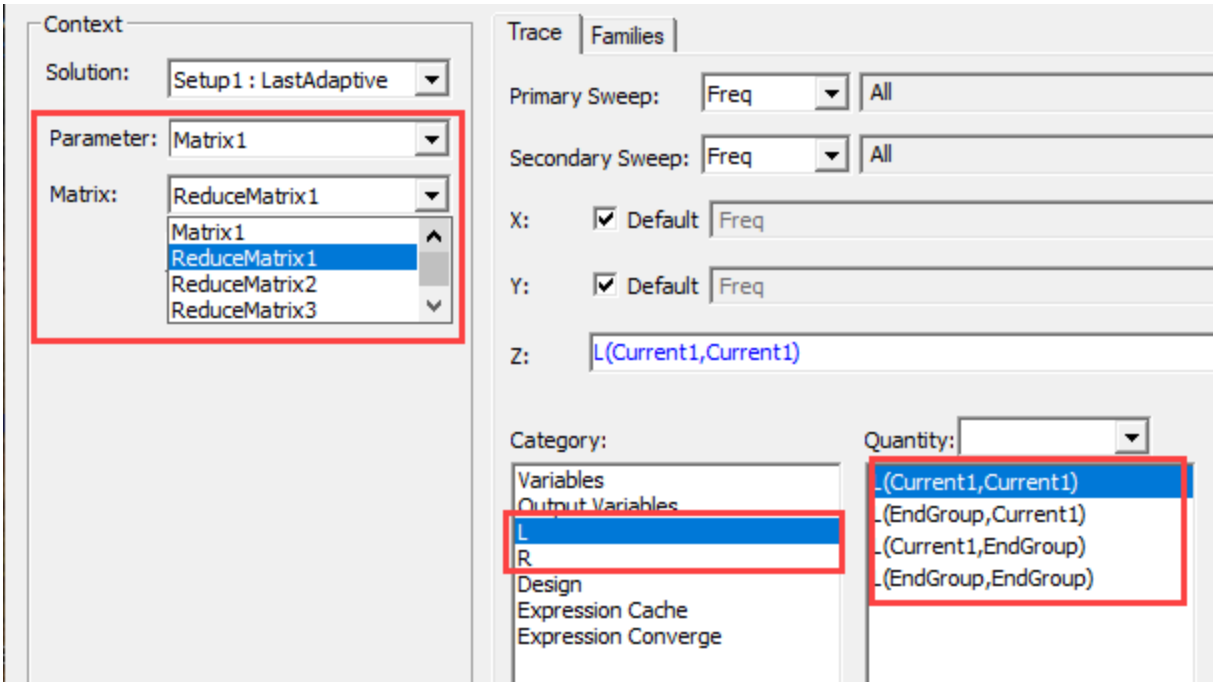
1. On the **Results** menu (Maxwell menu or right-click on **Results** on the Project tree), click **Create <*type*> Report**, and select **Rectangular Stacked Plot**.

   The **Report** dialog appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
   - *For Eddy Current projects only*:

     Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **X** (Primary sweep) line, specify the quantity to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the

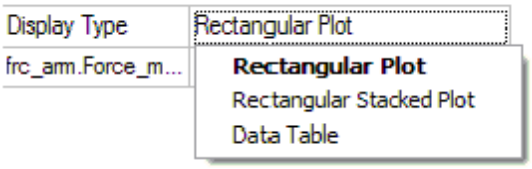
Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

   The new trace will appear as a separate plot “stacked” above the first plot. The stacked plots share a common x-axis scale. However, each plot has its own independent y-axis scale.

You can also modify the display type of an existing plot from the Properties window for that plot. Select the Report icon in the Project tree to display the Properties window. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

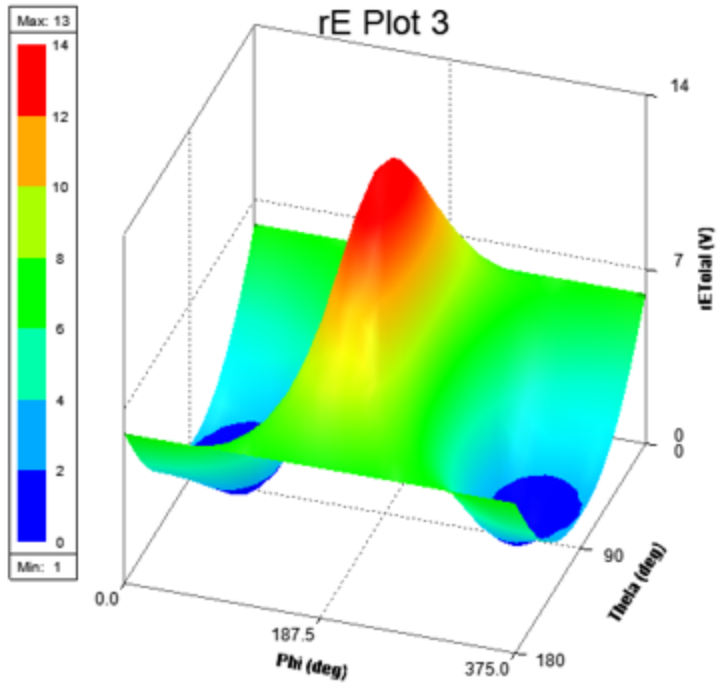
Creating 3D Rectangular Plots

Below is an example of a 3D rectangular plot.



Working with a 3D Rectangular Plot

You can Rotate, Zoom and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the Properties dialog box. the properties are grouped appropriately under various tabs, which correspond to plot entities:

- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title.
- Axis [X|Y|Z]: Properties related to the 3 axes
- Grid [XY|YZ|ZX]: Properties related to the 3 grids
- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Plot" on page 23-56 .

Creating a 3D Rectangular Plot

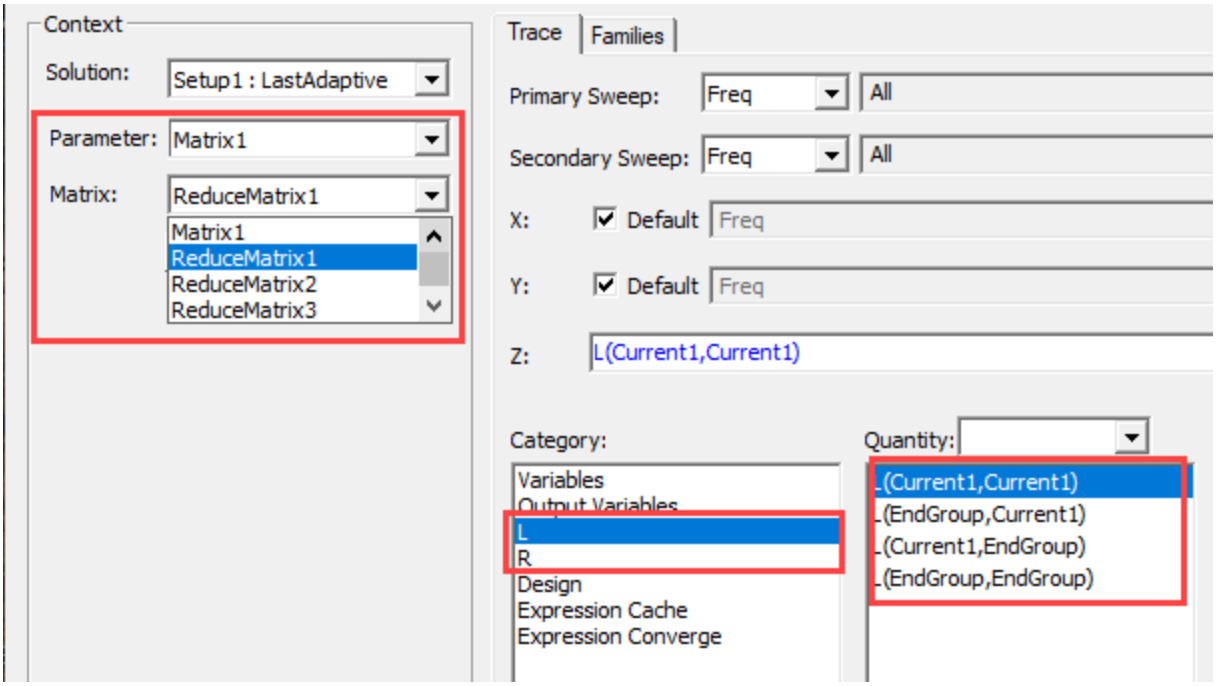
1. On the **Results** menu (Maxwell or RMxprt menu or right-click on **Results** on the Project tree), click **Create <*type*> Report**, and select **3D Rectangular Plot** from the report type menu.

   The **Report** dialog appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the **<*type*>** selected.
   - *For Eddy Current projects only*:

     Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.
- For Rmxprt only: Domain field with a pull down selection list containing options for plotting vs ElectricDegree, Speed, or a user-selected Parameter.

3. Under the **Trace** tab, **Z** Component area, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **Y** (**Secondary Sweep**) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the Secondary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab, **X** (**Primary Sweep**) lines, specify the information to plot along the x-axis in one of the following ways:

- Select the sweep variable to use from the Primary Sweep drop down list.
- If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.

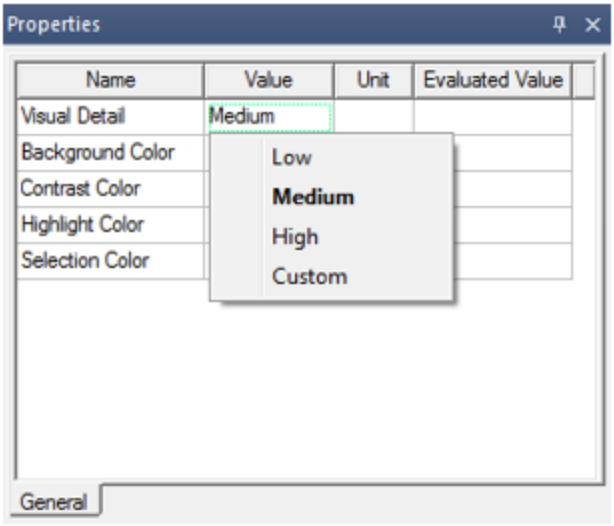
6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the project tree.When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.
8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Controlling Visual Detail in a 3D Plot

If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.

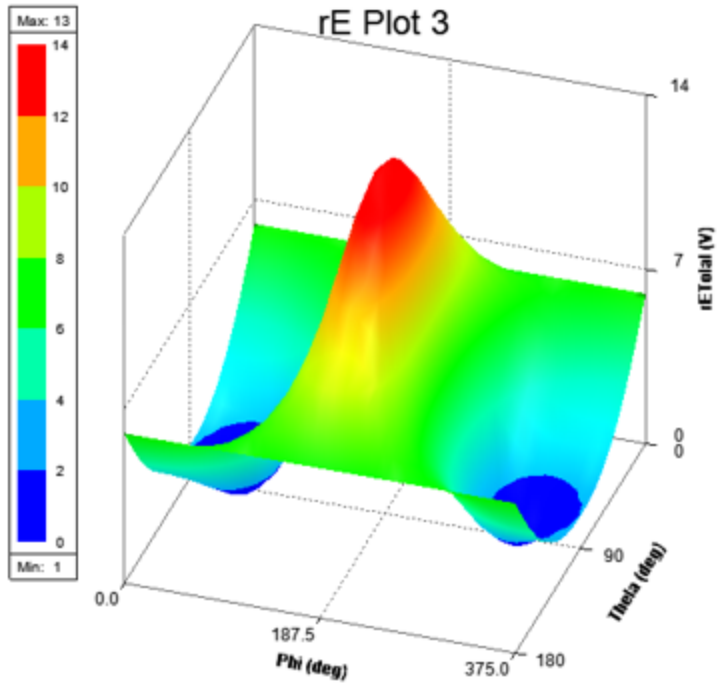


The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and

the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

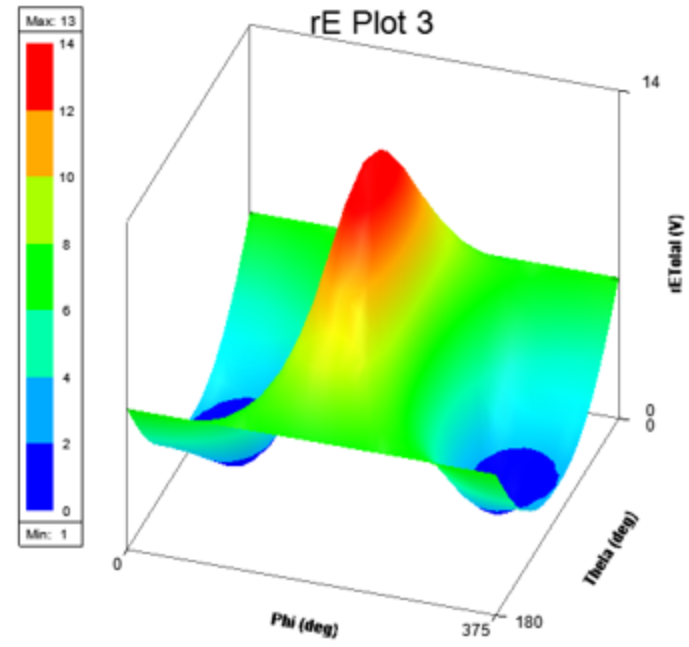
You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Rectangular Plot with Medium Visual Detail



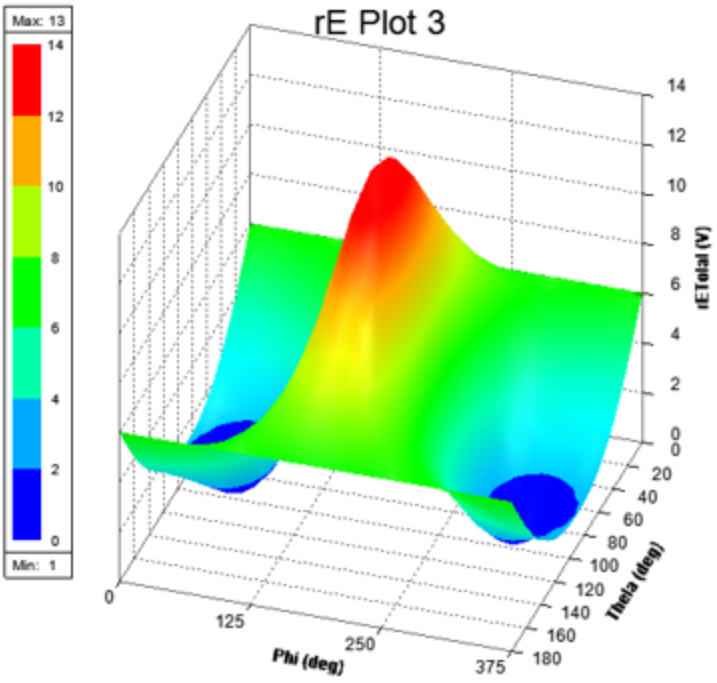
On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

3D Rectangular Plot with Low Visual Detail



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

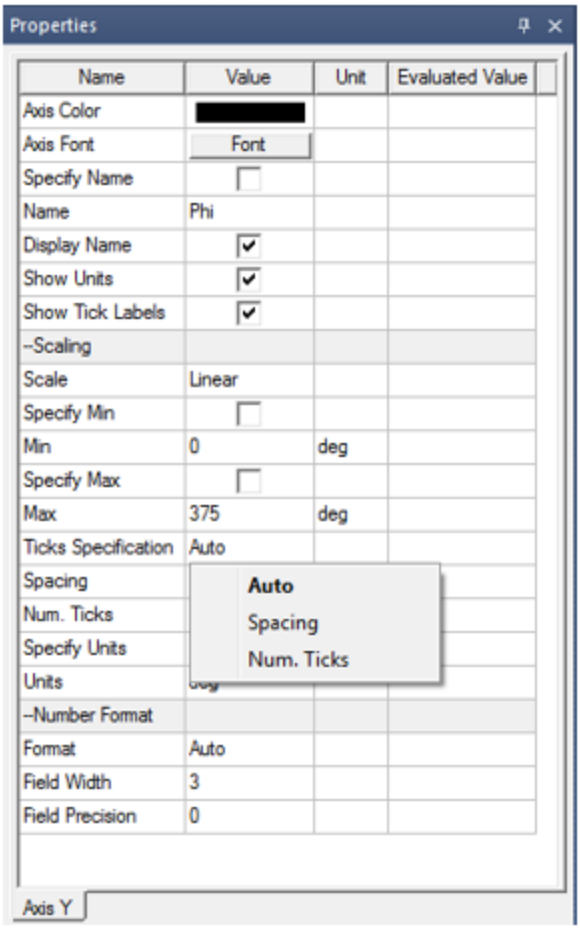
3D Rectangular Plot with High Visual Detail



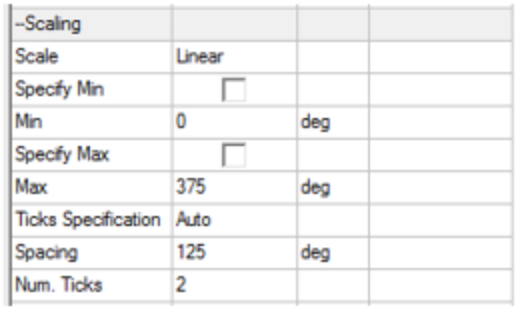
With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:



You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

Note	With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

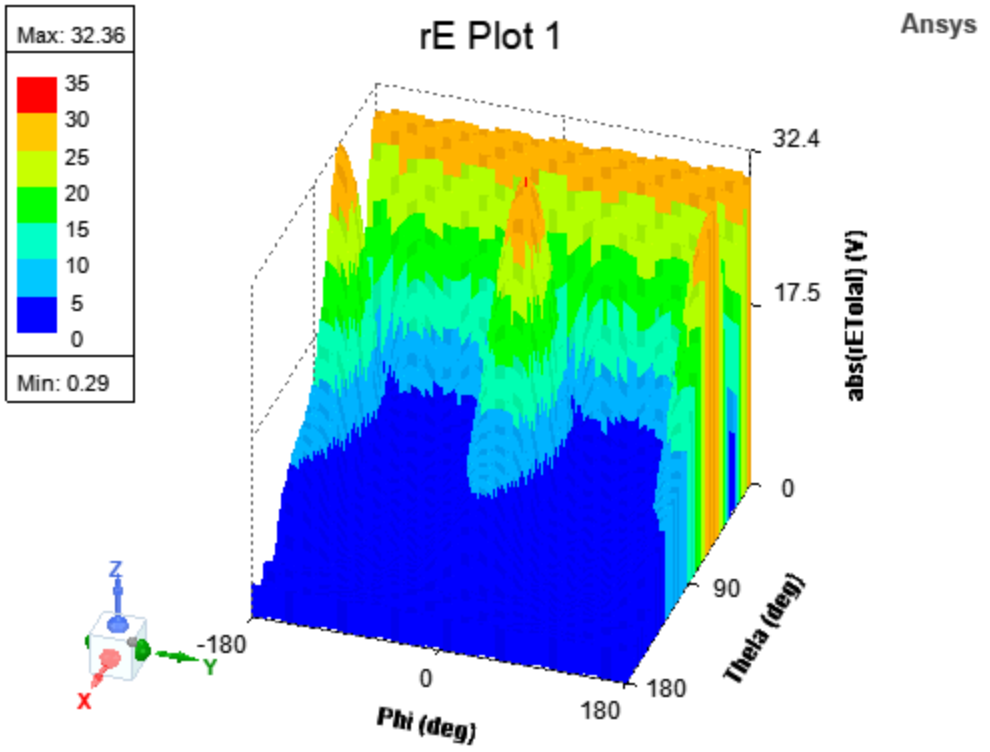
Sweeping a Variable

Working with Traces

Adding Trace Characteristics

Creating 3D Rectangular Bar Plots

This is a 3D, x-y-z graph of results as rectangular bars.

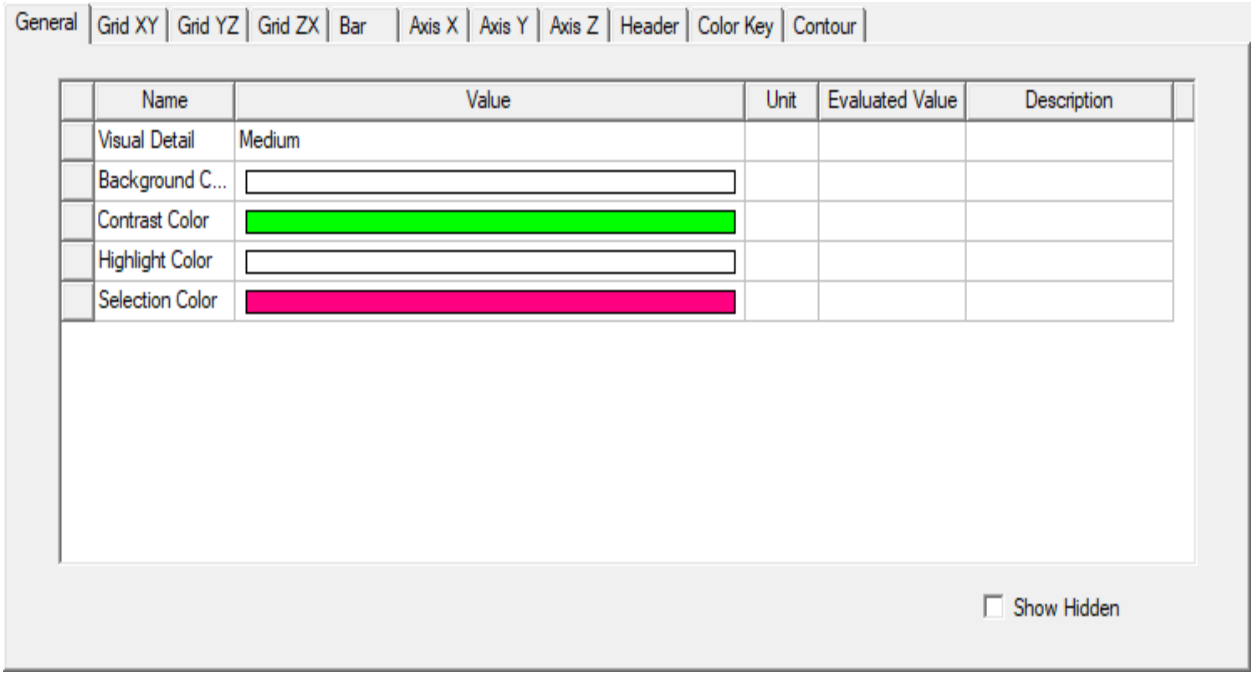


Working with a 3D Rectangular Plot

You can Rotate, Zoom, and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the **Properties** dialog box.



The properties tabs for a 3D Rectangular Bar plot are:

- General: For general plot properties such as Visual Detail level and background color
- Grid [XY|YZ|ZX]: Properties related to the 3 grids
- Bar: Properties related to rectangular bars.
- Axis [X|Y|Z]: Properties related to the 3 axes
- Header: Properties related to plot Header/Title.
- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all surfaces

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Rectangular Bar Plot" on page 23-66 .

Creating a 3D Rectangular Bar Plot

1. On the **Results** menu (under the **Maxwell** menu or right-click **Results** in the Project Manager), click **Create *<type>* Report**, and select **3D Rectangular Bar plot** from the report type menu, or select the Results tab of the ribbon, and select the 3D Rectangular Bar icon for the Report type you want to create.

   The *Report* dialog box appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop-down selection list. This lists the available solutions, whether sweeps or adaptive passes.

b. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.

3. Under the **Trace** tab **Z** Component area, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot. The category you select provides the default plot name.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

      > **Note:**
      >
      > Color shows valid expression.

   e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

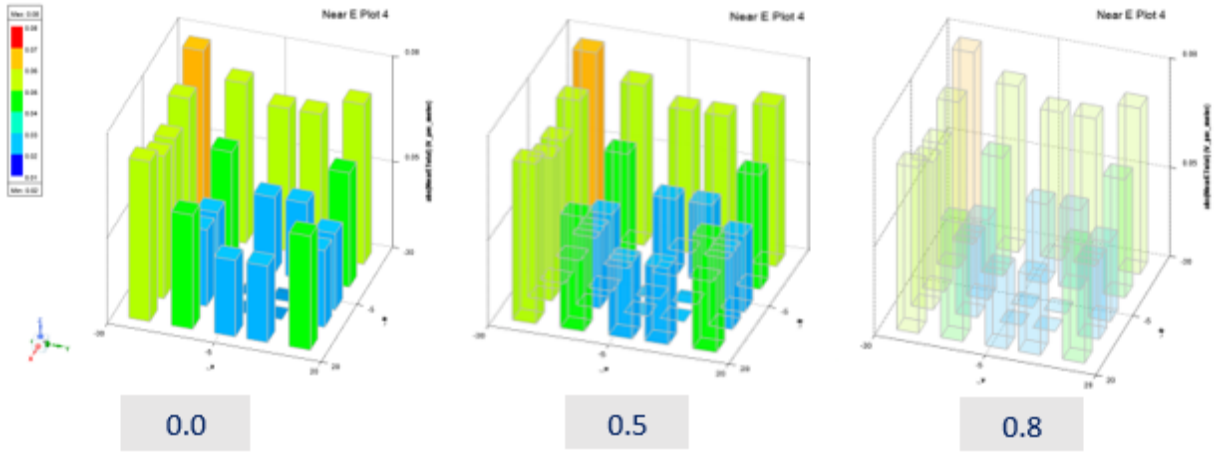
   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the Project Manager. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.
7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

3D Rectangular Bar Customization

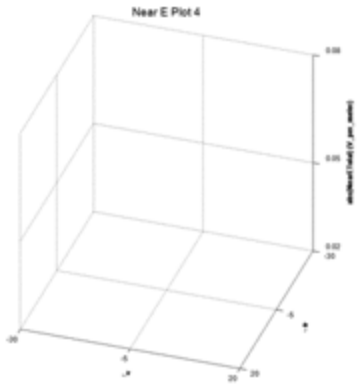
Selecting a bar in the plot shows the customizable attributes of bars in a 3D Rectangular Bar plot.

The customizable attributes of the bars in a 3D Rectangular Bar plot include:

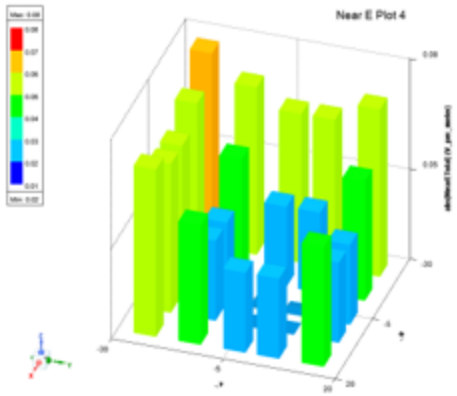
- Transparency



- Filled

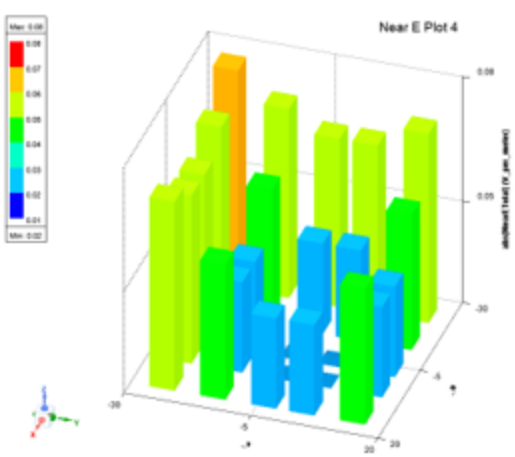


Filled [ ]

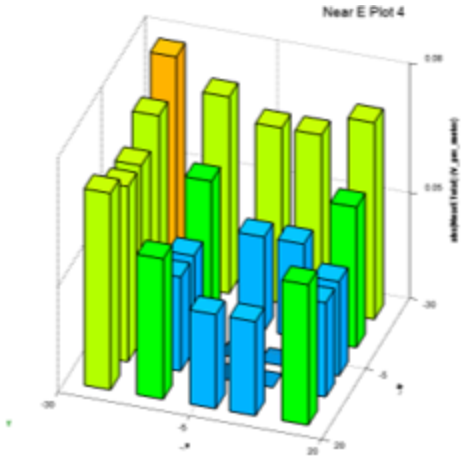


Filled [√]

- Show Outline



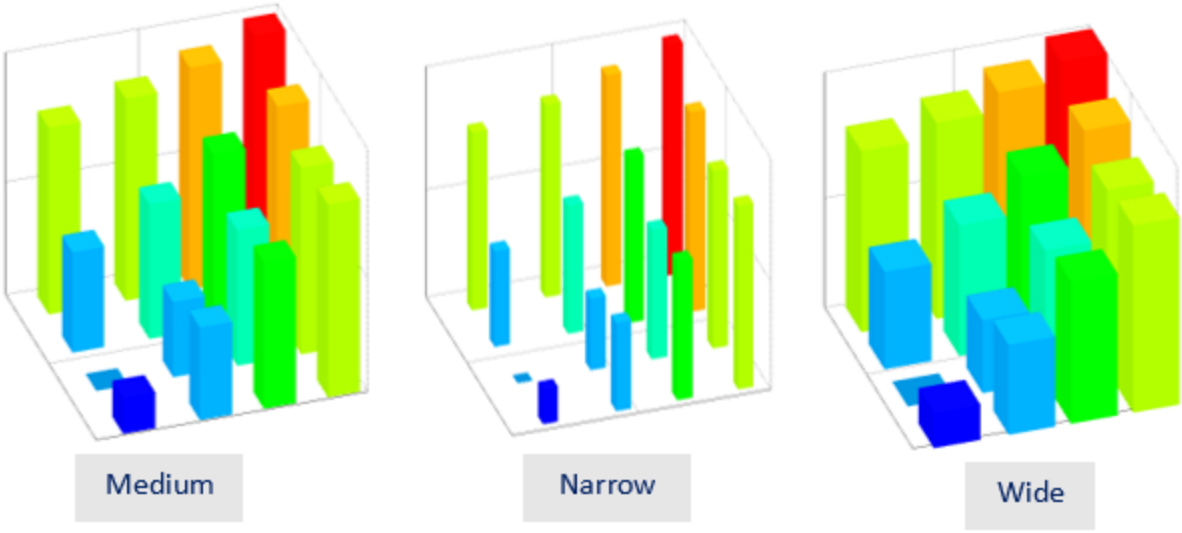
Show Outline []



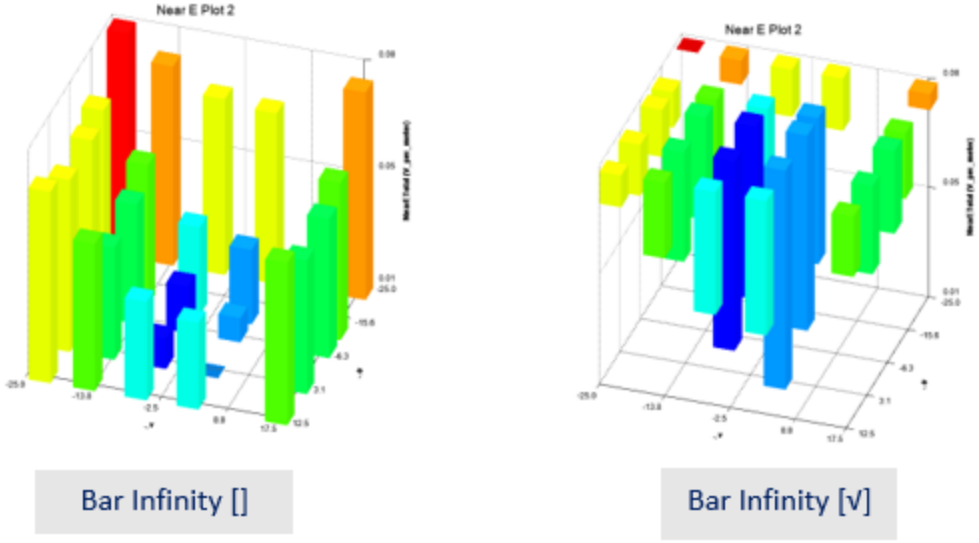
Show Outline [√]

- Outline Color (customizable, see plot above)
- Outline Width (customizable, see plot above)

- Bar Width, controls the thickness of the bar. Medium (default), Wide and Narrow are the width that equals to ½, ¾ and ¼ of the min spacing between adjacent points respectively.

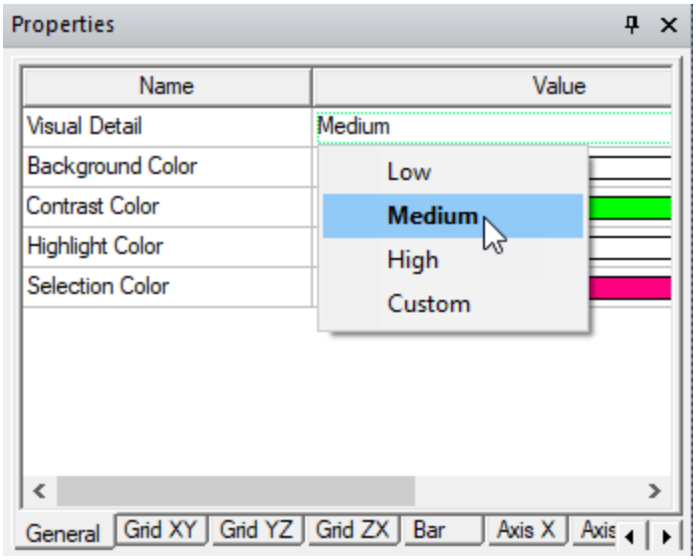


- Bar Infinity represents the third coordinate (z) using the bottom of the bar.



Controlling Visual Detail in a 3D Rectangular Bar Plot

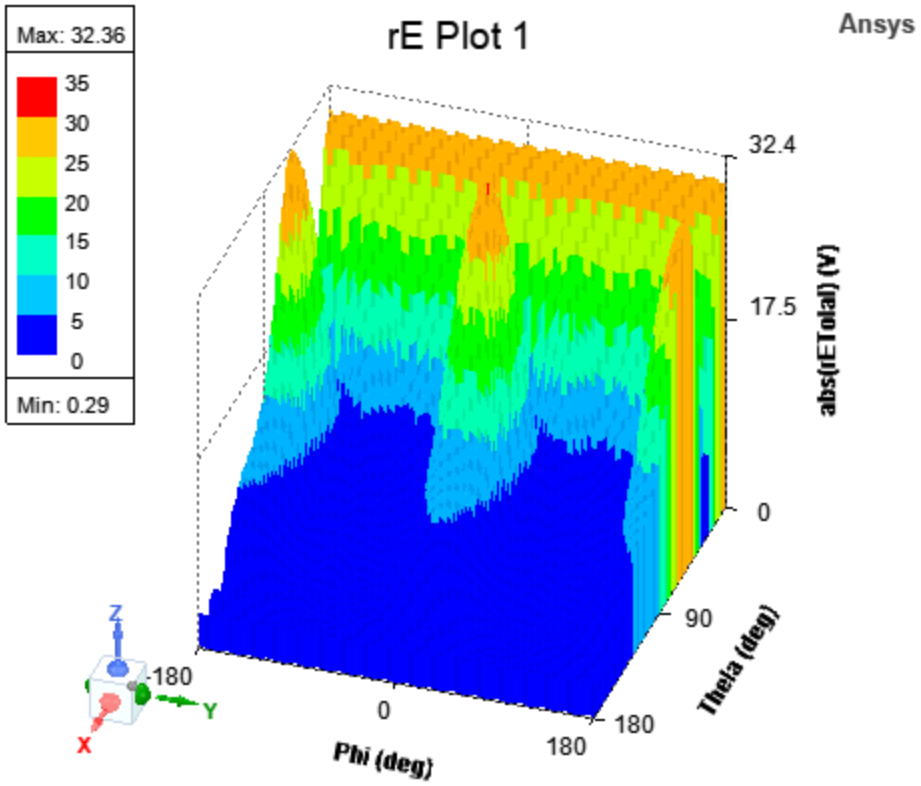
If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.



The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

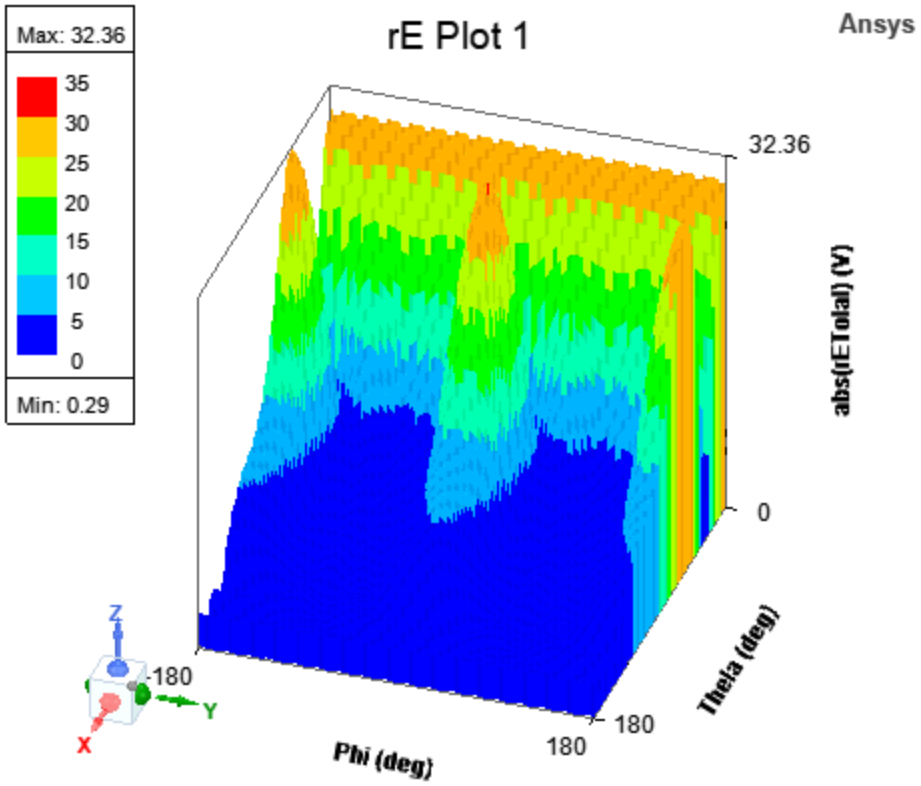
You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Rectangular Plot with Medium Visual Detail



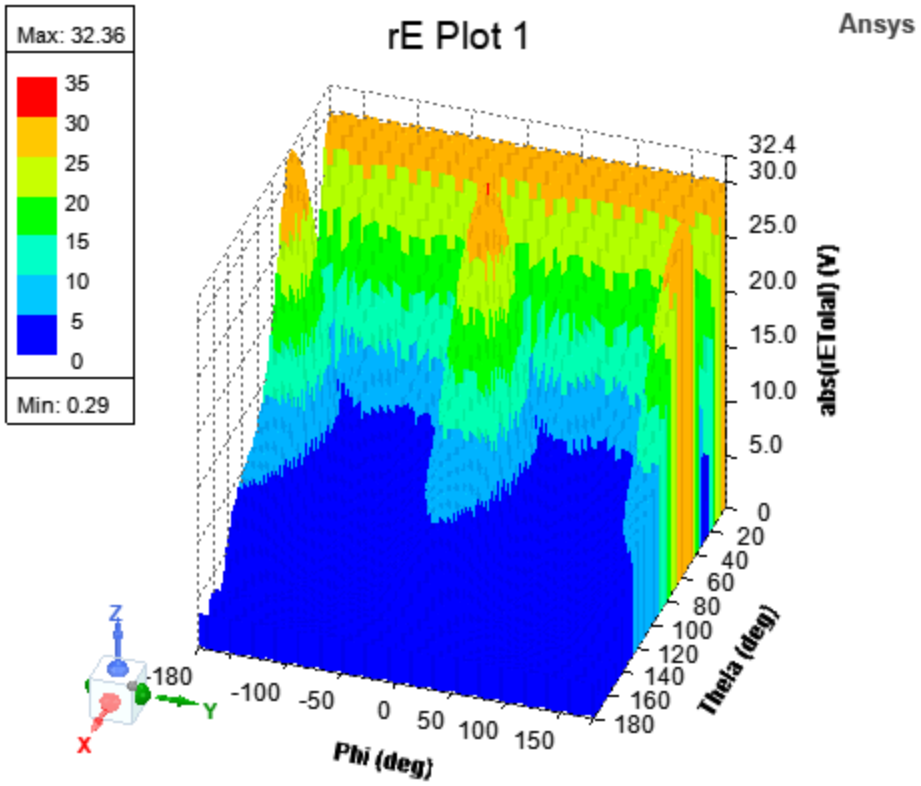
On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

3D Rectangular Bar Plot with Low Visual Detail



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

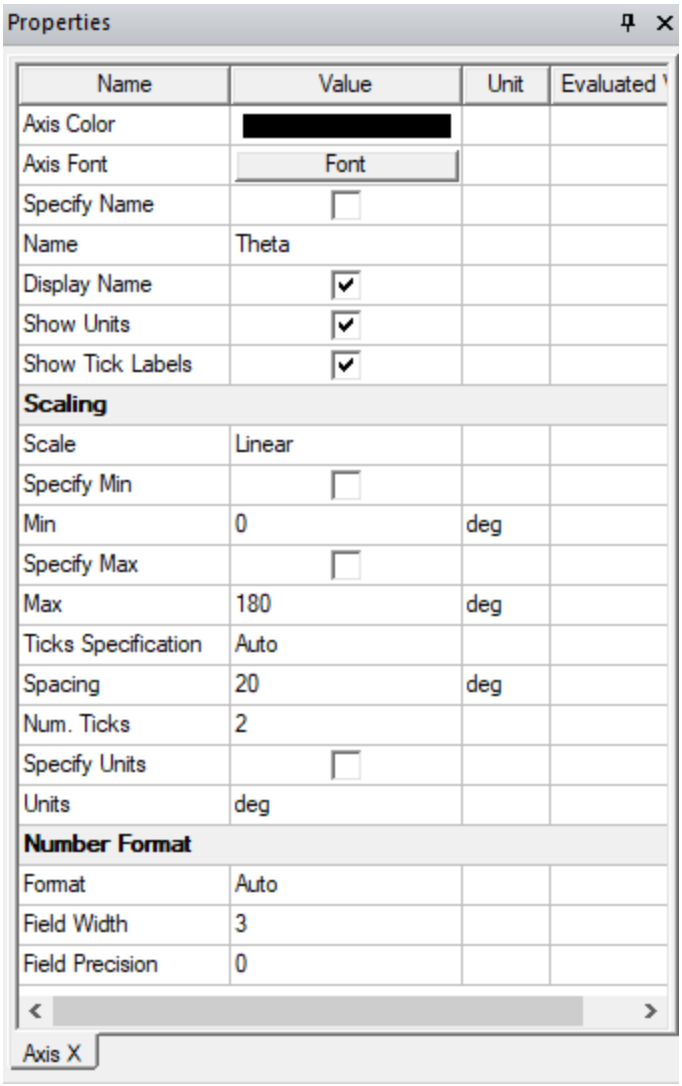
3D Rectangular Bar Plot with High Visual Detail



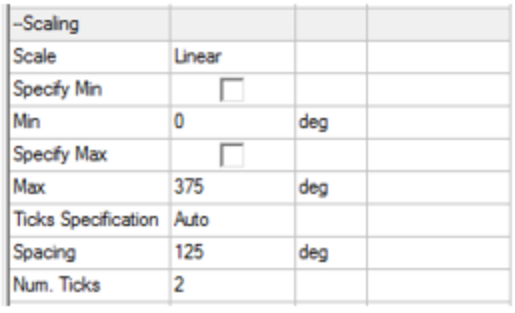
With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:



You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

Adding Characteristics to a Trace

Using the Orientation Gadget

Plotting a Quantity Versus Adaptive Pass

Any quantity that can be plotted in the reporter may be plotted versus the adaptive solution pass, primarily to evaluate the convergence of the quantity versus the mesh.

1. On the **Results** menu (Maxwell menu or right-click on **Results** on the Project tree), click **Create <*type*> Report**, and select **Rectangular plot** from the report type menu.

   The **Report** dialog appears.
2. In the **Context** section, select the **AdaptivePass** context for the Setup of interest. The **Trace** tab **X** value drop down list will contain an option to plot against **Pass**.
3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information (for example, Expression Cache or Output Variable) to plot.

b. In the **Quantity** list, click the value to plot.
c. In the **Function** list, click the mathematical function of the quantity to plot.
d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
5. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog.

   The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.
6. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Creating Data Tables

A data table is a grid with rows and columns that displays, in numeric form, selected quantities against a swept variable or other quantities.

1. On the **Maxwell3D or Maxwell2D** menu, point to **Results**, and then click **Create <*type*> Report, or right click on the Results icon in the Project tree and click Create <*type*> Report**.
2. In the **display type** menu, click **Data Table**.

   The **Report** dialog box appears.
3. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.

- *For Transient projects only*:

  Domain field with a pull down selection list containing options for plotting vs time (Sweep Domain) or plotting vs frequency (Spectral Domain).

- *For Transient projects only*:

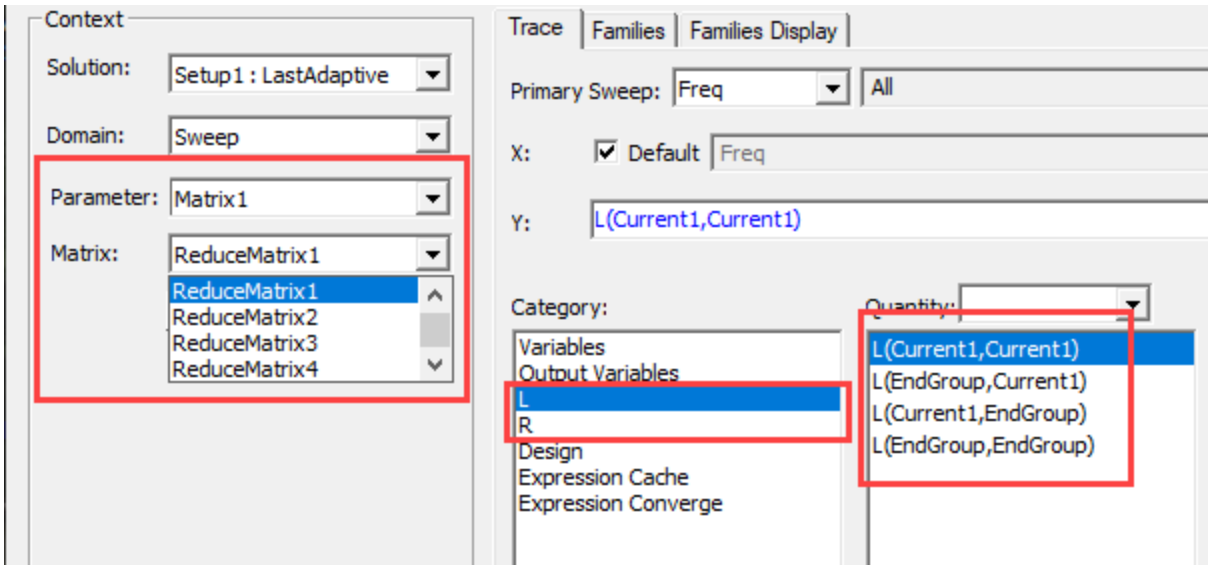
  Domain field with a pull down selection list containing options for **Average and RMS** and **Transient D-Q** for electric machines. Click **Machine Options** to setup the machine specific parameters.

- *For Eddy Current projects only*:

  Domain field with a pull down selection list containing options for plotting vs frequency (Sweep Domain) or plotting vs time (Time Domain).

  Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

4. Under the **Trace** tab, **Y** component section, select the quantity you are interested in and its associated function:
   a. On the **Category** drop down list, click the type of information to plot.
   b. On the **Quantity** list, click the values to plot. Use CTRL-click to make multiple selections.
   c. In the **Function** list, click the mathematical function to apply to the quantity for the plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

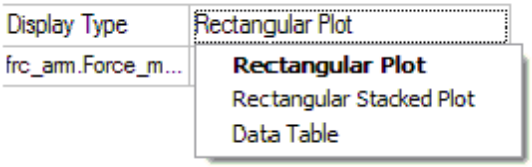
Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
5. On the **Trace** tab, **X (Primary Sweep) line,** select the sweep variable from the drop down list. By default **All** of the chosen sweep's values are used. You can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting).
6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report**.

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, for example, Force Plot *n* or Output Variables Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The Y quantity will be listed at each variable value or additional quantity value you specified. The data table is listed under **Results** in the project tree. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.
8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

If you choose to print a data table:

- Selecting print "All" prints the whole table for current data page (if there is more than one data page).
- Selecting print "Pages" prints user-specified pages.
- If the table is bigger than the screen view (that is, it has a scroll bar), printing first scrolls right, prints until no more scrolling occurs, and then scrolls down.
- The Page number appears at the bottom of the page, aligned at center.
- The table layout of each page follows the screen, but without the scroll bar being printed, and no data page bar as on screen.

Creating Rectangular Contour Plots

This is an x-y-z graph of results. Any data that you can current plot in 3D is a candidate for a contour plot.

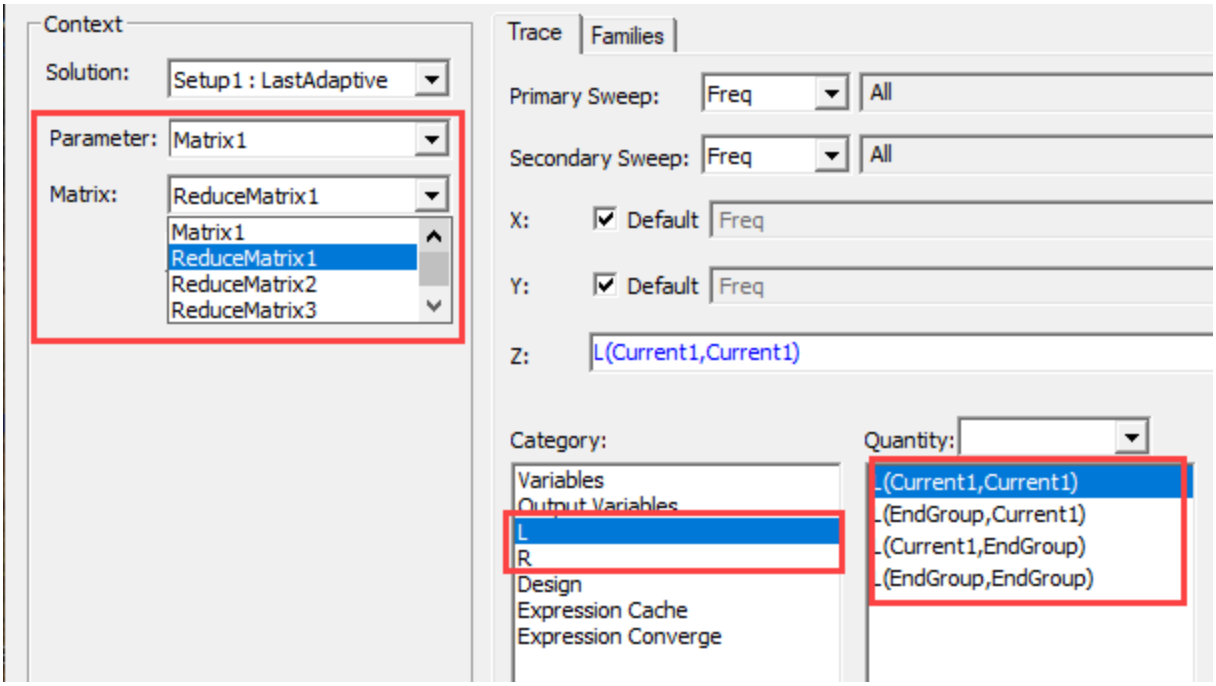
1. On the **Results** menu (Maxwell menu or right-click on **Results** on the Project tree), click **Create <*type*> Report**, and select **Rectangular Contour plot** from the report type menu.

   The **Report** dialog appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   - **Solution** field with a drop down selection list. This lists the available setups and sweeps. As a minimum, the LastAdaptive solution and AdaptivePass solution is available to choose.

     The AdaptivePass solution context can be selected to allow any value or parameter to be plotted versus the adaptive pass. This function is usually used to evaluate the convergence of the solution.
   - **Parameter** field with a drop down selection list. Whether this field appears, and the parameters listed depend on the Solution type and the ***<type>*** selected.
   - *For Eddy Current projects only*:

     Matrix field with a pull down selection list containing options for plotting *matrix* and *reduce matrix* parameters.

Note	In Maxwell Eddy Current designs, the user can create *matrix* parameters, which will cause the solver to produce an impedance *matrix* for the selected excitations. In addition, the user can group (wire) two or more excitations to one excitation in either a series or parallel connection referred to as a *reduce matrix*. The **Matrix** field appears only if a matrix entry is selected in the **Parameter** field. (Refer to *Assigning a Matrix* for information on creating a *matrix* and *Assigning a Reduce Matrix* for information on creating *reduced* matrix parameters for Eddy Current designs.)



- *For Fields and Noise Vibration reports*: **Geometry** field with a drop down selection list. This applies the quantity to a specific geometry.

3. Under the **Trace** tab **Z** Component area, specify the information to plot as contours:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the Secondary Sweep drop down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the Primary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time

sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.

6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the project tree.When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.
8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Delta Markers in 2D Reports

To view the difference between any two marker points in a report:

1. Set the first marker by left-clicking and holding the mouse button.
2. Move the mouse; without releasing the left button, to another position, and then release the left button to create the second marker.

In the marker text window, the difference between the two markers is displayed instead of the X, Y value of the each marker.

Adding Data Markers to Traces

Working with Traces

A trace in a 2D or 3D report defines one or more curves on a graph. A trace in a data table defines part of the displayed matrix of text values.

The values used for a plot's axes, which may be X, Y, Z, phi, theta, or R depending on the display type, can be variables in the design, such as frequency, or functions and expressions based on the design's solutions. If you have solved one or more variables at several values, you can “sweep” over some or all of those values, resulting in a curve in 2D or 3D space.

A report can include any number of traces and, for 2D Rectangular and Rectangular Contour plots, up to 20 independent y-axes.Traces appear in the Project tree under their report. They can be selected, copied and pasted.

When you move a cursor over a trace in a report, the cursor changes to show that you can make a selection:

- For PC systems, the cursor changes to the color of the selectable trace.
- For Unix systems, the cursor changes to a solid black arrow, rather than the default black outline.

In general, to add a trace to a report:

1. Select a report in the Project window and right-click and select **Modify Report**.
2. In the **Report** dialog specify the Y component information.
   a. Specify the Category of information you want to plot from the drop down menu.
      The Category drop down menu lists the available categories for the Solution type and the current design. Selecting a category changes the Quantity and Function lists to represent what is available for that category.
   b. Specify the Quantity you want to plot by selecting from the Quantity list.
      The selected quantity appears in the Value field, operated on any selected function.
   c. Select the Function to apply to the specified quantity.
   d. The Value field shows the trace being readied for plotting on the Y-axis. This field is editable when the text cursor is present. You can modify the information to be plotted by typing the name of the quantity or sweep variable to plot along an axis directly in the text boxes.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
3. In the **Report** dialog specify the X axis information (for example Primary Sweep).
4. Click **Add Trace**.

   A trace is added to the traces list under its report icon in the Project tree. The trace represents the function of the quantity you selected and will be plotted against other quantities or swept variable values. Selecting a Trace in the Project tree displays the Properties window for that Trace.

   Trace icons can be selected, copied, and pasted for their definitions or their data. They can be selected and deleted from the Project tree.

   By default, the Trace name is the definition (the category, quantity and function). The trace will be visible in the report when you click **Add Trace**.

Trace properties can be edited directly in the Properties window or edited in the **Report** dialog box. To change the name of definition of a trace, see Editing Trace Properties. To edit other display properties of a trace, see Editing the Display Properties of Traces.

Editing Trace Properties

You can edit trace properties such as the name, the Y Axis association, the component definition, the context, or the variables select the trace in the Project tree.

To edit a trace name:

1. Select the trace in the Project tree.

   This displays a docked Properties window for the Trace.
2. Check the Specify Name box.

   This enables editing of either the Name field in the docked properties dialog box, or the Trace label text in the Project tree. Editing this name changes the display in the Legend and in the Project tree, but not the underlying Y-component definition.

Note	To control the display of the Solution Name and Variation Key in the Legend, see Report 2D: Legend Tab.

To edit the Y Axis associated with the trace (2D Rectangular and Rectangular Contour plots):

1. Select the trace in the Project tree.
2. In the docked Properties window for the trace, select the Y Axis to be associated with the trace from the drop down menu. Up to 20 independent Y axes can be added to a plot.

To edit a trace component definition:

1. Select the trace in the Project tree.
2. In the docked Properties window for the trace, select the component field of interest, and select Edit... from the drop down menu.

This displays the an edit Component field window.form which you can edit the category, quantity and function.

3. Click OK to apply the changes and close the dialog.

To edit a trace Context:

1. Select the trace in the Project tree to display the docked properties window.
2. In properties window, click the Solution field or the Domain field. If other selections are possible, they can be selected from the drop down menu.

To edit a variable for a trace:

1. 1. Select the trace in the Project tree to display the docked properties window.
2. 2. Under the -Variables category, on the Families line, click the Edit button to display the Edit families dialog.

   From this dialog box, you can select the Sweeps or Variations radio buttons.

   If other nominal values are available you can click the ellipsis button to select from a list.

Editing the Display Properties of Traces

To edit the display properties of a trace:

1. Select a trace in an open **Report** window.
2. Click once on the trace to view a **Docked Properties** window, or double click to open **Properties** window.

   The display properties window for a trace includes a **General** tab and an **Attributes** tab.

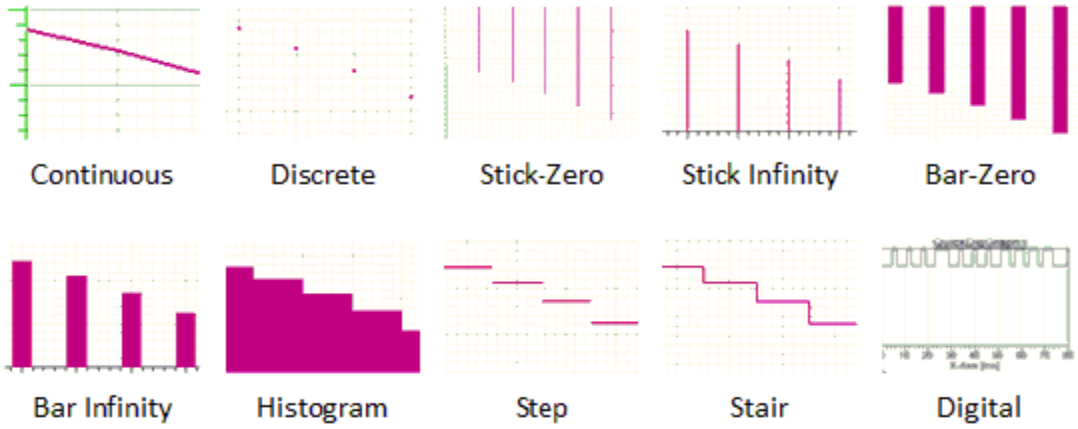
   The **General** tab properties apply to the general appearance of the plot. They include the Background color, Contrast color, Field width, and Whether to use Scientific notation for marker and delta marker displays. (X and Y notation display is set separately, in the Axis property tabs.)

   The Attributes Tab properties apply specifically to the trace. The defaults are set in the Report2D options. They include:

- **Name** – not editable by selecting the trace from the Report. It shows the characteristics of the trace as defined in the Report dialog box.

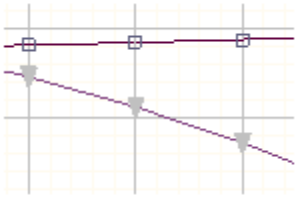
To edit a trace name, see Editing Trace Properties

- **Color** – shows the Trace color. Double click to open a Color dialog box. You can select from Basic colors, or custom colors. You can define up to 16 custom colors by selecting or by editing the Hue, Saturation, Luminescence, and the Red, Green, and Blue values.
- **Line style** – a drop down menu lets you select Solid, Dot, Dash, or Dot-dash.
- **Line width** – a text field lets you edit the numeric value.
- **Trace type** – he drop down menu contains entries for Continuous, Discrete, Bar-Zero, Bar Infinity, Stick Zero, Stick Infinity, Histogram, Step, Stair, and Digital.



Notice the difference between Stair and Digital is that each Stair centers on a data point with transitions halfway between points, and Digital transitions from each data point to the next value.

The next four properties work together to define whether to show a symbol on data points, the symbol frequency, the symbol style, and whether to display the symbol as solid or hollow.



- **Show Symbol** – whether to show a symbol at the data points on the line.
- **Symbol Frequency** – how often to show symbols on the trace, based on the number of data points per symbol used. For example, specify 1 for one symbol per data point. Specify 10 for one symbol for every 10 data points.

- **Symbol Style** – use a drop down menu to select from box, circle, vertical ellipse, horizontal ellipse, vertical up triangle, vertical down triangle, horizontal left triangle, horizontal right triangle
- **Fill Symbol** – use the check box to set the symbol display as a solid or as hollow.
- **Symbol Arrows** – use the check box to use arrows on the curve ends.

Note	So that curves with single points always appear, Box is the default symbol. For Maxwell 12, None cannot be selected.

3. Edit the properties of interest and click **OK** to apply the changes and close the window.

To edit the display properties of a trace in a 3D report:

1. Double click on the trace. This opens a Properties dialog for the plot with a tab named for the trace selected.
2. The editable properties include Point size, Point Style, whether to show points, whether to show line, line width, and line style.

Adding Data Markers to Traces

The Reporter includes **Report 2D>Marker>** menu commands that let you add markers to traces. A marker appears as "m*N*" at the marked point, where *N* increments from 1 as you place additional markers. Each marker can be selected and has editable properties including name, font, background and color. As you place markers, one or more marker legends may be displayed, depending on the **View>Active View Visibility** settings for the legends. The main marker legend appears in the upper left of the plot, and lists the marker names and their X and Y values in a table. You can control the number format for the table values via the Properties window, General tab. Under Marker/Other Number format, you can specify field width, precision, and whether to use scientific notation. This value is independent of the Axis tab number properties. A separate marker legend appears for Delta Markers, as described for the **Delta Marker** command.

When you enter Marker mode, the cursor arrow is accompanied by an "m" while a circle on the selected trace shows the current position for a potential marker.

To end Marker mode, right-click to display the shortcut menu, and select **End Marker Mode**.

The available Marker mode commands and associated icons are the following:

- 
  Add Marker – this command lets you place a marker at an arbitrary point on a selected trace.

- 
  Add Delta Marker – enters delta marker mode, placing a circle on the selected trace. Clicking on the trace sets an initial point and subsequent clicks on arbitrary points on the trace place additional markers until you leave marker mode. These markers have their own legend, which includes the following information for each pair of markers specified.:

Name	Delta(X)	Delta(Y)	Slope(Y)	InvSlope(Y)
d(m2,m3)	0.4700	1.8319	3.8976	0.2566

- **Export Marker Table** – allows you to export the marker table data as a .csv or .tab file.
- **Export Delta Marker Table** – allows you to export the delta marker table data as a .csv or .tab file.

- 
  Add Maximum – places a marker at the Maximum value on the selected trace.

- 
  Add Minimum – places a marker at the Minimum value on the selected trace.
- **X Marker** – this command adds up to 10 movable markers at the origin of the plot with a vertical line rising from the X axis. Each added marker has its own color and editable properties. You can change the X marker value either by dragging the marker, or by editing the X marker property **X value**. To move an X marker, click on the X label and drag it to the desired location. The label at the bottom of the line gives the X coordinate, and a flag on the vertical line identifies the Y coordinate on the trace. A **Lock Drag** trace property lets you lock the drag feature to leave the marker in place. If more than one X marker is present, marker properties include a connecting line between adjacent markers and the delta X value between the markers. The X markers are cleared by the **Clear All** command.
- **Bring X Marker into view** – this command is enabled if an X Marker is not visible in the plot. It allows you to select from a list of existing X Markers to bring into view.
- **Y Marker** – this commands adds up to 10 movable markers at the origin of the plot with a horizontal line extending from the Y axis. Each added marker has its own color and editable properties. You can change the Y marker value either by dragging the marker, or by editing the Y marker property **Y value**. To move a Y marker, click on the Y label and drag it to the desired location. The label at the left of the line gives the Y coordinate, and a flag on the horizontal line identifies the Y coordinate on the trace. A **Lock Drag** property lets you lock the drag feature to leave the marker in place. If more than one Y marker is present, marker properties include a connecting line between adjacent markers and the delta Y value

between the markers. The Y markers are cleared by the **Clear All** command. For more detail on Y Markers and their use, see Y Markers in stacked XY plots.

- **Bring Y Marker into view** – this command is enabled if a Y Marker is not visible in the plot. It allows you to select from a list of existing Y Markers to bring into view.
-  **Next Peak** – moves a selected marker on the next peak on a trace. You must exit marker mode and select a marker to enable this command.
-  **Next Minimum** – moves a selected marker to the next minimum on a selected trace. You must exit marker mode and select a marker to enable this command.
-  **Previous Peak** – moves a selected marker on the previous peak on a selected trace. You must exit marker mode and select a marker to enable this command.
-  **Previous Minimum** – places a marker on the previous minimum on a selected trace. You must exit marker mode and select a marker to enable this command.
- **Go to Start** (Right arrow) – moves a selected trace marker to the first data point. Enabled by leaving marker mode and selecting a marker.
- **Go to Previous** (Left arrow) – moves a selected trace marker to the previous data point.
- **Go to Next** – moves a selected trace marker to the next data point.
- **Go to End** – moves a selected trace marker to the last data point.
- **Next Curve** – selects the next curve in the report, based on the order in the trace legend.
- **Previous Curve** – selects the previous curve in the report, based on the order in the trace legend.
- **Clear All** – clears all markers on a report.

Zooming in or out.

Fitting Objects in the view window.

Showing Objects

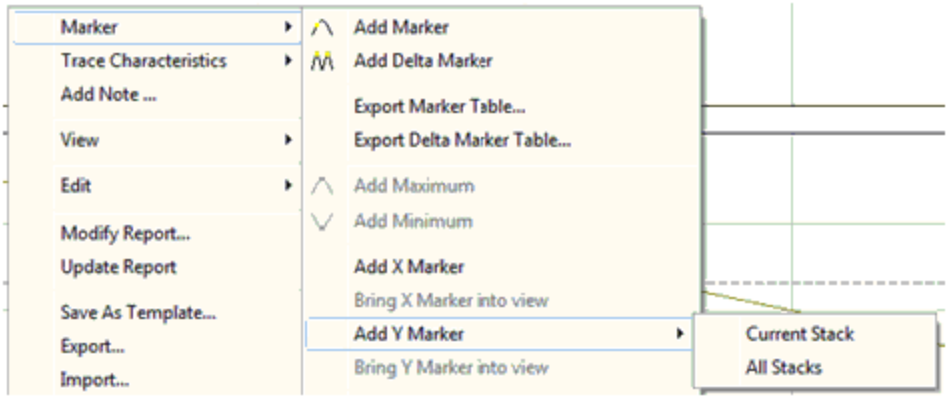
Hiding Objects from View
Delta Markers in 2D Reports
Y Markers in stacked XY plots

Y Markers in stacked XY plots

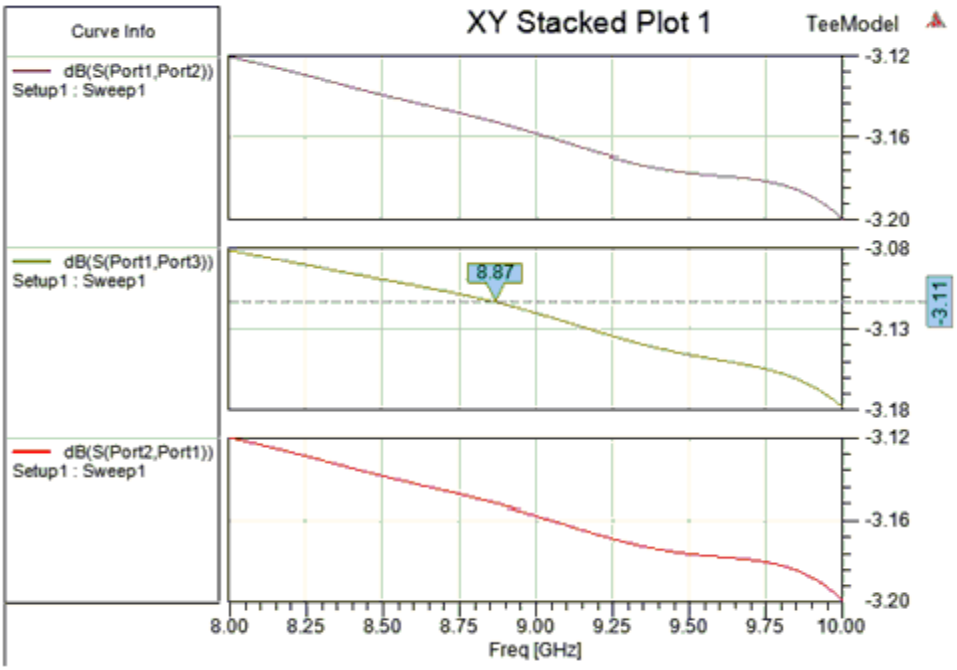
Y Markers allow for easy analysis and comparison of curves at a particular y-coordinate. Y Markers can be used to compare stacked curves.

Creating Y Markers in Stacked Plots

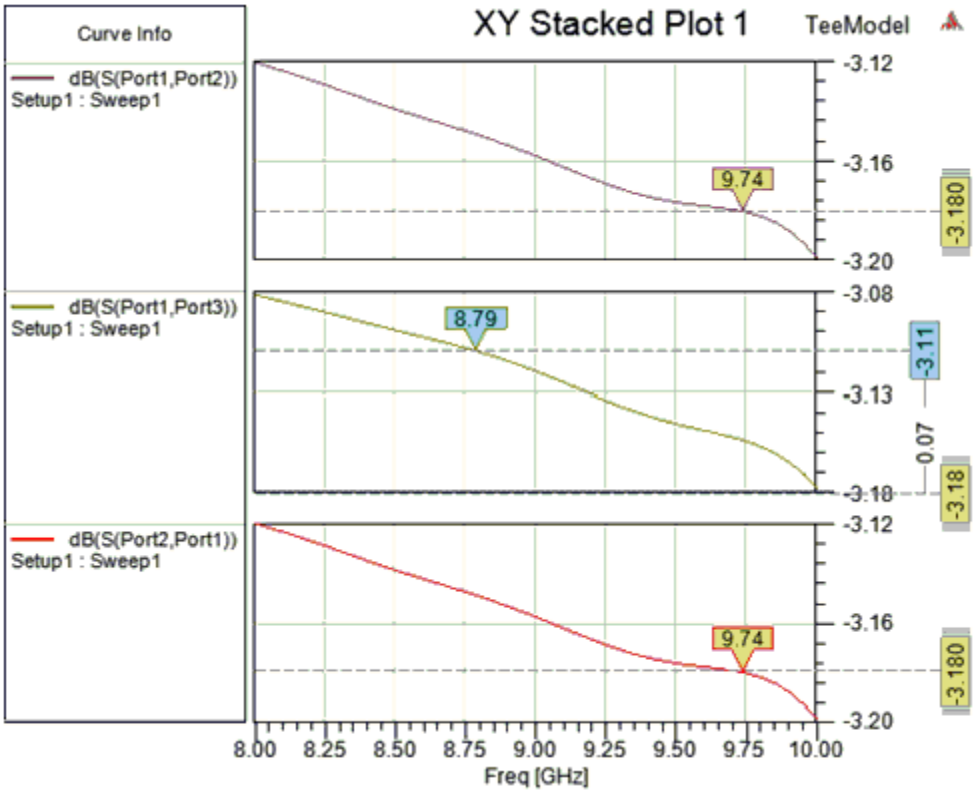
There are two ways to create Y Markers in Stacked Plots. You can create a Y Marker for a particular stack or for all stacks. Right clicking on any stack shows the following context menu:



Add Y Marker > Current Stack creates a Y marker for the stack on which the user performed right mouse button click. The following figure shows that a Y Marker was added to the second stack only:



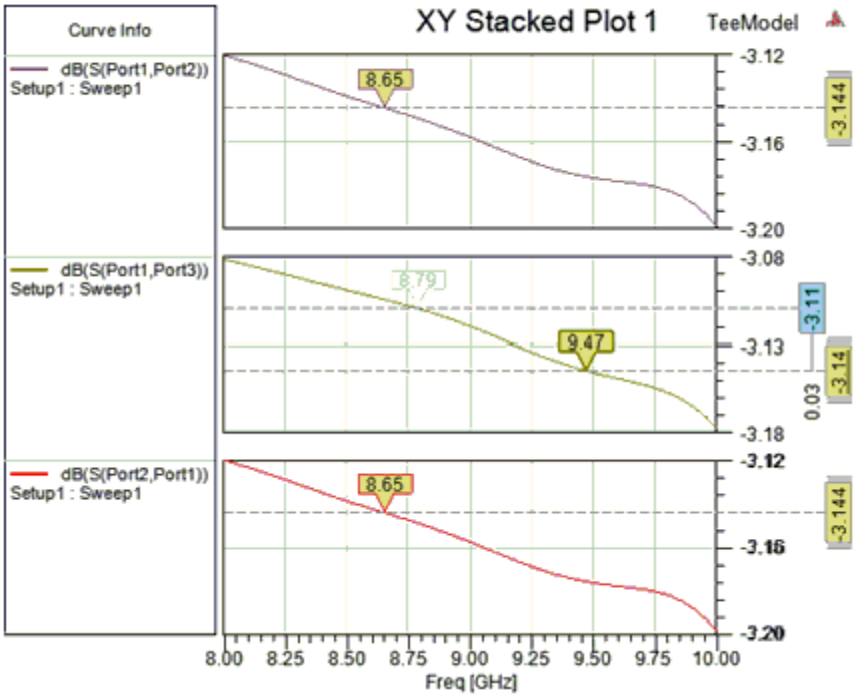
Add Y Marker >All Stacks creates one Y marker in each stack with the same value. Initially this value is the minimum Y value of the Y ranges in all the stacks. This is shown is the figure below:



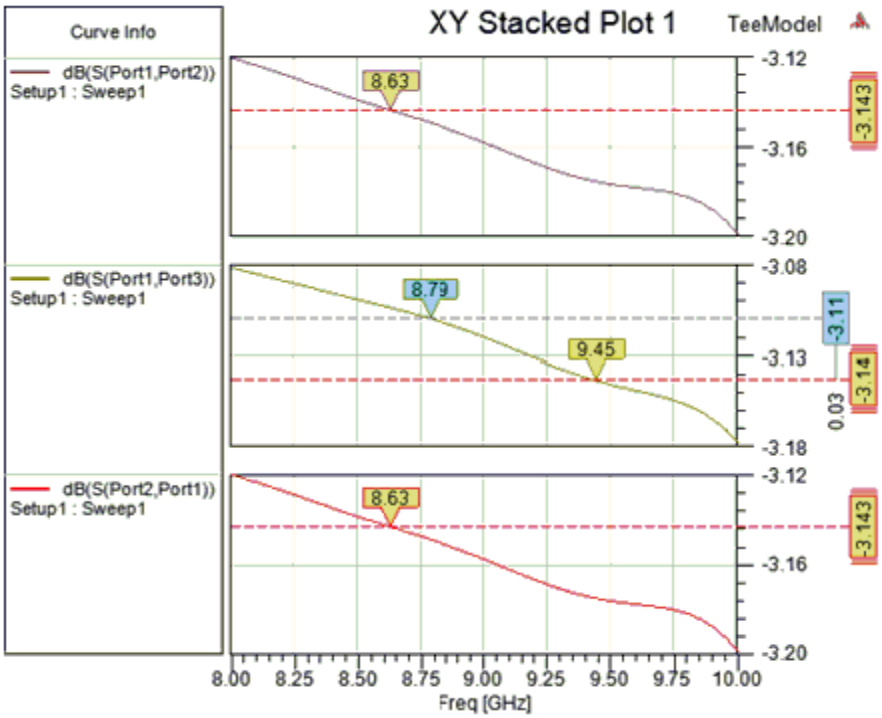
Notice that the Y Marker for All Stacks has a different appearance than the Y Marker for a particular stack: that is, it has double parallel lines above and below the Y Marker textbox.

Synchronized Y Markers

All the "same" Y markers for all stacks are synchronized, that is to say that if one Y marker is dragged or its value is changed, all the "same" Y markers in all the stacks will change their position too. The following figure shows that when a Y marker in the bottom stack was dragged, the Y marker in top stacks moved as well:

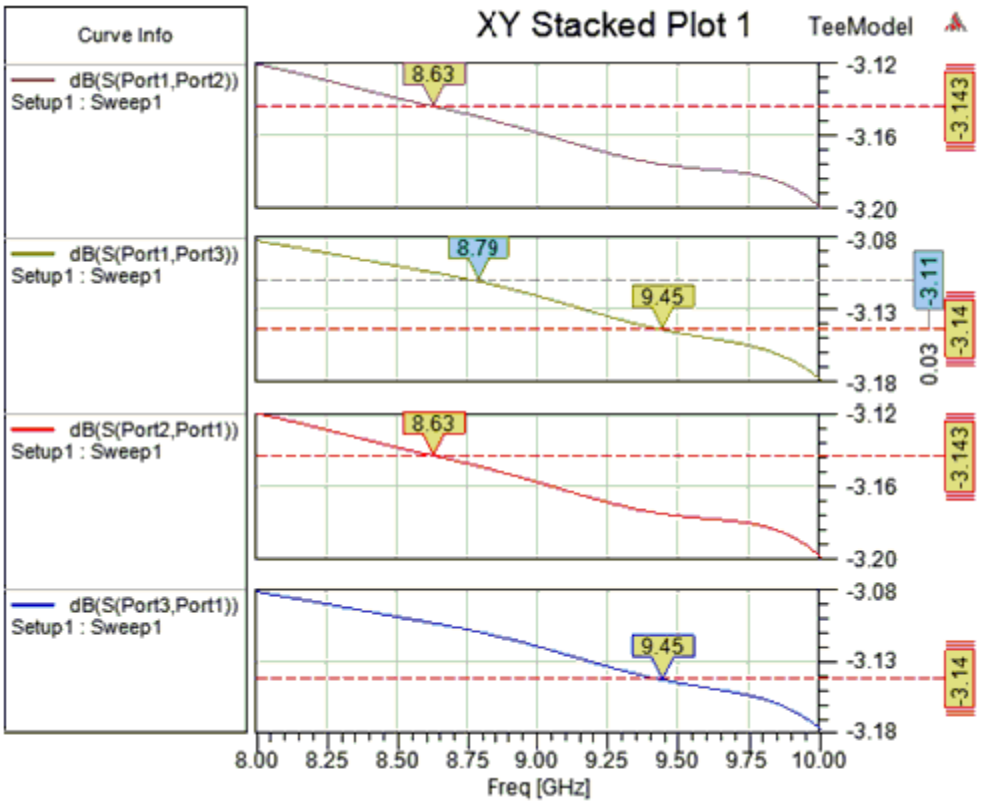


Also if a property of any one Y Marker is changed, all the "same" Y Markers show the change in property as well. For example, the following figure shows that when the line color of a Y Marker in the top stack was changed to a red color, a Y Marker in the bottom stack shows the same line color as well:



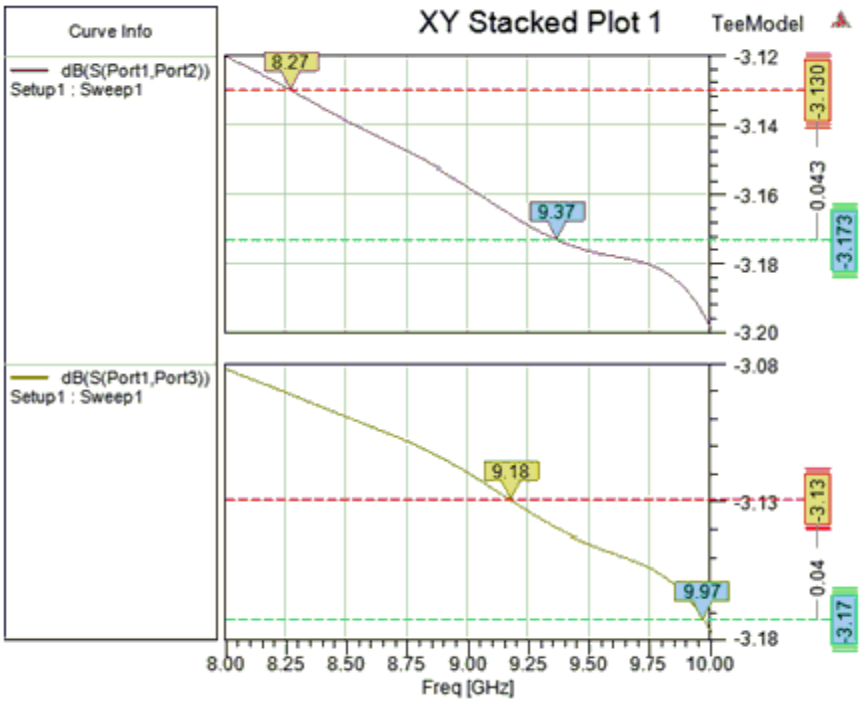
Automatic Y Markers for the new stack

When a new curve is added to the plot, it gets all the Y Markers for all stacks in other stacks, excluding the Y Marker for particular stacks.The following figure shows that when the new curve "dB(S(Port3, Port1)" was added, a Y Marker was added to it with value -3.14 and it has all the same properties as other "same" Y Markers in other stacks:



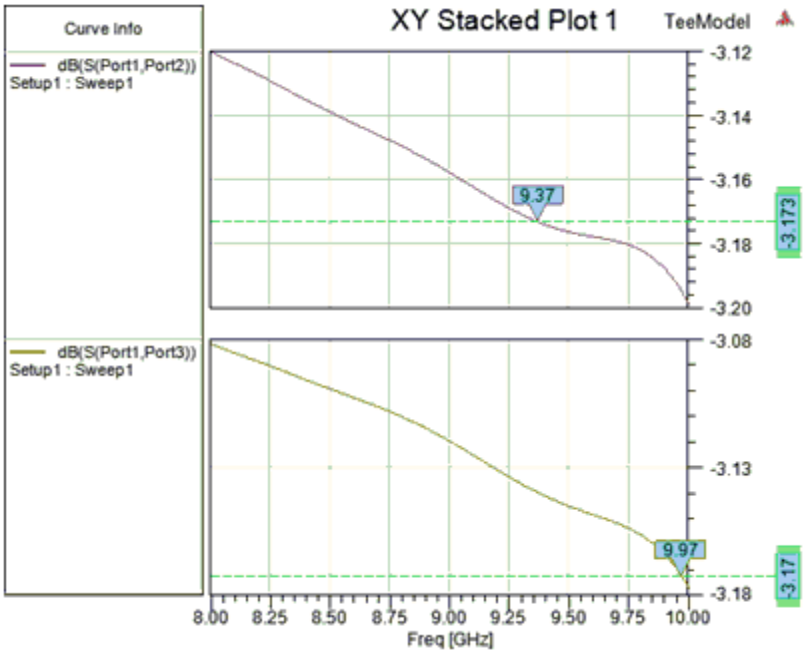
Y Marker Delta Annotations

When two more Y Markers are present in a Stacked Eye Diagram, then delta annotations are shown between a pair of adjacent Y Markers in all the stacks, as shown in the following figure:



Deleting a Y Marker

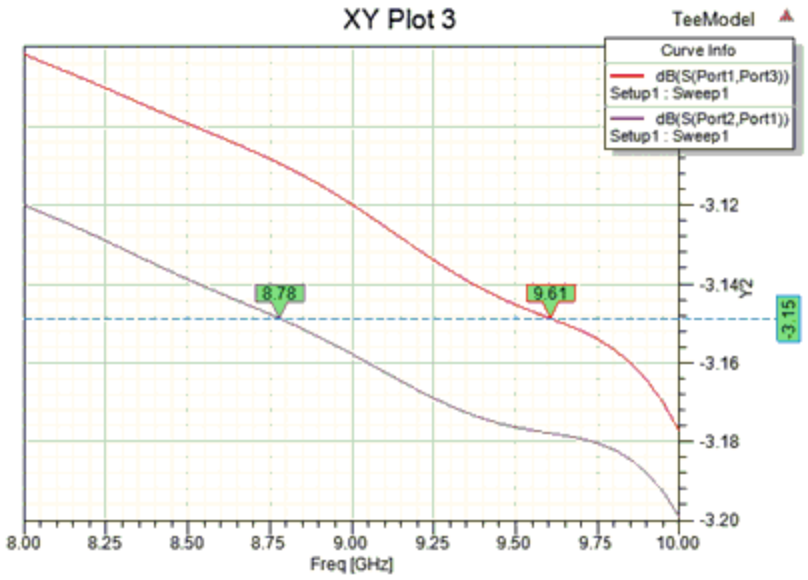
To delete a Y Marker, select a Y Marker in any stack and press the Delete key. This action will also delete all the corresponding Y Markers in all the stacks. For example, when the Y Marker with value -3.13 (red Y Marker) was deleted from the bottom-most stack, all of the corresponding Y Markers were also deleted:



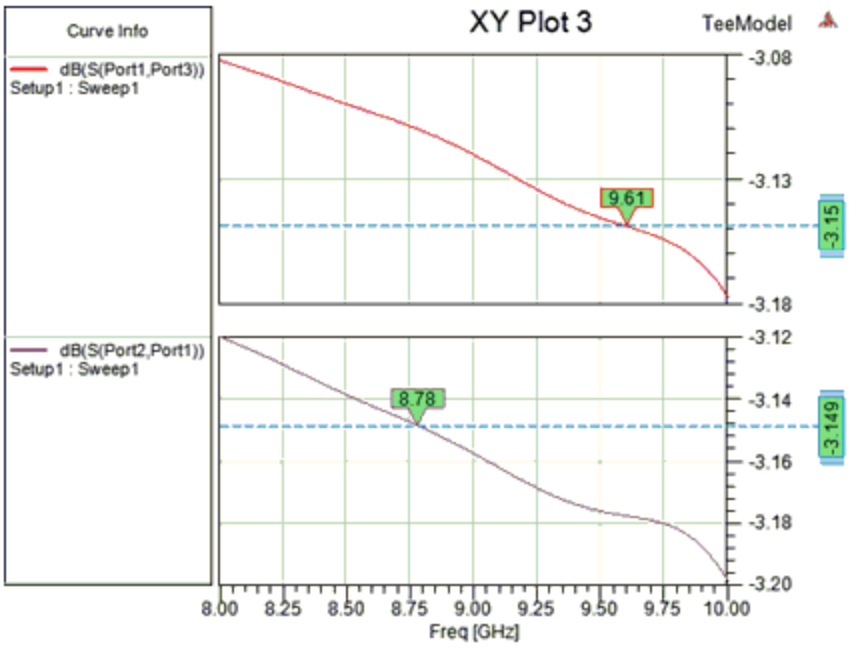
Note that on deleting a stack, Y Markers in other stacks are not affected.

Converting Rectangular XY Plot to Rectangular Stacked XY Plot

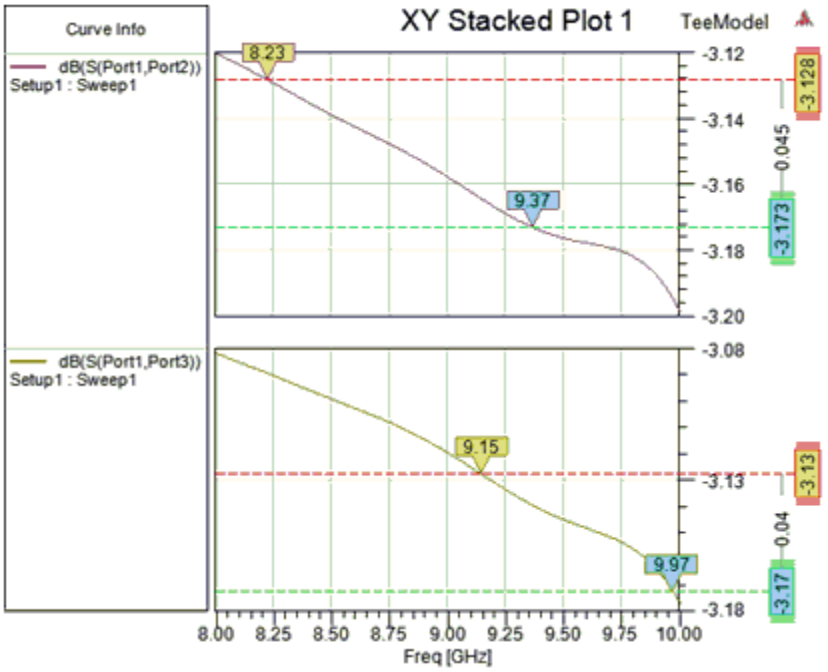
The following figure shows a Rectangular XY Plot with two curves and a Y Marker with value -3.15 (blue Y Marker):



If you change the Display Type property of this plot to Rectangular Stacked Plot, then a Rectangular Stacked XY Plot is created with each curve in its own stack and a Y Marker is shown in each stack with value -3.15 (blue Y Marker):



Similarly when you change a Rectangular Stacked XY Plot to a Rectangular XY Plot, then all the "same" Y Markers in all the stacks are shown as a single Y Marker in the Rectangular XY Plot as shown in following figures:



The Rectangular Stacked XY Plot in the previous figure, when converted to Rectangular XY Plot, looks like the following figure:

Adding Data Markers to Traces
Rectangular Stacked Plot

Discarding Report Values Below a Specified Threshold

To prevent real small numbers from skewing a plot, you can discard small values (below a specifiable threshold).

1. Double-click on the X or Y axis of interest on an open plot display.
   This opens the **Properties** window for the Axis
2. Under the **Axis** tab, use the scroll bar to find the **Specify Discard Values** property.
3. Click the check box to enable the property.
4. Enter a value in the **Discard Below** field. Units specified elsewhere in the Axis property are applied to this value. The Discard Below text box is inactive if the Specify Discard Values check box is not enabled.
5. Click **OK** to apply the Discard Values to the report.

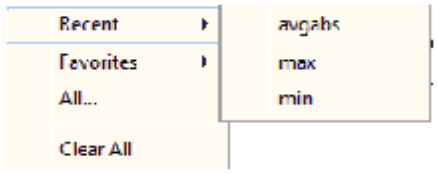
Adding Characteristics to a Trace

There are several options for adding characteristics to a trace. When you click **Report 2D>Trace Characteristics**, or right-click a selected trace, the short cut menu is displayed. The following example shows the menu with expanded **Recent** selections.



Adding a Recently Used Trace Characteristic

Adding a Trace Characteristic from Favorites
Adding Trace Characteristics to your Favorites
Adding Characteristics using the Add Trace Characteristics Dialog
Removing All Trace Characteristics

Adding a Recently Used Trace Characteristic

If you recently used a characteristic, you can add it to a selected trace by selecting from a list of recently used characteristics. A maximum of 10 is displayed in the menu, and they are sorted alphabetically.

To add a recently used characteristic to a selected trace:

1. Select a trace in a report plot or legend.
2. Click **Report 2D>Trace Characteristics**, or right-click on the selected trace to display the short cut menu.
3. Select **Recent**, and then select the function you want. The specified characteristic is added to the trace.

Adding Trace Characteristics to your Favorites

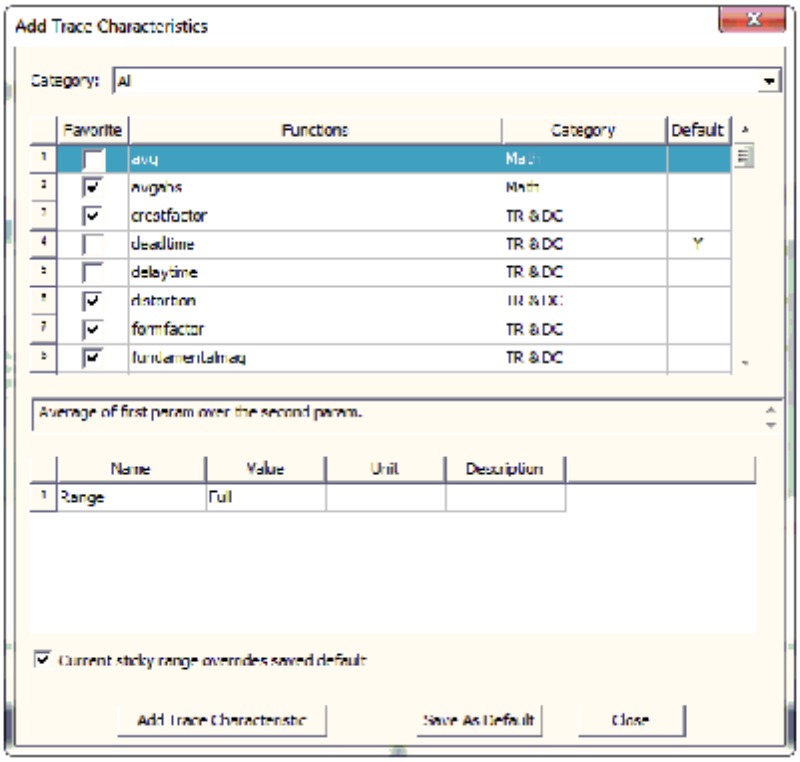
You can add trace characteristics to your list of favorites.

To add characteristics to your list of favorites:

1. Select a trace in a report plot or legend.
2. Click **Report 2D>Trace Characteristics**, or right-click on the selected trace to display the short cut menu.
3. Select **All**. This displays the **Add Trace Characteristics** dialog box.



4. Click the **Favorite** check box in front of any function you want to add to Favorites. You can define as many favorites as you need, but no more than 10 are displayed in the menu, and they are displayed in alphabetical order.
5. Click **Close**. You can view the current favorites by selecting Favorites in the Category drop-down list

Note	You can remove favorites by clearing the **Favorite** check box for one or more functions, and clicking **Close**.

Adding a Recently Used Trace Characteristic

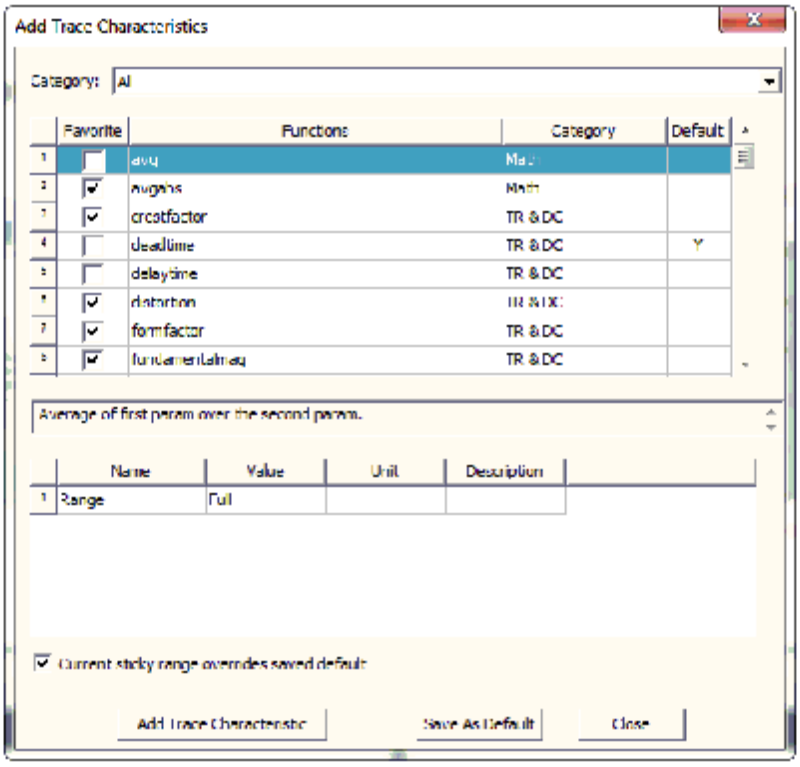
Adding a Trace Characteristic from Favorites

Adding Characteristics using the Add Trace Characteristics Dialog

You can add characteristics to a selected trace by selecting from the **Add Trace Characteristics** dialog box.

To add additional characteristics to a selected trace:

1. Select a trace in a report plot or legend.
2. Click **Report 2D>Trace Characteristics**, or right-click on the selected trace to display the short cut menu.
3. Select **All**. This displays the **Add Trace Characteristics** dialog box.

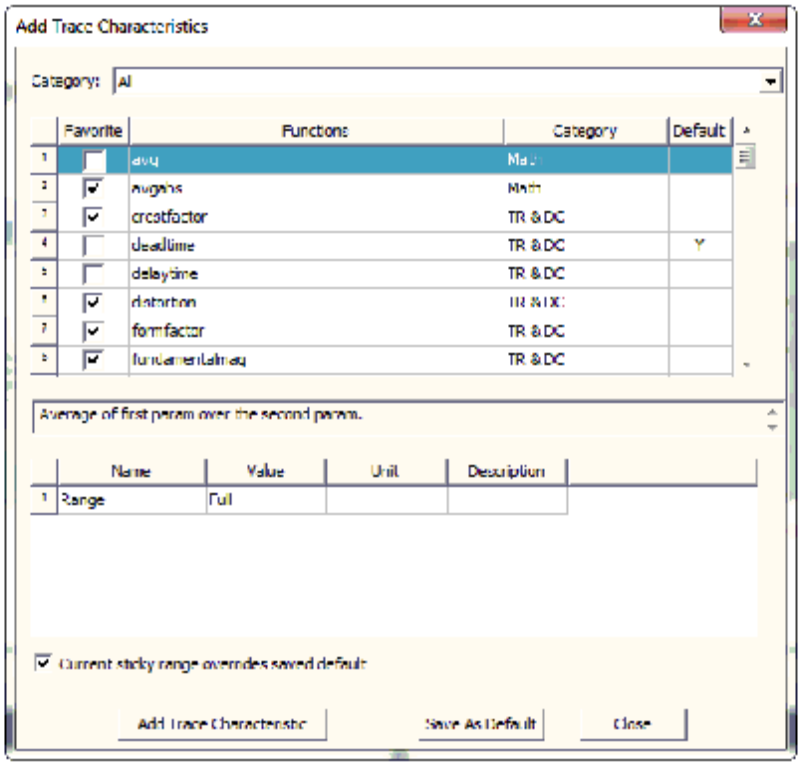


4. Select the **Category**. The available categories depend on the plot, and the selecting of a category displays its associated functions.

Category	Functions
Recent	Displays the most recent functions used, sorted by the time they were added.
Favorites	Displays all favorites. The defaults are avg, max, min, and pk2pk.
All	Displays all available functions.
Math	avg, avgabs, integ, integabs, max, mean, min, pk2pk, pkavg, ripple, rms, rmsAC, stddev, sum, variance, XatYMax, XatYMin, XatYVal, XWidthAtYVal, YatXMax, YatXMin, YatXVal
PulseWidth	pulsefall9010, pulsefront1090, pulsefront3090, pulsemax, pulsemaxtime, pulsemin, pulsemintime, pulsetail50, pulsewidth5050, pw_minus, pw_minus_avg, pw_minus_max, pw_minus_min, pw_minus_rms, pw_plus, pw_plus_avg, pw_plus_max, pw_plus_min, pw_plus_rms
Overshoot/ Undershoot	overshoot, overshootAbs, undershoot, undershootAbs
TR & DC	crestfactor, deadtime, delaytime, distortion, formfactor, fundamentalmag, risetime, settlingtime
Error	iae, ise, itae, itse
Period	per, pmax, pmin, prms
AC	gainmargin, phasemargin, gaincrossover, phasecrossover, lowercutoff, uppercutoff, bandwidth, peakgain, peakgainfreq
Radiation	lSidelobeY, rSidelobeY, lSidelobeX, rSidelobeX, xdb10Beamwidth, xdb20Beamwidth
Eye Measurements	EyeLevelZero, EyeLevelOne, EyeAmplitude, EyeHeight, EyeSignalToNoise, EyeOpeningFactor, EyeWidth, EyeJitterP2P, EyeJitterRMS, EyeRiseTime, EyeFallTime, MinEyeWidth, MinEyeHeight
TDR	Shunt_C_in_pF, Series_L_in_nH

For a selected function, the **Add Trace Characteristics** dialog displays the function's purpose in a text field.

5. Some categories and functions call for you to specify one or two additional values in a table. You can save these values using the **Save as Default** button. The Default column shows a Y if there is a saved default value for the function.



6. Select the **Current sticky range overrides saved default** check box if you do not want the range value in the table to be changed when the function selection is changed: the current range value becomes the “sticky range.” If the check box is not checked, the range value is updated from the saved default values and becomes a new sticky range.
7. Click the **AddTrace Characteristic** button to add the specified characteristics to the trace.
8. Click **Close**.

Removing Traces

You can remove traces from the traces list in the following ways:

To *remove one trace* from the report:

- Select the trace you want to remove from the Project tree, and then click **Delete**.

To *remove all traces* from the report:

- Select all the traces and click **Delete**.

Copy and Paste of Report and Trace Definitions

You can copy and paste report and individual trace definitions within a single design or across designs. The report or trace definition will be evaluated within the context of the target design or report.

Note	If the report or trace definition contains properties that do not exist in the target design (for example, a port name) an error will be posted that indicates a solution does not exist for this trace

Note	You must copy and paste trace definitions between the same report types.

To copy a Report Definition:

Right click on the report name in the project tree and select **Copy Definition** from the shortcut menu.

To paste the Report Definition:

Right click on Results in the project tree of the target design and select **Paste**.

A new report is created and it contains the copied definitions.

To copy an individual Trace Definition(s):

Right click on the trace or traces under a report name in the project tree and select **Copy Definition**.

To paste the Trace Definition(s):

Right click on the report in the target design to which you would like to copy the trace or traces and select **Paste**.

A new trace(s) is added to the report and it contains the copied trace definition(s).

Note	If you copy and paste a report or trace definition to a design which contains a definition with the same name, then an incremented number is appended to the pasted report or trace name.

Copy and Paste of Report and Trace Data

Copy and Paste of Report and Trace Data

You can copy and paste report and individual trace data within a single design or across designs. The report and trace definitions and all underlying data within the report or trace are copied and pasted to the target design or report.

To copy all data from a report:

Right click on the report name in the project tree and select **Copy Data**, or use the menu bar **Edit>Copy Data**, or right click within a plot to display a shortcut menu with **Copy Data**.

To paste copied report data:

Right click on Results in the project tree of the target design and select **Paste**.

To copy data from an individual trace(s) in a report:

Right click on the trace or traces under a report name in the project tree and select **Copy Data**.

To paste copied trace data:

Right click on the report in the target design to which you would like to copy the trace data and select **Paste**.

Note	If you copy and paste report or trace data which contains the same name definition as a report or trace in the target design then an incremented number will be appended to the pasted name

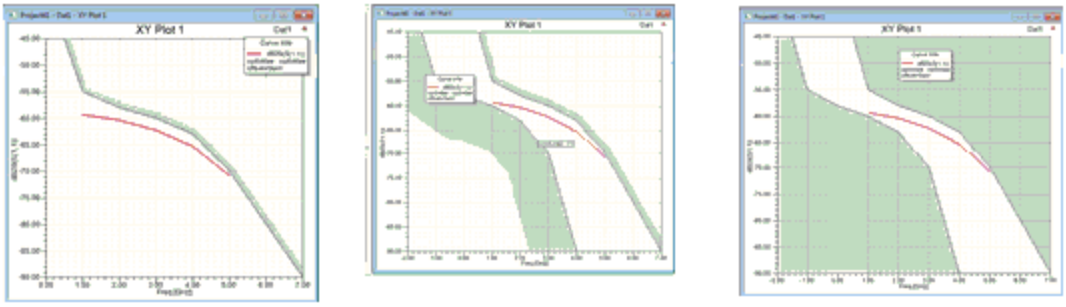
Limit Lines in Cartesian Plots

Limit lines are simple graphical representations of constraints on XY plots. These are modeled as a sequence of XY point pairs. For example, you can designate a single limit line to delineate either an upper or lower limit, or two limit lines to delineate upper and lower limits. You can add as many limit lines as you want. You can control the display properties of the line including color and hatch width.



Note	Limit lines are available only on Rectangular (XY) plots - not on XY-like plots such as Bode, Rectangular Stacked, etc.)

You can create limit lines in the following ways:

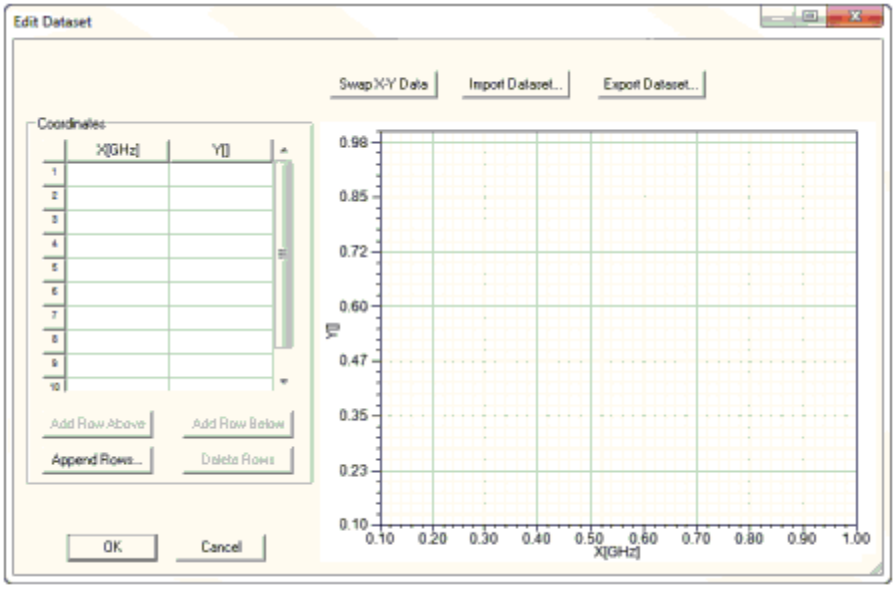
- by specifying points to define the line(s)
- from a selected curve on the plot.

Related Topics

Specifying Points to Create Limit Lines
Creating Limit Lines From a Selected Curve
Editing Limit Lines
Modifying the Background Properties of a Report

Specifying Points to Create Limit Lines

1. Click **Report2D>Add Limit Line>Specify Points** or right-click on an XY plot and select **Add Limit Line>Specify Points** from the context menu to open the **Edit Dataset** dialog.



You can use this dialog to:

- Enter the XY coordinate values directly.
- Import XY values from a tab-delimited **.tab** file.
- Export Dataset to a file.

If you require additional data points, you can use the buttons to **Append Rows** to the **Coordinates** table. If you select a row in the Coordinates table, you can then use the buttons to add a row above or a row below the selected rows, or to delete rows.

You can use Shift+click to select multiple adjacent rows, or Ctrl+click to select any combination of rows for deletion.

Note	Each limit line is associated with a particular Y axis (since it has to be scaled the same way as all the curves associated with the axis, follow its log/linear scale, etc.). This Y axis association defaults to the first available Y axis when the limit line is created. However, if the plot contains multiple Y axes, it can be associated with a different Y axis later via its properties tab.

2. When you click **OK**, the limit line you defined is added to the plot. The line divides the plot into regions within the context of its length. By default, the region above the limit line is

hatched.

Creating Limit Lines From a Selected Curve

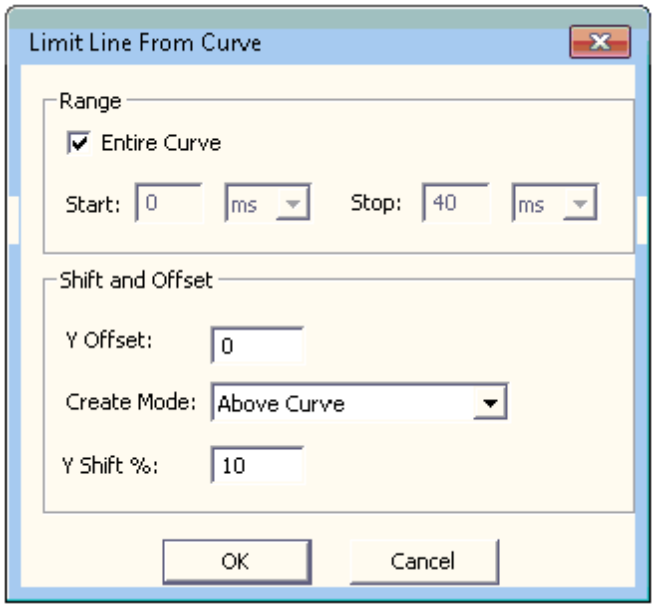
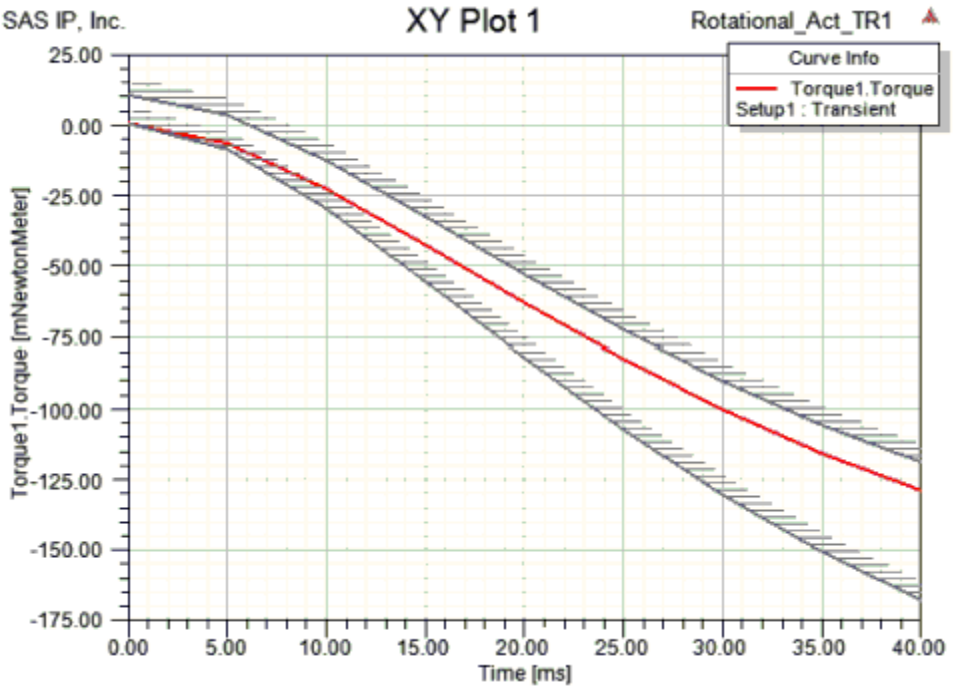
1. To create limit lines from a selected curve you must first click on the desired plot curve and then select **From Selected Curve** to open the **Limit Line From Curve** dialog.



2. The **Limit Line From Curve** dialog allows you to create limit lines over the **Range** of the **Entire Curve**, or between specified X-axis **Start** and **Stop** points. **Create Mode** controls whether limit lines are **Above Curve**, **Below Curve**, or **Above and Below Curve**. You can also specify a **Y Offset** value, which sets a constant distance between the curve and limit line(s); and a **Y Shift %**, which shifts the limit line(s) by the specified percentage of the Y-axis values. In the following example the upper limit line has a Y Offset value of 0.01 and no Y Shift %, while the lower limit line has a Y Shift % of 30 and no Y Offset,



3. When you click **OK**, the limit lines you defined are added to the plot. The lines divide the plot into regions within the context of its length. By default, the region above a limit line is hatched.

Related Topics

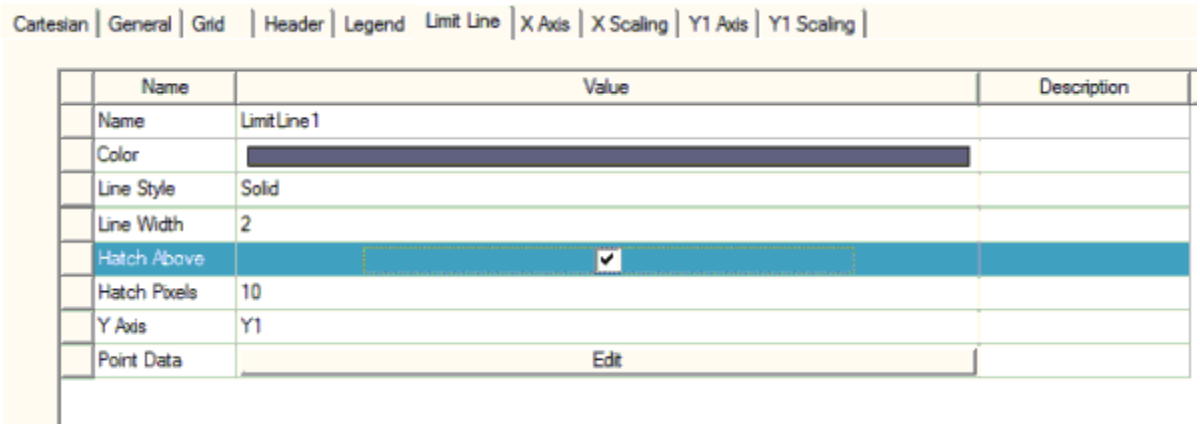
Specifying Points to Create Limit Lines

Editing Limit Lines

Modifying the Background Properties of a Report

Editing Limit Lines

You can select a limit line in a plot to edit the following properties on the **Limit Line** tab of the plot properties dialog.



- Color – affects both line and hatching
- Style and Width – affects only the line, not the hatching
- Y Axis Y– axis associated with the limit line
- Hatch Pixels – sets the length of the hatch lines
- Point Data – edit the data that defines the limit line
- Hatch Above – sets the direction of the hatch lines (above or below) the limit line

For example, if you add a second limit line, you could designate it as hatch below by unchecking **Hatch Above** to produce a “tunnel” marking the upper and lower constraints.

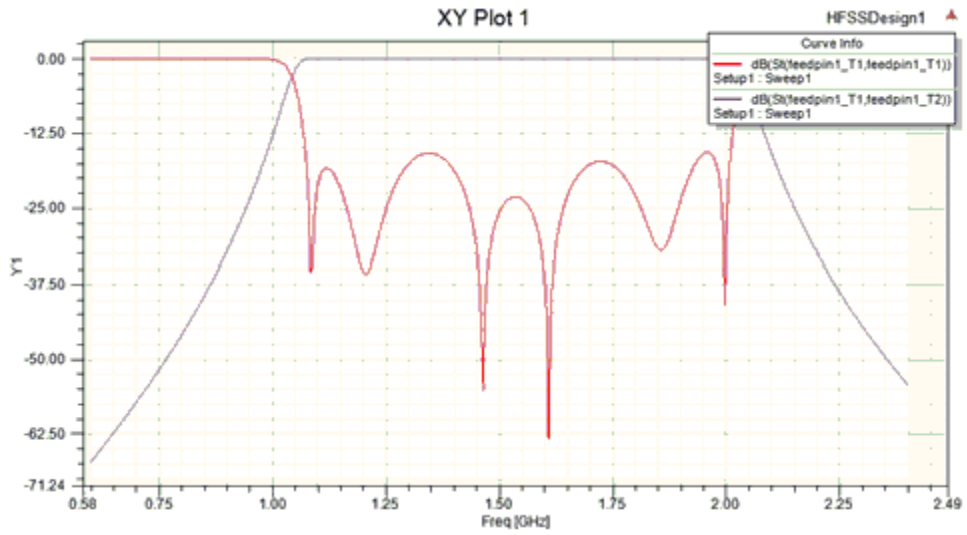
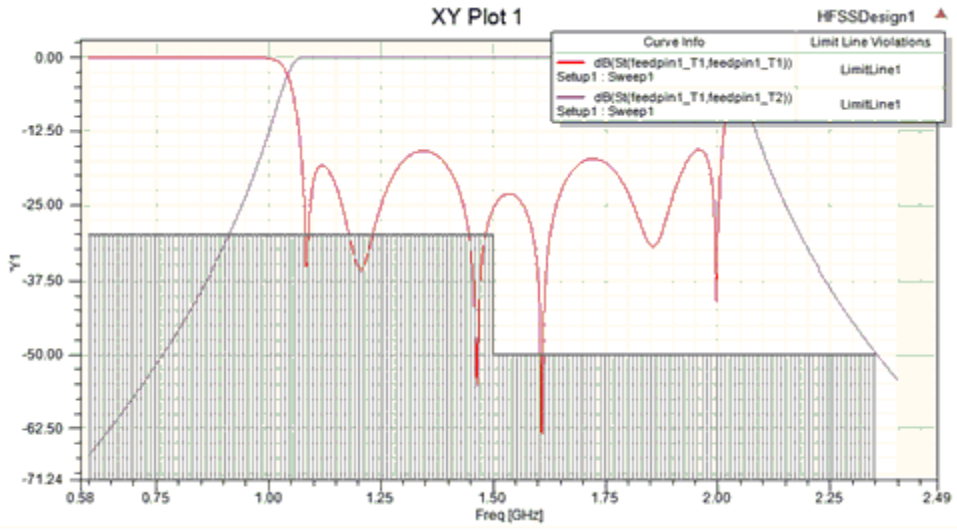
Limit Line Violations

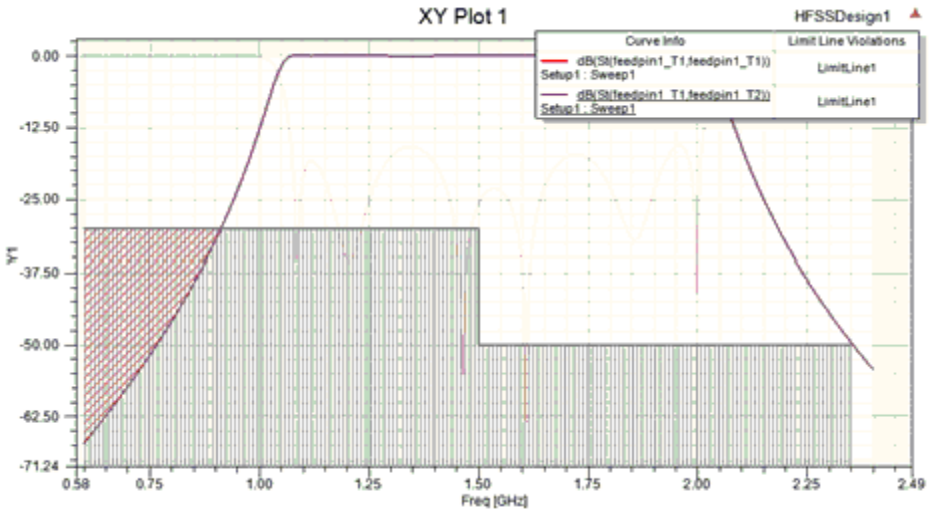
A plot feature can help you detect whether or not a curve violates the limits set by a limit line. Consider the following plot, which shows two curves:



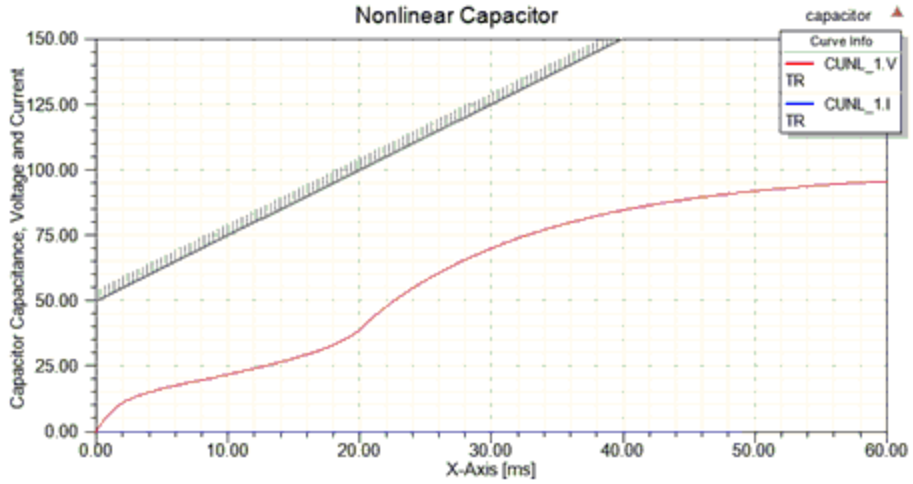
Suppose that the desired response cannot be below -30 dB at frequencies below 1.5 GHz and below -50 dB above 1.5 GHz. If you add a limit line for these requirements in the plot, the plot automatically calculates whether a curve violates this limit line requirement and displays it in the legends window, as shown in following figure:



If a curve is selected, the plot shows the region of the curve that violates the limit line (shaded with slanted red lines), as shown in following figure:



If no curve violates a limit line, the limit line hatching is limited to 10 pixels, as shown in the following figure. This is done to retain focus on the curves instead of the limit lines.



Error Handling

If plot encounters an error while calculating Limit Line Violations, the legend window shows NaN (Limit Line name) in front of the curve in the Limit Line Violations column. This ensure that you do not get misleading information about no-violations when the issue is actually a limitation in our code.

Sweeping a Variable in a Report

In Maxwell, a swept variable is an intrinsic, project, or design variable that typically has more than one value. You can plot any calculated or derived quantity against one or more of the swept variable's values.

To specify the swept variable values to plot a selected quantity against:

1. In the **Report** dialog box, select the variable from the X (Primary Sweep) pull-down menu.
2. To modify the values that will be plotted for a variable:
   a. Click the ellipsis **[...]** button on the **X (Primary Sweep)** line of the **Report** dialog to displays a popup list of the possible values.
   b. Select **Use all values** or **Select values** and click the **Edited** button to display a dialog that lets you specify the sweeps to use.
   All of the selected variable's values will be plotted.

Note	When specifying a Time sweep for a solution that is defined with varying save field, it is recommended that you select **Use all values**.

Sweeping Values Across a Distance

1. If you are plotting a field quantity along a line, define a polyline object in the problem region.
2. In the **Report** dialog box, click the line geometry of interest in the **Geometry** list.
3. Specify the quantities you want to plot along the axes.
4. For the **X (Primary Sweep)**, select the **Distance** variable.
   The values at which the selected quantity or quantities will be plotted are listed to the right. By default, a post-processing polyline object is divided into 100 equally spaced points.

Selecting a Function

The value of a quantity being plotted depends upon its mathematical function, which you select from the **Function** list in the **Report** dialog box. The available, valid functions depend on the type of quantity (real or complex) that is being plotted. The function is applied to the quantity which is implicitly defined by all the swept and current variables. "Volume(Stator)" is the volume of the model object named Stator for every swept combination of variables ("height" and so forth).

These functions can also be applied to previously specified Quantities and Functions as **Range Functions** when using the **Set Range Function** dialog.

Some of these functions can operate along an entire curve. These are: min, max, integ, rms, pk2pk, cang_deg and cang_rad.

You can select from the following functions in the **Trace** tab **Function** list or type them directly into the Y or X field, if necessary:

abs	Absolute value of the simulation quantity which results in a number that is always positive.
acos	Arc cosine (the inverse function of a cosine).
acosh	Inverse hyperbolic arc cosine.
ang	Magnitude of an angle.
ang_deg	Angle (phase) of a complex number, cut at +/-180. Returns angular values in degree units, and not suitable for use in Optimetrics, which works in SI values and evaluates ang_deg expressions in radians. See ang_deg_val.
ang_deg_val	Angle (phase) of a complex number in unitless degree values, and suitable for use in Optimetrics, which works in SI values. Returns simple numbers.
ang_rad	Angle in radians.
arg	Argument of a complex number. It is the angle the complex number makes with the positive x axis. Same as **ang_deg**.
asin	Arc sine (the inverse function of sine).
asinh	Inverse hyperbolic sine.
atan	Arc tangent (the inverse function of a tan).
atanh	Inverse hyperbolic tan.
atan2	Two argument function. For non-0 x,y, the function returns the angle between the + x-axis and the given x,y coordinates.
avg	Returns the average of the values of the selected quantity. avg = (Area between the curve and the X-axis) / (X length of the curve)
avgabs	Returns the mean of the absolute value of the selected quantity.
bandwidth	Returns the 3dB bandwidth of the selected simulation quantity. For bandwidth, the calculation is based on 3dB below the maximum peak.
cang_deg	Cumulative angle (phase) of the first parameter (a complex number) in degrees, along the second parameter (typically sweep variable). Returns a double precision value cut at +/-180. Returns angular values in degree units, and not suitable for use in Optimetrics, which works in SI values and evaluates cang_deg expressions in radians. See cang_deg_val.
cang_deg_val	Cumulative angle (phase) of the first parameter of the selected simulation quantity in unitless degree values and suitable for use in Optimetrics, which works in SI values. . Returns simple numbers.
cang_rad	Cumulative angle of the first parameter in radians along a second parameter (typically a sweep variable). Returns a double precision value.
cmplx(*re*, *im*)	A complex number, where *re* is the real part and *im* is the imaginary part.

conjg	Conjugate of the complex number.
cos	Cosine.
cosh	Hyperbolic cosine.
crestfactor	Returns the crest factor (peak/RMS) for the selected quantity.
cum_integ	The cumulative integral function returns a set of values that have the same length as the original set of points (the first element will always be zero). Element *I* of the set returned by cum_integ is the integral of elements 1 through *I* of the original data set.
cum_sum	The cumulative sum function returns a data set that has the same length as the original set of points. Element *I* of the set returned by cum_sum is the sum of elements 1 through *I* of the original data set.
dB(x)	20*log10(|x|) to base 10.
dBc	Decibels relative to the carrier. It is the power ratio of the signal to a carrier signal. Gives the relative signal strength.
dBm(x)	10*log10(|x|) +30.
dBm	(for electric field quanitities) is computed as: 20.0*log10(x) + 60.0
dBu	(for electric field quanitities) is computed as: 20.0*log10(x) + 120.0
dBW(x)	10*log10(|x|).
dB10	10*log(|x|) to base 10.
dB10normalize	10*log [normalize(mag(x))].
dB20	20*log(x) to base 10.
dB20normalize	20*log [normalize(mag(x))].
deadtime	Obtains the latest time when the qtyl is within a tolerance of zero.
delaytime	Obtains the time from zero to 50% of the target point.
degel	Conversion from degrees electrical to seconds with respect to Hz.
deriv	Derivative of a given parameter.
distortion	Returns the total distortion for the selected simulation quantity and an additional argument frequency, which is the frequency in Hz at which to calculate the fundamental RMS of the simulation quantity.
even	Returns 1 if integer part of the number is even; returns 0 otherwise.
exp	Exponential function (the natural anti-logarithm) of the simulation quantity.
formfactor	Returns the form factor (RMS/Mean Absolute Value) for the selected quantity.
fundamentalmag	Returns the RMS value of the fundamental frequency for the selected quantity, and an additional argument, Frequency, which specifies the fundamental frequency.
gaincrossover	Returns the gain crossover frequency (where the gain is 0 dB) of the selected simulation quantity in Hz.
gainmargin	Returns the gain margin in dB at the phase crossover frequency of the

	selected simulation quantity. It also requires a reference simulation quantity to which the measured quantity is compared and the AC magnitude and phase angle of the reference quantity. These are entered as the arguments Reference Channel, Base Source Magnitude, and Base Source Angle.
iae	Returns the integral of the absolute deviation of the selected quantity from a target value that is entered via the additional argument.
if	if(cond_exp,true_exp, false_exp).
im	Imaginary part of the complex number.
int	Truncated integer function.
integ	Integral of the selected quantity. Uses trapezoidal area.
integabs	Absolute value of integral.
ise	Returns the integral of the squared deviation of the selected quantity from a target value that is entered via an additional argument.
itae	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument.
itse	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.
j0	Bessel function of the first kind (0^{th} order).
j1	Bessel function of the first kind (1^{st} order).
jn	Bessel function of the first kind (nth order).
ln	Natural logarithm.
log	Natural logarithm (same as ln).
log10	Logarithm base 10.
lowercutoff	Returns the lower 3dB frequency of the selected simulation channel in Hertz.
lsidelobeX	The 'x' value for the left side lobe: the next highest value to the left of the max value.
lsidelobeY	The 'y' value for the left side lobe: the next highest value to the left of the max value.
mag	Magnitude of the complex number.
max	Returns maximum value of the simulation quantity.
max_swp	Returns maximum value of a sweep.
max2	Maximum value of the two simulation quantities. For example, **max2(a,b)** will plot maximum of **a** and **b** for a particular instance.
mean	Returns the average in the set of quantities selected. mean = sum(all y-value) / (number of y-values)

min	Returns the minimum value of the simulation quantity.
min_swp	Returns the minimum value of a sweep.
min2	Minimum value of the two simulation quantities. For example, **min2(a,b)** will plot minimum of **a** and **b** for a particular instance.
mod	Returns the modulus or absolute value of the simulation quantity.
nint	Nearest integer.
none	Returns null value.
normalize	Divides each value within a trace by the maximum value of the trace. ex. normalize(mag(x)).
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise.
overshoot	Calculates peak overshoot given a threshold value and number of evenly spaced points over entire time range.
peakgain	Returns the peak value of gain of the selected simulation quantity in dB.
peakgainfreq	Returns the frequency in Hz at which the peak gain of the selected simulation quantity occurs.
polar	Coverts the complex number in rectangular co-ordinates to polar co-ordinates.
per	Returns the period of a simulation quantity.
phasecrossover	Returns the phase crossover frequency, at which the phase is -180 degrees, in Hz for the selected simulation quantity.
phasemargin	Returns the phase angle in degrees at the gain crossover frequency of the selected simulation quantity.
pk2pk	Peak to peak. Difference between max and min of the first parameter over the second parameter. Returns the peak-to-peak value for the selected simulation quantity.
pkavg	Returns the ratio of the peak to peak-to-average for the selected quantity.
pmax	Maximum period of the selected simulation quantity.
pmin	Minimum period of the selected simulation quantity.
pow	Raises x to the power of y; pow(x,y).
prms	Period Root Mean Square.
pulsefall9010	Returns the pulse fall time of the selected quantity according to the 90%-10% estimate.
pulsefront1090	Returns the pulse front time of the selected quantity according to the 10%-90% estimate.
pulsefront3090	Returns the pulse front time of the selected quantity according to the 30%-90% estimate.
pulsemax	Returns the pulse maximum from the front and tail estimates for the selected quantity.
pulsemaxtime	Returns the time at which the maximum pulse value of the selected

	quantity is reached.
pulsemin	Returns the pulse minimum from the front and tail estimates for the selected quantity.
pulsemintime	Returns the time at which the minimum pulse value of the selected quantity is reached.
pulsetail50	Returns the pulse tail time of the selected quantity from the virtual peak to 50%.
pulsewidth5050	Returns the pulse width of the selected quantity as measured from the 50% points on the pulse front and pulse tail.
pwl	Piecewise Linear.
pwl_periodic	Piecewise Linear for periodic extrapolation on x.
pwlx	Piecewise Linear x with linear extrapolation on x.
pw_minus	Pulse width of the first negative pulse.
pw_minus_avg	Returns the average of the negative pulse width input stream.
pw_minus_max	Returns the maximum pulse width of the negative pulse of input stream.
pw_minus_min	Returns the minimum pulse width of the negative pulse of input stream.
pw_minus_rms	RMS of the negative pulse width input stream.
pw_plus	Pulse width of the first positive pulse.
pw_plus_avg	Average of the positive pulse width input stream.
pw_plus_max	Max. Pulse width of the positive pulse of input stream.
pw_plus_min	Min. Pulse width of the positive pulse of input stream.
pw_plus_rms	RMS of the positive pulse width input stream.
re	Real part of the complex number.
rect	Converts the complex number in polar to rectangular co-ordinates.
rem	Fractional part of the selected simulation quantity (the remainder).
ripple	Returns the ripple factor (AC RMS/Mean) for the selected quantity.
risetime	Obtains the time taken to go from 10% to 90% of target point.
rms	Returnns the root mean square value of the selected quantity.
rmsAC	Returns the AC RMS for the selected quantity.
root	nth root function.
rSidelobeX	Returns the X value of right side-lobe occurrence.
rSidelobeY	Returns the Y value of right side-lobe occurrence.
settlingtime	Returns the latest time at which the value of the selected simulation quantity fell outside its tolerance band. The target value of the quantity and the +/- bandwidth of the tolerance band are the additional args.
sgn	Sign extraction.
sin	Sine.

sinh	Hyperbolic sine.
slidingmean	Returns the moving average value of the selected simulation quantity (specified by the first argument). The average is calculated over a period (specified by the second argument).
slidingrms	Returns the moving RMS value of the selected simulation quantity (specified by the first argument). The RMS value is calculated over a period (specified by the second argument).
sqr	Square of the selected simulation quantity.
sqrt	Square root of the selected simulation quantity.
stddev	Returns the standard deviation of given values.
sum	Returns the sum of the given values.
tan	Tangent.
tanh	Hyperbolic tangent.
undershoot	Calculates peak undershoot given a threshold value and number of evenly spaced points over entire time range.
uppercutoff	Returns the upper 3dB frequency of the selected simulation channel in Hz.
variance	Calculates the variance of the given values.
XAtYMax	Threshold crossing time: report first time (x value) at which an output quantity crosses YMax.
XAtYMin	Threshold crossing time: report first time (x value) at which an output quantity crosses a user definable threshold.
XAtYVal	Returns the X value at the first occurrence of Y value.
XWidthAtYVal	Returns the X width between the first 2 occurrence of Y value.
xdb10beamdwidth	Width between left and right occurrences of values 'x' db10 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
xdb20beamwidth	Width between left and right occurrences of values 'x' db20 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
YAtXMax	Returns the X value at maximum value of Y.
YAtXMin	Returns the Y value at minimum value of X.

Selecting Solution Quantities to Plot

Each trace in a report includes a quantity that is plotted along an axis. The quantity being plotted can be a value that was calculated by Maxwell, such as L_{11}, or a value from a calculated expression.

To select a parameter to plot:

1. In the **Report** dialog box, select one of the solution type dependent categories. Some of the available categories and descriptions of their associated quantities are listed below. The actual list you see will depend upon the solution type and solution setup for your design. The selected category provides the default name for the plot, such as Force Plot *n*. You can edit the plot names in the project tree and the plot header in the report properties.

Variables	Intrinsic variables, such as frequency or theta, or user-defined project variables, such as the length of a quarter-wave transformer.
Output Variables	Derived quantities from the original field solution.
L, R, or Z	Inductance, Resistance, and Impedance matrix entries when the matrix parameter is defined.
Force or Torque	Force or Torque values when the parameter is defined.
Loss	▪ **Loss quantities for 2D and 3D transient solutions include:** CoreLoss, EddyCurrentLoss, ExcessLoss, HysteresisLoss, SolidLoss, StrandedLoss, StrandedLossR, and StrandedLossAC. [1] The availability of solution data for CoreLoss, EddyCurrentLoss, ExcessLoss, and HysteresisLoss depends on the material definitions in the design: ◦ If the design is hysteresis model-based, the solver provides solution data to plot only for HysteresisLoss, EddyCurrentLoss, and TotalLoss. ◦ If the design contains a non- hysteresis based model, core loss model type: Electrical Steel, the solver provides solution data to plot for all four quantities (CoreLoss, EddyCurrentLoss, ExcessLoss, and HysteresisLoss). ◦ For all other cases (for example: linear, power ferrite), the solver provides solution data to plot only for CoreLoss. **Note** For 2D transient solutions only, object-based quantities of CoreLoss, EddyCurrentLoss, ExcessLoss, and HysteresisLoss are also calculated, and can be selected for plotting, for objects whose **Core Loss Setting** has been checked in the **Set Core Loss** dialog box.. ▪ **Loss quantities for 2D and 3D eddy current solutions include:**

	CoreLoss, SolidLoss, StrandedLoss, StrandedLossAC, and StrandedLossR.
End Connection	• If a 2D transient End Connection excitation has been assigned, quantities include: Current, InducedVoltage, RingCurrent (the current in the first segment of the ring), and SolidLoss. • If a 2D eddy current End Connection excitation has been assigned, quantities include: Current and InducedVoltage.
Expression Cache	The values of expressions listed in the Expression cache of the Solution setup can be plotted, for example, as a function of adaptive pass to monitor their convergence.
Expression Converge	This can be used to plot convergence, as a function of adaptive pass, of expressions defined in the Expression cache of the Solution setup. When defining the report, for "Context", select Solution: *SetupN:Adaptive Pass*.

[1]*NOTE: StrandedLoss includes DC losses only; while StrandedLossAC includes DC losses and additional AC losses due to skin effect and proximity effect.*

2. Select a quantity to plot from the **Quantity** list. The available quantities depend on the selected category and the setup of the design.

Assigning an End Connection for a 2D Transient Solver

Selecting a Field Quantity to Plot

When plotting field quantities in the **Report** dialog box, the quantity can be a value that was calculated by Maxwell, such as a value from a calculated expression.

When you select **Fields** as the **Report Type** and select a line geometry from the **Solutions** pull-down list, three options are available for plotting versus length:

- Plot vs. actual distance along the line (in the units you specified).
- Plot vs. normalized distance.
- Plot vs. actual coordinate values of the line.

Plotting Imported Solution Data

1. In the **Solution** pull-down list in the **Report** dialog box, click the imported data you want to plot.
2. Follow the procedure for creating a report.

Post-Processed Quantities

Both pre-processing and post-processing quantities are available when creating reports.

For example, when you create a Magnetostatic Report for the **Magnetostatic Solver** the following are four of the quantities that appear in the **Category** list in the **Report** dialog box:

- **L** – The post-processed value of inductance (for example, the inductance of a 1-turn coil).
- **Lnom** – The inductance quantity that is solved with no post processing.
- **MagFlux** – The post-processed value of the total magnetic flux as seen by the coil (current source) including all sources (current, magnets, etc.).
- **MagFluxNom** – The total magnetic flux quantity that is solved with no post processing as seen by the coil (current source) including all sources (current, magnets, etc.)

Similarly, for an Eddy Current Report, the following are three of the quantities that appear in the **Category** list:

- **Winding** – If the design includes windings, Flux Linkage, Induced Voltage, Input Current, Input Voltage, and Current quantities are available (depending on the winding type). See also "Viewing Winding Results (Eddy Current)" on page 23-16 .
- **Loss** – Hysteresis Loss (Maxwell 2D Eddy current solutions only), Core Loss, Solid Loss, Stranded Loss Stranded Loss R, and Stranded Loss AC. See also "Viewing Loss Results (Eddy Current)" on page 23-17 .
- **End Connection** (Maxwell 2D Eddy current solutions only) – Induced Voltage, and Current. See also "Viewing End Connection Results (2D Eddy Current)" on page 23-16 .

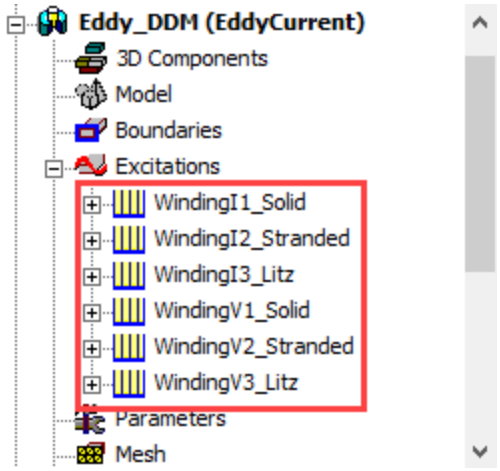
Per-Winding Loss Outputs for Maxwell 2D/3D Transient and Eddy Current Designs

Maxwell 2D/3D transient (T-omega only) and eddy current designs support loss quantity outputs for each winding when creating reports.

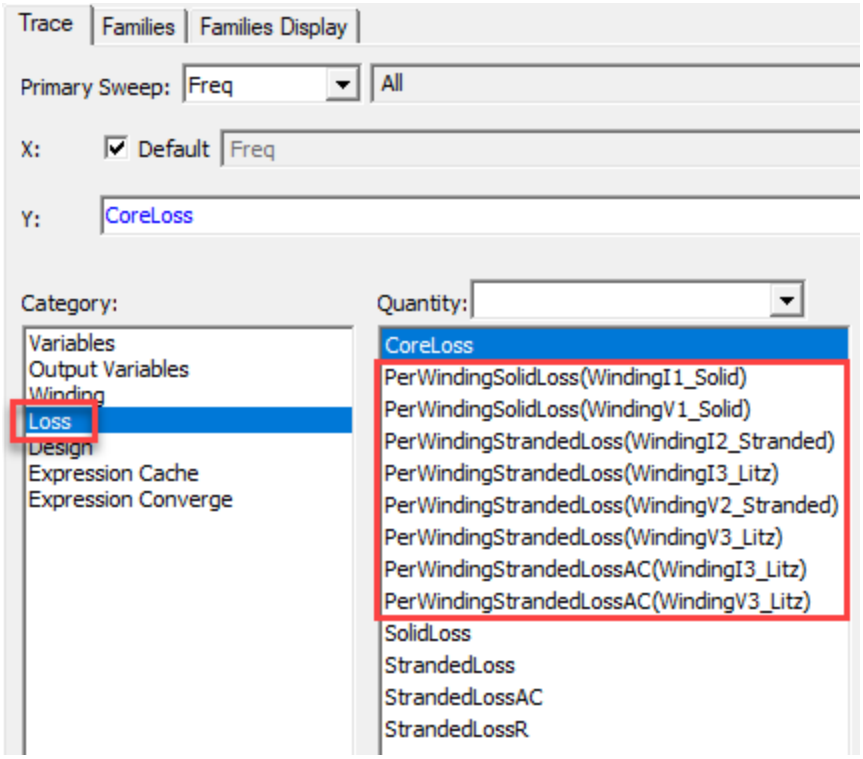
For the various winding types, the supported per-winding loss quantities are:

- Solid winding
  - **SolidLoss**
- Stranded winding without Litz wire
  - **StrandedLoss**
- Stranded winding with Litz wire
  - **StrandedLoss**
  - **StrandedLossAC**

For example, the winding assignments in the eddy current design shown below,



result in the following per-winding loss quantities available in the reporter.



> **Note:** Per-winding loss quantities will not affect legacy project reports.

Setting a Range Function

To apply a range function to the Y, Z, or Mag component of a trace:

Note	All range functions are available in the list regardless of solution context. You must select a function that is appropriate for the solution context and data type you are working with.

1. Click the **Range Function** button in the **Reports** dialog box.

   This opens the **Set Range Function** dialog. The functions available are the same as described in the Selecting a Function section, with the exception of those for the Eye Measurements category.

2. Click the Specified radio button on the Range function line.

   This enables the Range Function fields.

3. Select the **Category**, and then an associated Function to apply. The available categories depend on the plot, and Category enables the display of associated functions.

Category	Functions for the Category
Math	max, min, pk2pk, rms, integ, integabs, avgabs, rmsAC, ripple, pkavg, XatYMin, XatYMax, XatYVal
PulseWidth	pulsefall9010, pulsefront9010, pulsefront3090, pulsemax, pulsemaxtime, pulsemin, pulsemintime, pulsetail50, pulsewidth5050, pw_plus, pw_plus_max, pw_plus_min, pw_plus_avg, pw_plus_rms, pw_minus_max, pw_minus_min, pw_minus_avg, pw_minus_rms
Overshoot, Undershoot	overshoot, undershoot.
TR & DC	crestfactor, formfactor, distortion, fundamentalmag, delaytime, risetime, deadtime, settlingtime,
Error	iae, ise, itae, itse
Period	per, pmax, pmin, prms
Radiation	xdb10bandwidth, xdb20bandwidth, lSidelobeX, lSidelobeY, rSidelobeX, rSidelobeY
Eye Measurements	EyeLevelZero, EyeLevelOne, EyeAmplitude, EyeHeight, EyeSignalToNoise, EyeOpeningFactor, EyeWidth, EyeJitterP2P, EyeJitterRMS, EyeRiseTime, EyeFallTime

   Given a selected Function, and Category, the **Set Range Function** dialog displays a text field that explains the Purpose of the function. For a full list of functions and their definitions, see Selecting a Function.

   Selecting a function causes the display of a description in the **Purpose** field. If the function requires a value (such as the XatYVal Math function or the pw_minus_max Pulse Width

function), the following table the function field displays the name, editable value field, unit, and description.

4. Use the **Over Sweep** drop down menu to select from available sweeps.
5. To select from available Sweeps, or to edit them, click the ellipsis [**...**] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps). By default, **Use all values** is selected.
   - For sweeps other than Time, unchecking **Use all values** enables a list of available sweep values. You can use the buttons to **Clear All** or **Select All** sweep values.
     a. Select the Sweeps **Default** or **Edited** radio buttons to specify whether to accept the default or edited sweeps.
     b. To edit the sweeps further, select the ellipsis [**...**] button to display an **Edit Sweep** dialog box. For frequency variables, this lets you specify a single value, linear step, linear count, decade count, octave count, or exponential count. You can **Add** legal values to the list of sweep values, **Update** the list for changes, or **Delete** selected entries.
     c. When finished selecting/editing sweep values, close the dialog box. The sweep values you select are displayed on the Over Sweep line.
   - For Time sweeps:
     a. Select the **Specify range** radio button to enable the **Min** and **Max** value fields.
     b. Enter the desired **Min** and **Max** values, and choose the associated units of measure from the drop down lists.
     c. When finished, close the dialog box. The sweep values you select are displayed on the Over Sweep line.
6. Click **OK** to apply the range function.

Selecting a Function

Eye Measurement Range Function Parameters

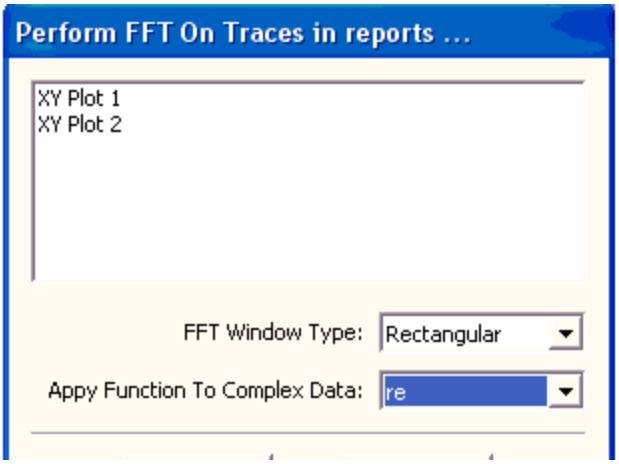
The Eye Measurement category of range functions provide the means to evaluate several characteristics of eye diagrams. Each of the Eye Measurement functions includes the following parameters. Specify the Value by editing the Value text field for the parameter name. Specify the unit for the parameter by selecting from the Unit drop down menu.

Name	Default Value	Default Unit	Description
Unit Interval	0	ns	Unit interval of signal
Start Offset	0	ns	Offset at beginning of signal
End Offset	0	ns	Offset at end of signal
Autocrossing	1		Nonzero number means that crossing amplitude is

Name	Default Value	Default Unit	Description
amplitude			calculated automatically.
Crossing amplitude	0	mV	Specify crossing amplitude used for eye measurement data computation.

Perform FFT on a Report

You can perform FFT on an existing 2D plot by using the **Results>Perform FFT** command. This opens the **Perform FFT on Traces in Reports** dialog.



1. Select the report you want from the list in the dialog.
2. Select the FFT Window type from a drop down list.

   Select the window type to apply. Windowing functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies.
3. Select the function to apply to complex data.

The new report displays and appears in the Project tree. The new report name prefixes FFT to the name of the original report. Trace names are also prefixed with FFT.

FFT Window Functions

The window type list for **Perform FFT on Report** includes:

Window Function	Preferred Use
Rectangular	A low dynamic range function offering good resolution for signals of comparable strength. Poor when signals have very different amplitudes. $w(n)=1$. Tri	A Bartlett window with the endpoints valued at zero. Van Hann	A moderate dynamic range function, designed for narrow band applications. $$w(n) = 0.5\left(1-\cos\frac{2\pi n}{N-1}\right)$$

Window Function	Preferred Use
	 Hann window; B = 1.50
Blackman	A high dynamic range function, with lower resolution, designed for wide band applications. $w(n) = a_0 - a_1 \cos\left(\frac{2\pi n}{N-1}\right) + a_2 \cos\left(\frac{4\pi n}{N-1}\right)$ where $a_0 = (1-\alpha)/2$; $\alpha_1 = 1/2$; $\alpha_2 = \alpha/2$  Blackman window; α = 0.16; B=1.73

Window Function	Preferred Use
Hamming	A moderate dynamic range function, designed for narrow band applications. It minimizes the maximum sidelobe. $$w(n) = 0.54 - 0.46\cos\left(\frac{2\pi n}{N-1}\right)$$  Hamming window; B=1.37
Lanczos	The Lanczos window offers a windowed form of the infinite sinc filter, providing the central lobe of a horizontally-stretched sinc, sinc(x/a) for -a £ x £ a.  Sinc or Lanczos window; B=1.31
Weber	
Welch	This approach applies a parabola-shaped window to the frequency domain data. It is based on the Bartlett method but splits the signal into overlapping segments, which are then windowed. The intent is to balance the influence of data in the center of the function.

FFT Window Functions
Perform FFT on a Report
Perform TDR on a Report

Perform TDR on Report

The idea behind Time-Domain Reflectometry (TDR) is to excite a structure with a step or impulse function, and inspect the reflections as a function of time. Before you can examine the time domain, you must perform a sweep for a transient or eddy current solution. You can perform TDR

on an existing 2D plot by using the **Results>Perform TDR on Report** command. This opens a **Perform TDR On Traces in reports...** dialog.

1. Select the report you want from the list in the dialog.
2. Specify the input signal as Step or Impulse and give the rise time.
3. Select the TDR Window type from a drop down list.

   Select the window type to apply. Windowing functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies.

   You may choose to specify a window width as a percentage.

   If you select the Kaiser function, you can specify a Kaiser number.

The new report displays and appears in the Project tree. The new report name prefixes TDR to the name of the original report. Trace names are also prefixed with TDR.

TDR Windowing Functions

Windowing functions cause the FFT of the signal to have non-zero values away from ω. Each window function trades off the ability to resolve comparable signals and frequencies versus the ability to resolve signals of different strengths and frequencies. The window type list includes:

Window Function	Preferred Use
Rectangular	A low dynamic range function offering good resolution for signals of comparable strength. Poor when signals have very different amplitudes. $w(n)=1$. Bartlett	A high dynamic range function, with lower resolution, designed for wide band

Window Function	Preferred Use
	applications. $$w(n) = a_0 - a_1\left|\frac{n}{N-1} - \frac{1}{2}\right| - a_2\cos\left(\frac{2\pi n}{N-1}\right)$$ where a_0=0.62; a_1=0.48; a_2=0.38  Bartlett-Hann window; B=1.46
Blackman	A high dynamic range function, with lower resolution, designed for wide band applications. $$w(n) = a_0 - a_1\cos\left(\frac{2\pi n}{N-1}\right) + a_2\cos\left(\frac{4\pi n}{N-1}\right)$$ where a_0 =(1-α)/2; α_1=1/2; α_2=α/2  Blackman window; α = 0.16; B=1.73

Window Function	Preferred Use
Hamming	A moderate dynamic range function, designed for narrow band applications. It minimizes the maximum sidelobe. $$w(n) = 0.54 - 0.46\cos\left(\frac{2\pi n}{N-1}\right)$$  Hamming window; B=1.37
Hanning (default)	A moderate dynamic range function, designed for narrow band applications. $$w(n) = 0.5\left(1-\cos\frac{2\pi n}{N-1}\right)$$  Hann window; B = 1.50
Kaiser	Selecting the Kaiser plot also enables a field to specify an associated Kaiser parameter. The larger the Kaiser parameter, the wider the window. The

Window Function	Preferred Use
	parameter controls the trade off between width of the central lobe and the area of the side lobes.  Kaiser window, α =2; B=1.5  Kaiser window, α =3; B=1.8
Welch	This approach applies a parabola-shaped window to the frequency domain data. It is based on the Bartlett method but splits the signal into overlapping segments, which are then windowed. The intent is to balance the influence of data in the center of the function.

You can use the **Save as Default** to set the current values as a default, and the **Use Defaults**

Spectral Domain Plots in Transient (FFT)

When plotting in the spectral domain, you must specify the parameters for the Fast Fourier Transform (FFT). The FFT function used by Maxwell uses windowing; therefore, the user must enter a start and stop time within which the data is periodic.

To enter the FFT parameters:

1. In the **Report** window, be sure the **Domain** is set to **Spectral**.
2. In the **Context** section of the reporter dialog box, click **FFT Options.**

   The **FFT Options** dialog appears.
3. Enter the **Start Time** for the window using the pull-down menu.
4. Enter the **End Time** using the pull-down menu.
5. Enter the **Window Type** using the pull-down menu.

The Samples and number of points are calculated based on the chosen start and end values. The signal must be periodic during the time interval chosen or an error will result.

Related Topics

Time Domain Plots in Eddy (IFFT)

Time Domain Plots in Eddy (IFFT)

When creating time domain plots from frequency domain data, you must specify the parameters for the Inverse Fast Fourier Transform (IFFT):

1. In the **Report** window, be sure the **Domain** is set to **Time**.
2. In the **Context** section of the reporter dialog box, click **IFFT Options.**

   The **IFFT Options** dialog appears.
3. In the **Input Signal** section of the dialog select either **Impulse** or **Step** signal to use in performing the IFFT.
4. For **Step** signal, input the rise time for the pulse. The rise time should chosen so that the frequency content is within the bandwidth of the available frequency sweep data.
5. Select the **Window Type** from the pull-down menu.
6. Enter the window **Width** in percent.

The **Maximum Plot Time** and the **Delta Time** are calculated based on the solution data available.

Spectral Domain Plots in Transient (FFT)

Specifying Output Variables

You can access the **Output Variables** window in several ways.

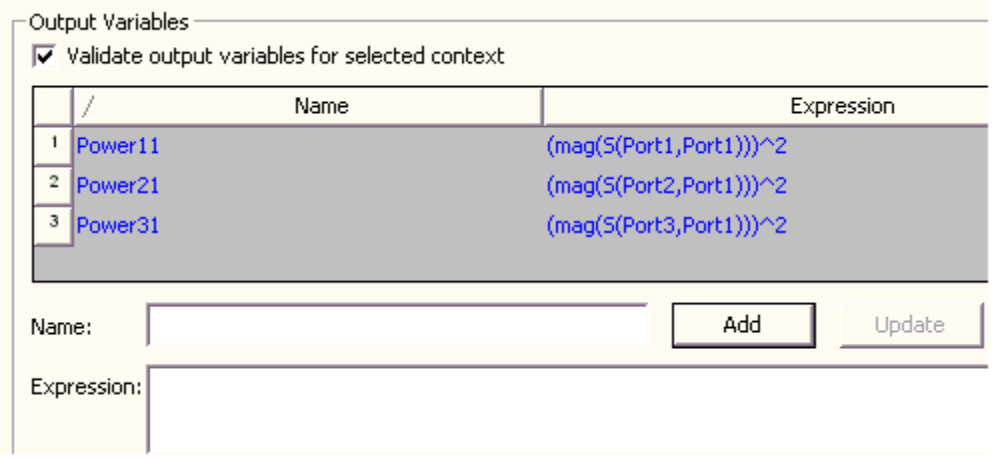
- Click **Maxwell3D, Maxwell2D,** or **RMxprt** and then select **Results>Output Variables**.
- In the Project tree, right-click on **Results** and select **Output Variables** from the short-cut menu.
- In the **Solution Setup** dialog box, select the **Expression Cache** tab, click the **Add...** button to display the **Add to expression cache** dialog box, and click the **Output Variables** button.
- Click the **Output Variables** button the **Reports** dialog.

The **Output Variables** window contains four sections:

- **Context section,** where you specify the Report type, the Solution, and for appropriate report types, the Domain. Changing the Report type affects whether the Domain menu appears, and may affect the functions listed in the Calculation section.

- **Output Variables** section, where you can specify the name and expression for a new output variable. Existing variables appear in the list at the top of the window. Clicking the triangle in the Name bar inverts the sort order.

  At top of the **Output Variables** window, you can use a check box to **Validate output variable for selected context**.



- **Calculation section**, where you can insert quantities into the Expression area of the **Output Variables** section.
- **Function section**, where you can insert completed expressions into the Expression area of the **Output Variables** section.

Adding a New Output Variable

To add an output variable:

1. Click **Maxwell3D, Maxwell2D,** or **RMxprt** and then select **Results>Output Variables** or, in the Project tree, right-click on **Results** and select **Output Variables** from the short-cut menu, or on the **Modify Report** dialog box, click the Output Variables button.

   The **Output Variables** window appears. Variables defined using the **Results>Output Variables** command appear in the list at the top of the window.
2. In the **Output Variables** section, enter a name for the new variable in the **Name** box.
3. To enter an expression, do one or both of the following:
   a. Type part or all of the expression directly in the **Expression** area. Valid functions appear in blue. Invalid functions appear in red.

b. Insert part or all of the expression using the options in the Calculation and Function sections.

4. Optionally, choose to **Validate output variables for selected context**.
5. Click **Add** to add the new variable to the list.
6. Repeat steps 2 through 4 to add additional variables.
7. When you are finished adding output variables, click **Done** to close the **Output Variables** window.

Related Topics

Deleting Output Variables

Building an Expression Using Existing Quantities

Viewing the Output Variable Convergence

Building an Expression Using Existing Quantities

When you are entering an expression for a new output variable, you can insert part or all of the expression using the options in the **Calculation** and **Function** sections of the **Output Variables** window.

To add an input variable by inserting part or all of the expression:

1. Click **Maxwell3D, Maxwell2D,** or **RMxprt** and then select **Results>Output Variables** or, in the Project Tree, right-click on **Results** and select **Output Variables** from the short-cut menu, or on the **Modify Report** dialog box, click the Output Variables button.

   The **Output Variables** window appears.
2. In the **Output Variables** section, enter a name for the new variable in the **Name** box.
3. To insert a quantity:
   a. From the **Report Type** pull-down list, select the type of report from which you want to select the quantity.
   b. From the **Solution** pull-down list, select the solution from which you want to select the quantity.
   c. From the **Category** list, select the type of quantity you want to enter.
   d. From the **Quantity** list, select the quantity or the geometry.
   e. From the **Function** list, select a ready-made function (this option is the same as inserting the function from the **Function** section).
   f. If applicable, from the **Domain** list, select the solution domain.
   g. Click **Insert Into Expression**.
   The selected quantity is entered into the **Expression** area of the **Output Variables** section.
4. To insert a function:
   a. In the **Function** section, select a ready-made function from the pull-down list.
   b. Click **Insert Function into Expression**.
   The function appears in the **Expression** area of the **Output Variables** section.

5. When you are finished defining the variable in the **Expression** area, click **Add** to add the new variable to the list.
6. Repeat steps 2 through 5 to add additional variables.
7. When you are finished adding output variables, click **Done** to close the **Output Variables** window.

Note	Remember the evaluated value of an expression is always interpreted as in SI units. However, when a quantity is plotted in a report, you have the option to plot values in units other than SI.

Function List for Output Variables

The Output Variables dialog includes a second function list containing functions to enter directly into the Expression field. These functions can also be applied to previously specified Quantities and Functions.

Some of these functions can operate along an entire curve. These are: deriv, min, max, integ, rms, pk2pk, cang_deg and cang_rad.

You can select from the following functions in the **Output Variables** dialog **Function** list, or type them directly into the Expression field, if necessary:

abs	Absolute value
acos	Arc cosine
acosh	Hyperbolic arc cosine
ang_deg	Angle (phase) of a complex number, cut at +/-180
ang_rad	Angle in radians
arg	Argument of a complex number. It is the angle the complex number makes with the positive x axis. Same as **ang_deg**.
asin	Arc sine
asinh	Hyperbolic arc sine
atan	Arc tangent. Takes a tangent value as an argument. Because there are two angles in a circle that can have the same tangent value, and atan can return only one value, it returns a value in the range between -90 degrees and +90 degrees (or between -pi/2 and pi/2 in radians).
atan2(y,x)	A two-argument version of the **atan** function. Takes the y and x coordinates (including sign information) of a point as arguments and returns the angle from the X-axis. Can return angle values for the full circle (-180 degrees to +180 degrees or -pi to +pi in radians).

atanh	Hyperbolic arc tangent
avgabs	Absolute value of average.
cang_deg	Cumulative angle (phase) of the first parameter (a complex number) in degrees, along the second parameter (typically sweep variable). Returns a double precision value cut at +/-180.
cang_rad	Cumulative angle of the first parameter in radians along a second parameter (typically a sweep variable) Returns a double precision value.
cmplx(*re*, *im*)	A complex number, where *re* is the real part and *im* is the imaginary part.
conjg	Conjugate of the complex number.
cos	Cosine
cosh	Hyperbolic cosine
crestfactor	Peak/RMS (root mean square) for the selected simulation quantity
dB(x)	20*log10(|x|)
dB10	10*log(|x|) to base 10.
dBm(x)	10*log10(|x|) +30
dBW(x)	10*log10(|x|)
dBc	Decibels relative to the carrier. It is the power ratio of the signal to a carrier signal. Gives the relative signal strength.
db10normalize	10*log [normalize(mag(x))]
db20normalize	20*log [normalize(mag(x))]
degel	Conversion from degrees electrical to seconds with respect to Hz.
deriv	Derivative of a given parameter.
even	Returns 1 if integer part of the number is even; returns 0 otherwise
exp	Exponential function (the natural anti-logarithm)
if	if(cond_exp,true_exp, false_exp).
im	Imaginary part of the complex number
int	Truncated integer function
j0	Bessel function of the first kind (0^{th} order)
j1	Bessel function of the first kind (1^{st} order)
ln	Natural logarithm
log	Natural logarithm (same as ln).
log10	Logarithm base 10
mag	Magnitude of the complex number
mod	Returns the modulus or absolute value of the simulation quantity.
nint	Nearest integer
normalize	Divides each value within a trace by the maximum value of the trace. ex.

	normalize(mag(x))
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise
polar	Converts the complex number in rectangular to polar
pow	Raise x to y power., pow(x,y).
pwl	Piecewise Linear
pwl_periodic	Piecewise Linear for periodic extrapolation on x
pwlx	Piecewise Linear x with linear extrapolation on x.
re	Real part of the complex number
rect	Converts the complex number in polar to rectangular
rem	Returns the fractional part of a decimal number such that rem(x) = x-int(x) Syntax: rem(x)
root	Take the y root of x, root(x,y)
sgn	Sign extraction
sin	Sine
sinh	Hyperbolic sine
sliding mean	sliding mean.
slidingrms	sliding root mean square
sqr	Square.
sqrt	Square root
tan	Tangent
tanh	Hyperbolic tangent
y0	Bessel function of the second kind (0^{th} order)
y1	Bessel function of the second kind (1^{st} order)
yn	Bessel function of the second kind (nth order)

Report Data

The follow sections describe how you can view, update, export, import, override, and delete various values used for display in plots and reports.

The topics for this section include:

Updating Reports (Post-Processing Data)

Deleting Reports

Exporting Plot Data

Importing 2D Plot Data

Report File Formats

Exporting Graphics Files from a Plot

Plotting Imported Solution Data

Setting a Range Function

Updating Reports (Post-Processing Data)

To manually update the report that is active in the design area using the latest simulation results, right-click in the report and select **Update Report** from the menu. Alternatively, you can right-click on the report under **Results** in the Project Manager and select **Update Report** from the context menu.

If you wish to update all reports in the design, select **Maxwell 2D** (or **Maxwell 3D**)**>Results>Update All Reports**. Alternatively, right-click on the **Results** icon in the Project Manager and select **Update All Reports** from the menu.

Deleting Reports

- To delete a single report, right-click on the report in the **Results** section of the **Project Manager** window for the design, and click **Delete** on the menu.

Warning	Solution data that have been deleted cannot be

	recovered!

- To delete all reports, either select **Maxwell 2D** (or **Maxwell 3D** or **RMxprt**)**>Results>Delete All Reports**, or right-click on the **Results** icon in the **Project Manager** window for the design, and click **Delete All Reports** on the pop-up menu.

Warning	Deletions occur as soon as you click this button and cannot be undone. If you change your mind while in this window, click **Cancel** BEFORE clicking **Do Deletions**.

Opening Reports

- To open a single report, right-click on the report in the **Results** section of the **Project Manager** window for the design, and click **Open Report** on the menu.
- To open all reports, either select **Maxwell 2D** (or **Maxwell 3D**)**>Results>Open All Reports**, or right-click on the **Results** icon in the **Project Manager** window for the design, and click **Open All Reports** on the pop-up menu.

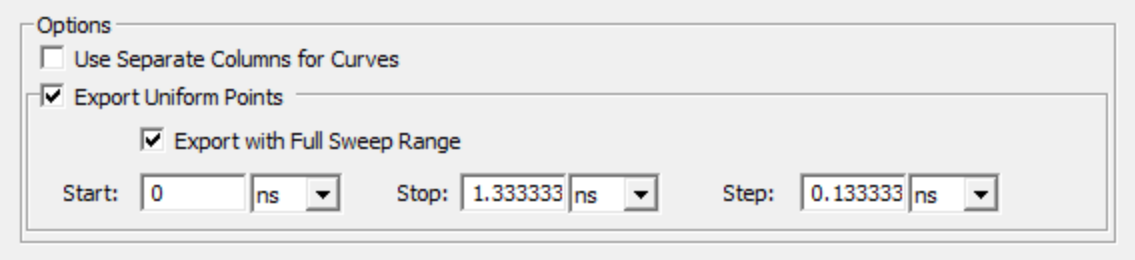
Exporting Reports

You can export reports in a variety of text and graphic formats. You must have an existing plot open to see the corresponding Report2D or Report3D menu.

1. Click **Report2D** or **Report 3D** on the top menu, and then select **Export**. Alternatively, right-click on the plot, and then click **Export ...** on the shortcut menu.

   The **Export Report** dialog box opens.
2. Use the file browser to find the directory where you want to save the file.
3. Type the name of the file in the **File name** box.
4. Select one of the following file formats from the **Save as type** pull-down list:
   - ***.csv** – Comma delimited data files.
   - ***.tab** – Tab delimited data files.
   - ***.dat** – Ansoft PlotData files (2D reports only).
   - ***.txt** – Post processor format files (2D reports only).
   - ****.exy*** – Ansys EnSight XY date files. (2D reports only).
   - ***.case** – Ansys case files. (3D reports only).
   - ***.rdat** – Ansoft Report Data format files.
   - ***.emf** – Microsoft EMF files.
   - ***.gif** – Graphics Interchange Format files.
   - ***.bmp** – Bitmap files.
   - ***.wrl** – Virtual Reality Modeling Language (VRML) files.
   - ***.tif, *.tiff** – Tagged Image File Format files.
   - ***.jpg, *.jpeg** – Joint Photographics Experts Group files.

5. Optionally, for .csv and .tab files, you can check, Use Separate Columns for curves.
6. Optionally, for 2D reports, you can choose to Export Uniform Points, which enables fields in which you can specify the start, stop, and step values and units to output uniformly spaced point data.



7. Click **Save** to export the report to the specified location in the selected data or graphical format.

Importing 2D Plot Data

To import 2D plot data to a report:

1. Left-click **Report2D** on the top menu, and then select **Import Data**.
   The **Open** dialog box opens.
2. Browse to the directory where the data file is located.
3. Select the file format from the **Files of type** drop-down. Options include:
   - ***.csv** – Comma delimited data files.
   - ***.tab** – Tab delimited data files.
   - ***.dat** – Ansoft PlotData files.
   - ***.txt** – Post processor format files.
   - ***.rdat** – Ansoft Report Data files.

   For more information, see Report File Formats.
1. Select the filename.
2. Click **Open** to import and plot the data, or click **Cancel** to close the dialog box without importing any data.

Report File Formats

Report File Formats

The following table provides information about the file formats that can be imported into plot data reports:

File Extension	Information
csv	• Uses a comma (,) as the separation character. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the information for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
tab	• Uses the tab character as the separation character. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the information for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
txt	• The txt file must begin with a header that contains the following: • A first line made of 92 equal signs (=) • A second line that begins with the company name and ends with the date in MM/DD/YY format • A third line that begins with a plot name and ends with the time in hh:mm:ss format • A fourth line, which is empty • A fifth line made of 92 hyphens (-) **Note:** Each header line must be 92 characters in length, except the empty line. • Each column has a fixed width, separated by white space. • The x-axis value is in the first column. Each curve's Y-values make up one column, and the curves are in the same order as in the plot legend. • The first row is the X-axis name [unit] and the trace name [unit] for each curve, which is the same as the plot curve legend. • The second row is an empty column and the variable values for each curve, which is the same as the plot curve legend. • Other rows are the X-axis value and the Y-value for each curve.
dat	DAT is an Ansys-specific format. Ansys recommends that you do not generate files using this format. Files imported with these formats should be exported only

File Extension	Information
	from Ansys products.
rdat	RDAT is an Ansys-specific format. Ansys recommends that you do not generate files using this format. Files imported with these formats should be exported only from Ansys products.

Exporting Reports

Creating Custom Report Templates and Defaults

You can edit properties from any report type and save it as a template or as the default. This can save repeated editing of properties (for example, the company name, or color schemes) when you create other reports. Once you create templates, you can access them from the **Results>Report Templates>** menu and the **2D Reports> Report Templates>Apply Settings** menu.

See Modifying the Background Properties of a Report for a discussion of format changes you can make to any report.

To save an edited report as a template:

1. In the Project Tree, right-click on the report name of interest to display the shortcut menu and click **Report Templates>Save**. You can also click **Report2D>Report templates>Save**.

   This displays the **Report Save As Report Template** file browser. By default, the directory is your AnsysEM\<*productName*>\userlib\ReportTemplates directory. You can also save to the SysLib directory.
2. Typically, you accept the directory.
3. You must provide a file name, which will be given an .rpt extension.

   It is good practice to give the template a descriptive name, showing both the kind of format you begin with (such as XY Plot or 3D Plot) and apt description of the distinguishing edits (such as for company name, or color scheme). Once saved, this name will appear on the **PersonalLib** menu.
4. The **Save As Typ**e field currently supports the Ansoft Report Format (.rpt) format.
5. Click **Save** to save the template to the PersonalLib menu.

All .rpt templates in the directory appear on the **Results>Report Templates>PersonalLib** menu. Selecting a report from the PersonalLib menu opens a report that you can then Modify to add traces or perform other edits. Templates in the SysLib directory appear on the **Report Templates** menu.

To save an edited report as a default:

1. In the Project Tree, right-click on the report name of interest to display the shortcut menu and click **Report Templates>Save Settings as default**. You can also click **Report2D>Report templates>Save Settings as default** or **Report3D>Save Settings as default**.

Exporting Reports as Graphics

You can export reports as figures in several formats. You must have an existing plot open to see the Report2D or Report 3D menu.

To export a graphics file:

1. On the **Report 2D** or **Report3D** menu, click **Export**.

   The **Export Report** dialog box opens:
2. Click the **Browse...** button to open the Export Report browser window.
3. Specify the file location and name, and select a graphics format from the dropdown list.
4. Select the desired graphics file format from the **Save as type** drop-down list.

- ***.jpg** – Joint Photographics Experts Group files.
- ***.gif** – Graphics Interchange Format files.
- ***.bmp** – Bitmap files.
- ***.tiff** – Tagged Image File Format files.
- ***.wrl** – Virtual Reality Modeling Language (VRML) files.

5. Click **Save**. The file is exported to the specified location as a graphics file.

To export an image file of a report to specified high resolution:

1. Set platform environment variables for the desired width and height values, (for example, for 8k, use width var = 7680 and height var=4320): ANSYS_EM_EXPORTED_IMAGE_WIDTH and ANSYS_EM_EXPORTED_IMAGE_HEIGHT.
2. Click With a report open, click **Report2D**>**Export...** or **Report3D**> **Export...**and choose an image format like .jpeg, and Export.

   The image created at the specified resolution. If you record a script for the image export, the parameters for the width and height will match those specified by the system

environment variables. Fonts and line thickness is not scaled. Only the image. You will have to iteratively increase font sizes till you find a suitable output.

Copying Reports to the Clipboard as Images

You can copy images of reports to the clipboard, so that they can be pasted into other applications as follows:

1. Make the report the active window. Alternatively, for a plot-on-schematic, click on the plot to select it.
2. Click **Edit>Copy Image**, or right-click on the report window or plot-on-schematic and select **Copy Image** on the context menu to copy the report to the clipboard as an image.
3. Open the application into which you want to paste the image, and paste the image.

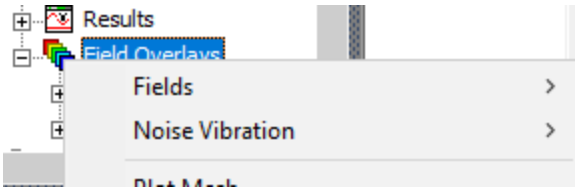
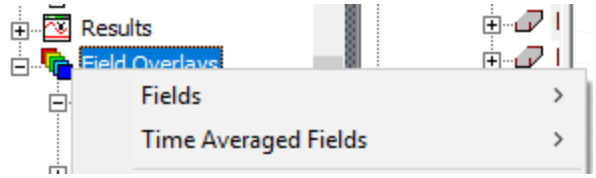
Plotting Field Overlays

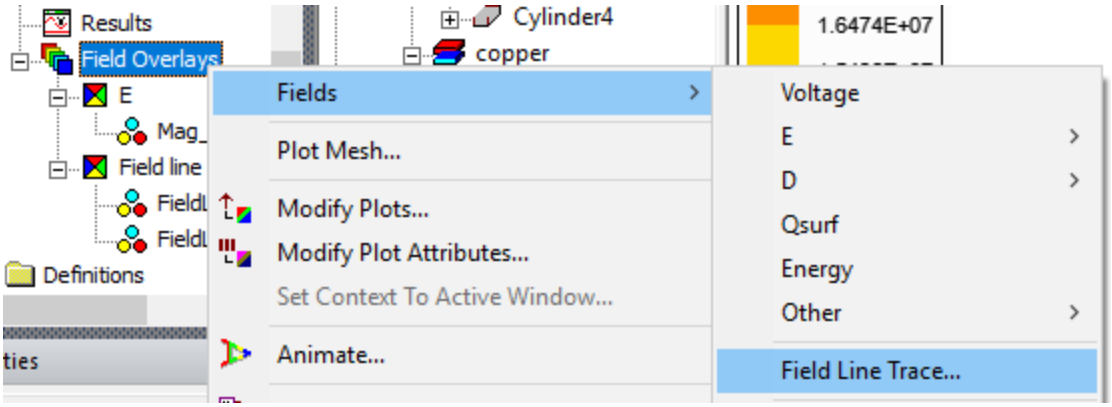
Field overlays are representations of basic or derived field quantities on surfaces or objects for the current design variation. You must select a geometry to create a plot. You can set the design variation via the **Set Design Variation** dialog box. This dialog box is accessible from the **Solution Data** window via by clicking the ellipsis button on the right of the Design Variation field, and via the **Results>Apply Solved Variation** command.

You can control the visibility of Field Overlays by means of the **View>Visibility>Active View Visibility** dialog box, **Fields Reporter** tab, shown above or by right clicking on the Field plot in the Project tree and checking or unchecking **Plot Visibility**.

There are several types of Field overlays that you can plot:







- **Fields**
- **Time Averaged Fields** (*Transient designs only*)
- **Noise Vibration** *(Transient designs if element-based harmonic forces are set up)*
- **Field Line Trace** (*Electrostatic designs only*)

Plotting Standard Fields Overlays

Field overlays are representations of basic or derived field quantities on surfaces or objects for the current design variation. You can set the design variation via the **Set Design Variation** dialog box. This dialog box is accessible from the **Solution Data** window via by clicking the ellipsis button on the right of the Design Variation field, and via the **Results>Apply Solved Variation** command.

To plot a standard field quantity:

1. Select a point, line, surface, or object to create the plot on or within. You may also select a plane or object list in the **History Tree**.

> **Note:** For 2D Designs, a plane selection must be consistent with the drawing plane or an error will result.

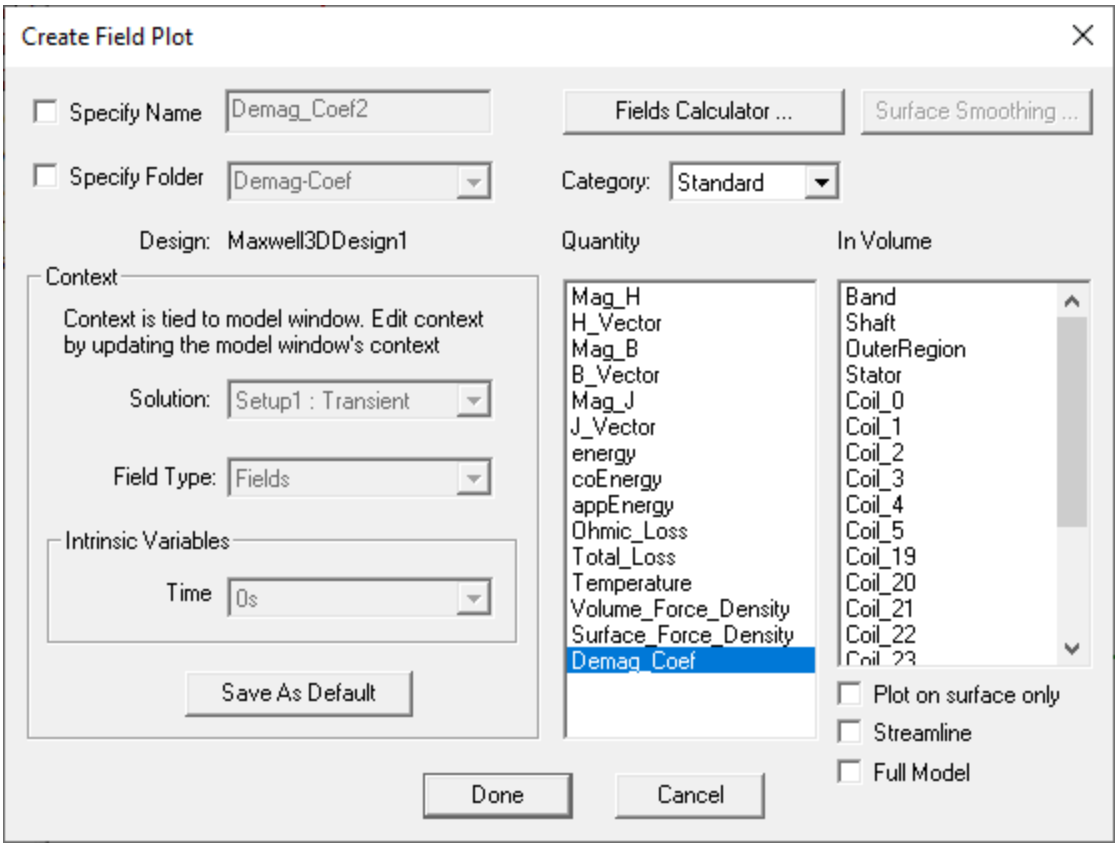
If it does not exist, create it.

2. On the main menu bar, click **Maxwell3D>Fields>Fields** or **Maxwell2D>Fields>Fields**.
3. On the **Fields** sub-menu, click the field quantity you want to plot. Available selections depend on the solved solution. (You can also right-click on **Field Overlays** in the Project Manager and select **Fields>***field_quantity*).

   If you select a scalar field quantity, a scalar surface or volume plot is created. If you select a vector field quantity, a vector surface or volume plot is created. If you select a vector quantity, you will be able to specify a Streamline plot. If the quantity you want to plot is not listed, see *Calculating a Derived Field Quantity*.

   For projects with Temperature dependent materials, the **Maxwell>Fields>Fields>Other...** menus selections include **Temperature**.

   After you select the field quantity to plot, the **Create Field Plot** dialog box appears.



> **Note:** For Maxwell 2D transient solutions in which **Use Skew Model is enabled on the Model Settings tab**, an additional **Slice** field displays in the **Intrinsic Variables** panel.
>
> >

The **Specify Name** field shows a name based on the field quantity you selected, and the **Quantity** list shows the field quantity selected.

4. To specify a name for the plot other than the default, select **SpecifyName**, and then type a new name in the **Name** box.
5. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the pull-down list. Plot folders are listed under **Field Overlays** in the project tree. Plot folders let you group plots with the same quantity together. All field plots under the same folder share the same color key.

> **Note:** All plots (field overlays) in the same folder have the same scale settings. To plot the same field with a different scale, you can create or move the new plot to a separate folder. By default, current density plots are stored in a folder called **J**, but you can specify a different or new folder. Plots in different folders have a different plot keys.

6. Select the solution to plot from the **Solution** pull-down list.
7. Select the **Fields** type to plot in the **Field Type** pull-down list.
8. Under **Intrinsic Variables**, select the variable value(s) at which the field quantity is evaluated. Variables available vary depending on the solution type.

> **Note:** For Maxwell 2D transient solutions in which **Use Skew Model is enabled on the Model Settings tab**, a **Slice** field displays in the **Intrinsic Variables** panel showing the slice currently selected for viewing in the modeler window.

9. If desired, you can choose a different field quantity to plot from the **Quantity** list. For scalar quantities plotted on the surface of a geometry, the **Surface Smoothing** button is enabled.

   > **Note:** If you selected an *object*, you must check **Plot on surface only** to enable the **Surface Smoothing** button.

   For vector quantities, the **Surface Smoothing** button is disabled. For details on using the **Surface Smoothing** button, see Modifying Field Plots.

10. Select the volume or surface (region) in which to plot the field from the **In Volume** list.

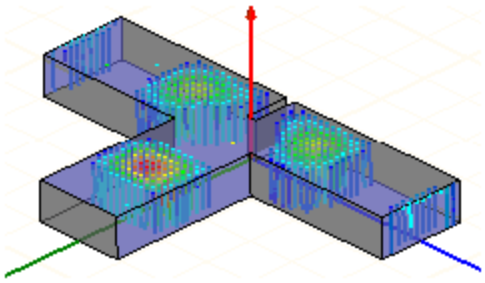
    This selection enables you to limit plots to the intersection of a volume with the selected object or objects. You can select and deselect any items in the **In Volume** list. You can mix model objects with non-model boxes. For example you might want to see a plot from part of two model objects by restricting the region to a non-model box overlapping those parts.

    > **Note:** Multiple selection should be used when there is a discontinuous field on a surface. If not, the field on both sides of the surface is plotted and each interferes with the other.

    > **Note:** Non-convex 3D non-model solids are not supported for Field Overlay Plots and Fields Calculator computations.

    > **Note:** Object lists containing non-model object(s) are supported for Field Overlay Plots but are not supported for Fields Calculator computations.

11. If you selected a vector quantity, you can use the check box to select **Streamline** plot. Streamlines are often used to indicate magnetic flux lines, etc. in plots.



Note	• Before creating the Streamline plot, select both starting and ending edges (in 2D) or both surfaces (in 3D). • In the **Create Field Plot** dialog box, select **In Volume:** region, which is the region in which the streamlines will appear. Streamlines are outside of objects that are excited (sources).

	• To show more streamlines after the plot is created, on the **Modify attributes...** dialog **Plots** tab, reduce the **Seeds density** value. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large. Refer to Setting Field Plot Attributes for adjusting the Streamline display parameters, and Setting Fields Reporter Options for setting Streamline defaults. . For exporting Streamline plots, refer to Exporting Field Plots.

12. *Optionally*, you can select the **Plot on surface only** check box to obtain a plot around the surfaces of selected objects.
13. *Optionally*, for model objects in partial model designs, click the **Full Model** check box to calculate the fields on the full model based on the partial model solution.
14. *Optionally*, click **Fields Calculator** to open the fields calculator in which you can create named expressions, which can then be selected in the Create Field Plot dialog by choosing **Calculator** as the Category. The named expression(s) appear in the **Quantity** list.
15. Click **Done**.

    The field quantity is plotted on the surfaces or within the objects you selected. The plot uses the attributes specified in the **Plot Attributes** dialog box.

    The new plot appears in the view window. It is listed in the specified plot folder in the project tree. If you have created a field plot on a simulation in progress, the field plot is updated after the last adaptive solution.

    If you want to update the field overlay before then, to view progress in the solution, select the Field icon in the Project tree that contains the field plot of interest, right-click to display the short cut menu, and select **Update Plots**.

    To turn off the display of the plot, right click on the plot and select **Plot Visibility** from the short-cut menu. Unchecking **Plot Visibility** turns off the plot display.

Plotting Standard Field Quantities

Maxwell makes numerous quantities available for field plotting derived directly from the field solution. The quantities available depend upon the solution type (magnetostatic, eddy current, etc), on the design type (3D or 2D) and other parameters such as the use of lossy materials. The chart below lists possible solution quantities available when using **Maxwell3D>Fields>Fields**, or **Maxwell2D>Fields>Fields**.

Description	Quantity	2D	3D
Vector Potential	**Flux_Lines, A_Vector**	Magnetostatic, Eddy Current, Transient	
Magnetic Field Intensity	**Mag_H, ComplexMag_H, H_ Vector**	Magnetostatic, Eddy Current, Transient	Magnetostatic, Eddy Current, Transient
Magnetic Flux Density	**Mag_B, ComplexMag_B,B_ Vector**	Magnetostatic, Eddy Current, Transient	Magnetostatic, Eddy Current, Transient
Current Density	**JatPhase, Mag_J, ComplexMag_J, J_ Vector, Jphi, Jz**	Magnetostatic, Eddy Current, Transient, ACConduction, DCConduction	Magnetostatic, Eddy Current, Transient, DCConduction, Electric Transient, ACConduction
Direct Current Density	**Mag_Jc, ComplexMag_Jc, Jc_ Vector**		ACConduction
Electric Flux Density	**DatPhase, Mag_D, ComplexMag_D, D_ Vector**	Eddy Current, Electrostatic, ACConduction	Eddy Current, Electrostatic, DCConduction, Electric Transient, ACConduction
Electric Field Intensity	**Mag_E, ComplexMag_E, E_ Vector**	Electrostatic, ACConduction, DCConduction	Eddy Current, Electrostatic, DCConduction, Electric Transient
Surface Charge Density	**QSurf**		Electrostatic, ACConduction, DCConduction, Electric Transient
Surface Current Density (on an impedance boundary)	**Jsurf**		Eddy Current

Description	Quantity	2D	3D
Voltage	**Voltage**	Electrostatic, ACConduction, DCConduction	Electrostatic, DCConduction, Electric Transient, ACConduction, Transient A-Phi
Energy in the Field **Electric** **Magnetic**	**energy**	Magnetostatic, Eddy Current, Transient, Electrostatic	Magnetostatic, Eddy Current, Transient, Electrostatic, ACConduction, DCConduction, Electric Transient
Magnetic CoEnergy	**coEnergy**	Magnetostatic, Eddy Current, Transient	Magnetostatic, Transient
	appEnergy	Magnetostatic, Eddy Current, Transient	Magnetostatic, Transient
Ohmic Loss	**Ohmic_Loss**	Magnetostatic, Eddy Current, Transient, Electrostatic, ACConduction, DCConduction	Magnetostatic, Eddy Current, Transient, DCConduction, Electric Transient, ACConduction
Total Loss	**Total_Loss**	Transient (Magnetic)	
Hysteresis Loss	**Hysteresis_Loss**	Eddy Current	Eddy Current
Dielectric Loss	**Dielectric_Loss**	Eddy Current	Eddy Current ACConduction
Surface Loss Density	**SurfaceLossDensity**		Eddy Current
Edge Force Density	**edgeForceDensity**	Magnetostatic, Eddy Current (DC component only), Transient, Electrostatic	
Temperature	**Temp**	Magnetostatic, Eddy Current, Electrostatic	Magnetostatic, Eddy Current, Electrostatic
Surface Force Density	**surfaceForceDensity**	Magnetostatic, Eddy Current (DC component only), Transient, Electrostatic	Magnetostatic, Eddy Current (DC component only), Transient, Electrostatic, Electric Transient
Volume Force Density	**volumeForceDensity**		Magnetostatic, Eddy Current, Transient,

Description	Quantity	2D	3D
			Electrostatic, Electric Transient
Displacement	**Displacement_ Vector, Mag_ Displacement**	Magnetostatic, Eddy Current, Electrostatic	Magnetostatic, Eddy Current, Electrostatic
Sum of Ohmic, Hysteresis, and Dielectric Loss	**emloss**	Eddy Current	
Loss on Impedance boundary applied to a conductor	**edgeLossDensity**	Eddy Current	
Demagnetization coefficient	**Demag_coef**	Magnetostatic, Transient	Magnetostatic, Transient
Loss Density	**LossDensity**	Transient	Transient

Force Density Quantities

Edge Force Density	The edge density is available only in Maxwell2D. It is available only on object outlines adjacent to air or vacuum space. It is defined as: $f = \overline{S} \cdot n$

	$$\overline{S} = \frac{1}{\mu_0}\begin{bmatrix} B_x^2 - B^2/2 & B_x B_y \\ B_x B_y & B_y^2 - B^2/2 \end{bmatrix} + \epsilon_0 \begin{bmatrix} E_x^2 - E^2/2 & E_x E_y \\ E_x E_y & E_y^2 - E^2/2 \end{bmatrix}$$ where **B** and **E** are the magnetic flux density and electric field intensity at the midpoint of the edge, respectively, and **n** is the outward normal direction of the edge. For electrostatic, AC, and DC solvers, only the electric field is included; while for magnetostatic, Eddy current, and magnetic transient solvers, only the magnetic field is considered. For AC solver and Eddy current solver, edge force density is the averaged (DC) force density.
Surface Force Density	In Maxwell2D, surface force density is defined as: $$\boldsymbol{f} = \frac{\sum_{i=0}^{i=N} \overline{S_i} \cdot \boldsymbol{n_i}\, l_i r_i}{area\ of\ element * r_c}$$ $$\overline{S_i} = \frac{1}{\mu}\begin{bmatrix} B_x^2 - B^2/2 & B_x B_y \\ B_x B_y & B_y^2 - B^2/2 \end{bmatrix} + \epsilon \begin{bmatrix} E_x^2 - E^2/2 & E_x E_y \\ E_x E_y & E_y^2 - E^2/2 \end{bmatrix}$$ where N is the number of sides of the element, l_i is the length of side i of the element. For the RZ case, r_i and r_c are the radius of side i and the radius of the element center, respectively. μ and ϵ are the permeability and permittivity in the ith neighboring element. In the XY plane, r_i and r_c are set to 1. In Maxwell3D, surface force density is only available on object faces adjacent to air or vacuum space. It is defined as: $$\boldsymbol{f} = \overline{S} \cdot \boldsymbol{n}$$ $$\overline{S} = \frac{1}{\mu_0}\begin{bmatrix} B_x^2 - B^2/2 & B_x B_y & B_x B_z \\ B_x B_y & B_y^2 - B^2/2 & B_z B_y \\ B_x B_z & B_z B_y & B_z^2 - B^2/2 \end{bmatrix} + \epsilon_0 \begin{bmatrix} E_x^2 - E^2/2 & E_x E_y & E_x E_z \\ E_x E_y & E_y^2 - E^2/2 & E_z E_y \\ E_x E_z & E_z E_y & E_z^2 - E^2/2 \end{bmatrix}$$

	where **B** and **E** are the magnetic flux density and electric field intensity at the center of the surface face, respectively, and **n** is the outward normal direction of the surface face. For electrostatic, AC, and DC solvers, only the electric field is included; while for magnetostatic, Eddy current, and magnetic transient solvers, only the magnetic field is considered. For AC solver and Eddy current solver, surface force density is the averaged (DC) force density.
Volume Force Density	Volume force density is only available in Maxwell3D. It is calculated as: $$\boldsymbol{f} = \frac{\sum_{i=0}^{i=N} \overline{\boldsymbol{S_i}} \cdot \boldsymbol{n_i} A_i}{Volume\ of\ element} \qquad (7)$$ $$\overline{S_i} = \frac{1}{\mu}\begin{bmatrix} B_x^2 - B^2/2 & B_x B_y & B_x B_z \\ B_x B_y & B_y^2 - B^2/2 & B_z B_y \\ B_x B_z & B_z B_y & B_z^2 - B^2/2 \end{bmatrix} + \epsilon\begin{bmatrix} E_x^2 - E^2/2 & E_x E_y & E_x E_z \\ E_x E_y & E_y^2 - E^2/2 & E_z E_y \\ E_x E_z & E_z E_y & E_z^2 - E^2/2 \end{bmatrix}$$ μ and ϵ are the permeability and permittivity in the ith neighboring element. A_i is area of side i of element. For electrostatic, AC, and DC solvers, only the electric field is included; while for magnetostatic, Eddy current, and magnetic transient solvers, only the magnetic field is considered. For AC solver and Eddy current solver, volume force density is the averaged (DC) force density. Lorentz force density is calculated instead of volume force density from Equation (7) in pure conductors containing source current in magnetostatic, Eddy current, and magnetic transient solvers: $$\boldsymbol{f} = \boldsymbol{J} \times \boldsymbol{B}$$

Loss Quantities

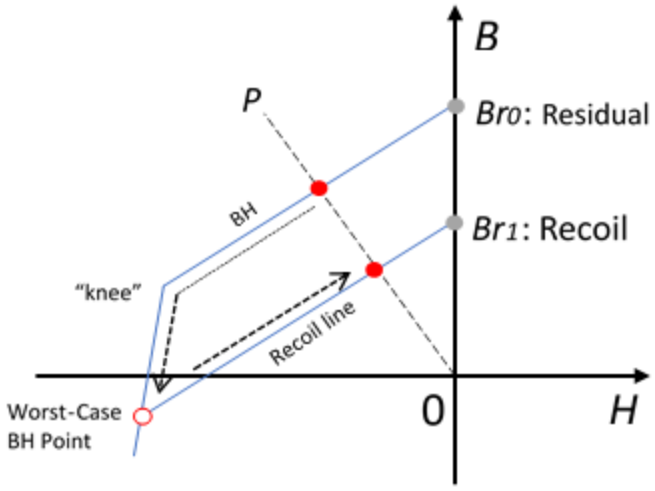
Ohmic loss	Ohmic loss is always associated with conduction current distribution in conductors which are not perfect. Thus the resistivity of conductors is responsible for the ohmic power loss when current flows in such conductors. It is also called the Joule-Lenz effect. There is always a heating effect due to the ohmic loss, often called Joule heating.

Total loss	Total loss is associated with loss density fields in 2D and 3D magnetic transient solutions only. Total loss uses the total integrated loss output from the solver and averages it, using each solver timestep between the last two consecutive save-field times. It is useful for passing loss density information from Maxwell to the Ansys thermal solvers with fewer save-field times. For Litz Wire only, total loss also includes StrandedLossAC. Unlike most other loss quantities which are instantaneous values, total loss is a running average over time, i.e. at time T1 it is calculated with fields from T1 to T2.
Hysteresis loss	Hysteresis loss is associated with loss density fields in 2D and 3D eddy current solutions only. Hysteresis loss is short for magnetic hysteresis loss and represents power loss in some magnetic materials (electric steels or ferrites) in alternating (sinusoidal) magnetic fields. This loss is due to a phenomenon called "magnetic viscosity" which causes the B and H fields to have a phase shift between them. In the B-H plane, for linear materials, the relationship between these two fields describes an ellipse. The hysteresis loss is proportional to the area of the ellipse.
Dielectric loss	Dielectric loss is associated with loss density fields in 2D and 3D eddy current solutions only. Dielectric loss or electric hysteresis loss represents power loss in ferroelectric materials (such as barium titanate, lead zirconate titanate) in alternating (sinusoidal) electric fields. This loss is due to a phenomenon called "electric viscosity" which causes the D and E fields to have a phase shift between them. In the D-E plane, for linear materials, the relationship between these two fields describes an ellipse. The dielectric loss is proportional to the area of the ellipse.
SurfaceLoss Density	The surface loss density is associated with the induced eddy current on the impedance boundary.
Emloss	In 2D and 3D eddy current solvers only: Emloss combines the ohmic loss, dielectric loss, hysteresis loss, and StrandedLossAC (for Litz Wire only).
Edgeloss density	Edge loss density represents losses associated with impedance boundary applied on conductive surfaces on the boundary of the solution domain or on surface of excluded objects. It assumes an exponential spatial decay (toward the interior of the respective material) of induced current magnitudes and of associated losses. Integrating the loss along the edge produces the entire loss associated with the "edge".
Core loss	The core loss combines eddy current losses and hysteresis losses for a transient solution type. It is a post-processing calculation, based on already calculated transient magnetic field quantities. It is applicable for the evaluation of core losses in steel laminations (frequently used in applications such as electric machines, transformers) or in power ferrites.
Solid Loss	The solid loss represents the resistive loss in a 2D or 3D volume and is calculated by:

	$$SolidLoss = \frac{1}{\sigma}\int_{vol} J^2 \cdot dV$$ For **2DXY** designs, the length is given by **Set Model Depth**, while for **RZ** designs the volume is based upon the rotation of the cross-section around the symmetry axis.
Stranded Loss (3 types)	There are three types of stranded loss quantities: **StrandedLoss**, **StrandedLossAC**, and **StrandedLossR**, which represent the loss in a 2D or 3D winding utilizing multi-turn coil terminals. • **StrandedLoss** is dependent on the object's material conductivity of a stranded source. It represents the loss due to the DC resistance only and uses the cross-sectional area of the object that is assigned with the excitation. Where ***J*** is the current density, it is calculated by: $$StrandedLoss = \frac{1}{\sigma}\int_{vol} J^2 \cdot dV$$ ◦ When Litz wire *is not defined*, StrandedLoss is computed by assuming fill factor = 100% (the ratio of net conductor area to coil terminal area). ◦ When Litz wire *is defined*, StrandedLoss is computed by using the actual fill factor based on the specified Litz stranding and represents the DC loss only. ◦ StrandedLoss does not include the losses of end-coil resistance in 2D. ◦ StrandedLoss can be used to scale the loss density to a coupled thermal analysis. • **StrandedLossAC** is reported when using Litz wire model, and is dependent on the object's material conductivity of a stranded source. It represents the loss due to the DC resistance as well as AC eddy current losses due to proximity effects and skin effects. ◦ StrandedLossAC = StrandedLoss + AC eddy current losses due to proximity effects and skin effects. ◦ StrandedLossAC does not include the losses of end-coil resistance in 2D.

	◦ StrandedLossAC can be used to transfer loss density to a coupled thermal analysis. • **StrandedLossR** represents the loss based on I^2 times the resistance **R**, by using the resistance value entered in the Winding properties for a voltage type winding only (Reported for a stranded voltage source not in an external circuit).
LossDensity	For Time Averaged Fields (for transient 2D and 3D solutions), the loss density is the time averaged loss density between a start time and end time, i.e., the accumulated loss density from start time to end time divided by the time duration.

Demagnetization Coefficient Plots



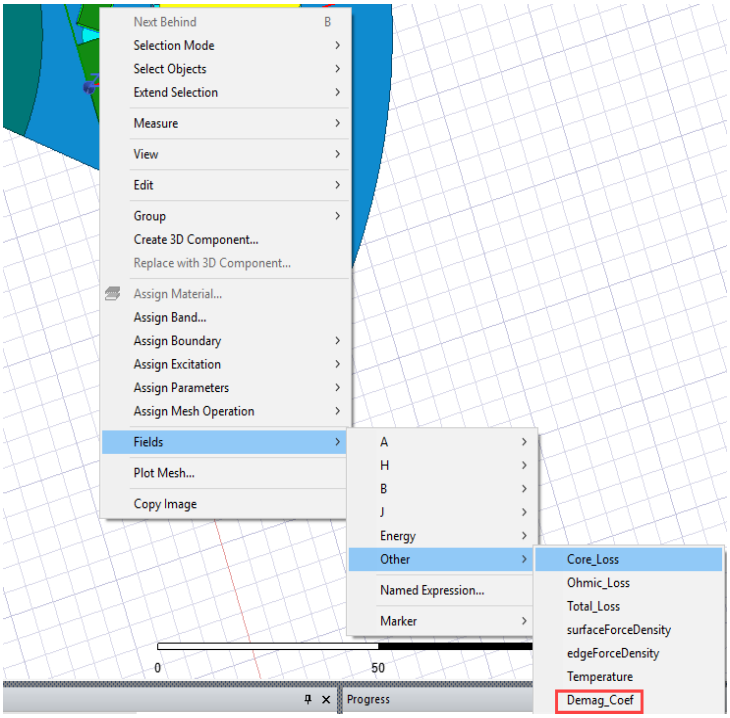
Demagnetization Coefficient: Demag_coef[%] = Br1/Br0*100%

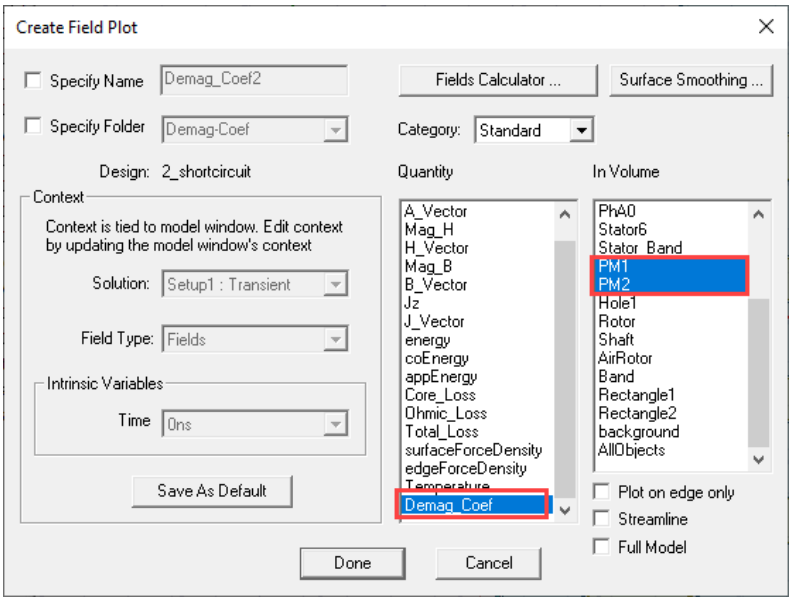
When Demag_Coef = 1, the magnet behaves without any demagnetization at that location;

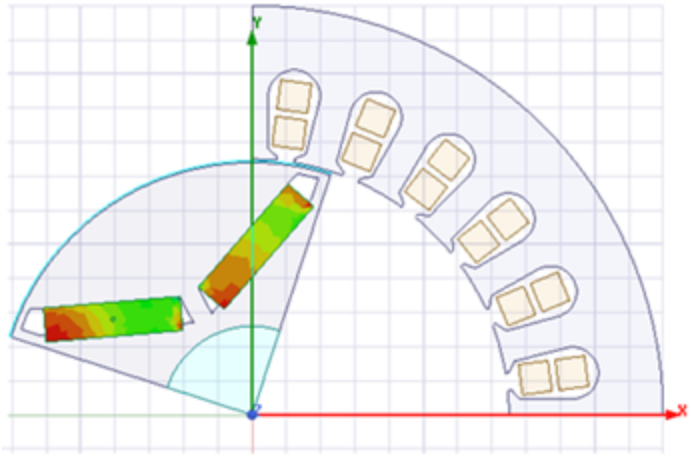
When Demag_Coef = 0, the magnet is fully demagnetized at that location.

Demag_Coef plot over the geometry of nonlinear permanent magnets:

Demag_Coef is a scalar value between 0 and 1, and is displayed as a color shaded plot inside nonlinear permanent magnets. **Demag_Coef** is applicable to 2D/3D transient solutions, and 2D/3D magnetostatic solutions - assign to objects by right-clicking them and selecting **Fields>Other>Demag_Coef**. Solvers provide the quantity at each node element-by-element to the post-processor for all nonlinear permanent magnetic objects at each time step with the saved field.

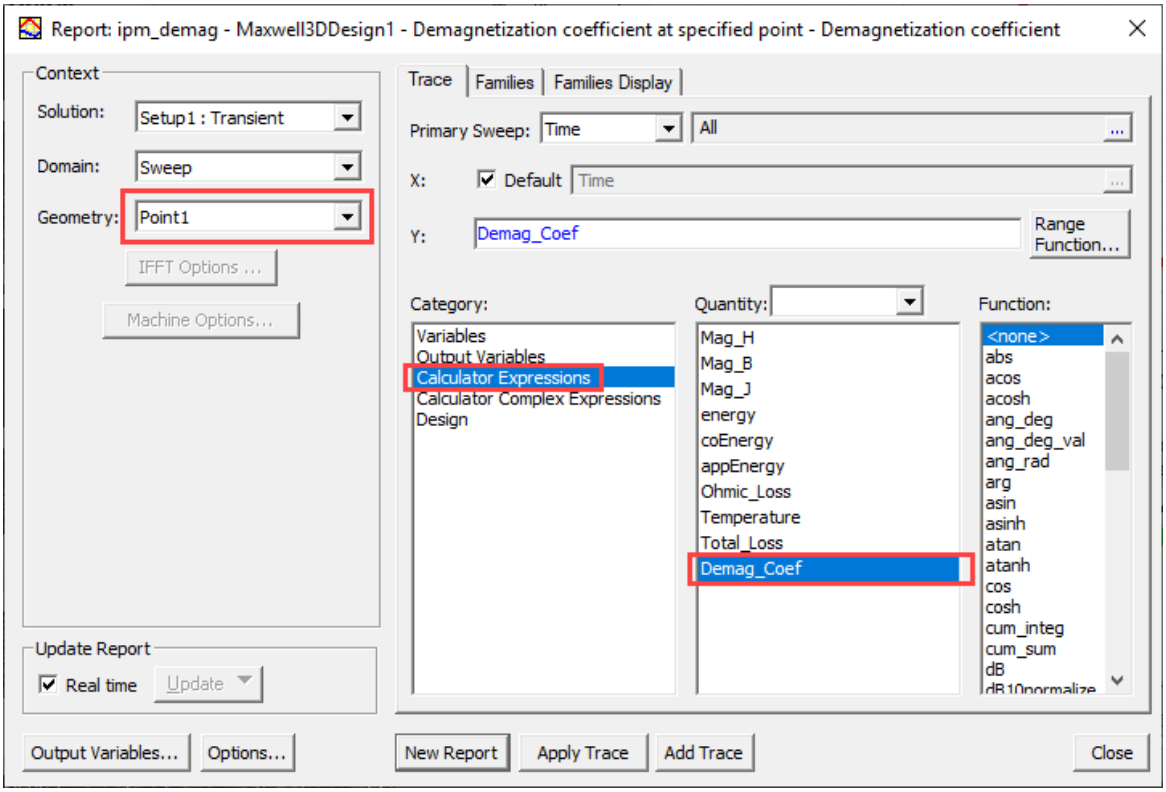


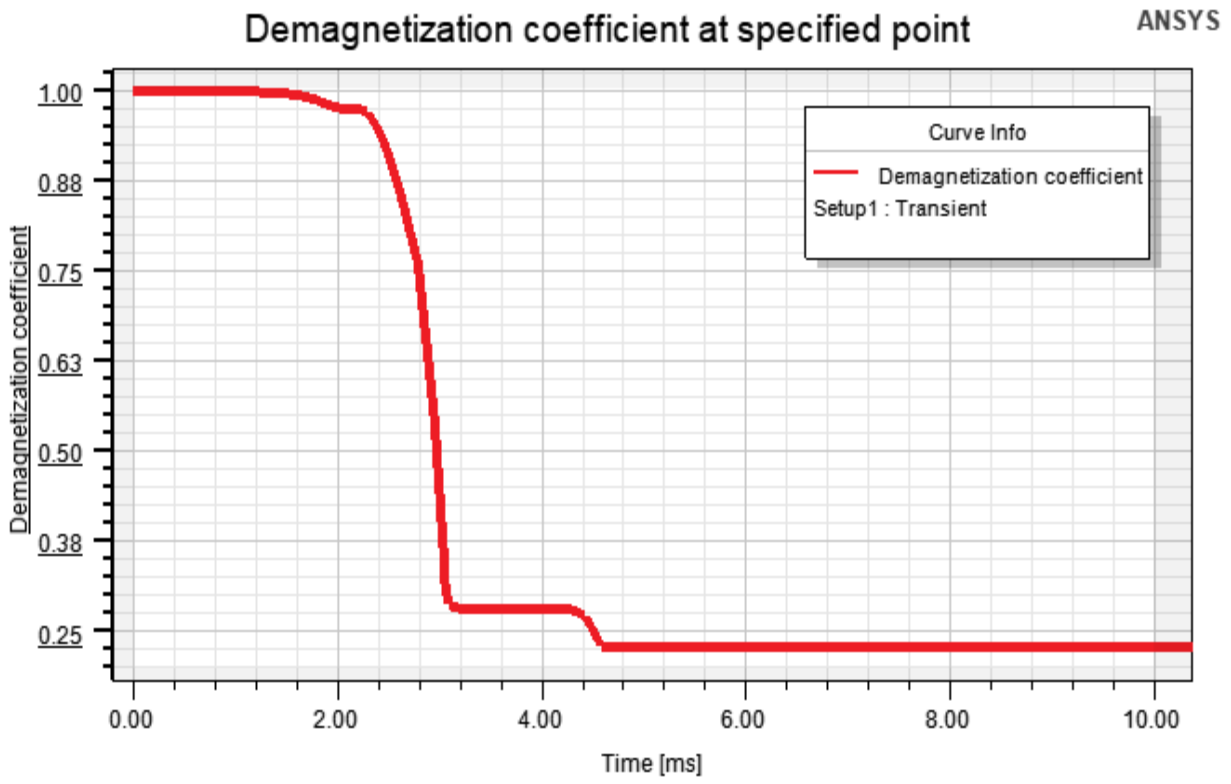




Demag_Coef curve as a function of time at specific locations:

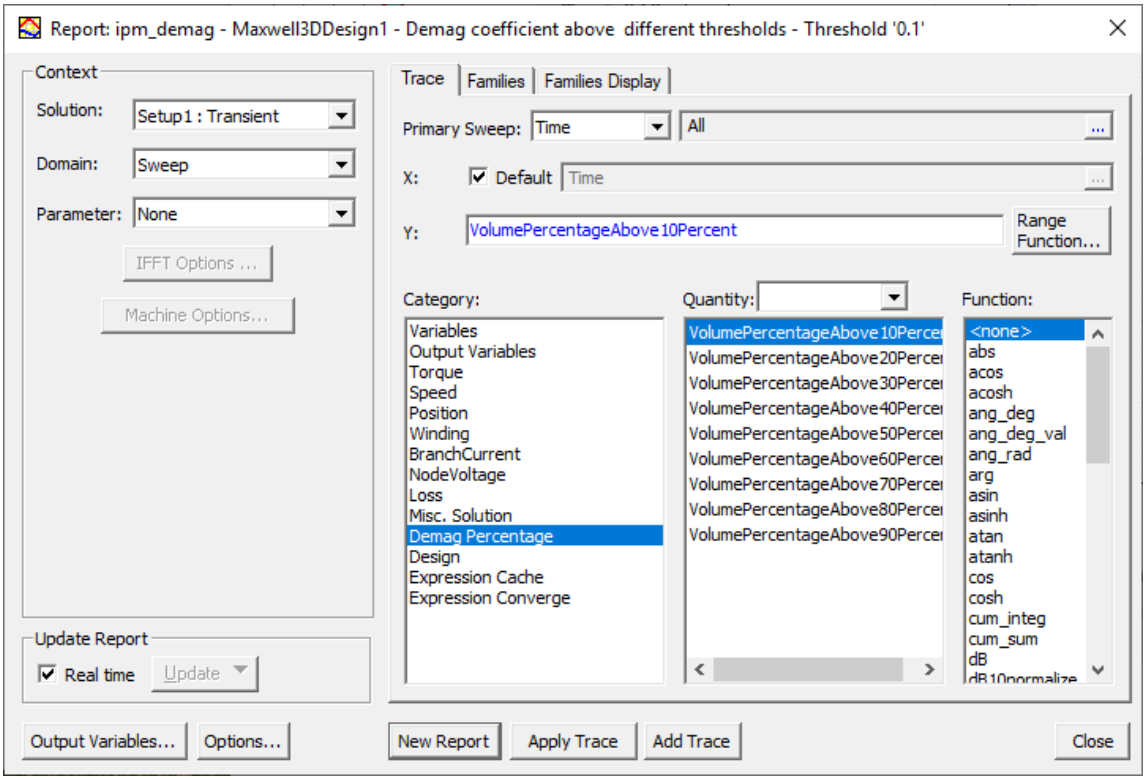
This is provided in terms of the expression cache at any specified point in the magnet. This plot is only applicable to 2D/3D transient solutions.



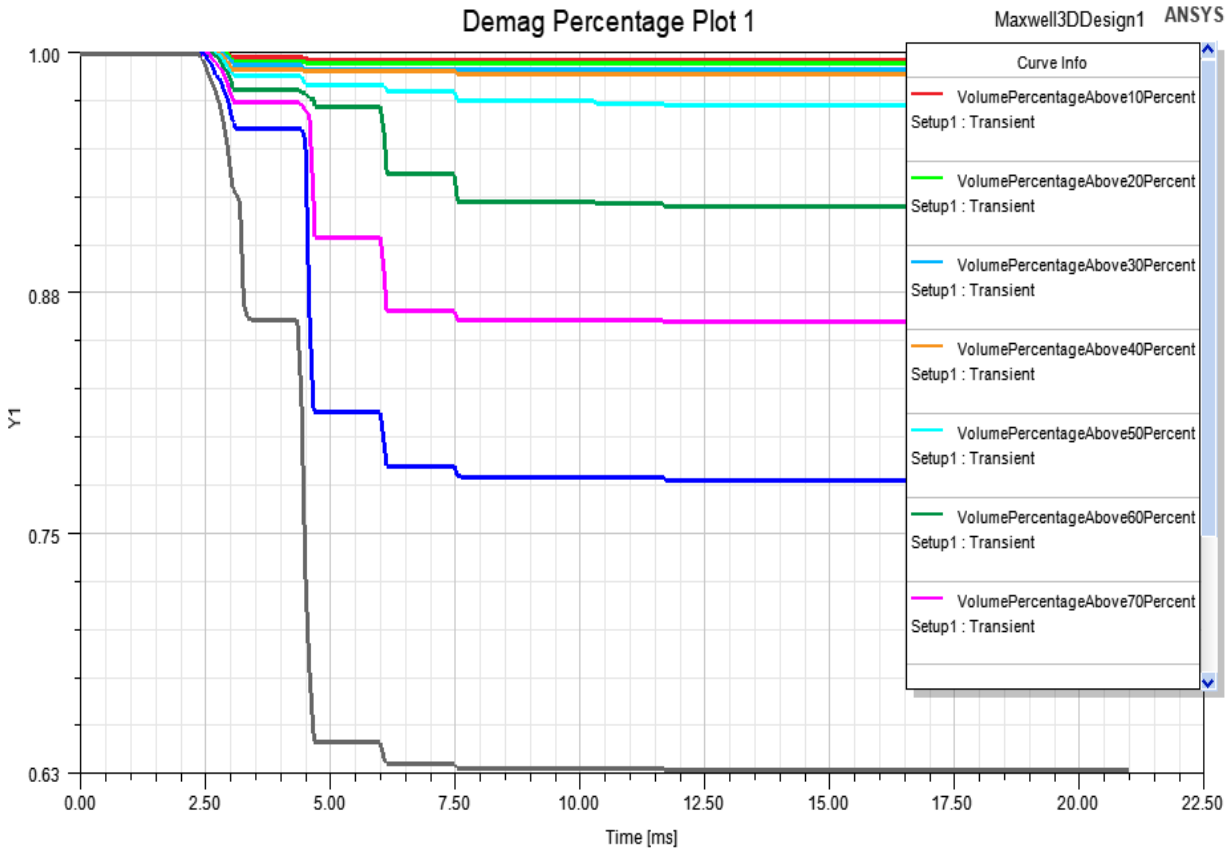


Demagnetization Percentage statistics curve as a function of time over all magnet volumes

For a specified Demag_Coef threshold, determine what the *percentage of total volume* for all magnets is, whose Demag_Coef is equal or greater than the specified Demag_Coef threshold. To determine this, the solver uses the Demag_Coef threshold values from 0.1 to 0.9, with 0.1 as the step interval, to compute the **Demag Percentage** statistics (**VolumePercentageAbove10Percent** through **VolumePercentageAbove90Percent**) at each time step.



As a result, the output is a series of nine curves from 0.1 to 0.9 similar to the example shown below. This plot is only applicable to 2D/3D transient solutions.



Plotting Time Averaged Fields Overlays

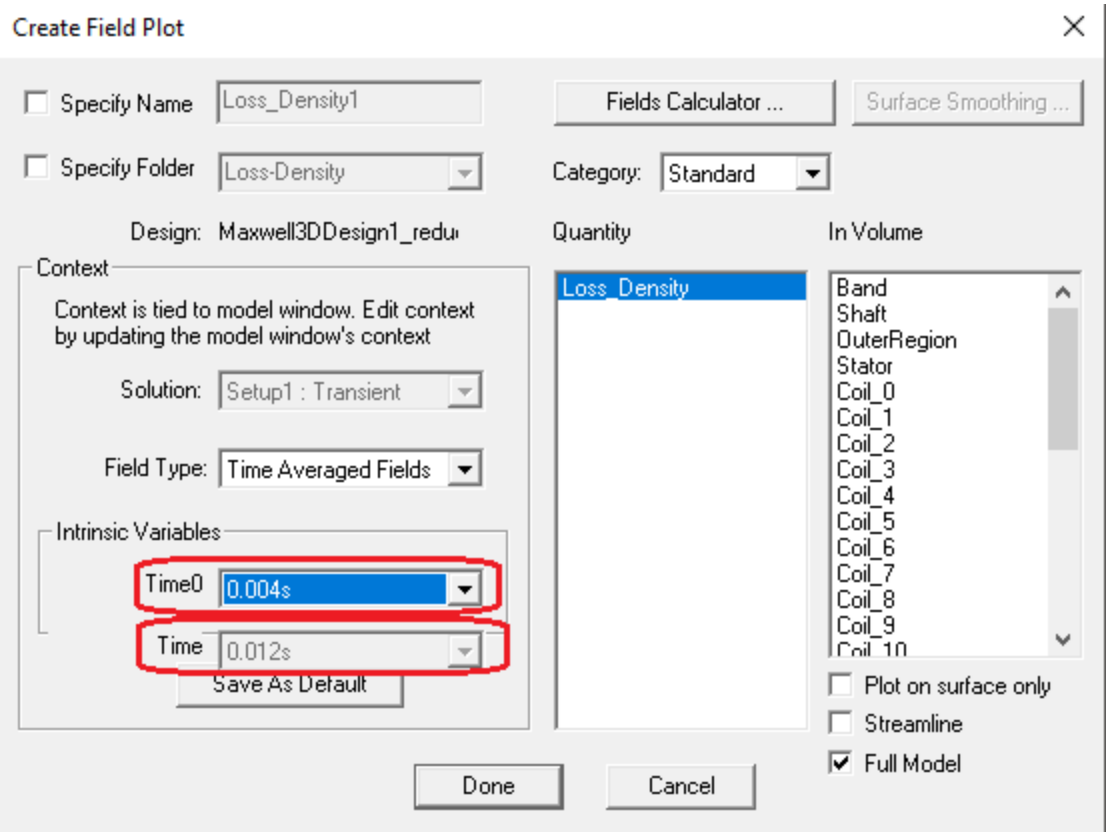
Time Averaged Field overlays are representations of time averaged field quantities, such as LossDensity, on surfaces or objects between specified start and end times divided by the time duration.

To plot a time averaged field quantity:

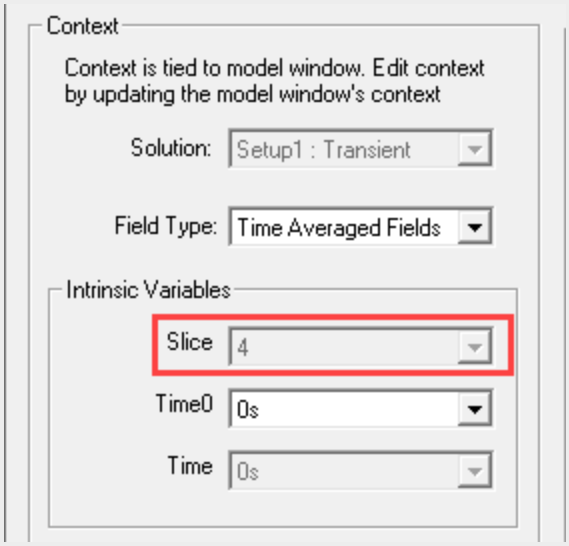
1. Select a point, line, surface, or object to create the plot on or within. You may also select a plane or object list in the **History Tree**.
2. On the main menu bar, click **Maxwell3D>Fields>Time Averaged Fields** or **Maxwell2D>Fields>Time Averaged Fields**.
3. On the **Time Averaged Fields** sub-menu, click the field quantity you want to plot. Available selections depend on the solved solution. (You can also right-click on **Field Overlays** in the Project Manager and select **Time Averaged Fields>***field_quantity*).

   If you select a scalar field quantity, a scalar surface or volume plot is created. If you select a vector field quantity, a vector surface or volume plot is created. If you select a vector quantity, you will be able to specify a Streamline plot. If the quantity you want to plot is not listed, see *Calculating a Derived Field Quantity*.

   After you select the field quantity to plot, the **Create Field Plot** dialog box appears.



Note: For Maxwell 2D transient solutions in which **Use Skew Model is enabled on the Model Settings tab**, an additional **Slice** field displays in the **Intrinsic**



Variables panel.

The **Specify Name** field shows a name based on the field quantity you selected, and the **Quantity** list shows the field quantity selected.

4. To specify a name for the plot other than the default, select **Specify Name**, and then type a new name in the box.
5. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the pull-down list. Plot folders are listed under **Field Overlays** in the project tree. Plot folders let you group plots with the same quantity together. All field plots under the same folder share the same color key.

Note	All plots (field overlays) in the same folder have the same scale settings. To plot the same field with a different scale, you can create or move the new plot to a separate folder. Plots in different folders have a different plot keys.

6. Select the solution to plot from the **Solution** pull-down list.
7. Select the fields type to plot in the **Field Type** to plot in the pull-down list. Choices are **Fields** or **Time Averaged Fields**.
8. Under **Intrinsic Variables**, select the variable value(s) at which the field quantity is evaluated. Variables available vary depending on the solution type.

> **Note:** For Maxwell 2D transient solutions in which **Use Skew Model is enabled on the Model Settings tab**, a **Slice** field displays in the **Intrinsic Variables** panel showing the slice currently selected for viewing in the modeler window.

9. If desired, you can choose a different field quantity to plot from the **Quantity** list.

Note	If you selected an *object*, you must check **Plot on surface only** to enable the **Surface Smoothing** button.

For vector quantities, the **Surface Smoothing** button is disabled. For details on using the **Surface Smoothing** button, see Modifying Field Plots.

10. Select the volume or surface (region) in which to plot the field from the **In Volume** list.

This selection enables you to limit plots to the intersection of a volume with the selected object or objects. You can select and deselect any items in the **In Volume** list. You can mix model objects with non-model boxes. For example you might want to see a plot from part of two model objects by restricting the region to a non-model box overlapping those parts.

Note	Multiple selection should be used when there is a discontinuous field on a surface. If not, the field on both sides of the surface is plotted and each interferes with the other.

11. If you selected a vector quantity, you can use the check box to select **Streamline** plot.

Note	• Before creating the Streamline plot, select both starting and ending edges (in 2D) or both surfaces (in 3D). • In the **Create Field Plot** dialog box, select **In Volume:** region, which is the region in which the streamlines will appear. Streamlines are outside of objects that are excited (sources).

	• To show more streamlines after the plot is created, on the **Modify attributes...** dialog **Plots** tab, reduce the **Seeds density** value. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large. Refer to Setting Field Plot Attributes for adjusting the Streamline display parameters, and Setting Fields Reporter Options for setting Streamline defaults. . For exporting Streamline plots, refer to Exporting Field Plots.

12. *Optionally*, you can select the **Plot on surface only** check box to obtain a plot around the surfaces of selected objects.
13. *Optionally*, for model objects in partial model designs, click the **Full Model** check box to calculate the fields on the full model based on the partial model solution.
14. *Optionally*, click **Fields Calculator** to open the fields calculator in which you can create named expressions, which can then be selected in the Create Field Plot dialog by choosing **Calculator** as the Category. The named expression(s) appear in the **Quantity** list.
15. Click **Done**.

    The time averaged field quantity is plotted on the surfaces or within the objects you selected. The plot uses the attributes specified in the **Plot Attributes** dialog box.

    The new plot appears in the view window. It is listed in the specified plot folder in the project tree. If you have created a field plot on a simulation in progress, the field plot is updated after the last adaptive solution.

    If you want to update the field overlay before then, to view progress in the solution, select the Field icon in the Project tree that contains the field plot of interest, right-click to display the short cut menu, and select **Update Plots**.

    To turn off the display of the plot, right click on the plot and select **Plot Visibility** from the short-cut menu. Unchecking **Plot Visibility** turns off the plot display.

Plotting Noise Vibration Overlays *(Transient designs only)*

Noise vibration field overlays are representations of basic or derived noise vibration field quantities on surfaces or objects for the current design variation. You can set the design variation via the **Set Design Variation** dialog box. This dialog box is accessible from the **Solution Data** window via by clicking the ellipsis button on the right of the Design Variation field, and via the **Results>Apply Solved Variation** command.

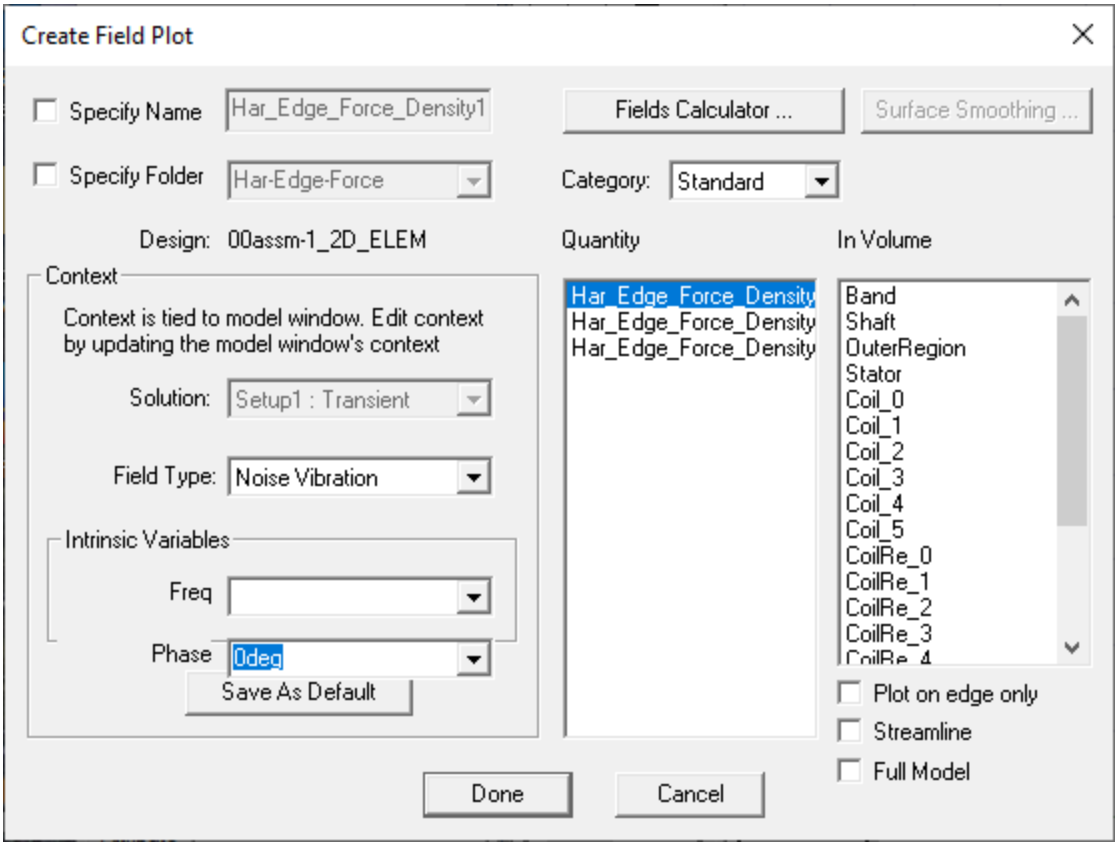
The **Noise Vibration** field type is available for Maxwell 2D and 3D Transient designs if element-based harmonic forces are set up. The **Noise Vibration** field type handles surface and volume force density in 3D, and surface and edge force density in 2D. **Frequency** and **Phase** intrinsic variables are used instead of **Time**. The **Noise Vibration** field overlays share the same Maxwell solution as the standard Fields overlays.

To plot a noise vibration field quantity:

1. Select a surface or volume for a 3D design; or an edge or surface for a 2D design, to create the plot on or within the selected objects.
2. On the main menu bar, click **Maxwell3D>Fields>Noise Vibration** or **Maxwell2D>Fields>Noise Vibration**.
3. On the **Noise Vibration** sub-menu, click the field quantity you want to plot. (You can also right-click on **Field Overlays** in the Project Manager and select **Fields>Noise Vibration>***field_quantity*).

   If you select a scalar field quantity, a scalar surface or volume plot is created. If you select a vector field quantity, a vector surface or volume plot is created. If you select a vector quantity, you will be able to specify a Streamline plot. If the quantity you want to plot is not listed, see *Calculating a Derived Field Quantity*.

   After you select the field quantity to plot, the **Create Field Plot** dialog box appears.



The **Specify Name** field shows a name based on the field quantity you selected, and the **Quantity** list shows the field quantity selected.

4. To specify a name for the plot other than the default, select **Specify Name**, and then type a new name in the box.
5. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the pull-down list. Plot folders are listed under **Field Overlays** in the project tree. Plot folders let you group plots with the same quantity together. All field plots under the same folder share the same color key.

Note	All plots (field overlays) in the same folder have the same scale settings. To plot the same field with a different scale, you can create or move the new plot to a separate folder. Plots in different folders have a different plot keys.

6. Select the solution to plot from the **Solution** pull-down list.
7. Select **Noise Vibration** in the **Field Type** pull-down list.
8. Under **Intrinsic Variables**, select the variable value(s) at which the field quantity is evaluated. For Noise Vibration, the variables available are **Freq**ency and **Phase**.
9. If desired, you can choose a different field quantity to plot from the **Quantity** list. For the **Har_Surf_Force_Density_Peak** quantity plotted on the surface of a geometry, the **Surface Smoothing** button is enabled. For the other two quantities, the **Surface**

Smoothing button is disabled. For details on using the **Surface Smoothing** button, see Modifying Field Plots.

10. Select the volume or surface (region) in which to plot the field from the **In Volume** list.

    This selection enables you to limit plots to the intersection of a volume with the selected object or objects. You can select and deselect any items in the **In Volume** list. You can mix model objects with non-model boxes. For example you might want to see a plot from part of two model objects by restricting the region to a non-model box overlapping those parts.

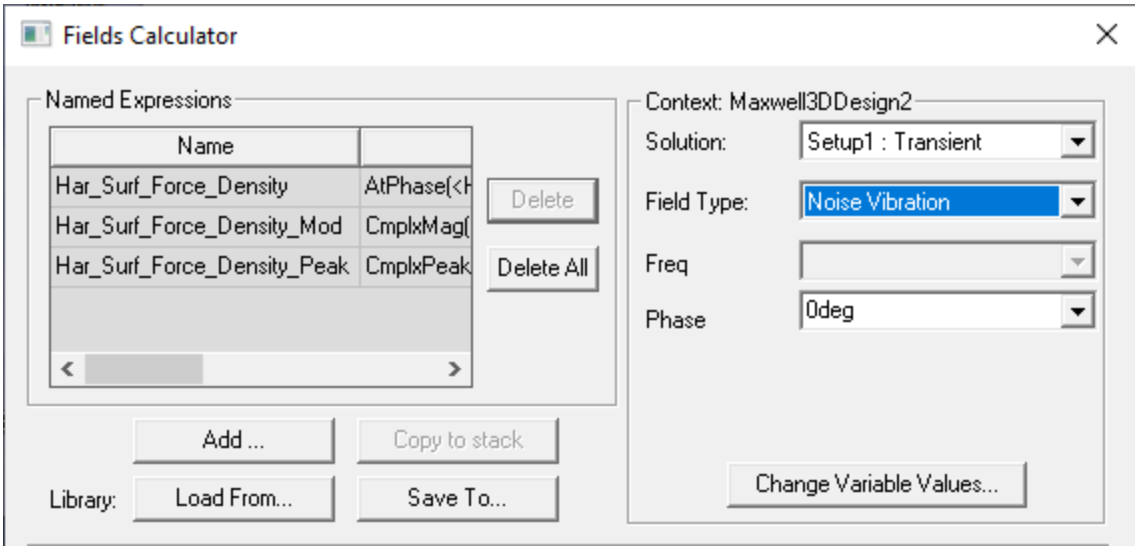
Note	Multiple selection should be used when there is a discontinuous field on a surface. If not, the field on both sides of the surface is plotted and each interferes with the other.

Note	• Non-convex 3D non-model solids are not supported for Field Overlay Plots and Fields Calculator computations. • Object lists containing non-model object(s) are supported for Field Overlay Plots but are not supported for Fields Calculator computations.

11. *Optionally*, You can use the check box to select **Streamline** plot.

Note	• Before creating the Streamline plot, select both starting and ending edges (in 2D) or both surfaces (in 3D). • In the **Create Field Plot** dialog box, select **In Volume:** region, which is the region in which the streamlines will appear. Streamlines are outside of objects that are excited (sources). • To show more streamlines after the plot is created, on the **Modify attributes...** dialog **Plots** tab, reduce the **Seeds density** value. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large. Refer to Setting Field Plot Attributes for adjusting the Streamline display parameters, and Setting Fields Reporter Options for setting Streamline defaults. . For exporting Streamline plots, refer to Exporting Field Plots.

12. *Optionally*, for 3D designs you can select the **Plot on surface only** check box to obtain a plot around the surfaces of selected objects. Similarly, for 2D designs, you can select **Plot on edge only** to obtain a plot around the edges of selected objects.
13. *Optionally*, for model objects in partial model designs, click the **Full Model** check box to calculate the fields on the full model based on the partial model solution.
14. *Optionally*, click **Fields Calculator** to open the fields calculator in which you can create named expressions.



These can then be selected in the **Create Field Plot** dialog by choosing **Calculator** as the Category. The named expression(s) appear in the **Quantity** list.

15. Click **Done**.

    The field quantity is plotted on the surfaces or within the objects you selected. The plot uses the attributes specified in the **Plot Attributes** dialog box.

    The new plot appears in the view window. It is listed in the specified plot folder in the project tree. If you have created a field plot on a simulation in progress, the field plot is updated after the last adaptive solution.

    If you want to update the field overlay before then, to view progress in the solution, select the Field icon in the Project tree that contains the field plot of interest, right-click to display the short cut menu, and select **Update Plots**.

    To turn off the display of the plot, right click on the plot and select **Plot Visibility** from the short-cut menu. Unchecking **Plot Visibility** turns off the plot display.

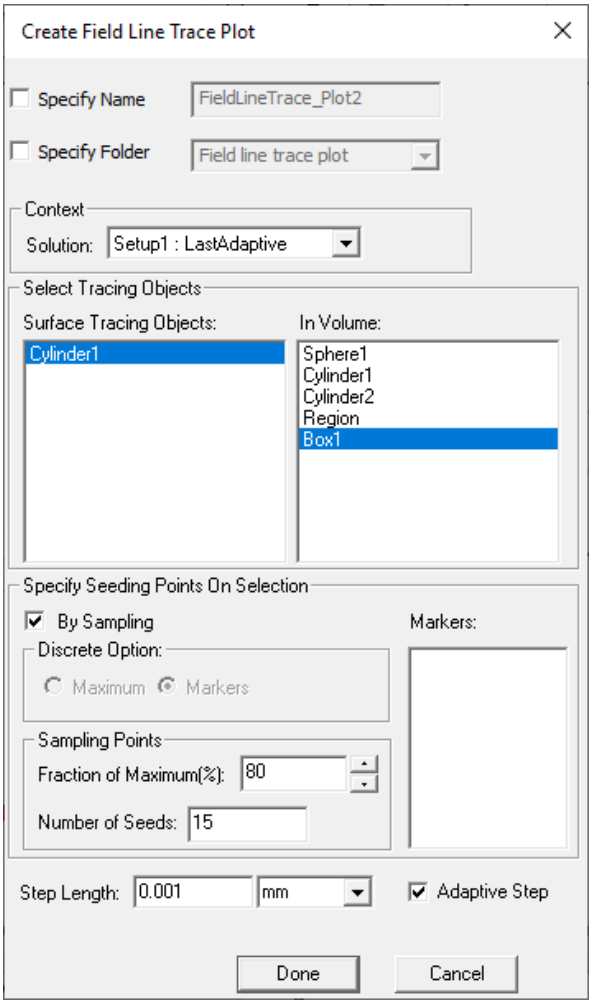
Setting a Plot's Visibility

Plotting Field Line Trace Overlays

For Maxwell electrostatic solutions, Field Line Trace overlays allow you to plot E field lines in 3D space and on insulator surfaces. The E field lines allow users to calculate the inception voltages for breakdown analyses.

To plot a field line trace overlay:

1. Select a surface from the geometry model or from a scalar surface plot.
2. Launch the **Create Field Line Trace Plot** dialog from the main **Maxwell>Fields>Field>Field Line Trace** menu, from the modeler context menu, or from the **Fields Overlay** context menu in the project tree.



3. To specify a name for the plot other than the default, select **Specify Name**, and then type a new name in the box. The **Specify Name** field shows a default name based on the field quantity you selected,
4. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the pull-down list. Plot folders are listed under **Field Overlays** in

the project tree. Plot folders let you group plots with the same quantity together. All field plots under the same folder share the same color key.

Note	All plots (field overlays) in the same folder have the same scale settings. To plot the same field with a different scale, you can create or move the new plot to a separate folder. Plots in different folders have a different plot keys.

5. Select the desired **Surface Tracing Objects** and **In Volume** from the respective lists. You can use the **Ctrl** and **Shift** keys to select multiple items.
6. The **Specify Seeding Points on Selection** panel allows you to manage the seeding points that will be used when calculating the trace lines:
    - If **By Sampling** is not selected, you can select either the **Maximum**, or **Markers** if markers for an E Field overlay plot have been set.
    - If **By Sampling** is selected, **Maximum** and **Markers** choices are disabled, and you can set a **Fraction of Maximum (%)** percentage value and the **Number of Seeds** to be used when calculating trace lines.
7. Enter the **Step Length** and unit. Step length controls the spacing between evaluation points along the E field direction. If **Adaptive Step** is checked, the step length will be inversely proportional to the E field strength.
8. Click **Done** to close the dialog box.

You can now analyze the design to generate the field line trace plot. After the field line trace plot has been generated, you can invoke the **Inception Voltage Evaluation** dialog box, which allows you to calculate the breakdown voltage - the voltage at which corona discharge will occur for the selected seed position and gas type.

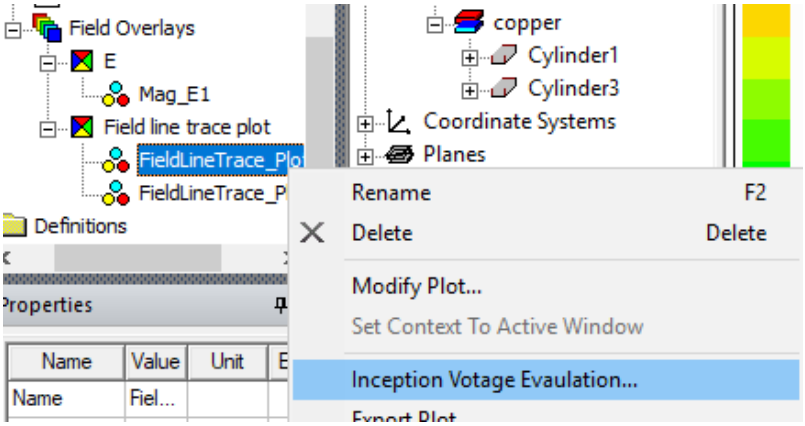
Inception Voltage Evaluation

Inception Voltage Evaluation

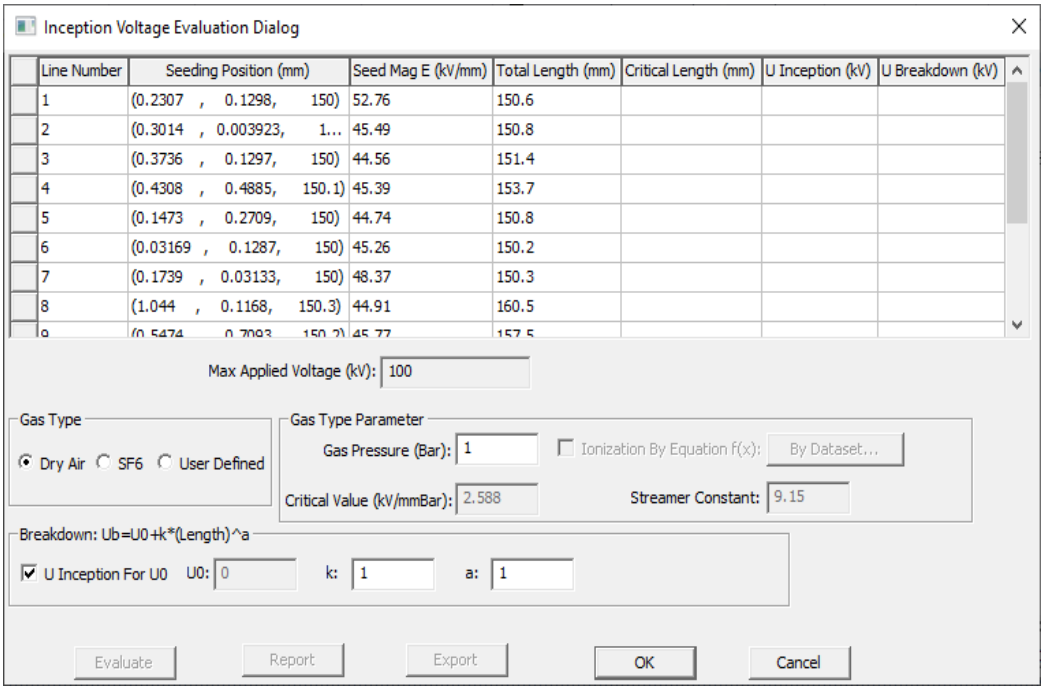
For Maxwell electrostatic solutions, Field Line Trace overlays allow you to plot E field lines in 3D space and on insulator surfaces. After a field line trace plot has been generated, you can invoke the **Inception Voltage Evaluation** dialog box, which allows you to calculate the breakdown voltage – the voltage at which a corona discharge will occur for the selected seed positions and gas type.

To evaluate inception voltages:

1. For any solved field line trace plot, launch the **Inception Voltage Evaluation Dialog** from the **Fields Overlay** context menu in the project tree.



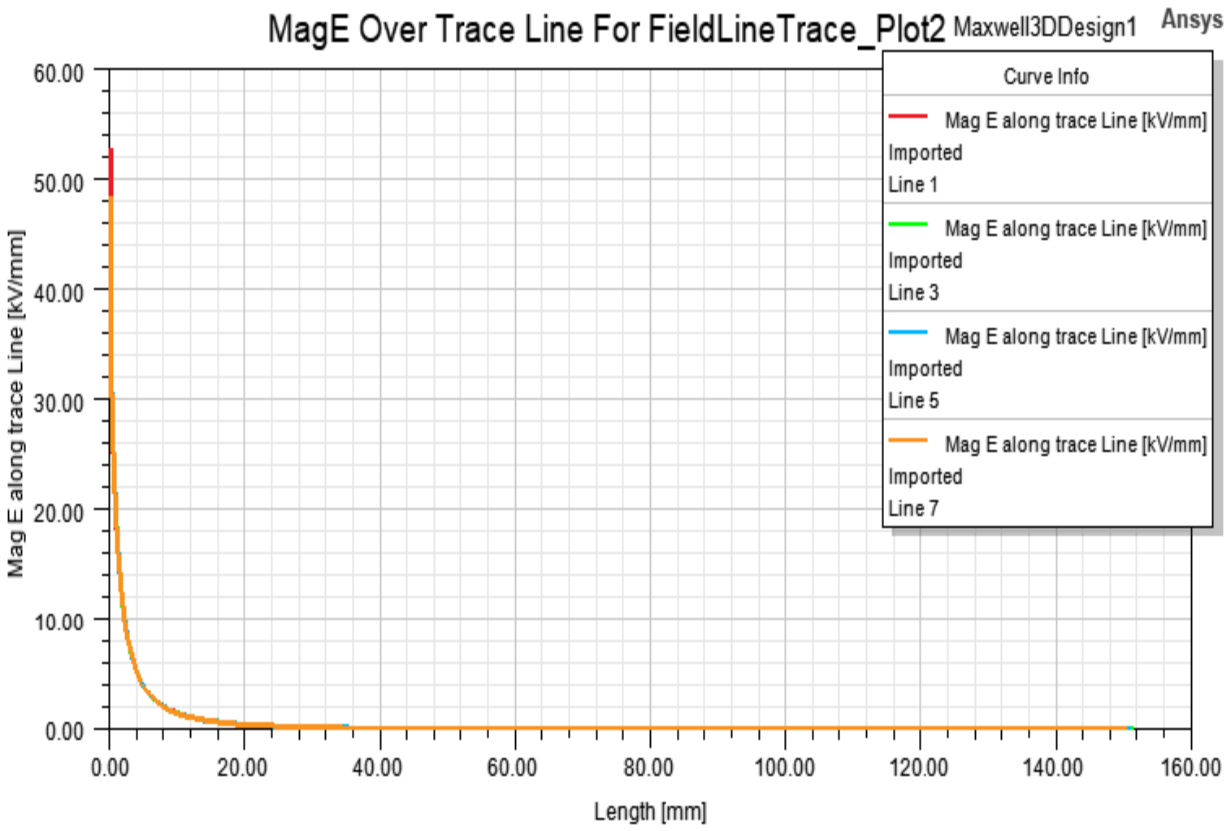
The **Inception Voltage Evaluation Dialog** opens.



2. The **Gas Type** panel allows you to choose either **Dry Air**, **SF6** (sulfur hexaflouride), or a **User Defined** gas. The selection controls which gas type parameters can be entered.
3. In the **Gas Type Parameter** panel:
    - For **Dry Air** and **SF6**, only the **Gas Pressure** value (in **Bar** units) can be adjusted. The **Critical Value** and **Streamer Constant** parameters are set to predetermined values.
    - For **User Defined** gas types, in addition to **Gas Pressure**, you can also set values for the **Critical Value** and **Streamer Constant** parameters. Additionally, you can click the **By Dataset** button to open an **Edit Dataset** dialog in which you can enter data

points that define the **Ionization Coefficient Curve** for the gas type you are using. If you check **Ionization By Equation f(x)**, you can specify a function for Ionization (for example, 16.8*x –81.0). Typically, the **User Defined** values would come either from experimental test results or from a manufacturer.

4. In the **Breakdown** panel with **U Inception for U0** unchecked, you can enter the **U0**, **k**, and **a** parameters for the breakdown equation where the **Length** is the total length of the concerned trace line. When **U Inception for U0** is checked, **U0** is the evaluated inception value.
5. Select the row(s) for which you wish to evaluate **Critical Length (mm)** and **U Inception (kV)**, and **U Breakdown (kV)** values. You can use the **Ctrl** and **Shift** keys to select multiple rows. You can select all rows by double clicking any cell. You can sort by column by clicking the column header, click it again to reverse the order.
6. Click **Evaluate** to have Maxwell generate the **Critical Length (mm)**, **U Inception (kV)**, and **U Breakdown (kV)** values for the selected rows. This data can be useful when choosing the insulation for a design.
7. You can select one or more rows from the Inception table to create a XY plot by clicking the “Report” button. A curve will be created for each selected trace line. It will be a curve of MagE of each point on the trace line vs the segment length of the point to the starting point of the trace line. For example:



8. When **U Inception (kV)** and **U Breakdown (kV)** are computed for any trace lines, the **Export** button is enabled. You can select any rows to export or export all computed rows if there is no selection. (However, if any of the selected lines don't have computed inception/breakdown data, the "Export" button will be disabled.) The data is exported as a text file.

   A sample exported text file (*.txt) is shown below, which includes the *Field Line Plot Inception Settings* that are used to compute the inception and breakdown voltages. It also includes the maximum applied voltage for the design and the inception table for the exported lines.

Plotting Field Line Trace Overlays

Named Expressions

Named expressions can contain any combination of scalar, vector, or geometry functions. When you plot a field overlay or create a report based on a named expression, only corresponding quantities are available.

For example, if you select a point for the **Geometry** and a **Category** that is a named expression based on the point (or other scalar, non-3D value), then the **Quantity** list only lists expressions that returns a single scalar value. If you have added named expressions that take the magnitude of the ScalarX(), ScalarY(), or ScalarZ() of a vector point value, then you can create output variables for those expressions only in this case.

Named expressions can be plotted in the following three ways:

To create a field overlay of a named expression, the expression must be a real value (scalar or vector) that has values everywhere in space (or at least on every point in the geometry you plan to use for the field overlay).

To create a 2D report from a named expression that evaluates in the Fields Calculator as a single scalar value, the expression must result in a single-valued, real, scalar value. A single-valued item could be the value on a single point in space or the result of a function that returns a single value (such as an integration, max/value, min/value, or other function).

To create a 2D report from a named expression that is evaluated (in the Fields Calculator) along a polyline, the expression must be a real scalar that has values everywhere in space (or at least everywhere on the line object you want to use to sample the values).

Named expressions can be created in the Fields Calculator.

Plotting Derived Field Quantities

Derived field quantities are field quantity representations that have been deduced from the original field solution using the Fields Calculator.

1. Select a point, line, surface, or object to create the plot on or within. You may also select a plane or object list in the **History Tree**.

Note	For 2D Designs, a plane selection must be consistent with the drawing plane or an error will result.

   If it does not exist, create it.
2. Click **Maxwell3D or Maxwell2D and select Fields>Fields>Named Expression**.

   The **Selecting calculated expression** dialog box appears.
3. Select the derived quantity you want to plot, and then click **OK**.

   The **Create Field Plot** dialog box appears.
4. To specify a name for the plot other than the default, select **SpecifyName**, and then type a new name in the **Name** box.
5. To specify a folder other than the default in which to store the plot, select **Specify Folder**, and then click a folder in the pull-down list. Plot folders are listed under **Field Overlays** in the project tree.
6. Select the solution to plot from the **Solution** pull-down list.

7. Select the derived field quantity to plot from the **Quantity** list.

Note	If you select a point for the **Geometry** and a **Category** that is a named expression based on the point (or other scalar, non-3D value), then the **Quantity** list only lists expressions that returns a single scalar value. If you have added named expressions that take the magnitude of the ScalarX(), ScalarY(), or ScalarZ() of a vector point value, then you can create output variables for those expressions only in this case.

Note	If you select a polyline for the **Geometry** and a **Category** that is a named expression based on the line, then the **Quantity** list only lists corresponding expressions (i.e., will not list scalar values when a line is selected as the geometry).

8. Select the volume or surface (region) in which to plot the field from the **In Volume** list.

   This selection enables you to limit plots to the intersection of a volume and the selected object.

9. Click **Done**.

   The derived field quantity you created in the Fields Calculator is plotted on the surfaces or objects you selected. The new plot is listed in the project tree under **Field Overlays**.

Creating 2D Reports From Named Expressions

You can create a 2D report from named expressions that evaluate as a single scalar value or that evaluate along polylines.

To create a report from a named expression evaluating as a single scalar value:

1. Click **Maxwell2D or Maxwell3D>Results>Create Report**.

   The **Create Report** dialog box appears.

2. In the **Target Design** pull-down list, click the design containing the solution data you want to plot.
3. Select **Fields** from the **Report Type** pull-down list.
4. In the **Display Type** pull-down list, select the type of report you want to create.
5. Click **OK**.

   The **Traces** dialog box appears.

6. In the **Solution** pull-down list, click the solution containing the data you want to plot.
7. Add one or more traces to include in the report.

Note	If you select a point for the **Geometry** and a **Category** that is a named expression based on the point (or other scalar, non-3D value), then the **Quantity** list only lists expressions that returns a single scalar value. If you have added named expressions that take the magnitude of the ScalarX(), ScalarY(), or ScalarZ() of a vector point value, then you can create output variables for those expressions only in this case.

8. Click **Done**.

The report appears in the view window and is listed in the project tree. The default name based on the Report <type> you selected, (for example, Modal Solution Data Plot *n* or Far Fields Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes. Once you have created a report, additional options become available on the **Results** submenu.

To create a report from a named expression evaluating along a polyline:

1. Click **Maxwell3D, Maxwell2D or RMxprt and select Results>Create Report**.

   The **Create Report** dialog box appears.
2. In the **Target Design** pull-down list, click the design containing the solution data you want to plot.
3. Select **Fields** from the **Report Type** pull-down list.
4. In the **Display Type** pull-down list, select the type of report you want to create.
5. Click **OK**.

   The **Traces** dialog box appears.
6. In the **Solution** pull-down list, click the solution containing the data you want to plot.
7. Select the geometry you want to plot from the **Geometry** pull-down list.
8. Add one or more traces to include in the report.

Note	If you select a polyline for the **Geometry** and a **Category** that is a named expression based on the line, then the **Quantity** list only lists corresponding expressions (i.e., will not list scalar values when a line is selected as the geometry).
9. Click **Done**.

   The report appears in the view window and is listed in the project tree. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes. Once you have created a report, additional options become available on the **Results** submenu.

Creating Scalar Field Plots

A scalar plot uses shaded colors or contoured lines to illustrate the magnitude of field quantities on surfaces or volumes.

1. Do one of the following:
   a. To create a scalar surface plot, select the faces on which you want to plot the fields.
   b. To create a scalar volume plot, select the objects within which you want to plot the fields.
2. Click **Maxwell3D or Maxwell2D and then select Fields>Fields**.
3. On the **Fields** submenu, click the scalar field quantity you want to plot.

   The **Create Field Plot** dialog box appears.
4. Follow the procedure for plotting field overlays.

The new plot is listed in the specified plot folder in the project tree.

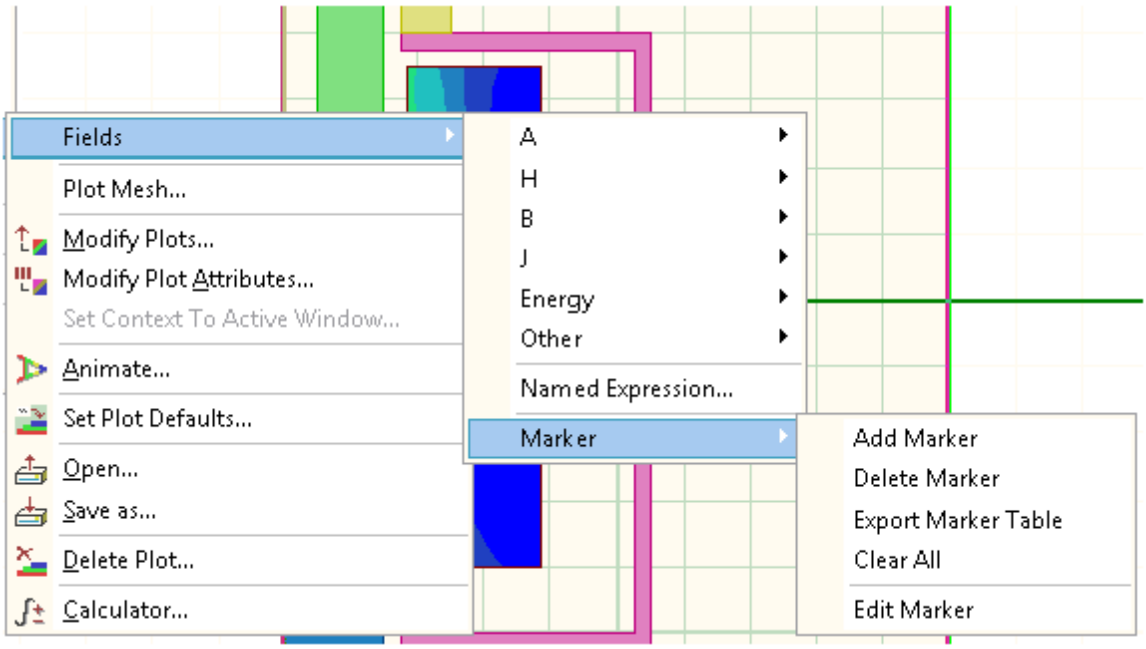
Related Topics

Modifying Field Plot Attributes

Working with Scalar Field Plot Markers

The field overlay plot marker feature enables you to create a marker at selected points in the scalar field overlay plot geometry, and to obtain the field value at that point. The fields Marker sub-menu enables you to:

- Add Marker
- Delete Marker
- Export Marker Table
- Clear All markers
- Edit Marker



Adding a Field Plot Marker

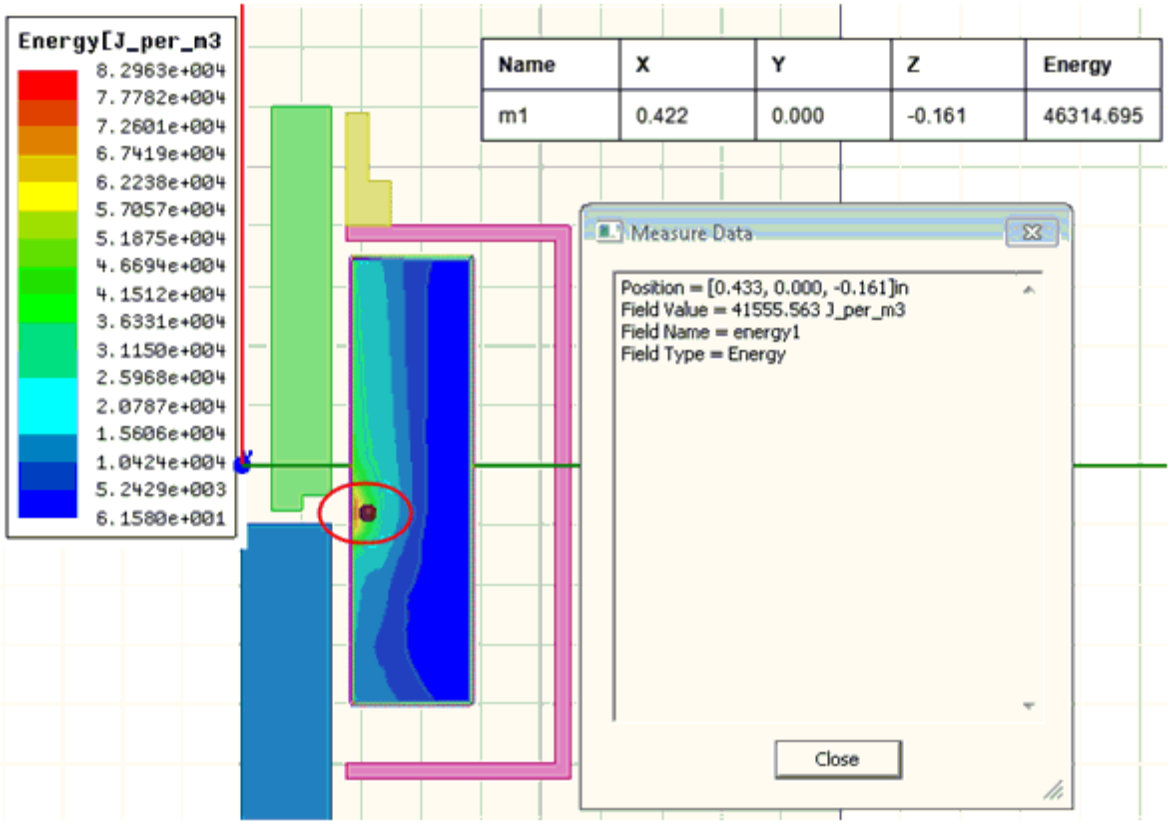
To add one or more field plot markers to a scalar field:

1. On the main menu click **Maxwell3D or Maxwell2D and then select Fields>Fields>Marker>AddMarker**. Alternatively you can right-click anywhere in the

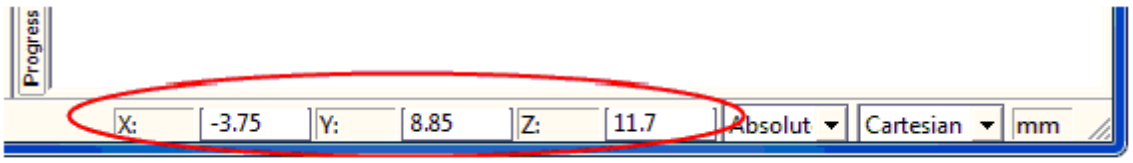
modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields>Marker>AddMarker**.

The **Measure Data** dialog box opens and a round dot appears at the tip of the cursor.

2. Drag the dot over the spot on the field overlay plot where you want to add a marker. The Measure Data dialog shows detailed information for the spot currently under the dot.



3. Click the desired point in the field overlay plot to add the marker at that location. Alternatively you can select the position of the marker by entering the values manually in the edit fields at the bottom of the window as shown below.



A table showing the marker coordinates and associated field value is also created and added to the modeler window.

4. Repeat as desired to add additional markers.
5. Press the **Esc** key when finished adding markers.

Deleting a Field Plot Marker

To delete a field plot marker:

1. Click on the marker you want to delete to select it. The row corresponding to the selected marker will be highlighted in the marker table.

   Press and hold the **Ctrl** key and click to select multiple markers.
2. On the main menu click **Maxwell3D or Maxwell2D and then select Fields>Fields>Marker>Delete Marker** to delete the selected marker(s).

   – Alternatively you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields>Marker>Delete Marker**.

   – You can also simply press the **Delete** key to delete the selected marker(s).

Exporting a Field Plot Marker Table

You can export a field plot marker table to either a comma- or tab-delimited file as follows:

1. On the main menu click **Maxwell3D or Maxwell2D and then select Fields>Fields>Marker>Export Marker Table**.

   Alternatively you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields>Marker>Export Marker Table**.
2. In the **Export As** dialog box, choose the export format, either **.csv** or **.tab**, and save the file in the desired location.

   The exported file can then be imported into another application such as a spreadsheet.

	A	B	C	D	E
1	Name	X	Y	Z	H[A_per_m]
2	m1	2	22.935	1.517	1234
3	m2	1.517	17.373	1.517	123
4	m3	2.488	23.516	1.517	234
5	m4	2.751	23.828	1.517	1324
6					

Clearing All Field Plot Markers

To clear all field plot markers in the active modeler window do one of the following:

- On the main menu click **Maxwell3D or Maxwell2D and then select Fields>Fields>Marker>Delete All**.
- Alternatively you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields>Marker>Delete All**.

Deleting all the markers also removes the marker table.

Editing Field Plot Markers

To edit field plot markers:

1. On the main menu click **Maxwell3D or Maxwell2D and then select Fields>Fields>Marker>Edit Marker**.

   Alternatively you can right-click anywhere in the modeler window, or on the Field Overlays folder icon in the Project Manager, and select **Fields>Marker>Edit Marker**.
2. Click on the marker you wish to edit. The row corresponding to the selected marker is highlighted in the marker table. The properties of the marker are displayed in the Properties window.
3. You can change **Position** of the selected marker by editing its coordinate values. The marker table changes to reflect the new value. You can also click the **Color** value bar to select a new color for the marker.
4. Optionally, press the **Delete** key to delete the marker and its corresponding entry in the marker table.
5. When finished editing markers, press **Esc** to exit the marker editing function.

Creating Vector Field Plots

A vector plot uses arrows to illustrate the magnitudes of the x-, y-, and z-components of field quantities. Vector plots can be created on surfaces or volumes.

1. Do one of the following:
   a. To create a vector surface plot, select the faces on which you want to plot the fields.
   b. To create a vector volume plot, select the objects within which you want to plot the fields.
2. Click **Maxwell3D** or **Maxwell2D** and then select **Fields>Fields**.
3. On the **Fields** submenu, click the vector field quantity you want to plot.
4. Follow the procedure for plotting field overlays.

   If you select a vector quantity, you can also check Streamline for the plot.

Note	• Before creating the Streamline plot, select both starting and ending edges (in 2D) or both surfaces (in 3D). • In the **Create Field Plot** dialog box, select **In Volume:** region, which is the region in which the streamlines will appear. Streamlines are outside of objects that are excited (sources). • To show more streamlines after the plot is created, on the **Modify attributes...** dialog **Plots** tab, reduce the **Seeds density** value. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large. See Setting Field Plot Attributes for adjusting the Streamline display parameters, and Setting Fields Reporter Options for setting Streamline defaults. . For exporting Streamline plots, refer to Exporting Field Plots.

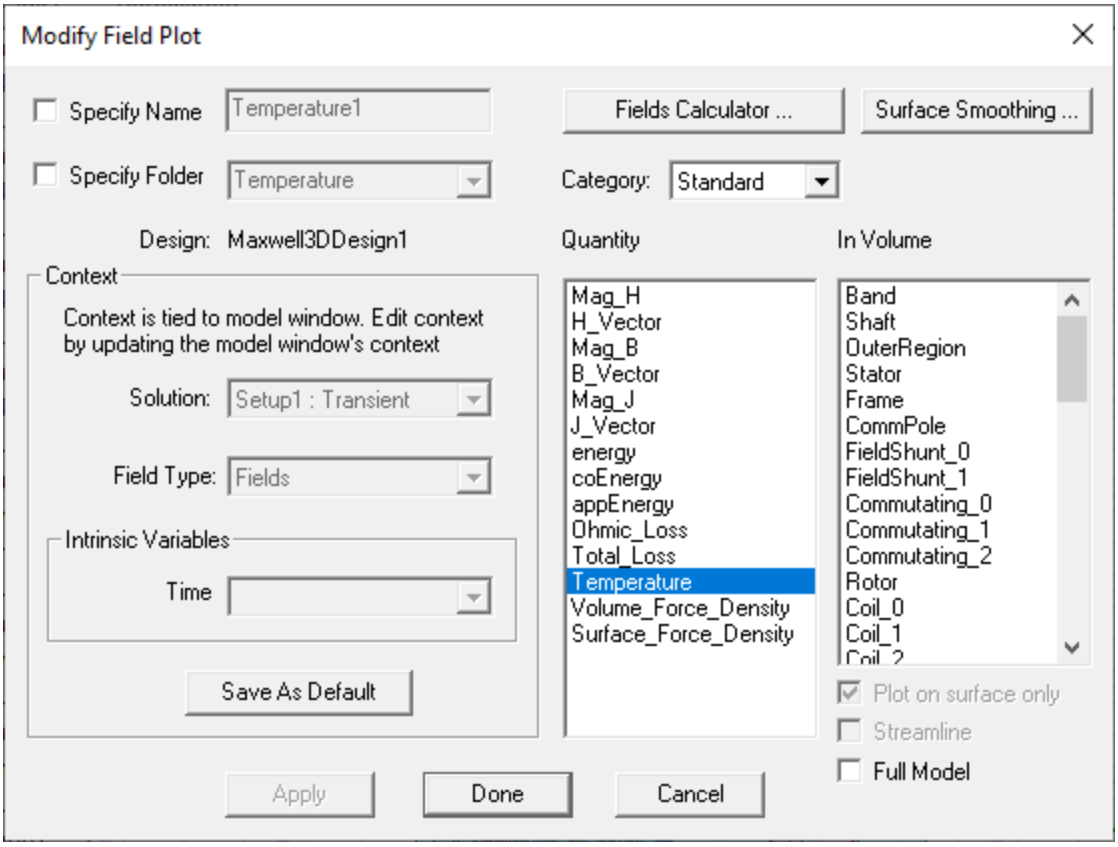
Plotting Field Overlays

Modifying Field Plots

1. Click **Maxwell 3D** or **Maxwell 2D** and then select **Fields>Modify Plots**, or in the Project tree, select the **Field Overlays** icon, right-click, and select **Modify Plots** or use the **M** hotkey.

   The **Select Field Plot(s)** dialog box appears.
2. Select the plot you want to modify from the **Select** column, and then click **OK**.

   The **Modify Field Plot** dialog box appears.



Note	Optionally, you can right-click an existing plot listed under the Field Overlays in the Project tree, and select **Modify Plot** to open its **Modify Field Plot** dialog box.

3. Optionally, click a different solution to plot from the **Solution** pull-down list.
4. Optionally, click a different field type (Fields or Noise Vibration) from the **Field Type** pull-down list.
5. Optionally, click the **Specify Name** check box to enable the name field.
6. Optionally, select the **Specify Folder** check box to enable the drop-down menu to select a folder in which to store the plot.
7. Optionally, select a different field quantity to plot from the **Quantity** list.
    - To choose a calculated expression, select **Calculator** from the **Category** pull-down list.
    - To choose a predefined field quantity, select **Standard** from the **Category** pull-down list.
    - For scalar quantities plotted on the surface of a geometry, the **Surface Smoothing** button is enabled. For vector quantities, the **Surface Smoothing** button is disabled. **Surface Smoothing** applies a selected level of smoothing based on the Gaussian Blur algorithm. Clicking **Surface Smoothing** opens the **Gaussian Smoothing** dialog box.

    Select the **Enable Gaussian Smoothing** check box to enable the feature and use the slider to set the degree of smoothing.

    Note: You must click **Apply** in the **Modify Field Plots** dialog box to see the changes.
7. Under **Intrinsic Variables**, select the variable value(s) at which the field quantity is evaluated. Variables available vary depending on the solution type.
8. Select the volume, or region, in which the field is to be plotted from the **In Volume** list. This selection enables you to limit plots to the intersection of a volume and the selected object.
9. For model objects in partial model designs, click the **Full Model** check box to calculate the fields on the full model based on the partial model solution.
10. Click **Apply**, and then click **Done**.

    The field quantity is plotted on the surfaces or within the objects you selected. The new plot is listed in the specified plot folder in the project tree.

    The plot uses the attributes specified in the **Plot Attributes** dialog box.

Setting Field Plot Attributes

After creating a vector or scalar field overlay on a surface or volume, you can modify its appearance by changing the settings in the **Plot Attributes** dialog box. When you modify the settings for a plot folder, all plots in that folder are modified with the same attributes.

1. Click **Maxwell3D or Maxwell2D and select Fields>Modify Plot Attributes** , or in the Project Manager window, select the **Field Overlays** icon, and select **Modify Attributes**.

   The **Select Plot Folder** window appears.
2. Select the field plot folder you want to modify, and then click **OK**. You can also select the specific plot in the Project tree, and select **Modify Attributes** from the right click menu. (For mesh plots, refer to *Setting Mesh Plot Attributes*.)

   A dialog box with attribute settings for the selected plot appears.
3. Change the desired plot attributes. Under the following tabs in the dialog box, you can control the following attributes:

Color map	The number of colors used and how they are displayed.
Scale	The scale of field quantities.
Marker/Arrow	• The appearance of points (for scalar point plots). • The appearance of arrows (for vector plots).
Deformation Scale	• Select whether to show or hide the deformation and also scale the plot. (Applicable only when stress feedback coupling with ANSYS Structural is enabled.)
Plots (if not streamline)	• The plot selected. • To display or hide the mesh on the plot's surface or volume. • The type of isovalue display (for scalar plots.) • Whether to use Shading (for scalar plots), if lighting is turned on. By default, the Shading is set to None which is equivalent to "Do not use lighting."

	 • The transparency based on solution value. • Whether to add a grid (that is, a mesh overlay), and to set the grid color. • Specify the plot resolution as **Coarse**, **Normal**, **Fine**, or **Very Fine**. This affects the use of memory for animating plots. For large plots with more frames to animate, use **Coarse** or **Normal** to reduce memory requirements and improve performance. For smaller plots with few frames, if higher resolution is required, use **Fine** or **Very Fine**. • The spacing of arrows (for vector plots).
Plots (if streamline is checked)	• The plot selected • The linestyle as solid or cylinder from drop-down menu. • Line width, specified using a slider. • Whether to show marker on streamline. • Seeds density spacing. This affects the number of stream lines used to represent the quantity in the plot. Moving the slider to the left decreases the spacing and increases the number of stream lines. Moving the slider to the right increases the spacing and decreases the number of lines used to represent the quantity. • Min. and Max. values represented.

4. Optionally, click **Save as default** if you want the tab's settings to apply to field overlay plots created after this point.
5. Select **Real time mode** if you want the changes to take effect immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.
6. Click **Close** to dismiss the dialog box.

Modifying Field Plot Colors

1. Click **Maxwell3D or Maxwell2D and select Fields>Modify Plot Attributes** , or in the Project tree, right click on the Field Overlays icon and select **Modify Plots** from the short-cut menu,.

   The **Select Plot Folder** window appears.
2. Select the plot you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Color map** tab.
4. Select one of the following color types:

Uniform	Field quantities are plotted in a single color. Select the plot color from the **Color** palette.
Ramp	Field quantities are plotted in shades of a single color. Select the plot color from the **Color** palette. The shade of the color corresponds to its field value.
Spectrum	Field quantities are plotted in multiple colors. Select a color spectrum from the pull-down list. Each field value is assigned a color from the selected spectrum.

   You can choose **Save as Default**, if you want to use the current settings.

   Select **Real time mode** if you want these, or subsequent changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
5. Click the **Scale Tab**.
6. In the **Num. Divisions** field, enter the number of colors to use in the plot.

   You can choose **Save as Default**, if you want to use the current settings.

   Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
7. Click **Close** to dismiss the dialog box.

Setting a Plot's Visibility

Setting the Color Key Visibility

Moving the Color Key

Setting the Color Key Visibility

The color key (shown below) displays the range of plotted field values for a field overlay plot. It displays the colors that correspond to the range of field values on the plot.

1. Click **View**>**Active View****Visibility**  .

   The **Active View Visibility** dialog box appears.
2. Click the **Color Keys** tab.
3. In the **Visibility** column, select the field overlay or mesh plots in which you want to display the color key. Clear the plots for which you want to hide the color key from view.
4. Click **Done** to close the dialog box.

   Alternatively, to hide the color key, right-click on the color key in the view window, and then click **Hide** from the shortcut menu.

   Only the color keys in the selected plots are visible.

Modifying the Field Plot Scale

To change how field quantities are scaled on the field overlay plot:

1. Click **Maxwell3D or Maxwell2D and select Fields>Modify Plot Attributes** or in the Project tree, right click on the Field Overlays icon and select **Modify Plots** from the short-cut menu.

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Scale** tab.
4. Optionally, to change the number of divisions in the field plot scale, set the **Num. Division** field to a new value. You can click **Save as Default**, if desired.
5. Select one of the following scale options:

Auto	The full range of field values will be plotted on the selected surface or volume. Selecting **Auto** enables the **Auto Scale Options** and disables the **Min** and **Max** fields. By default, precision is not limited and auto-min is the actual computed min on the plotted geometry.
Use Limits	Only the field values between the minimum and maximum values will be plotted. Field values below or above these values will be plotted in the colors assigned to the minimum or maximum limits, respectively. Selecting **Use Limits** enables the **Min** and **Max** fields and disables the **Auto Scale Options**. Field values have a precision of at most 6 decimal places (field solution files are saved in floating precision), so Min/Max numbers are displayed to this precision.
Specify Values	This enables a **Scale Values** button.

a. If you selected **Use Limits**, enter the lowest field value to be plotted in the **Min.** box and the highest field value to be plotted in the **Max.** box.
b. If you selected **Auto**, the **Auto Scale Options** are enabled. You should only change this for cases where auto-min is a small number. Use the **Limits Max/Min precision to** check box to enable setting the drop down menu for the precision limit. The auto-min is the greater of the following:
   - Actual computed Min
   - Max/pow(10, num digits of field precision)
c. If you selected **Specify Values**, you can click the **Scale Values** button. This opens a dialog with an editable, scrollable list of the current scale values. To apply the changes you make, click the **OK** button. To close the dialog without make changes, click **Cancel**.
d. Optionally, when dB is checked, the dB scale is used for the plot.

6. Optionally, use the **Units** drop down menu to select the default unit of measure for the plot.

   The units specified here appear on the Color map for the fields plot, and for the properties dialog for the field quantities.

7. If you selected **Auto** or **Use Limits** and without have **dB** checked, you can select one of the following options:

Linear	Field values are plotted on a linear scale.
Log	Field values are plotted on a logarithmic scale. If field plots have negative and positive values and when auto-scale is selected, the log-scale choice automatically sets the Min value as the Max/Min Ratio. (If field plots have all negative values, **Log** is not allowed.)

8. Specify the **Number Format** for the plot field values as Auto, Scientific or Decimal. You can also specify Width and Precision if Number Format is Scientific or Decimal.
9. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.

10. Optionally, you can use the **Save As Default** button to save the following to registry:
    - Whether to limit field precision,
    - The number of digits of field precision,
    - Whether to use log/linear scale.
    - Whether to use dB.

    Auto scale is always be default for new plots. For scalar-in-volume plots, iso-surface (rather than cloud) is the default display

11. Click **Apply**, and then click **Close** to dismiss the window.

Modifying Vector Field Plot Arrows

To change the appearance of a vector field plot's arrows:

1. Click **Maxwell3D or Maxwell2D and selectFields>Modify Plot Attributes** .

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Marker/Arrow** tab.
4. Under **Arrow options**, select one of the following arrow types from the **Type** pull-down list:

Line	The arrows are displayed as 2D/flat.
Cylinder	The arrow tails are displayed as cylinders. The arrowheads are displayed as 3D/round.
Umbrella	The arrow tails are displayed as 1D lines. The arrowheads are displayed as 3D/round.

5. Use the **Size** slider to increase (move to the right) or decrease (move to the left) the length and dimensions of the arrows. The arrows are resized relative to the size of the model geometry.
6. Select **Map size** to scale the size of the arrows to the magnitude of the field quantity being plotted.
7. Select **Arrow tail** to include tails on all arrows.
8. Click the **Plots** tab.

Note	Maxwell plots arrows on a grid that is superimposed on the surface or object you selected for the plot.

9. Under **Vector plot**, use the **Spacing** slider to increase (move to the right) or decrease (move to the left) the distance between arrows (grid points.)
10. If you want the arrows to be spaced equally, select **Uniform**, and enter values in the Min and Max boxes.
11. Select **Real time mode** if you want the changes to take effect immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.
12. Click **Apply**, and then click **Close** to dismiss the window.

Setting the Mesh Visibility on Field Plots

To display or hide the mesh on field plots or to change the mesh's color:

1. Click **Maxwell3D or Maxwell2D and selectFields>Modify Plot Attributes** .

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Plots** tab.
4. Select **Add grid** to display the mesh.
5. Optionally, select a color for the mesh from the **Color** palette.
6. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
7. Click **Apply**, and then click **Close**.

Plotting the Mesh

Setting a Plot's Visibility

Modifying Scalar Field Plot Isovalues

1. Click **Maxwell3D** or **Maxwell2D** and select **Fields>Modify Plot Attributes** .

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Plots** tab.
4. If the plot is a scalar surface plot, do the following:
   a. Select one of the following isosurface display types from the **IsoValType** pull-down list:

Line	Lines are drawn along the isovalues.
Fringe	Color is constant between isovalues.

Tone	Color varies continuously between isovalues.
Gourard	Color varies continuously across the plot.

b. Optionally, if you selected **Fringe** or **Tone**, select **Outline** to add a border line between isovalues.

c. If you select **Map transp.**, the transparency of field values increases as the solution values decrease. Use the **Map transp.** slider to increase (move to the right) or decrease (move to the left) the transparency of the plot.

d. For shading, if you are using Lighting, you can adjust the **Shading** as:

None	Equivalent to selecting **Do not use lighting** on the Lighting Properties dialog box.
Flat	Provides a flat rendering of the field plot.
Smooth	Provides a smooth rendering of the field plot.

5. If the plot is a scalar volume plot, do the following:

a. Select one of the following display types:

IsoValSurface	Color is drawn on the isovalues.
Cloud	Field values are represented by points that illustrate the spatial distribution of the solution. The higher the solution value, the greater the cloud density.

b. Optionally, if you selected **Cloud**, use the **Particle spacing** slider to increase or decrease the number of points that represent the density on the volume. The Min and Max fields allow you to set the limits for the Particle spacing slider.

c. Optionally, if you selected **Cloud**, enter a size for particles in the clouds in the **Particle size** box.

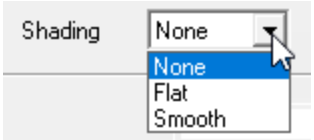
d. For shading, if you are using Lighting, you can adjust the **Shading** as:

None	Equivalent to **Do not use lighting** on the Lighting Properties dialog box.
Flat	Provides a flat rendering of the field plot.
Smooth	Provides a smooth rendering of the field plot.

8. Select **Real time mode** if you want the changes to take effect immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.
9. Click **Close** to dismiss the window.

Modifying Scalar Field Plot Shading

1. Click **Maxwell** > **Fields**> **Modify Plot Attributes**.
   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.
   All plots in the selected folder will be modified.
   A dialog box with attribute settings for the selected folder appears.
3. Click the **Plots** tab.
4. If the plot is either a scalar surface plot or a scalar volume plot, do the following:
   a. Select one of the following from the Shading drop-down menu:



None	Equivalent to selecting **Do not use lighting** on the Lighting Properties dialog box.
Flat	Provides a flat rendering of the field plot.
Smooth	Provides a smooth rendering of the field plot.

5. Select **Real time mode** if you want the changes to take effect immediately in the view window.
   If this option is cleared, click **Apply** when you want to see the changes.
6. Click **Close** to dismiss the window.

Mapping Scalar Field Plot Transparency to Field Values

1. Click **Maxwell3D or Maxwell2D and selectFields**>**Modify Plot Attributes** .
   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Plots** tab.
4. Use the **Map transp.** slider to increase (move to the right) or decrease (move to the left) the transparency of the plot.

- If you select **Map transp.**, the transparency of field values increases as the solution values decrease.

5. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
6. Click **Apply**, and then click **Close** to dismiss the window.

Modifying Markers on Point Plots

For scalar point plots, a marker is used to represent a field quantity at a selected point. (For vector point plots, arrows are used.) Modify the shape and size of markers in the plot attributes window.

1. Click **Maxwell3D or Maxwell2D and selectFields>Modify Plot Attributes**.

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Marker/Arrow** tab in the plot attributes window.
4. Under **Marker options**, select one of the following marker types to represent the field quantity at the point:
   - **Sphere**
   - **Box**
   - **Tetrahedron**
   - **Octahedron**
5. Use the **Size** slider to increase (move to the right) or decrease (move to the left) the size of the marker.
6. Select **Map size** to scale the size of the marker to the magnitude of the quantity being plotted.
7. Select **Real time mode** if you want the changes to take effect immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.
8. Click **Apply**, and then click **Close**.

Related Topics

Drawing a Point

Viewing Data Markers

The difference between two markers can be viewed on a plot.

1. Click **Report 2D>Data Marker**.
2. Click the first point on the graph.
3. Hold-and-drag the mouse and release at the second point.

Under the XY plot, you can see the difference between the two marker points.

Modifying Line Plots

Field quantities can be plotted directly on a line object. Scalar quantities are plotted as 3D color-shaded lines. Vector quantities are plotted as arrows that are based on the line.

To modify the appearance of line plots:

1. Click **Maxwell3D or Maxwell2D and selectFields>Modify Plot Attributes** .

   The **Select Plot Folder** window appears.
2. Select the plot folder you want to modify, and then click **OK**.

Note	All plots in the selected folder are modified.

   A dialog box with attribute settings for the selected folder appears.
3. Click the **Plots** tab.
4. Select one of the following isosurface display types from the **IsoValType** pull-down list:

Fringe	Color is constant between isovalues.
Tone	Color varies continuously between isovalues.
Gourard	Color varies continuously across the plot.

5. Select one of the following styles for the line object from the **Line style** pull-down list:

Cylinder	The line object is shaped like a cylinder.
Solid	The line object is a 3D solid.
Dash-Dash	The line object is represented by dashed black line segments.
Dot-Dot	The line object is represented by a series of dots.
Dash-Dot	The line object is represented by a series of alternating dashed black line segments and dots.

6. Use the **Line width** slider to increase (move to the right) or decrease (move to the left) the thickness of the line.

7. By default, a polyline object is divided into 100 equally spaced points for post processing. To modify the number of points on the line, type a new value in the **Number of points** box.
8. Select **Real time mode** if you want the changes to take effect immediately in the view window. If this option is cleared, click **Apply** when you want to see the changes.
9. Click **Apply**, and then click **Close**.

Related Topics

Drawing a Polyline

Setting a Plot's Visibility

To display or hide a field overlay or mesh plot from view in the **3D Modeler** window:

1. Click **View>Visibility>Active View Visibility**.

   Alternatively, you can select the **Active View Visibility** icon  on the **View** ribbon.

   The **Active View Visibility** dialog box appears.
2. Click the **FieldsReporter** tab.
3. In the **Visibility** column, select the field overlay or mesh plots you want to display. Clear the plots you want to hide from view.
4. Click **Done**.

   Only the selected plots are visible.

Saving a Field Overlay Plot

Field overlay and mesh plots are saved in the project file (.adsn); however, you can save a plot to a Maxwell Field Plot File format (.dsp) and then open it in Maxwell.

To save field overlay or mesh plot data to a .dsp file:

1. In the project tree, click the plot you want to export.

2. Click **Maxwell3D or Maxwell2D and selectFields>Save as** .

   The **Select Field Plot(s)** dialog box appears.
3. Select the plots you want to export by checking the **Select** box, and then click **OK**.

   A file browser appears.
4. Make sure that **Field Plot Files (.dsp)** is the selected file type.
5. Specify the name of the .dsp file and the location in which to save it.
6. Click **Save**.

The plot is exported to the specified .dsp file.

The file you created can be opened in Maxwell version 9 and later. Simply click **Maxwell3D or Maxwell2D and selectFields>Open**.

Opening a Field Overlay Plot

To open a field overlay or mesh plot that you have saved to Maxwell Field Plot File format (.dsp) in Maxwell version 9 and later:

1. Click **Maxwell3D or Maxwell2D and selectFields>Open** .

   A file browser **Open** dialog box appears.
2. Make sure that **Field Plot Files (.dsp)** is the selected file type in the **Files of type** pull-down list.
3. Browse to the location of the .dsp file you want to open, and then click the file name.
4. Click **Open**.

   The plot appears in the view window and is listed under **Field Overlays** in the project tree.

Deleting a Field Overlay Plot

1. Click **Maxwell3D or Maxwell2D and selectFields>Delete Plot** .

   The **Delete Plots** dialog box appears.
2. Select the plot(s) you want to delete by checking the **Delete** check box in the appropriate row.
3. Click **OK**.

   The selected plots are deleted.

Alternatively, click the plot in the project tree that you want to delete, and then press **Delete**.

Setting Field Plot Defaults

Each new field plot uses the default plot settings specified in the **Set Plot Defaults** dialog box.

To modify the default plot settings:

1. If a plot folder has not been created, click **Field Overlays** in the project tree.

2. Click **Maxwell3D or Maxwell2D and selectFields>Set Plot Defaults** .

The **Set Plot Defaults** dialog box appears.

3. Select the solution to plot from the **Solution** pull-down list.
4. Select the plot folder in which new plots will be stored from the **Plot Folder** pull-down list. Select from one of the following options:

New Folder	Each new plot is stored in a separate folder in the project tree.
Automatic	Each new plot is stored in a folder determined by Maxwell as the most appropriate based on the plotted field quantity. For example, all surface magnitude E plots are stored in the same folder.
An existing folder	Select the existing folder in which you want to store new plots.

Note	Plots stored in the same folder use the same color key. The **Auto** scale setting is based on the maximum field solution value present in a plot.

5. Under **Intrinsic Variables**, specify the frequency and phase angle at which the field quantity is evaluated.
6. Click **OK**.

Renaming a Plot

To rename a plot, do the following in the project tree:

1. Under **Field Overlays**, expand the field type, and right-click the specific plot you want to rename.

   A shortcut menu appears.
2. Select **Rename**.

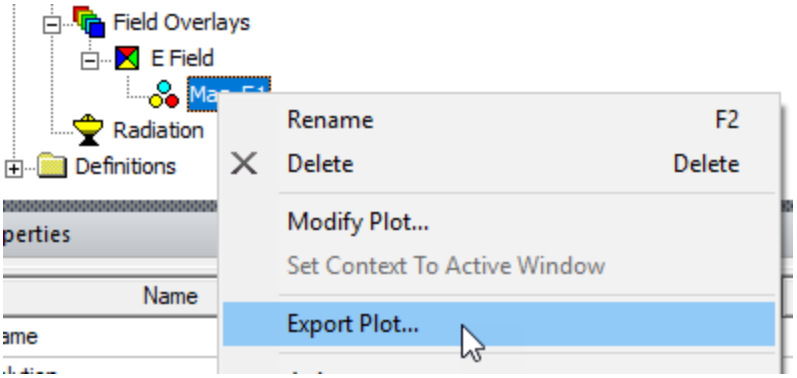
   The text becomes editable in the project tree.
3. Type the new name, and press **Enter**.

Exporting Field Plots

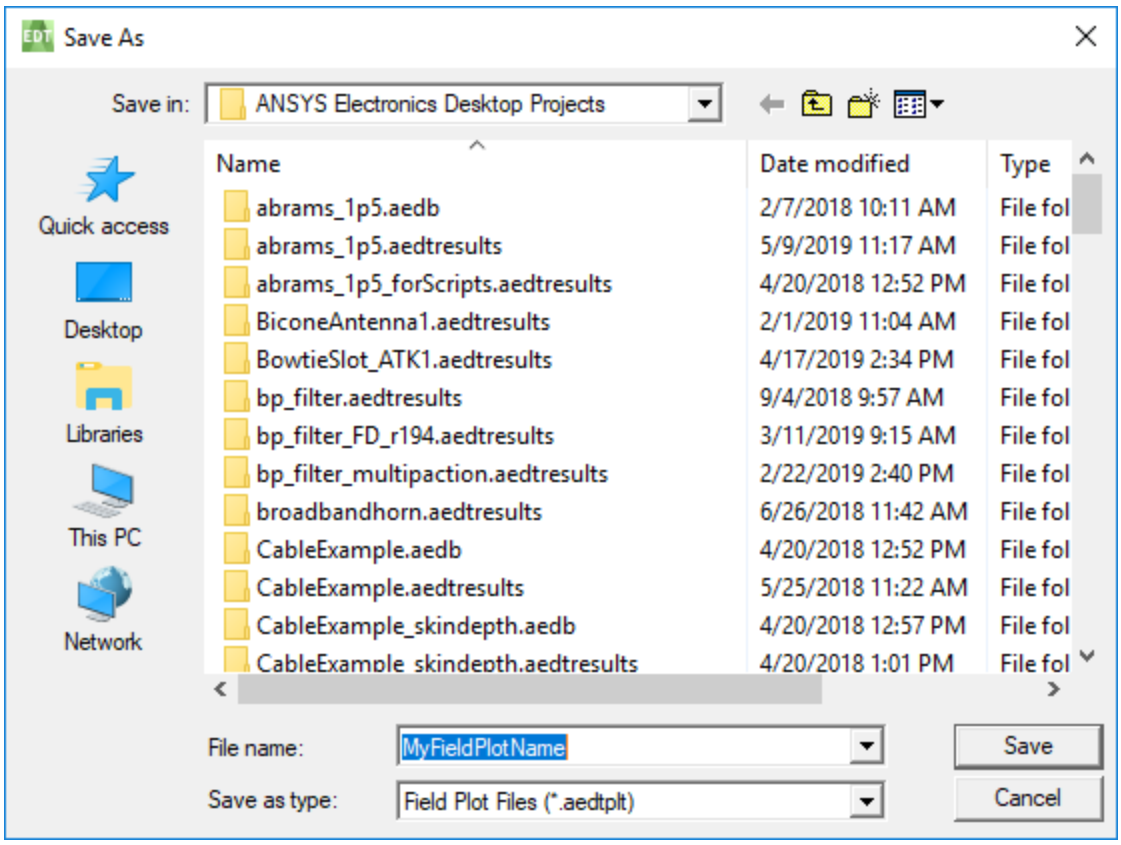
The **Export Plot...** command lets you export a field plot to a format that supports full data precision without the need to go through the Fields Calculator.

1. Create the field plot you want to export.

2. In the **History tree**, right click on the field plot icon and in the shortcut menu, click **Export Plot...**.



The **Save As** dialog box appears.



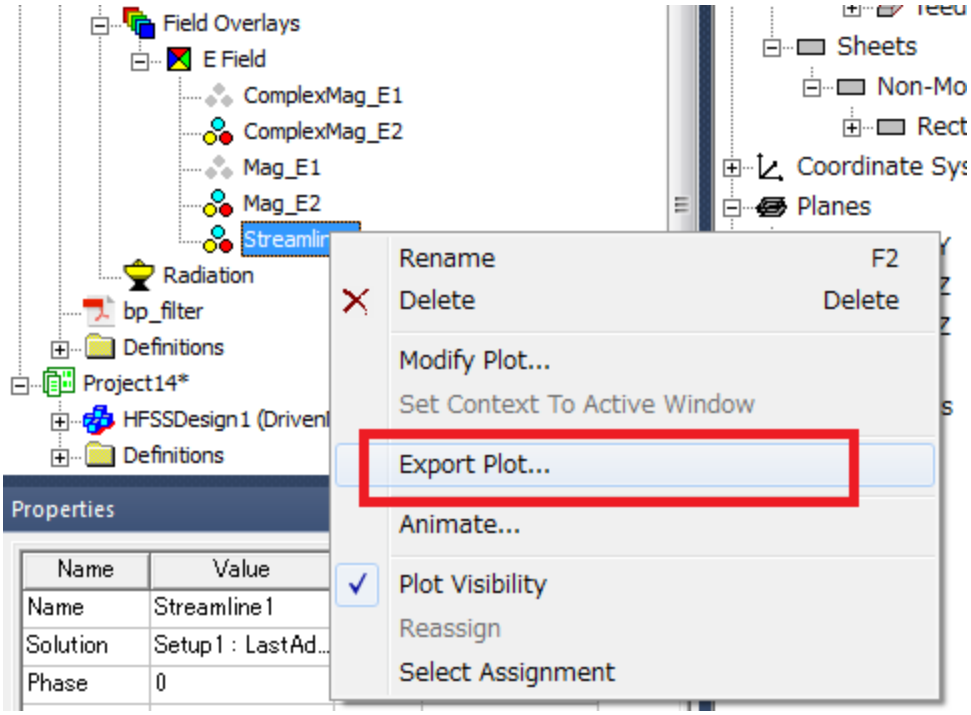
3. Specify the directory to **Save in**, the **File name** and use the **Save as type** as Field Plot Files (*.aedtplot) or Ensight Case Gold Files (*.case).

   If the Plot is a Streamline plot you can choose Streamline files (*.fldplt).

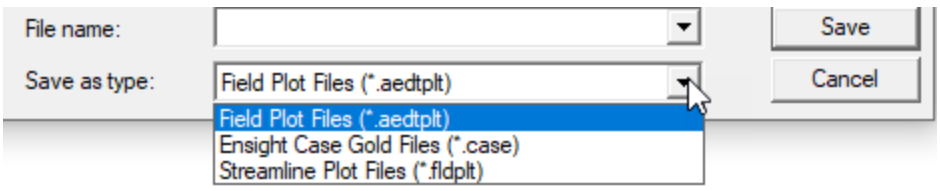
Note	• Before creating the Streamline plot, select both starting and ending edges

	(in 2D) or both surfaces (in 3D). • In the **Create Field Plot** dialog box, select **In Volume:** region, which is the region in which the streamlines will appear. Streamlines are outside of objects that are excited (sources). • To show more streamlines after the plot is created, on the **Modify attributes...** dialog **Plots** tab, reduce the **Seeds density** value. If no streamlines appear, reduce this by a factor of 10 (or 100) because the default seeding was too large. Refer to Setting Field Plot Attributes for adjusting the Streamline display parameters, and Setting Fields Reporter Options for setting Streamline defaults.

You can export a Streamline plot in .fldplt format by right-clicking on the plot in the Project tree, and selecting **Export Plot...**



This opens a dialog for you to specify a plot name and location.



The Field Plot is exported to the file format you specified.

Field Plot Data Export Format (*.aedtplt)

A partial sample file with 2 drawings:

File format description

The first line starts with the “#” symbol and continues with the product name and its version that is used to produce this file. The 2nd line also starts with the “#” symbol and continues with the file format version.

The next line shows the number of drawings in this file. The above example shows 2 drawings. Each drawing has two big data blocks (the **mesh data block** and **field data block**). Each drawing starts with **$begin Drawing_***** and ends with **$end Drawing_***** (where ***** should be replaced with the drawing index, starting from 1).

Mesh data block

This contains all the mesh information about the current drawing include element type, number of nodes of each element, node coordinates, and element node connectivity. At the beginning of the block, it shows if it has curve element and then lists the bounding box of this mesh. The bounding box format is **BoundingBox(lowerX, lowerY, lowerZ, upperX, upperY, upperZ)**. These are double values.

Next comes the elements part, starting with **Elements(**. The first integer is the total number of nodes for this mesh, and the next is the total number of elements. After that, it repeats the following information for each element: element type, reserved integer 1, reserved integer 2, reserved integer 3, number of nodes for this element, node index 1, node index 2 till the number of nodes for this element. All these numbers are integers. The **Elements** part ends with a **)**. The list of element types is listed in the Element types section below.

Element type description	Element type value
point	0
line	1
triangle	2
quad	3
tetradedron	4
pyramid	5
wedge	6
hexahedron	7

The last part of the mesh data block is the nodes part. It contains the coordinates (x,y,z) of all the nodes for this mesh. It starts with **Nodes(** and continue with a list of tuples of 3 double values which are the x, y, z coordinates of the first, 2nd, last nodes and it ends with **)**.

Field data block

This contains two parts. The first part includes node field data of each element. Node field data could either be scalar or vector data which means either it has 1 component or it has 3 component (x, y, z).

This part starts with **ElemSolution(**, the next two double values are the minimal and maximal field value of this drawing. The next integer shows the total number field data for each element. It should be a multiple of the number of nodes of each element (e.g., if field data is vector data, then it should be 3 times of the number of nodes of each element). For vector data, each element should have data like (**node1_x, node1_y, node1_z, node2_x, node2_y, node2_z, …**). This part ends with **)**.

The second part shows two location points. It starts with **ElemSolutionMinMaxLocation(**. The first 3 double values are the (x,y,z) coordinates of the location where the minimal field value is located, while the next 3 numbers are for the maximal field value. This part ends with **)**.

For 2nd order element node index convention, please refer to http://www.vki.com/2013/Support/docs/vistools-1.html#1.2. Lagrange Parabolic is used.

Using the Fields Calculator

The Fields calculator enables you to perform computations using basic field quantities. The calculator computes derived quantities from the general electromagnetic field solution; writes field quantities to files, locates maximum and minimum field values, and performs other operations on the field solution.

The calculator allows you to define a series of calculations to be performed on the field solution but does not actually perform the computations until data is required, for a field plot as an example. This makes it more efficient, saving computing resources and time. You can do all the calculations without regard to data storage of all the calculated points of the field. It is generally easier to do all the calculations first, then plot the results.

Note	In **Maxwell2D**, the Fields Calculator accounts for the difference between XY and RZ models when handling data and results. For example, the integral command will perform an XY integral on the model assuming a 1 meter depth, while for an RZ model it will perform an integral on the 360 degree equivalent volume.

Related Topics

Opening the Fields Calculator

Context Area

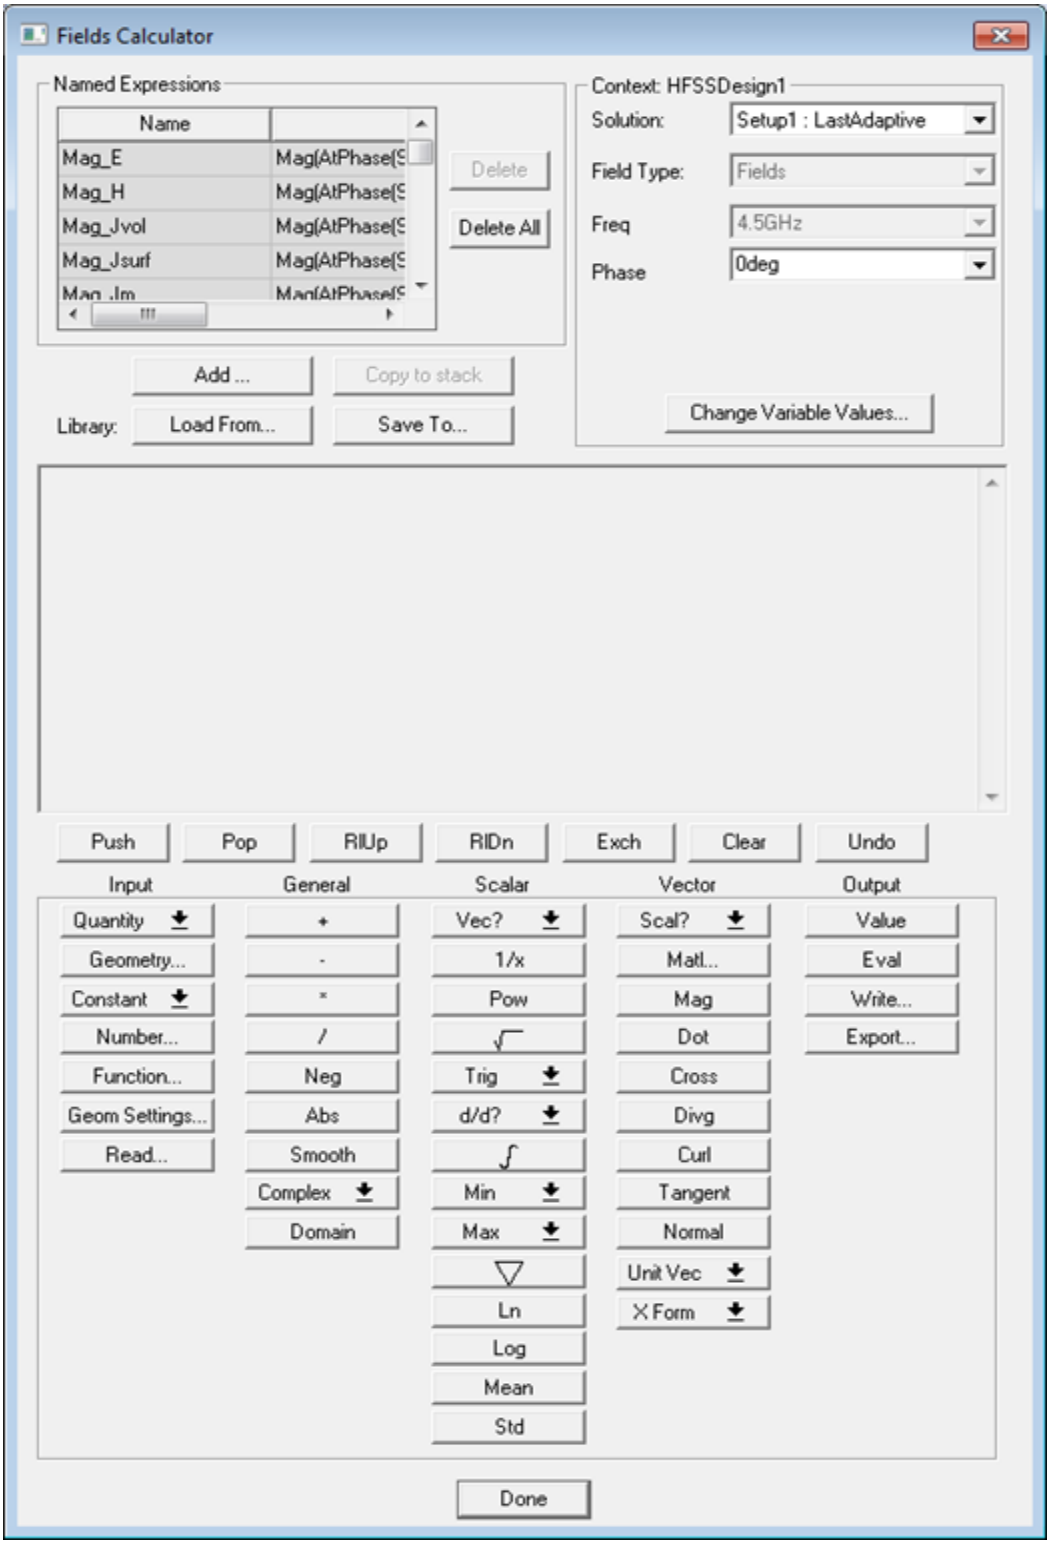
Opening the Fields Calculator

To open the Fields Calculator, do one of the following:

- Click **Maxwell3D or Maxwell2D and select Fields>Calculator**  .
- Right-click **Field Overlays** in the project tree, and then click **Calculator** on the shortcut menu.

The **Fields Calculator** dialog box appears.

To view information on a command or screen area, click over the button or screen area on the illustration below.



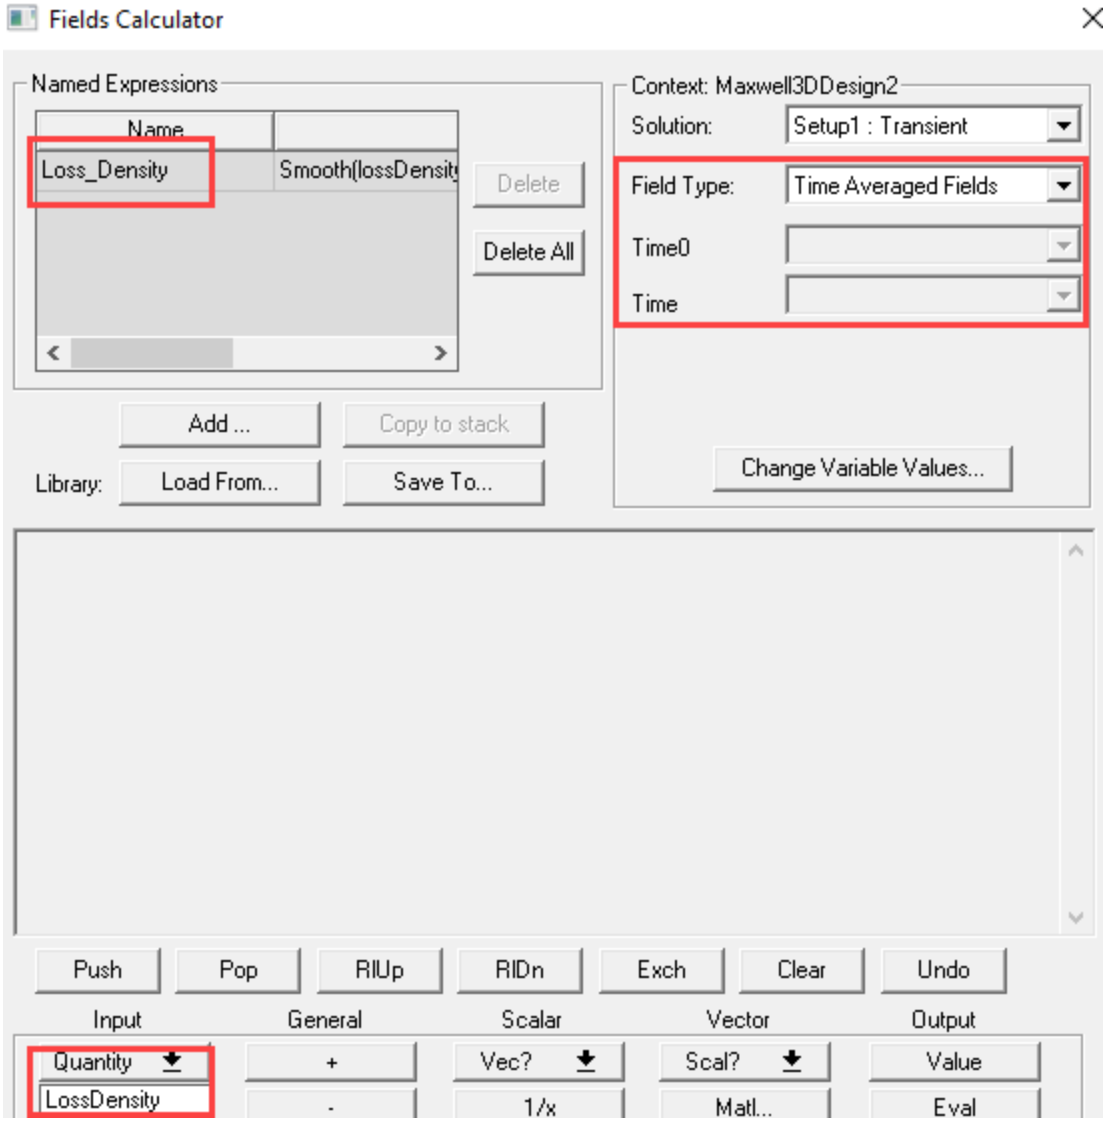
Context Area

The panel at the upper right of the window identifies the context to be used for the calculations. The top line identifies the design. Depending on the design, text entry boxes allow you to select a **Solution**, **Field Type**, **Phase**, or **Time**.

Note	The Field Type here is not related to the edit sources. This is a general term among Ansys Electromagnetics products (HFSS, Maxwell, Q3D, Icepak, and Mechanical). Some products have more than one field type for different solution types. If only one Field Type is available the box is grayed out.

For Maxwell 2D and 3D transient solutions, the field type can be either **Fields** or **Time Averaged Fields**. Selecting **Time Averaged Fields** adds an additional **Time0** field, which is used when calculating time averaged losses. Selecting **Time Averaged Fields** also adds **Loss_Density** as a **Named Expression**, and **LossDensity** as a **Quantity command** selection.

The **Change Variable Values** button opens a **Set Variable Values** dialog box. By default it has **Use Nominal Design** checked. Unchecking the box lets you select another variable value. **OK** the dialog to accept the selection.



For Maxwell 2D transient solutions in which **Use Skew Model is enabled on the Model Settings tab**, an additional **Slice** field displays, which allows you to select the skew model slice to use for fields calculations.

Opening the Fields Calculator

The Calculator Stack

The calculator is made up of a stack of registers, each of which can hold:

- Field quantities.
- Functional or constant scalars and vectors.
- Geometries — points, lines, surfaces, or volumes — on which a field quantity is to be evaluated.

To perform a computation on the field solution, you must first load a basic field quantity into a register on the stack. Once a quantity is loaded into a register, it can be:

- Manipulated using mathematical operations such as curls, gradients, cross products, divergences, and dot products.
- Integrated over lines, surfaces, or subvolumes of the solution region — either predefined surfaces, volumes, and lists, or lines, surfaces, and volumes that were defined using the **Draw** commands.
- Plotted on a point, line, surface, or volume.
- Exported to a file, allowing you to superimpose saved solutions.

Related Topics

Registers

Using the Fields Calculator

Registers

Calculator registers hold field quantities, numbers, vectors, and geometries. No registers are created until you load something into the calculator; therefore, this part of the window is initially blank. As items are loaded into the calculator, it creates new registers to hold them.

Each register is labeled with its contents as follows:

Vec	Vector quantities, which have both direction and magnitude at each point in space. The x-, y-, and z-components of these quantities are stored in the register.
Scl	Scalar quantities, which have a magnitude only.
CVc	Complex vector quantities.
CSc	Complex scalar quantities.
Pnt	Points.
Lin	Lines.
Srf	Surfaces.
Vol	Volumes.
SclLin	Scalar value on a line.
VecLine	Vector value on a line.
SclSrf	Scalar value on a surface.
VecSrf	Vector value on a surface.

When examining calculator registers, keep the following in mind:

- To move or delete calculator registers, use the stack commands.
- To save a register to a disk file, use the **Write** command.

Enlarging the Register Display Area

Units of Measure

Enlarging the Register Display Area

If there are too many registers to fit into the display area, do one of the following:

- Use the scroll bars to view the hidden registers.
- Enlarge the calculator window using the window's borders.

Related Topics

Registers

Units of Measure

Unless you are prompted specifically for the unit of measure, all measurements should be assumed to be in SI base units, not model units.

Related Topics

Registers

Stack Commands

Use these commands to manipulate the registers in the calculator stack.

Push

Reloads the quantity in the top register onto the top of the stack, creating a new register. The contents of the top two registers are identical.

Pop

Deletes the top register from the stack.

RlUp

Rolls the top register to the bottom of the stack, moving the other registers up the stack.

RlDn

Rolls the bottom register to the top of the stack, moving the other registers down the stack.

Exch

Exchanges the top two registers in the stack.

Clear

Clears the contents of the stack.

Undo

Use this command to undo the effect of the last operation you performed on the contents of the top register. Successive **Undo** commands act on any previous operations.

Note	You cannot undo a simple operation such as loading a field quantity, constant, function, or geometry into the calculator. Instead, use the **Pop** or **Clear** commands to delete these items from the calculator stack.

Related Topics

Using the Fields Calculator

Input Commands

Use the following commands to load data onto the top of the calculator stack:

Quantity	Basic quantities, such as current, magnetic field, etc.
Geometry	Geometries such as planes, points, polylines, and volumes.
Constant	Predefined constants such as π, ε_0, and conversion factors between various units of measurement.
Number	Vector and scalar constants, including complex numbers.
Function	Previously saved calculator registers containing field quantities.
Geom Settings	Vector and scalar math functions.
Read	Reads an input saved externally.

These quantities can be manipulated using the **Stack** commands, **General** commands, **Scalar** commands, and **Vector** commands. The results of these calculations can then be examined using the **Output** commands.

Related Topics

Using the Fields Calculator

Quantity Command

The **Quantity** command loads a field quantity into the top register of the calculator. The quantities available depend upon the solution and design type. These are the same field quantities available for plotting from the **Maxwell3D>Fields** and **Maxwell2D>Fields** menu.

Related Topics

Plotting Standard Field Quantities

Using the Fields Calculator

Geometry Command

The Fields Calculator **Geometry** command opens a dialog that lets you select a geometry to load into the top register of the calculator. Do this to:

- Find the value of derived field quantities on any point, line, surface, or volume.
- Plot quantities directly from the calculator.

- Display a previously defined isosurface, maximum or minimum field point using the **Draw** command.

The following types of geometries are available:

Point - See drawing a point object. Points you draw are listed in the history tree, and in the Calculator **Geometry** dialog when you select Point.
Line- See drawing a line object. Lines you draw are listed in the history tree, and in the Calculator **Geometry** dialog when you select Line. To set the number of points on a line, see Geom Settings.
Surface - Sheet objects and face lists which you can make, are listed under surface in the history tree and in the Calculator **Geometry** dialog when you select Surface. Due to the ambiguity of the normal vector of a sheet, the result may require a multiplication by (1) or (-1).
Volume - 3D objects, Regions, and object lists of 3D objects including AllObjects are available in the Calculator **Geometry** dialog when you select Volume.
Coord -Coordinate systems are available in the Calculator **Geometry** dialog when you select Coord.

To load a geometry into the calculator:

1. In the Fields Calculator, click **Geometry**.

   The **Geometry** dialog box appears.
2. Select a geometry type.

   A list of all available geometries appears.

Note	• Non-convex 3D non-model solids are not supported for Field Overlay Plots and Fields Calculator computations. • Object lists containing non-model object(s) are supported for Field Overlay Plots but are not supported for Fields Calculator computations.

3. Click the geometry.
4. Click **OK** to load the geometry.

Note	Consider a box (Box2) that is completely enclosed in a bigger box (Box1), so that no faces of Box2 are touching any faces of Box1. If you explicitly subtract Box2 from Box1, any calculation on the surface (faces) of Box1 will use the 6 exterior faces and the 6 interior faces. Any calculation on the volume of Box1 will use the difference in volume between Box1 and Box2. If you do not explicitly subtract Box2 from Box1, the inner box is only implicitly subtracted. Any calculation on the surface of Box1 in this case will use only the 6 exterior faces of Box1. Any calculation on the volume of Box1 will use the entire volume without subtracting the volume of Box2.

Constant Command

The **Constant** command loads one of these predefined constants or a conversion constant into the top register of the calculator:

Pi	$\pi = 3.14159265358979$
Epsi0	The permittivity of free space, $\varepsilon_0 = 8.85418782 \times 10^{-12}$ F/m.
Mu0	The permeability of free space, $\mu_0 = 4\pi \times 10^{-7}$ H/m.
C	The speed of light in vacuum, $c = 2.99792458 \times 10^{8}$ m/s.
conversion constant	Displays the **Enter Units Conversion Factor** dialog box. This dialog box lists a range of **Quantities** (such as frequency, resistance, and others) along with a list of Units (Hz to Thz, and rps) to convert **From** and **To**. The ratio of the **Units from** to the **Units to** is displayed for the selected values as the **Conversion Factor**.

Related Topics

Using the Fields Calculator
Input Commands

Number Command

The **Number** command enters one of the following into the top register of the calculator:

Scalar	A scalar constant. To enter a constant scalar number: 1. Click **Number**. The **Input Number** dialog box appears. 2. Select **Scalar**. 3. Type the scalar value in the **Value** box. 4. Click **OK** to load the number into the top register.
Vector	A vector constant.

	To enter a constant vector: 1. Click **Number**. The **Input Number** dialog box appears. 2. Select **Vector**. 3. Enter the x-, y-, and z-components of the vector. 4. Click **OK** to load the vector into the top register.
Complex	A complex constant. Complex constants are entered in the form *C=A+jB*, where *A* represents the real part of the constant and *B* represents the imaginary part. 1. Click **Number**. The **Input Number** dialog box appears. 2. Select **Scalar** or **Vector**. 3. Select **Complex**. 4. Enter the real and imaginary components of the number. 5. Click **OK** to load the number into the top register.

Related Topics

Using the Fields Calculator
Input Commands

Function Command

Any functions you use must be defined before using this operation.
Enters one of the following into the top register of the calculator:

Scalar	A scalar function. To enter a function: 1. Click **Function**. The **Function** dialog box appears. 2. Select **Scalar**. 3. Select the function from the list. 4. Click **OK** to load the functional scalar into the top register.
Vector	A vector function, in which the values of the vector's x-, y-, and z-components are given by functions. To enter a functional vector: 1. Click **Function**. The **Function** dialog box appears. 2. Select **Vector**.

	3. Select the function from the list. 4. For each component of the vector, click **SetX**, **SetY**, and **SetZ**. 5. Click **OK** to load the functional vector into the top register.

Note	• The predefined variables **X**, **Y**, **Z**, **RHO**, **THETA**, **R**, and **PHI** and any functions that you created can be used to define functional scalar and vector quantities. • Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

Related Topics

Using the Fields Calculator

Input Commands

Geometry Settings

Clicking the **Geom Settings** button opens the **Geometric Settings** dialog box. The dialog box allows you to specify the line discretization, the number of equally-spaced points used to integrate fields and other quantities on a line. The default is 1000 points.

To set the line spacing for geometry settings:

1. In the Fields Calculator, click **Geom Settings**.

   The **Geometry Settings** dialog box appears.
2. Enter a value in the **Line Discretization** box, and click **OK**.

Related Topics

Using the Fields Calculator

Input Commands

Reading an External Input

This command copies the contents of a disk file into the top register. The register must be one that has been saved using the Write output command.

To read an external input into the register:

1. Click **Read**.

   The **Open** dialog box appears.
2. Use the file browser to specify the register's file name and directory path. A .reg extension is automatically assumed for register files, and click **Open**.

   The contents of the file are copied to the top register in the stack.

Related Topics

Using the Fields Calculator

Input Commands

General Commands

Use these Fields Calculator commands to perform operations on both vector and scalar quantities.

+ (Add)	/ (Divide)	Smooth
- (Subtract)	Neg	Complex
* (Multiply)	Abs	Domain

+ (Add)

Adds the quantities in the top two registers of the calculator.

– (Subtract)

Subtracts the quantity in the top register from the quantity in the second register. The two registers must hold the same type of quantity (both scalar or both vector). You cannot subtract a scalar from a vector (or vice versa).

*** (Multiply)**

Multiplies the quantity in the top register by the quantity in the second register. One of the two registers must contain a scalar value; the other register can be either a scalar or a vector.

/ (Divide)

Divides the quantity in the second register by the quantity in the top register. The second register must contain a scalar value; the top register can be either a scalar or a vector.

Neg

Changes the sign of the quantity in the top register.

Abs

Takes the absolute value of the quantity in the top register.

Smooth

Smooths the quantity in the top register. Because of the numerical solution technique used, field values are not always continuous across the boundaries of the individual elements that

make up the finite-element mesh. Smoothing makes the values continuous. In general, use smoothing before plotting a quantity.

Complex

These commands perform operations on a complex quantity in the top register. Complex quantities are indicated by a **C** at the beginning of the register label. They can be represented in terms of real and imaginary components, or in terms of magnitude and phase:

$$C = A + jB = Me^{j\phi}$$

where:

- *A* is the real part of the complex number.
- *B* is the imaginary part of the complex number.
- *M* is its magnitude, which is equal to sqrt(A^2 + B^2).
- ϕ is its phase, which is equal to **atan**(B/A).

The **Complex** commands let you do the following:

Real	Takes the real part of the complex quantity (A).
Imag	Takes the imaginary part of the complex quantity (B).
CmplxMag	Takes the magnitude of the complex quantity (M). Due to interpolation issues, the sequence of calculations may cause a loss of accuracy. It is best to define the points, separately obtain the value of the real part, then the imaginary part, and use those values to calculate the magnitude and phase. For the sequence for using the Fields Calculator to obtain the real and imaginary parts, see the procedure here.
CmplxPhase	Takes the phase of the complex quantity (ϕ).
Conj	Takes the complex conjugate of the quantity in the top register. If a complex number is given by $C = A + jB$, its complex conjugate is given by $C^* = A - jB$.
AtPhase	Specify the phase angle, ωt, at which a field quantity is evaluated. These quantities can be represented in the form: $$A(x,y,z,t) = A(x,y,z)\cos(\omega t + \theta(x,y,z))$$ where • ω is the angular frequency at which the quantities are oscillating, specified during the solution.

	• θ(x,y,z) is the phase angle (the offset from a cosine wave that peaks at t=0). Entering the phase angle lets you compute the real part of the field's magnitude at different points in its cycle.
CmplxReal	Converts the real scalar of the top register to the real part of a complex number.
CmplxImag	Converts the real scalar of the top register to the imaginary part of a complex number.
ComplxPeak	Calculates the peak value of a given complex vector. Intuitively, this calculates the maximum magnitude of the equivalent real vector in a waveform.

Domain

This limits a calculation to the volume you specify. The domain filter works for scalars, vectors, complex scalars and complex vectors. This operation requires the top two entries of the stack to be a volume geometry and a numeric field quantity. To do this:

1. Load the field quantity into the top register, and perform any necessary operations on it.
2. Load the volume using the **Geometry** command.
3. Click **Domain**.

   The **Domain** command is often used to limit a calculation or plot to the intersection of a surface and an object or group of objects. If you export a domain filtered numeric, points that are filtered out by the domain will not be written out.

Export Command

Steps for Calculating the Complex Vector Electric Field

Steps for Calculating the Complex Vector Electric Field

These are the field calculator steps to obtain the real part, the imaginary part, and the magnitude of the x-directed, y-directed, and z-directed components of the phasor electric field. For each of these vector components, the magnitude should be equal to sqrt(real^2+imag^2), but the need to interpolate values and the calculation sequence means that Maxwell does not give this value unless the specified location is directly on a mesh element node.

1. Calculate real part of complex vector electric field (in x, y, and z directions):
   a. Qty > E
   b. Complex > Real
   c. Geometry > Point > fieldcalc_point
   d. Value
   e. Eval
2. Calculate imaginary part of complex vector electric field (in x, y, and z directions):

a. Qty > E
b. Complex > Imag
c. Geometry > Point > fieldcalc_point
d. Value
e. Eval

Use the real and imaginary components to manually calculate the magnitude as the sqrt ($Real^2+imag^2$).

Scalar Commands

Use these commands to perform operations on scalar quantities.

Vec?	Makes the scalar quantity in the top register a vector component.
1/x	Takes the inverse of the scalar quantity in the top register.
Pow	Raises a scalar quantity to the power you specify.
Square Root	Takes the square root of the quantity in the top register.
Trig	Takes a trigonometric value of the value in the top register of the calculator stack.
d/d?	Takes the partial derivative of the quantity in the top register with respect to x, y, or z as chosen in the pull-down menu.
Integral	Takes the integral of a scalar quantity over a volume, surface, or line.
Min	Computes the minimum of a scalar field quantity on a line, surface, or volume.
Max	Computes the maximum of a scalar field quantity on a line, surface, or volume.
Gradient	Computes the minimum of a scalar field quantity on a line, surface, or volume.
Ln	Calculates the log (base e) value.
Log	Calculates the logarithmic value (base 10).
Mean	Takes the mean of the quantity in the top register.
Std	Takes the standard deviation of the quantity in the top register.

Related Topics

Using the Fields Calculator

Vec? Command

Makes the scalar quantity in the top register a vector component. Choose from the following:

VecX	The x-component of a vector.

VecY	The y-component of a vector.
VecZ	The z-component of a vector.

Related Topics

Using the Fields Calculator
Scalar Commands

1/x (Inverse) Command

Takes the inverse of the scalar quantity in the top register.

Related Topics

Using the Fields Calculator
Scalar Commands

Pow Command

Raises a scalar quantity to the power you specify.

To raise a scalar quantity to a power:

1. Enter the quantity into the calculator.
2. Enter the exponent to which it is to be raised into the calculator.
3. Click **Pow**.
   The results are displayed in the top register.

Related Topics

Using the Fields Calculator
Scalar Commands

(Square Root) Command

Takes the square root of the quantity in the top register.

Related Topics

Using the Fields Calculator
Scalar Commands

Trig

Takes one of the following trigonometric values of the value(s) in the top register(s) of the calculator stack:

Sin	Sine.
Cos	Cosine.
Tan	Tangent.
ASin	Arcsine.
ACos	Arccosine.
ATan	Arctangent.
ATan2	A two-argument version of the **ATan** function. Takes the y and x coordinates of the point (in the top two stack registers).

Related Topics

Using the Fields Calculator
Scalar Commands

d/d? (Partial Derivative) Command

Takes the partial derivative of the quantity in the top register:

d/dx	Takes the partial derivative of the quantity with respect to x.
d/dy	Takes the partial derivative of the quantity with respect to y.
d/dz	Takes the partial derivative of the quantity with respect to z.

Related Topics

Using the Fields Calculator
Scalar Commands

d/d? (Partial Derivative) Command

Takes the partial derivative of the quantity in the top register:

d/dx	Takes the partial derivative of the quantity with respect to x.
d/dy	Takes the partial derivative of the quantity with respect to y.
d/dz	Takes the partial derivative of the quantity with respect to z.

Related Topics

Using the Fields Calculator

Scalar Commands

∫

(Integral) Command

Takes the integral of a scalar quantity over a volume, surface, or line. The top register must contain a geometry, and the second register must contain the scalar quantity to be integrated.

To perform an integration:

1. Load a quantity into the top register of the calculator, and perform any required operations on it.
2. Use one of the **Geometry** commands to load the line, surface, or volume over which the quantity is to be integrated.

Note	If you computed the tangent or normal of the quantity to be integrated, you do not have to load a geometry onto the calculator stack. Maxwell integrates the tangential or normal component of the quantity over the line on which you computed its tangent, or the surface on which you computed its normal.

3. Click the **Integral** command to integrate the scalar quantity over the geometry. In 2D designs, you must further select either **XY** or **RZ**.

To find the numerical results of an integration, use the **Eval** command.

Note	In **Maxwell2D**, the Fields Calculator accounts for the difference between XY and RZ models when handling data and results. The integral command will perform an XY integral on the model assuming a 1 meter depth, while for an RZ model it will perform an integral on the 360 degree equivalent volume.

Related Topics

Using the Fields Calculator

Scalar Commands

Min Command

Computes the minimum of a scalar field quantity on a line, surface, or volume. Two options are available:

Value	Finds the magnitude of the minimum value of the field.
Position	Finds the point where the minimum field value occurs. You can then: • Plot the minimum field value at the point using the **Plot** command. • Plot basic field quantities at the point. • Load the point into the calculator. • Change the point's location.

These commands operate in the same way as the **Max** commands. Use the **Eval** command to display the actual minimum field value or the coordinates of the point where it occurs.

Related Topics

Using the Fields Calculator

Scalar Commands

Max Command

Computes the maximum of a scalar field quantity on a line, surface, or volume. Two options are available:

Value	Finds the magnitude of the maximum value of the field.
Position	Finds the point where the maximum field value occurs. You can then: • Plot the maximum field at the point using the **Plot** command. • Plot field quantities at the point. • Load the point into the calculator. • Change the point's location.

To compute the maximum field value:

1. Load a field quantity into the calculator, and perform any necessary operations on it. Keep the following in mind:
   - You cannot find the maximum value of a vector quantity. Therefore, make sure that the result is a scalar.
   - Before computing the maximum value of a complex quantity, you must convert it to a scalar quantity using the**Cmplex/Real** or **Cmplex/AtPhase** commands.
2. Load a point, line, or volume into the calculator using one of the **Geometry** commands.
3. Do one of the following:
   - Click **Max/Value** to compute the maximum field value on the geometry.
   - Click **Max/Position** to identify the point at which this value occurs.

Use the **Eval** command to display the actual maximum field value or the coordinates of the point where it occurs.

Vector Commands

Use these commands to perform operations on vector quantities.

Scal?	Replaces the vector in the top register with a scalar quantity that is a component of the vector.
Matl	Multiplies or divides the vector field quantity in the top register by a material property.
Mag	Takes the magnitude of the vector quantity in the top register. The magnitude of a complex vector is defined to be the length of the real vector resulting from taking the modulus of each component of the original complex vector.
Dot	Takes the dot product of the vector quantities in the top two registers
Cross	Takes the cross product of the vector quantities in the top two registers.
Divg	Takes the divergence of the vector quantity in the top register.
Curl	Takes the curl of the vector quantity in the top register.
Tangent	Computes the tangential component of a vector quantity along a line.
Normal	Computes the normal component of a vector quantity on a surface such as a

	cutplane or object surface.
Unit Vec	Computes the normal or tangent unit vector. The unit vector is a "wild card" entry. The context is specified at the time of plotting, integrating, or report generation.
XForm	Transforms the vector quantity in the top register from Cartesian coordinates into either Spherical or Cylindrical coordinates

Scal? Command

Replaces the vector in the top register with a scalar quantity whose value is a component of the vector. Choose from the following:

ScalarX	Returns the x-component of the vector.
ScalarY	Returns the y-component of the vector.
ScalarZ	Returns the z-component of the vector.

Related Topics

Using the Fields Calculator

Vector Commands

Matl Command

Multiplies or divides the vector field quantity in the top register by a material property. At each tetrahedron, the field quantity is multiplied or divided by the value of the selected material property — taking the different material attributes of each object into account.

To multiply or divide a vector quantity by a material property:

1. Click **Matl**.

   The **Material Operation** dialog box appears.
2. Select a property from the **Material Properties** list. Options include the following, depending on what solution type is assigned:
   - Permeability (mu): defined as $\mu_0\mu_r$

     where μ_0 is the permeability of free space
   - Differential Permeability (dmu)
   - Conductivity (cond)
   - Permittivity (epsi)

- Mass Density: based on the value of the Mass Density material property. MassDensity is treated like a named expression. Selecting MassDensity disables the Operation radio buttons for Multiply or Divide in the Material Operations dialog.
- Admittivity

3. Select an operation — **Multiply** or **Divide**.
4. Click **OK** to multiply or divide the field quantity by a material property or **Cancel** to stop the operation. If you selected MassDensity and click **OK**, a scalar named expression MassDensity is pushed onto the stack.

Related Topics

Using the Fields Calculator
Vector Commands

Mag Command

Takes the magnitude of the vector quantity in the top register. The magnitude of a complex vector is defined to be the length of the real vector resulting from taking the modulus of each component of the original complex vector.

With a complex vector on the calculator stack, the **Mag** button returns a nonnegative scalar. In previous software versions, this command returned a complex scalar.

Curl Command

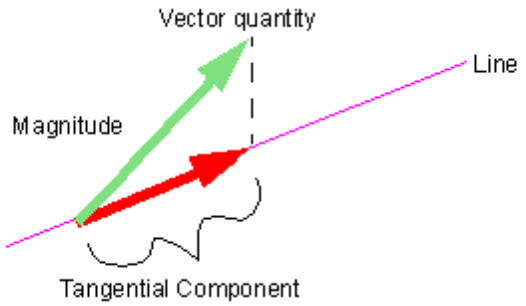
Takes the curl of the vector quantity in the top register.

Related Topics

Using the Fields Calculator
Vector Commands

Tangent Command

Computes the tangential component of a vector quantity along a line.



To take the tangent of a vector:

1. Load a vector quantity into the top register.
2. Load a line into the top register using the **Geometry/Line** command.
3. Click **Tangent**.

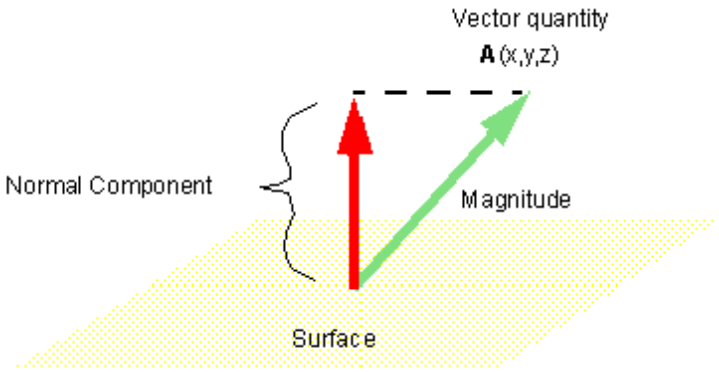
Related Topics

Using the Fields Calculator
Vector Commands

Normal Command

Computes the normal component of a vector quantity on a surface such as a cutplane or object surface. This is the equivalent of taking the dot product of the quantity with the surface's unit normal vector:

$$Normal = \boldsymbol{A}(x,y,z) \bullet \hat{\boldsymbol{n}}$$



To take the normal of a vector:

1. Load a vector quantity into the top register.
2. Load a surface into the top register using the **Geometry/Surface** command.
3. Click **Normal**.

Note	Because surface normals of sheets are not well defined the fields calculator can produce incorrect results if an expression is evaluated on a sheet. To enforce the correct direction of the surface normal of a sheet, a faceted 3D object (such as a box) can be defined such that one of its planar faces is coincident with the sheet. Because surface normals of a valid object are always defined in an outward direction in Maxwell, the fields calculator uses the surface normal of the face of the 3D object that is coincident with the sheet.

Related Topics

Using the Fields Calculator

Vector Commands

Unit Vec Command

Computes the normal or tangent unit vector. The unit vector is a "wild card" entry. The context is specified at the time of plotting, integrating, or report generation.

Select from the following:

Tangent	Computes the unit vector tangent to the line in the top register of the calculator stack.
Normal	Computes the unit vector normal to the surface in the top register of the calculator stack.
CoordSys (X)	Computes the unit vector in the X-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.
CoordSys (Y)	Computes the unit vector in the Y-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.
CoordSys (Z)	Computes the unit vector in the Z-dimension of the relative coordinate system in the top register of the calculator stack. Add the relative CS as a geometric object using the **Geometry/Coord** command.

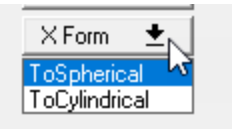
Using the Fields Calculator

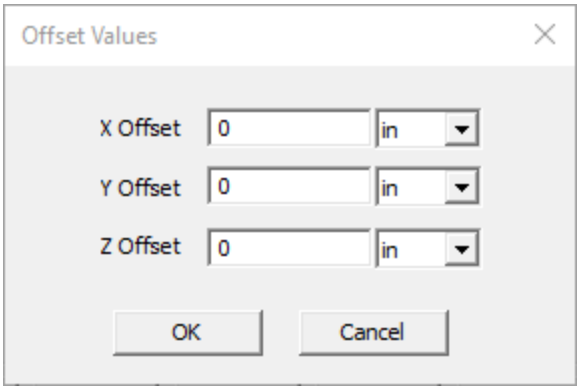
Vector Commands

XForm Command

Fields are defined in the Cartesian coordinate system. In many applications it is much more convenient to use a cylindrical or spherical coordinate system – for example, when the object is of cylindrical or spherical shape. The **XForm** command allows the user to transform vectors into either the cylindrical or spherical coordinate system. Selecting **XForm** displays a selection menu for the coordinate system (**ToCylindrical** or **ToSpherical**):



After you select the coordinate system you want, the **Offset Values** dialog displays.



Here you enter X, Y, and Z offsets to be used as the origin of the new coordinate system.

Click **OK** to compute the offset coordinate transformation to apply to the (complex) vector quantity in the top register on the calculator stack based on your selection of Cylindrical or Spherical coordinates and your input of X, Y, and Z offsets. The new expression will be pushed onto the stack. This provides the origin of the new coordinate system. It will be something like CVc : ToCylindrical(<Ex,Ey,Ez>,offset<0mil,0mil,0mil>) or CVc : ToSpherical (<Ex,Ey,Ez>,offset<0mil,0mil,0mil>) respectively.

After you transform the quantities, you can then access the vector components in the Fields Calculator.

You will then use the ScalarX/ScalarY/ScalarZ commands under **Scal?**. For a vector converted to cylindrical coordinates, ScalarX gives the radial component, ScalarY gives the phi (polar) component, and ScalarZ gives the Z component. For a vector in spherical coordinates, ScalarX gives the radial component, ScalarY gives the phi (polar) component and ScalarZ gives the theta (azimuthal) component.

Using the Fields Calculator

Vector Commands

Output Commands

Use these commands to compute or evaluate expressions and to output the data in the calculator.

Value command	Computes the value of a field quantity at a point.
Eval command	Numerically evaluates and displays the results of calculator operations.
Write command	Saves the contents of the top register to a disk file.

Export command	Saves field quantities in a format that can be read by other modeling or post-processing software packages.

Related Topics

Using the Fields Calculator

Value Command

This computes the value of a field quantity at a point. Use it to find:

- The magnitude of a scalar field quantity at that point.
- The x-, y-, and z-components of a vector field quantity at that point.

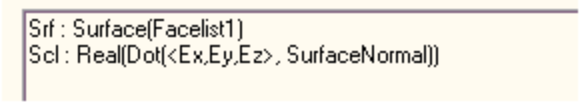
To find the value of a field quantity at a point:

1. Load the field quantity into the top register, and perform any needed operations on it.
2. Load the appropriate point into the calculator using the **Geometry/Point** command.
3. Click **Value**.

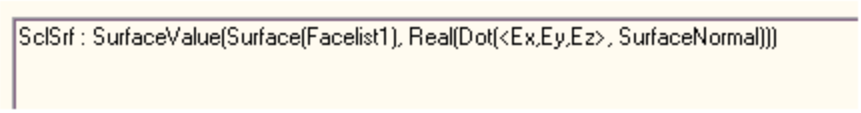
To view the numerical results of this operation, use the **Eval** command.

You can also use the **Value** command to access the intermediate SurfaceValue function

For example, after inputting an expression for a quantity, such as an E field, and then selecting a surface geometry, the calculator stack displays something like this.



Clicking the **Value** command changes the display to the following, showing the intermediate SurfaceValue function.



In this case SurfaceValue provides the x, y, z, coordinates of the FEM mesh and Lagrangian points so you can use **Write** to generate an .fld file containing an evaluated scalar quantity at those points. In general for **Value**:

1. Enter any quantity onto the stack.
2. Enter a volume / surface / line / point onto the stack.
3. Press the **Value** button and you will get an appropriate geometry value on the stack.

Now you can perform suitable operations such as Write, Integrate, etc. For PointValue you can also do **Eval**.

Related Topics

Using the Fields Calculator

Eval Command

This command numerically evaluates and displays the results of calculator operations such as integrations, maximum or minimum field computations, field values at points, and so forth. The quantity to be evaluated must be in the top register. The **Eval** command computes the numerical results of the operation, which replace the contents of the register.

For instance, to find the current around a loop, you must numerically evaluate the following

$$I = \oint H \bullet dl$$

integral for that loop: .

Since **H** and **I** are complex quantities, you first need to evaluate the real part of **H** to obtain the real part of **I**, then evaluate the imaginary part of **H** to obtain the imaginary part of **I**. To do this:

1. Load **H** into the calculator using the **Qty** command.
2. Take the real part of **H** using the **Cmplex/Real** command.
3. Load the rectangular loop using the **Geom/Line** command. Create the loop, a closed polyline, to integrate over.
4. Click **Tangent** to get the component of **H** along the line.
5. Take the integral around the loop using the $\int$ command.
6. Click **Eval** to evaluate the integral. The real part of **I** appears in the top register.
7. Repeat this process using the imaginary part of **H** (found with the **Complex/Imag** command) to obtain the imaginary part of **I**.

Related Topics

Using the Fields Calculator

Write Command

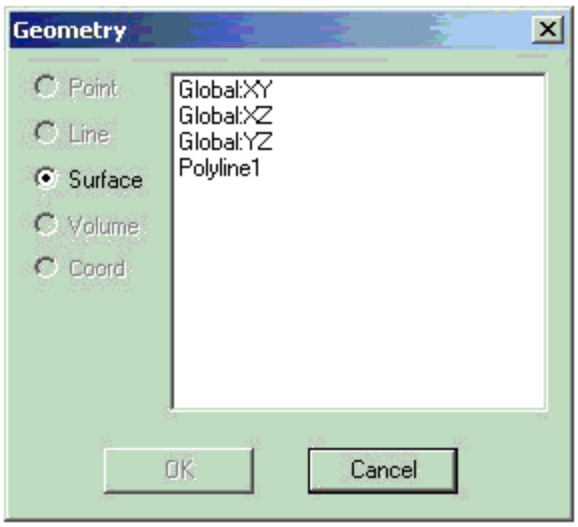
This command saves the contents of the top register to a disk file. Use this command to:

- Save registers for use during a later post-processing session.
- Save a field quantity for use when post processing a different model.

Note	Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

To save a register:

1. Click **Write**.
2. If the register includes numeric with a constrained quantity (such as jsurf), you see a dialog that gives a choice of constraining geometries. For example:



3. Select the geometry of interest, and select **OK**.

   This displays a file browser.
4. Use the file browser to specify the register's file name and directory path. A .reg extension is automatically assigned to register files and a .fld extension is assigned to field files. You can choose to save both .reg and .fld files, or either one.
5. Click **OK**.

   The contents of the file are saved to the file you specified.

Related Topics

Using the Fields Calculator

Export Command

This command opens the **Export Solution** dialog, from which you can export the field quantity in the top register to a file, mapping it to a grid of points. Use this command to save field quantities in

a format that can be read by other modeling or post-processing software packages. Two options are available for defining the grid points on which to export:

Input grid points from file	Maps the field quantity to a customized grid of points. Before using this command, you must create a file containing the points and units.
Calculate grid points	Maps the field quantity to a three-dimensional cartesian grid. You specify the dimensions and spacing of the grid in the x, y, and z directions, with units that you specify. The initial units are taken from the model.

Note	Use of the Global Coordinate System is assumed. Local coordinate systems are not used.

To export a field quantity to a customized grid:

1. Load the quantity into the top register for the fields calculator, and perform any operations on it.
2. If desired, load a volume using the **Geometry** command.

   You can use the Domain command to limit the calculation to the volume you specify. If you export a Domain filtered numeric, points that are filtered out by the domain will not be written out.
3. Click the **Export button in the Fields Calculator.**

   This opens the **Export Solution** dialog.
4. Type or select the name of the file in which the field quantity is to be saved in the **Output File Name** text box. You can use the file icon to open the file browser to specify the file name and directory path. A **.reg** extension is automatically assigned to this file.
5. Click either the **Input grid points from file** button if you have a created a **.pts** file containing the grid points, or click the **Calculate grid points** button.
   - If you select **Input grid points from file**, either type the name and directory of the file containing the points on which the field is to be mapped, or, click on the file icon and use the file browser to locate the point file (**.pts** extension).

Note	By default, the field calculator uses **SI** units. Optionally, you can also specify the units that you want while exporting. Add a line in the beginning of the .pts file to specify the units. For example, if you want to use **mm**, a sample file would like this:
	
	`Unit=mm`
	`-5.5 -5.5 -5.21475`
	`-5.5 -5.5 -5.14425`
	`-5.5 -5.5 -5.07375`
	`-5.5 -5.5 -5.021`

   - If you select **Calculate grid points** button, you can specify the coordinate system as Cartesian, Cylindrical, or Spherical.

Cartesian: for each grid dimension on X, Y, and Z, enter the Minimum, Maximum, and grid point spacing.

Cylindrical: for each dimension Rho, Phi, and Z, enter the Minimum, Maximum, and grid point Spacing. You can also specify an origin of Offset.

Spherical: for each dimension R, Theta, and Phi, enter the Minimum, Maximum, and grid point Spacing. You can also specify an origin of Offset.

Note	When you export fields on a 1D or 2D line/surface from the field calculator, the start and stop values must be the same for one or two of the coordinate system start/stop ranges. If you specify a zero spacing for a dimension, the export uses only the minimum value.

The default coordinate system is Cartesian. The default offset will be all zeros. The length units will default to model unit and default angle unit will be degree. At the start the minimum/maximum/Spacing entries are blank. The user-entered values are not remembered when the dialog is closed.

6. For larger files, you may want to uncheck the **Include points in output file** box. If you uncheck the box, the file header will include minimum, maximum and spacing information from which you can recalculate the grid points.
7. Click **OK** to export the file.

   The field quantity is mapped to the grid and saved to the file you specified (**.reg** extension.).

Calculating Derived Field Quantities

The **Named Expressions** panel displays expressions that can be included in register definitions by name. You can add additional expressions to the Named expression list by creating the expression in the register display area, and the clicking the Add button. This lets you add to the Named expression library.

When a Maxwell design is open and a Solution Setup has been performed, numerous predefined named expressions may be available depending upon the solution type. Generally, predefined expressions related to electric or magnetic field magnitude, current magnitude, vector field values, energy, and losses are available

Click on a named expression to select it. When a named expression has been selected, the **Copy to Stack** button is activated. Click **Copy to Stack** to push the expression on the top of the stack.

Related Topics

Named Expressions

Named Expression Library

Named Expression Library

The named expression library in the Fields Calculator provides a way to conveniently calculate frequently used quantities. The library comes with several predefined expressions. You can combine calculator Input commands in any legal fashion, including complex quantities, to produce new named expressions.

- Adding named expressions to the Fields Calculator expression library
- Copying named expressions to the Calculator Stack
- Saving named expressions to a Personal Library
- Loading named expressions
- Deleting named expressions that you added

To add a named expression of your own to the Fields Calculator list:

1. In the register display area, create the expression by using the calculator Input commands.

   You can combine input commands in any legal fashion, including the use of complex quantities. If you select an input command that is not legal for a current operation, you receive an error message.
2. When you finish creating the expression, click **Add in the Named Expressions panel**.

   The **Named Expression** dialog box appears.
3. Type a name for the expression in the **Name** text box.

   The new expression is added to the list of named expressions.

To copy a named expressions to the Calculator Stack

- You can scroll through the list, select any desired named expression, and click **Copy to Stack** to move it to the calculator stack, where you can use it to generate calculated outputs.

To delete named expressions that you added:

When the **Named Expression** list contains one or more user-defined expressions, the **Delete** and **Clear All** buttons are active (you cannot delete or clear the predefined named expressions.)

- To delete the selected user-defined named expression, click **Delete**. To delete all user-defined named expressions, click **Clear All**.

To save one or more named expressions for the Fields Calculator to a personal Library:

1. Click the **Save To** button on the Fields Calculator.

   The **Select Expressions for Saving** dialog displays.
2. If any new named expressions exist, you can select one or more to save to a file.
3. Give a file name, and click **OK** to save the file.

To load named expressions for the Fields Calculator from a personal library:

1. From the Fields Calculator, click **Load From**.

   This displays a file browser that you can use to search for existing .clc files.
2. Select the library to load and click **OK**.

This loads the expression file you have selected.

Plotting the Mesh

Before or after the solution is complete, you can plot the finite element mesh on surfaces or within 3D objects.

1. Select a surface or object to create the mesh plot on or within.
   If it does not exist, create it.
2. Click **Maxwell3D>Fields>Plot Mesh** or **Maxwell2D>Fields>Plot Mesh**.
   The **Create Mesh Plot** dialog box appears.
3. Enter a name, or accept the default name.
4. Select the solution to plot from the **Solution** pull-down list.
5. Select the field quantity to plot from the **Field Type** pull-down list.
6. Click **Done**.
   The mesh appears on the surface or object you selected. An icon for the mesh also appears in the **Project** tree under **Field Overlays -- Mesh Plots**.
   If a solution is ongoing, you can select the Mesh Plots icon in the in the Project tree, right-click to display the shortcut menu, and click **Update Plots**. This updates the mesh plot to latest data available. After the last adaptive pass, the Mesh plot is automatically updated.
   If a mesh includes seeding, these effects appear at the start of the adaptive passes. Any mesh adaptation at the start of a sub sequent pass is not plotted until after that pass is completed. This delay ensures that mesh plots and actual solutions remain consistent with each other.
   You can modify an existing plot by selecting the plot and changing the properties. If you modify the geometry of an object, the solution is invalidated, and the mesh plot is removed.
   If you have plotted the mesh of a Solve-Inside object, you can view the internal mesh by using either the clip-plane feature or the Model Analysis dialog box. Also see the discussion here, under **Visualization for Skin Depth Refinement Mesh Results**. The same techniques for visualization for internal mesh plots apply even if seeding is not used.

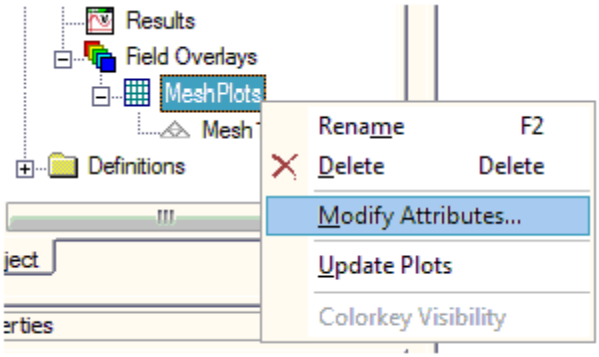
Related Topics

Setting Mesh Plot Attributes

Mesh Feedback Tab

Setting Mesh Plot Attributes

1. Select the Mesh Plots icon under Field Overlays in the Project tree, right-click, and select Modify Attributes to display the **Mesh Plots** dialog.



You can also click **Maxwell 2D** or **Maxwell 3D>Fields>Modify Plot Attributes** , after which the **Select Folder** window appears. Select the folder containing the mesh plot you want to modify, and then click **OK** to display the **Mesh Plots** dialog.

For Mesh plots, the following attributes can be modified:

Plot	A drop down list of available plots.
Scale Factor	The size at which the tetrahedra are displayed. Scaling may let you analyze particular situations better. For example, a scale factor of 80% draws the tetrahedra at 80% of their original size. Use the **Scale factor** slider to increase (move to the right) or decrease (move to the left) the percentage of the tetrahedra size.
Transparency	The degree of transparency for the tetrahedra. This is useful for viewing objects or plots behind the current plot. Use the **Transparency** slider to increase (move to the right) or decrease (move to the left) the transparency of the plot.
Mesh type	Whether to display the tetrahedra as wire frame or shaded, and whether to

	Add Grid.
Mesh Color for Line and Fill	The color for the tetrahedra edge lines and fill. Clicking the button for each displays a color selection dialog.
Surface Only	Whether to plot the surface only, or all tetrahedra inside selected objects.
Real Time	Whether to show changes to a mesh in real time.

2. Click the **Save as default** button if you want the tab's settings to apply to mesh plots created after this point.
3. Select **Real time mode** if you want the changes to take effect immediately in the view window.

   If this option is cleared, click **Apply** when you want to see the changes.
4. Click **Close** to dismiss the dialog box.

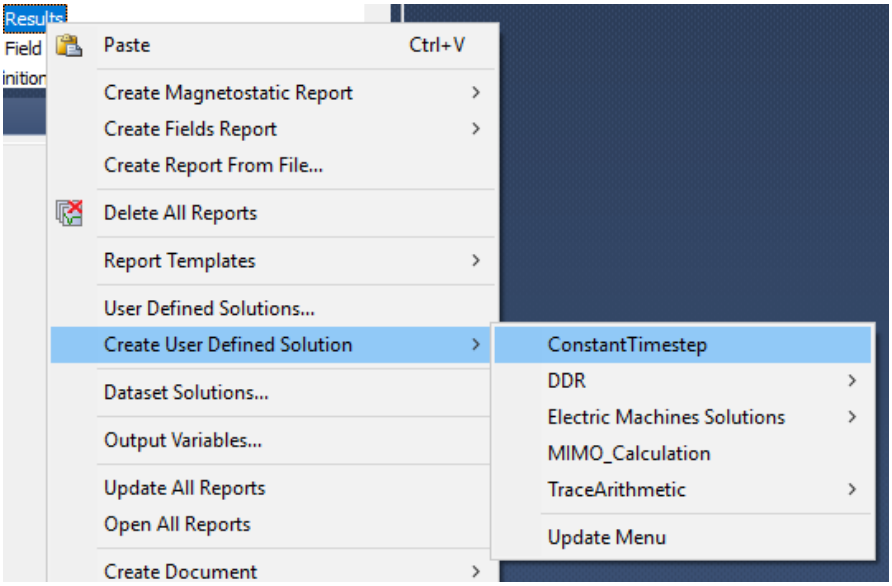
Plotting Field Overlays

User Defined Outputs: Introduction

User defined outputs (UDOs) allow users to define calculations through IronPython scripts or any .NET language (and used by the IronPython script). The UDO scripts need to be in the **UserDefinedOutputs** directory under either of **syslib**, **userlib** or **Personallib** with any directory structure needed for organization. (The **Lib** directory name is special and its purpose will be explained in a subsequent section.)

The UDO scripts that are in **syslib/UserDefinedOutputs**, **userlib/UserDefinedOutputs**, or **Personallib/UserDefinedOutputs** become available to the user to create "User Defined Solutions" through the **Results>Create User Defined Solution** menu.

Use **Results>Create User Defined Solution>Update Menu** to refresh the menu to include the new UDO scripts that might have been copied to syslib, userlib or Personallib, or exclude them if they have been deleted, after the launch of desktop. Once the user-defined-solution is created, the solution and the calculations defined by UDO become available in Reporter as any other quantities in a new "User Defined" report type. (**Electric Machines Solutions** sub-menu is available only on Windows.)



Named Probes and Properties in User Defined Outputs

Dimensions Reduction by UDO Calculations

Dynamic Probes

Related Topics

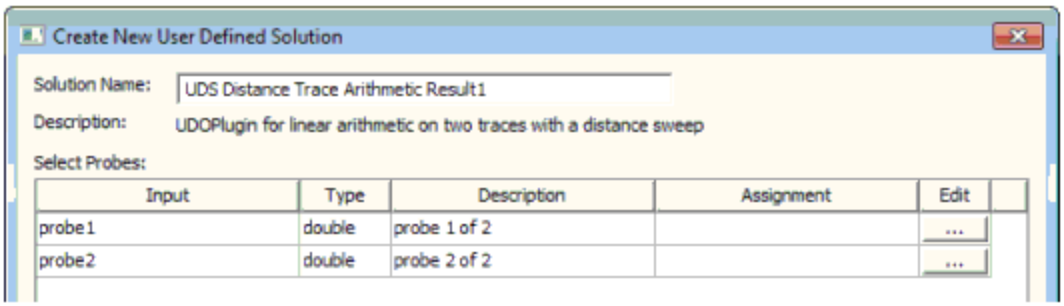
User Defined Outputs: Python Script API

User Defined Outputs: Script Organization

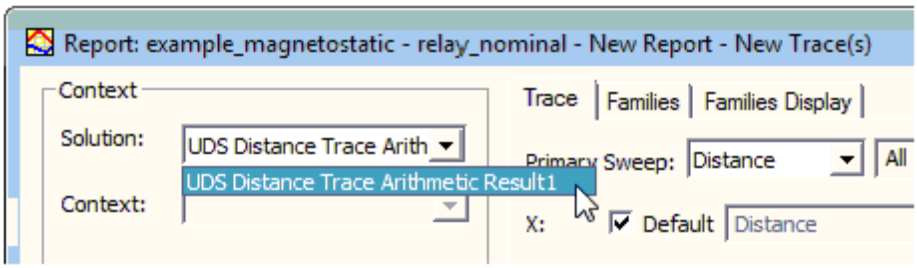
Named Probes and Properties in User Defined Outputs

UDOs allow processing data across traces, solutions and report types. A UDO specifies the named probes and properties for which user selects/enters the values at the time of creation of user defined solution. Probes are very similar to traces except that the user selects the values of only intrinsic variables for probes. The values of design/project variables are selected when a trace is created based upon the user defined solution in reporter.

For example, you could create a user defined solution called UDS Distance Trace Arithmetic Result1.



You can then access this solution in the Reporter.



Related Topics

User Defined Outputs: An Introduction

Computation of Traces Based UDO Calculations

Dimensions Reduction by UDO Calculations

Dynamic Probes

Computation of Traces Based UDO Calculations

When traces that are based upon UDO outputs are computed, the data for probes is computed and passed to the UDO script for each design variation. Along with the probe data, the values of properties entered by user are also passed. The information about the UDO calculations that need to be computed is also made available. The UDO then performs the computation and passes the results to reporter. Note that UDOs can compute and pass back more calculations than have been requested at that point of time. This allows UDOs to compute a set of calculations that take almost same amount of computational resources as any one calculation in that set and cache that with reporter.

Note	When those calculations are subsequently plotted by the user, reporter will use the cached results instead of invoking the computation on UDO.

Dynamic Probes

Dimensions Reduction by UDO Calculations

The probes in a UDO can have heterogeneous dimensions of data, for example, one probe in a UDO can have data that is function of **n** intrinsic variable, while another probe in same UDO can have data that is a function of **m** intrinsic variables, with **n** and **m** potentially being different. UDOs allow reducing any number of these intrinsic variables e.g in above example UDO calculations can be function of any number of intrinsic variables including not being function of any intrinsic variable at all. UDO calculations can also be a function an intrinsic variable that none of the probes is function of. **The only restriction is that Freq cannot be reduced if any of the probes are on a Fields report type.**

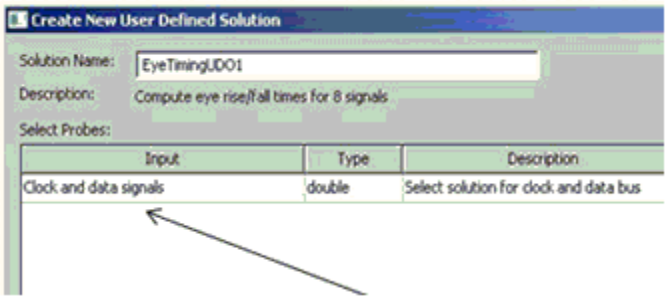
Dimensions Reduction by UDO Calculations
Dynamic Probes

Dynamic Probes

In addition to named probes and properties, UDOs can specify named dynamic probes. The difference between probes and dynamic probes is that while the end-user of UDO specifies the complete trace definition for probe, the expression for dynamic probe is specified by UDO code itself and not by the end-user. This allows UDOs to access the data for probes without having the end-user enter each individual probe. For example a UDO can access data for a huge S matrix for a 100 port design without requiring the end-user to enter the probe information for each of those 10,000 quantities. Each dynamic probe is associated with a named probe that is entered by the user; and information about solution, context, and intrinsic variables is used from user-selected probe. However multiple dynamic probes can be associated with the same user-selected probe. The dynamic probes are enquired from UDOs at the time of trace computation and not at the time of creation of user-defined solution.



This means that you select solution, context, and values of intrinsic variables just once; and the same information is used (in this case) for all clock and data signals. The expression for those signals comes from the UDO code.

UDO Extension IMPLEMENTATION

The purpose, argument list and expected return types for each of the **IUDOPluginExtension** abstract methods, which the UDO author is expected to implement are described below.

Import Statements

UDOExtension Class

IUDOPluginExtension Abstract Class

Related Topics

User Defined Outputs: Python Script API

Import Statements

The base class to be used and the types it uses in turn are contained in .NET assemblies. The use of these requires that the assemblies be imported into the UDO script: the following import statements should be added to the top of the python script:

```
from Ansys.Ansoft.ModulePluginDotNet.Common.API import *
from Ansys.Ansoft.ModulePluginDotNet.Common.API.Interfaces import *
from Ansys.Ansoft.ModulePluginDotNet.UDO.API.Interfaces import *
from Ansys.Ansoft.ModulePluginDotNet.UDO.API.Data import *
```

Related Topics

UDO Extension IMPLEMENTATION

UDOExtension Class

The UDO itself should be implemented as an IronPython class called ***UDOExtension*** which **must** derive from the ***IUDOPluginExtension*** abstract base class **(**from the **Ansys.Ansoft.ModulePluginDotNet.UDO.API.Interfaces** namespace**)**.

Note that power users could derive a class hierarchy tuned toward a specific type of UDOs and that they can derive from their own base classes. The only requirement is that directly or indirectly, the UDO class must derive from ***IUDOPluginExtension.***

Example:

```
def BaseClassUDO ((IUDOPluginExtension):
#base class implementation
    …
def UDOExtension ((BaseClassUDO):
#UDO class implementation
…
```

Related Topics

UDO Extension IMPLEMENTATION

IUDOPluginExtension Abstract Class

The implementation of the IUDOPluginExtension class will be described in this section using a simple UDO example that expects a single probe and reduces its dimension returning as its outputs, the max, min and average of its input probe data. The script in its entirety will also be listed later on.

Required functions:

The IUDOPluginExtension abstract class declares the following abstract methods that must be implemented in the UDOExtension class or one of its base classes. Not implementing any of these methods will result in a run-time error and a non functioning UDO. The UDS refers to user Defined Solution parameters.

GetUDSName()

GetUDSDescription()

GetUDSSweepNames()

GetCategoryNames()

GetQuantityNames(string categoryName)

GetQuantityInfo(string quantityName)

GetInputUDSParams(List<UDSProbeParams> udsParams,

GetDynamicProbes(List<UDSDynamicProbes> dynamicProbes);

Compute(IUDSInputData inData,

Related Topics

UDO Extension IMPLEMENTATION

GetUDSName()

- **Purpose**: Return a string that is used as a prefix for all solution instances created using this UDO.
- **Returns**: string.

Example:

```
def GetUDSName(self):

return "MinMaxAvg
```

Related Topics

IUDOPluginExtension Abstract Class

GetUDSDescription()

- **Purpose**: Returns a description for the UDO, its purpose etc. This is used in multiple UDO related dialogs in the application to describe the UDO.
- **Returns**: string.

Example:

```
def GetUDSDescription(self):

return "Sample UDO for dimension reducing quantities
```

Related Topics

IUDOPluginExtension Abstract Class

GetUDSSweepNames()

- **Purpose**: Returns a list of sweep names to be used for the solution generated by the UDO. These will appear in the sweeps list displayed in the standard reporter dialog when used to create reports from the solution generated by the UDO.
- **Returns**: list of strings. If the UDO outputs have no sweeps, return the empty list [].

Example:

```
# Returns list of sweeps names
# We have no sweeps as we reduce them.
def GetUDSSweepNames(self):

return []
```

Related Topics

IUDOPluginExtension Abstract Class

GetCategoryNames()

- **Purpose**: The outputs that the UDO solution provides/generates can be classified into multiple categories (like how the application does as displayed in the report creation dialog). These will be listed in the categories box in the dialog when creating reports from the UDO generated solution data.
- **Returns**: list of strings.

Example:

```
def GetCategoryNames(self):

return ["UDOOutputs"]
```

Related Topics

IUDOPluginExtension Abstract Class

GetQuantityNames(string categoryName)

- **Purpose**: For each of the category names returned from the *GetCategoryNames* method, this function is called to return a list of quantities to be organized under that category name. **Note that the quantity names must be unique across the categories: that is, no two categories can have quantities with the same name.**
- **Parameters**:
  - categoryName (input python string) - category name.
- **Returns**: python list of strings.

Example:

```
# returns a list of quantity names for the supplied category name
def GetQuantityNames(self, catName):

if catName == "UDOOutputs":

    return ["min_val", "max_val", "avg_val"]

else:

    return []
```

Related Topics

IUDOPluginExtension Abstract Class

GetQuantityInfo(string quantityName)

- **Purpose**: For each quantity that the UDO creates, it must also describe the quantity (unit and other details). This method is called for each quantity name (across all categories) as returned from an earlier call of the *GetQuantityNames* method.
- **Parameters**:
  - quantityName (input string) - quantity name.
- **Returns**: Object of type QuantityInfo.

Example:

```
# Returns an instance of QuantityInfo for the qtyName supplied or None if such a
# quantity could not be found
def GetQuantityInfo(self, qtyName):
```

```
# All the quantities we have are simple doubles
# we can leave them unitless
return QuantityInfo(Constants.kDoubleParamStr)
```

Related Topics

IUDOPluginExtension Abstract Class

GetInputUDSParams(List<UDSProbeParams> udsParams,

IPropertyList propList,

List<UDSProbeParams> userSelectionForDynamicProbes)

- **Purpose**: This is the main definition part of the UDO. The supplied arguments are used to populate details of the parameters to which the UDO user will specify value, specify the probe names and their types as well as the dynamic probe selections.
- **Parameters**:
  - udsParams - .NET list of UDSProbeParams objects: The UDO script is expected to add one instance of UDSProbeParams for each probe definition it wants displayed. The UDO user will, when creating the UDO solution assign a matching quantity to each such probe.
  - propList - IPropertyList object: The propList object is used to add properties that should be displayed to the user for data collection. These properties with the user supplied values will be returned to the UDO script in the Compute methods.
  - userSelectionForDynamicProbes - .NET list of UDSProbeParam objects.
- **Returns**: boolean: True on success, False on failure.

Example:

```
# Returns list of UDSParams and list of dynamic properties
# Adds setup time properties to the propList
def GetInputUDSParams(self, udsParams, propList, userSelectedDynamicProbes):

# Add the probes. We need only one double quantity
param1 = UDSProbeParams("probe1",
  "double quantity probe",
  Constants.kDoubleParamStr,
  "", "")
udsParams.Add(param1)

# Add the properties we want the user to supply
```

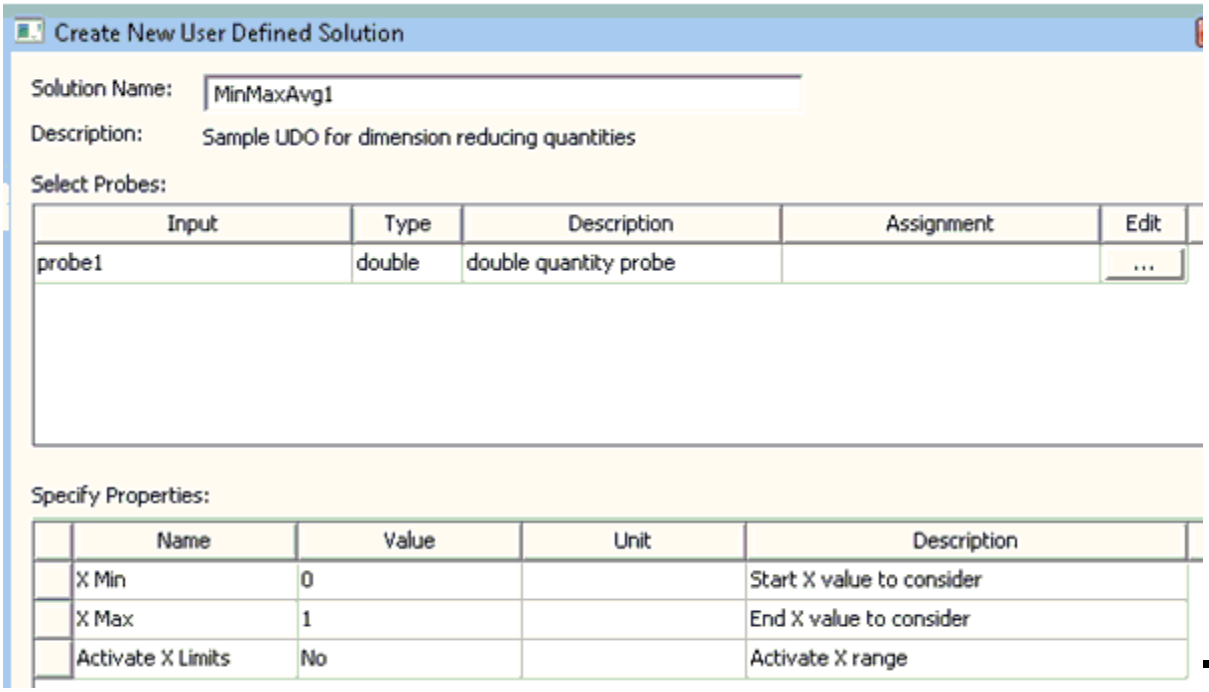
```
    # In this case, we will ask for a start/end range for
    # X parameters. Since we cannot reasonably provide defaults
    # as we have no idea what the sweep limits will be, we will
    # also ask if the limits are to be activated.
    prop = propList.AddNumberProperty("X Min", "0")
    prop.Description = "Start X value to consider"

    prop = propList.AddNumberProperty("X Max", "1")
    prop.Description = "End X value to consider"

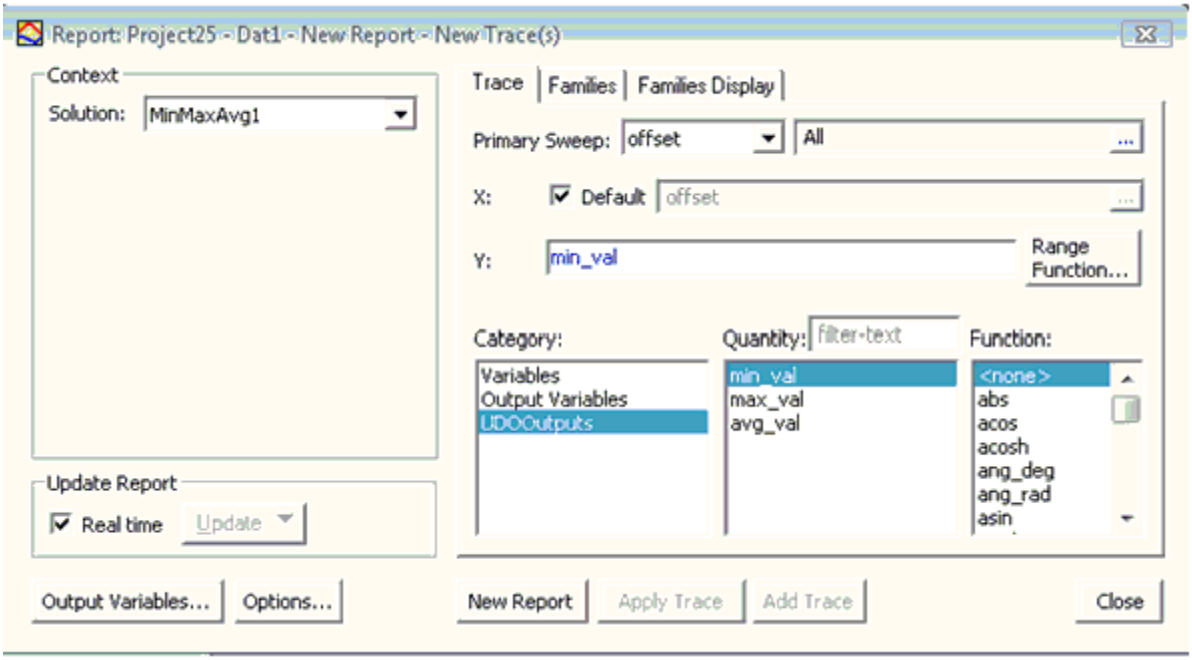
    # For menus, the first option is the default.
    prop = propList.AddMenuProperty("Activate X Limits", ["No", "Yes"])
    prop.Description = "Activate X range"

    return True
```

The above function results in the following dialog when you click **Reports>Create User Defined Solution**. The mapping from the UDSParams and the properties to the GUI elements should be unambiguous. The name and description of the UDS are also displayed in this dialog.



When a report is created from the UDO dialog box, the category/quantity names specified by the UDO are used (as shown below).



Related Topics

IUDOPluginExtension Abstract Class

GetDynamicProbes(List<UDSDynamicProbes> dynamicProbes);

- **Parameters**: dynamicProbes - .Net list of UDSDynamicProbes objects. Output parameter.
- **Returns**: True on success, False on failure.

Example:

```
# Returns list of UDSParams and list of dynamic properties
# output UDSDynamicProbeCollection probes
def GetDynamicProbes(self, probes):
pass
```

Related Topics

IUDOPluginExtension Abstract Class

Compute(IUDSInputData inData,

IUDSOutputData outData,

IPropertyList propList,

IProgressMonitor progressMonitor)

- **Purpose**: This is the main computation method which generates the data for the quantities that make up the UDO solution.
- **Parameters**:
  - ***inData*** – UDSInputData object: Used to get the input probe data.
  - ***outData*** – UDSOutputData object: Used to set the UDO solution quantity and sweep data.
  - ***propList*** – IPropertyList object: Used to get the user entered values for each of the properties defined during the *GetInputUDSParams* call.
  - ***progressMonitor*** – IProgressMonitor object. This can be used to set progress for long running calculations, check for user initiated abort etc.
- **Returns**: True on success, False on failure.

The data is received from UI using ***IUDSInputData*** API***.*** It is processed and the result data is sent to UI using ***IUDSOutputData*** API.

Example:

```
# IUserDefinedSolutionHandle API implementation.
# Calculates output values and sets them using IUDSInputData/IUDSOutputData API.
def Compute(self, inData, outData, propList, progMon):

    # Get the sweeps associated with the probe and validate
    # use the probe name that we had defined earlier
    sweeps = inData.GetSweepNamesForProbe("probe1")
    if( sweeps == None or sweeps.Count > 1):
    AddErrorMessage(self.GetName() + "Unexpected sweep count 0 or > 1 in Compute")
    return False

    # Get the data associated with our probe
    probeData = inData.GetDoubleProbeData("probe1")
    sweepData = inData.GetSweepsDataForProbe("probe1", sweeps[0])

    # Get the user specified properties.
    # Note that ideally, these "X Min" etc names should be written as
```

```
# constant membets and referred to in both the GetInputUDSParams
# and in Compute to reduce the change of typos.
useXRangeProp = propList.GetMenuProperty("Activate X Limits").SelectedMenuChoice
xRangeStart = propList.GetNumberProperty("X Min").ValueSI
xRangeEnd = propList.GetNumberProperty("X Max").ValueSI

# At this stage, one can look at the RequestedQuantities and create
# a dictionary to later check against. However, I am simply computing
# all the quantities.
minVal = 0
maxVal = 0
avgVal = 0

# Check if we need to perform range computation
if useXRangeProp == "Yes":
    seenAny = False
    avgSum = 0
    count = 0

# zip is used since we also need to pull in sweep data
# an index and the array notation could also have been used
for probeVal, sweepVal in zip(probeData, sweepData):
  if sweepVal < xRangeStart or sweepVal > xRangeEnd:
  pass

  # Note that in a better written script, this code would be
  # refactored into it's own function to avoid code
  # duplication
  if not seenAny:
  minVal = probeVal
  maxVal = probeVal
  avgSum = probeVal
  seenAny = True
  count = 1
  else:
  if probeVal < minVal:
```

```
minVal = probeVal

        if probeVal > maxVal:
maxVal = probeVal

        avgSum += probeVal
        count += 1

          if seenAny:
        avgVal = avgSum/count

      else:
          seenAny = False
          avgSum = 0
          for probeVal in probeData:
        if not seenAny:
        minVal = probeVal
        maxVal = probeVal
        avgSum = probeVal
        seenAny = True
        else:
        if probeVal < minVal:
minVal = probeVal

        if probeVal > maxVal:
maxVal = probeVal

        avgSum += probeVal

          if seenAny:
        avgVal = avgSum/probeData.Count

      # Finally set the output values. Note that these are always set as

      # lists even if we have just one item.
```

```
outData.SetDoubleQuantityData("min_val", [minVal])
outData.SetDoubleQuantityData("max_val", [maxVal])
outData.SetDoubleQuantityData("avg_val", [avgVal])

# And we are done.
return True
```

IUDOPluginExtension Abstract Class

Optional Functions in IDO Extension Abstract Class

The following functions, while a part of the IUDOExtension abstract class, have meaningful default implementations and are therefore optional. However, they can be overridden to take advantage of advanced functionality.

Validate(List<string> errorStringList,

Related Topics

User Defined Outputs: Python Script API

Validate(List<string> errorStringList,

List<UDSProbeParams> udsProbParams,

IPropertyList propList,

List<UDSProbeParams> userSelectionForDynamicProbes)

- **Purpose**: This method is used to validate the user choices. The values of the properties entered, the probes etc. can be checked for suitability.
- **Parameters**:
  - udsProbParams - C# list of UDSProbeParams objects.
  - ***propList*** – _IPropertyList object.
  - userSelectionForDynamicProbes - C# list of UDSProbeParams objects.
  - errorStringList - C# list of python strings. Output parameter. Should be set only if validation failed; ignored if validation is successful. One error string should be set per each validation error.
- **Returns**: True on validation success, False on failure.
- **Default implementation**: always returns true.

Example:

```
def Validate(self, errorStringList,probeList,propList, dynamicProbes):
```

```
if probeList == None or probeList.Count == 0:
    errorStringList.Add("Empty probe list")
    return False
return True
```

Related Topics

Optional Functions in IDO Extension Abstract Class

Data Types Used in Python Script

There are several types that you must use while authoring the python script. Some of them are used to pass data from UI to python script and to provide interface for working with this data. Some are used to pass data from python script to UI.

To pass data from python script to UI the objects of the C# class must be created in python script using their C# constructors. Then they can be set as functions return values or set to the output parameters using their API.

Constants class

kTraceTypeStr : string constant used to specify an input of trace type

kSolutionTypeStr : string constant used to specify an input of solution type

kNumberTypeStr : string constant used to specify an input of number type

kTextTypeStr : string constant used to specify an input of text type

kBoolTypeStr : string constant used to specify an input of boolean type

kStandardReportStr : string constant to specify a standard report

kEyeDiagramReportStr : string constant to specify an eye diagram report

kUserDefinedReportStr : string constant to specify a user defined report

kSweepDomainStr : string constant to specify the sweep domain

kTimeDomainStr : string constant to specify the time domain

UDDInputParams class

The objects of this class must be created in python script in the **GetUDDInputParams()** function and the **SetUDDInputParams()** function.

Attributes :

Input Name (string)

Input Description (string)

Input Type (Can be Boolean, Number, Text, Trace or Solution) (string)

BoolData (boolean)

DoubleData (double)

TextData (string)

ReportType (string)

SolutionName (string)

DomainName (string)

Constructors:

UDDInputParams(string name, string description, string type)

UDDInputParams(string name, string description, string type, bool data)

UDDInputParams(string name, string description, string type, double data)

UDDInputParams(string name, string description, string type, string data)

UDDInputParams(string name, string description, string type, string reportType, string solutionName, string domainName)

Property Accessors :

Name : Get/Set the name of an input

Description : Get/Set the desccription of an input

Type : Get/Set the type of an input

BoolData : Get/Set the data of a boolean input

DoubleData : Get/Set the data of a number input

TextData : Get/Set the data of a text input

ReportType : Get/Set the report type

SolutionName : Get/Set the name of the solution

DomainName : Get/Set the name of the domain

IProgressMonitor Abstract Class

The object of this class is a progress monitor. It is used to display calculations progress in UI and check is the user has requested an abort of the computation.

When displayed in the application, each progress message has four items:

A task name

A sub-task name

The progress amount

A button to abort the task in progress.

All of this functionality and abort interaction is achieved using the following functions.

SetTaskName (string taskName):

SetSubTaskName (string subTaskName)

BeginTask (string name)

SetTaskProgressPercentage(int progressPercent)

CheckForAbort(): If the quantities being generated are computationally expensive, the UDO author can periodically call this method and then call EndTask with Fail and return False.

EndTask (bool passFail)

Example:

```
progMon.BeginTask("Process DQS")
progMon.SetSubTaskName("Compute UI segments")
progMon.SetTaskProgressPercentage(33)
progMon.SetSubTaskName("Compute the rest")
progMon.SetTaskProgressPercentage(100)
progMon.EndTask(True)
```

IUDSInputData

The purpose of this class is to get data (probe and sweep) from Desktop.

Examples in this section are just to show proper syntax of the function calls. For actual usage of the class see Compute function example.

GetDoubleProbeData(probeName)

GetSweepsDataForProbe(probeName, sweepName)

GetComplexProbeData(probeName)

GetSweepNamesForProbe(probeName)

GetRequiredQuantities()

GetVariableValues()

GetInterpolationOrdersData(probeName);

Related Topics

Data Types Used in Python Script

GetDoubleProbeData(probeName)

- **Purpose**: This is the primary mechanism by which the UDO script obtains the probe data (as double precision values) for its compute process.
- **Parameters**:
  - probeName: string representing the probe name for which data is requested. This has to be one of the many probes supplied during a call to the UDO's **GetInputUDSParams** method.
- **Returns**: .NET double Array of data for the specified probe if the probe exists or null if the probe is unknown.

Example:

```
# doubleData is a list of floats
doubleData = inData.GetDoubleProbeData("probe1")
```

Related Topics

Data Types Used in Python Script

GetSweepsDataForProbe(probeName, sweepName)

- **Purpose**: All probe data that is supplied is associated with one ore more sweep (an intrinsic quantity like Time, Frequency, Theta, Phi etc that is swept) quantities.
- **Parameters**:
  - probeName - probe name for which which want the sweep data
  - sweepName - sweep name
- **Returns**: .NET double Array of data for the specified probe and sweep.

Example:

```
# sweepData is C# Array of doubles (floats in python)
sweepData = inData.GetSweepsDataForProbe("FarFieldsProbe","Freq"])
```

Related Topics

Data Types Used in Python Script

GetComplexProbeData(probeName)

- **Purpose**: The primary mechanism by which the UDO retrieves data for its input probes (if it expects complex data for the probe).
- **Parameters**:
  - probeName - probe name for which complex data is requested
- **Returns**: .NET double Array (float in python) of data for the specified probe. Each pair of floats represent one complex number: first value is for real part, second value for imaginary part. For instance, array [10.0, 0, 5.1, 2.1] represents 2 complex numbers: (10.0, 0) and (5.1, 2.1).

Example:

```
# complexDataAsDouble is C# Array of doubles (floats in python)
# each pair of floats represents one complex number
complexDataAsDouble = inData.GetComplexProbeData("FarFieldsProbe")
# creating a list of complex numbers from complexDataAsDouble array
complexData = []
if complexDataAsDouble != None:
    for i in xrange(0,complexDataAsDouble.Count , 2):
        complexData.append(complex(complexDataAsDouble[i],complexDataAsDouble[i+1]))
```

Related Topics

Data Types Used in Python Script

GetSweepNamesForProbe(probeName)

- **Purpose**: To obtain the list of sweep quantity names associated with a given probe. This also indicates the dimensionality of the data. One name implies that the probe-data is 2D (probe-quantity vs Sweep Quantity) and two names implies 3D data (probe-quantity vs Sweep 1 X Sweep 2).
- **Parameters**:
  - probeName - probe name.
- **Returns**: .NET IList<string> - list of sweep names for the current probe name.

Example:

```
# sweepNames is C# Array of strings
sweepNames = inData.GetSweepNamesForProbe("FarFieldsProbe")
```

Related Topics

Data Types Used in Python Script

GetRequiredQuantities()

- **Purpose**: A given UDO can specify that it provides one of more computed quantities. The user might choose to create a report from only a few among the various available UDO outputs. This function, returns that list of the UDO output quantities that the user has requested. Only these need be computed in the UDO's compute method.
- **Returns**: .NET IList<string> - list of required quantities names.

Example:

```
# quantities is C# Array of strings
quantities= inData.GetRequiredQuantities()
```

Related Topics

Data Types Used in Python Script

GetVariableValues()

- **Purpose**: This allows the UDO to obtain the names and values of all the design variables for which the UDO quantities are being requested.
- **Returns**: .NET IDictionary<string,string> of key-value pairs for variables. Both key and value are strings.

Example:

```
# theDict is C# Dictionary<string, string>
theDict = inData.GetVariableValues()
if theDict != None:
#varPair is of .Net KeyValuePair type
for varPair in theDict:
    varName = varPair.Key #string
    varValue = varPair.Value #string
```

Related Topics

Data Types Used in Python Script

GetInterpolationOrdersData(probeName);

- **Purpose**: Returns the interpolation orders that are associated with the probe-data. The probe data is specified at each value of the various sweeps. Any value in between the sweep data points, can use the interpolation data to get a possibly more accurate (compared to linear interpolation) inter-sweep value.
- **Parameters**:
  - probeName (input python string) - probe name.
- **Returns**: NET byte Array of interpolation order for the specified probe. These are to be treated as 8bit signed integers, that is, their values range from 0-127.

Example:

```
# interData is C# Array of bytes (integers in python)
interData = inData.GetInterpolationOrdersData(kProbeNames[0])
for interValue in theDict:
    order = interValue # interValue and order are integers
```

Related Topics

Data Types Used in Python Script

IUDSOutputData

This type is a twin of the IUDSInputData in that it is used to store the values computed by the UDO's compute method.

Examples in this section are just to show proper syntaxis function calls. For actual usage of the class see the Compute function example.

SetSweepsData(sweepName, sweepData)

SetDoubleQuantityData(qtyName,qtyData)

SetComplexQuantityData(qtyName, qtyData)

Related Topics

Data Types Used in Python Script

SetSweepsData(sweepName, sweepData)

- **Purpose**: Each quantity that is computed by the UDO can be associated with a sweep. If it is, the values that make up the sweep's data points must be specified using this call.
- **Parameters**:
  - sweepName (string) - sweep name.
  - sweepData (python list of floats) - sweep data for the specified sweep.
- **Returns**: True on success, False on failure.

Example:

```
sweepList = [12.3, 14.5, 16.7]
outData.SetSweepsData("Freq", sweepList)
```

Related Topics

Data Types Used in Python Script

SetDoubleQuantityData(qtyName,qtyData)

- **Purpose**: This method is used to record the computed quantity data for each output that is computed. Please note that unless all the sweeps are reduced, this should be used in conjunction with SetSweepsData
- **Parameters**:
  - qtyName (string) - quantity name.
  - qtyData (python list of floats) - quantity data for the specified quantity.
- **Returns**: True on success, False on failure.

Example:

```
doubleList = [12.3, 14.5, 16.7]
outData.SetDoubleQuantityData("V1PlusV2", doubleList)
```

Related Topics

Data Types Used in Python Script

SetComplexQuantityData(qtyName, qtyData)

- **Purpose**: If the quantity computed is a complex quantity, use this method to set the quantity values. Any sweep values must be set separately via the SetSweepsData method.
- **Parameters**:
  - qtyName (string) - quantity name.
  - qtyData (python list of floats) - quantity data for the specified quantity. Complex numbers are passed as pairs of floats
- **Returns**: True on success, False on failure.

Example:

```
doubleFromComplexList=[]
complexList = [(1+1j), (2+4j), (9.1+3.2j)]
for aComplex in complexList:
doubleFromComplexList.append(aComplex.imag)
doubleFromComplexList.append(aComplex.real)
outData. SetComplexQuantityData ("V1PlusV2", doubleFromComplexList)
```

Working With Properties for UDO

A property is the unit for collecting and using input from the user that is used to influence the UDO's Compute. These are initially set up when the UDOs **GetInputUDSParams** method is called and are retrieved in the UDO's Compute method.

There are 3 supported property types that could be used in the UDO script:

- INumberProperty to specify number properties (with unit support).
- IMenuProperty to allow the user to select from a list of options.
- ITextProperty to allow the user to enter text.

The IPropertyList type implements a collection for these properties.

IPropertyList Abstract class

IProperty Abstract class

INumberProperty Abstract class

ITextProperty Abstract class

IMenuProperty Abstract class

Related Topics

User Defined Outputs: Python Script API

IPropertyList Abstract class

Attributes:

- AllProperties (IEnumerable<IProperty> - see *IProperty*)
- NumProperties (int)

Functions:

- GetProperty(string propName): Returns a named property as an IProperty.
- GetMenuProperty (string propName): Returns the named property as an IMenuProperty.
- GetTextProperty (string propName): Returns the named property as an ITextProperty
- GetNumberProperty (string propName): Returns the named property as an INumberProperty
- DeleteProperty (string propName): Deletes an already added named property
- AddNumberProperty(string name, string numberWithUnits): Adds a new number property. If a property with the same name already exists, it is overwritten.
- AddTextProperty(string name, string textValue): Adds a new named text property with the supplied value. Any existing property with the same name is overwritten.
- AddMenuProperty(string name, IList<string> menuChoices): Creates a new named menu property with the supplied list of choices. The default selection is set to item 0 (the first item). Any property with the same name is overwritten.

IProperty Abstract class

Attributes:

- Name (string)
- Description (string)
- PropType (read-only EPropType - see Constants)

Constructor:

- IProperty(string name, EPropType type)

The class is used as base class for INumberProperty, IMenuProperty, and ITextProperty.

INumberProperty Abstract class

Base class:

- abstract class IProperty

Attributes:

- ValueSI (read-only double)
- ValueInUnits (read-only double)
- Units (read-only string)
- HasUnits (read-only bool)

Constructor:

- INumberProperty(string name)

Functions:

- Set(string numberWithUnits)
- SetDouble(double number, string unitString)

ITextProperty Abstract class

Base class:

- abstract class IProperty

Attributes:

- Text (string)

Constructor:

- ITextProperty(string name)

IMenuProperty Abstract class

Base class:

- abstract class IProperty

Attributes:

- MenuSelection (int): *This represents the index into the MenuChoices list.*
- SelectedMenuChoice (string): *This is the item in the MenuChoices list corresponding to the MenuSelection index*
- MenuChoices (IList<string>)

Constructor:

- IMenuProperty (string name)

Example:

```
# adding data to IPropertyList propList; used in Compute function
prop = propList.AddNumberProperty('Offset 1', '0')
prop.Description = 'Trace 1 Offset'
prop = propList.AddNumberProperty("TRATE", "800 MHz")
prop.Description = "Frequency"
prop = propList.AddTextProperty("Text", "The Text")
prop.Description = "Text Property"
prop = propList.AddMenuProperty('Operation', ['Add', 'Subtract', 'Max' ,'Min','Mean'])
prop.Description = 'Operation menu'

# reading data from IPropertyList propList; used in Validate function
numOfNumberProperties = 0
if propList != None and propList.AllProperties != None:
```

```
    for prop in propList.AllProperties:
if prop.PropType == Constants.EPropType.PT_NUMBER:
numOfNumberProperties ++
```

Other Application Specific Classes Used in Python Scripts

This section describes other classes used in Python scripts:

Constants Class

UDSProbeParams Class

UDSDynamicProbes Class

QuantityInfo Class

IProgressMonitor Abstract Class

Related Topics

User Defined Outputs: Python Script API

Constants Class

The constants used in python script are defined in the Constants class.

Attributes:

- kDoubleParamStr : string constant used to specify *double* as the type of a quantity
- kComplexParamStr: string constant used to specify *complex* as the type of a quantity

Enum EPropType: (used to set property type)

```
EPropType.PT_NUMBER
 EPropType.PT_TEXT
 EPropType.PT_MENU
```

Example:

```
paramType = Constants.kDoubleParamStr
propType = Constants.EPropType.PT_NUMBER
```

Related Topics

Other Application Specific Classes Used in Python Scripts

UDSProbeParams Class

The objects of this class must be created in python script in **GetInputUDSParams** function**.** They are supplied to the Validate function if implemented.

Attributes:

- ProbeName (read-only string)
- ProbeDescription (read-only string)
- ParamType (read-only string)
- ReportTypeName (read-only string)
- ComponentExpression (read-only string)

Constructor: UDSProbeParams(string probeName, string probeDescription, string paramType, string reportTypeName, string componentExpression);

- probeName - required.
- probeDescription - optional (can be empty string).
- paramType - required; can be one of the Constants
  - kDoubleParamStr
  - kComplexParamStr
- reportTypeName - optional (can be empty string)
- ComponentExpression - optional (can be empty string)

Example:

```
udsProbParam = UDSProbeParams("probe1","", Constants.kDoubleParamStr, "", "",)
```

Related Topics

Other Application Specific Classes Used in Python Scripts

UDSDynamicProbes Class

Attributes:

- UDSParam (read-only UDSProbeParams)
- UserSelectedProbeName (read-only string)

Constructor: UDSDynamicProbes (UDSProbeParams udsParam, string userSelectedProbeName.

- udsParam - required
- userSelectedProbeName - required

Example:

```
udsProbParam = UDSProbeParams("probe1","", Constants.kDoubleParamStr, "", "",)
selectedName = "probe1"
udsDynamicProbParam = UDSDynamicProbes(udsProbParam , selectedName )
```

Related Topics

Other Application Specific Classes Used in Python Scripts

QuantityInfo Class

Attributes:

- ParamType (read-only string)
- FullUnitType (read-only string)

Constructors:

- QuantityInfo(string paramType)
- QuantityInfo(string paramType, string fullUnitType)
- **Parameters**:
  - paramType can be one of the Constants

    kDoubleParamStr

    kComplexParamStr

- fullUnitType is a case insensitive string representing full unit type. It is not defined in Constants. Instead you can use any of the units in string representation - for example, "mm" or"ghz".

Example:

```
quantityInfo1 = QuantityInfo(Constants.kDoubleParamStr)
quantityInfo2 = QuantityInfo(Constants.kDoubleParamStr,"ghz")
```

Related Topics

Other Application Specific Classes Used in Python Scripts

IProgressMonitor Abstract Class

The object of this class is a progress monitor. It is used to display calculations progress in UI and check is the user has requested an abort of the computation.

When displayed in the application, each progress message has four items:

- A task name
- A sub-task name
- The progress amount
- A button to abort the task in progress.

All of this functionality and abort interaction is achieved using the following functions.

- SetTaskName (string taskName):
- SetSubTaskName (string subTaskName)
- BeginTask (string name)
- SetTaskProgressPercentage(int progressPercent)
- CheckForAbort(): If the quantities being generated are computationally expensive, the UDO author can periodically call this method and then call EndTask with Fail and return False.
- EndTask (bool passFail)

Example:

```
progMon.BeginTask("Process DQS")
progMon.SetSubTaskName("Compute UI segments")
progMon.SetTaskProgressPercentage(33)
progMon.SetSubTaskName("Compute the rest")
progMon.SetTaskProgressPercentage(100)
progMon.EndTask(True)
```

Other Application Specific Classes Used in Python Scripts

Using .NET Collection Classes and Interfaces in Python Scripts

Some of the API functions specified above use .Net collection classes and interfaces, that is, Array class, IList interface, IEnumerable interface, and IDictionary interface. The following section describes how to work with the .Net collection objects in Python scripts.

.NET Array, IEnumerable, and IList objects can be indexed and iterated over as if they were Python lists. You can also check for membership using 'in'. To get .Net Array and IList sizes you can use python's 'len' or .Net 'Count'.

Example:

Getting size:

```
arraySize = doubleDataArray.Count
arraySize = len(doubleDataArray)

listSize = sweepsNamesList.Count
listSize = len(sweepsNamesList)
```

Iterating:

```
for sweep in sweepsNamesList:
    print sweep

for in in xrange(listSize)
    print sweepsNamesList[i]
```

Checking for membership:

```
if 'Time' in sweepsNamesList:
    doThis()
```

```
else:
    doThat()
```

For .NET IDictionary, the same as for Array and IList, you can get size with 'len' or 'Count' and check for membership of the keys using 'in'. Getting values for the keys also works the same way as in python 'dict'.

Example

Getting size:

```
varValuesSize = varValues.Count
varValuesSize = len(varValues)
```

Checking for membership:

```
if 'offset' in varValues:
    print varValues['offset']
```

Getting value:

```
if 'offset' in varValues:
    offsetValue = varValues['offset']
```

As for iteration .NET Dictionary is different from python dict. While iterating, python dict will return keys, .Net Dictionary will return .Net KeyValuePair.

Example:

Iterating:

for .Net IDictionary:

```
for varPair in varValues: #varPair is of .Net KeyValuePair type
    varName = varPair.Key
    varValue = varPair.Value
```

for python dict:

```
for varName in varValues:
    varValue = varValues[varName]
```

You can use python types instead of .Net types if you prefer. For this you need to cast .Net Array and .Net iList to python list type and .Net Dictionary to python dict type.

Casting should not be used for data arrays - it can be extremely costly for the memory usage as well as time consuming.

Example:

```
aPythonList = list(dotNetArray)
```

```
    aPythonList = list(dotNetList)
    aPythonDict = dict(dotNetDictionary)
```

User Defined Outputs: Python Script API

User Defined Outputs: Messaging Methods

Messaging methods are provided to convey additional information to the user from any of the UDOs methods. The Compute function is the one typically location where such use is anticipated. Any message sent via these functions are displayed in the application's message window using the appropriate icon.

These functions can also be used for debugging purposes.

- **AddErrorMessage(string)**: Call this method to convey an error condition to the user.
- **AddWarningMessage(string)**: Call this method to convey a warning message: typically used for conditions that are not ideal but can be tolerated by the script.
- **AddInfoMessage(string)**: Call this method to convey an informational message to the user. This is the call to use when outputting messages for debugging purposes.

User Defined Outputs: An Introduction

User Defined Outputs: Python Script API

Using Script Libraries

If you decide that you need base classes, additional data files, and etc., to organize your UDOs better, you can do so. This type of library organization allows code reuse between similar UDOs and can be very helpful. There is special support provided for this type of script-library organization:

- **All script-library and other support files need to be in a *Lib* sub-directory under the UserDefinedOutputs directory**. Any *.py* files found in such **Lib** directories are ignored and not displayed in the GUI as a valid UDO choice.
- For a UDO script at any given directory depth, all Lib directories in its parent directories will be automatically added to the system include path (and so, any support script files from any Lib directory till the top level UserDefinedOutputs directory can be imported)

Related Topics

User Defined Outputs: Script Organization

Additional .NET Assemblies

Using additional .NET assemblies

Because the UDO functionality uses IronPython, we have access to the full .NET eco system. If needed, any subset of the UDO functionality can be implemented in any .NET language and used by the UDO script. There are simple rules to follow to achieve this.

1. Build your .NET assembly for .NET 2.0 runtime.
2. Drop the built assembly in any **Lib** directory upstream of the UDO script location: that is, if you have your UDO script in *C:\Users\x\PersonalLib\UserDefinedOutputs\a\b\c\myudo.py* and have a .NET assembly called *com.Acme.UDOLib* You can keep the .NET assembly under
   - UserDefinedOutputs\Lib,
   - UserDefinedOutputs \a\Lib,
   - UserDefinedOutputs \a\b\Lib
   - UserDefinedOutputs\a\b\c\Lib
3. Add the following line to your python script
   - Import clr
   - clr.AddReference("com.Acme.UDOLib")
   - import com.Acme.UDOLib -or-- from com.Acme.UDOLib import * *etc*

If for some reason you cannot place the .NET assemblies into a Lib directory under UserDefinedOutputs, you need to do a couple more steps before step 3 listed above.

```
Import sys
sys.path.append("full path to your .NET assembly
location")
```

Using Script Libraries

Toolkit

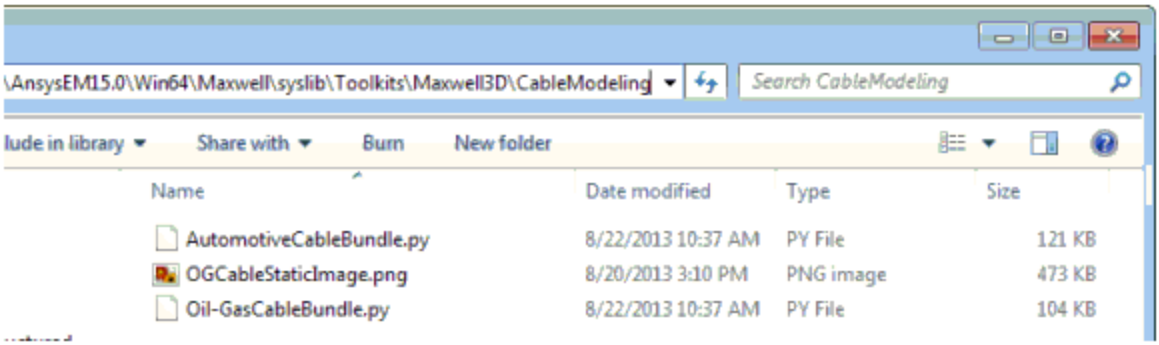
The Toolkit command in the Maxwell menu provides access to a design type-specific IronPython script or a module-specific task. The python script provides a default but customizable UI and canned automations. The UDD format can be adjusted/extended as needed. The default UI is a modal dialog.

This allows Maxwell the flexibility to support changing standards or multiple standards. Similarly, you can create new UDDs to customize the test report.

UDDs are saved in the project result directory. This type of report can be created prior to simulation, but will only be populated when there is a solution.

Undo/Redo/Scripting is supported. If a script includes multiple commands, it takes multiple undo (s) to revert all the changes made by the python script. Also, note that the script playback might not work if the baseline of the design has changed.

A directory called "Toolkits" appears in the syslib, userlib, and personallib of the Maxwell installation. You can add product specific-directories (Maxwell2D, Maxwell3D, RMxprt) in Toolkits, and each directory contains toolkits (scripts) that are specific for that product.



Use the **Maxwell>Toolkit>Update Menu** command to add newly added toolkit scripts to the Toolkit menu. Menu items for files found in <installation>/syslib will be inserted at the first level of the menu.

Related Topics

Toolkit Examples

Toolkit Examples

Maxwell includes the following toolkits for generating 2D and 3D cable bundle models:

- AutomotiveCableBundle
- Oil-GasCableBundle

Automotive Cable Bundle Toolkit

To work with the Automotive Cable Bundle toolkit:

1. Click **Maxwell 2D** (or **Maxwell 3D**)**>Toolkit>CableModeling>AutomotiveCableBundle**.

The **Cable Modeling - Automotive** dialog box appears with a default set of **Cable Parameters** listed.

2. Type the **Name** of the toolkit, and select the **Units** to be used for displayed values.
3. Modify the **Cable Parameters**:
   a. Select the wire **Standard**. You can choose to use either **ISO** or **AWG** standard. The **Wire Type** and **Insulation Type** fields are updated with menus of values corresponding to the chosen standard.
   b. Select the **Wire Type**. The **Conductor Diameter** parameter updates with the corresponding standard value.
   c. Optionally, modify the number of wires (**#Wires**) in the bundle that have this row's set of parameters
   d. Optionally, modify the **Conductor Diameter**.
   e. Select the **Conductor Material**.
   f. Select the **Insulation Type**.
   g. Optionally, modify the **Insulation Thickness**.
   h. Optionally, modify the **Insulation Material**.
4. To add additional cable types, click the **+** button. A row is added in which you can define a new set of cable parameters. Add as many rows as needed to create a bundle consisting of several different types of cable.
5. If you have previously imported a customized set of parameters, you can click **Use Defaults** to use the default values.
6. To export the cross-section parameters into a .csv or .tab file, click **Export**. The **Export Cable Parameters** dialog box appears. Specify the **File name** and **type** (either comma delimited **.csv** or tab delimited **.tab**), and click **Save**.
7. To read in either a comma delimited **.csv** or tab delimited **.tab** file and populate parameters in the toolkit panel, click **Import**. The **Import Cable Parameters** dialog box appears.

Specify the **File name** and **type**, then click **Open**.

8. Specify the **Outer Jacket Parameters**: for the jacket that will encase the cable bundle.
   a. Specify the **Thickness** value for the outer jacket.
   b. Specify the **Material** to be used for the outer jacket.
   c. Specify the **Seeding for wire arrangement** value. The value entered here is the seed value for the pseudo-random number generator used in the conductor packing compute process. Changing this value results in different arrangements of the conductors. This can be useful for performing statistical analysis of the cables.
   d. When finished specifying all of the cable and outer jacket parameters for the bundle, click **Compute** to calculate the minimal bundle diameter of the cable bundle.

Note	The wire radii are adjusted downward very slightly (on the order of 0.1%) at the end of the packing process to eliminate any residual overlaps between the wires and to make the model easier to mesh.

Note	The Circle Packing algorithm is used to compute the values. It tries to automatically pack the conductors in the bundle tightly with a minimum of empty space between them. It generates and tests a large number of random variations in the conductor positions and attempts to minimize the overall diameter of the bundle.

1. To add new variables, click **Variables**. This opens the **Edit Variables** dialog box. All variables that are already present in the project and design levels are listed. Click **Add** to add a new row to create new variables.
2. Optionally, for 3D designs only, click **Extrude**. (The **Extrude** button is not present for 2D designs.) The **Extrude to 3D** dialog box appears.
   - Click **Sweep Along Vector** to extrude along the z axis. Z length is the input parameter.
   - Click **Sweep Along Path** to extrude along a selected path.

Note	3D models of cables are hard to solve if the ratio of extruded length to cross-section diameter is high.

3. Click **Draw** to draw the 2D or 3D cross-section geometry. A validation check is run. This catches errors like any variable missing a value, or any parameter missing a value. For 3D designs, if you chose to **Extrude**, the 3D geometry is drawn.

Oil-Gas Cable Bundle Toolkit

To work with toolkits in the oil and gas industries:

1. Click **Maxwell 2D** (or **Maxwell 3D**)**>Toolkit>CableModeling>Oil-GasCableBundle**.

The **Cable Modeling - Oil & Gas** dialog box appears.

2. Type the **Name** of the toolkit, and select the **Units** to be used for displayed values.
3. Modify the various **Cable Parameters** as needed.
4. If you have previously imported a customized set of parameters, you can click **Use Defaults** to use the default values.

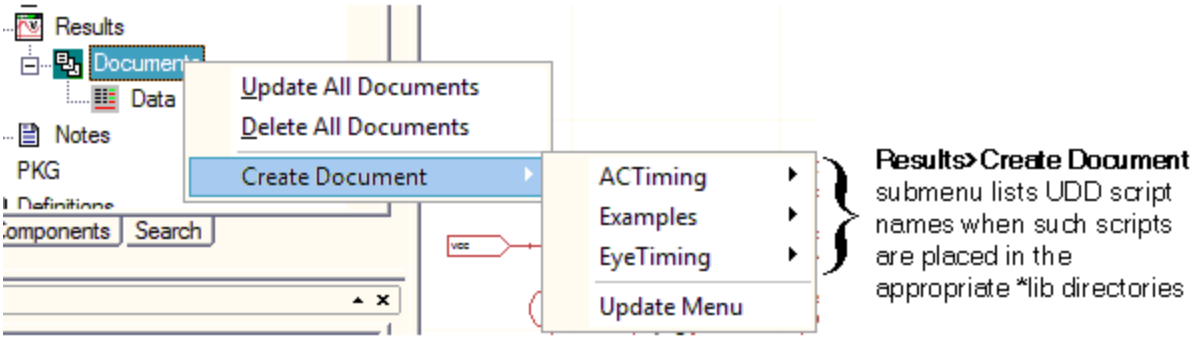
5. To export the cross-section parameters into a .csv or .tab file, click **Export**. The **Export Cable Parameters** dialog box appears. Specify the **File name** and **type** (either comma delimited **.csv** or tab delimited **.tab**), and click **Save**.
6. To read in either a comma delimited **.csv** or tab delimited **.tab** file and populate parameters in the toolkit panel, click **Import**. The **Import Cable Parameters** dialog box appears. Specify the **File name** and **type**, then click **Open**.
7. To add new variables, click **Variables**. This opens the **Edit Variables** dialog box. All variables that are already present in the project and design levels are listed. Click **Add** to add a new row to create new variables.
8. Optionally, for 3D designs only, click **Extrude**. (The **Extrude** button is not present for 2D designs.) The **Extrude to 3D** dialog box appears.
   - Click **Sweep Along Vector** to extrude along the z axis. Z length is the input parameter.
   - Click **Sweep Along Path** to extrude along a selected path.

Note	3D models of cables are hard to solve if the ratio of extruded length to cross-section diameter is high.

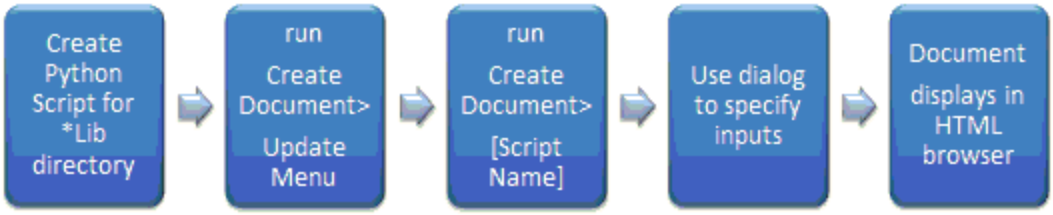
9. Click **Draw** to draw the 2D or 3D cross-section geometry. A validation check is run. This catches errors like any variable missing a value, or any parameter missing a value. For 3D designs, if you chose to **Extrude**, the 3D geometry is drawn.

User Defined Documents (UDDs)

User defined documents (UDDs) are custom reports that you define through IronPython scripts. Once placed in a Lib directory, you can access the scripts via the **Create Document** command. The scripts describe a **Create User Defined Document** dialog that lets you specify trace and solution inputs. After you confirm your input selections, an xml, html and pdf document is generated. A web browser window opens to display the generated html file. The created document appears in the Project tree, under Results in the Documents folder.



The general UDD process flow is as follows.



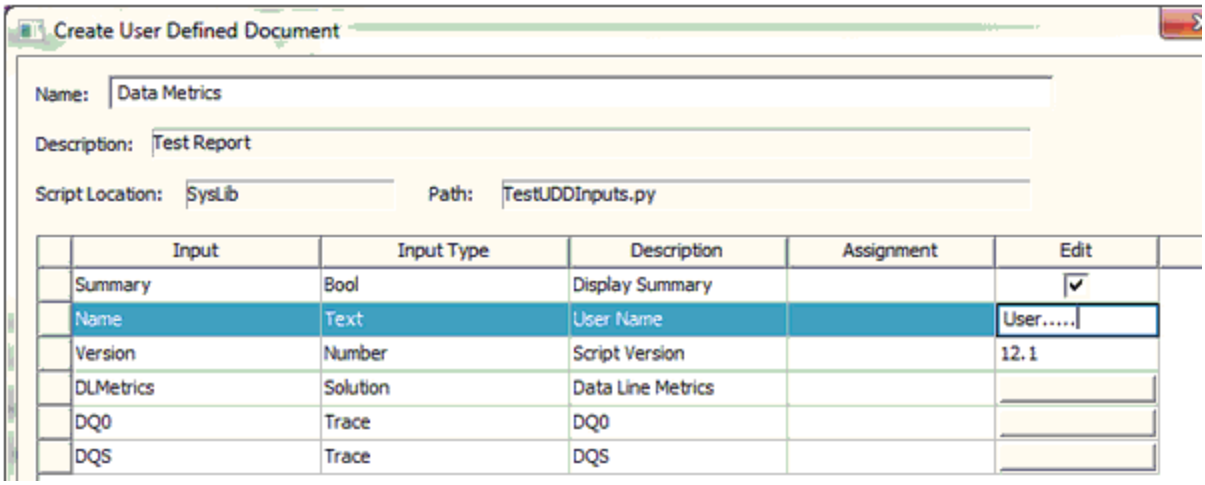
The UDD python scripts must be placed in the **UserDefinedDocuments** directory under either of **syslib**, **userlib** or **Personallib** with any subdirectory structure needed. The Lib directory can contain python scripts that have common code that other scripts can use.

Use **Results>Create Document>Update Menu** to refresh the menu to include the new UDD scripts that have been copied to syslib, userlib or Personallib, or to exclude them if they have been deleted, after the launch of desktop.

The UDD scripts that are in syslib/UserDefinedDocuments, userlib/UserDefinedDocuments or Personallib/UserDefinedDocuments become available through the **Results >Create Document** menu.

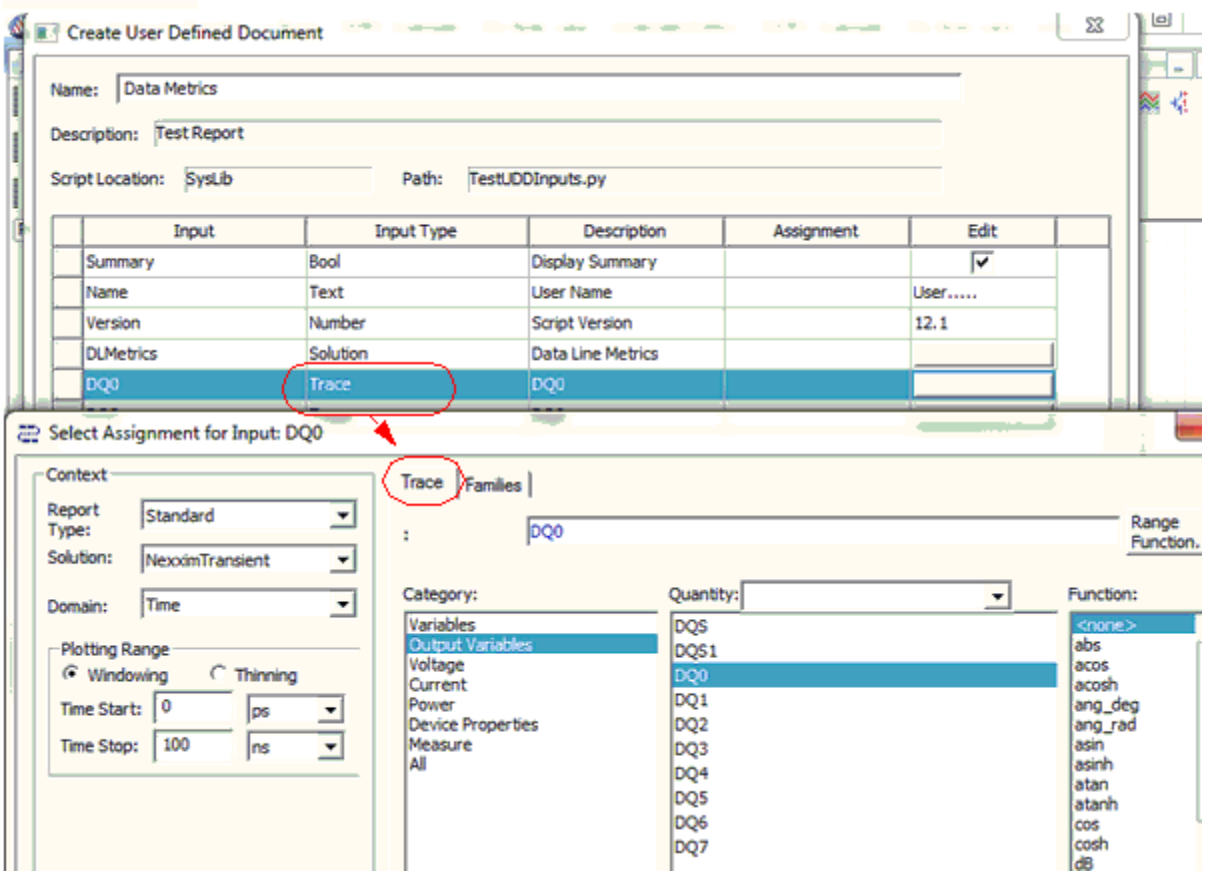
Create User Defined Document Dialog Inputs

User defined documents allow data from traces, solutions and report types as inputs. A UDD can specify the named inputs for which you select or enter the values in the **Create User Defined Document** dialog that displays when you run **Results>Create Document>**<*scriptName*>.



Input Types can be of Boolean, number, text, trace or solution type. The boolean, number and text type can be given a default value that you can interactively override when the document is created or modified. For example, you can select a trace when you create or modify a UDD document. The trace data is available to the user and can be accessed from the python script.

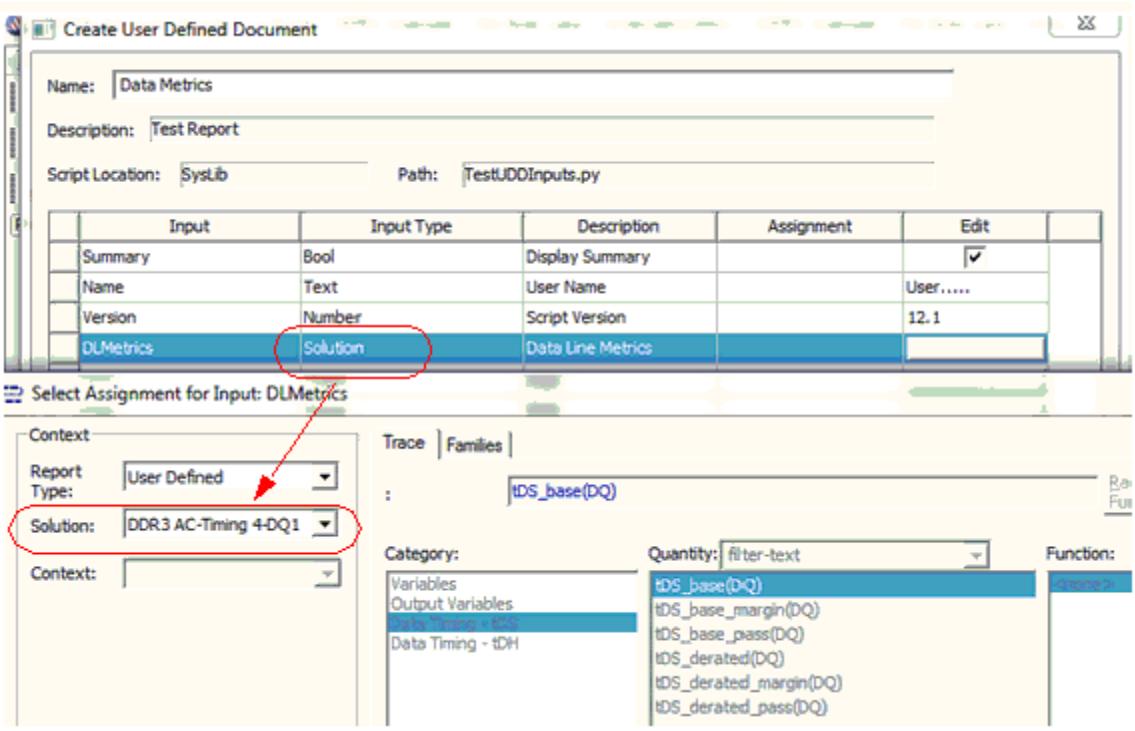
At the time of selection you can choose from the **Reporter** dialog box, the report type (Standard, Eye Diagram, User Defined), solution name, context and the quantity for which you want the trace data.



Input Type can also be Solution. You can select an entire solution when the document is created or modified. The solution data in its entirety, is now available to the user and can be accessed from the python script.

At the time of selection you can choose from the reporter dialog box, the report type (Standard, Eye Diagram, User Defined), solution name and context. A specific quantity cannot be selected since data for all quantities in the solution are available.

(Note: The category/Quantity/Function portion of the dialog is disabled for user input)



UDD Document Creation and Display

After all the input selections for a UDD are confirmed, based on the script, an xml, html and pdf document is generated based on the inputs provided by the user. (The xml, html and pdf generation is based on specific calls in the python script, which are explain in a following section). A web browser window also opens to display the generated html file.

The created document will be placed under a new folder named "Documents" under the "Results" folder. All documents that are created by the user for the design will be placed under this folder.

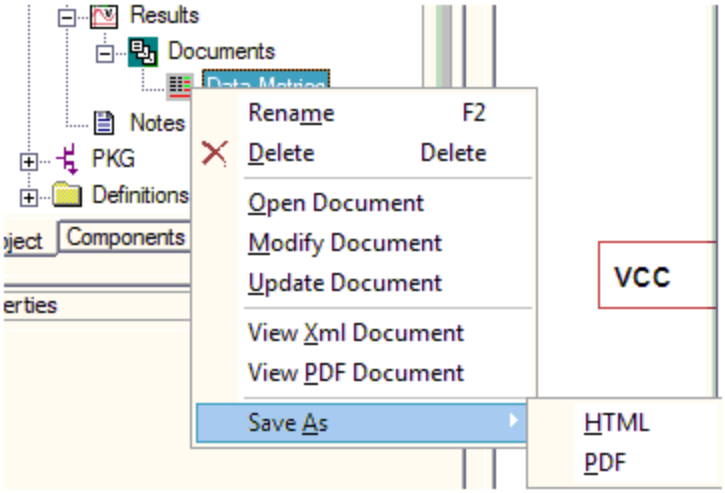
UDD Script Libraries

User Defined Documents: Python Script API

Managing Documents Listed in the Project Window Under Results

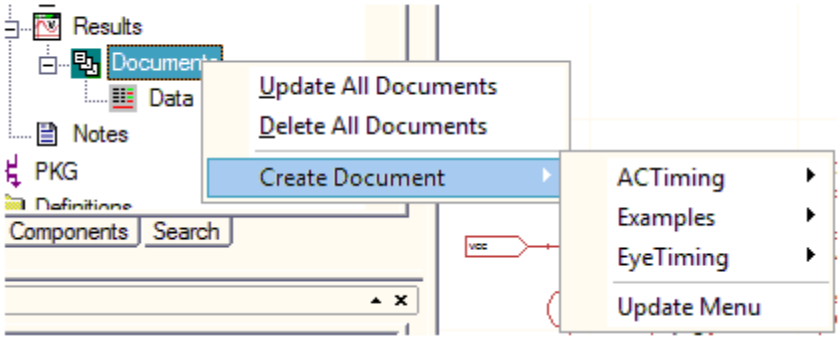
Right click on a user defined document displayed in the Project Manager tree to bring up a menu where you can rename, delete the document. **Open document** opens the web browser with the html document. **Modify document** opens the setup dialog where you can change the selections

for the input. To view the xml and the pdf document simply choose the appropriate menu items. There is also a menu item to save the document in a different location.



Documents folder right click menu

Right click on the documents folder has the menu options to Update All Documents or Delete All Documents. It also provides the option of creating a document from here.

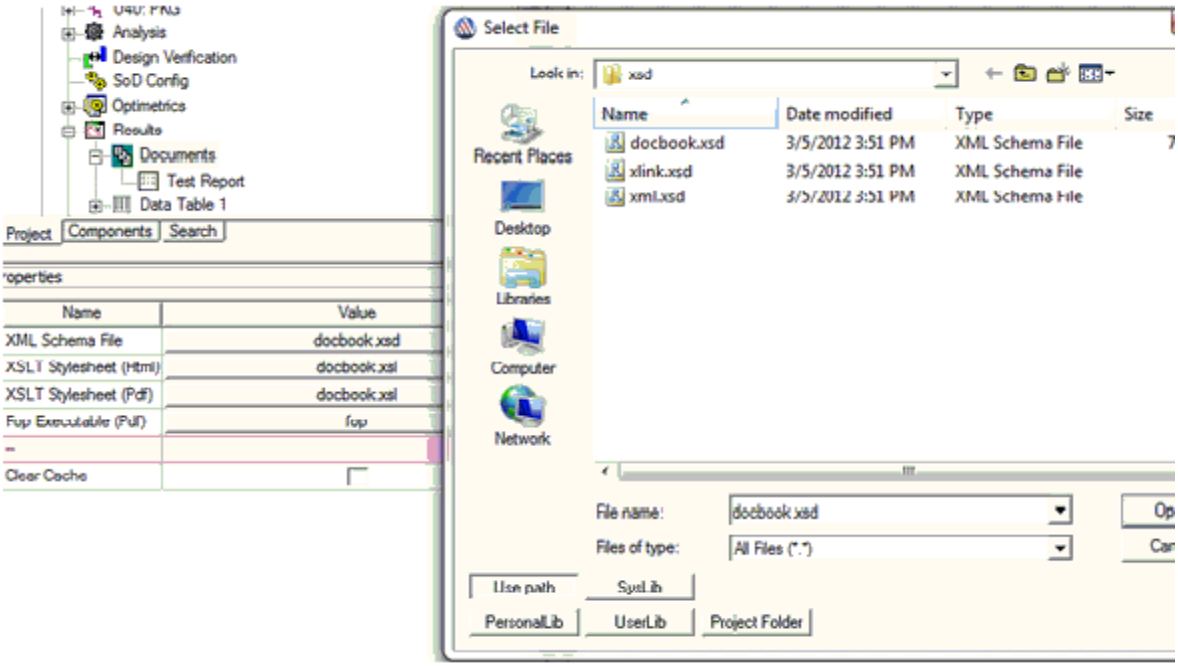


Document folder Property window

When the documents folder is selected, the Property window shows the following properties

- XML Schema File - File path to the XML schema file.
- XSLT StyleSheet (Html) - File path to the XSLT stylesheet file used for Html generation.
- XSLT StyleSheet (Fo) - File path to the XSLT stylesheet file used for Pdf generation.
- Fop Executable (Pdf) - File path the Fop executable used for Pdf generation.
- Clear Cache - Clears the cached XSL transform object and forces creation of a new one. (The caching is done to save time during document generation, so subsequent generation

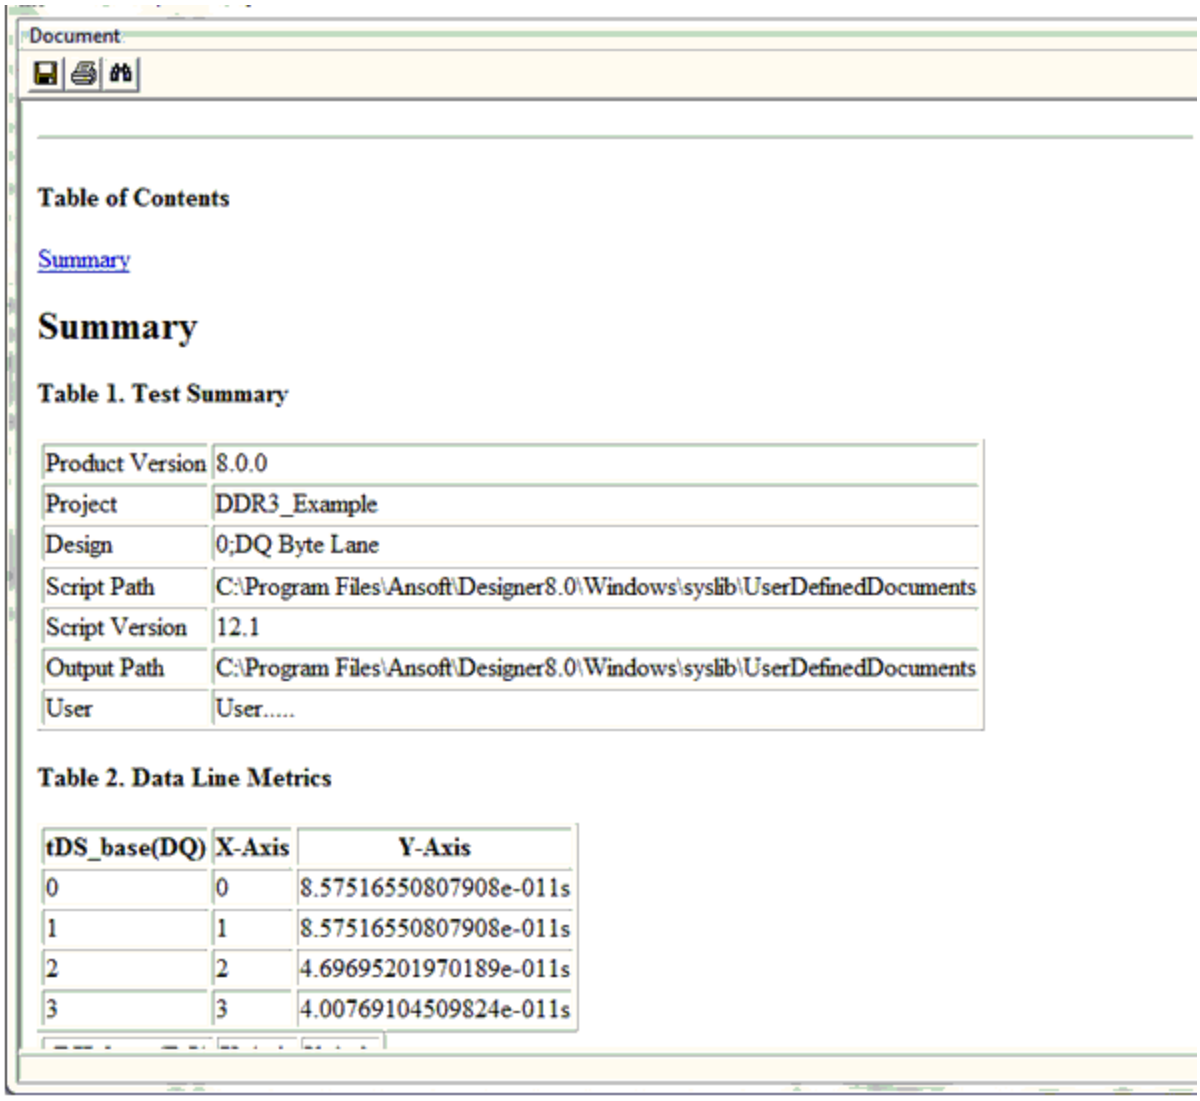
or update of the document can use the cached transform object. But sometimes you may want to force a recompile of the document if you change the stylesheet).



The XML, HTML and PDF generation require the XML schema file and XSLT stylesheets to generate proper output. In addition, the PDF generation requires a FOP executable. You can use the defaults provided in the installation or provide the file paths of your own preferred stylesheets and fop executable installed in his machine.

Viewing UDDs with an Html Web Browser

The XML and HTML documents can be viewed in a web browser with some basic functionality like printing the document, searching the document for a phrase or sentence and saving the document.



Document

Table of Contents

Summary

Summary

Table 1. Test Summary

Product Version	8.0.0
Project	DDR3_Example
Design	0;DQ Byte Lane
Script Path	C:\Program Files\Ansoft\Designer8.0\Windows\syslib\UserDefinedDocuments
Script Version	12.1
Output Path	C:\Program Files\Ansoft\Designer8.0\Windows\syslib\UserDefinedDocuments
User	User.....

Table 2. Data Line Metrics

tDS_base(DQ)	X-Axis	Y-Axis
0	0	8.57516550807908e-011s
1	1	8.57516550807908e-011s

UDD Script Libraries

Base classes and data files shared between similar UDDs can be organized to reuse the code in a better way. All script-library and other support files need to be in a Lib sub-directory under the UserDefinedDefinitions directory. Any .py files found in such Lib directories are ignored and not displayed in the GUI as a valid UDD choice. For a UDD script at any given directory depth, all Lib directories in its parent directories will be automatically added to the system include path (and so, any support script files from any Lib directory till the top level UserDefinedDefintions directory can be imported)

The UDD functionality uses IronPython so we have access to all the .NET assembles. If needed, any subset of the UDD functionality can be implemented in any .NET language and used by the UDD script. There are simple rules to follow to achieve this.

1. Build your .NET assembly for .NET 2.0 runtime.
2. Drop the built assembly in any Lib directory upstream of the UDD script location: that is, if you have your UDD script in C:\Users\x\PersonalLib\UserDefinedDefintions\a\b\c\myudd.py and have a .NET assembly called com.Acme.UDDLib You can keep the .NET assembly under
   - UserDefinedDefintions\Lib,
   - UserDefinedDefintions\a\Lib,
   - UserDefinedDefintions\a\b\Lib
   - UserDefinedDefintions\a\b\c\Lib
3. Add the following line to your python script
   - Import clr
   - clr.AddReference("com.Acme.UDDLib")
   - import com.Acme.UDDLib -or-- from com.Acme.UDDLib import * etc

   If for some reason you cannot place the .NET assemblies into a Lib directory under UserDefinedDefintions, you need to do a couple more steps before step 3 listed above.

```
Import sys
sys.path.append("full path to your .NET assembly location")
```

User Defined Documents: Python Script API

User Defined Documents: Python Script API

A User Defined Documents (UDD) extension is implemented as an IronPython script that defines a class with a specific name: **UDDExtension** which derives from a specific base class **IUDDPluginExtension** and implements its abstract methods.

Import Statements

The base class to be used and the types it uses in turn are contained in .NET assemblies. The use of these requires that the assemblies be imported into the UDD script: the following import statements should be added to the top of the python script:

```
from
Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Data
import *
from
Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Interfac
es import *
```

UDDExtension Class

The UDD itself should be implemented as an IronPython class called **UDDExtension** which must derive from the **IUDDPluginExtension** abstract base class (from the **Ansys.Ansoft.DocGeneratorPluginDotNet.DocGenerator.API.Interfaces** namespace).

Note that power users could derive a class hierarchy tuned toward a specific type of UDDs and that they can derive from their own base classes. The only requirement is that directly or indirectly, the UDD class must derive from **IUDDPluginExtension**.

Example:

```
def BaseClassUDD ((IUDDPluginExtension):
#base class implementation
…
def UDDExtension ((BaseClassUDD):
#UDD class implementation
…
```

Note	All of the above text has been copied from the help section for the UDOs and modified for the UDDs. Since the UDDs are modelled after the UDOs, the usage is also similar.

IUDDPluginExtension Abstract Class

Required functions:

The **IUDDPluginExtension** abstract class declares the following abstract methods that must be implemented in the UDDExtension class or one of its base classes. Not implementing any of these methods will result in a run-time error and a non functioning UDD.

GetUDDName() : Return a string that is used as a prefix for all solution instances created using this UDD.

Example:

```
def GetUDDName(self):
return "MinMaxAvg
```

GetUDDDescription() : Returns a description for the UDD, its purpose etc.

Example:

```
def GetUDDDescription(self):
return "Sample UDD"
```

ShowDefaultSetupDialog() : Returns True if the default dialog is to be shown. Return False if the user does not want the default dialog box. In this case the user might want to implement/show a customized setup dialog.

Example:

```
def ShowDefaultSetupDialog(self):
return True
```

GetUDDInputParams(List<UDDInputParams> uddInputs) : Returns the list of inputs parameters for the User Defined Document. Returns boolean: True on success, False on failure.

The supplied input parameters are used to populate details of the parameters to which the UDD user will specify value, specify the input names and their types.

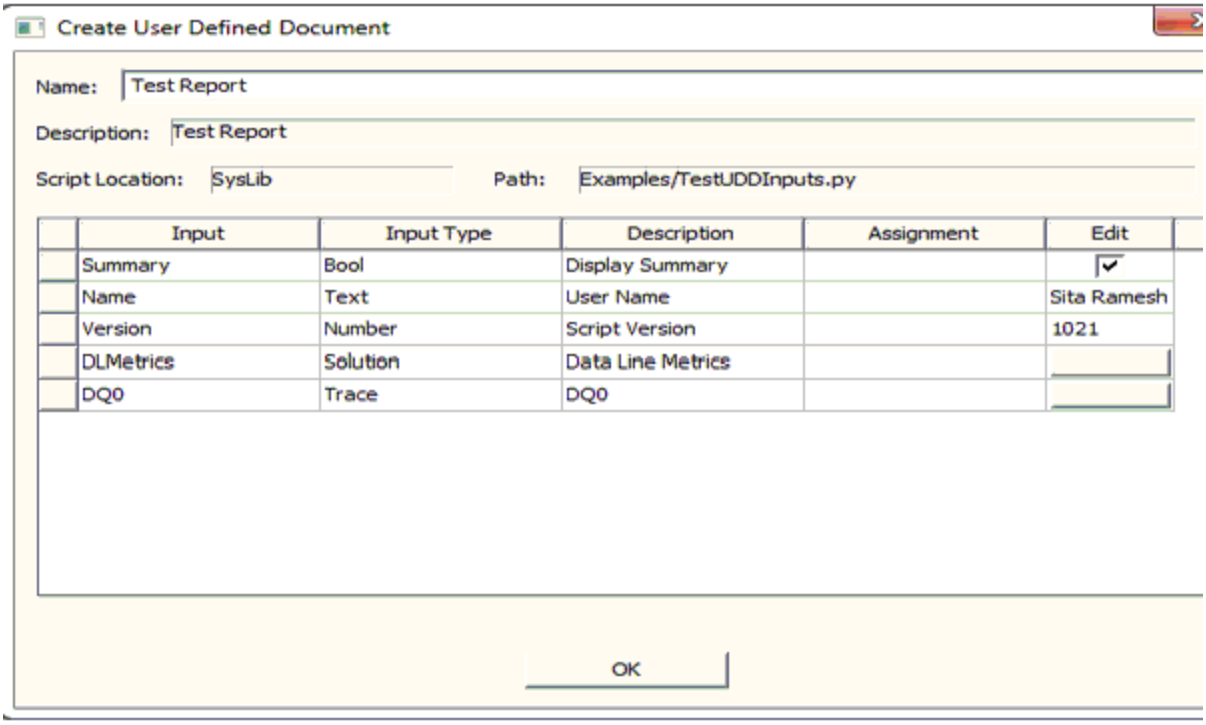
uddInputs: .NET list of UDDInputParams objects. The UDD script is expected to add one instance of UDDInputParams for each input definition it wants displayed. The UDD user will, when creating the UDD, assign a matching value to each such input.

Example:

```
def GetUDDInputParams(self, uddInputs)
# Boolean input
param1 = UDDInputParams("Summary","Display Summary",
Constants.kBoolTypeStr, True)
uddInputs.Add(param1)
# Text input
param2 = UDDInputParams("Name","User Name",
Constants.kTextTypeStr , "Sita Ramesh")
uddInputs.Add(param2)
# Number input
param3 = UDDInputParams("Version","Script Version",
Constants.kNumberTypeStr, 1021)
uddInputs.Add(param3)
# Solution input
param5 = UDDInputParams("DLMetrics","Data Line
Metrics",Constants.kSolutionTypeStr)
uddInputs.Add(param4)
# Trace input
param5 = UDDInputParams("DQ0","DQ0",Constants.kTraceTypeStr)
uddInputs.Add(param5)

return True
```

Based on the input params the following dialog is displayed when you click **Reports>Create Document**. The name and description of the UDD are also displayed in this dialog.



Generate(List<UDDInputData> uddInputs, IUDDGenerator generator, IProgressMonitor progressMonitor) : This is the main method which accesses the data from the uddInputs and generates the document.

uddInputs: The list of inputs that the user setup in the dialog box. They are now available to query for data.

generator: This is the document generator object which we use to create different elements of the document like titles, sections, tables, images and write the data too. This interface is explained in the Document Generator Interface document.

progressMonitor : IProgressMonitor object. This can be used to set progress for long running calculations, check for user initiated abort etc.

Example:

```
def Generate(self, input, docgen, progMon):

# Gather data from inputs
boolinput = input[0].Data()
textinput = input[1].Data()
dblinput = input[2].Data()

# Get document root
```

```
docroot = docgen.GetDocumentRoot()

# Add Section
section1 = docroot.AddSection("Summary", "Overall Results ")

# Add a table
table1 = section1.AddTable("Test Summary")

#Add a table group with 2 columns
tgroup1 = table1.AddTableGroup(2)

# get desktop application
oApp = self.GetUDDAppContext()
if oApp != None:
oDesktop = oApp.GetAppDesktop()
if oDesktop != None:
# version number
version = oDesktop.GetVersion()
text1 = tgroup1.AddContent()
text1 .Add(0, "Product Version")
text1 .Add(1, version)

oProject = oDesktop.GetActiveProject()
if oProject != None:
projectname= oProject.GetName()
text1 = tgroup1.AddContent()
text1 .Add(0, "Project")
text1 1.Add(1, projectname)

oDesign = self.GetUDDDesignContext()
if oDesign != None:
designname = oDesign.GetName()
text1 = tgroup1.AddContent()
text1 .Add(0, "Design")
text1 .Add(1, designname)

# Provides a script path
```

```
scriptpath = docgen.GetScriptPath()
text1 = tgroup1.AddContent()
text1 .Add(0, "Script Path")
text1 .Add(1, scriptpath )

#Provides the script version
text1 = tgroup1.AddContent()
text1 .Add(0, "Script Version")
text1 .Add(1, str(dblinput ))

#Provides the output xml path
outputpath = docgen.GetOutputFilePath()
text1 = tgroup1.AddContent()
text1 .Add(0, "Output Path")
text1 .Add(1, outputpath )

#Provides the user information
text1 = tgroup1.AddContent()
text1 .Add(0, "User")
text1 .Add(1, textinput)

# Generate Xml output
docgen.Write(False)

# Generate Html output
docgen.WriteHTML()

# Generate PDF output
docgen.WritePDF()

return True
```

Optional functions:

SetupUDDInputParams(List<UDDInputParams> uddInputs) : Displays a customized dialog and returns the user choices for the input params.

uddInputs- .NET list of UDDInputParams objects with values for each of them. These can be the user choice for each input obtained through a custom dialog or some other non graphical assignment.

We cannot process trace and solution types of input with a custom dialog because there is no way of assigning solution data to the input without the invocation of the reporter dialog.

Example:

```
    def SetupUDDInputParams(self, uddInputs)
    udddialog = BaseExampleUDDDialog()
    if udddialog.ShowDialog() == Forms.DialogResult.OK:
# Boolean input
param1 = udddialog.GetInput("Summary")
uddInputs.Add(param1)

# Text input
param2 = udddialog.GetInput("Name")
uddInputs.Add(param2)

# Number input
param3 = udddialog.GetInput("Version")
uddInputs.Add(param3)
```

HandleUDDEvents(List<string> eventTags) : The tags associated with the event is received by plugin using this abstract class.

This method is the event handler for all link events set by the SetEventLink() method on a IUDDText. Refer to the definition of the IUDDText object in the Document Generator Interface document.

Example:

```
    def HandleUDDEvents(self, uddLinks):
    if uddLinks[0] == "Open" Report":
# Get Design Name
oDesign = self.GetUDDDesignContext()
if oDesign != None:
  oDesign.OpenReport(uddLinks[1])
    return True
```

GetUDDSchema() : Returns the file path of the schema to validate the xml. This will override the default schema used. Return string containing the full file path of the schema.

```
    def GetUDDSchema(self):
```

```
return "C:\\Program
Files\\Ansoft\\Designer8.0\\Windows\\common\\docbook\\schema\\x
sd\\docbook.xsd"
```

GetUDDStyleSheetForHtml() : Returns the file path of the style sheet used to generate the html document. This will override the default stylesheet for html. Returns string containing the full file path of the style sheet.

```
def GetUDDStyleSheetForHtml(self):
return "C:\\Program
Files\\Ansoft\\Designer8.0\\Windows\\common\\docbook\\"
```

GetUDDStyleSheetForPdf() : Returns the file path of the style sheet used to generate the pdf document. This will override the default stylesheet for pdf. Returns string containing the full file path of the style sheet.

Example:

```
def GetUDDStyleSheetForPdf(self):
return "C:\\Program
Files\\Ansoft\\Designer8.0\\Windows\\common\\docbook\\xsl\\fo\\
docbook.xsl"
```

GetFopExecutable() : Returns the file path of the fop executable used to generate the pdf document. This will override the default stylesheet for pdf.Returns string containing the full file path of the fop executable.

Example:

```
def GetFopExecutable(self):
return "C:\\Program
Files\\Ansoft\\Designer8.0\\Windows\\common\\ApacheFOP\\fop-
1.0\\fop"
```

GetUDDAppContext() : Returns the UDD Owner (if set). This is a Dispatch wrapper that is essentially a COM IDispatch implementation and corresponds to the IDispatch pointing to the desktop app.

GetUDDDesignContext() : Returns the UDD Owner (if set). This is a Dispatch wrapper that is essentially a COM IDispatch implementation and corresponds to the IDispatch pointing to the Design.

Data Types Used in Python Script

There are several types that you must use while authoring the python script. Some of them are used to pass data from UI to python script and to provide interface for working with this data. Some are used to pass data from python script to UI.

To pass data from python script to UI the objects of the C# class must be created in python script using their C# constructors. Then they can be set as functions return values or set to the output parameters using their API.

Constants class

kTraceTypeStr : string constant used to specify an input of trace type

kSolutionTypeStr : string constant used to specify an input of solution type

kNumberTypeStr : string constant used to specify an input of number type

kTextTypeStr : string constant used to specify an input of text type

kBoolTypeStr : string constant used to specify an input of boolean type

kStandardReportStr : string constant to specify a standard report

kEyeDiagramReportStr : string constant to specify an eye diagram report

kUserDefinedReportStr : string constant to specify a user defined report

kSweepDomainStr : string constant to specify the sweep domain

kTimeDomainStr : string constant to specify the time domain

UDDInputParams class

The objects of this class must be created in python script in the **GetUDDInputParams()** function and the **SetUDDInputParams()** function.

Attributes :

Input Name (string)

Input Description (string)

Input Type (Can be Boolean, Number, Text, Trace or Solution) (string)

BoolData (boolean)

DoubleData (double)

TextData (string)

ReportType (string)

SolutionName (string)

DomainName (string)

Constructors:

UDDInputParams(string name, string description, string type)

UDDInputParams(string name, string description, string type, bool data)

UDDInputParams(string name, string description, string type, double data)

UDDInputParams(string name, string description, string type, string data)

UDDInputParams(string name, string description, string type, string reportType, string solutionName, string domainName)

Property Accessors :

Name : Get/Set the name of an input

Description : Get/Set the desccription of an input

Type : Get/Set the type of an input

BoolData : Get/Set the data of a boolean input

DoubleData : Get/Set the data of a number input

TextData : Get/Set the data of a text input

ReportType : Get/Set the report type

SolutionName : Get/Set the name of the solution

DomainName : Get/Set the name of the domain

IProgressMonitor Abstract Class

The object of this class is a progress monitor. It is used to display calculations progress in UI and check is the user has requested an abort of the computation.

When displayed in the application, each progress message has four items:

A task name

A sub-task name

The progress amount

A button to abort the task in progress.

All of this functionality and abort interaction is achieved using the following functions.

SetTaskName (string taskName):

SetSubTaskName (string subTaskName)

BeginTask (string name)

SetTaskProgressPercentage(int progressPercent)

CheckForAbort(): If the quantities being generated are computationally expensive, the UDO author can periodically call this method and then call EndTask with Fail and return False.

EndTask (bool passFail)

Example:

```
progMon.BeginTask("Process DQS")
progMon.SetSubTaskName("Compute UI segments")
progMon.SetTaskProgressPercentage(33)
progMon.SetSubTaskName("Compute the rest")
progMon.SetTaskProgressPercentage(100)
progMon.EndTask(True)
```

UDD Input interfaces

The Generate function takes in a list of inputs. These input interfaces allow the user to access data from the design.

IUDDInputBool : This interface exposes 3 methods

Name() : Gets the inputs name.

Type() : Gets the input type.

Data() : Gets the boolean data, set by the user in the setup dialog.

IUDDInputDouble : This interface exposes 3 methods

Name() : Gets the inputs name.

Type() : Gets the input type.

Data() : Gets the double data, set by the user in the setup dialog.

IUDDInputText : This interface exposes 3 methods

Name() : Gets the inputs name.

Type() : Gets the input type.

Data() : Gets the text data, set by the user in the setup dialog.

IUDDInputTrace : This interface exposes 3 methods

Name() : Gets the inputs name.

Type() : Gets the input type.

DoubleData() : Method used to return x and y double data as a IDictionary<double, double>

DoubleData(IDictionary<string, string> variation) : Method used to return x and y double data as a IDictionary<double, double>, given a variation.

ComplexData() : Method used to return x data and y complex data as a IDictionary<double, double[]>

ComplexData(IDictionary<string, string> variation) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a variation.

TextData() : Method used to return x data and y data as a IDictionary<string, string>

TextData(IDictionary<string, string> variation) : Method used to return x data and y data as a IDictionary<string, string>, given a variation.

VariableValues() : Method used to get a list of variations as a IList<Dictionary<string, string>>

IUDDInputSolution : This interface exposes 3 methods

Name() : Gets the inputs name.

Type() : Gets the input type.

DoubleData(string name) : Method used to return x and y double data as a IDictionary<double, double>, given a quantity name.

DoubleData(string name, IDictionary<string, string> variation) : Method used to return x and y double data as a IDictionary<double, double>, given a quantity name and a variation.

ComplexData(string name) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a quantity name.

ComplexData(string name, IDictionary<string, string> variation) : Method used to return x data and y complex data as a IDictionary<double, double[]>, given a quantity name and a variation.

TextData(string name) : Method used to return x data and y data as a IDictionary<string, string> given a quantity name.

TextData(string name, IDictionary<string, string> variation) : Method used to return x data and y data as a IDictionary<string, string>, given a quantity name and a variation.

CategoryNames() : Method to return a list of category names in the solution as an IList<string>

QuantityNames(string category) : Method to return a list of quantity names in the solution as an IList<string>, given a category.

VariableValues() : Method used to get a list of variations as a IList<Dictionary<string, string>>

Examples:

```
def Generate(self, input, docgen, progMon):
# Getting the boolean data set by the user
boolinput = input[0].Data()
# Getting the double data set by the user
dblinput = input[1].Data()
# Getting the text data set by the user
textinput = input[2].Data()
# Getting the category names in a solution
categories = input[3].CategoryNames()
# Getting the quantity names based on a category
```

```
quantities = input[3].QuantityNames(categories[0])
# Getting the XY data from the trace
xydata = input[4].DoubleData()
```

User Defined Document Scripting Interface

To access the UserDefineddocuments scripting object, use:

```
Set oModule = oDesign.GetModule("UserDefinedDocuments")
```

Once you have the scripting object, you can use the following methods:-

1. `AddDocument([in] VARIANT data, [in] VARIANT traces, [out, retval] BSTR* uniqueName)`
   a. Takes a VARIANT data which defines the document.
   b. Takes a VARIANT trace data for the inputs in the document.
   c. Returns a unique name
2. `EditDocument( [in] BSTR originalName, [in] VARIANT modifiedData, [in] VARIANT modifiedTraces, [out, retval] BSTR* uniqueName)`
   a. Takes the name of the original document.
   b. Takes a VARIANT data which defines the edited document.
   c. Takes a VARIANT trace data for the inputs in the document.
   d. Returns a unique name
3. `RenameDocument( [in] BSTR oldName, [in] BSTR newName)`
   a. Takes the name of the original document.
   b. Takes the new name of the document.
4. `DeleteDocument( [in] BSTR name)`
   a. Takes the name of the document to be deleted.
5. `UpdateDocument( [in] BSTR name)`
   a. Takes the name of the document to be updated.
6. `ViewHtmlDocument( [in] BSTR name)`
   a. Takes the name of the document to be viewed in HTML.
7. `ViewPdfDocument( [in] BSTR name)`
   b. Takes the name of the document to be viewed as a PDF.
8. `SaveHtmlDocumentAs( [in] BSTR name, [in] BSTR saveTo)`
   a. Takes the name of the document to be saved.
   b. Takes the file path to save the socument as.
9. `SavePdfDocumentAs( [in] BSTR name, [in] BSTR saveTo)`
   a. Takes the name of the document to be saved.
   b. Takes the file path to save the socument as.

10. `GetDocumentDefinitionNames( [in] BSTR separator, [out, retval] VARIANT* names)`
    a. 'separator' is used to convey the directory "level"
    b. Returns the (file) names of doc definitions according to the files in various installation directories.
11. `DeleteAllDocuments()`
12. `UpdateAllDocuments()`

For 6, 7, 8, and 9, the document must have an existing, generated HTML or PDF.

The UserDefinedDocument Data format in the script:

To define a document in VB script:

Array("NAME:Test Report", (Name of the document)
"Test Report", (Description of the document)
"SysLib", (Location of the python script(Syslib, Userlib, PeronalLib etc)
"TestUDDReport", (Relative path of the script in the UserDefinedDocuments folder)

// Start of input definition //
Array("NAME:Inputs", (Document Inputs keyword)
// Solution input //
Array("NAME:DLMetrics", (Input name)
"Solution", (Solution Input Type)
"Data Line Metrics", (Input Description)
-1, (Solution ID)
-1), (Report ID)
// Trace input //
Array("NAME:DQ0", (Input name)
"Trace", (Trace Input Type)
"DQ0", (Input Description)
-1, (Solution ID)
-1), (Report ID)
// Text input //
Array("NAME:Name", (Input name)
"Text", (Text Input Type)
"User Name", (Input Description)
Array("Sita Ramesh")), (Default Value)
// Bool input //

Array("NAME:Summary", (Input name)
"Bool", (Boolean Input Type)
"Display Summary", (Input Description)
Array(true)), (Default Value)
// Number input //
Array("NAME:Version", (Input name)
"Number", (Number Input Type)
"Script Version", (Input Description)
Array(1021)))), (Default Value)
// Trace selection for the solution and trace inputs //
Array("NAME:DocTraces", (Document traces keyword)
// For input "DLMetrics" //
Array("NAME:DLMetrics", (Input name)
// Trace defintion similar to the UDO. This trace definition is a User defined solution //
Array("User Defined",
"", "DDR3 AC-Timing 4-DQ1", Array("Context:=", ""), Array("Index:=", Array("All"), "Trise:=", Array ("Nominal"), "Tfall:=", Array("Nominal"), "Pulse_Width:=", Array("Nominal"), "Data_Rate:=", Array ("Nominal"), "Length:=", Array("Nominal")), Array("Probe Component:=", Array("")), Array())),
// For input "DQ0" //
Array("NAME:DQ0",
// Trace defintion similar to the UDO. This trace definiton is a Standard solution //
Array("Standard", "DQ0", "NexximTransient", Array("NAME:Context", "SimValueContext:=", Array(1, 0, 2, 0, false, false, -1, 1, 0, 1, 1, "", 0, 0, "DE", false, "0", "DP", _
false, "20000000", "DT", false, "0.001", "WE", false, "100ns", "WM", false, _
"100ns", "WN", false, "0ps", "WS", false, "0ps")), Array("Time:=", Array("All"), "Trise:=", Array(_
"Nominal"), "Tfall:=", Array("Nominal"), "Pulse_Width:=", Array("Nominal"), "Data_Rate:=", Array ("Nominal"), "Length:=", Array("Nominal")), Array("Probe Component:=", Array(_
"DQ0")), Array())))

Python Script to Define Document

To define a document in Python script:

```
[
"NAME:Test Report", "Test Report", "SysLib",
"Examples/TestUDDInputs",
[
"NAME:Inputs",
```

```
[
"NAME:DLMetrics","Solution", "Data Line Metrics", -1, -1
],
[
"NAME:DQ0", "Trace", "DQ0", -1, -1
],
[
"NAME:DQS", "Trace", "DQS", -1, -1
],
[
"NAME:Name", "Text", "User Name", ["Sita Ramesh"]
],
[
"NAME:Summary", "Bool", "Display Summary", [True]
],
[
"NAME:Version", "Number", "Script Version" [1021]
]
]
],
[
"NAME:DocTraces",
[
"NAME:DLMetrics",
[
"User Defined", "", "DDR3 AC-Timing 4-DQ1",
[
"Context:=" , ""
],
[
"Index:=" , ["All"], "Trise:=" , ["Nominal"], "Tfall:=" ,
["Nominal"], "Pulse_Width:=" ,
["Nominal"], "Data_Rate:=" , ["Nominal"], "Length:=" ,
["Nominal"]
],
[
"Probe Component:=" , [""]
```

```
],
[]
]
],
[
"NAME:DQ0",

Note	The product has to implement the GetModule call to create the UserDefinedDocument scripting object. For e.g. Check AltraSimDesign.cpp (function GetMgrIDispatch()).

Document Generator Interfaces

This document briefly describes the API interfaces available in the document generator plugin. (Ansys.Ansoft.DocGeneratorPluginDotNet.dll)

Scripting objects available in the script for the Generate function

- oApp = self.GetUDDAppContext(
  Gets the application context
  Usage:- Gets the active project ad the version of the product

```
oDesktop = oApp.GetAppDesktop()
```

if oDesktop != None:
vr = oDesktop.GetVersion()
oProject = oDesktop.GetActiveProject()

- oDesign = self.GetUDDDesignContext()
  Gets the design context
  Usage:- Gets the design name.

oDesign = self.GetUDDDesignContext()
if oDesign != None:
nm = oDesign.GetName()

- IUDDGenerator interface
  This interface available in the Generate method of the UDDPluginExtension.
  This interface can be used to

1. Set the document output file path.

```
docgen.SetOutput("C:\\Examples\\DocumentOutput.xml")
```

2. Get the document root.

```
docroot = docgen.GetDocumentRoot()
```

3. Write out to the output file.

```
docgen.Write()
```

4. Write Html document

```
void WriteHTML();
```

5. Write PDF document

```
void WritePDF();
```

6. Load the Html transform object

```
void LoadHTMLTransform();
```

7. Load the cached PDF transform object

```
void LoadPDFTransform();
```

8. Get script path
```
string GetScriptPath();
```

9. Get output file path
```
string GetOutputFilePath();
```

- IUDDRoot interface

  Calling GetDocumentRoot() on the IUDDGenerator interface provides you with the this interface. This interface can be used to

1. Add a new section to the document. Provide a section title.
```
section1 = docroot.AddSection("Section title")
```

2. Add a new section to the document. Provide a section title and subtitle
```
section1 = docroot.AddSection("Section title", "Section subtitle")
```

3. Add a new title
```
section1 = docroot.AddTitle("Title")
```

4. Add a new subtitle
```
section1 = docroot.AddSubtitle("Subtitle")
```

- IUDDSection interface

  Calling AddSection() on the IUDDRoot interface provides you with the this interface. This interface can be used to

1. Set an ID for the section for internal links.
```
section1.SetID("id")
```

2. Add a new table to the document. Provide a table title.
```
table1 = section1.AddTable("Table title")
```

3. Add a new image to the document. Provide an image title and a file path to the image file.
```
image1 = section1.AddImage("Image title")
```

4. Add text to the document.
```
text1 = section1.AddText("Random text........")
```

- IUDDImage interface

  Calling AddImage() on the IUDDSection interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the image for internal links.

   ```
   image1.SetID("id")
   ```

2. Set alignment information . can be "center", "left" and "right".

   ```
   image1.SetAligment("center")
   ```

3. Set the file path of the image file. Not necessary if image file path is set through the AddImage() method

   ```
   image1.SetFileRef("Image path")
   ```

4. Set the format of the image file. Can be "BMP", "PNG", "JPEG", "JPG", "DVI" etc.. Not sure about the necessity of this one.

   ```
   image1.SetFormat("format")
   ```

- IUDDText interface

  Calling AddText() on the IUDDSection interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the text for internal links.

   ```
   text1.SetID("id")
   ```

2. Set the emphasis attribute on the text

   ```
   text1.SetEmphasis()
   ```

3. Set the quotes attribute on the text

   ```
   Text1.SetQuotes()
   ```

4. Set the block quotes attribute on the text

   ```
   text1.SetBlockquotes()
   ```

5. Set quotes on the text

   ```
   Text1.SetQuotes()
   ```

6. Set the wordsize attribute on the text

   ```
   text1.SetSize(size as an integer)
   ```

7. Set a link to an ID of any element to provide internal links
   ```
   text1.SetLink("linkname")
   ```

8. Set an event link to handle an event. The HandleUDDEvents method should be implemented in the script to handle the event.
   ```
   text1.SetEventLink("linkname")
   ```

- IUDDTable interface

  Calling AddTable() on the IUDDSection interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the table for internal links.
   ```
   table1.SetID("id")
   ```

2. Set alignment information . can be "center", "left" and "right".
   ```
   table1.SetAlignment("center")
   ```

3. Set the background color of the table
   ```
   table1.SetBgColor(string bgcolor)
   ```

4. Set the frame type. Can be "all", "bottom", "top,", "sides", "topbot"
   ```
   table1.SetFrame(string frame)
   ```

5. Add a table group and specify the number of columns. A table can have multiple table groups.
   ```
   IUDDTableGroup table1.SetTableGroup(int columns)
   ```

- IUDDTableGroup interface

  Calling AddTableGroup() on the IUDDTable interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the table group for internal links.
   ```
   tgroup1.SetID("id")
   ```

2. Set alignment information . can be "center", "left" and "right".
   ```
   tgroup1.SetAlignment("center")
   ```

3. Set the column width of a column given the index of the column and the required width. Width can be set in 2 ways.
   - Width can be set relative to 1. E.g Setting it to "2*" makes the column width double the width of the others.

- If the entire table width is considered to be 99.99 units. Width can be a number relative to this.

```
tgroup1.SetColumnWidth(int index, string width)
```

4. Add a header to the table group

```
IUDDTableRow tgroup1.AddHeader()
```

5. Add a header with multiple rows to the table group. Takes number of sub rows.

```
IUDDTableRow tgroup1.AddHeader(int rows)
```

6. Add a row of content to the table group

```
IUDDTableRow tgroup1.AddContent()
```

7. Add content with multiple rows to the table group. Takes number of sub rows.

```
IUDDTableRow tgroup1.AddContent(int rows)
```

- IUDDTableRow interface

  Calling AddHeader() & AddContent() on the IUDDTableGroup interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the table row for internal links.

```
trow1.SetID("id")
```

2. Set alignment information . can be "center", "left" and "right".

```
trow1.SetAlignment("center")
```

3. Set cell text. Can be cell content or header text. Takes a column index and a text string. It is added to the first row.

```
IUDDTextElement trow1.Add(int column, string text)
```

4. Set cell text. Can be cell content or header text. Takes a column index, row index and a text string. Takes in a row number because a table row can have multiple sub rows.

```
IUDDTextElement trow1.Add(int column, int subrow, string text)
```

5. Set cell content. Takes a column index and an int value. It is added to the first row.

```
IUDDTextElement trow1.Add(int column, int value)
```

6. Set cell content. Takes a column index, row index and a int value.

```
IUDDTextElement trow1.Add(int column, int subrow, string text)
```

7. Set cell text. Takes a column index and a double value. It is added to the first row.
   ```
   IUDDTextElement trow1.Add(int column, double value)
   ```

8. Set cell text. Takes a column index, row index and a double value.
   ```
   IUDDTextElement trow1.Add(int column, int subrow, double value)
   ```

9. Set cell text spanning 2 columns. Can be cell content or header text. Takes a sub row index , starting column index., ending column index and a text string.
   ```
   IUDDTextElement trow1.AddSpanningcolumnst(int subrow, int
   columnstart, int columnend, string text)
   ```

10. Set cell text. Can be cell content or header text. Takes a column index, starting sub row index, ending sub row index and a text string.
    ```
    IUDDTextElement trow1.AddpanningRows(int column, int subrowstart,
    int subrowend, string text)
    ```

- IUDDTableRow interface

  Calling Add() on the IUDDTableGroup interface provides you with the this interface. On this interface you can call the following methods

1. Set an ID for the table row for internal links.
   ```
   trow1.SetID("id")
   ```

2. Set alignment information . can be "center", "left" and "right".
   ```
   trow1.SetAlignment("center")
   ```

Includes all the methods exposed by the IUDDText interface.

Chip Model Analyzer (CMA)

Ansys Chip Model Analyzer (CMA) is an advanced Chip Power Model (CPM) creation tool for performance checking and failure diagnosis of the Power Delivery Network (PDN). CMA can use either HSpice or Nexxim simulators. HSpice and external Nexxim require licenses, but the Nexxim Internal simulator does not.

CMA does not currently interact with Electronics Desktop. However, you can launch CMA from within Electronics Desktop by clicking **Tools > Chip Model Analyzer (CMA)**.

From there, you can import CPM files for analysis or create a pseudo CPM.

For more information about using CMA, consult the CMA training documentation by launching CMA and selecting **Help > Content**.

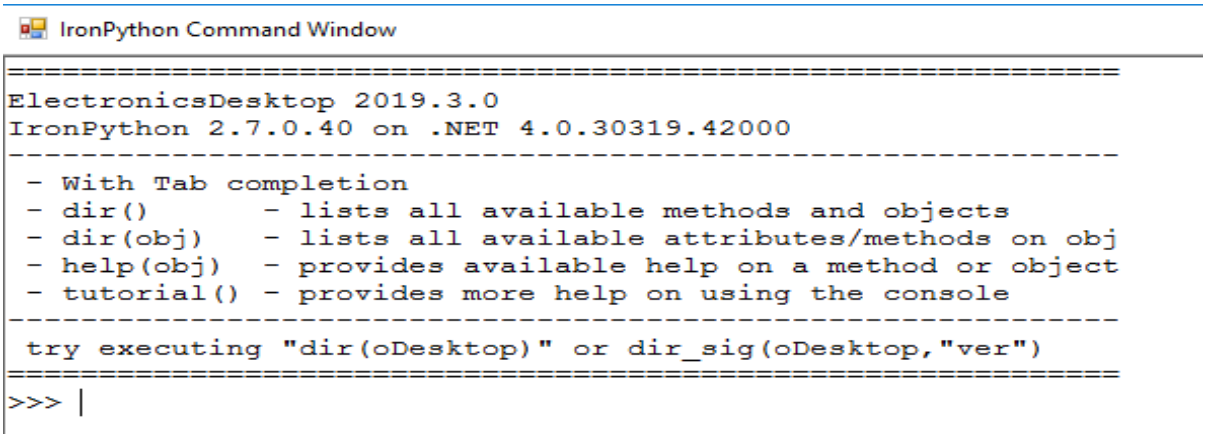
PinToPin Utility

The PinToPin utility can quickly extract HFSS or SIwave models for specified nets of package and PCB geometries. It establishes a repeatable process for robust geometry extraction, port configuration, and passive model assignment. Process execution can be done via the user interface (Windows only) or in non-graphical mode (Windows or Linux).

For more information, consult the SIwave and HFSS 3D Layout help.

24 - Desktop Scripting with IronPython

This document describes IronPython briefly and then goes on to describe the desktop provided IronPython scripting console and scripting with IronPython. You can open an IronPython Command Window by clicking **Tools>Open Command Window**.



The document assumes that you know how desktop scripting works using VBScript or Javascript.

Introduction to IronPython

Creating User Defined Primitives and User Defined Models in Python Scripts

Related Topics

User Defined Outputs: An Introduction

Introduction to IronPython

IronPython is an implementation of the Python programming language targeting the .NET runtime. What this means in practical terms is that IronPython uses the Python programming language syntax and standard python libraries and can additionally use .NET classes and objects to give one the best of both worlds. This usage of .NET classes is fairly seamless in that a class defined in a .NET assembly can be used as a base class of a python class.

Scope

Functioning as a tutorial on Python or IronPython is way out of the scope of this document. There are several excellent resources online that do a very good job in that regard. This document only attempts to provide a limited introduction to IronPython as used to script Ansys Electromagnetics products.

This document is also not a tutorial on the scripting of Ansys Electromagnetics products. It complements the existing scripting guide (available from a product's Help menu) and provides a pythonic interpretation of that information. The reader might have to refer to either the scripting guide or recorded samples of VBScript to follow some of the sections.

Python compatibility

The version of IronPython in use is **2.6.1** and built on the .NET framework version 2.0: this version targets **Python 2.6** language compatibility. While most python files will execute under IronPython with no changes, python libraries that make use of extensions written in the C programming language (NumPy or SciPy for instance), are not expected to work under IronPython. In such cases, it might be possible to locate .NET implementation of such libraries or explore the use of IronClad.

(http://code.google.com/p/ironclad/).

Advantages of IronPython

The advantages that IronPython use provides are significant:

- Python has a large eco-system with plenty of supporting libraries, Visual IDEs and debuggers. It is actively developed and enhanced.
- IronPython, in addition, has access to the entire .NET eco system. This allows us, for instance, to create a modern GUI using the **System.Windows.Forms** assembly from IronPython code and call any other .NET assembly for that matter.
- The use of IronPython's technologies enables the ability to interactively script Desktop (feature in development). This allows better discovery of the scripting APIs as well as directly programming to the scripting API in python, a language more tractable and platform independent compared with VBScript.
- The Python syntax of dictionaries is somewhat easier to read and write when supplying arguments to the scripting methods.

Scripting Using Iron Python: Putting it all Together

IronPython Samples

IronPython Mini-cookbook

While a tutorial on Python syntax is beyond the scope of this document, it will present simple counterparts the VBScript constructs that users tend to regularly use.

Comments

VBScript	IronPython
' Comments start with a single quote ' like this line	# Comments start with a sharp or hash # symbol, like these lines

Assigning/Creating Variables

VBScript	IronPython

' Declare with a Dim
Dim oDesktop
 	
'Assignment needs a Set instruction
Set oDesktop = oApp.GetAppDesktop ()
	# No Set syntax. Simply create and assign
	oDesktop = oApp.GetAppDesktop()

Create Lists/Arrays

VBScript	IronPython

' Declare as array of String with 11
' indices from 0 through 10
Dim myArray(0 to 10) as String
myArray(0) = "Hello"
myArray(1) = "bye"
 	
' **Declare n array with no size**
Dim array2() as String
 	
' **Re-Dimension the array once size is**
' **known**
ReDim array2(0 to 2) as String
array2(0) = "this"
array2(1) = "also"
	# Declare an empty array
	myEmptyArray = []
	
	# declare an array and initialize it with 5 ints
	myInitedArray = [1, 2, 3, 4, 5]
	
	# Python lists can have items of any type
	# and there is no pre-declaration
	# declare an array and init with mixed types
	mixed = ["hello", 1 ,2 ["nested"]]
	
	# append to an array
	mixed.append(3.5)

Create Dictionaries/Maps

VBScript	IronPython

' No direct equivalent is available as
' far as the author knows
	# an IronPython dictionary is a collection of
	# name value pairs. Just like arrays, there is
	# no restriction on the keys or the values.
	# For purposes of Ansys EM scripting however,
	# all keys must be strings
	
	# delimiters are curly braces
	# use a ":" between the key and the value
	# separate key value pairs with a ","
	myDict = {
	"a" : 1,
	"b" : "hello there",
	"c" : [1, 2, "abc"]
	}

Boolean Values

VBScript	IronPython
' Boolean literals are **in lower case** true false	# The first letter is capitalized True False

Converting Numbers to Strings and Vice Versa

VBScript	IronPython

' Use **CInt, CDbl, CBool, CLng**
' to convert the string representation
' to **the number representation. Use**
' **IsNumber to check before conversion**
Dim nStr = "100"
Dim n = CInt(nStr)
 	
' **Use CStr to convert a number to**
' its string representation
Dim v, vStr
v = 100
vStr = CStr(v)
	# use the integer() or float() or double()
	# functions to cast a string CONTAINING the
	# string representation of whatever you are
	# casting to.
	strInt = "3"
	intVal = int(strVal)
	floatVal = float(strVal)
	
	# invoke the str() function with the int/float
	# values as needed. You can alternately use
	# the string formatting method listed below
	strVal = str(42)
	strVal = str(42.345)

String formatting/concatenation

VBScript	IronPython

' string concatenation uses the &
' operator
Dim allStr, str1
str1 = " how are you"
allStr = "Hello " & " There" & str1
 	
' there seems to be no direct string
' formatting function in VBScript
' using string concatenation or using
' Replace are the two **builtin**
	# if you have two strings, you can always
	# concatenate then using the '+' operator
	str1 = "hello"
	str2 = "world"
	str12 = str1 + " " + str2
	
	# if you have different types though, string
	# and int say, you must use the string
	# formatting commands. When formatting
	# multiple arguments, they must be entered

options
Dim fmt = "{1} climbs stalk {2}"
Dim str = Replace(fmt, "{1}", "jack")
str = Replace(str, "{2"}, 10)
	# as a tuple (item1, item2,)
	num = 10
	str3 = "%s climbs stalk %d" % ("jack", num)
	str4 = "%d stalks" % num

Looping over lists

VBScript	IronPython

Dim myArray(0 to 2) as String
myArray(0) = "alpha"
myArray(1) = "bravo"
myArray(2) = "charlie"
 	
For Each i in myArray
Print i
Next
	vals = [1, 3, 3.456]
	
	def process(val):
	  return 2*val
	
	# is of the form
	# for variable_name in array
	':'
	# < indent> statement1
	# <indent> statement2
	for i in vals:
	  print i
	  print " -> " process(i)

Looping over a range

VBScript	IronPython
' Loop over a range, specify start, end ' and step For i = 0 To 10 Step 1 Print i Next	# prints out values from 0 through 9 for i in range(0, 10): print i

A note about indentation

Python is one of the languages where whitespace (spaces, tabs etc) are syntactically significant. You must understand the basics of indentation before scripting in python.

Any statement that introduces a block of code should be written such that every line of the block has the same indent (leading spaces or tabs) and the indent should be at least one more than the indent of the introducing statement.

```
    # define a function that starts at 0 indentation.
    def multInt(a,b):
# every line following the def multInt which is expected
# to be a part of the function, must have the indent used
# by the first line of the function (3 spaces)
# here we introduce one more block, the if condition
# each line that belongs to the body of this func should
# have an indent that is more than the indent used by the
# if statement
If a%2 == 0:
  # I am using an indent 2 more than the parent. i.e. 5
  # spaces in total
  return (a * b) + 100
else:
  return (a * b) + 1000
```

Obtaining more Information on Python

Reading a book and searching online are two of the standard options. There are several very good python tutorials online and the command window is also a great way to quickly execute code and learn by doing.

Much of the official python documentation is embedded into each python distribution and the command window can also be used to get more help. You can open the IronPython Command Window by clicking **Tools>Open Command Window**. You can also aces the command window executable, **Ipy.exe**, from the **IronPython** directory under the Ansys Electromagnetics product installation directory. You can use this window to interactively enter python commands (any of the pure python samples in this document)

Discovering Methods

For instance, if you want to list all methods available in the string module, you would type in "import string" to import the module first and then type in "dir(string)". You will get a list of all the methods available (as well as some __somename__ internal names that can be ignored)

```
>>> import string
>>> dir(string)
['Formatter', 'Template', '_TemplateMetaclass', '__builtins__', '__doc__', '__file__', '__name__',
'__package__', '_float', '_idmap', '_idmapL', '_int', '_long', '_multimap', '_re', 'ascii_letters',
'ascii_lowercase', 'ascii_uppercase', 'atof', 'atof_error', 'atoi', 'atoi_error', 'atol',
'atol_error', 'capitalize', 'capwords', 'center', 'count', 'digits', 'expandtabs', 'find',
'hexdigits', 'index', 'index_error', 'join', 'joinfields', 'letters', 'ljust', 'lower', 'lowercase',
'lstrip', 'maketrans', 'octdigits', 'printable', 'punctuation', 'replace', 'rfind', 'rindex', 'rjust',
'rsplit', 'rstrip', 'split', 'splitfields', 'strip', 'swapcase', 'translate', 'upper', 'uppercase',
'whitespace', 'zfill']
```

IronPython Samples

Translating Script commands from VBScript to IronPython

This chapter briefly describes Desktop scripting methods and arguments via VBScript samples. The distinctions made here are significant and come in use later when translating scripts written in VBScript to IronPython.

Script Method Argument

VBscript Method Call Types

VBScript Sub-Routines

Converting VBScript Function calls to IronPython Syntax

Related Topics

Introduction to IronPython
IronPython Mini-cookbook
Scripting Using Iron Python: Putting it all Together
IronPython Samples

Script Method Argument

Script method calls in VBscript are described later in this document, they generally take the form:

```
objectName .methodName ( arg1, arg2, ..)
```

The function call syntax is a standard followed by several programming languages, however, the argument types in VBScript objects, when used for product scripting, are restricted to the following

Primitive types
Named Array
Named Function

Primitive Types

Primitive types are the standard **bool, int, float, double** and **string**

Named Array

Named arrays are a special construct used very commonly and can be found in practically every recorded script sample.

It starts with **Array("NAME:someName**" and is followed by a collection of comma separated values which can be:

- A primitive value
- An array of primitive values
- Another named array
- A key, of the form "**keyName:="** followed by
  - A primitive value
  - A function (described next)

Named Function

Named functions are arrays which start with **Array(** and do not have a leading "NAME:name" item. **They are always introduced by a key** and can contain comma separated values of the following type:

- A primitive value
- A key (of the form "**keyName:="**) followed by

- A primitive value
- Another function (nested function)

Related Topics

Translating Script commands from VBScript to IronPython

VBscript Method Call Types

VBScript method calls fall into two categories and the distinction between the two results in syntax differences. These syntax differences are significant when converting VBScript to IronPython.

VBScript Functions

In VBScript terminology functions return values. The syntax for this is the one shared with practically all programming languages.

```
Set oDesktop = oAnsoftApp.GetAppDesktop()
Set oProject = oDesktop.NewProject
```

Sample Script 2: VBScript function call sample

Note that the significant item here is that the method name is **always** followed by an argument list enclosed in parentheses **if there are arguments**. If the argument list is empty as shown above for the *NewProject* call, the parentheses can be omitted.

VBScript Sub-Routines

VBScript Sub-Routines are those that do not have any return value. VBScript allows these to be written without any parentheses even if they have a non-empty argument list.

```
oModule.CreateReport "XY Plot1", "Standard", "XY Plot", "optimtee :
optimtee", _
    Array("Domain:=", "Sweep"), Array("Freq:=", Array("All"),
    "offset:=",_
    Array("0uin")), Array("X Component:=", "Freq", "Y Component:=", _
    Array("dB20(S(1,1))", "dB20(S(1,2))", "dB20(S(1,3))", _
     "dB20(S(2,1))", "dB20(S(2,2))", "dB20(S(2,3))", "dB20(S(3,1))",
     "dB20(S(3,2))", "dB20(S(3,3))")), Array()
```

Sample Script 3: VBScript Sub-Routine sample

Related Topics

Translating Script commands from VBScript to IronPython

Converting VBScript Function calls to IronPython Syntax

When converting functions, the important point to remember is that IronPython function names, when used for scripting, are **always** followed by parentheses. So:

- If you see a VBScript snippet that looks like a VBScript Sub-Routine, remember to add parentheses.
- If you see a VBScript function that has no arguments and no parenthesis, remember to add them around an empty argument list.

The parentheses change is the only one to keep in mind when converting VBScript function calls syntax to IronPython.

Return Values

Primitive Method Arguments

Named Array Argument

Named Array Values with All Key Value Pairs

Named Arrays with Nested Named Arrays

Function Blocks

Return Values

VBscript return values are sometimes assigned via the **Set** declaration. IronPython return values are simple assignment (see the cookbook chapter)

Related Topics

Converting VBScript Function calls to IronPython Syntax

Primitive Method Arguments

Replace each VBScript primitive with an equivalent IronPython primitive. The main thing to notice here is that Boolean values in IronPython have their first letter capitalized.

```
True instead of true and False instead of false
```

Related Topics

Converting VBScript Function calls to IronPython Syntax

Named Array Argument

The recommended approach here is to simply replace a VBScript array with a python array. The mapping is quite simple:

- Change **Array(** to **[** and close with a **]** instead of the **)**
- Remove the line continuation symbols: **_**

- Map Boolean values correctly

```
oEditor.CreateCone Array("NAME:ConeParameters", "XCenter:=", "0mm", _
"YCenter:=", "0mm", "ZCenter:=", "0mm", "WhichAxis:=", "Z", "Height:=", "2mm",_
"BottomRadius:=", "1.56204993518133mm", "TopRadius:=", "0mm"), Array("NAME:Attributes",
"Name:=", "Cone1", "Flags:=", "", "Color:=", _
"(132 132 193)", "Transparency:=", 0, "PartCoordinateSystem:=", _
"Global", "UDMId:=", "", "MaterialValue:=", _
"" & Chr(34) & "vacuum" & Chr(34) & "", "SolveInside:=", true)
```

Sample Script 4: Create cone recorded snippet

For instance, method and named VBScript arrays in the snippet above are translated to

```
    oEditor.CreateCone(
  [
    "NAME: ConeParameters",
    "XCenter:=" , "0mm",
    "YCenter:=" , "0mm",
    "ZCenter:=" , "0mm",
    "WhichAxis:=" , "Z",
    "Height:=" , "2mm",
    "BottomRadius:=" , "1.56204993518133mm",
    "TopRadius" , "0mm"
  ],
  [
    "NAME:Attributes",
    "Name:=" , "Cone1",
    "Flags:=" , "",
    "Color:=" , "(132 132 193)",
    "Transparency:=" , 0,
    "PartCoordinateSystem:=" , "Global",
    "UDMId:=" , "",
    "MaterialValue:=" , "\"vacuum\"",
    "SolveInside:=" , True
    ])
```

Sample Script 5: Create a cone in IronPython

Note that the formatting (which helps readability immensely) is not really needed. All that **had** to be done was

- Add the parentheses since the VBScript subroutine omits it
- Replace the **Array( )** delimiters with **[ ].**
- Remove the **Char(34)** function (which introduced a double quote) and replace it with the escaped double quote **\"** literal.
- Replace **true** with **True**
- Remove the line continuation symbol, **_**

Related Topics

Converting VBScript Function calls to IronPython Syntax

Named Array Values with All Key Value Pairs

While it is in general not allowed to replace the arrays and nested arrays with python dictionaries, in the case where the named array consists entirely of key value pairs (like the sample above), one can use a dictionary and **avoid typing the trailing ":=" symbols after the keys**. This further aids readability of the script.

- If all key value pairs
- Remove the trailing ":=" after each key
- Replace the "," after the key with a ":"
- If the named array is the top level argument, ensure that the "NAME:name" is present and is split into "NAME" : "name" as a key value pair
- Enclose the converted array in a { } pair to declare the dictionary.

```
   oEditor.CreateCone(
{
"NAME" : "ConeParameters",
"XCenter" : "0mm",
"YCenter" : "0mm",
"ZCenter" : "0mm",
"WhichAxis" : "Z",
"Height" : "2mm",
"BottomRadius": "1.56204993518133mm",
"TopRadius" : "0mm"
},
{
"NAME" : "Attributes",
"Name" : "Cone1",
"Flags" : "",
"Color" : "(132 132 193)",
"Transparency" : 0,
```

```
"PartCoordinateSystem": "Global",
"UDMId" : "",
"MaterialValue" : "\"vacuum\"",
"SolveInside" : True
}
```

Sample Script 6: CreateCone in IronPython using dictionary syntax

Related Topics

Converting VBScript Function calls to IronPython Syntax

Named Arrays with Nested Named Arrays

- Split the "NAME:name" field into a key value pair
- Translate array key value pair to a dictionary key value pair.
- Create a new key with the name of the nested array and keep the nested array (as an array or as a dictionary) as its value. If the nested array is being retained **as an array**, **the**"NAME**:name**" **field should be retained in the array**. If the nested array is being converted to a dictionary, the name is optional: if also retained in the nested array, it must match the outer key.

```
   [ "NAME:name",
"key1:=" , 1,
"key2:=" , 2,
["NAME:name2", "R:=", 255]
   ]
```

Sample Script 7: Named array with nested named array in array syntax

The above named array with a nested named array (after conversion to IronPython as named array) can be converted to a dictionary as well. The dictionary can take any of the following forms

```
   { "NAME" : "name",
"key1" : 1,
"key2" : 2,
"name2" : ["NAME:name2", "R:=", 255]
   }
```

Sample Script 8: Named array with nested named array as mixed dictionary + array

```
   { "NAME" : "name",
   "key1" : 1,
   "key2" : 2,
```

```
    "name2" : {"R" : 255}
    }
```

Sample Script 9: Named array with nested named array in all dictionary syntax

```
    { "NAME" : "name",
    "key1" : 1,
    "key2" : 2,
    "name2" : {
   "NAME" : "name2",
   "R" : 255
}
    }
```

Sample Script 10: Nested named array with optional "NAME:" field

Related Topics

Converting VBScript Function calls to IronPython Syntax

Function Blocks

Function blocks in VBScript argument syntax are represented as arrays without the "NAME:.." field. However, functions are always introduced by a key in a parent structure. Function blocks can therefore never exist as a top-level argument. They are only found as the value pairs inside a named array or inside another function block.

Note	Function blocks and their items cannot be converted to dictionaries even though they might be composed entirely of key value pairs.

The reason for this is the need to main the user-entered order. Every item in a function block is expect to be transmitted to the script method in exactly the same order as typed out and this is impossible to achieve when a dictionary is used (as the keys get reordered according to the dictionary's internal tree/key sorting scheme).

Note	When you see a function block, simply replace the Array( ) delimiters with the python array delimiters [ ]

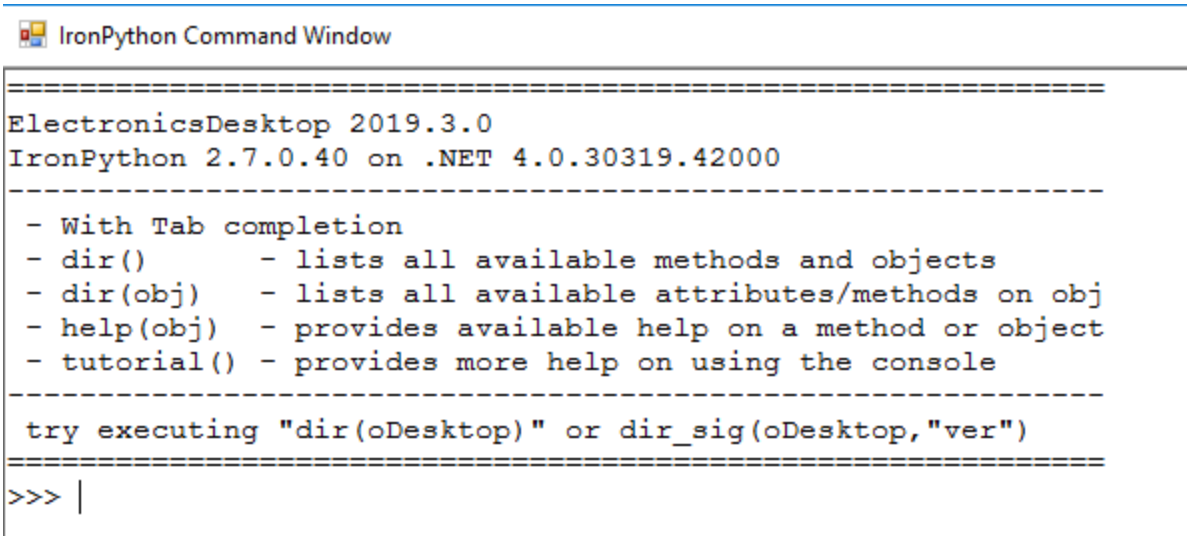
Translating Script commands from VBScript to IronPython

Appendix: IronPython Samples

IronPython Script Execution Environment

Scripts written in IronPython are executed by desktop in four different ways:

- **Tools>Open Command Window**, to open the **IronPython Command Window:**



- **Tools > Run Script** menu item, select "IronPython" from the file type drop-down list.
- Launch the product with a script argument.
  - Maxwell -runscript someScript.py to keep Maxwell GUI open after completing script execution.
  - Maxwell -features=beta -ng -runscriptandexit someScript.py to run Maxwell in a non-graphical mode and exit after script completion. Note that this is a beta feature.
- Register an IronPython script as an external tool using the **Tools > External Tools** menu item.

When desktop executes a script, it does so in an execution environment setup with predefined variables and functions. These predefined variables and functions are how the script communicates with the desktop and they come in three flavors.

Script Argument for IronPython

Script Argument for IronPython

When scripts are launched using the **Tools > Run Script** menu item, the dialog that pops up allows the user to specify arguments.

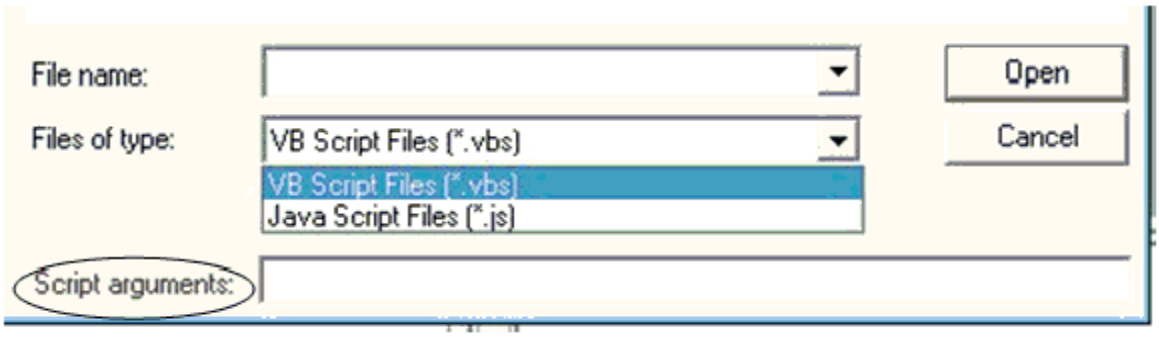


Figure 1: Run Script dialog and script arguments

Any argument specified here is communicated to the script being executed as the predefined variable **ScriptArgument**.

IronPython Script Execution Environment

Scripting using Embedded VBScript or JavaScript

Since script recording is still done in VBScript and users are expected to have a significant collection of VBScript or JavaScript assets, it is useful to continue to use existing script files and snippets even when scripting in IronPython. The various **Run<*>Command** methods have been designed for this purpose.

For instance: one can create a parameterized cone in HFSS by executing the following IronPython script from the **Tools>Run Script** menu.

```
# assign the VBScript snippet obtained from a script recording from
HFSS to
# coneScript and replace the BottomRadius recorded value with botRadius
coneScript = """Dim oAnsoftApp
Dim oDesktop
Dim oProject
Dim oDesign
Dim oEditor
Dim oModule
Set oAnsoftApp = CreateObject("AnsoftHfss.HfssScriptInterface")
Set oDesktop = oAnsoftApp.GetAppDesktop()
oDesktop.RestoreWindow
Set oProject = oDesktop.GetActiveProject()
oProject.InsertDesign "HFSS", "HFSSPyTestDesign", "DrivenModal", ""
Set oDesign = oProject.SetActiveDesign("HFSSPyTestDesign")
Set oEditor = oDesign.SetActiveEditor("3D Modeler")
oEditor.CreateCone Array("NAME:ConeParameters", _
 "XCenter:=", "0mm", "YCenter:=", "0mm", "ZCenter:=", "0mm",_
 "WhichAxis:=", "Z", "Height:=", "2mm", _
 "BottomRadius:=", "3mm", _
 "TopRadius:=", "0mm"), Array("NAME:Attributes", "Name:=", _
 "Cone1", "Flags:=", "", "Color:=", "(132 132 193)", "Transparency:=",
0, _
```

```
 "PartCoordinateSystem:=", "Global", "UDMId:=", "", "MaterialValue:=",
_
 "" & Chr(34) & "vacuum" & Chr(34) & "", "SolveInside:=", _
 true)
"""
SetScriptingLanguageToVBScript()
RunScriptCommand(coneScript)
```

Sample Script 11: Hybrid VBScript + IronPython scripting: parameterized Cone Creation

Even though recorded VBScript is used for scripting, the incremental functionality that is provided using IronPython is the ability to write a GUI using IronPython/.NET, collect information from the user and then modify or generate the VBScript commands to actually script the Ansys Electromagnetics desktop. This GUI functionality is cross platform and a significant positive. The following example demonstrates a contrived use of a .NET window form to display the argument supplied to the IronPython script (via the ***ScriptArgument*** variable).

```
        #import the CLR references
        import clr
        clr.AddReference("System.Windows.Forms")

        from System.Windows.Forms import Application, Form, Label,
        Button, DockStyle

        # the GUI form to show some text
        # the class below derives from From (System.Windows.Forms.Form)
        # imported above from the .NET assembly.
        class ShowPropertiesForm(Form):
    def __init__(self, name, text):
      self.Name = name
      self._label = Label()
      self._label.Text = text
      self._label.Dock = DockStyle.Fill

      _button = Button()
      _button.Text = "Close"
      _button.Dock = DockStyle.Bottom
      _button.Click += self._buttonPressed

      self.Controls.Add(self._label)
```

```
    self.Controls.Add(_button)

def _buttonPressed(self,sender,args):
    self.Close()

    #----------------------------------------------------
    # Main script code
    #----------------------------------------------------
    #display the ScriptArgument variable as the text label
    # in the form.
    gui = ShowPropertiesForm("Sample Form", ScriptArgument)

    # This makes it a modal dialog.
    gui.ShowDialog()

    # the following will make it a non-modal dialog
    #Application.Run(gui)
```

Sample Script 12: Demonstrates the use of a .NET form from IronPython

While creating cross platform user interfaces from scripts is one of the main motivations driving the adoption of IronPython, any .NET assembly can be used with the caveat that Linux use requires Mono compatibility of any used assemblies.

While this hybrid approach is useful when you have existing VBScript commands that you want to reuse or when you want to quickly parameterize a recorded sample, the one significant limitation of this approach is the inability to capture return values from VBScript or JavaScript calls that do return something. Full two way communication with the product requires the use of pure IronPython to directly invoke the script objects as described below.

Related Topics

IronPython Script Execution Environment

Scripting with IronPython

While this section talks about directly interacting with the script objects, note that you can execute VBScript or Javascript at any point using any of the available Run*Command functions. using your existing script assets in this fashion and mixing with IronPython code for new functionality as needed is a viable and option.

Access to the application scripting objects is provided via the predefined **oDesktop** object (as listed in Script Objects). Interacting with the script objects is very natural, method calls are made just like in VBScript except that the argument syntax is somewhat simplified to follow natural

Python syntax. All primitive types (string, integer, double) map to the natural primitive types in python. The only differences from the VBScript syntax are seen when specifying array type arguments. The differences are described in earlier chapters.

Note	The typical VBScript calls to obtain the registered COM scripting interface via CreateObject calls and then obtain the oDesktop object from it using the GetAppDesktop() is not needed (or even supported on all platforms). Since all scripting occurs in the context of a running workbench, the available Desktop object is always provided and expected to be used directly.

Scripting using the IronPython scripting API is very much like scripting with VBScript except that

- Any argument is supplied via the built in **ScriptArgument** variable
- The **oDesktop** object is always available
- The scripting method names are identical to the ones used with VBScript
- Method calls, while the name is the same have to adhere to the rule of ensuring trailing parentheses irrespective of whether the function returns anything or has any arguments.
- Any compound/block arguments should be translated to the appropriate IronPython array or dictionary syntax.

The samples section lists a collection of pure IronPython snippets: these, along with the various script snippets listed in this document should serve as a guide and reference.

Related Topics

IronPython Script Execution Environment

Standalone IronPython and Desktop IronPython

In general, it is easier to run a script directly from Electronics Desktop. Standalone IronPython does not implement all the functionality available when a script is run from Electronics Desktop. It only implements full support for COM functions.

Running Standalone IronPython

Standalone IronPython uses COM to get the handle to the AnsysEDT app. To run standalone IronPython, you'll need to call the IronPython interpreter ipy64.exe.

It is located in:

```
<AnsysEDTInstallationPath>\<version>\<platform>\common\IronPython\ipy64.exe
```

For example, to run myScript.py, type the following in the command line:

```
"C:\Program Files\AnsysEM\v231\Win64\common\IronPython\ipy64.exe" "<filePath>\myScript.py"
```

You can set the interpreter to be the default program when double-clicking the .py script. You can use any recorded script as the basis for a standalone script and simply add an installation-internal path to the python module search path (as shown below) and end the script with a new shutdown call.

Using a Recorded Script

A python script recorded in AnsysEDT already has the required lines to be run as a standalone, except for the first two lines (path settings) and the final `Shutdown()` call. See the example script below.

Creating an External Script

When creating a script outside of Electronics Desktop, the following lines should be included at the beginning of your script:

- `import sys`

  # Imports the sys module containing system-specific functions native to IronPython.
- `sys.path.append("<InstallationPath>")`

  # Adds the Electronics Desktop installation path to the list of directories Python searches for modules and files.
- `sys.path.append("<InstallationPath>/PythonFiles/DesktopPlugin")`

  # Adds the PythonFiles/DesktopPlugin subfolder to the list of directories Python searches for modules and files.
- `import ScriptEnv`

  # This imports ScriptEnv.py from the installation path specified above. ScriptEnv.py performs an operating system check and defines functions used in Electronics Desktop scripts. See the annotations in the ScriptEnv.py file for more information.
- `ScriptEnv.Initialize("Ansoft.ElectronicsDesktop")`

  or `ScriptEnv.InitializeNew(NonGraphical=True)`

  # `Initialize` and `InitializeNew` are functions within ScriptEnv.py. The first option launches Electronics Desktop. The second allows you to run a script without launching Electronics Desktop. See the annotations in the ScriptEnv.py file for more information.

You must end the script with:

- `ScriptEnv.Shutdown()`

  # This stops ScriptEnv.py. If you are running multiple scripts, include this only at the end of the last script.

Example Script

```
import sys
sys.path.append(r"C:\Program Files\AnsysEM\v231\Win64")
sys.path.append(r"C:\Program
Files\AnsysEM\v231\Win64\PythonFiles\DesktopPlugin")

import ScriptEnv
ScriptEnv.Initialize("Ansoft.ElectronicsDesktop")
```

```
oDesktop.RestoreWindow()
oProject = oDesktop.NewProject()
oProject.InsertDesign("HFSS", "HFSSDesign1", "DrivenModal", "")
oDesign = oProject.SetActiveDesign("HFSSDesign1")
oEditor = oDesign.SetActiveEditor("3D Modeler")
oEditor.CreateRectangle(
[
"NAME:RectangleParameters",
"IsCovered:= ", True,
"XStart:= ", "-0.2mm",
"YStart:= ", "-3mm",
"ZStart:= ", "0mm",
"Width:= ", "0.8mm",
"Height:= ", "1.2mm",
"WhichAxis:= ", "Z"
],
[
"NAME:Attributes",
"Name:= ", "Rectangle1",
"Flags:= ", "",
"Color:= ", "(132 132 193)",
"Transparency:= ", 0,
"PartCoordinateSystem:=", "Global",
"UDMId:= ", "",
"MaterialValue:= ", "\"vacuum\"",
"SolveInside:= ", True
])
oDesign.SetDesignSettings(['NAME:Design Settings Data', 'Allow Material
Override:=', True, 'Calculate Lossy Dielectrics:=', True])
oEditor.SetModelUnits(['NAME:Units Parameter', 'Units:=', 'mil',
'Rescale:=' , False ])
ScriptEnv.Shutdown()
```

IronPython Samples

Change property

The following snippets show how a change property command (in this case, to change the color of a cone) looks in VBScript and its two possible IronPython variants.

```
   oEditor.ChangeProperty Array("NAME:AllTabs", Array
   ("NAME:Geometry3DAttributeTab",_
Array("NAME:PropServers", "Cone1"), _
Array("NAME:ChangedProps", _
Array("NAME:Color", "R:=", 255, "G:=", 255, "B:=", 0))))
```

Sample Script 13: ChangeProperty command to change color of a cone in VBScript

```
   oEditor.ChangeProperty(
   ["NAME:AllTabs",
["NAME:Geometry3DAttributeTab",
["NAME:PropServers", "Cone1"],
["NAME:ChangedProps",
["NAME:Color", "R:=", 0, "G:=", 0, "B:=", 64]
]
   ]
   ])
```

Sample Script 14: ChangeProperty command to change color of cone using Python arrays

Any time there are named arrays composed purely of key-value pairs, they can always be represented using a Python dictionary, irrespective of the nesting of said named array.

```
   oEditor.ChangeProperty(
["NAME:AllTabs",
["NAME:Geometry3DAttributeTab",
  ["NAME:PropServers", "Cone1"],
  ["NAME:ChangedProps",
  {
  "NAME":"Color",
  "R" : 0,
"G" : 64,
"B" : 0
}]]
   ])
```

Sample Script 15: ChangeProperty command to change the color of a cone using Python arrays and dictionaries

Create a Cone using IronPython

Most scripting tasks using IronPython are expected to be formatted as the following example. One starts with the predefined **oDesktop** object and drills down to the design, editors, modules etc and issues any required commands on the object while formatting the script command arguments in natural python syntax.

```
    oProject = oDesktop.GetActiveProject()
    oDesign = oProject.InsertDesign
    ("HFSS","Random","DrivenModal","")
    oEditor = oDesign.SetActiveEditor("3D Modeler")
    oEditor.CreateCone(
    {
"NAME" : "ConeParameters",
"XCenter" : "0mm",
"YCenter" : "0mm",
"ZCenter" : "0mm",
"WhichAxis" : "Z",
"Height" : "2mm",
"BottomRadius" : "1.56204993518133mm",
"TopRadius" : "0mm"
},
{
"NAME" : "Attributes",
"Name" : "Cone1",
"Flags" : "",
"Color" : "(132 132 193)",
"Transparency" : 0,
"PartCoordinateSystem": "Global",
"UDMId" : "",
"MaterialValue" : "\"vacuum\"",
"SolveInside" : True
}
)
```

Sample Script 16: IronPython script to create a cone

Create geometry and then create a grid from it using copy/paste/move

The following script demonstrates slightly more advanced use of scripting and the use of return values from script methods. It creates a 5x5 grid of cones and also demonstrates the adding of information messages to the application's message window.

```
    oProject = oDesktop.GetActiveProject()
    oDesign = oProject.InsertDesign("HFSS","Hersheys
    Kisses","DrivenModal","")
    oEditor = oDesign.SetActiveEditor("3D Modeler")

    # create the first cone
    AddInfoMessage("Creating first cone")
    firstConeName = "firstCone"
    coneBotRad = "1.5mm"
    oEditor.CreateCone(
[
"NAME" : "ConeParameters",
"XCenter" : "0mm",
"YCenter" : "0mm",
"ZCenter" : "0mm",
"WhichAxis" : "Z",
"Height" : "2mm",
"BottomRadius": coneBotRad,
"TopRadius" : "0mm"
],
[
"NAME" : "Attributes",
"Name" : firstConeName,
"Flags" : "",
"Color" : "(132 132 193)",
"Transparency" : 0,
"PartCoordinateSystem": "Global",
"UDMId" : "",
"MaterialValue" : "\"vacuum\"",
"SolveInside" : True
]
)

    # Now replicate this a few times and create an array out of it
```

```
        AddInfoMessage("Replicating it 24 times")
        for x in range(5):
    for y in range(5):
# leave the first one alone in it's created
# position
        if x == 0 and y == 0:
continue

        # all other grid positions, replicate from the
        # first one

        # copy first
        oEditor.Copy(
    {
    "NAME" : "Selections",
    "Selections" : firstConeName
    }
        )

        # paste it and capture the pasted name
        # the pasted names come in an array as we could
        # be pasting a selection cmposed of multiple objects
        pasteName = oEditor.Paste()[0]

        # now move the pasted item to it's final position
        oEditor.Move(
    {
    "NAME" : "Selections",
    "Selections" : pasteName
    },
    {
    "NAME" : "TransalateParameters",
    "CoordinateSystemID" : -1,
    "TranslateVectorX" : "%d * 3 * %s" % (x, coneBotRad),
    "TranslateVectorY" : "%d * 3 * %s" % (y, coneBotRad),
    "TranslateVectorZ" : "0mm"
    }
```

```
)

# Now fit the display to the created grid
oEditor.FitAll()
```

Sample Script 17: Sample script to create a cone and then use copy/paste/move to replicate it.

Scripting Using Iron Python: Putting it all Together

Creating User Defined Primitives and User Defined Models in Python Scripts

You can create User Defined Primitives and User Defined Models in Python scripts (based on the IronPython implementation).

For more information, consult the Maxwell Scripting Guide.

25 - Optimetrics

Optimetrics enables you to determine the best design variation among a model's possible variations. You create the original model, the *nominal design*, and then define the design parameters that vary, which can be nearly any design parameter assigned a numeric value in Maxwell. For example, you can parameterize the model geometry or material properties. You can then perform the following types of analyses on your nominal Maxwell design:

Parametric	In a parametric analysis, you define one or more *variable sweep definitions,* each specifying a series of variable values within a range. For example, you can parameterize component values. (See Variables in Maxwell for more information.) Optimetrics solves the design at each variation. You can then compare the results to determine how each design variation affects the performance of the design. Parametric analyses are often used as precursors to optimization solutions because they help to determine a reasonable range of variable values for the optimization analysis.
Optimization	For an optimization analysis, you identify the cost function and the optimization goal. Optimetrics changes the design parameter values to meet that goal. The cost function can be based on any solution quantity that Maxwell can compute.
Sensitivity	In a sensitivity analysis, you use Optimetrics to explore the vicinity of the design point to determine the sensitivity of the design to small changes in variables.
Tuning	Tuning allows you to change variable values interactively while monitoring the performance of the design.If you want to ensure that tuning does not resolve variations already solved by parametric setup, you must check **Save Fields Mesh** in the **Options** tab of the optimetrics setup.
Statistical	In a statistical analysis, you use Optimetrics to determine the distribution of a design's performance, which is caused by a statistical distribution of variable values.
Design of Experiments	Design of Experiments involves the creation of a response surface that depicts and predicts how variable values will affect the design.
DesignXplorer	An optimization tool for studying a range of design variations, used with Design of Experiments.
opiSLang	optiSLang simulations can be integrated with Ansys Electronics Desktop, such that you can create a setup very much like an Optimetrics setup to run through an optisLang installation.

Note	Sweeping or using a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

Parametric Overview

Running a parametric analysis enables you to simulate several design variations using a single model. You define a series of variable values within a range, or a variable sweep definition, and Maxwell generates a solution for each design variation. You can then compare the results to determine how each design variation affects the performance of the design.

You can vary design parameters that are assigned a quantity, such as geometry dimensions, material properties, and boundary and excitation properties. (See the help topic for the specific parameter you want to vary.) The number of variations that can be defined in a parametric sweep setup is limited only by your computing resources.

To perform a parametric analysis, you first create a nominal design. A nominal design is created like any other design, except that variables are assigned to those aspects of the model you want to change. All variables must be defined before you start the parametric analysis. Although you are not required to solve the nominal design before performing a parametric analysis, doing so helps ensure that the model is set up and operates as intended. Alternatively, you can perform a validation check on the nominal design before performing a parametric analysis.

Parametric analyses are often used as precursors to optimization analyses because they enable you to determine a reasonable range of variable values for an optimization analysis.

Setting up a Parametric Analysis

Setting Up a Parametric Analysis

A *parametric setup* specifies all of the design variations that Optimetrics drives Maxwell to solve. A parametric setup is made up of one or more *variable sweep definitions*, which are a set of variable values within a range that you want Maxwell to solve when you run the parametric setup.

You can define more than one parametric setup per design.

Note	Once you have created a parametric setup, you can copy and paste it, and then make changes to the copy, rather than redoing the whole process for minor changes.

To add a parametric setup to a design:

1. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click

   

   Add Parametric .

   - Alternatively, right-click **Optimetrics** in the project tree, and then click **Add>Parametric** on the shortcut menu.

   The **Setup Sweep Analysis** dialog box appears.
2. Add a variable sweep definition.

After you define a parametric sweep, a shortcut menu becomes available when you right-click the setup name.

Note	Sweeping or using a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

Parametric Overview

Adding a Variable Sweep Definition

A parametric setup is made up of one or more *variable sweep definitions*. A variable sweep definition is a set of variable values within a range that Optimetrics drives Maxwell to solve when the parametric setup is analyzed. You can add one or more sweep definitions to a parametric setup.

Note	Sweeping a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

1. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click

   

   Add Parametric .

- Alternatively, right-click **Optimetrics** in the project tree, and then click **Add>Parametric** on the shortcut menu.

The **Setup Sweep Analysis** dialog box appears.

2. Under the **Sweep Definitions** tab, click **Add**.

   The **Add/Edit Sweep** dialog box appears.

   All the independent variables associated with the design are listed in the **Variable** pull-down list of the **Add/Edit Sweep** dialog.

3. Click the variable for which you are defining the sweep definition from the **Variable** pull-down list.

   If you do not define a sweep definition for a variable in the list, the variable's current value in the nominal design is used in the parametric analysis.

4. Specify the variable values to be included in the sweep.
5. Click **Add**, and then click **OK**.

   You return to the **Setup Sweep Analysis** dialog box. The variable sweep is listed in the top half of the window.

6. View the design variations that are to be solved in table format under the **Table** tab. Viewing the sweep definition in table format enables you to visualize the design variations that are to be solved and manually adjust sweep points if necessary.
7. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
8. Click **OK**.

Modifying a Variable Sweep Definition Manually

Overriding a Variable's Current Value in a Parametric Setup

Specifying Variable Values for a Sweep Definition

To specify the variable values to include in a sweep definition:

1. Select one of the following in the Add/Edit Sweep dialog box:

Single value	Specify a single value for the sweep definition.
Linear step	Specify a linear range of values with a constant step size.
Linear count	Specify a linear range of values and the number, or count of points within this range.
Decade count	Specify a logarithmic (base 10) series of values, and the number of values to calculate in each decade.
Octave count	Specify a logarithmic (base 2) series of values, and the number of values to calculate in each octave.
Exponential count	Specify an exponential (base e) series of values, and the number of values to calculate.

2. If you selected **Single value**, type the value of the sweep definition in the **Value** box.

   If you selected another sweep type, do the following:

   a. Type the starting value of the variable range in the **Start** text box.
   b. Type the final value of the variable range in the **Stop** text box.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

3. If you selected **Linear step** as the sweep type, type the step size in the **Step** box.

   The step size is the difference between variable values in the sweep definition. The step size determines the number of design variations between the start and stop values. Maxwell will solve the model at each step in the specified range, including the start and stop values. The step size can be negative, when the **Stop** value is less than the **Start** value

   If you selected another sweep type, type the number of points, or variable values, in the sweep definition in the **Count** text box. For **Decade count** and **Octave count**, the **Count** value specifies the number of points to calculate in every decade or octave. For **Exponential count**, the **Count** value is the total number of points. The total number of points includes the start and stop values.

Related Topics

Synchronizing Variable Sweep Definitions

Synchronizing Variable Sweep Definitions

By default, variable sweep definitions are nested. Alternatively, you can synchronize the variable sweep definitions if they have the same number of sweep points.

For example, if you synchronize a sweep definition that includes values of 1, 2, and 3 inches with a second sweep definition that includes values of 4, 5, and 6 inches, Maxwell will solve 3 design

variations. The first variation is solved at the variable values of 1 and 4; the second variation is solved at the variable values 2 and 5; and the third variation is solved at the final variable values 3 and 6.

To synchronize variable sweep definitions:

1. Under the **Sweep Definitions** tab of the **Setup Sweep Analysis** dialog box, select the rows containing the sweep definitions you want to synchronize.
2. Click **Sync**.

   The synchronized sweeps are given a group number, which is listed in the **Sync #** column.

Optionally, view the design variations that are to be solved in table format under the **Table** tab.

Related Topics

Specifying Variable Values for a Sweep Definitions

Modifying a Variable Sweep Definition Manually

You can manually modify the variable values that are solved for a parametric setup by explicitly changing, adding, or deleting existing points in a variable sweep definition under the **Table** tab of the **Setup Sweep Analysis** dialog box.

To manually modify a variable sweep definition:

1. Click the **Table** tab of the **Setup Sweep Analysis** dialog box.

   The design variations Maxwell solves for the parametric setup listed in table format.
2. Do one of the following:
   - To modify a variable value, click a value text box in the table and type a new value.
   - To delete a variable value from the sweep definition, click the row you want to delete, and then click **Delete**.
   - To add a new variable value to the sweep definition, click **Add**. Then click in the value text box and type a new value.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

Your modifications are tracked and available for viewing at the bottom of the **Setup Sweep Analysis** dialog box under the **Sweep Definitions** tab. The operations you performed are listed with descriptions.

Warning	If you modify an original sweep definition using the **Add/Edit Sweep** dialog box after you have manually modified its table of design variations, your manual modifications become invalid and are removed. A warning is displayed to inform you that your manual values are about to become invalid, so you can decide whether or not to proceed.

Overriding a Variable's Current Value in a Parametric Setup

Overriding a Variable's Current Value in a Parametric Setup

If you choose not to sweep a variable, Maxwell uses the variable's current value set for the nominal design when it solves the parametric setup. To override the current variable value for a parametric setup:

1. In the **Setup Sweep Analysis** dialog box, click the **General** tab.

   Under **Starting Point**, all of the current independent design variable values are listed.
2. Click the **Value** box of the variable with the value you want to override for the parametric setup.
3. Type a new value in the **Value** box, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered will be used for the parametric setup. For this parametric setup, the new value will override the current value in the nominal design.

Note	Alternatively, you can select the **Override** option first, and then type a new variable value in the **Value** box.

4. Optionally, click a new unit in the **Units** box.

To revert to the current variable value, clear the **Override** option.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

Specifying the Solution Quantity to Evaluate for Parametric Analysis

When you add a parametric setup, you can identify one or more solution quantities to be presented in the **Post Analysis Display** dialog box. The solution quantities are specified by mathematical expressions that are composed of basic quantities, such as output variables. When you view the results, Maxwell extracts the solution quantities and lists them in the results table.

1. In the **Setup Sweep Analysis** dialog box, click the **Calculations** tab.

   This displays a table that will show Solutions and associated Calculations. Below the table, are control buttons to **Setup Calculations...** and **Delete**.
2. Click **Setup Calculations**.

   This displays the **Add/Edit Calculation** dialog. The dialog contains panes to set the **Context**, the **Trace** tab for the **Calculation Expression**, and the **Calculation Range** tab for the **Calculation Range**.

   Follow the procedure to Setup Calculations for Optimetrics.
3. Click **Add Calculation** to add the expression in the **Add/Edit Calculation** dialog **Calculation Expression** field to the Calculations tab of the **Setup Sweep Analysis** dialog.
4. Click **Done** to close the **Add/Edit Calculation** dialog.

Setup Calculations for Optimetrics

The **Setup** dialogs for each of the Optimetrics types include a **Setup Calculations** button. Clicking this displays the **Add/Edit Calculation** dialog box. The dialog box contains distinct panes and tabs to set the **Context**, the **Calculation Expression**, and the **Calculation Range**.

The **Context** pane contains fields for the Report Type to use, the Solution, and depending on the Report Type selection, the Geometry.

The **Trace** tab contains fields for the Calculation expression, and, to build the expression, a Category list, a Quantity list with a Text Filter field, and a list of Functions available for the selected Category. The Range function button opens a dialog in which you can define a range function to apply a function to the expression.

The Category list for the **Trace** tab includes Variables and Output Variables. An Output Variables... button lets you open a dialog box to define and edit the Output Variables.

Note	When specifying field calculation for a solution that is defined with varying save field, select "All" time points as the Calculation Range and apply a range function to the Calculation as shown in the parametric setup example below.  Field calculation with geometry context is not supported for a solution that is defined with varying save field.

To setup an Optimetrics calculation:

1. Click the **Setup Calculations** button to open the **Add/Edit/Calculation** dialog.
2. In the **Report Type** text field in the **Context** pane, select from the drop down list of available types.

   Selecting Fields as the Report type causes the **Geometry** field to display.
3. In the **Solution** text box, select from the drop down list of available solutions.
4. If the **Geometry** field is available, select from the drop down list.
5. In the **Trace tab**, specify the solution Category, a Quantity, and Functions. The resulting expression will be displayed in the **Calculation Expression** field.
   a. Select the **Category** from the list.
      The selection appears in the **Calculation Expression** field, and the Quantity and Function fields list what is available for the corresponding selection.
   b. Select the **Quantity** from the list.
      The selected quantity appears in the **Calculation Expression** field.
      If the **Quantity** list is long, you can filter it for easier selection by typing in the text filter field. Only quantities that contain those alphanumeric characters anywhere in their name will remain visible in the list.
      If you want to create an output variable that represents the solution quantity, do the following:
      - Click the **Output Variables** button.

        The **Output Variables** dialog box appears.
      - Add the expression you want to evaluate, and then click **Done**.

        The recently created output variable appears in the **Quantity list**.

- Click a new output variable in the Quantity pull-down list.

Note	The calculation you specify must be able to be evaluated into a single, real number.

The selected Quantity appears in the **Calculation Expression** field.

c. Select the **Function** from the list.
The selected function is applied to the **Quantity** in the **Calculation Expression** field.

6. To apply a **Range function** to the **Calculation Expression**, see Setting a Range function.
7. Click **Add Calculation** to add the expression in the **Add/Edit Calculation** dialog **Calculation Expression** field to the Calculations tab of the **Setup Sweep Analysis** dialog.
8. Click **Done** to close the **Add/Edit Calculation** dialog box.

Related Topics

Specifying a Solution Quantity to Evaluate

Setting a Range Function

Specifying a Solution Quantity's Calculation Range

The calculation range of a solution quantity determines the value of intrinsic variables such as frequency (F) at which the solution quantity will be extracted. For a parametric setup, the calculation range must be a single value.

1. In the **Setup Sweep Analysis** dialog box, click the **Calculations** tab.
2. Click the **Setup Calculations** button.
The **Add/Edit/Calculation** dialog box appears.
3. Select the **Calculation Range** tab.
4. In the **Variable** list, click an intrinsic variable.
Depending on the variable and Report Type, either a single value or All appears in the Value field.
5. To change the Value, click the ellipsis button.to display a dialog box that lets you select particular values, or specify a range of values (for Time sweeps). By default, **Use all values** is selected.
   - For variables other than Time, unchecking **Use all values** enables a list of available values. You can use the buttons to **Clear All** or **Select All** values.
     a. Select the **SweepDefault** or **Edited** radio buttons to specify whether to accept the default or edited sweeps.
     b. To edit the sweeps further, select the ellipsis [**...**] button to display an **Edit Sweep** dialog box. For frequency variables, this lets you specify a single value, linear step, linear count, decade count, octave count, or exponential count. You can **Add** legal values to the list of sweep values, **Update** the list for changes, or **Delete** selected entries.

c. When finished selecting/editing sweep values, close the dialog box. The values you select are displayed in the Value field.

- For Time sweeps:
  a. Select the **Specify range** radio button to enable the **Min** and **Max** value fields.
  b. Enter the desired **Min** and **Max** values, and choose the associated units of measure from the drop down lists.
  c. When finished, close the dialog box. The values you selected are displayed in the Value field.

6. Click **Update**, and then click **Done**.

Using Distributed Analysis

If you have purchased the appropriate license, Maxwell supports distributed solve, which involves distributing rows of a parametric table during Optimetrics solve.

If you do a distributed solve, Maxwell launches solver engines on multiple machines, assuming that you have configured your machines appropriately.

To run a distributed analysis:

1. Under **Optimetrics** in the project tree, right-click the specific parametric setup.
   A shortcut menu appears.
2. Select **Distribute Analysis** from the shortcut menu.

Note	After you define a parametric sweep, a shortcut menu becomes available when you right-click the setup name.

   While the analysis is running, you can access parent and child progress bars. By default, only the main progress bar is displayed, while the child progress bars (or subtasks) remain hidden. You can toggle between showing and hiding the child progress bars.

   To show the child progress bars:

   - Right-click the progress window, and select **Show Subtask Progress Bars**.

   To hide the child progress bars:

   - Right-click the progress window, and select **Hide Subtask Progress Bars**.

Adding a Parametric Sweep from a File

You can specify the parameters for a parametric sweep in a spreadsheet that uses either a .csv (comma delimited) or .txt (tab delimited) format. You can then import the parametric sweep using

the **Maxwell (2D or 3D)>Optimetrics Analysis>Add Parametric from File** command.

For example, a .txt spreadsheet file could resemble the following:

```
a $b $c[in] d[m] $e $f
0.1 mil 2mm 11 21 0.6in 8
0.2mil 3mm 1.3 2.6mm 3 9cm
...
```

The first row lists the Project and Design Variable names, and when followed by parentheses, the units. The following rows provide the variable values and units. Project or Design variables must be defined before they are accepted from a file. The characters in variable names are not case sensitive. Consecutive separators are treated as one separator.

The header row also takes units in ( ) as well as the conventional [ ].

Optimization Overview

Optimetrics interfaces with Ansys Electromagnetics products to enable the optimization of a wide variety of design parameters based on variable geometry, materials, excitations, component values, etc. Optimization is the process of locating the minimum of a user-defined cost function. Optimetrics modifies the variable values until the minimum is reached with acceptable accuracy.

Related Topics

Setting Up an Optimization Analysis

Choosing an Optimizer

Choosing an Optimizer

Conducting an optimization analysis allows you to determine an optimum solution for your problem. In Maxwell optimization analyses, you have five choices of optimizer, though in most cases, the Sequential Nonlinear Programming optimizer is recommended.

- Sequential Nonlinear Programming (SNLP)
- Sequential Mixed Integer NonLinear Programming (SMINLP)
- Quasi Newton
- Pattern Search
- Genetic Algorithm
- MATLAB Optimizer

Additional Optimizers: These use a Decision Support Process (DSP) based on satisfying criteria as applied to the parameter attributes using a weighted aggregate method. In effect, the DSP can

be viewed as a postprocessing action on the Pareto fronts as generated from the results of the various optimization methods.

- Screening (Search based): This is a non-iterative direct sampling method that uses a quasi-random number generator based on the Hammersley algorithm. You can start with Screening to locate the multiple tentative optima and then refine with NLPQL or MISQP to zoom in on the individual local maximum or minimum value. Usually Screening is used for preliminary design, which can lead you to apply one of the other approaches for more refined optimization results.
- Multi-Objective Genetic Algorithm: This is an iterative random search algorithm that can optimize problems with continuous input parameters. It is better for calculating the global optima. You can start with MOGA to locate the multiple tentative optima and then refine with NLPQL or MISQP to zoom in on the individual local maximum or minimum value.
- Nonliner Programming by Quadratic Lagrangian (Gradient): This is a gradient-based, single-objective optimizer based on quasi-Newton methods. Ideally suited for local optimization.
- Mixed-Integer Sequential Quadratic Programming (Gradient and Discrete): This is a gradient-based, single-objective optimizer that solves mixed-integer non-linear programming problems by a modified sequential quadratic programming (SQP) method. Ideally suited for local optimization.
- Adaptive Multiple Objective (Gradient): This is an iterative, multi-objective optimizer that employs a Kriging response surface and MOGA. In this method, the use of a Kriging response surface allows for a more rapid optimization process because all design points are not evaluated except when necessary and part of the population is simulated by evaluations of the Kriging response surface, which is constructed of all design points submitted by Multi-Objective Genetic Algorithm (MOGA).
- Adaptive Single Objective (Gradient): This is a gradient-based, single-objective optimizer that employs an OSF (Optimal Space-Filling) DOE, a Kriging response surface, and MISQP.

The optimizers assume that the nominal problem you are analyzing is close to the optimal solution; therefore, you must specify a domain that contains the region in which you expect to reach the optimum value.

All optimizers allow you to define a maximum limit to the number of iterations to be executed. This prevents you from consuming your remaining computing resources and allows you to analyze the obtained solutions. From this reduced range, you can further narrow the domain of the problem and regenerate the solutions.

All optimizers also allow you to enter a coefficient in the **Add Constraints** window to define the linear relationship between the selected variables and the entered constraint value. For the SNLP and NMINLP optimizers, the relationship can be linear or nonlinear. For the Quasi Newton and Pattern Search optimizers, the relationship must be linear.

Cost functions can be quite nonlinear. As a result, during the function evaluations of the algorithm, the cost function can vary significantly. Also, it is important to understand the relationship between optimization function evaluation and iteration. Every iteration, depending on the number of parameters to be optimized, performs several function evaluations. These function evaluations, depending on how nonlinear the cost function is, could show drastic changes. The presence of drastic changes has no bearing on whether the optimization algorithm converged or not.

In the case of non-gradient search-based optimization algorithms, such as "pattern search," which are entirely based on function evaluations, one could see drastic changes in the function evaluations depending on how nonlinear the cost function is. This could seem misleading as if the algorithm did not converge since in theory one expects the cost function to decrease from one iteration to the next. The optimetrics, however, reports function evaluations and not necessarily the optimizer performance per iteration.

Note	The MATLAB optimizer displays function evaluation when the **Show all functions evaluation** check box is selected. If the check box is not selected, it displays iteration.

Quasi Newton

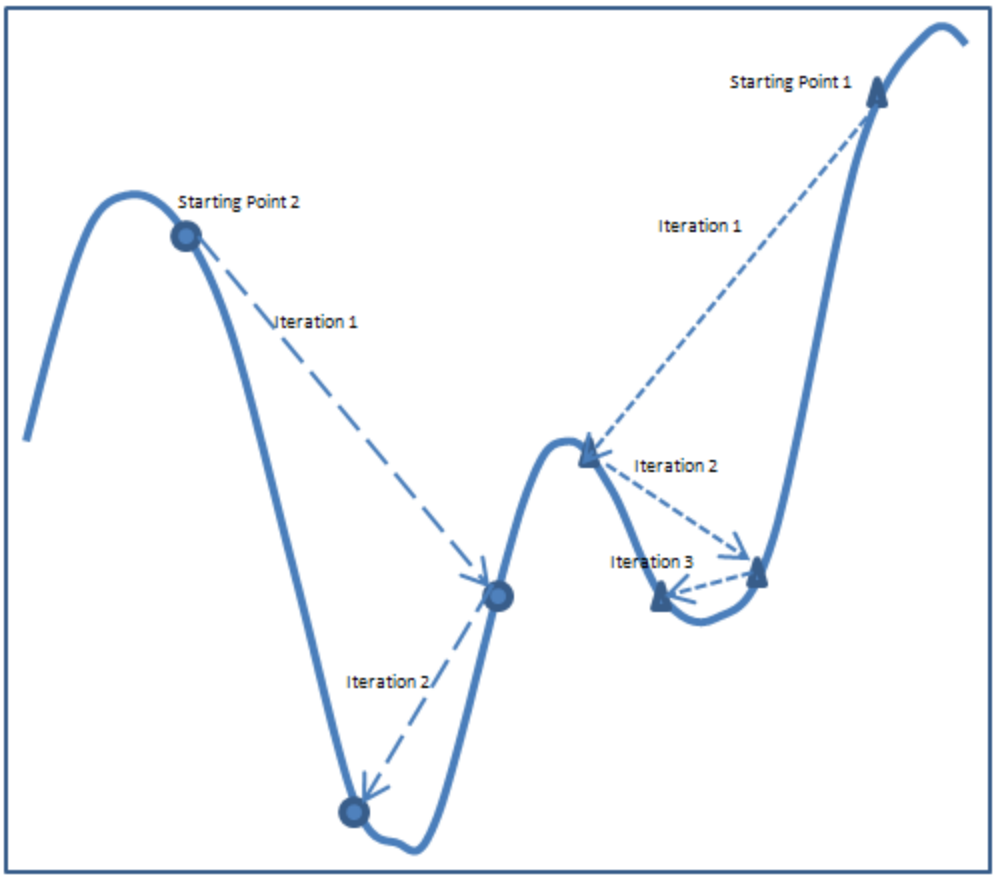
If the Sequential Non Linear Programming Optimizer has difficulty, and if the numerical noise is insignificant during the solution process, use the Quasi Newton optimizer to obtain the results. The Quasi Newton optimizer works on the basis of finding a minimum or maximum of a cost function which relates variables in the model or circuit to overall simulation goals. The user defines one or more variables in the problem definition and a cost function in the optimization setup. The cost function relates the variable values to field quantities, design parameters like force or torque, power loss, etc. The optimizer can then maximize or minimize the value of the design parameter by varying the problem variables.

Sir Isaac Newton first showed that the maximum or minimum of any function can be determined by setting the derivative of a function with respect to a variable (x) to zero and solving for the variable. This approach leads to the exact solution for quadratic functions. However, for higher order functions or numerical analysis, an iterative approach is commonly taken. The function is approximately locally by a quadratic and the approximation is solved for the value of x. This value is placed back into the original function and used to calculate a gradient which provides a step direction and size for determining the next best value of x in the iteration process.

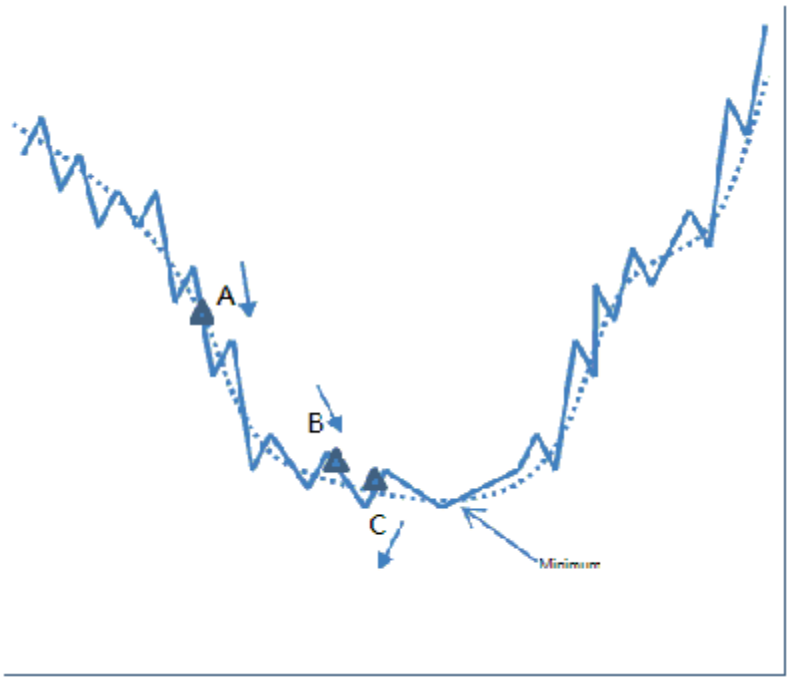
In the Quasi-Newton optimization procedure, the gradients (Hessian) are not well behaved functions and are calculated numerically. Essentially, the change in the estimate of x and the change in the gradient are used to estimate the Hessian for the next iteration. The ratio of the change in the gradients to the change in the values of x provides the Hessian for the next step and is know as the quasi-Newton condition. In order to perform the Quasi-Newton optimization, at least three solutions are required for each parameter being varied. This can have a significant computational cost depending upon the type of analysis being performed.

There are numerous methods described in the literature for solving for the Hessian and the details of the method used by Optimetrics are beyond the scope of this document. However, as the Quasi-Newton method is, at its heart, a gradient method, it suffers from two fundamental problems common to optimization. The first is the possible presence of local minima. The following figure illustrates the problem of local minima. In this scenario, you can see that in order to find the minimum of the function over the domain, a number of factors will determine the overall success including the initial starting point, the initial set of gradients calculated, the allowable step size, etc. Once the optimizer has located a minimum, the Quasi-Newton approach will locate the bottom and will not search further for other possible minima. In the example shown, when the optimizer

begins at the point labeled "Starting Point 1" the minima it finds is a local minima and not a good global solution to the problem.



The second basic issue with Quasi-Newton optimization is numerical noise. In gradient optimization, the derivatives are assumed to be smooth, well behaved functions. However, when the gradients are calculated numerically, the calculation involves taking the differences of numbers that get progressively smaller. At some point, the numerical imprecision in the parameter calculations becomes greater than the differences calculated in the gradients and the solution will oscillate and may never reach convergence. To illustrate this, consider the figure shown below. In this scenario, the optimizer is looking for the point labeled "minimum". Three possible solutions are labeled A, B and C, with each arrow indicating the direction of the derivative of the function at that point. If points A and B represent the last two solution points for the parameter, then it is easy to see that the changes in the magnitude and the consistent direction of the derivatives will serve to push the solution closer to the desired minimum. If, however, points A and C are the last two solution points respectively, the magnitude indicates the proper direction of movement, but the derivatives are opposite, possibly causing the solution to move away from the minimum, back in the direction of point A.



In order to use the Quasi-Newton optimizer effectively, the cost function should be based on parameters that exhibit a smooth characteristic (little numerical noise) and a starting point of the optimization should be chosen somewhat close to the expected minimum based on an understanding of the physical problem being optimized. This becomes increasingly difficult, however, when multiple parameters are being varied or when multiple parameters are to be optimized. In addition, the computational burden of multivariate optimization with Quasi-Newton increases geometrically with the number of variables being optimized. As a result, this method should only be attempted when 1 or 2 variables are being optimized as a time.

For more information regarding Quasi-Newton optimization methods, see the following reference:

Schoenberg, Ronald. *Optimization with the Quasi-Newton Method*. Aptech Systems, Inc. 2001.

Related Topics

Optimization Setup for Quasi Newton Optimizer

Pattern Search

If the noise is significant in the nominal project, use the Pattern Search optimizer to obtain the results. It performs a grid-based simplex search, which makes use of simplices: triangles in 2D space or tetrahedra in 3D space. A simplex is a Euclidean geometric spatial element having the

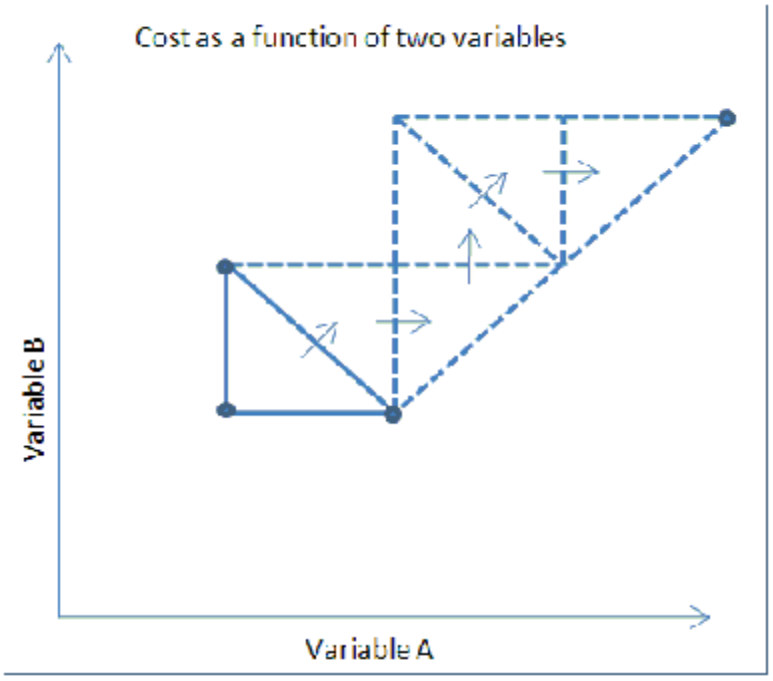
minimum number of boundary points, such as a line segment in one-dimensional space, a triangle in two-dimensional space, or a tetrahedron in three-dimensional space.

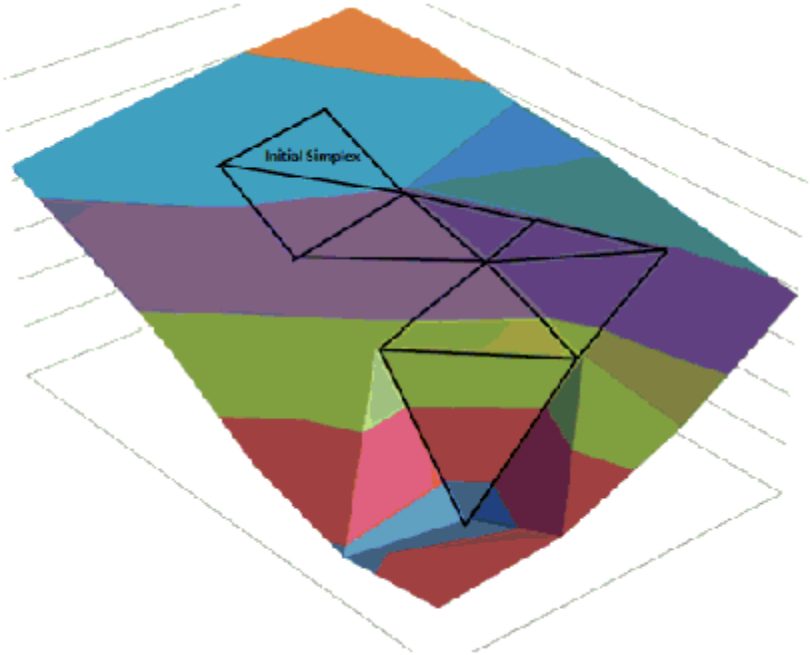
The cost value is calculated at the vertices of the simplex. The optimizer mirrors the simplex across one of its faces based on mathematical guidelines and determines if the new simplex provides better results. If it does not produce a better result, the next face is used for mirroring and the pattern continues. If no improvement occurs, the grid is refined. If improvement occurs, the step is accepted and the new simplex is generated to replace the original one. The figures below illustrates a triangular simplex mirrored several times to demonstrate the pattern search approach in two variables and the simplices superimposed on a 2D cost function to demonstrate the convergence toward a minimum in the cost function.

Cost functions can be quite nonlinear. As a result, during the function evaluations of the algorithm, the cost function can vary significantly. Also, it is important to understand the relationship between optimization function evaluation and iteration. Every iteration, depending on the number of parameters to be optimized, performs several function evaluations. These function evaluations, depending on how nonlinear the cost function is, could show drastic changes. The presence of drastic changes has no bearing on whether the optimization algorithm converged or not.

In the case of non-gradient search-based optimization algorithms, such as "pattern search," which are entirely based on function evaluations, one could see drastic changes in the function evaluations depending on how nonlinear the cost function is. This could seem misleading as if the algorithm did not converge since in theory one expects the cost function to decrease from one iteration to the next. The optimetrics, however, reports function evaluations and not necessarily the optimizer performance per iteration.

Note	The MATLAB optimizer displays function evaluation when the **Show all functions evaluation** check box is selected. If the check box is not selected, it displays iteration.





The Pattern Search algorithms are extensible to three variable optimization by using tetrahedral simplices, however, they are not easily represented in graphical form. Generally, Pattern Search algorithms are not used when more than three variables are used in the optimization.

When there is not improvement in the cost function regardless of the direction the simplex is mirrored, then the simplex is subdivided into smaller simplices and the process restarted.

Pattern Search algorithms have several advantages over Quasi-Newton algorithms. First, they are less sensitive to noise because the cost function is evaluated at all node points on the simplex and the numerical noise averages out over the simplex. The second advantage is that the number of initial solutions is generally smaller as shown in the table. However, since the pattern search does not use gradient information to locate the minimum the process converges more slowly toward the true minimum, taking more steps to successively divide the simplices as the minimum is approached.

Related Topics

Optimization Setup for Pattern Search Optimizer

Sequential Non-linear Programming (SNLP)

The main advantage of SNLP over Quasi Newton is that it handles the optimization problem in more depth. This optimizer assumes that the optimization variables span a continuous space. As a result, there is no Minimum Step Size specified in this optimizer and the variables may take any value within the allowable constraints and within the numerical precision limits of the simulator. Like Quasi Newton, the SNLP optimizer assumes that the noise is not significant. It does reduce the effect of the noise, but the noise filtering is not strong.

The SNLP optimizer approximates the FEA characterization with Response Surfaces (RS). With the FEA-approximation and with light evaluation of the cost function, SNLP has a good approximation of the cost function in terms of the optimization variables. This approximation allows the SNLP optimizer to estimate the location of improving points. The overall cost approximations are more accurate. This allows the SNLP optimizer a faster practical convergence speed than that of quasi Newton.

The SNLP Optimizer creates the response surface using a Taylor Series approximation from the FEA simulation results available from past solutions. The response surface is most accurate in the local vicinity. The response surface is used in the optimization loop to determine the gradients and calculate the next step direction and distance. The response surface acts as a surrogate for the FEA simulation, reducing the number of FEA simulations required and greatly speeding the problem. Convergence improves as more FEA solutions are created and the response surface approximation improves.

The SNLP method is similar to the Sequential Quadratic Programming (SQP) method in two ways: Both are sequential, updating the optimizer state to the current optimal values and iterating. Sequential optimization can be thought of a walking a path, step by step, toward an optimal goal. SNLP and SQP optimizers are also similar in that both use local and inexpensive surrogates.

However, in the SNLP case, the surrogate can be of a higher order and is more generally constrained. The goal is to achieve a surrogate model that is accurate enough on a wider scale, so that the search procedures are well lead by the surrogate, even for relatively large steps. All functions calculated by the supporting finite element product (for example, Maxwell 3D or HFSS) is assumed to be expensive, while the rest of the cost calculation (for example, an extra user-defined expression) — which is implemented in Optimetrics — is assumed to be inexpensive. For this reason, it makes sense to remove inexpensive evaluations from the finite element problem and, instead, implement them in Optimetrics. This optimizer holds several advantages over the Quasi Newton and Pattern Search optimizers.

Most importantly, due to the separation of expensive and inexpensive evaluations in the cost calculation, the SNLP optimizer is more tightly integrated with the supporting FEA tools. This tight integration provides more insight into the optimization problem, resulting in a significantly faster optimization process. A second advantage is that the SNLP optimizer does not require cost-derivatives to be approximated, protecting against uncertainties (noise) in cost evaluations. In addition to derivative-free state of the RS-based SNLP, the RS technique also proves to have noise suppression properties.

Related Topics

Optimization Setup for SNLP Optimizer

Sequential Mixed Integer NonLinear Programming

The Sequential Mixed Integer Nonlinear Programming (SMINLP) optimizer is equivalent to the SNLP optimizer with only one difference. Many problems require variables take only discrete values. One example might be to optimize on the number of turns in a coil. To be able to optimize on number of turns or quarter turns, the optimizer must handle discrete optimization variables. The SMINLP optimizer can mix continuous variables among the integers, or can have only integers, and works if all variables are continuous. The setup resembles the setup for SNLP, except that you must flag the integer variables.supporting integer variables. You can set up internal variables based on the integer optimization variable.

For example, consider N to be an integer optimization variable. By definition it can only assume integer values. You can establish another variable, which further depends on this one: K = 2.345 * N, or K = sin(30 * N). This way K has a discrete value, but is not necessarily integer. Or, one can use N directly as a design parameter.

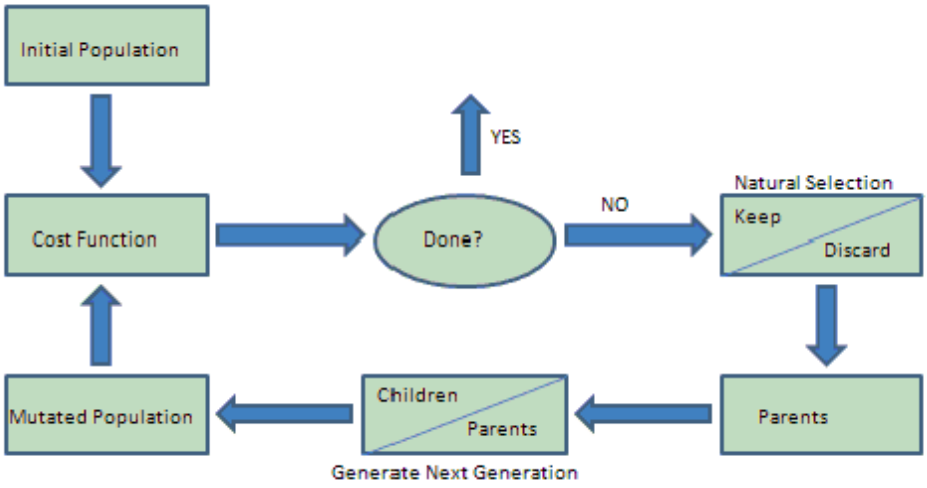
Optimization Setup for SMINLP Optimizer

Genetic Algorithm

Genetic Algorithm (GA) optimizers are part of a class of optimization techniques called stochastic optimizers. They do not use the information from the experiment or the cost function to determine where to further explore the design space. Instead, they use a type of random selection and apply it in a structured manner. The random selection of evaluations to proceed to the next generation has the advantage of allowing the optimizer to jump out of a local minima at the expense of many random solutions which do not provide improvement toward the optimization goal. As a result, the GA optimizer will run many more iterations and may be prohibitively slow.

The Genetic Algorithm search is an iterative process that goes through a number of generations (see picture below). In each generation some new individuals (Children / Number of Individuals) are created and the grown population participates in a selection (natural-selection) process that in turn reduces the size of the population to a desired level (Next Generation / Number of Individuals).



When a smaller set of individuals must be created from a bigger set, the GA selects individuals from the original set. During this process, better fit (in relation to the cost function) individuals are preferred. In the elitist selection, simply the best so many individuals are selected, but if you turn on the roulette selection, then the selection process gets relaxed. An iterative process starts selecting the individuals and fill up the resulting set, but instead of selecting the best so many, we use a roulette wheel that has for each selection-candidate divisions made proportional to the fitness level (relative to the cost function) of the candidate. This means that the fitter the individual is, the larger the probability of his survival will be.

Advanced Genetic Algorithm Optimizer Options

MATLAB Optimizer

The MATLAB optimizer option lets you pass a script to MATLAB to perform the optimization. When the optimization is analyzed, MATLAB is launched and a script is passed in to MATLAB to perform the optimization. During the optimization, MATLAB will call back into our application to perform the solve and compute the cost. The cost will be reported back to MATLAB, and MATLAB's optimization will determine the next step in the optimization.

The optimization script is specified as part of the optimization setup. By modifying the optimization script, users can change the optimization parameters and optimization method as well as use the full power of MATLAB in their optimization.

Running the Optimization

The MATLAB optimization is launched just like any other optimization. The Message Window will display status messages when MATLAB is being launched, and status messages will be generated for each solve that is being performed.

In most cases, MATLAB will terminate when the optimization has been completed. Some reasons why MATLAB would not terminate are:

- The user has modified the MATLAB script to not terminate MATLAB after the optimization.
- A syntax error or some other has occurred.
- The user has added some other code which runs after the optimization has completed.

System Requirements

In order to use MATLAB to perform optimizations from your application:

- A version of MATLAB must be installed on your system.
- The computing platform (i.e. 64 bit or Linux) of MATLAB MUST match the platform of the Ansys application you are using it with.
- You must have the MATLAB Optimization Toolkit installed.

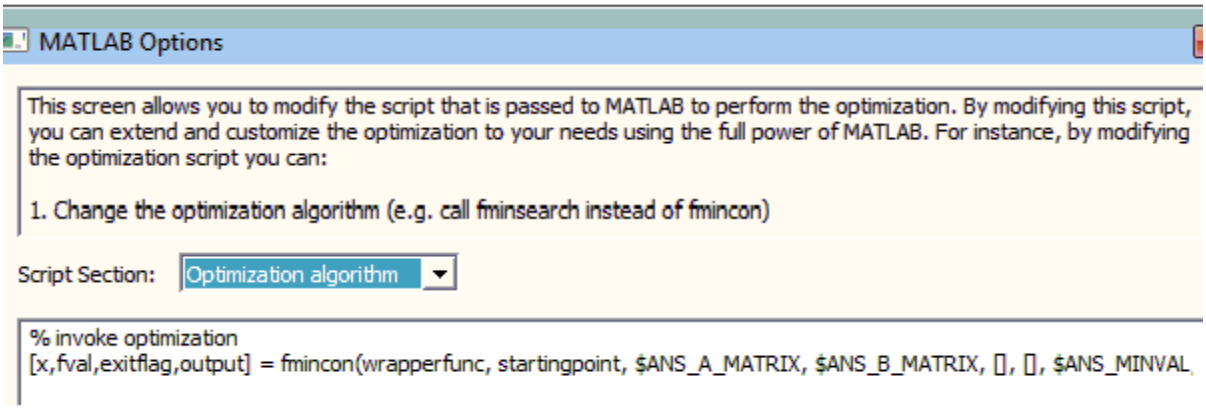
Specifying the MATLAB Location

The Miscellaneous options panel contains a setting for the MATLAB application location. This setting must to point to the version of MATLAB to be used for performing the optimization. The platform (i.e. 64 bit or Linux) of the specified version of MATLAB must match the platform of this application.

MATLAB Optimization Setup

MATLAB optimization starts by creating an optimization and selecting MATLAB from the optimizer dropdown list. If you select MATLAB as the optimizer, the **Setup Optimization** dialog displays a **Setup...** button.

Select **Setup...** to open the **MATLAB Options** dialog.



Thee upper text panel is informative. The Script section drop down lets you select a lower panel display for Optimization algorithm, Options, or the Full script template.

This panel allows you to modify the script that is passed to MATLAB to perform the optimization. The complete script contains all the instructions necessary for MATLAB to connect to Maxwell and perform the optimization. The drop-down selection lets you view only the portion of code of interest without having to view the full script. The choices are:

- **Optimization algorithm**: displays only the line of code invoking the actual optimization function. By changing this line, the user can use a different MATLAB function for optimization. By default we use `fmincon()`, which is a derivative-based constrained optimization. By modifying this line, the user could replace the `fmincon()` call with `fminsearch()` to use an unconstrained pattern searching optimizer or another optimization function. *See the MATLAB documentation for details about available optimization functions.*
- **Options**: Each optimization function contains many options and parameters, which are set in the MATLAB script prior to actually calling the optimization function. By modifying these options, the optimization can be customized as desired. For instance, options can be set for `fmincon()` to specify the algorithm that it uses internally. *See the MATLAB documentation for details about options available for each optimization function.*
- **Full script template**: This choice displays the full optimization script that is passed to MATLAB.

The initial Script Section display for the Optimization algorithm shows the following:

```
% invoke optimization
[x,fval,exitflag,output] = fmincon(wrapperfunc, startingpoint,
[], [], [], [], $ANS_MINVAL, $ANS_MAXVAL, nlcon, options)
```

The initial Script Section Options display shows the following:

```
% customers can add their own options below
options = optimset(options, 'display', 'iter')
options = optimset(options, 'Algorithm', 'interior-point')
% options = optimset(options, 'PlotFcns', @optimplotfval)
```

You can modify the script to extend and customize the optimization to your needs. You must ensure that the script follows MATLAB syntax. For instance, by modifying the optimization script you can:

- Change the optimization algorithm (e.g. call fminsearch instead of fmincon)
- Change the parameters/options of the optimization algorithm (see the MATLAB documentation for details).
- Specify a plot function to provide graphical output during optimization.
- Specify a user defined output function to be called at completion or per iteration.

Symbols:

When modifying the MATLAB code, users can use symbols to represent values from the optimization setup. The symbols and their definitions are listed below.

$ANS_VARIABLE_LIST:	list of variables we are optimizing
$ANS_STARTING_POINT:	vector of starting values of variables used in the optimization
$ANS_MAXITERATIONS:	maximum number of iterations specified in optimization setup
$ANS_MINVAL:	vector of minimum values from optimization setup
$ANS_MAXVAL:	vector of maximum values from optimization setup
$ANS_MINSTEP:	vector of minimum step sizes from optimization setup
$ANS_MAXSTEP:	vector of maximum step sizes from optimization setup
$ANS_A_MATRIX	matrix of linear constraint coefficients (left-hand side) generated from optimization setup
$ANS_B_MATRIX	matrix of linear constraint bounds (right-hand side) generated from optimization setup

Note	The linear constraints as generated for MATLAB have the form [A][x] <= [B], where [A] is the coefficient matrix, [x] is the variable list matrix (column vector), and [B] is the bounds matrix (column vector).

Note	While modifying the script, please ensure that the script follows MATLAB syntax.

MATLAB Optimization Script Template

The script template shown in the Script Section is as follows:

```
% make sure platform matches
if strcmp(computer, '$ANS_EXPECTED_PLATFORM') ~= 1
 h = msgbox('32/64 platform does not match calling application,
exiting')
 uiwait(h)
 exit
end
% add installation dir to search path so .mex file can be found
originalpath = addpath('$ANS_EXEDIR')
% connect back to opticomengine
callbackinterface = optimex('connect', '$ANS_CONNECTIONSTRING')
% set up optimization
% variables are: $ANS_VARIABLELIST
startingpoint = $ANS_STARTINGPOINT
options = optimset('MaxIter', $ANS_MAXITERATIONS)
iterationCallbackWrapper = @(x, optimValues, state) optimex
('notifyiterationcomplete', callbackinterface, x, optimValues.fval,
state)
options = optimset(options, 'OutputFcn', iterationCallbackWrapper)
% halt execution so debugger can be attached
% h = msgbox('attach debugger if desired')
% uiwait(h)
% attributes that user can pass to optimization algorithm
% variables are: $ANS_VARIABLELIST
% this is the objective function which returns cost
wrapperfunc = @(x)optimex('eval', callbackinterface, x)
% this is our non linear constraint function, returns no constraints
returnempty = @(x)[];
nlcon = @(x) deal(returnempty(x), returnempty(x));
% DO NOT EDIT THIS LINE - START OPTIONS SECTION
% customers can add their own options below
options = optimset(options, 'display', 'iter')
options = optimset(options, 'Algorithm', 'interior-point')
% options = optimset(options, 'PlotFcns', @optimplotfval)
% DO NOT EDIT THIS LINE - END OPTIONS SECTION
```

```
% DO NOT EDIT THIS LINE - START OPTIMIZATION ALGO SECTION
% invoke optimization
[x,fval,exitflag,output] = fmincon(wrapperfunc, startingpoint, $ANS_A_
MATRIX, $ANS_B_MATRIX, [], [], $ANS_MINVAL, $ANS_MAXVAL, nlcon,
options)
% DO NOT EDIT THIS LINE - END OPTIMIZATION ALGO SECTION
% write exit message to Ansoft message window
(warning=0,error=1,info=2)
optimex('postansoftmessage', callbackinterface, 2, output.message)
% notify opticomengine that optimization is finished
optimex('optimizationfinished', callbackinterface, exitflag)
% restore original path
path = originalpath
% note: comment below line if you want MATLAB to remain

Screening (Shifted Hammersley Sampling) Optimization

The Screening (Shifted Hammersley Sampling) algorithm is used for sample generation by all methods except NLPQL. The conventional Hammersley sampling algorithm is a quasi-random number generator, which has very low discrepancy and is used for quasi-Monte Carlo simulations.

A low-discrepancy sequence is defined as a sequence of points that approximate the equidistribution in a multi-dimensional cube in an optimal way. This means that the design space is populated almost uniformly by these sequences and that dimensionality is not a problem because of the inherent properties of Monte Carlo sampling. The number of points does not increase exponentially with an increase in the number of input parameters.

The conventional Hammersley sampling algorithm is constructed by using the radical inverse function. Any integer n can be represented as a sequence of digits n_0, n_1, n_2,..., n_m by the following equation:

$$n = n_0 n_1 n_2 n_3 \cdots n_m$$

For example, consider the integer 687459, which can be represented this way as n_0=6, n_1=8, and so on. Because this integer is represented with radix 10, you can write it as 687459=9+5*10+4*100 and so on. In general, for a radix *R* representation, the equation is:

$$n=n_m+n_{m-1}*R+\cdots+n_0$$

The inverse radical function is defined as the function that generates a fraction in (0, 1) by reversing the order of the digits in the previous equation about the decimal point, as shown.

$$\Phi_R(n)=0\,n_m\,n_{m-1}\,n_{m-2}\cdots n_0$$
$$=n_m*R^{-1}+n_{m-1}*R^{-2}+\cdots+n_0*R^{-(m-1)}$$

Thus, for a *k*-dimensional search space, the Hammersley points are given by the following expression:

$$H_k(i)=[i/N,\Phi_{R1}(i),\Phi_{R2}(i),\cdots,\Phi_{Rk-1}(i)]$$

Where *i*=0, ..., *N* indicates the sample points. Now, from the plot of these points, it is seen that the first row (corresponding to the first sample point) of the Hammersley matrix is zero and the last row is not 1. This implies that, for the *k*-dimensional hypercube, the Hammersley sampler generates a block of points that are skewed more toward the origin of the cube and away from the far edges and faces. To compensate for this bias, a point-shifting process is proposed that shifts all Hammersley points by the amount that follows:

$$\Delta=\frac{1}{2}N$$

This moves the point set more toward the center of the search space and avoids unnecessary bias. Thus, the initial population always provides unbiased, low-discrepancy coverage of the search space.

Multi-Objective Genetic Algorithm (MOGA)

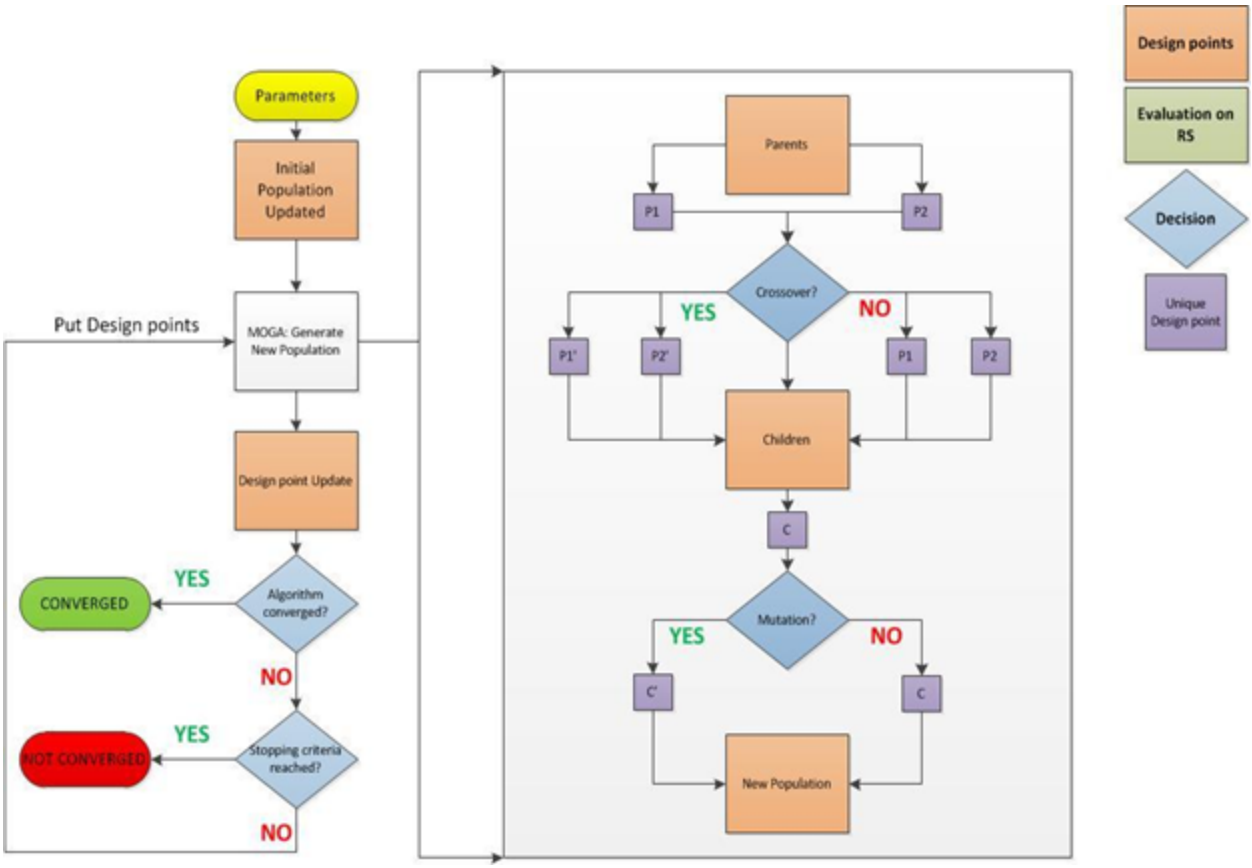
The Multi-Objective Genetic Algorithm (MOGA) used in GDO is a hybrid variant of the popular NSGA-II (Non-dominated Sorted Genetic Algorithm-II) based on controlled elitism concepts. It supports all types of input parameters. The Pareto ranking scheme is done by a fast, non-

dominated sorting method that is an order of magnitude faster than traditional Pareto ranking methods. The constraint handling uses the same non-dominance principle as the objectives. Therefore, penalty functions and Lagrange multipliers are not needed. This also ensures that the feasible solutions are always ranked higher than the infeasible solutions.

The first Pareto front solutions are archived in a separate sample set internally and are distinct from the evolving sample set. This ensures minimal disruption of Pareto front patterns already available from earlier iterations. You can control the selection pressure (and, consequently, the elitism of the process) to avoid premature convergence by altering the Maximum Allowable Pareto Percentage property. For more information about this and other MOGA properties, see Setup Multi-Objective Genetic Algorithm.

MOGA Workflow

The MOGO workflow follows:



MOGA Steps

1. **First Population of MOGA**

   The initial population is used to run MOGA.

2. **MOGA Generates a New Population**

MOGA is run and generates a new population via cross-over and mutation. After the first iteration, each population is run when it reaches the number of samples defined by the Number of Samples Per Iteration property. For details, see **MOGA Steps to Generate New Population** below.

3. **Design Point Update**

   The design points in the new population are updated.

4. **Convergence Validation**

   The optimization is validated for convergence.

   - **Yes: Optimization Converged**

     MOGA converges when the Maximum Allowable Pareto Percentage or the Convergence Stability Percentage has been reached.

   - **No: Optimization Not Converged**

     If the optimization is not converged, the process continues to the next step.

5. **Stopping Criteria Validation**

   If the optimization has not converged, it is validated for fulfillment of stopping criteria.

   - **Yes: Stopping Criteria Met**

     When the Maximum Number of Iterations criterion is met, the process is stopped without having reached convergence.

   - **No: Stopping Criteria Not Met**

     If the stopping criteria have not been met, MOGA is run again to generate a new population (return to Step 2).

6. **Conclusion**

   Steps 2 through 5 are repeated in sequence until the optimization has converged or the stopping criteria have been met. When either of these things occurs, the optimization concludes.

MOGA Steps to Generate a New Population

The process MOGA uses to generate a new population has two main steps: **Cross-over** and **Mutation**.

1. **Cross-over**

   Cross-over combines (mates) two chromosomes (parents) to produce a new chromosome (offspring). The idea behind cross-over is that the new chromosome can be better than both of the parents if it takes the best characteristics from each of the parents. Cross-over occurs during evolution according to a user-definable cross-over probability.

- **Cross-over for Continuous Parameters**

  A cross-over operator that linearly combines two parent chromosome vectors to produce two new offspring according to the following equations:

$$\text{Offspring1}=\mathbf{a}*\text{Parent1}+(1-\mathbf{a})*\text{Parent2}$$
$$\text{Offspring2}=(1-\mathbf{a})*\text{Parent1}+\mathbf{a}*\text{Parent2}$$

Consider the following two parents (each consisting of four floating genes), which have been selected for cross-over:

$$\text{Parent 1: } (0.3)(1.4)(0.2)(7.4)$$
$$\text{Parent 2: } (0.5)(4.5)(0.1)(5.6)$$

If a = 0.7, the following two offspring would be produced:

$$\text{Offspring1: } (0.36)(2.33)(0.17)(6.86)$$
$$\text{Offspring2: } (0.402)(2.981)(0.149)(6.842)$$

- **Cross-over for Discrete Parameters and Continuous Parameters with Manufacturable Values**

Each discrete parameter or continuous parameter with manufacturable values is represented by a binary chain corresponding to the number of levels. For example, a parameter with two values (levels) is encoded to one bit, a parameter with seven values is encoded to three bits, and an -bits chain represents a parameter with values.

The concatenation of these chains forms the chromosome, which crosses over with another chromosome.

Three different kinds of cross-over are available:

- One-Point

A one-point cross-over operator that randomly selects a cross-over point within a chromosome then interchanges the two parent chromosomes at this point to produce two new offspring.

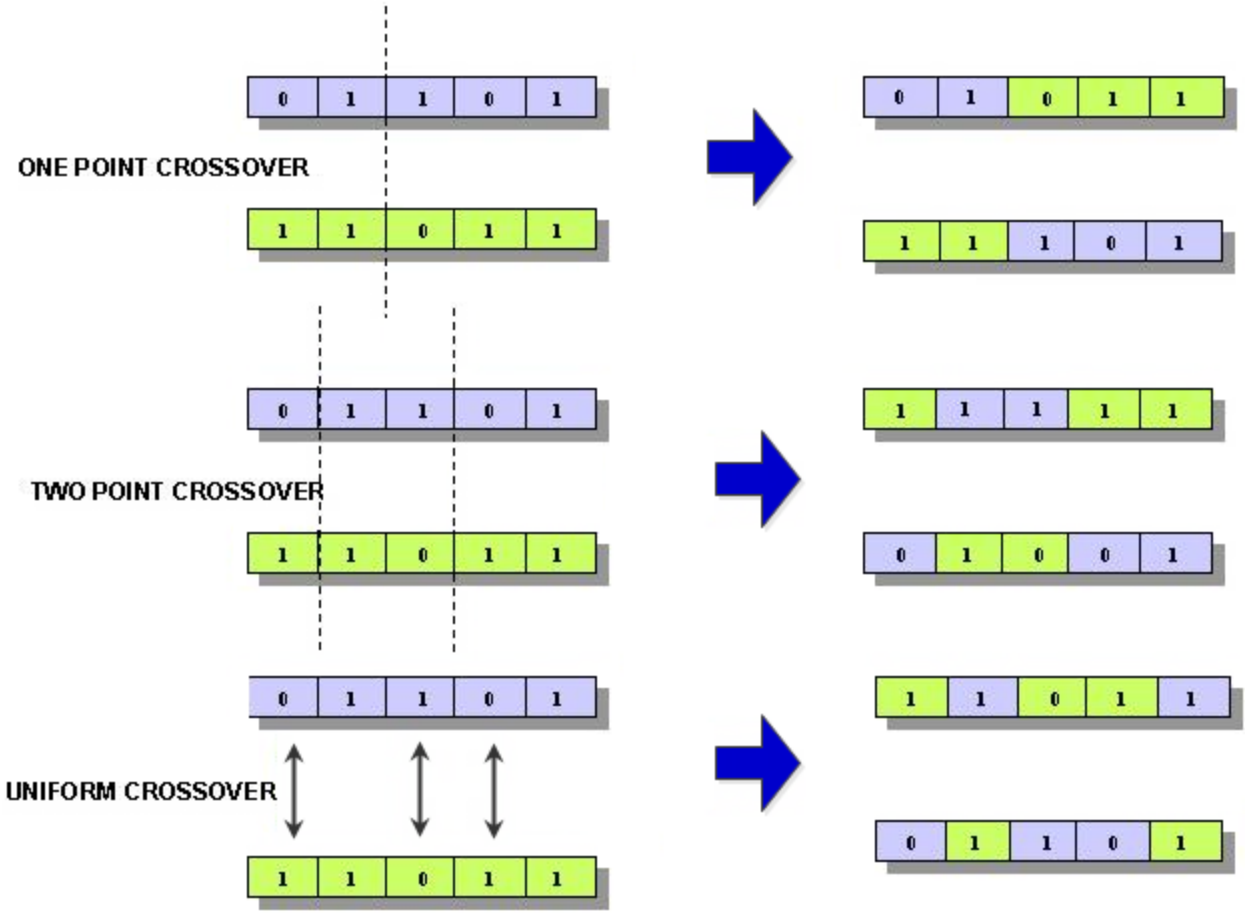
- Two-Point

A two-point cross-over operator randomly selects two cross-over points within a chromosome then interchanges the two parent chromosomes between these points to produce two new offspring.

- Uniform

A uniform cross-over operator decides (with some probability, which is known as the "mixing ratio") which parent contributes each of the gene values in the offspring chromosomes. This allows the parent chromosomes to be mixed at the gene level rather than the segment level (as

with one and two-point cross-over). For some problems, this additional flexibility outweighs the disadvantage of destroying building blocks.



2. **Mutation**

   Mutation alters one or more gene values in a chromosome from its initial state. This can result in entirely new gene values being added to the gene pool. With these new gene values, the genetic algorithm might be able to arrive at a better solution than was previously possible. Mutation is an important part of the genetic search, as it helps to prevent the population from stagnating at any local optima. Mutation occurs during evolution according to a user-defined mutation probability.

   - **Mutation for Continuous Parameters**

   For continuous parameters, a polynomial mutation operator is applied to implement mutation.

$$C = P + (\text{UpperBound} - \text{LowerBound})\delta$$

   where C is the child, P is the parent, and δ is a small variation calculated from a polynomial distribution.

- **Mutation for Discrete Parameters and Continuous Parameters with Manufacturable Values**

  For discrete parameters or continuous parameters with manufacturable values, a mutation operator simply inverts the value of the chosen gene (0 goes to 1 and 1 goes to 0) with a probability of 0.5. This mutation operator can only be used for binary genes. The concatenation of these chains forms the chromosome, which crosses over with another chromosome.

Convergence Criteria in MOGA-Based Multi-Objective Optimization

Convergence criteria are the conditions that indicate when the optimization has converged. In the Multi-Objective Genetic Algorithm (MOGA)-based multi-objective optimization methods, the following convergence criteria are available:

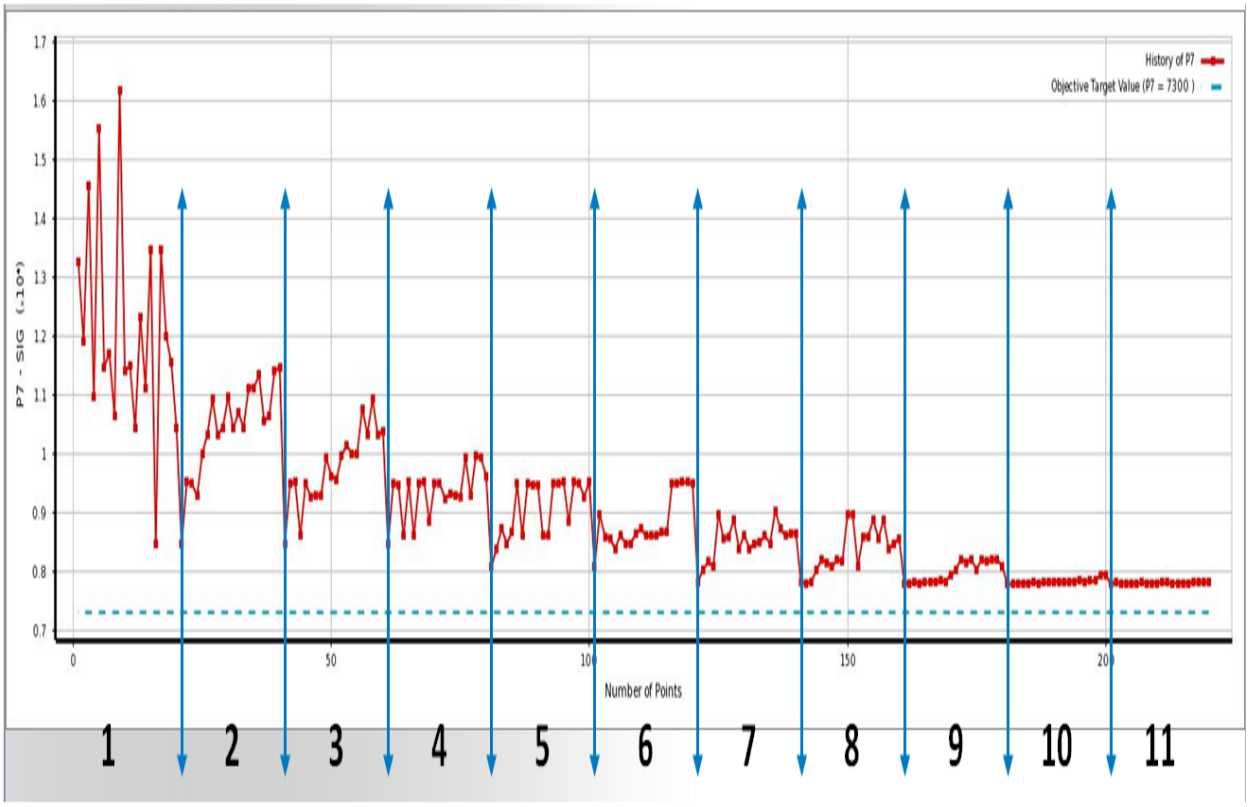
Maximum Allowable Pareto Percentage

The **Maximum Allowable Pareto Percentage** criterion looks for a percentage that represents a specified ratio of Pareto points per Number of Samples Per Iteration. When this percentage is reached, the optimization is converged.

Convergence Stability Percentage

The **Convergence Stability Percentage** criterion looks for population stability, based on mean and standard deviation of the output parameters. When a population is stable with regards to the previous one, the optimization is converged. The criterion functions in the following sequence:

- **Population 1**: When the optimization is run, the first population is not taken into account. Because this population was not generated by the MOGA algorithm, it is not used as a range reference for the output range (for scaling values).
- **Population 2**: The second population is used to set the range reference. The minimum, maximum, range, mean, and standard deviation are calculated for this population.
- **Populations 3 – 11**: Starting from the third population, the minimum and maximum output values are used in the next steps to scale the values (on a scale of 0 to 100). The mean variations and standard deviation variations are checked. If both of these are smaller than the value for the Convergence Stability Percentage property, the algorithm is converged.



At each iteration and for each active output, convergence occurs if:

$$\frac{|Mean_i - Mean_{i-1}|}{Max - Min} < \frac{S}{100}$$

and

$$\frac{|StdDev_i - StdDev_{i-1}|}{Max - Min} < \frac{S}{100}$$

Where:

S=Stability Percentage

$Mean_i$= Mean of the *i*-th Population

$StdDev_i$ = Standard Deviation of the *i*-th Population

Max = Maximum Output Value calculated on the first generated population of MOGA

Min = Minimum Output Value calculated on the first generated population of MOGA

Related Topics

Convergence Rate % and Initial Finite Difference Delta % in NLPQ and MISQP

Typically, the use of Nonlinear Programming by Quadratic Lagrangian (NLPQL) or Mixed-Integer Sequential Quadratic Programming (MISQP) optimizers is suggested for continuous problems when there is only one objective function. The problem might or might not be constrained and must be analytic. This means that the problem must be defined only by continuous input parameters and that the objective functions and constraints should not exhibit sudden "jumps" in their domain.

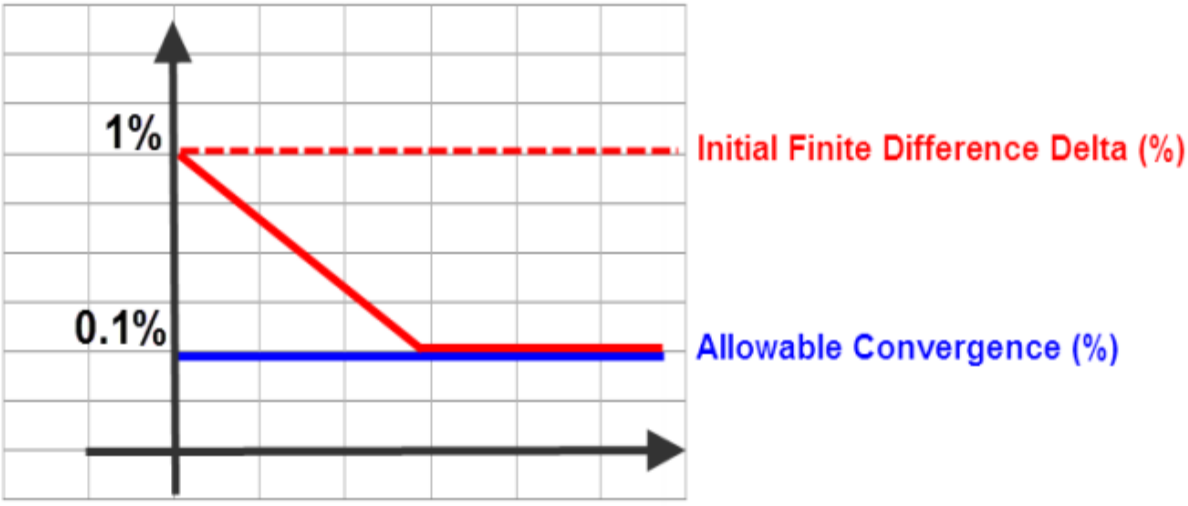
The main difference between these algorithms and Multi-Objective Genetic Algorithm (MOGA) is that MOGA is designed to work with multiple objectives and does not require full continuity of the output parameters. However, for continuous single objective problems, the use of NLPQL or MISQP gives greater accuracy of the solution as gradient information and line search methods are used in the optimization iterations. MOGA is a global optimizer designed to avoid local optima traps, while NLPQL and MISQP are local optimizers designed for accuracy.

For NLPQL and MISQP, the default convergence rate, which is specified by the Allowable Convergence (%) property, is set to 0.1% for a Direct Optimization system. The maximum value for this property is 100%. This is computed based on the (normalized) Karush-Kuhn-Tucker (KKT) condition. This implies that the fastest convergence rate of the gradients or the functions (objective function and constraint) determine the termination of the algorithm.

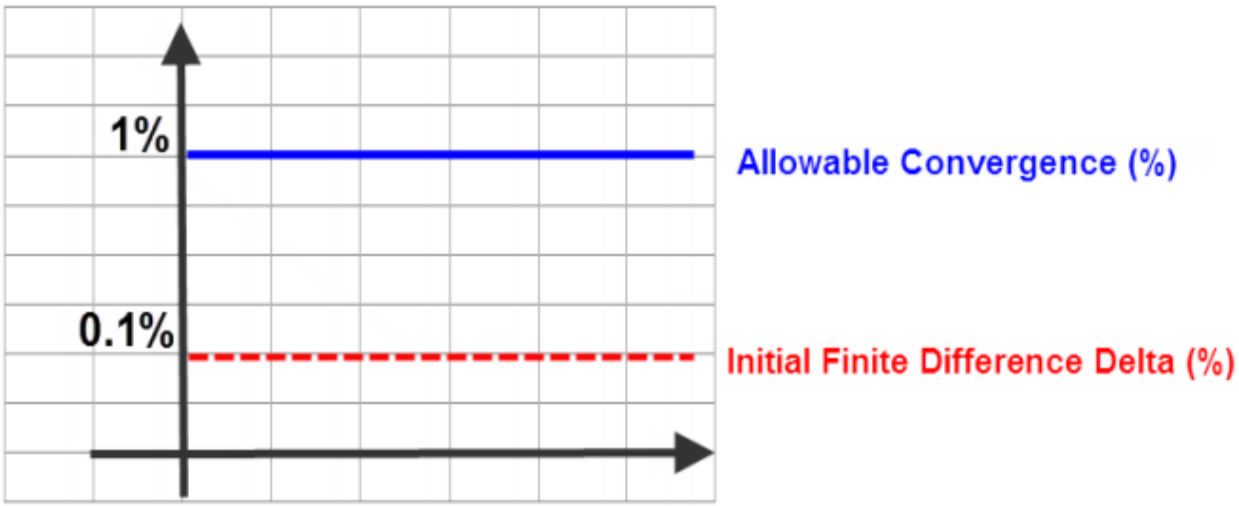
The default convergence rate is used in conjunction with the initial finite difference delta percentage value, which is specified by the Initial Finite Difference Delta (%) advanced property. This property defaults to 1% for a Direct Optimization system. You use this property to specify a percentage of the variation between design points to ensure that the Delta use in the calculation of finite differences is large enough to be seen over simulation noise. The specified percentage is defined as a relative gradient perturbation between design points.

The advantage of this approach is that for large problems, it is possible to get a near-optimal feasible solution quickly without being trapped into a series of iterations involving small solution steps near the optima. To work most effectively with NLPQL and MISQP, keep the following guidelines in mind:

- If the Initial Finite Difference Delta (%) is greater than the Allowable Convergence (%), the relative gradient perturbation gets iteratively smaller, until it matches the allowable convergence rate. At this point, the relative gradient value stays the same through the rest of the analysis.



- If the Initial Finite Difference Delta (%) is less than or equal to the Allowable Convergence (%), the current relative gradient step remains constant through the rest of the analysis.



- Both the Initial Finite Difference Delta (%) and Allowable Convergence (%) should be higher than the magnitude of the noise in your simulation.

When setting the values for these properties, you have the usual trade-offs between speed and accuracy. Smaller values result in more convergence iterations and a more accurate (but slower) solution, while larger values result in fewer convergence iterations and a less accurate (but faster) solution. At the same time, however, you must be aware of the amount of noise in your model. For the input variable variations to be visible in the output variables, both values must be greater than the magnitude of the simulation's noise.

In general, default values for Initial Finite Difference Delta (%) and Allowable Convergence (%) cover the majority of optimization problems. For example, if you know that the noise magnitude in

your direct optimization problem is 0.0001, then the default values (Allowable Convergence (%) = 0.001 and Initial Finite Difference Delta (%) = 0.01) are good.

When the defaults are not a good match for your problem, of course, you can adjust the values to better suit your model and your simulation needs. If you require a more numerically accurate solution, you can set the convergence rate to as low as 1.0E-10% and then set the Initial Finite Difference Delta (%) accordingly.

Related Topics

Mixed-Integer Sequential Quadratic Programming

Mixed-Integer Sequential Quadratic Programming (MISQP) is a mathematical optimization algorithm as developed by Oliver Exler, Thomas Lehmann and Klaus Schittkowski (NLPQL). This method solves Mixed-Integer Non-Linear Programming (MINLP) of the form:

Minimize:

$$f(x,y)$$

Subject to:

$$g_j(x,y)=0,\ j=1,\ldots,m_e,$$

$$g_j(x,y)\geq 0,\ j=m_e+1,\ldots,m$$

Where:

$$x\in\mathbb{R}^{n_c}, y\in\mathbb{N}^{n_i}$$

$$x_l\leq x\leq x_u$$

$$y_l\leq y\leq y_u$$

The symbols and denote the vectors of the continuous and integer variables, respectively. It is assumed that problem functions and are continuously differentiable subject to all . It is not assumed that integer variables can be relaxed. In other words, problem functions are evaluated only at integer points and never at any fractional values in between.

MISQP solves MINLP by a modified sequential quadratic programming (SQP) method. After linearizing constraints and constructing a quadratic approximation of the Lagrangian function, mixed-integer quadratic programs are successively generated and solved by an efficient branch-and-cut method. The algorithm is stabilized by a trust region method as originally proposed by Yuan for continuous programs. Second order corrections are retained. The Hessian of the

Lagrangian function is approximated by BFGS updates subject to the continuous and integer variables. MISQP is able to solve also non-convex nonlinear mixed-integer programs.

Setup Mixed Integer Quadratic Sequential Optimization

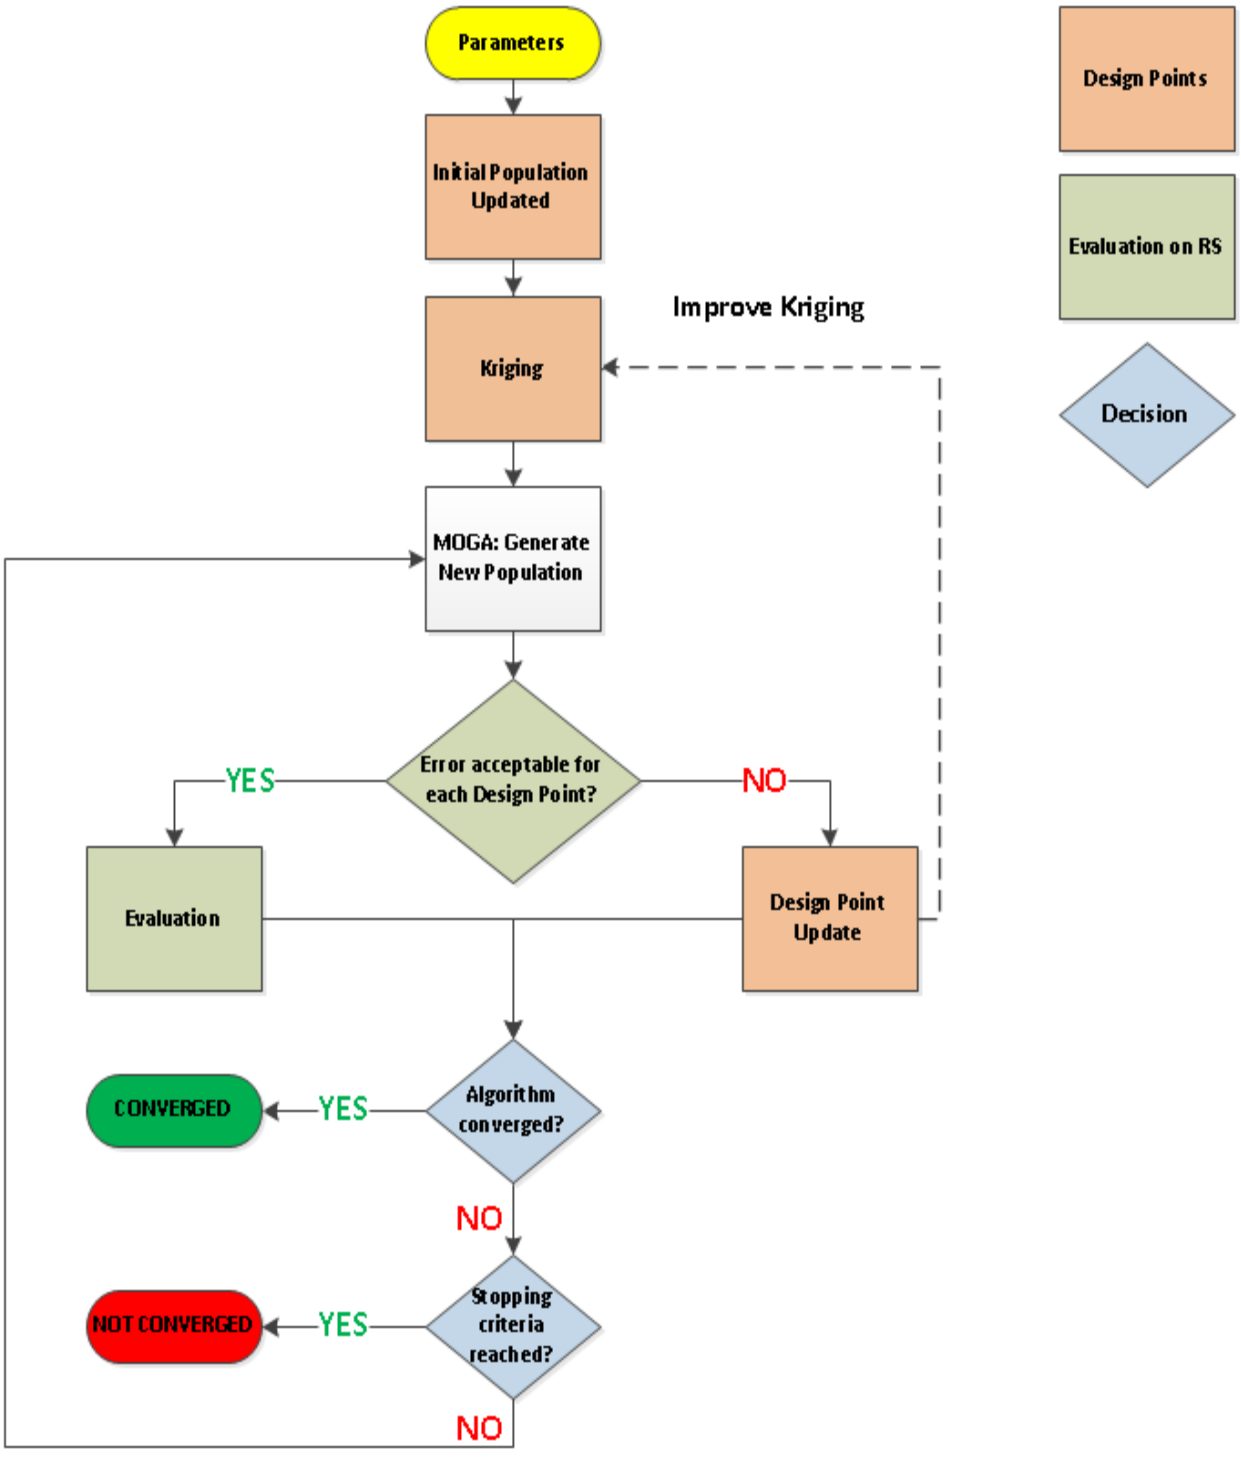
Adaptive Multiple Objective Optimization

Adaptive Multiple-Objective (AMO) is a mathematical optimization that combines a Kriging response surface and MOGA. It allows you to either generate a new sample set or use an existing set, providing a more refined approach than the Screening method. Except when necessary, the optimizer does not evaluate all design points. The general optimization approach is the same as MOGA, but a Kriging response surface is used. Part of the population is "simulated" by evaluations of the Kriging response surface. The Kriging error predictor reduces the number of evaluations used in finding the first Pareto front solutions.

AMO supports multiple objectives and multiple constraints. It is limited to continuous parameters, including those with manufacturable values. It is available only for a Direct Optimization system. When discrete parameters are used, MOGA is the more efficient optimization method. For more information, see Multi-Objective Genetic Algorithm (MOGA).

AMO Workflow

The workflow of AMO follows:



AMO Steps

1. **First Population of MOGA**

   The initial population is used to run MOGA.

2. **Kirging Generation**

   A Kriging response surface is created for each output, based on the first population and then improved during simulation with the addition of new design points.

3. **MOGA**

   MOGA is run, using the Kriging response surface as an evaluator. After the first iteration, each population is run when it reaches the number of samples defined by the Number of Samples Per Iteration property.

4. **Evaluate the Population**

5. **Error Check**

   The Kriging error predictor is checked for each point.

   - **Yes: Error Acceptable**

     Each point is validated for error. If the error for a given point is acceptable, the approximated point is included in the next population to be run through MOGA (return to Step 3).

   - **No: Error Not Acceptable**

     If the error is not acceptable, the points are promoted as design points. The new design points are used to improve the Kriging response surface (return to Step 2) and are included in the next population to be run through MOGA (return to Step 3)

6. **Convergence Validation**

   The optimization is validated for convergence.

   - **Yes: Optimization Converged**

   MOGA converges when the maximum allowable Pareto percentage has been reached. When this happens, the process is stopped.

   - **No: Optimization Not Converged**

     If the optimization is not converged, the process continues to the next step.

7. **Stopping Criteria Validation**

   If the optimization has not converged, it is validated for fulfillment of the stopping criteria.

   - **Yes: Stopping Criteria Met**

   When the maximum number of iterations has been reached, the process is stopped without having reached convergence..

   - **No: Stopping Criteria Not Met**

   If the stopping criteria have not been met, the MOGA algorithm is run again (return to Step 3).

8. **Conclusion**

   Steps 2 through 7 are repeated in sequence until the optimization has converged or the stopping criteria have been met. When either of these things occurs, the optimization concludes.

Optimization Variables in Design Space

Cost Function

Adaptive Single Objective Optimization

Adaptive Single-Objective (ASO) is a mathematical optimization method that combines an OSF (Optimal Space-Filling) DOE, a Kriging response surface, and MISQP. It is a gradient-based algorithm based on a response surface, which provides a refined, global, optimized result.

ASO supports a single objective and multiple constraints. It is available for continuous parameters, including those with manufacturable values. It does not support the use of parameter relationships in the optimization domain and is available only for a Direct Optimization system.

Like MISQP, ASO solves constrained nonlinear programming problems of the form:

Minimize:

$$f = f(\{x\})$$

Subject to:

$$g_k(\{x\}) \leq 0, \forall k = 1,2,\ldots,K$$

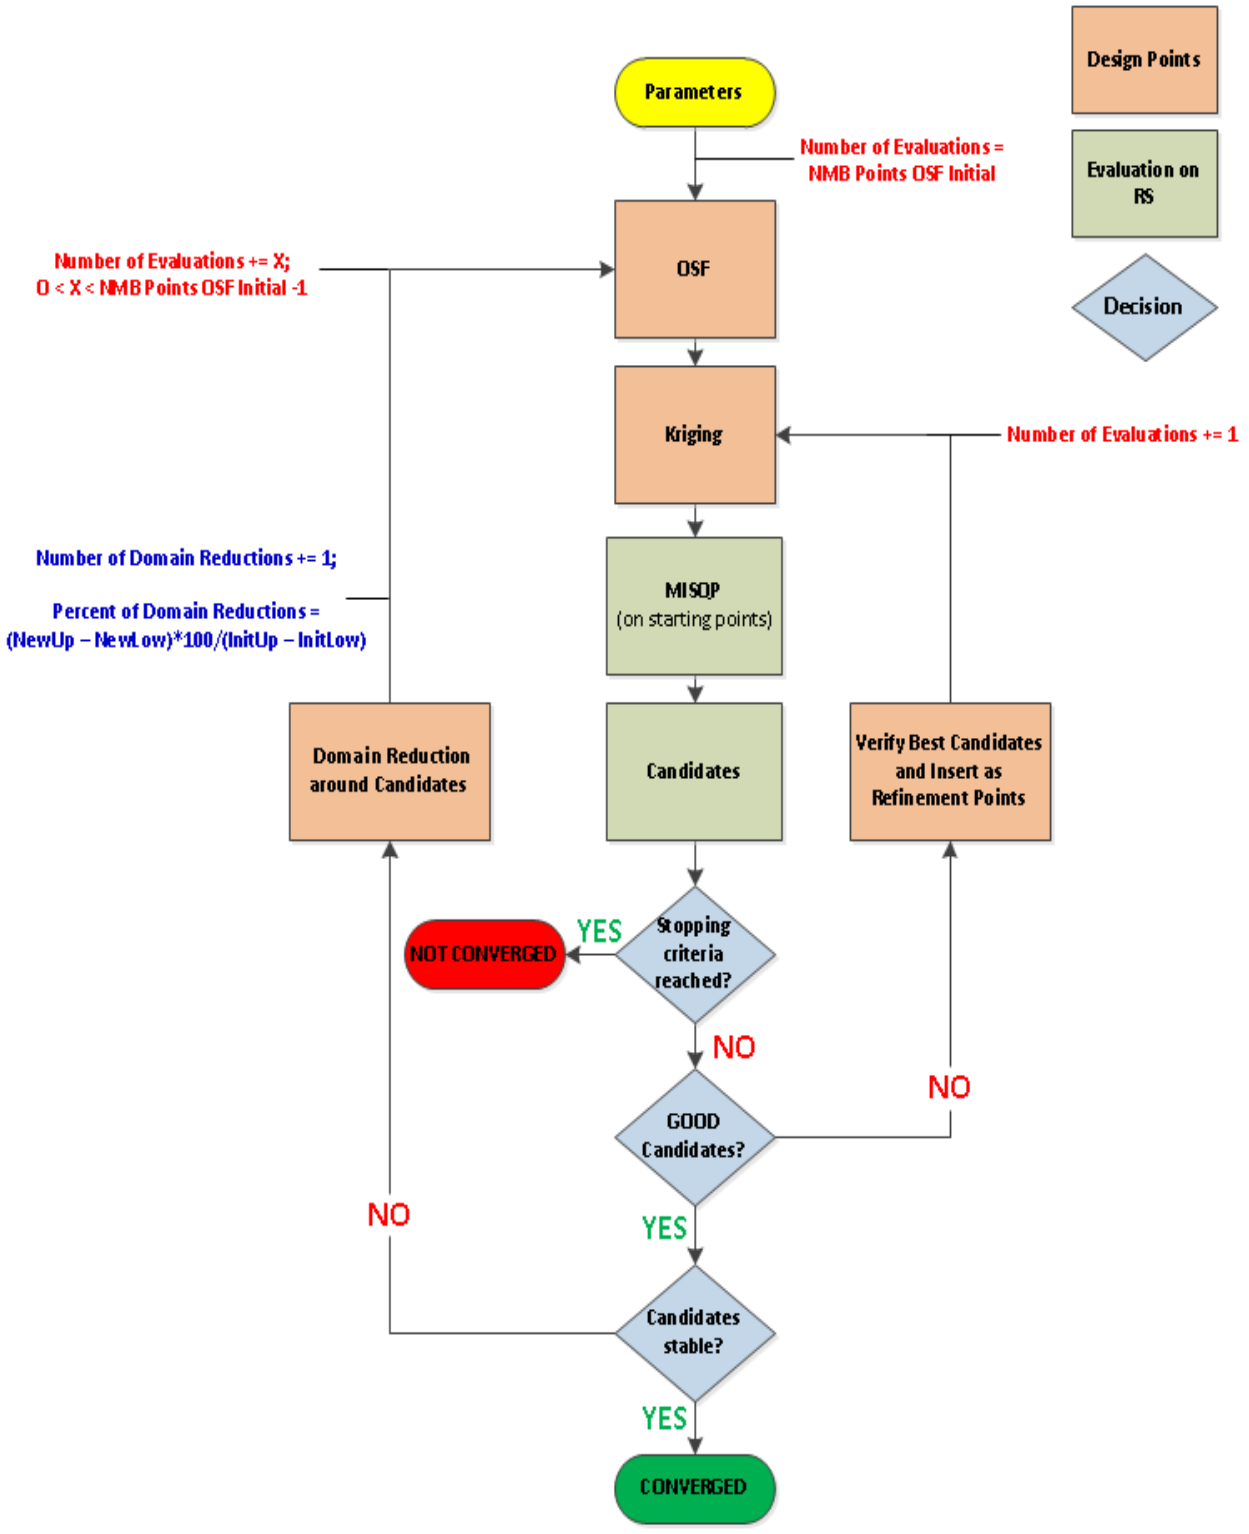
$$h_l(\{x\}) = 0, \forall I = 1,2\ldots,L$$

Where:

$$\{x_L\} \leq \{x\} \leq \{x_U\}$$

ASO Workflow

The workflow of ASO follows:



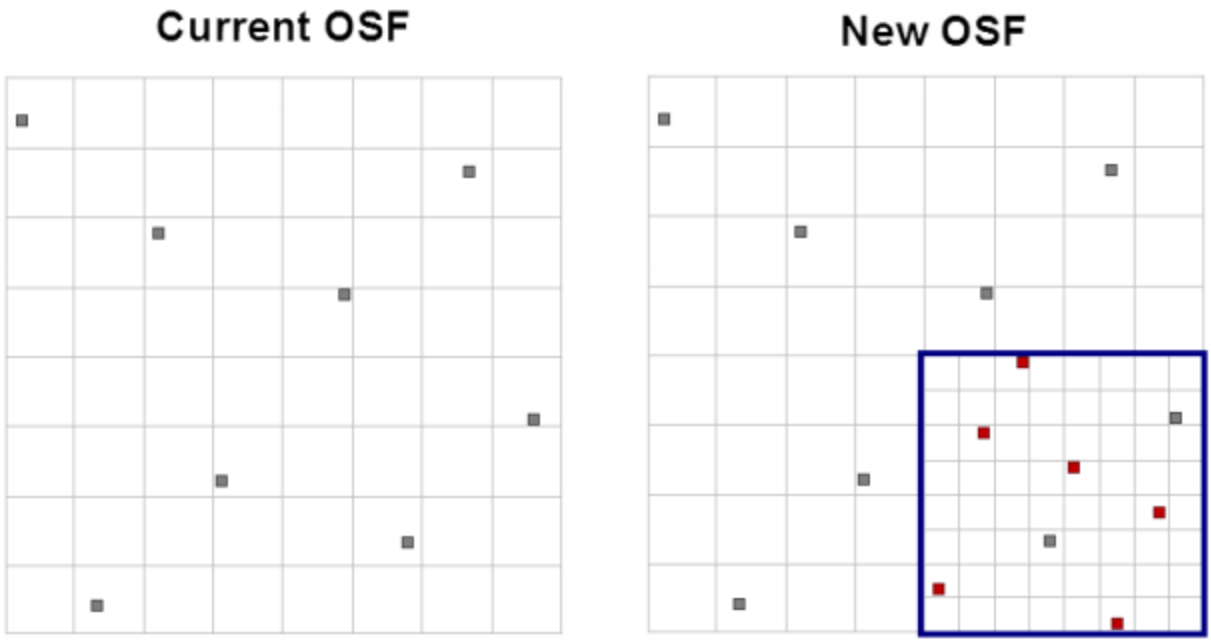
AMO Steps

1. **OSF Sampling**

   OSF (Optimal Space-Filling Design) is used for the Kriging construction. In the original OSF, the number of samples equals the number of divisions per axis and there is one sample in each division.

   When a new OSF is generated after a domain reduction, the reduced OSF has the same number of divisions as the original and keeps the existing design points within the new bounds. New design points are added until there is a point in each division of the reduced domain.

   In the following example, the original domain has eight divisions per axis and contains eight design points. The reduced domain also has eight divisions per axis and includes two of the original design points. To have a design point in each division, six new design points need to be added.



2. **Kirging Generation**

   A response surface is created for each output, based on the current OSF and consequently on the current domain bounds.

   A Kriging response surface is created for each output, based on the first population and then improved during simulation with the addition of new design points.

   For more information on Kriging algorithms, see Kriging Algorithms.

3. **MISQP**

   MISQP is run on the current Kriging response surface to find potential candidates. A few MISQP processes are run at the same time, beginning with different starting points, and consequently, giving different candidates.

4. **Candidate Point Validation**

   All the obtained candidates are either validated or not, based on the Kriging error predictor. The candidate point is checked to see if further refinement of the Kriging surface changes the selection of this point. A candidate is considered as acceptable if there aren't any points, according to this error prediction, that call it into question. If the quality of the candidate is not called into question, the domain bounds are reduced. Otherwise, the candidate is calculated as a verification point.

   - **Refinement Point Creation** (If the selection is ***not*** to be changed)

     When a new verification point is calculated, it is inserted in the current Kriging response surface as a refinement point and the MISQP process is restarted.

   - **Domain Reduction**(If the selection is to be changed)

     When candidates are validated, new domain bounds must be calculated. If all of the candidates are in the same zone, the bounds are reduced, centered on the candidates. Otherwise, the bounds are reduced as an inclusive box of all candidates. At each domain reduction, a new OSF is generated (conserving design points between the new bounds) and a new Kriging response surface is generated based on this new OSF.

5. **Convergence and Stop Criteria**

   The optimization is considered to be converged when the candidates found are stable. This occurs when all of the MISQP processes run on the response surface converge to the same verified candidate point. However, there are four stop criteria that can stop the algorithm: Maximum Number of Evaluations, Maximum Number of Domain Reductions, Percentage of Domain Reductions, and Convergence Tolerance.

Optimization Variables in Design Space

Cost Function

Optimization Variables and the Design Space

Once the optimization variables are specified, the optimizer handles each of them as an *n*-dimensional vector *x*. Any point in the design space corresponds to a particular *x*-vector and to a design instance. Each design instance may be evaluated via FEA and assigned a cost value;

therefore, the cost function is defined over the design space (cost(*x*): $R^n \rightarrow R$, where *n* is the number of optimization variables.

In practice, a solution of the minimization problem is sought only on a bounded subset of the Rn space. This subset is called the feasible domain and is defined via linear constraints.

Setting Up an Optimization Analysis

Optimization allows you to vary predefined variables in the nominal design to search for the solution that best satisfies a set of user defined goals or cost functions. Optimetrics modifies the variable values until the minimum is reached with acceptable accuracy.

Note	• You can define more than one optimization analysis setup per design. • You can create an Optimization setup before defining variables but all variables must be defined before you start the Optimization analysis. • Once you have created an optimization analysis setup, you can copy and paste it, and then make changes to the copy, rather than redoing the whole process for minor changes.

To provide a broad range of capability, Optimetrics incorporates the following types of numerical optimizers:

- Sequential Nonlinear Programming (Gradient) (SNLP)
- Sequential Mixed Integer Nonlinear Programming (Gradient and Discrete) (SMINLP)
- Quasi Newton (Gradient)
- Pattern Search (Search-based)
- Genetic Algorithm (Random search)
- MATLAB
- Screening (Search based)
- Multi-Objective Genetic Algorithm
- Non-linear Programming by Quadratic Lagrangian (Gradient)
- Mixed-Integer Sequential Quadratic Programming (Gradient and Discrete)
- Adaptive Multiple Objective (Gradient)
- Adaptive Single Objective (Gradient)

Click on the links above to view the setup procedure for each optimizer. Options for the analysis are listed in the table.

The following ***optional*** optimization solution setup options can also be used:

- Modify the starting variable value.
- Modify the minimum and maximum values of variables that will be optimized.
- Exclude variables from optimization.
- Modify the values of fixed variables that are not being optimized.
- Set the minimum and maximum step size between solved design variations (For the Quasi Newton and Patterns Search optimizers, Variables tab).
- Set the minimum and maximum focus size. (For the SNLP and SMINLP optimizers, Variables tab).
- Set Linear constraints.
- Request that Optimetrics solve a parametric sweep before an optimization analysis.
- Request that Optimetrics solve a parametric sweep during an optimization analysis.
- Automatically update optimized variables to the optimal values during an optimization or after an optimization analysis is completed.

- Change the norm used for the cost function calculation (Advanced Option)
- Set **HPC and Analysis Options**, which allows you to select or create an analysis configuration.

Note	Sweeping or using a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

Optimization Overview

Choosing an Optimizer

Optimization Setup for the Quasi Newton(Gradient) Optimizer

Following is the procedure for setting up an optimization analysis using the Quasi Newton (gradient) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Optimization**  .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Quasi Newton(Gradient)** from the **Optimizer** pull-down list. Selecting Quasi Newton enables the **Acceptable Cost** and **Noise** fields.
4. Type the maximum number of iterations you want Optimetrics to perform during the optimization analysis in the **Max. No. of Iterations** text box.
5. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
6. Type the value of the cost function at which the optimization process should stop in the **Acceptable Cost** text box.
7. Type the cost function noise in the **Noise** text box.
8. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

   The **Cost Function Norm Type** pull-down list appears.

   - Select **L1**, **L2**, or **Maximum**.

   A norm is a function that assigns a positive value to the cost function.

For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

9. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Step Size** for the analysis.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
12. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation.This will provide some speed improvement in the overall optimization process.

Optimization Setup for the Pattern Search (Search-based) Optimizer

Following is the procedure for setting up an optimization analysis using the Pattern Search (Search-based) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Optimization**  .

The **Setup Optimization** dialog box appears.

3. Under the **Goal**s tab, select the optimizer by selecting **Pattern Search(Search-based)** from the **Optimizer** pull-down list. Selecting Pattern Search enables the **Acceptable Cost** and **Noise** fields.
4. Type the maximum number of iterations you want Optimetrics to perform during the optimization analysis in the **Max. No. of Iterations** text box.
5. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
6. Type the value of the cost function at which the optimization process should stop in the **Acceptable Cost** text box.
7. Type the cost function noise in the **Noise** text box.
8. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

   The **Cost Function Norm Type** pull-down list appears.

   - Select **L1**, **L2**, or **Maximum**.

   A norm is a function that assigns a positive value to the cost function.

   For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

   The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

9. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Step Size** for the analysis.
    - You may also override the variable starting values by clicking the **Override** checkbox and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.

12. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation.This will provide some speed improvement in the overall optimization process.

Optimization Setup for the Sequential Nonlinear Programming (Gradient) Optimizer

Following is the procedure for setting up an optimization analysis using the Sequential Nonlinear Programming (Gradient) Optimizer or SNLP Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Optimization**  .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Sequential Nonlinear Programming(Gradient)** from the **Optimizer** pull-down list.
4. Type the maximum number of iterations you want Optimetrics to perform during the optimization analysis in the **Max. No. of Iterations** text box.
5. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
6. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

   The **Cost Function Norm Type** pull-down list appears.

   - Select **L1**, **L2**, or **Maximum**.

   A norm is a function that assigns a positive value to the cost function.

   For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

7. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
8. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Focus** for the analysis.
   - You may also override the variable starting values by clicking the **Override** checkbox and entering the desired value in the **Starting Value** field.
   - Optionally, modify the values of fixed variables that are not being optimized.
   - Optionally, set Linear constraints.
   - Select the **View all columns** check box to see all columns, including hidden columns.
9. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

   Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
10. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation.This will provide some speed improvement in the overall optimization process.

Optimization Setup for the Sequential Mixed Integer Nonlinear Programming (Gradient and Discrete) Optimizer

Following is the procedure for setting up an optimization analysis using the Sequential Mixed Integer Nonlinear Programming (Gradient and Discrete) Optimizer or SMINLP. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click

   Add Optimization .

   The **Setup Optimization** dialog box appears.

3. Under the **Goals** tab, select the optimizer by selecting **Sequential Mixed Integer Nonlinear Programming(Gradient and Discrete)** from the **Optimizer** pull-down list.
4. Type the maximum number of iterations you want Optimetrics to perform during the optimization analysis in the **Max. No. of Iterations** text box.
5. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
6. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

   The **Cost Function Norm Type** pull-down list appears.

   - Select **L1**, **L2**, or **Maximum**.

   A norm is a function that assigns a positive value to the cost function.

   For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

   The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.
7. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
8. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Focus** for the analysis.
   - You may also override the variable starting values by clicking the **Override** checkbox and entering the desired value in the **Starting Value** field.
   - Optionally, modify the values of fixed variables that are not being optimized.
   - Optionally, set Linear constraints.
   - Select the **View all columns** check box to see all columns, including hidden columns.
9. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

   Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
10. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or

source excitation.This will provide some speed improvement in the overall optimization process.

Optimization Setup for the Genetic Algorithm (Random search) Optimizer

Following is the procedure for setting up an optimization analysis using the Genetic Algorithm (Random search) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Optimization**  .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Genetic Algorithm(Random search)** from the **Optimizer** pull-down list.
4. Click the **Setup...** button to modify the Advanced Genetic Algorithm Optimizer Options.
5. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
6. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

   The **Cost Function Norm Type** pull-down list appears.

   - Select **L1**, **L2**, or **Maximum**.

   A norm is a function that assigns a positive value to the cost function.

   For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

   The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.
7. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
8. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Focus** for the analysis.
   - You may also override the variable starting values by clicking the **Override** checkbox and entering the desired value in the **Starting Value** field.
   - Optionally, modify the values of fixed variables that are not being optimized.

- Optionally, set Linear constraints.
- Select the **View all columns** check box to see all columns, including hidden columns.

9. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

   Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.

10. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation.This will provide some speed improvement in the overall optimization process.

Optimization Setup for the MATLAB Optimizer

Following is the procedure for setting up an optimization analysis using the MATLAB Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

1. Set up the variables you want to optimize in the **Design Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Optimization**  .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **MATLAB** from the **Optimizer** pull-down list. Selecting MATLAB enables the **Acceptable Cost** and **Noise** fields.
4. Click the **Setup...** button to modify the MATLAB Optimizer Options.
5. Type the maximum number of iterations you want Optimetrics to perform during the optimization analysis in the **Max. No. of Iterations** text box.
6. Under **Cost Function**, add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.
7. Type the value of the cost function at which the optimization process should stop in the **Acceptable Cost** text box.
8. Type the cost function noise in the **Noise** text box.
9. If you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

The **Cost Function Norm Type** pull-down list appears.

- Select **L1**, **L2**, or **Maximum**.

A norm is a function that assigns a positive value to the cost function.

For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

10. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
11. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Min/Max Step Size** for the analysis.
    - You may also override the variable starting values by clicking the **Override** checkbox and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
12. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** checkbox will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
13. Under the **Options** tab, if you want to save the field solution data for every solved design variation in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

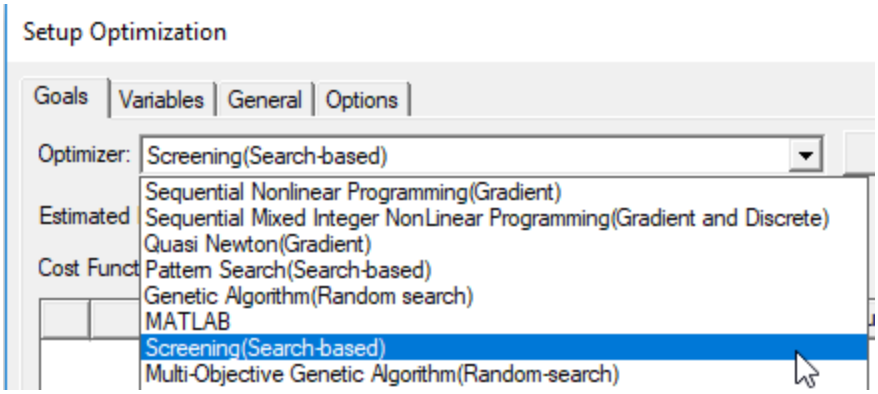
Setup Screening (Search Based) Optimizer

Following is the procedure for setting up an optimization analysis using the Screening Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

This is a non-iterative direct sampling method that uses a quasi-random number generator based on the Hammersley algorithm. You can start with Screening to locate the multiple tentative optima and then refine with NLPQL or MISQP to zoom in on the individual local maximum or minimum value. Usually Screening is used for preliminary design. Then, if you want to refine, these candidate points are used as starting points for gradient methods.

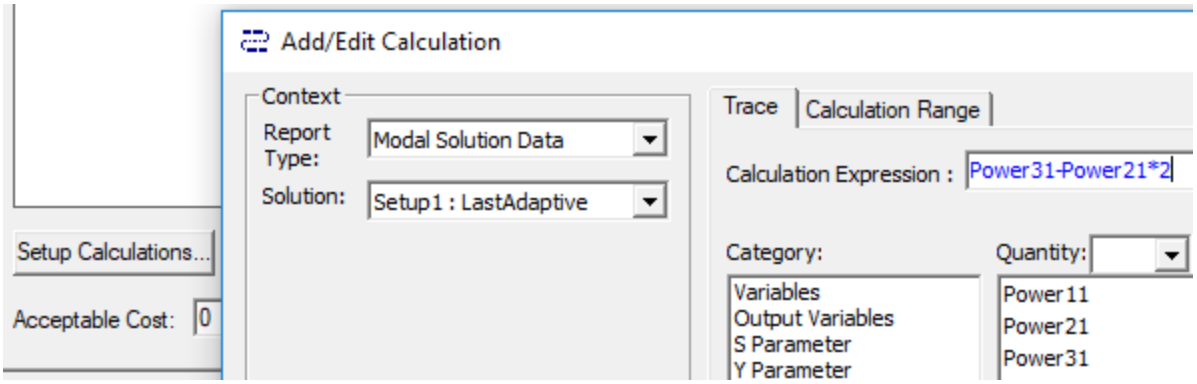
1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.
2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis**>**Add** **Optimization** .

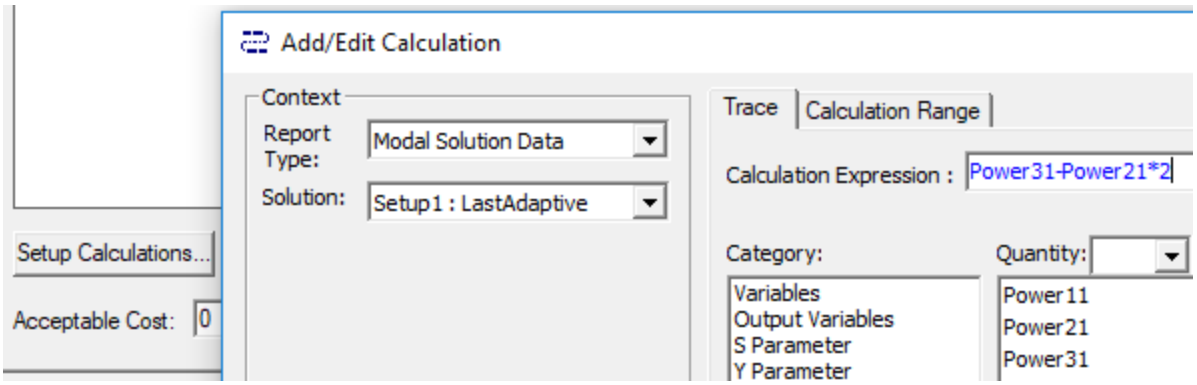
   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Screening (Search Based)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options window** to change the default number of samples from 100.

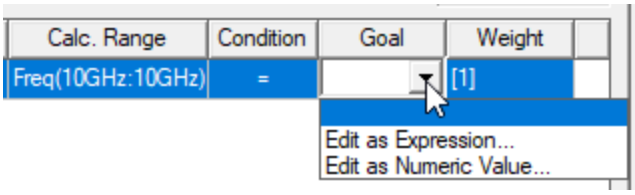
   The number of samples must be greater than the number of enabled input parameters. The number of enabled input parameters is also the minimum number of samples required to generate the Sensitivities chart. You can enter a minimum of 2 and a maximum of 10,000. The default is 100 for a Direct Optimization system.
5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.



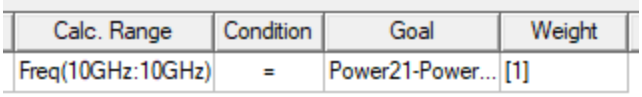


When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either Edit as Expression or Edit as Numeric Value...



This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to the **Goal** column.



7. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:

- Check the **Show Advanced Option** check box.

  The **Cost Function Norm Type** pull-down list appears.
- Select **L1**, **L2**, or **Maximum**.

  A norm is a function that assigns a positive value to the cost function.

  For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

  The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

8. Optionally, set the Acceptable Cost and Cost Function Noise.
9. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
12. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setup Multi-Objective Genetic Algorithm(Random Search) Optimizer

Following is the procedure for setting up an optimization analysis using the Multi-Objective Genetic Algorithm (Random Search) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

The Multi-Objective Genetic Algorithm (MOGA) is a hybrid variant of the popular NSGA-II (Non-dominated Sorted Genetic Algorithm-II) based on controlled elitism concepts. It supports all types of input parameters. The Pareto ranking scheme is done by a fast, non-dominated sorting method that is an order of magnitude faster than traditional Pareto ranking methods. The constraint handling uses the same non-dominance principle as the objectives. Therefore, penalty functions and Lagrange multipliers are not needed. This also ensures that the feasible solutions are always ranked higher than the infeasible solutions.

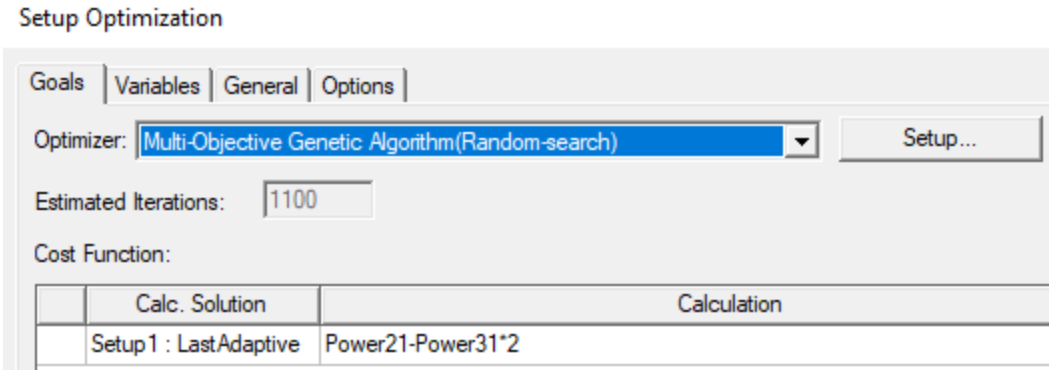
The first Pareto front solutions are archived in a separate sample set internally and are distinct from the evolving sample set. This ensures minimal disruption of Pareto front patterns already available from earlier iterations. You can control the selection pressure (and, consequently, the elitism of the process) to avoid premature convergence by altering the Maximum Allowable Pareto Percentage property.

1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.
2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis>Add**

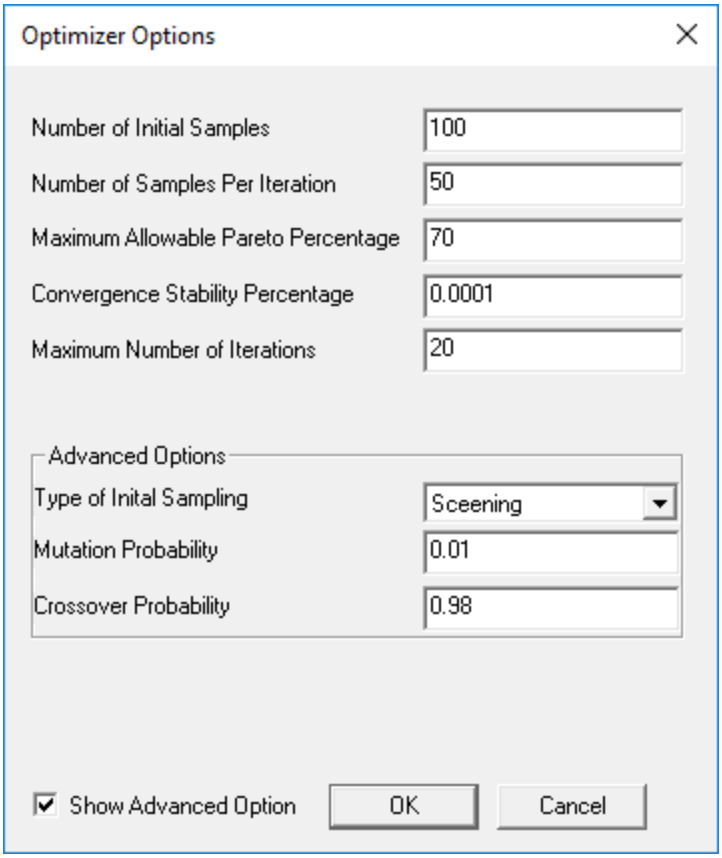
   

   Optimization .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Multi-Objective Genetic Algorithm (Random Search)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options window**.



- **Number of Initial Samples**: Initial number of samples to use. This number must be greater than the number of enabled input parameters. The minimum recommended number of initial samples is 10 times the number of enabled input parameters. The larger the initial sample set, the better your chances of finding the input parameter space that contains the best solutions.

  The number of enabled input parameters is also the minimum number of samples required to generate the Sensitivities chart. You can enter a minimum of 2 and a maximum of 10000. The default is 100.

  If you switch from the Screening method to the MOGA method, MOGA generates a new sample set. For the sake of consistency, enter the same number of initial samples as you used for the Screening method.
- **Number of Samples Per Iteration**: Number of samples to iterate and update with each iteration. This number must be greater than the number of enabled input parameters but less than or equal to the number of initial samples. The default is for a Direct Optimization system.

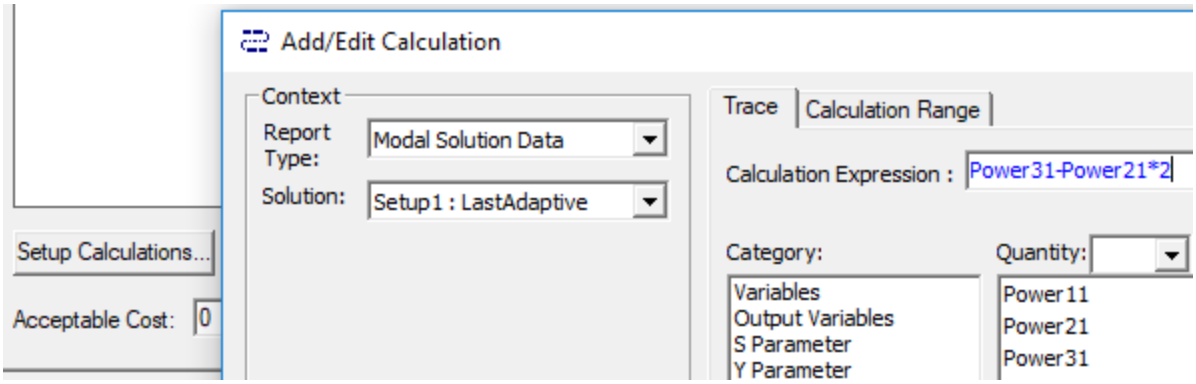
  You can enter a minimum of 2 and a maximum of 10000.
- **Maximum Allowable Pareto Percentage**: Convergence criterion. Percentage value that represents the ratio of the number of desired Pareto points to the number of samples per iteration. When this percentage is reached, the optimization is converged. For

example, a value of 70 with Number of Samples Per Iteration set to 200 would mean that the optimization should stop once the resulting front of the MOGA optimization contains at least 140 points. Of course, the optimization stops before that if the maximum number of iterations is reached.

- If the **Maximum Allowable Pareto Percentage** is too low (below 30), the process can converge prematurely. If the value is too high (above 80), the process can converge slowly. The value of this property depends on the number of parameters and the nature of the design space itself. The default is 70. Using a value between 55 and 75 works best for most problems. For more information, see Convergence Criteria in MOGA-Based Multi-Objective Optimization .
- **Convergence Stability Percentage**: Convergence criterion. Percentage value that represents the stability of the population based on its mean and standard deviation. This criterion allows you to minimize the number of iterations performed while still reaching the desired level of stability. When the specified percentage is reached, the optimization is converged. The default percentage is 2. To not take the convergence stability into account, set to 0. For more information, see Convergence Criteria in MOGA-Based Multi-Objective Optimization .
- **Maximum Number of Iterations**: Stop criterion. Maximum number of iterations that the algorithm is to execute. If this number is reached without the optimization having reached convergence, iterations stop. This also provides an idea of the maximum possible number of function evaluations that are needed for the full cycle, as well as the maximum possible time it can take to run the optimization. For example, the absolute maximum number of evaluations is given by:

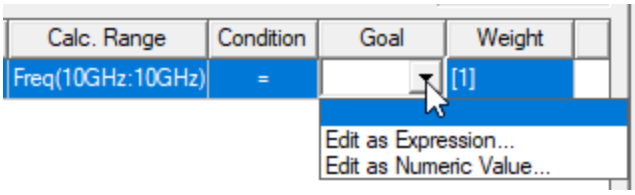
  Number of Initial Samples + Number of Samples Per Iteration * (Maximum Number of Iterations - 1)
- **Type of Initial Sampling**: Advanced option for generating different kinds of sampling. If you do not have any parameter relationships defined, set to Screening (default) or Optimal Space-Filling. If you have parameter relationships defined, the initial sampling must be performed by the constrained sampling algorithms because parameter relationships constrain the sampling. For such cases, this property is automatically set to Constrained Sampling.
- **Mutation Probability**: Advanced option for specifying the probability of applying a mutation on a design configuration. The value must be between 0 and 1. A larger value indicates a more random algorithm. If the value is 1, the algorithm becomes a pure random search. A low probability of mutation (<0.2) is recommended. The default is 0.01. For more information on mutation, see MOGA Steps to Generate a New Population.
- **Crossover Probability**: Advanced option for specifying the probability with which parent solutions are recombined to generate offspring solutions. The value must be between 0 and 1. A smaller value indicates a more stable population and a faster (but less accurate) solution. If the value is 0, the parents are copied directly to the new population. A high probability of crossover (>0.9) is recommended. The default is 0.98.

5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.

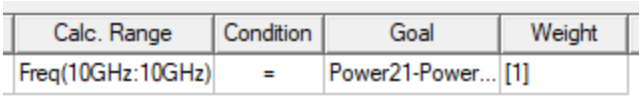


When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either **Edit as Expression...** or **Edit as Numeric Value...**.



This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to the **Goal** column.



7. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

     The **Cost Function Norm Type** pull-down list appears.
   - Select **L1**, **L2**, or **Maximum**.

     A norm is a function that assigns a positive value to the cost function.

     For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

     The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

8. Optionally, set the Acceptable Cost and Cost Function Noise.
9. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
12. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setup Nonlinear Programming by Quadratic Lagrangian (Gradient) Optimizer

Following is the procedure for setting up an optimization analysis using the Nonlinear Programming by Quadratic Lagrangian (Gradient) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

The NLPQL (Nonlinear Programming by Quadratic Lagrangian) method can be used for Direct Optimization systems. It allows you to generate a new sample set to provide a more refined approach than the Screening method. Available for continuous input parameters only, NLPQL can handle only one output parameter goal. Other output parameters can be defined as constraints. For more information, see Convergence Rate % and Initial Finite Difference Delta % in NLPQL and MISQP and Nonlinear Programming by Quadratic Lagrangian (NLPQL).

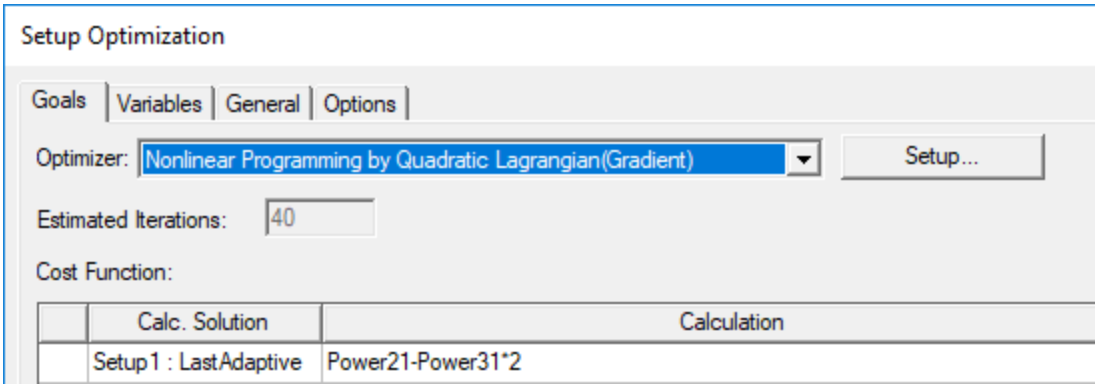
To generate samples and perform an NLPQL optimization:

1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.
2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis>Add**

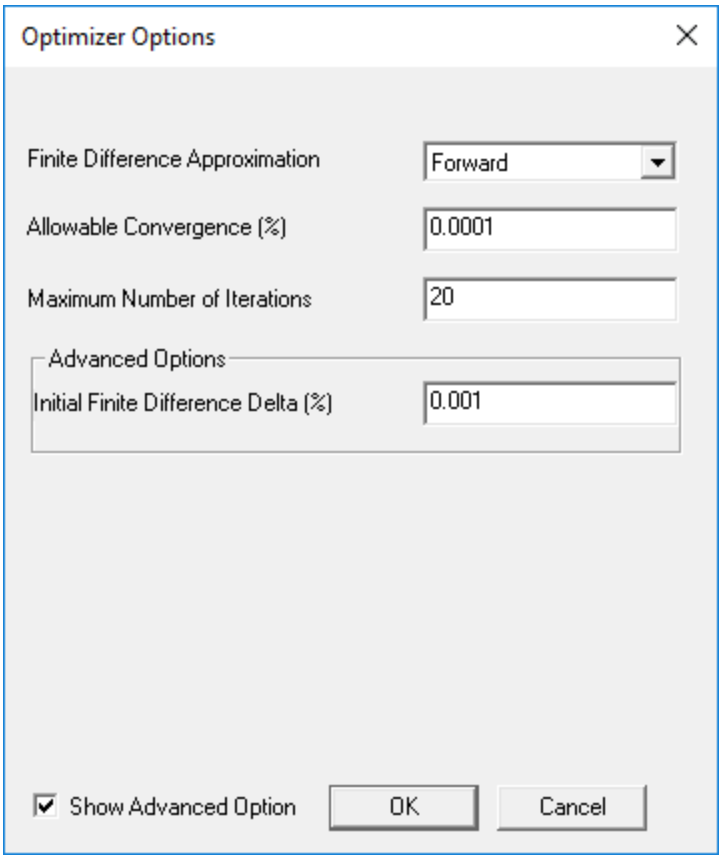
Optimization .

The **Setup Optimization** dialog box appears.

3. Under the **Goals** tab, select the optimizer by selecting **Nonlinear Programming by Quadratic Lagrangian (Gradient)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options window**.



- **Finite Difference Approximation**: When analytical gradients are not available, NLPQL approximates them numerically. This property allows you to specify the method of approximating the gradient of the objective function. Choices are:

- **Central**: Increases the accuracy of the gradient calculations by sampling from both sides of the sample point but increases the number of design point evaluations by 50%. This method makes use of the initial point, as well as the forward point and rear point.
- **Forward**: Uses fewer design point evaluations but decreases the accuracy of the gradient calculations. This method makes use of only two design points, the initial point and forward point, to calculate the slope forward. This is the default method for new Direct Optimization systems.

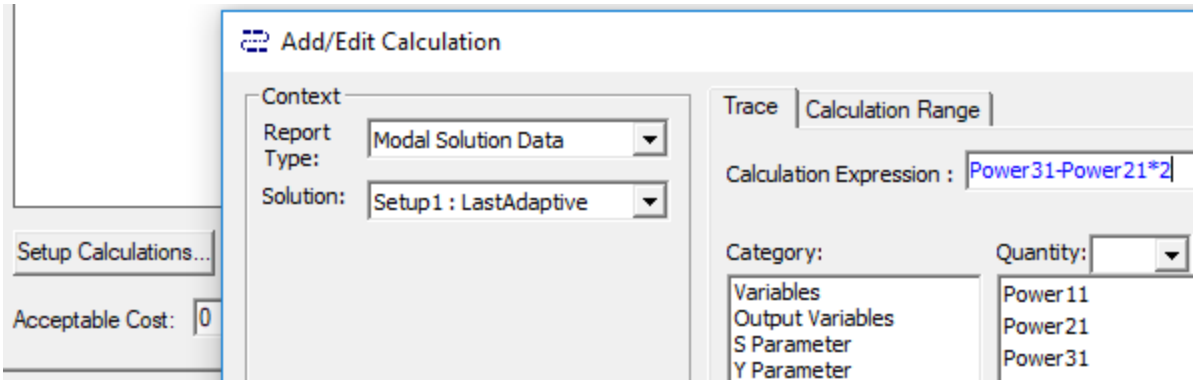
- **Maximum Number of Iterations**: Stop criterion. Maximum number of iterations that the algorithm is to execute. If convergence happens before this number is reached, the iterations stop. This also provides an idea of the maximum possible number of function evaluations that are needed for the full cycle. For NLPQL, the number of evaluations can be approximated according to the Finite Difference Approximation gradient calculation method, as follows:

  For **Central**: number of iterations * (2*number of inputs +1)

  For **Forward**: number of iterations * (number of inputs+1)
- **Allowable Convergence (%)**: Stop criterion. Tolerance to which the Karush-Kuhn-Tucker (KKT) optimality criterion is generated during the NLPQL process. A smaller value indicates more convergence iterations and a more accurate (but slower) solution. A larger value indicates fewer convergence iterations and a less accurate (but faster) solution. For a Direct Optimization system, the default percentage value is 0.1. The maximum percentage value is 100. These values are consistent across all problem types because the inputs, outputs, and gradients are scaled during the NLPQL solution.
- **Initial Finite Difference Delta (%)**: Advanced option for specifying the relative variation used to perturb the current point to compute gradients. Used in conjunction with Allowable Convergence (%) to ensure that the delta in NLPQL's calculation of finite differences is large enough to be seen above the noise in the simulation problem. This wider sampling produces results that are more clearly differentiated so that the difference is less affected by solution noise and the gradient direction is clearer. The value should be larger than both the value for Initial Finite Difference Delta (%) and the noise magnitude of the model. However, smaller values produce more accurate results, so set Initial Finite Difference Delta (%) only as high as necessary to be seen above simulation noise.

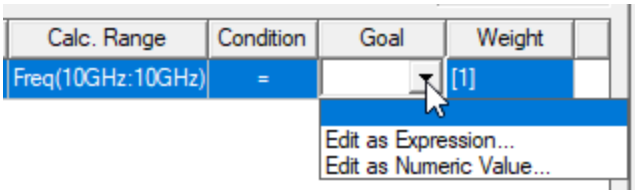
  The default percentage value is 1. The minimum is 0.0001, and the maximum is 1. For parameters with Allowed Values set to **Manufacturable Values** or Snap to Grid, the value for Initial Finite Difference Delta (%) is ignored. In such cases, the closest allowed value is used to determine the finite difference delta.

5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.

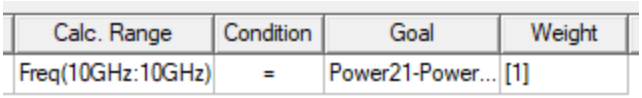


When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either Edit as Expression or Edit as Numeric Value...



7. This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to the **Goal** column.



6. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

     The **Cost Function Norm Type** pull-down list appears.
   - Select **L1**, **L2**, or **Maximum**.

     A norm is a function that assigns a positive value to the cost function.

     For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

7. Optionally, set the Acceptable Cost and Cost Function Noise.
8. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
9. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
   - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
   - Optionally, modify the values of fixed variables that are not being optimized.
   - Optionally, set Linear constraints.
   - Select the **View all columns** check box to see all columns, including hidden columns.
10. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
11. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setup Mixed-Integer Sequential Quadratic Programming (Gradient and Discrete) Optimizer

Following is the procedure for setting up an optimization analysis using the Mixed-Integer Sequential Quadratic Programming optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

The Mixed-Integer Sequential Quadratic Programming (Nonlinear Programming by Quadratic Lagrangian) method (MISQP)can be used for Direct Optimization systems. It allows you to generate a new sample set to provide a more refined approach than the Screening method. MISQP is available for both continuous and discrete input parameters, which is why mixed is in its name. MISQP can handle only one output parameter goal.. Other output parameters can be defined as constraints. For more information, see Convergence Rate % and Initial Finite Difference Delta % in NLPQL and MISQP and Nonlinear Programming by Quadratic Lagrangian (NLPQL).

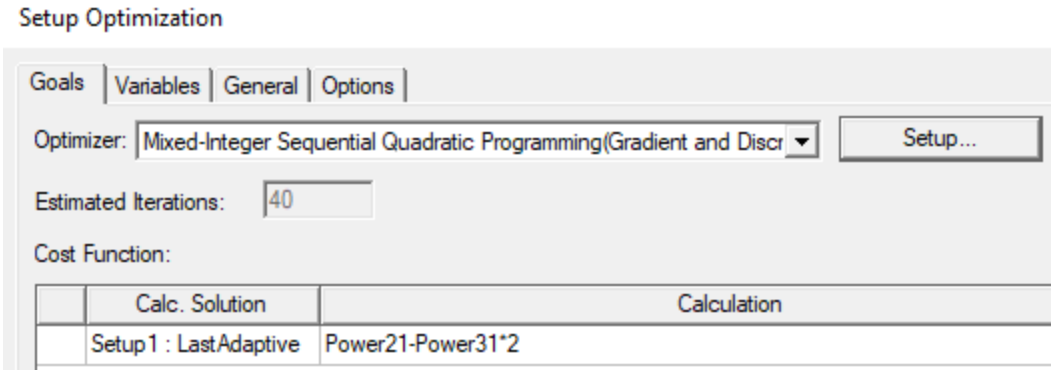
To generate samples and perform an NLPQL optimization:

1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.
2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis>Add**

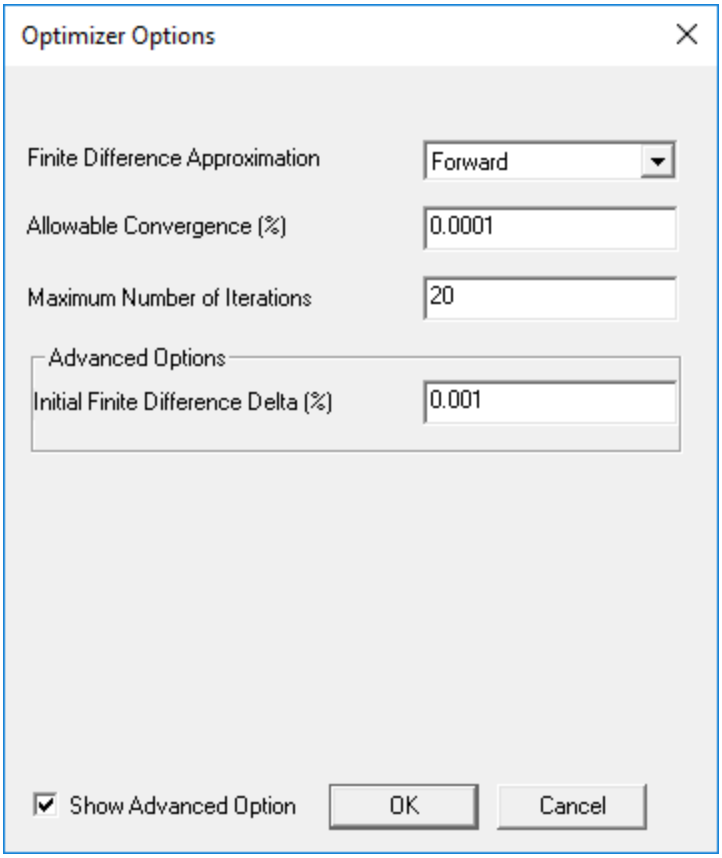
   

   Optimization .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Mixed-Integer Sequential Quadratic Programming (Gradient and Discrete)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options window**.



- **Finite Difference Approximation**: When analytical gradients are not available, MISQP approximates them numerically. This property allows you to specify the method of approximating the gradient of the objective function. Choices are:
- **Central**: Increases the accuracy of the gradient calculations by sampling from both sides of the sample point but increases the number of design point evaluations by 50%. This method makes use of the initial point, as well as the forward point and rear point.
- **Forward**: Uses fewer design point evaluations but decreases the accuracy of the gradient calculations. This method makes use of only two design points, the initial point and forward point, to calculate the slope forward. This is the default method for new Direct Optimization systems.
- **Maximum Number of Iterations**: Stop criterion. Maximum number of iterations that the algorithm is to execute. If convergence happens before this number is reached, the iterations stop. This also provides an idea of the maximum possible number of function evaluations that are needed for the full cycle. For MISQP, the number of evaluations can be approximated according to the Finite Difference Approximation gradient calculation method, as follows:

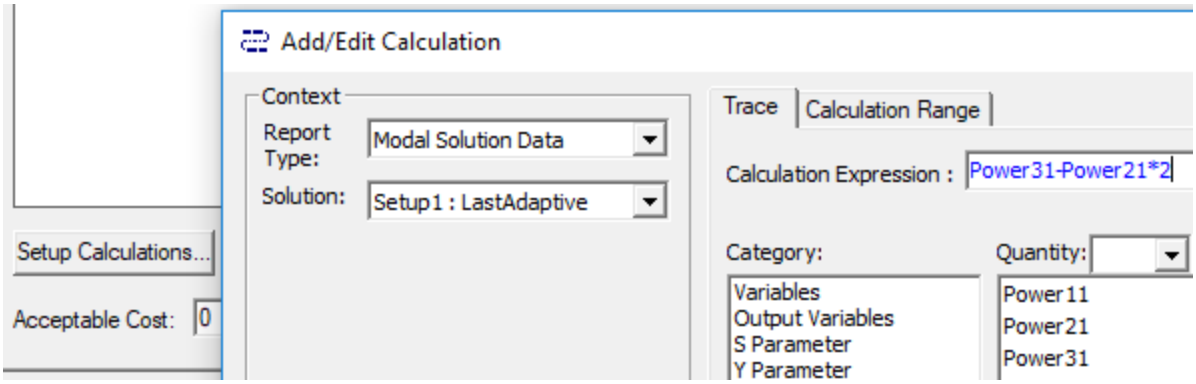
  For **Central**: number of iterations * (2*number of inputs +1)

For **Forward**: number of iterations * (number of inputs+1)

- **Allowable Convergence (%)**: Stop criterion. Tolerance to which the Karush-Kuhn-Tucker (KKT) optimality criterion is generated during the MISQP process. A smaller value indicates more convergence iterations and a more accurate (but slower) solution. A larger value indicates fewer convergence iterations and a less accurate (but faster) solution. For a Direct Optimization system, the default percentage value is 0.1. The maximum percentage value is 100. These values are consistent across all problem types because the inputs, outputs, and gradients are scaled during the MISQP solution.
- **Initial Finite Difference Delta (%)**: Advanced option for specifying the relative variation used to perturb the current point to compute gradients. Used in conjunction with Allowable Convergence (%) to ensure that the delta in MISQP's calculation of finite differences is large enough to be seen above the noise in the simulation problem. This wider sampling produces results that are more clearly differentiated so that the difference is less affected by solution noise and the gradient direction is clearer. The value should be larger than both the value for Initial Finite Difference Delta (%) and the noise magnitude of the model. However, smaller values produce more accurate results, so set Initial Finite Difference Delta (%) only as high as necessary to be seen above simulation noise.

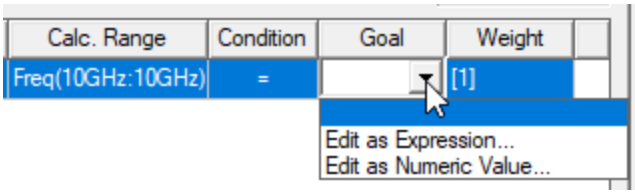
  The default percentage value is 1. The minimum is 0.0001, and the maximum is 1. For parameters with Allowed Values set to **Manufacturable Values** or Snap to Grid, the value for Initial Finite Difference Delta (%) is ignored. In such cases, the closest allowed value is used to determine the finite difference delta.

5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.

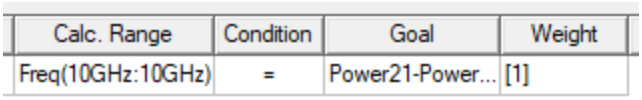


When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either Edit as Expression or Edit as Numeric Value...



This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to the **Goal** column.



7. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

     The **Cost Function Norm Type** pull-down list appears.
   - Select **L1**, **L2**, or **Maximum**.

     A norm is a function that assigns a positive value to the cost function.

     For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

     The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.
8. Optionally, set the Acceptable Cost and Cost Function Noise.
9. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.

12. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setup Adaptive Multiple-Objective (Random Search) Optimizer

Following is the procedure for setting up an optimization analysis using the Adaptive Multiple Objective (Random Search) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

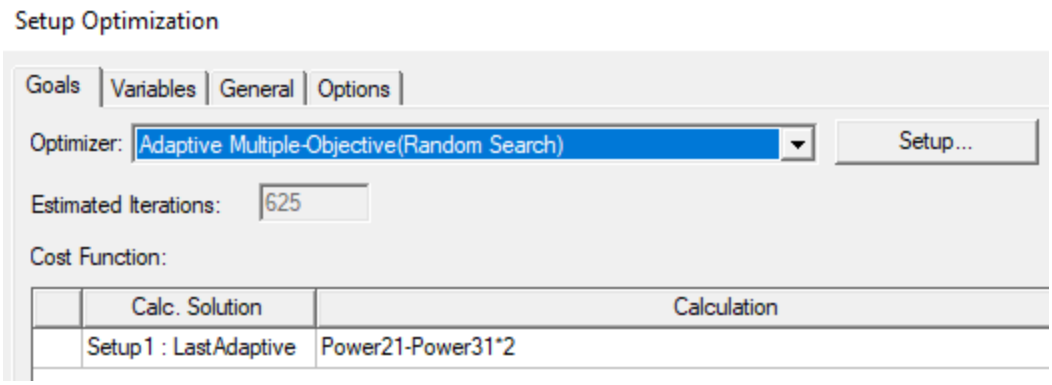
The Adaptive Multiple Objective (Kriging + MOGA) is an iterative algorithm that allows you to either generate a new sample set or use an existing set, providing a more refined approach than the Screening method. It uses the same general approach as MOGA, but applies the Kriging error predictor to reduce the number of evaluations needed to find the global optimum. The Adaptive Multiple-Objective method is available only for continuous input parameters, including those with manufacturable values. It can handle multiple objectives and multiple constraints. For more information, see Adaptive Multiple-Objective Optimization.

1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.
2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis>Add**

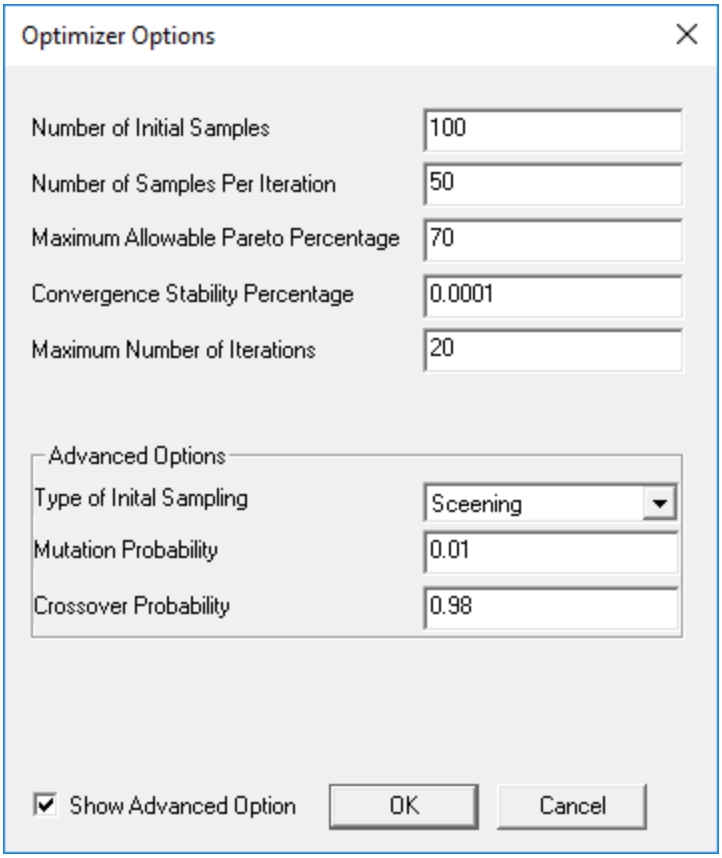
   

   Optimization .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Adaptive Multiple Objective (Random-search)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options window**.



- **Number of Initial Samples**: Initial number of samples to use. This number must be greater than the number of enabled input parameters. The minimum recommended number of initial samples is 10 times the number of enabled input parameters. The larger the initial sample set, the better your chances of finding the input parameter space that contains the best solutions.

  The number of enabled input parameters is also the minimum number of samples required to generate the Sensitivities chart. You can enter a minimum of 2 and a maximum of 10000. The default is 100.

  If you switch from the Screening method to the MOGA method, MOGA generates a new sample set. For the sake of consistency, enter the same number of initial samples as you used for the Screening method.
- **Number of Samples Per Iteration**: Number of samples to iterate and update with each iteration. This number must be greater than the number of enabled input parameters but less than or equal to the number of initial samples. The default is for a Direct Optimization system.

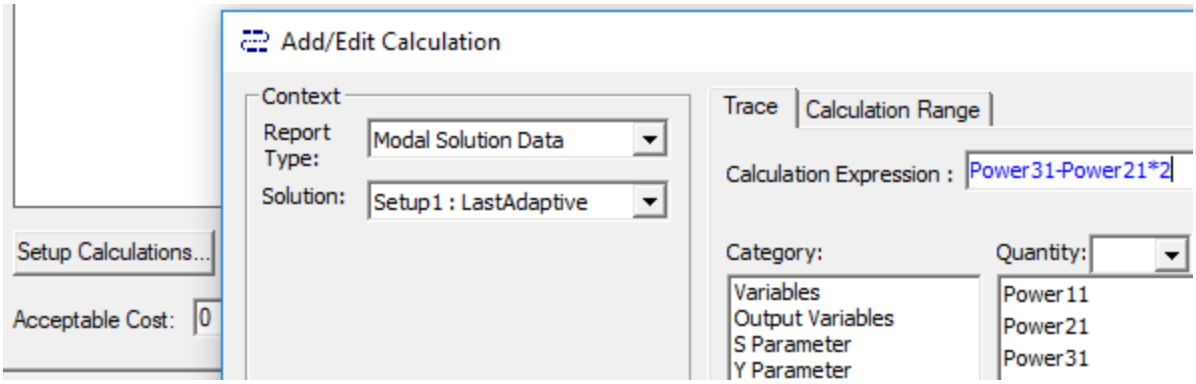
  You can enter a minimum of 2 and a maximum of 10000.
- **Maximum Allowable Pareto Percentage**: Convergence criterion. Percentage value that represents the ratio of the number of desired Pareto points to the number of samples per iteration. When this percentage is reached, the optimization is converged. For

example, a value of 70 with Number of Samples Per Iteration set to 200 would mean that the optimization should stop once the resulting front of the MOGA optimization contains at least 140 points. Of course, the optimization stops before that if the maximum number of iterations is reached.

- If the **Maximum Allowable Pareto Percentage** is too low (below 30), the process can converge prematurely. If the value is too high (above 80), the process can converge slowly. The value of this property depends on the number of parameters and the nature of the design space itself. The default is 70. Using a value between 55 and 75 works best for most problems. For more information, see Convergence Criteria in MOGA-Based Multi-Objective Optimization .
- **Convergence Stability Percentage**: Convergence criterion. Percentage value that represents the stability of the population based on its mean and standard deviation. This criterion allows you to minimize the number of iterations performed while still reaching the desired level of stability. When the specified percentage is reached, the optimization is converged. The default percentage is 2. To not take the convergence stability into account, set to 0. For more information, see Convergence Criteria in MOGA-Based Multi-Objective Optimization .
- **Maximum Number of Iterations**: Stop criterion. Maximum number of iterations that the algorithm is to execute. If this number is reached without the optimization having reached convergence, iterations stop. This also provides an idea of the maximum possible number of function evaluations that are needed for the full cycle, as well as the maximum possible time it can take to run the optimization. For example, the absolute maximum number of evaluations is given by:

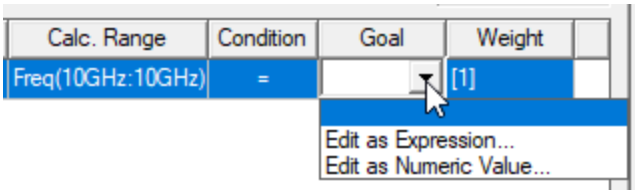
  Number of Initial Samples + Number of Samples Per Iteration * (Maximum Number of Iterations - 1)
- **Type of Initial Sampling**: Advanced option for generating different kinds of sampling. If you do not have any parameter relationships defined, set to Screening (default) or Optimal Space-Filling. If you have parameter relationships defined, the initial sampling must be performed by the constrained sampling algorithms because parameter relationships constrain the sampling. For such cases, this property is automatically set to Constrained Sampling.
- **Mutation Probability**: Advanced option for specifying the probability of applying a mutation on a design configuration. The value must be between 0 and 1. A larger value indicates a more random algorithm. If the value is 1, the algorithm becomes a pure random search. A low probability of mutation (<0.2) is recommended. The default is 0.01. For more information on mutation, see MOGA Steps to Generate a New Population.
- **Crossover Probability**: Advanced option for specifying the probability with which parent solutions are recombined to generate offspring solutions. The value must be between 0 and 1. A smaller value indicates a more stable population and a faster (but less accurate) solution. If the value is 0, the parents are copied directly to the new population. A high probability of crossover (>0.9) is recommended. The default is 0.98.

5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.

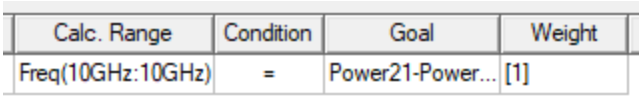


When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either **Edit as Expression...** or **Edit as Numeric Value...**.



This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to the **Goal** column.



7. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

     The **Cost Function Norm Type** pull-down list appears.
   - Select **L1**, **L2**, or **Maximum**.

     A norm is a function that assigns a positive value to the cost function.

     For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

     The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.

8. Optionally, set the Acceptable Cost and Cost Function Noise.
9. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
12. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setup Adaptive Single-Objective (Gradient) Optimizer

Following is the procedure for setting up an optimization analysis using the Adaptive Single-Objective (OSF + Kriging + MISQP) Optimizer. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the whole process for minor changes.

This gradient-based method employs automatic intelligent refinement to provide the global optima. It requires a minimum number of design points to build the Kriging response surface, but, in general, this method reduces the number of design points necessary for the optimization. Failed design points are treated as inequality constraints, making it fault-tolerant.

The Adaptive Single-Objective method is available for input parameters that are continuous, including those with manufacturable values. It can handle only one output parameter goal, although other output parameters can be defined as constraints. It does not support the use of parameter relationships in the optimization domain. For more information, see Adaptive Single-Objective Optimization (ASO). It requires advanced options. Ensure that the Show Advanced Options check box is selected.

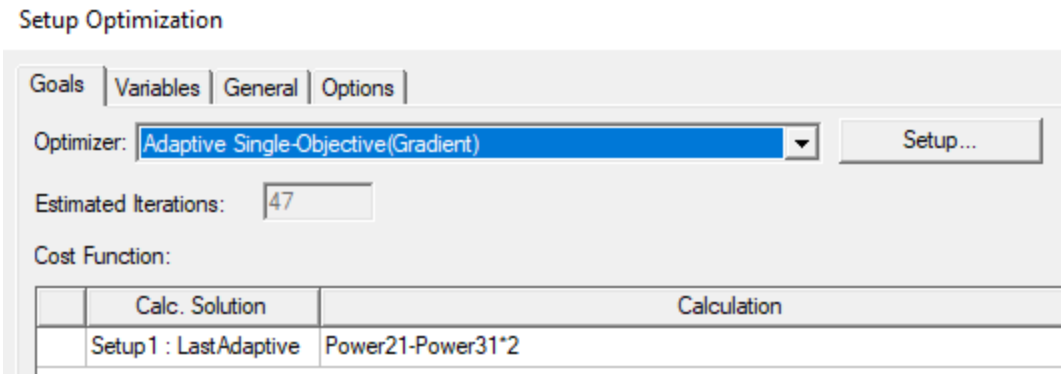
1. Set up the variables you want to optimize in the **Design Properties** dialog box. The variables must be swept in a Parametric setup.

2. Click **HFSS** or **Q3D Extractor** or **2D Extractor>Optimetrics Analysis>Add**

   Optimization .

   The **Setup Optimization** dialog box appears.
3. Under the **Goals** tab, select the optimizer by selecting **Adaptive Single Objective (Gradient)** from the **Optimizer** drop-down menu.



4. Optionally press the **Setup** button to open the **Optimizer Options** window and check Advanced Options.

  - **Number of Initial Samples**: Number of samples generated for the initial Kriging and after all domain reductions for the construction of the next Kriging. You can enter a minimum of (NbInp+1)*(NbInp+2)/2 (also the minimum number of OSF samples required for the Kriging construction) or a maximum of 10,000. The default is (NbInp+1)* (NbInp+2)/2.

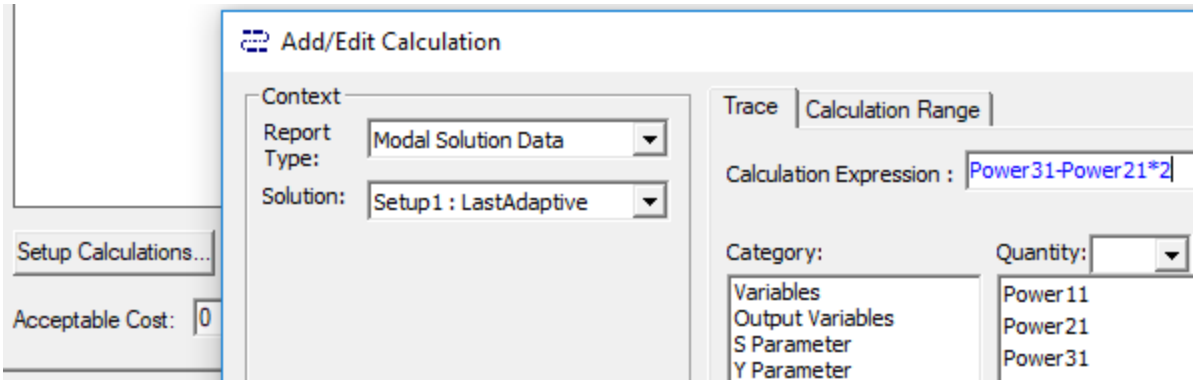
    Because of the Adaptive Single-Objective workflow (in which a new OSF sample set is generated after each domain reduction), increasing the number of OSF samples does not necessarily improve the quality of the results and significantly increases the number of evaluations
  - **Maximum Number of Evaluations**:Stop criterion. Maximum number of evaluations (design points) that the algorithm is to calculate. If convergence occurs before this number is reached, evaluations stop. This value also provides an idea of the maximum possible time it takes to run the optimization. The default is 20*(NbInp +1).
- **Convergence Tolerance**: Stop criterion. Minimum allowable gap between the values of two successive candidates. If the difference between two successive candidates is smaller than the value for Convergence Tolerance multiplied by the maximum variation of the parameter, the algorithm is stopped. A smaller value indicates more convergence iterations and a more accurate (but slower) solution. A larger value indicates fewer convergence iterations and a less accurate (but faster) solution. The default is 1E-06.
- **Random Generator Seed**: The value for initializing the random number generator invoked internally by OSF. The value must be a positive integer. This property allows you to generate different samplings by changing the value or to regenerate the same sampling by keeping the same value. The default is 0.
- **Maximum Number of Cycles**: Number of optimization loops that the algorithm needs, which in turns determines the discrepancy of the OSF. The optimization is essentially combinatorial, so a large number of cycles slows down the process. However, this makes the discrepancy of the OSF smaller. The value must be greater than 0. For practical purposes, 10 cycles is usually good for up to 20 variables. The default is 10.
- **Number of Screening Samples**: Number of samples for the screening generation on the current Kriging. This value is used to create the next Kriging (based on error prediction) and verified candidates.

    You can enter a minimum of (NbInp+1)*(NbInp+2)/2 (also the minimum number of OSF samples required for the Kriging construction) or a maximum of 10,000. The default is 100*NbInp for a Direct Optimization system. There is no default for a Response Surface Optimization system.

    The larger the screening sample set, the better the chances of finding good verified points. However, too many points can result in a divergence of the Kriging.
- **Number of Starting Points**: Determines the number of local optima to explore. The larger the number of starting points, the more local optima explored. In the case of a linear surface, for example, it is not necessary to use many points. This value must be less than the value for **Number of Screening Samples** because these samples are selected in this sample. The default is the value for **Number of Initial Samples**.

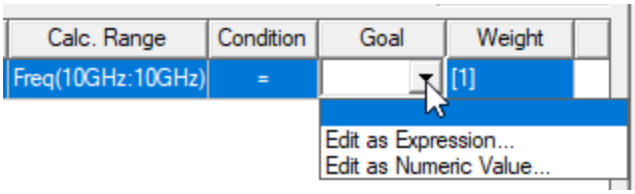
- **Maximum Number of Domain Reductions**: Stop criterion. Maximum number of domain reductions for input variation. (No information is known about the size of the reduction beforehand.) The default is 20.
- **Percentage of Domain Reductions**: Stop criterion. Minimum size of the current domain according to the initial domain. For example, with one input ranging between 0 and 100, the domain size is equal to 100. The percentage of domain reduction is 1%, so the current working domain size cannot be less than 1 (such as an input ranging between 5 and 6). The default is 0.1.
- **Retained Domain per Iteration (%)**: Advanced option that allows you to specify the minimum percentage of the domain you want to keep after a domain reduction. The percentage value must be between 10 and 90. A larger value indicates less domain reduction, which implies better exploration but a slower solution. A smaller value indicates a faster and more accurate solution, with the risk of it being a local one. The default percentage value is 40.

5. Add a cost function by selecting the **Setup Calculations** button to open the **Add/Edit Calculation** dialog.



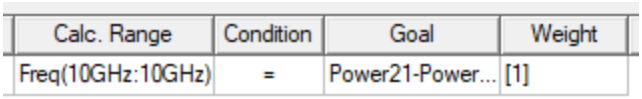
When you have created the calculation, click **Add Calculation** to add it to the **Optimization** setup, and **Done** to close the **Add/EditCalculation** dialog.

6. In the Optimization setup, in the dropdown for the Goal column, select either **Edit as Expression...** or **Edit as Numeric Value...**.



This reopens the **Add/Edit Calculation** dialog box. If you are satisfied with the expression or value displayed, click **Done** to close the dialog box. This enters the expression/value to

the **Goal** column.



Calc. Range	Condition	Goal	Weight
Freq(10GHz:10GHz)	=	Power21-Power...	[1]

7. In the **Optimization** setup, if you want to select a **Cost Function Norm Type**:
   - Check the **Show Advanced Option** check box.

     The **Cost Function Norm Type** pull-down list appears.
   - Select **L1**, **L2**, or **Maximum**.

     A norm is a function that assigns a positive value to the cost function.

     For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors. For **L2** norm (the default) the actual cost function uses the weighted sum of squared values of the individual goal error. For the Maximum norm the cost function uses the maximum among all the weighted goal errors, which means that it is always less than zero. (For further details, see Explanation of the L1, L2, and Max Norms in Optimization.)

     The norm type doesn't impact goal setting that use as condition the "minimize" or "maximize" scenarios.
8. Optionally, set the Acceptable Cost and Cost Function Noise.
9. Optionally, click the button for setting HPC and Analysis Options, which allows you to select or create an analysis configuration.
10. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization.
    - You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
    - Optionally, modify the values of fixed variables that are not being optimized.
    - Optionally, set Linear constraints.
    - Select the **View all columns** check box to see all columns, including hidden columns.
11. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.

    Enabling the **Update design parameters' value after optimization** check box will cause Optimetrics to modify the variable values in the nominal design to match the final values from the optimization analysis.
12. Under the **Options tab**, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

    You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation. This will provide some speed improvement in the overall optimization process.

Setting the Maximum Iterations for an Optimization Analysis

The **Max. No. of Iterations** value is the maximum number of design variations that you want Optimetrics to solve during an optimization when using the **SNLP**, **SMINLP**, **Quasi Newton**, or **Pattern Search Optimizer**. This value is a stopping criterion; if the maximum number of iterations has been completed, the optimization analysis stops. If the maximum number of iterations has not been completed, the optimization continues by performing another iteration, that is, by solving another design variation.

If the maximum number of iterations has not been reached, the optimizer performs iterations until the acceptable cost function is reached or until the optimizer cannot proceed as a result of other optimization setup constraints, such as when it searches for a variable value with a step size smaller than the minimum step size.

Note	The **Genetic Algorithm** optimizer does not use the **Max. No. of Iterations** criteria.

To set the maximum number of iterations for an optimization analysis:

- Under the **Goals** tab of the **Setup Optimization** dialog box, type a value in the **Max. No. of Iterations** text box.

Related Topics

Adding a Cost Function

Cost Function

Optimetrics manipulates the model's design variable values to find the minimum location of the cost function; therefore, you should define the cost function so that a minimum location is also the optimum location.

When using the Quasi Newton optimizer, which is appropriate for designs that are not sensitive to noise, the best cost function is a smooth, second-order function that can be approximated well by quadratics in the vicinity of the minimum; the slope of the cost function should decrease as Optimetrics approaches the optimum value. The preferred cost function takes values between 0 and 1. In practice, most functions that are smooth around the minimum are acceptable as cost functions. Most importantly, the cost function should not have a sharp dip or pole at the minimum. A well designed cost function can significantly reduce the optimization process time.

The cost function is defined in the **Setup Optimization** dialog box or the **Design of Experiments** setup when you set up an optimization analysis. If you know the exact syntax of the solution quantity on which you want to base the cost function, you can type it directly in the **Calculation** text box. You can also use **Setup Calculations** to add a solution quantity via the **Add/Edit Calculation** dialog box, or to create an output variable that represents the solution quantity in the Output Variables dialog box.

Acceptable Cost

The acceptable cost is the value of the cost function at which the optimization process should stop; otherwise known as the *stopping criterion*.The cost function value must be equal to or below the acceptable cost value for the optimization analysis to stop. The acceptable cost may be a negative value.

Related Topics

Cost Function
Adding a Cost Function

Cost Function Noise

The numerical calculation of the electromagnetic field introduces various sources of noise to the cost function, particularly because of changes in the finite element mesh. You must provide the optimizer with an estimate of the noise. The noise indicates whether a change during the solution process is significant enough to support achievement of the cost function.

For example, if the cost function, *c*, is

$$c = 10000 \cdot \left| L_{11} \right|^2$$

where $|L_{11}|$ is the magnitude of the inductance, at the minimum, $|L_{11}|$ is expected to be very small,

$$\left| L_{11} \right| \approx 0$$

.

From the solution setup, the error in $|L_{11}|$ is expected to be $E_{L11} \approx 0.01$. The perturbed cost function is therefore

$$c_{perturbed} = 10000 \cdot (|L_{11}|_{min} + E_{L11})^2$$

Near the minimum, the error in the cost function E_c is given by

$$E_c = c_{perturbed} - c_{min} = 10000 \cdot (0.0 + 0.01)^2 - (10000 \cdot 0.0) = 1.0$$

Therefore, the cost function noise would be 1.0.

Cost Function

Adding a Cost Function

A cost function can include one or more goals for an optimization analysis. Optimetrics manipulates the model's design variable values to fulfill the cost function.The optimization will stop when the solution quantity meets the acceptable cost criterion.

Following is the general procedure for adding a cost function with a single goal:

1. Under the **Goals** tab of the **Setup Optimization** dialog box, click **Setup Calculations...**
   The Add/Edit Calculation dialog box is displayed.
2. In the **Add/Edit Calculation** dialog box, follow these general steps to set up a cost function.
   a. Set the **Context** for the calculation.
   b. Choose the **Category** of available data type depending upon the Solution type of the design being optimized.
   c. Select the **Quantity** to add to the **Calculated Expression** field. Available quantities depend upon the **Category** selection.
   d. You may optionally make a selection from the function list to apply to the calculated expression.
   e. When the **Calculation Expression** has the desired equation, click **Add Calculation** to add the expression to the cost function table.

f. Repeat to add additional calculations to the cost function or click **Done** to exit the **Add/Edit Calculation** dialog box and return to **Setup Optimization**.

3. To modify the **Solution** on which the calculation is based, click in the **Solution** column and select the solution from which the cost function is to be extracted from the pull-down list.
4. To edit the calculation on which to base the cost function goal, select **Edit** from the pull-down list.
5. In the **Condition** text box, click one of the following conditions from the pull-down list:

<=	Less than or equal to
=	Equal to
>=	Greater than or equal to
Minimize	Reduce the cost function to a minimum value
Maximize	Identify a maximized condition

6. In the **Goal** text box, type the value of the solution quantity that you want to be achieved during the optimization analysis. If the solution quantity is a complex calculation, the goal value must be complex; two goal values must be specified. The **Minimize** and **Maximize** options do not require you to specify a **Goal** value.
7. Optionally, if you have multiple goals and want to assign higher or lower priority to a goal, type a different value for the goal's weight in the **Weight** text box. The goal with the greater weight is given more importance. If the goal is a complex value, the weight value must be complex; two weight values must be specified. The weight value cannot be variable dependent.

Note	Click the **Edit Goal/Weight** button to open the **Edit Goal Value/Weight** dialog box where you can modify weights for all goals simultaneously; as well as, set the **Goal Values** to expressions.

8. Optionally, click the button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
9. Specify other options (such as acceptable cost, noise, and number of passes), and then click **OK**.

The optimization stops when the solution quantity meets the acceptable cost criterion.

Adding/Editing a Cost Function Calculation

The Add/Edit Calculation dialog box allows you to define the mathematical equation for one or multiple cost functions. It represents the calculation to be performed on the optimization variables to compare to the goal values. To set up a calculation for a cost function:

1. In the **Context** section of the dialog:
   - Select the **Report Type** with a pull-down selection list containing the available types for this design.
   - Select the **Solution** from the drop down selection list. This lists the available setups and sweeps. As a minimum, the **LastAdaptive** solution is available.
   - Select the Geometry from the drop down selection list or select none (the default). This modifies the list of quantities available to the ones that apply to the specific geometry.
2. The **Output Variables** button opens the Output Variables dialog box allowing you to create special output variables to be used in the cost function.
3. The **Calculated Expression** field in the **Trace** tab is used to enter the equation to be used for the cost function. To enter an expression, you may type it directly into the field or use the **Category**, **Quantity**, and **Function** lists as follows:
   - Select the **Category**, these depend on the Solution type and the design. This lets you specify the category of information to be used in the cost function.
   - Select a **Quantity** from the list. Available quantities depend upon the Solution type, as well as the Geometry and Category selection. Selecting a Quantity automatically enters it into the Calculated Expression field.
   - Select a **Function** to apply to the value in the calculated expression.
   - For swept variables, the Range **Function** button opens the **Set Range Function** dialog to apply functions to the expression that apply over the sweep range.
4. The **Calculation Range** tab applies to swept variables and allows you to specify the range of the sweep over which to apply the calculation.
5. When the desired **Calculated Expression** has been obtained, click the **Add Calculation** button to add the entry to the cost function table. You may add multiple entries to the table simply by changing the **Calculated Expression** and using the **Add Calculation** button.
6. To update or edit a selected cost function, enter the desired Calculated Expression and click the **Update Calculation** button.
7. Click **Done** to return to the Setup Calculations dialog box.

Specifying a Solution Quantity for a Cost Function Goal

When setting up a cost function, you must identify the solution quantity on which to base each goal. Solution quantities are specified by mathematical expressions that are composed of basic quantities, such as matrix parameters, and output variables.

1. Add a row (a goal) to the cost function table:
   a. Under the **Goals** tab of the **Setup Optimization** dialog box, click **Add**.
      A new row is added to the **Cost Function** table.

b. In the **Solution** column, click the solution from which the cost function is to be extracted.

2. In the **Solution** text box, click the solution from which the solution quantity is to be extracted.
3. In the **Calculation** text box, specify the solution quantity in one of the following ways:
   - If you know the syntax of the mathematical expression or the output variable's name, type it in the **Calculation** text box.
   - If you want to create an output variable that represents the solution quantity, do the following:
     a. Click **Edit Calculation**.
        The **Output Variables** dialog box appears.
     b. Add the expression you want to evaluate, click **Done**.
     c. Click **Done** to close the **Output Variables** dialog box.
        In the **Setup Optimization** dialog box, the most recently created output variable appears in the **Calculation** text box.
     d. To specify a different defined output variable, click the **Calculation** text box. It becomes a pull-down list that displays all of the defined output variables. Click an output variable from the pull-down list.

Setting the Calculation Range of a Cost Function Goal

The calculation range is the range within which you want a cost function goal to be calculated. It can be a single value or a range of values, depending on the solution or solution quantity selected for the goal.

1. Under the **Goals** tab in the **Setup Optimization** dialog box, click **Edit Cal. Range**.
2. In the **Variable** pull-down list, click a variable.

   If you chose to solve a parametric setup during the optimization analysis, the variables swept in that parametric setup are available in the **Variable** pull-down list. If you sweep a variable in the parametric setup that is also being optimized, that variable is excluded from the optimization.

   Other examples of available variables include frequency, if the solution quantity is an S-parameter quantity, and phi or theta, if the solution quantity is a radiated field quantity.
3. After you select a variable from the **Variable** pull-down list, you can select a range of values for the calculation range as follows:
   a. Select **Range**.
   b. In the **Start** text box, type the starting value of the range.
   c. In the **Stop** text box, type the final value of the range.
4. To select a single value for the calculation range:
   a. Select **Single Value**.
   b. In the **Value** text box, type the value of the variable at which the cost function goal is to be extracted.
5. Click **Update**, and then click **OK**.

Setting a Goal Value

A goal is the value you want a solution quantity to reach during an optimization analysis. It can be a real value or a complex value. If the solution quantity is a complex calculation, the goal value must be complex. You can type the goal value in the **Goal** text box. Alternatively, you can use the **Edit Goal/Value Weight** dialog box to specify the goal value as a single value, a mathematical expression, or a value dependent on a variable such as frequency.

Related Topics

Specify a single goal value.
Specify an expression as the goal value.
Specify a variable-dependent goal value.

Specifying a Single Goal Value

1. Under the **Goals** tab in the **Setup Optimization** dialog box, click **Edit Goal/Weight**.

   The **Edit Goal/Weight** dialog box appears.

2. Under the **Goal Value** tab, click **Simple Numeric Value** from the **Type** list.
3. If the goal value is complex, click **real/imag** in the pull-down list to the right if you want to specify the real and imaginary parts of the goal value.

   Alternatively, click **mag/ang** if you want to specify the magnitude and angle of the goal value.

4. Type the goal value in the **Goal Value** table.

   If the goal value is complex, type both parts of the goal value in the text box below the **Goal Value** heading. For example, type **1, 1** to specify the real part of the goal value as 1 and the imaginary part as 1.

   If the goal value is real, type a real goal value in the text box below the **Goal Value** heading.

5. Click **OK**.

   The goal value you specified appears in the **Goal** text box.

Specifying an Expression as a Goal Value

1. Under the **Goals** tab in the **Setup Optimization** dialog box, click **Edit Goal/Weight**.

   The **Edit Goal/Weight** dialog box appears.

2. Under the **Goal Value** tab, click **Expression** from the **Type** list.
3. If you know the syntax of the mathematical expression or the existing output variable's name, type it in the text box below the **Goal Value** heading.

   Alternatively, if you want to create an output variable that represents the goal value, do the following:

   a. Click **Edit Expression**.
   The **Output Variables** dialog box appears.
   b. Add the expression you want to be the goal value, and then click **Done**.
   Maxwell enters the most recently created output variable in the text box below the **Goal Value** heading.
4. Click **OK**.

   The goal value you specified appears in the **Goal** text box.

Specifying a Variable-Dependent Goal Value

1. Under the **Goals** tab in the **Setup Optimization** dialog box, click **Edit Goal/Weight**.

   The **Edit Goal/Weight** dialog box appears.
2. Under the **Goal Value** tab, click **Variable Dependent** from the **Type** list.
3. Click a variable from the pull-down list to the left of the table.
4. Type the value of that variable in the first column of the table.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

5. Type a corresponding goal value for that variable value in the text box below the **Goal Value** heading.
6. Click **Add** to add another row to the reference curve.
7. Repeat steps 4, 5, and 6 until you have specified the reference curve.
8. Click **OK**.

   The goal value is listed as being variable dependent in the **Goal** text box.

Goal Weight

If an optimization setup has a cost function made up of multiple goals, you can assign a different weight to each goal. The goal with the greater weight is given more importance during the cost calculation.

The error function value is a weighted sum of the sub-goal errors. Each sub-goal, at each frequency at which it is evaluated, gives rise to a (positive) error value that represents the

discrepancy between the simulated response and the goal value limit. If the response satisfies the goal value limit, then the error value is 0. Otherwise, the error value depends on the differences between the simulated response and the respective goal limit. The error function may be defined as follows:

$$\sum_{j}^{G} \frac{W_j}{N_j} \cdot \sum_{i}^{N_j} e_i$$

where

- G is the number of sub-goals.
- W_j is the weight factor associated with the j^{th} sub-goal.
- N_j is the number of frequencies for the j^{th} sub-goal.
- e_i is the error contribution from the j^{th} sub-goal at the i^{th} frequency.

The value of e_i is determined by the band characteristics, target value, and the simulated response value. The choices for band characteristics are <=, =, and >=.

Band Characteristics (Condition)	**e_i evaluation where s_i is the simulated response and g_i is the desired limit.**
<=	$e_i = \begin{cases} 0 & s_i \le g_i \\ s_i - g_i & s_i > g_i \end{cases}$
=	$e_i = \lvert s_i - g_i \rvert$

>=	$e_i = \begin{cases} 0 & s_i \geq g_i \\ g_i - s_i & s_i < g_i \end{cases}$

If the total error value is within the acceptable cost, the optimization stops.

Modifying the Starting Variable Value for Optimization

A variable's starting value is the first value to be solved during the optimization analysis. Optimetrics automatically sets the starting value of a variable to be the current value set for the nominal design. You can modify this value for each optimization setup.

Note	If you choose to solve a parametric setup before an optimization analysis, a variable's starting value is ignored if a more appropriate starting value is calculated for it during the parametric analysis.

1. In the **Setup Optimization** dialog box, click the **Variables** tab.

   All of the variables that were selected for the optimization analysis are listed.
2. Type a new value in the **Starting Value** text box for the value you want to override, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is used for this optimization analysis, and the current value set for the nominal model is ignored.
   - Alternatively, you can select the **Override** option first, and then type a new variable value in the **Starting Value** text box.
3. Optionally, click a new unit system in one of the **Units** text boxes.

Note	To revert to the default starting value, clear the **Override** check box.

Related Topics

Step Size

Setting the Min and Max Focus

Modifying the Starting Variable Value for Sensitivity Analysis

Modifying the Starting Variable Value for Statistical Analysis

Setting the Min. and Max. Variable Values for Optimization

For every optimization setup, Optimetrics automatically sets the minimum and maximum values it will consider for a variable being optimized. Optimetrics sets a variable's minimum value equal to approximately 50% of its starting value. (The starting value is the variable's current value set for the nominal design.) Optimetrics sets the variable's maximum value equal to approximately 150% of the starting value. During the optimization analysis, variable values that lie outside of this range are not considered.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

Related Topics

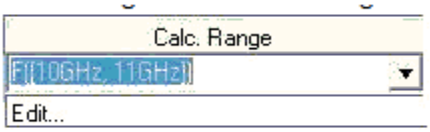
Text Entry for Calc. Range or Edit Calculation Range Dialog

Override the default min and max variable values for a single optimization setup.

Change the default min and max variable values for every optimization setup.

Text Entry for Calc. Range or Edit Calculation Range Dialog

In the **Setup Optimization** dialog, you can enter the Calc. Range Sweep Min/Max by directly editing the Calc. Range field or by accessing an **Edit Calculation Range** dialog.



The edit field accepts the following forms of text:

- sweep that allows you to select different discrete values:

  discrete values, for example, F(10GHz, 11GHz)

  min/max range, for example, F([10GHz, 11GHz])
- editable sweep, which allows you to customize values (that is, a sweep that has an enabled "edited" radio button in sweep selection dialog):

The min/max is used on top of selected values. For example, if you use the sweep dialog and choose "0 deg, 60 deg, 180 deg, 240 deg", then [60deg, 240deg] will select values "60 deg, 180 deg, 240 deg".

- sweep that uses a full range:

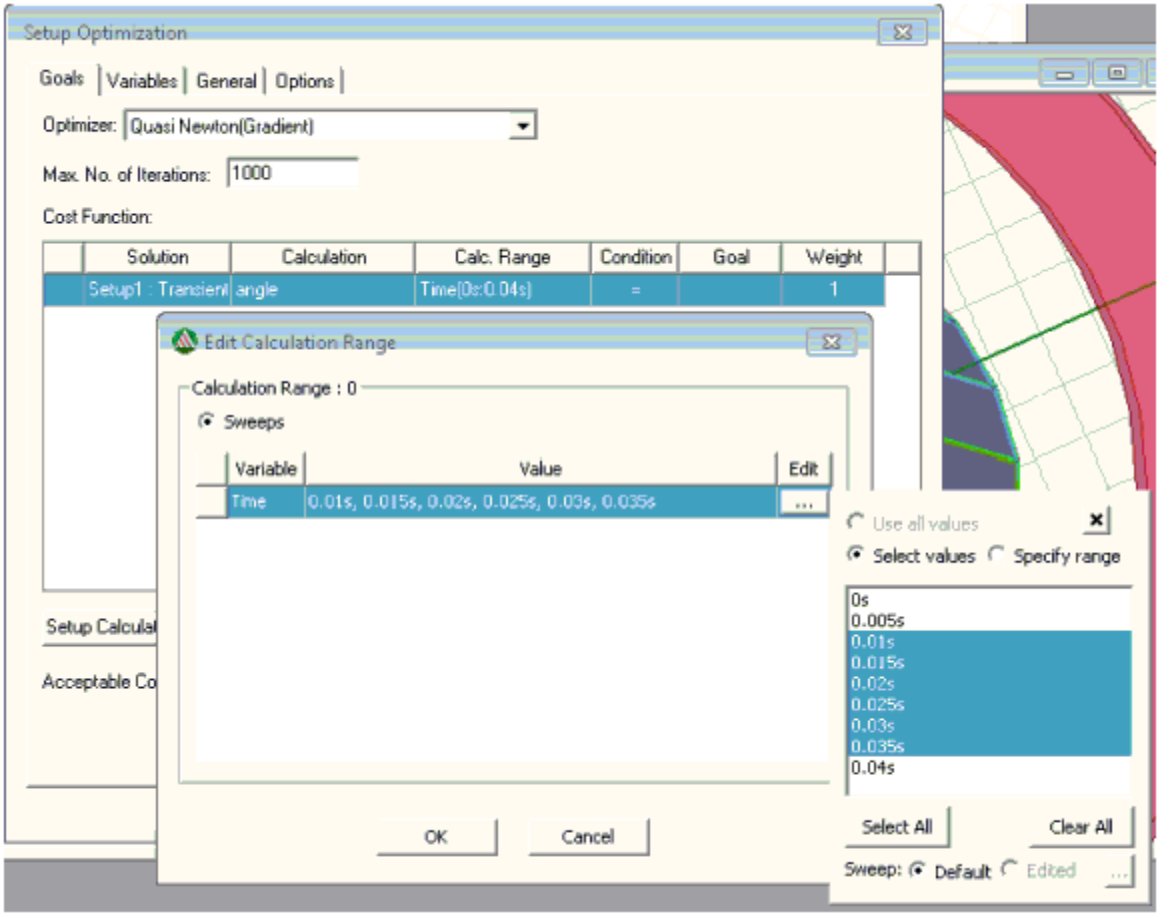
  all values, for example, Time(All)

  min/max range, for example, Time([1ms, 2ms])
- You solve 1 to 20 GHz step .1 and specify F[10.381GHz, 11.381GHz]: it is equivalent to selecting values between 10.4GHz and 11.3GHz.
- You can specify multiple sweep values by separating those with a comma (,).

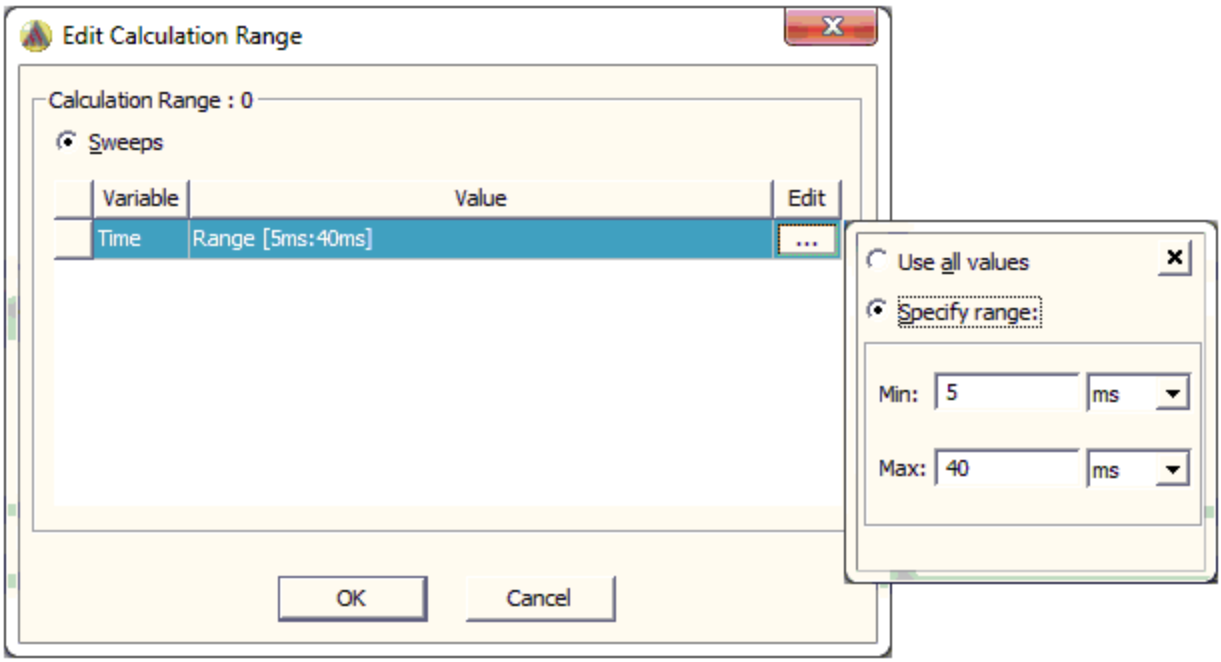
  For example, F(1GHz), cap(1pf, 1.2pf)

  For example, Distance(All), Freq([1ghz,2ghz]), Phase(0 deg)

If you click **Edit** on the menu, you see the **Edit Calculation Range** dialog box. Click on the ellipsis [...] button to select Use all values, Select values, or Specify range. The Select values option is available depending on the solution type.



This example shows how the range appears in the Calc. Range field when you specify a range,.



You could also enter the range directly in the Cal. Range field.

Overriding the Min. and Max. Variable Values for a Single Optimization Setup

1. In the **Setup Optimization** dialog box, click the **Variables** tab.

   All of the variables that were selected for optimization analysis are listed.
2. Type a new value in the **Min** or **Max** text box for the value you want to override, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is used for this optimization analysis; the variable's current **Min** or **Max** value in the nominal design is ignored.
   - Alternatively, you can select the **Override** option first, and then type a new value in the **Min** or **Max** text box.
3. Optionally, click a new unit system in one of the **Units** text boxes.

To revert to the default minimum and maximum values, clear the **Override** option.

Changing the Min. and Max. Variable Values for Every Optimization Setup

1. Make sure that the variable's minimum and maximum values are not being overridden in any single optimization setup.
2. If the variable is a design variable, do the following: Click **Maxwell3D or Maxwell2D>Design Properties**.

If the variable is a project variable, do the following: Click **Project**>**Project Variables**.

The **Properties** dialog box appears.

3. Select **Optimization**.
4. Type a new value in the **Min** or **Max** text box for the value you want to override, and then press **Enter**.
5. Click **OK**.

   When Optimetrics solves an optimization setup, it does not consider variable values that lie outside of this range.

Step Size

To make the search for the minimum cost value reasonable, the search algorithm is limited in two ways. First, you do not want the optimizer to continue the search if the step size becomes irrelevant or small. This limitation impacts the accuracy of the final optimum. Second, in some cases you do not want the optimizer to take large steps either. In case the cost function is suspected to possess large variations in a relatively small vicinity of the design space, large steps may result in too many trial steps, which do not improve the cost value. In these cases, it is safer to proceed with limited size steps and have more frequent improvements.

For these two limitations, the optimizer uses two independent distance measures. Both are based on user-defined quantities: the minimum and maximum step limits for individual optimization variables. Since the particular step is in a general direction, these measures are combined together in order to derive the limitation for that particular direction.

The step vector between the i^{th} and $(i+1)^{th}$ iterate is as follows:

$$s_i = x_{i+1} - x_i$$

The natural distance measure is,

$$\|s_i\| = \sqrt{s_i^T s_i}$$

which is the Euclidean norm.

A more general distance measure incorporates some "stretching" of the design space:,

$$\|s_i\|_D = \sqrt{s_i^T D^T D s_i}$$

where the matrix *D* incorporates the linear operation of the stretching of design space. The simplest case is when the *D* matrix is diagonal, meaning that the design space is stretched along the orthogonal direction of the base vectors.

The optimizer stops the search if,

$$\|s_i\|_{D_{min}} < 1$$

where D_{min} consists of diagonal elements

equal to the inverse of the **Min. Step** value assigned to the corresponding optimization variable. Similarly the optimizer truncates steps for which

$$\|s_i\|_{D_{max}} > 1$$

where D_{max} has diagonal elements equal to the inverse of **Max. Step** values of the corresponding optimization variables.

Setting the Min. and Max. Step Sizes

Cost Function

Adding a Cost Function

Setting the Min. and Max. Step Sizes

For the Quasi Newton and Pattern Search optimizers, the step size is the difference in a variable's value between one solved design variation and the next. The step size is determined when Optimetrics locates the next design variation that should be solved in an effort to meet the cost function.

1. In the **Setup Optimization** dialog box, click the **Variables** tab.
2. Optimetrics displays **Min Step** and **Max Step** columns, with default values for each variable to be optimized.
3. In the **Min Step** text box, type the minimum step size value. Optionally, modify the unit system in the **Units** text box.
4. In the **Max Step** text box, type the maximum step size value. Optionally, modify the unit

system in the **Units** text box.

5. Click **OK**.

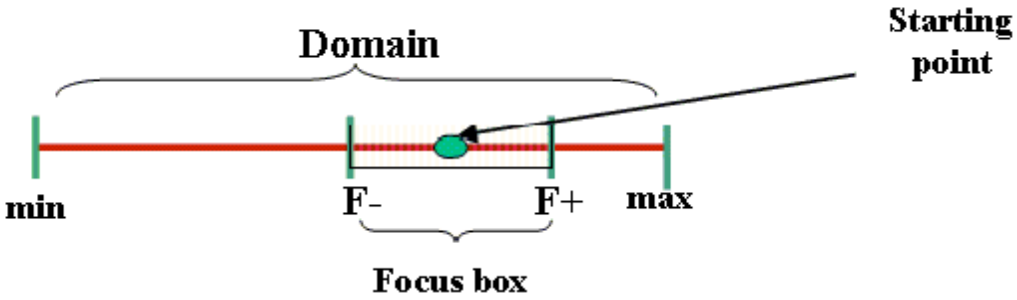
Hint	A value of zero is recommended for the minimum step size.

Related Topics

Step Size

Setting the Min and Max Focus

For the SNLP, SMINLP and Genetic Algorithm optimizers, the min focus and max focus criteria allow you to specify a sub-range of parameter values where the optimizer should look when performing the optimization. This focus box is where you suspect the optimal solution will be, so it is a hint for the optimizer.



- The domain limits the search. The domain = physical limits.
- The focus box does not limit the search. Rather, the Focus box = an initial guess of optimum search domain. The starting point is the center of the focus box, but the search does extend beyond the box.
- This focus must be inside the domain limits. Consequently, it has to be equal or smaller size. An error message is generated if you specify a focus outside the domain.
- The focus box must be at least one hundredth of the domain size. Otherwise, an error message is sent.

Equalizing the influence of different optimization variables.

The optimizer seeks optimal values for the optimization variables. These variables are usually quantities with specified units. The change in one variable could be measured in [mm] and the change in other variable could be measured in [mA]. Instead of those units, the optimizer uses internal abstract units, so that a change in one variable changes the design behavior about as much as the same change in another variable, where changes are measured in the respective internal abstract units. When you define the focus box, the unit of the abstract internal unit is

defined as the difference of the upper and lower focus limits. This way you can use the focus box to equalize the influence of different optimization variables on the design behavior.

To set the Min and Max Focus values:

1. In the **Setup Optimization** dialog box, click the **Variables** tab.
2. Optimetrics displays **Min. Focus** and **Max. Focus** columns, with default values for each variable to be optimized.

   If you do not have an initial guess based on your knowledge of the problem, make the focus box equal to the domain; that is, the physical limits. This tells SNLP to search the entire decision space.
   - In the **Min. Focus** text box, type the minimum value of the focus range. Optionally, modify the unit system in the **Units** text box.
   - In the **Max. Focus** text box, type the maximum value of the focus range. Optionally, modify the unit system in the **Units** text box.
   - Click **OK**.

Solving a Parametric Setup Before an Optimization

Solving a parametric setup before an optimization setup is useful for guiding Optimetrics during an optimization.

To solve a parametric setup before an optimization setup:

1. In the **Setup Optimization** dialog box, click the **General** tab.
2. In the **Parametric Analysis** pull-down list, click the parametric setup you want Optimetrics to solve before optimization.

Note	The parametric setup must include sweep definitions for the variables you are optimizing.

3. Select **Solve the parametric sweep before optimization**.

If the parametric setup has not yet been solved, Optimetrics solves it. Optimetrics uses the cost value evaluated at each parametric design variation to determine the next step in the optimization analysis. This enables you to guide the direction in which the optimizer searches for the optimal design variation.

Related Topics

Solving a Parametric Setup During an Optimization

Solving a Parametric Setup During an Optimization

Solving a parametric setup during an optimization analysis is useful when you want Optimetrics to solve every design variation specified in the parametric setup at each optimization iteration. A cost function goal could then depend on the value of the variable swept in the parametric setup.

To solve a parametric setup during an optimization analysis:

1. In the **Setup Optimization** dialog box, click the **General** tab.
2. In the **Parametric Analysis** pull-down list, click the parametric setup you want Optimetrics to solve during an optimization.
3. Select **Solve the parametric sweep during optimization**.
4. Optionally, you can adjust the sweep values to be used during the optimization.
   a. Click on the **Goal** tab, click **Setup Calculations** to specify a calculation.
      The **Add/Edit Calculation** dialog box is displayed.
   b. Click the **Calculation Range** tab.
   c. Click the **Edit** button for the sweep to be modified.
   d. In the pop-up dialog box, select the sweep values to use.
   e. Close the pup-up dialog box. Click **Done** to close the **Add/Edit Calculation** dialog.

Automatically Updating a Variable's Value After Optimization

When Optimetrics finds an optimal variable value by solving an optimization setup, it can automatically update that variable's current value set for the nominal model to the optimal value.

1. In the **Setup Optimization** dialog box, click the **General** tab.
2. Select **Update design parameters' values after optimization**.
   When optimization is complete, the current variable value for each optimized variable is changed to the optimal value.

Changing the Cost Function Norm

You can select the norm to be used in the calculation of the cost goal.

1. In the **Setup Optimization** dialog box, click the **Goals** tab.
2. Select **Show Advanced Options**.
3. Select a norm from the pull-down in the **Cost Function Norm Type** field. The options are **L1**, **L2**, and **Maximum**. **L2** is the default.

Explanation of L1, L2 and Max Norms in Optimization
Cost Function

Explanation of L1, L2 and Max norms in Optimization

When you set multiple goals for an optimization, the question arises as to what is actually going to drive the optimizer which is not a multi-objective one. The cost function will have a lot to do with it. The following discussion explains how the cost function is put together when there are multiple goals.

The general goal setting structure in Optimetrics is a logical sentence with the format:

Calculation$_{(i)}$ *Condition*$_{(i)}$ *Goal*$_{(i)}$ *Weight*$_{(i)}$

The cost function that the optimizer uses is built based on the norm setting as long as there are multiple goals and none of those use the “minimize” or “maximize” conditions. Thus, in this case the error associated with each individual goal (weighted) is combined in a way that is specific for each norm type chosen.

For **L1** norm the actual cost function uses the sum of absolute weighted values of the individual goal errors:

$$Cost = \sum_{1}^{N} \left| w_i \varepsilon_i \right|$$

For **L2** norm the actual cost function uses the weighted sum of absolute values of the individual

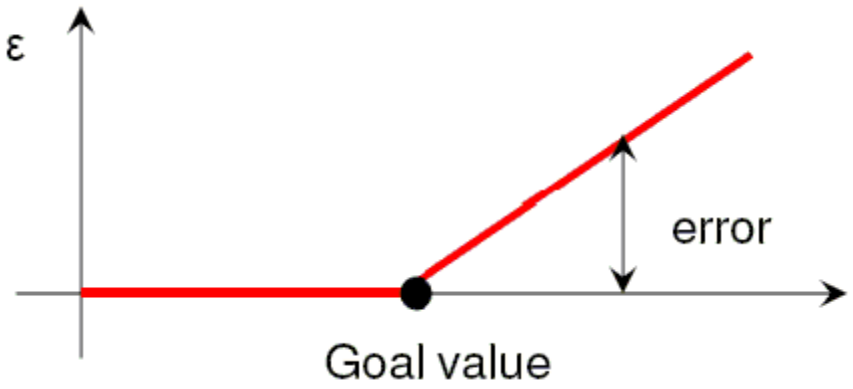
$$Cost = \sum_{1}^{N} w_i \varepsilon_i^2$$

For the **Maximum** norm the cost function uses the maximum among all the weighted goal errors:

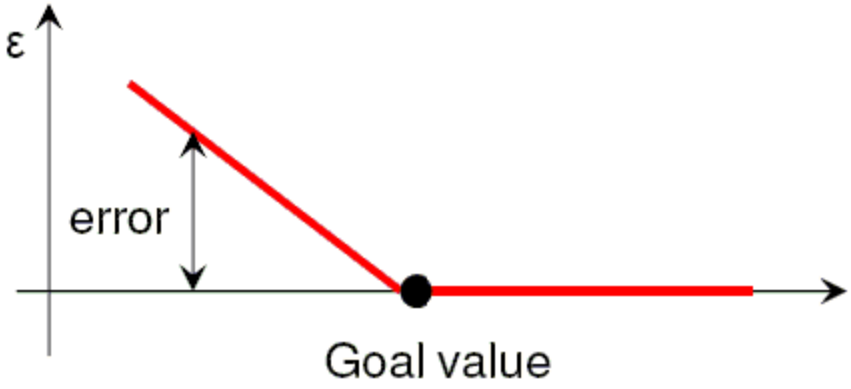
$$Cost = \max_{1}^{N} W_i \cdot \varepsilon_i$$

For all the above situations N is the number of individual goals $w_i\varepsilon_i$ are individual weighting factors and residual error respectively. A minimization of the cost function is performed during optimization since it makes sense to minimize the error in the sense of the chosen norm type.

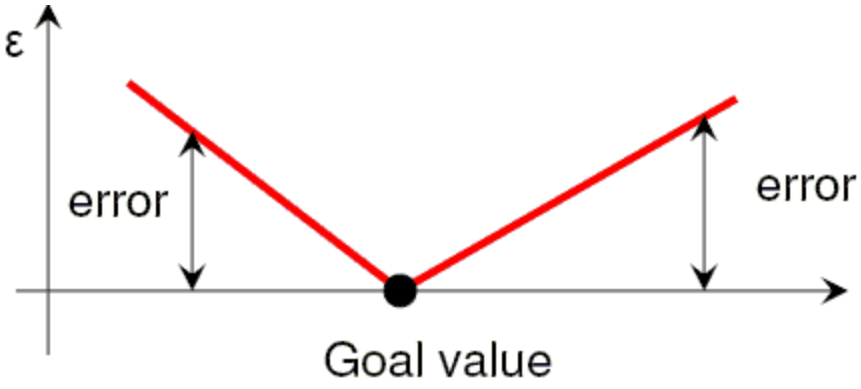
The graphical representation of the error is possible and depends upon the actual condition being used. If a “<” condition is used, the error can be represented as below:



If a “>” condition is used, the error can be represented as below:



If a “=” condition is used, the error is double-sided and can be represented as below:



The norm type doesn’t impact goal setting that use as condition the “minimize” or “maximize” scenarios. Note that when using “minimize” or “maximize” settings for the condition there should be a single goal setting which in this case coincides with the cost function.

Advanced Genetic Algorithm Optimizer Options

The Genetic Algorithm (GA) search for Optimization analysis is an iterative process that goes through a number of generations. In each generation some new individuals (Children / Number of Individuals) are created and the so grown population participates in a selection (natural-selection) process that in turn reduces the size of the population to a desired level (Next Generation / Number of Individuals).

If you select the Genetic Algorithm for an Optimization analysis, a **Setup** button is enabled on the **Setup Optimization** page.

1. Click the **Setup** button to open the **Advanced Genetic Algorithm Optimizer Options** dialog.
2. Select the Stopping Criteria. Any of the three following, or any combination of these can be selected.
   - **Maximum number of generations**. If checked, this enables a value field.
   - **Elapsed time**. If checked, this enables a drop down menu with times ranging from five minutes to two weeks.
   - **Slow convergence**.
3. Specify the Parents.

   The first step toward mating is a selection process that determines the participating individuals. Potential parents are selected from the Current Generation. This is a set of individuals that is always a subset of the current generation.
   - **Number of individuals** value field -- specify the number of parents for the optimizer to use. You can set the Number of Individuals to less than or equal to the size of the "Current Generation". One reason to consider fewer parents than the possible maximum is to steer the GA toward improvement by selecting the better portion of the current generation to be able to mate.
   - **Roulette selection** check box -- if checked, this enables the **Selection pressure** value field. This number defines how many times more probable is the selection of the best individual over the worst individual in an elementary spin of the roulette wheel.
4. Specify the Mating pool.

   The Mating pool is created by selecting randomly from the parents, but with each selection, the parent gets "cloned" so it can be selected again and again.
   - **Number of individuals** field -- specify the number individuals to include in the mating pool.
   - **Reproduction setup**-- this button opens the **Genetic Algorithm Optimizer Reproduction Setup** dialog box.

5. Click the **Reproduction setup** button for the dialog to specify the Crossover setup, and the Mutation setup.

   The crossover and mutation operator have different roles: *Crossover* mixes "features" of the parents in a new combination, while *mutation* slightly alters the "features" of the individuals. Both need to be present in a GA. The crossover is a way to discover new combinations while the mutation acts as a local search or fine-tuning step. Mutation also keeps diversity in a population, which is a must for GA.

   The crossover operator has two steps. It first alters the variable values of the parents according to a distribution. This tends to produce one child that looks a lot like one parent, and one child that looks a lot like the other parent. Next, some of the variable values of the two children can be exchanged in order to achieve more variation.

   For crossover there are four possible parameters.

   a. **Individual Crossover Probability** determines, for each pair in the mating pool, the probability that their features will be mixed. Usually, this probability should be close or equal to one. If you set it set less than one, some parents will produce two children which are exact clones of the parents. This means that some children inherit all the features of their parents unchanged.
   b. Parents often have multiple variables. If the parent is a candidate for mixing, the **Variable Crossover Probability** determines, for each variable, the probability of mixing. This is usually set high to ensure that most or all variables mix.
   c. **Variable Exchange Probability**: After the slight change in the variable values has been made, the crossover operation is also able to exchange the values of the variables between the two children that are being constructed. The Variable Exchange Probability governs the likelihood of exchange of any variable.
   d. **Mu** is a general parameter defining the sharpness of the distribution that might be used for the **Variable Crossover Probability**. Mu should be greater than one. There is no theoretical upper limit, but we recommend not exceeding 30.

6. Select one of the four **Crossover types** from the drop-down menu.

   The crossover type selected affects the options available.

Uniform	Individual crossover probability Variable crossover probability
One point	Individual crossover probability
Two point	Individual crossover probability
Simulated binary crossover	Individual crossover probability Variable crossover probability

	Variable exchange probability Mu

7. Select the **Mutation type**--this can be one of three types, which you select from a drop-down menu.
   - **Uniform Distribution**
   - **Gaussian Distribution**
   - **Polynomial Mutation.**
8. For the selected mutation type, set the following parameters:
   - **Uniform Mutation Probability**: If this is more than zero (recommendation is to have still a small probability here), then there will be some children whose features are simply a completely random design (design variables randomly selected over the domain).
   - **Individual Mutation Probability** controls, for each child, the likelihood of a mild mutation.
   - **Variable Mutation Probability**. If the child will be mutated, this probability controls at the variable level the likelihood of a mutation of the variables.
   - **Standard Deviation** is the standard deviation of the selected distribution that is being used for the mutation and it is measured relatively to the optimization-domain.
9. When you have completed the Reproduction setup in the **Genetic Algorithm Optimizer Reproduction Setup** dialog, click **OK** to close it and return to the **Advanced Genetic Algorithm Optimizer Options** dialog.
10. In the **Advanced Genetic Algorithm Optimizer Options** dialog box, specify the children as a Number of Individuals.
11. Set the **Pareto Front** value.

    This the number of the very best individuals (identified relative to the cost function) to keep for future generations.
12. Set the Next Generation parameters. The Next Generation is selected from the Parents, the children, and the Pareto front.
    - **Number of individuals** value field -- specify the number of individuals to survive to form the next generation for the optimizer to use.
    - **Roulette selection** check box -- if checked, this enables the **Selection pressure** value field. This number defines how many times more probable is the selection of the best individual over the worst individual in an elementary spin of the roulette wheel.
13. Click **OK** to accept the settings for the Genetic Algorithm and to close the dialog.

Sensitivity Analysis Overview

During a sensitivity analysis, Optimetrics explores the vicinity of the design point to determine the sensitivity of the design to small changes in variables. The variables and their attributes define the design point, the problem around which the sensitivity analysis is performed.

When Optimetrics performs a sensitivity analysis, its goal is to calculate the second-order regression polynomials for all of the design's output parameters. The algorithm first determines an appropriate interval for each variable. The intervals are further sub-divided according to the available number of iterations and variables. If the primary output is not used, the specified initial displacement values define those intervals.

When all of the design calculations are complete, the second-order polynomials are fitted for all the output parameters. Optimetrics then reports the following quantities:

- Regression value at the current variable value.
- First derivative of the regression.
- Second derivative of the regression.

Related Topics

Setting Up a Sensitivity Analysis
Selecting a Primary Output

Selecting a Primary Output

During a sensitivity analysis, the design variations that Optimetrics selects to solve are close to the design point, but not so close that numerical noise (from the finite element mesh) affects the analysis. The algorithm that Optimetrics uses to determine the design variations to solve must be based on only one output parameter and that output parameter's numerical noise. Therefore, if you have defined more than one output parameter, be sure to select **Primary Output** for the output variable on which you want the selection of design variations to be based.

Related Topics

Setting Up an Output Parameter
Setting Up a Sensitivity Analysis

Setting Up a Sensitivity Analysis

Following is the general procedure for setting up a sensitivity analysis. Once you have created a setup, you can **Copy** and **Paste** it, and then make changes to the copy, rather than redoing the

whole process for minor changes. You can create a sensitivity setup before defining variables but all variables must be defined before you start the sensitivity analysis.

1. Before a variable can be included in a sensitivity analysis, you must specify that you intend for it to be used during a sensitivity analysis in the **DesignProperties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, point to **Optimetrics Analysis**, and then click **Add Sensitivity**  .

   The **Setup Sensitivity Analysis** dialog box appears.
3. Under the **Calculations** tab, type the maximum number of iterations per variable value that you want Maxwell to perform in the **Max. No. of Iterations/Sensitivity Variable** text box.
4. Set up an output parameter calculation and select a Primary Output
5. Specify the value of the design point at which the sensitivity analysis should stop in the **Approximate Error in Primary Output** text box.
6. In the **Variables** tab, specify the **Min/Max** values for variables included in the optimization, and the **Initial Displacement (Initial Disp.)** for the analysis.

   You may also override the variable starting values by clicking the **Override** check box and entering the desired value in the **Starting Value** field.
7. In the **General** tab, specify whether Optimetrics should use the results of a previous Parametric analysis or perform one as part of the optimization process.
8. Under the **Options** tab, if you want to save the field solution data for every solved design variations in the optimization analysis, select **Save Fields And Mesh**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.

   You may also select **Copy geometrically equivalent meshes** to reuse the mesh when geometry changes are not required, for example when optimizing on a material property or source excitation.This will provide some speed improvement in the overall optimization process.

The following ***optional*** sensitivity analysis setup options can also be used:

- Modify the starting variable value.
- Modify the minimum and maximum values of variables that will be solved.
- Exclude variables from the sensitivity analysis.
- Set the initial displacement.
- Modify the values of fixed variables that are not being modified during the sensitivity analysis.
- Set linear constraints.
- Request that Optimetrics solve a parametric sweep **before** a sensitivity analysis.
- You can also request that Optimetrics solve a parametric sweep **during** a sensitivity analysis.

- Set **HPC and Analysis Options**, which allows you to select or create an analysis configuration.

Note	Sweeping or using a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

Related Topics

Sensitivity Analysis Overview

Setting the Maximum Iteration Per Variable

Setting the Maximum Iterations Per Variable

The **Max. No. of Iterations/Sensitivity Variable** value is the maximum number of design variations that Optimetrics solves per variable during a sensitivity analysis. This value is a stopping criterion; if the maximum number of iterations has been completed, the sensitivity analysis stops. If the maximum number of iterations has not been completed, the sensitivity analysis continues by performing another iteration, that is, by solving another design variation. It performs iterations until the approximate error in primary output value is reached or until Optimetrics cannot proceed as a result of other sensitivity setup constraints, such as when it searches for a variable value that is larger than the maximum value.

To set the maximum number of iterations for a sensitivity analysis:

- Under the **Calculations** tab of the **Setup Sensitivity Analysis** dialog box, type a value in the **Max. No. of Iterations/Sensitivity Variable** text box.

Related Topics

Setting Up an Output Parameter

Setting Up an Output Parameter

Following is the general procedure for adding an output parameter to a sensitivity setup:

1. Under the **Calculations** tab of the **Setup Sensitivity Analysis** dialog box, click **Setup Calculations** to open the **Add/Edit Calculations** dialog box.
2. In the **Add/Edit Calculations** dialog box, set up output parameter calculations to be evaluated for sensitivity.
3. To modify the solution from which the output parameter is to be extracted, click in the **Solution** column and select from the options in the pop-up list.
4. You can modify the Calculation specified by clicking on the output parameter in the table and selecting **Edit**.
5. For output parameters based on swept variable, you must choose a single value in the **Calculation Range** at which to evaluate the output parameter.

6. If you have more than one output parameter, select **Primary Output** if you want Optimetrics to use the output parameter to base its selection of solved design variations.

Note	During a sensitivity analysis, the design variations that Optimetrics selects to solve are close to the design point, but not so close that numerical noise (from the finite element mesh) affects the analysis. The algorithm that Optimetrics uses to determine the design variations to solve must be based on only one output parameter and that output parameter's numerical noise. If you have defined more than one output parameter, be sure to select **Primary Output** for the output variable on which you want the selection of design variations to be based.

Selecting a Primary Output

Specifying a Solution Quantity for an Output Parameter

When setting up an output parameter, you must identify the solution quantity on which to base the output parameter. Solution quantities are specified by mathematical expressions that are composed of basic quantities, such as matrix parameters; and output variables.

The **Add/Edit Calculation** dialog box allows you to define the mathematical equation for one or multiple output parameters. To set up an output parameter:

1. In the **Context** section of the dialog:
   - Select the **Report Type** with a pull-down selection list containing the available types for this design.
   - Select the **Solution** from the drop down selection list. This lists the available setups and sweeps. As a minimum, the **LastAdaptive** solution is available.
   - Select the **Geometry** from the drop down selection list or select none (the default). This modifies the list of quantities available to the ones that apply to the specific geometry.
   - When selecting a geometry, you may also be required to specify a point within the geometry where the calculation is to be performed.
2. The **Output Variables** button opens the Output Variables dialog box allowing you to create special output variables to be used in the output parameter.
3. The **Calculation Expression** field in the **Trace** tab is used to enter the equation to be used for the output parameter. To enter an expression, you may type it directly into the field or use the **Category**, **Quantity**, and **Function** lists as follows:
   - Select the **Category**, these depend on the Solution type and the design. This lets you specify the category of information to be used in the output parameter.
   - Select a **Quantity** from the list. Available quantities depend upon the Solution type, as well as the Geometry and Category selection. Selecting a Quantity automatically enters it into the Calculation Expression field.
   - Select a **Function** to apply to the value in the calculated expression.

- For swept variables, the Range **Function** button opens the **Set Range Function** dialog to apply functions to the expression that apply over the sweep range.

4. The **Calculation Range** tab applies to swept variables and allows you to specify the range of the sweep over which to apply the calculation.
5. When the desired **Calculation Expression** has been obtained, click the **Add Calculation** button to add the entry to the calculation table in the Setup Sensitivity Analysis dialog box. You may add multiple entries to the table simply by changing the **Calculation Expression** and using the **Add Calculation** button.
6. To update or edit a selected cost function, enter the desired Calculation Expression and click the **Update Calculation** button.
7. Click **Done** to return to the Setup Sensitivity Analysis dialog box.

Note	The solution quantity you specify must be able to be evaluated to a single, real number.

Related Topics

Setting the Calculation Range of an Output Parameter

Setting the Calculation Range of an Output Parameter

The calculation range of a solution quantity determines the intrinsic variable value at which the solution quantity is to be extracted. For a sensitivity setup, the calculation range must be a single value. If you specified that the solution quantity be extracted from a frequency sweep solution, by default, Optimetrics uses the starting frequency in the sweep.

1. Under the **Calculations** tab of the **Setup Sensitivity Analysis** dialog box, click **in the Calculation Range column of the table for the calculation to be modified.**

   The **Edit Calculation Range** dialog box appears.
2. In the **table**, click the **Edit** button in the row to be modified.

   If you choose to solve a parametric setup during the sensitivity analysis, the variables swept in that parametric setup are available in the pop-up list dialog box. If you sweep a variable in the parametric setup that is also a sensitivity variable, that variable is excluded from the sensitivity analysis.
3. **Click on the value for the calculation range in the list and dismiss the pop-up dialog box**.
4. Click **OK in the Edit Calculation Range dialog box to accept the new value for the intrinsic variable, and return to the Setup Sensitivity Analysis dialog box**.

Related Topics

Setting Up an Output Parameter

Modifying the Starting Variable Value for Sensitivity Analysis

The design point of the sensitivity analysis is the starting value of the sensitivity variable and is usually the first variation to be solved. Optimetrics automatically sets the starting value of a variable to be the current value set for the nominal design. You can modify the design point for each sensitivity setup.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

1. In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.

   All of the variables that were selected for the sensitivity analysis are listed.
2. Type a new value in the **Starting Value** text box for the value you want to override, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is to be used for this sensitivity analysis; the current value set for the nominal model will be ignored.
   - Alternatively, you can select the **Override** option first, and then type a new variable value in the **Starting Value** text box.
3. Optionally, click a new unit system in one of the **Units** text boxes.

To revert to the default starting value, clear the **Override** option.

Related Topics

Setting Up a Sensitivity Analysis

Setting the Min. and Max. Variable Values

For every sensitivity setup, Optimetrics automatically sets the minimum and maximum values that it will consider for a sensitivity variable. Optimetrics sets a variable's minimum value equal to approximately one-half its starting value. (The starting value is the variable's current value set for the nominal design.) Optimetrics sets the variable's maximum value equal to approximately 1.5 times the starting value. During sensitivity analysis, variable values outside this range are not considered.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

Related Topics

Override the default minimum and maximum variable values for a single sensitivity setup.

Change the default minimum and maximum variable values for every sensitivity setup.

Overriding the Min. and Max. Variable Values for a Single Sensitivity Setup

1. In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.

   All of the variables that were selected for sensitivity analysis are listed.
2. Type a new value in the **Min** or **Max** text box for the value you want to override, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is to be used for this sensitivity analysis; the variable's current **Min** or **Max** value set in the nominal design is ignored.
   - Alternatively, you can select the **Override** option first, and then type a new value in the **Min** or **Max** text box.
3. Optionally, click a new unit system in one of the **Units** text boxes.

To revert to the default minimum and maximum values, clear the **Override** option.

Related Topics

Setting Up a Sensitivity Analysis

Changing the Min. and Max. Variable Values for Every Sensitivity Setup

1. Make sure the variable's minimum and maximum values are not being overridden in any sensitivity setup.
2. If the variable is a design variable, do the following: Click **Maxwell3D or Maxwell2D>Design Properties**.

   If the variable is a project variable, do the following: Click **Project**>**Project Variables**.

   The **Properties** dialog box appears.
3. Select **Sensitivity**.
4. Type a new value in the **Min** or **Max** text box for the value you want to override, and then press **Enter**.

   When Optimetrics solves a sensitivity setup, it does not consider variable values that lie outside of this range.

Related Topics

Setting Up a Sensitivity Analysis

Setting the Initial Displacement

The initial displacement is the difference in a variable's starting value and the next solved design variation. During the sensitivity analysis, Optimetrics does not consider an initial variable value that is greater than this step size away from the starting variable value.

1. In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
2. Optimetrics displays the **Initial Disp.** column, with default values for each sensitivity variable.
3. In the **Initial Disp.** text box, type the initial displacement value. Optionally, modify the unit system in the **Units** text box.

Related Topics

Setting Up a Sensitivity Analysis

Solving a Parametric Setup Before a Sensitivity Analysis

Solving a parametric setup before a sensitivity setup is useful for guiding Optimetrics in a sensitivity analysis.

To solve a parametric setup before a sensitivity setup:

1. In the **Setup Sensitivity Analysis** dialog box, click the **General** tab.
2. Click the parametric setup you want Optimetrics to solve before the sensitivity setup from the **Parametric Analysis** pull-down list.

Note	The parametric setup must include sweep definitions for the sensitivity variables.

3. Select **Solve the parametric sweep before analysis**.

If the parametric setup has not yet been solved, Optimetrics solves it. Optimetrics uses the results (of the solution calculation you requested under the **Goals** tab of the **Setup Sensitivity** dialog box) to determine the next design variation to solve for the sensitivity analysis.

Statistical Analysis Overview

Statistical analysis allows you to explore the effects of random combinations of values of selected variables on selected global or local available analysis results. Therefore, before a variable can be included in a statistical analysis, you must specify that you intend for it to be used during a statistical analysis. For each variable you must specify the type of distribution (Uniform, Gaussian, Lognormal or User Defined) and the corresponding parameters of the selected distribution.

Note	A statistical analysis is currently limited to using a maximum of 30 variables.

In addition to specifying the variables to be used in the statistical analysis and the parameters of the chosen distribution, the output quantities of interest also need to be specified. These quantities can be global ones such as previously defined parameters (Force/torque, inductance / capacitance, etc), other named quantities, quantities defined in the field calculator as global (such a domain integral of a certain field quantity) or local (such as field value at a certain location). The calculations to be performed during the statistical analysis are specified during setup, in a manner similar to other types of analysis in Optimetrics.

Following the analysis the statistical distribution of the output quantities can be visualized in histogram format. To access available reports, after the statistical analysis is complete, right click the respective Statistical analysis setup and select **View Analysis Result**.

Specifying the Solution Quantity to Evaluate for Statistical Analysis

When you add a statistical setup, you can identify one or more solution quantities to evaluate. The solution quantities are specified by mathematical expressions that are composed of basic quantities. When you view the results, Maxwell displays the distribution of the solution quantities.

1. In the **Calculations** tab of the **Setup Statistical Analysis** dialog box, click **SetupCalculations**.

   The **Add/Edit Calculations** dialog box is displayed, allowing you to define one or more mathematical expressions for statistical evaluation.
2. In the **Context** section of the dialog:
   - Select the **Report Type** with a pull-down selection list containing the available types for this design.
   - Select the **Solution** from the drop down selection list. This lists the available setups and sweeps. As a minimum, the **LastAdaptive** solution is available.
   - Select the **Geometry** from the drop down selection list or select none (the default). This modifies the list of quantities available to the ones that apply to the specific geometry.
   - When selecting a geometry, you may also be required to specify a point within the geometry where the calculation is to be performed.
3. The **Output Variables** button opens the Output Variables dialog box allowing you to create special output variables to be used in the output parameter.
4. The **Calculation Expression** field in the **Trace** tab is used to enter the equation to be used for the solution quantities. To enter an expression, you may type it directly into the field or use the **Category**, **Quantity**, and **Function** lists as follows:
   - Select the **Category**, these depend on the Solution type and the design. This lets you specify the category of information to be used in the output parameter.
   - Select a **Quantity** from the list. Available quantities depend upon the Solution type, as well as the Geometry and Category selection. Selecting a Quantity automatically enters it into the Calculation Expression field.
   - Select a **Function** to apply to the value in the calculated expression.
   - For swept variables, the Range **Function** button opens the **Set Range Function** dialog to apply functions to the expression that apply over the sweep range.

5. The **Calculation Range** tab applies to swept variables and allows you to specify the range of the sweep over which to apply the calculation.
6. When the desired **Calculation Expression** has been obtained, click the **Add Calculation** button to add the entry to the calculation table in the Setup Statistical Analysis dialog box. You may add multiple entries to the table simply by changing the **Calculated Expression** and using the **Add Calculation** button.
7. To update or edit a selected cost function, enter the desired Calculation Expression and click the **Update Calculation** button.
8. Click **Done** to return to the Setup Statistical Analysis dialog box.

Note	The solution quantity you specify must be able to be evaluated to a single, real number.

Setting the Solution Quantity's Calculation Range

The calculation range of a solution quantity determines the intrinsic variable value at which the solution quantity is extracted. For a statistical setup, the calculation range must be a single value. If you specified that the solution quantity be extracted from a frequency sweep solution, Optimetrics will use the starting frequency in the sweep by default.The calculation range should be set during the setup of the solution quantity for statistical evaluation. In order to modify the calculation range, do the following:

1. Under the **Calculations** tab of the **Setup Statistical Analysis** dialog box, click **in the Calculation Range column of the table for the calculation to be modified**.

   The **Edit Calculation Range** dialog box appears.
2. In the **table**, click the **Edit** button in the row to be modified.

   If you choose to solve a parametric setup during the statistical analysis, the variables swept in that parametric setup are available in the pop-up list dialog box. If you sweep a variable in the parametric setup that is also a statistics variable, that variable is excluded from the statistics analysis.
3. **Click on the value for the calculation range in the list and dismiss the pop-up dialog box**.
4. Click **OK in the Edit Calculation Range dialog box to accept the new value for the intrinsic variable, and return to the Setup Statistical Analysis dialog box**.

Setting the Distribution Criteria

For every statistical setup, Optimetrics automatically sets the distribution criteria to be uniform within a 10% tolerance of the variable's starting value. You can modify the distribution type and criteria for a single statistical setup or for every statistical setup.

Related Topics

Override the default distribution criteria for a single statistical setup.

Change the default distribution criteria for every statistical setup.

Overriding the Distribution Criteria for a Single Statistical Setup

To override the default distribution criteria for a single statistical setup:

1. In the **Setup Statistical Analysis** dialog box, click the **Variables** tab.

   All of the variables that were selected for statistical analysis are listed.
2. Check or clear the **Include** check box for each variable to define the specific variables to be varied in the statistical analysis setup.
3. For each included variable, select **Uniform**, **Gaussian**, **Lognormal**, or **User Defined** in the **Distribution** column for the variable you want to override.

   If you changed the distribution type, the **Override** option is now selected. This indicates that the distribution type you selected is to be used for this optimization analysis; the current distribution type selected for the variable in the nominal design is ignored in this statistical analysis.
   - Alternatively, you can select the **Override** option first, and then select a different distribution type in the **Distribution** text box.
4. Optionally, if you want to change the distribution criteria, click in **Distribution Criteria** column for the variable you want to override.

   The **Edit Distribution** dialog box appears.
5. If the distribution type is **Gaussian**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box. This is a value =>0 and < 0.1.
   b. Type the mean value of the distribution in the **Mean** text box.
   c. Type the standard deviation of the distribution in the **Std Dev** text box.
   Maxwell will solve design variations using a Gaussian distribution within the low and high cutoff values.
6. If the distribution type is **Uniform**, do the following:
   - Enter a tolerance value in the text box.

     Maxwell will solve design variations within the tolerance range of the starting value, using an even distribution.
7. If the distribution type is **Lognormal**, do the following:

a. Enter the cutoff probability in the **Cutoff Probability** text box.
b. Enter the sigma value of the distribution in the **Sigma** text box and select a unit from the pull-down.
c. Enter the m value of the distribution in the **M** text box.
d. Enter the theta value in the Theta text box and select a unit from the pull-down.

8. If the distribution type is User Defined, do the following:
   a. Enter the cutoff probability in the **Cutoff Probability** text box.
   b. Click **Edit XY Data** to open the **Edit Datasets** dialog box in which you can select an existing dataset, or create a new one.
9. By default, all variables are set to sample using **Latin Hypercube** sampling. This sampling method provides for greater variability than random sampling by keeping track of chosen samples and guaranteeing that samples cannot be repeated. You may revert to random sampling by clearing the check box in the **Latin Hypercube** column for any desired variable.
10. Click **OK**.

To revert to the default distribution settings, clear the **Override** option.

Changing the Distribution Criteria for Every Statistical Setup

To change the default distribution criteria for every statistical setup:

1. Make sure that the variable's distribution criteria are not being overridden in any statistical setup.
2. If the variable is a design variable, do the following: On the **Maxwell3D or Maxwell2D** menu, click **Design Properties**.

   If the variable is a project variable, do the following: Click **Project**>**Project Variables**.

   The **Properties** dialog box appears.
3. Select **Statistics**.
4. Click in the **Distribution** column for the variable you want to change, and then select **Uniform**, **Gaussian**, **Lognormal**, or **User Defined**.
5. Optionally, if you want to change the distribution criteria, click in the **Distribution Criteria** column for the variable you want to change.

   If the distribution type is **Gaussian**, the **Gaussian Distribution** dialog box appears. If the distribution type is **Uniform**, the **Uniform Distribution** dialog box appears.
6. If the distribution type is **Gaussian**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box. This is a value =>0 and < 0.1.

b. Type the mean value of the distribution in the **Mean** text box.
c. Type the standard deviation of the distribution in the **Std Dev** text box.
Maxwell will solve design variations using a Gaussian distribution within the low and high cutoff values.

7. If the distribution type is **Uniform**, do the following:
   a. Type a cutoff probability value in the **Cutoff Probability** text box.
   b. Type mean and tolerance values in the corresponding text boxes.
   Maxwell will solve design variations within the tolerance range of the starting value, using an even distribution.
8. If the distribution type is **Lognormal**, do the following:
   a. Type a cutoff probability value in the **Cutoff Probability** text box.
   b. Type values for Sigma, M, and Theta in the corresponding text boxes.
9. If the distribution type is **User Defined**, do the following:
   a. Type a cutoff probability value in the **Cutoff Probability** text box.
   b. Click **Edit XY Data** to open the **Edit Dataset** dialog.
   c. Either type or import the X and Y data values for the distribution in the **Edit Dataset** dialog.
10. Click **OK**.

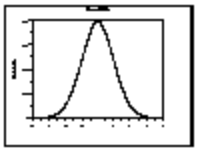
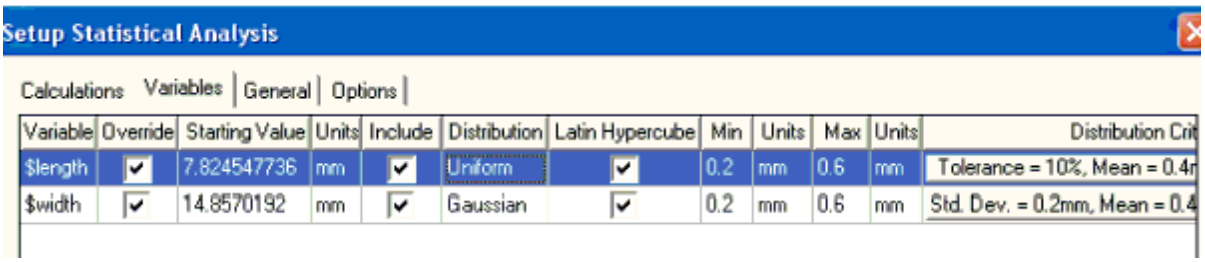
Statistical Cutoffs

Statistical Cutoffs

The cutoff probability values affects the Gaussian distribution criteria. This is a value =>0 and < 0.1. Maxwell solves design variations using a Gaussian distribution using a lower limit cutoff probability and specified mean and standard deviation values.



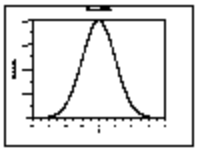


Uniform distributions such as variable “length” above use only the Tolerance value, and do not have a cutoff probability.

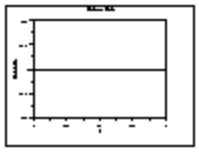
Edit Distribution

When setting the distribution type for a variable, you have the option of changing the distribution parameters from the default values.

1. If the distribution type is **Gaussian**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box. This is a value =>0 and < 0.1.
   b. Type the mean value of the distribution in the **Mean** text box.
   c. Type the standard deviation of the distribution in the **Std Dev** text box.
   Maxwell solves design variations using a Gaussian distribution within the specified mean and standard deviation values.

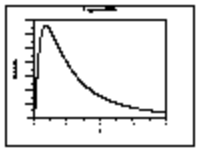


2. If the distribution type is **Uniform**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box.
   b. Type the mean value of the distribution in the **Mean** text box.
   c. Enter the tolerance in the **Tolerance** text box.
   Maxwell solves design variations within the tolerance range of the starting value, using an even distribution.



3. If the distribution type is **Lognormal**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box.
   b. Enter the shape parameter of the distribution in the **Sigma** text box.
   c. Enter the scale parameter in the **M** text box. The scale parameter should be set to 1 for the standard lognormal distribution.
   d. Enter the location parameter value for **Theta** in the text box. The value for a standard lognormal distribution is 0.

.Maxwell solves design variations with a logarithmic distribution using the shape, scale and location parameters provided.



4. If the distribution type is **User Defined**, do the following:
   a. Type the lower limit of the distribution in the **Cutoff Probability** text box.
   b. Select the **Edit XY Data** button to manually define the data distribution using datasets.

Modifying the Starting Variable Value for Statistical Analysis

A variable's starting value is the first value that is solved during the statistical analysis. Optimetrics automatically sets the starting value of a variable to be the current value set for the nominal design. You can modify this value for each statistical setup.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

1. In the **Setup Statistical Analysis** dialog box, click the **Variables** tab.

   All of the variables selected for the statistical analysis are listed.
2. Type a new value in the **Starting Value** text box for the value you want to override, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is to be used for this statistical analysis; the current value set for the nominal model will be ignored.
   - Alternatively, you can select the **Override** option first, and then type a new variable value in the **Starting Value** text box.
3. Optionally, click a new unit system in one of the **Units** text boxes.

To revert to the default starting value, clear the **Override** option.

Using Design of Experiments

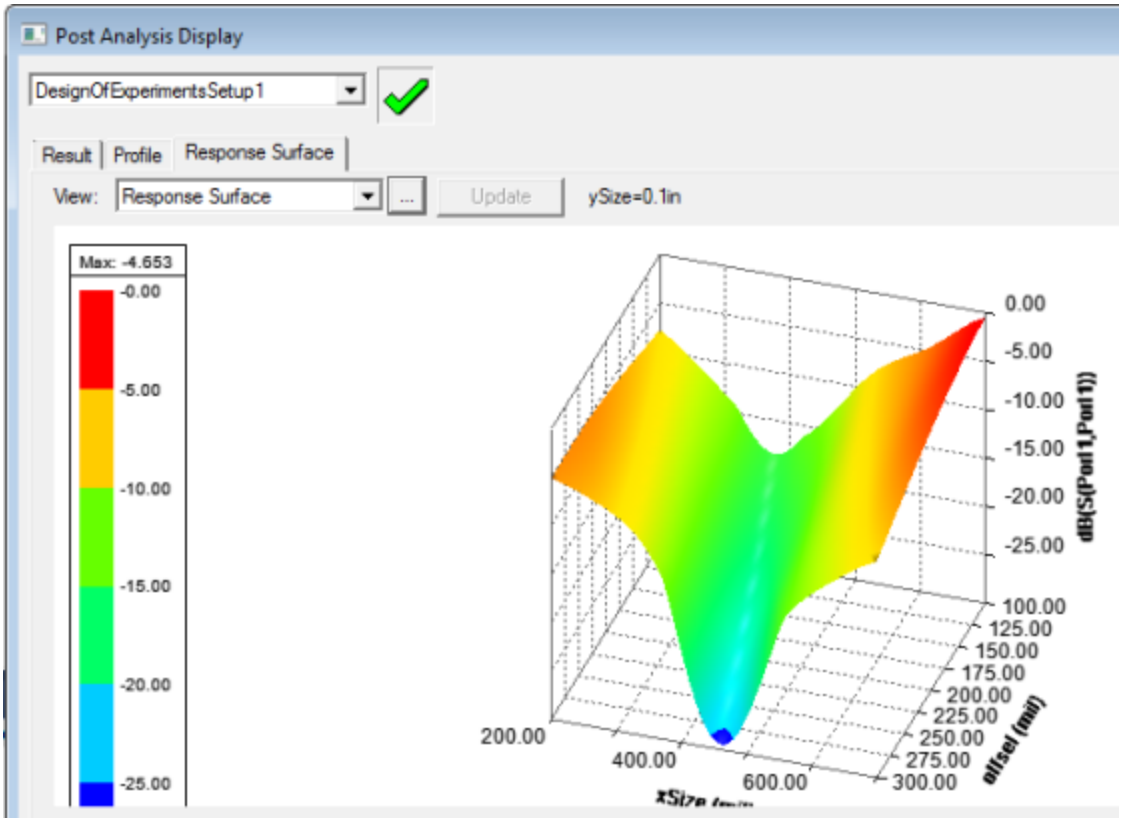
Design of Experiments (DOE) is a technique used to scientifically determine the location of sampling points and is included as part of the Response Surface, Goal Driven Optimization, and Analysis systems. Design of Experiments plus a mathematical approximation of output parameters lets you:

- Reduce the number of simulations
- Interactively explore the design space before running optimization

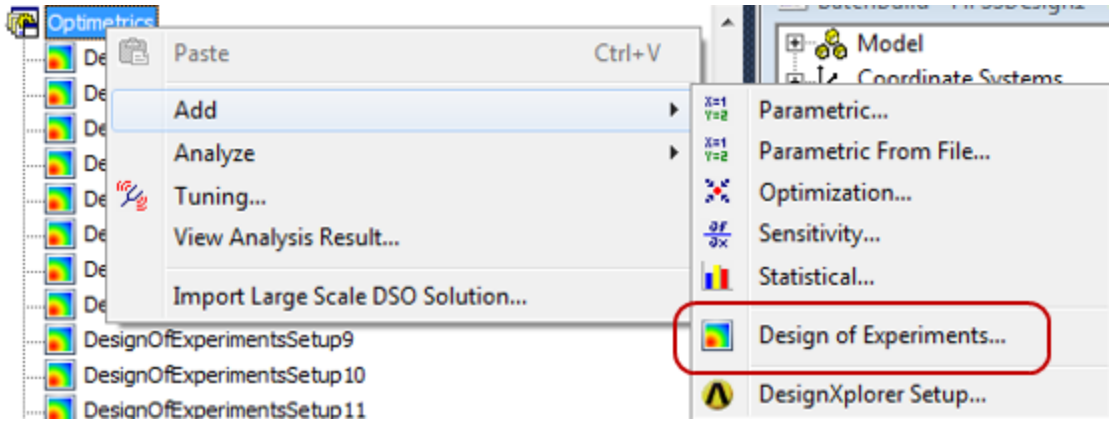
Design of Experiments describes the relationship between the design variables and the performance of the product by using Design of Experiments (DOE), combined with response surfaces. DOE and response surfaces provide all of the information required to achieve Simulation Driven Product Development. Once the variation of the performance with respect to the design variables is known, it becomes easy to understand and identify all changes required to meet the requirements for the product.

The goal is to create a response surface by interpolating through calculated points (a best curve fit). For each design, you can create a response surface for each output parameter. Once the response surfaces are created, you can share the information can in easily understandable terms: curves, surfaces, sensitivities, etc. They can be used at any time during the development of the

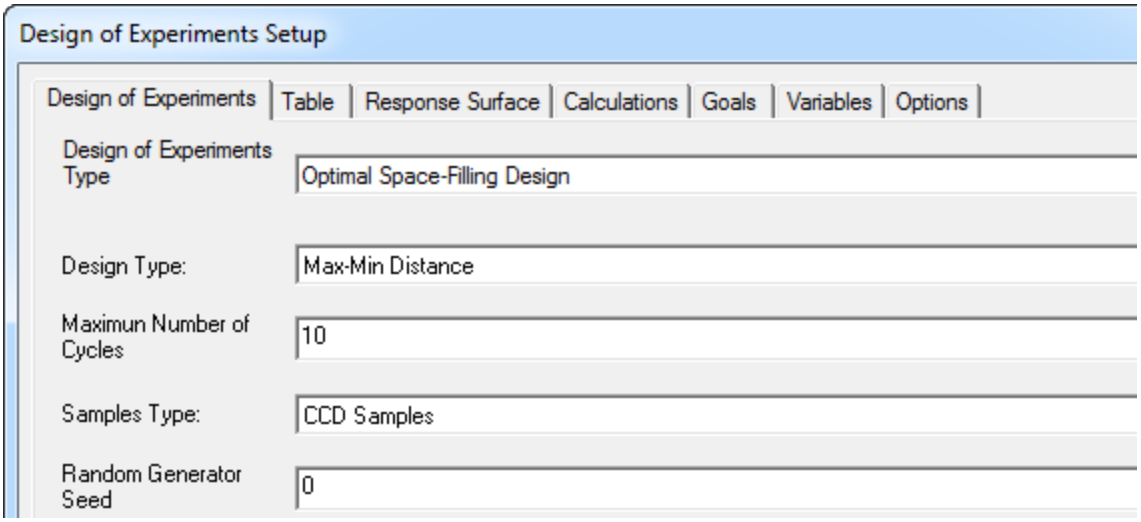
product without requiring additional simulations to test a new configuration.



The Design of Experiments feature is integrated inside Electronics Desktop. Combined with Electronics Desktop‘s distributed solve feature, you can build the response surfaces from the DOE variation table much faster.



Selecting a Design of Experiments under Optimization opens a dialog with several tabs:



In the Design of Experiments setup, you select the DOE type, select the Response Surface, specify goals, view and include variables.

There are a wide range of DOE algorithms or methods available in engineering literature. These techniques all have one common characteristic: they try to locate the sampling points such that the space of random input parameters is explored in the most efficient way, or obtain the required information with a minimum of sampling points. Sample points in efficient locations only reduce the required number of sampling points and increases the accuracy of the response surface generated. For more information on the available types of DOE, see Design of Experiments Types.

Once you have set up your input parameters, you can update the DOE, which submits the generated design points to the analysis system for solution. Design points are solved simultaneously if the analysis system is set up to do so; sequentially, if not. After the solution is complete, you can update the Response Surface cell, which generates response surfaces for each output parameter based on the data in the generated design points.

Note	Requirements and recommendations regarding the number of input parameters vary according to DOE type. For more information, see Number of Input Parameters for DOE Types.

If you change the Design of Experiments type after doing an initial analysis and preview the Design of Experiments Table, any design points generated for the new algorithm that are the same as design points solved for a previous algorithm will appear as up-to-date. Only the design points that are different from any previously submitted design points need to be solved.

You should set up your DOE Properties before generating your DOE Design Point matrix. The following topics describe setting up and solving your Design of Experiments, and viewing the results.

Setting Up Design of Experiments

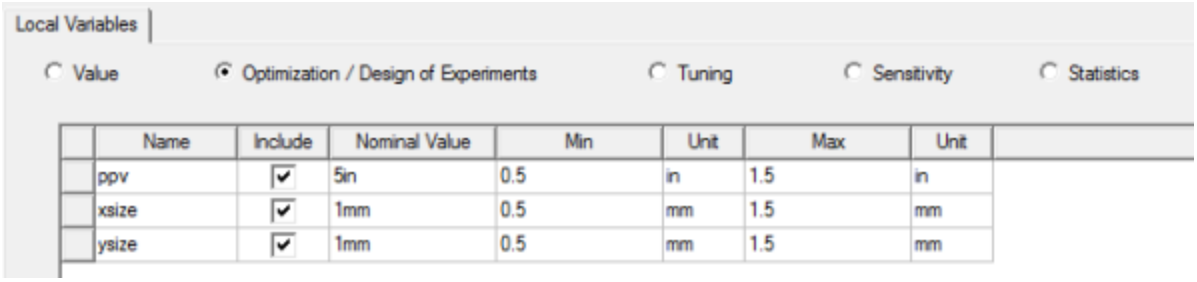
The process for setting up a Design of Experiments analysis is as follows:

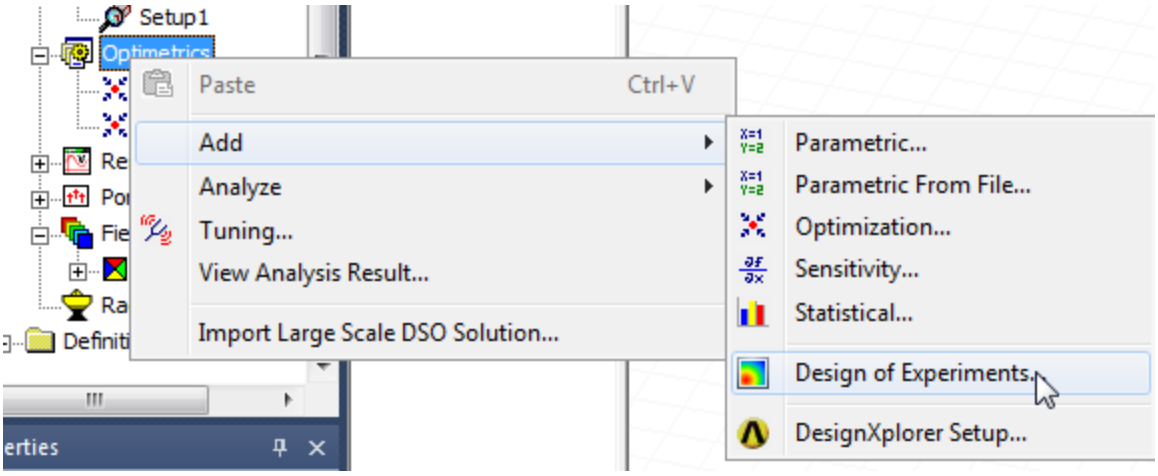
Choose the Variables for Design Exploration

You must define local or project variables as Optimization /Design of Experiments variables for the Design of Experiments setup to include the variable.

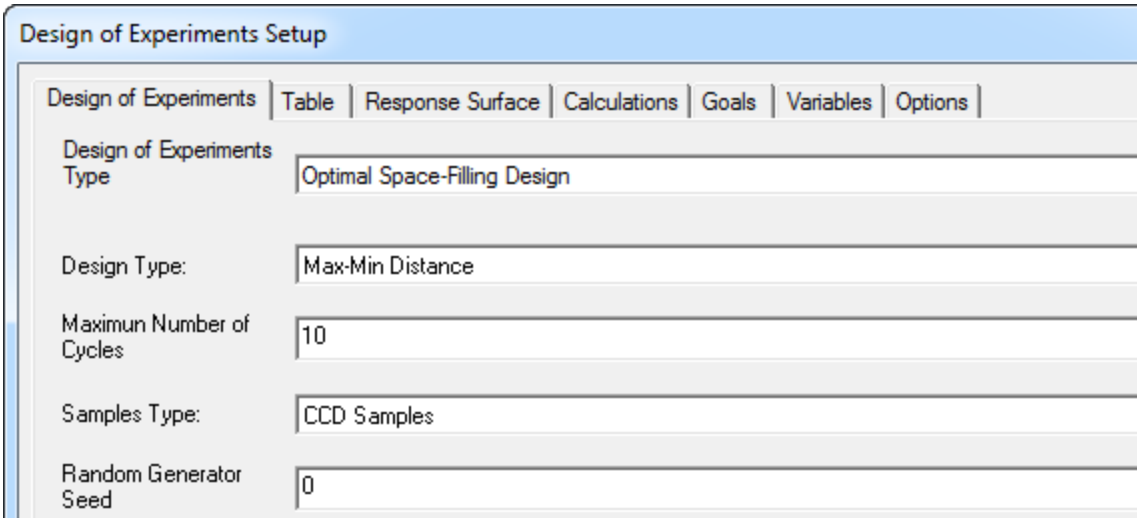


Add the Design of Experiments Setup

Right-click on the Optimetrics icon in the Project tree and select **Add>Design of Experiments**. You can also use **Maxwell 2D** (or **3D**)**>Optimetrics Analysis>Add Design of Experiments**.



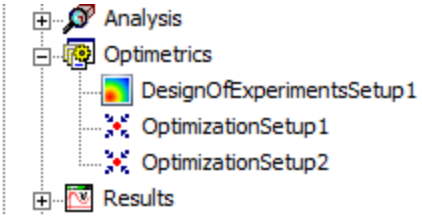
The Design of Experiments Setup dialog appears.



It has tabs for:

- Design of Experiments, where you specify the sampling points and associated parameters.
- Table, which shows the sampling points defined by the Design of Experiments settings you provide. If you select Custom and the Design of Experiments type, you can import data files as well as add or edit rows. You can also Export files of DOE sampling points you have defined by any method.
- Response Surface, which specifies the Response surface type, and Refinement parameters.
- Calculations, which accesses Optimetrics calculations.
- Goals, including cost functions calculations and norm type.
- Variables, previously defined for Optimization/Design of Experiments as Project or Design variables, and whether to include them, treat as discrete, whether to Use Manufacturable Variables, and the available Levels.
- Options, to Save Fields and Mesh, and whether to copy geometrically equivalent meshes.

Once you have set parameters and click **OK**, the **Design of Experiments** setup appears under the Optimetrics icon in the Project tree.



From here you can right click on the DesignOfExperiments setup for the shortcut menu to run **Analyze**, **Submit Job...** or **Validate for Large Scale DSO**.

Design of Experiments Tab

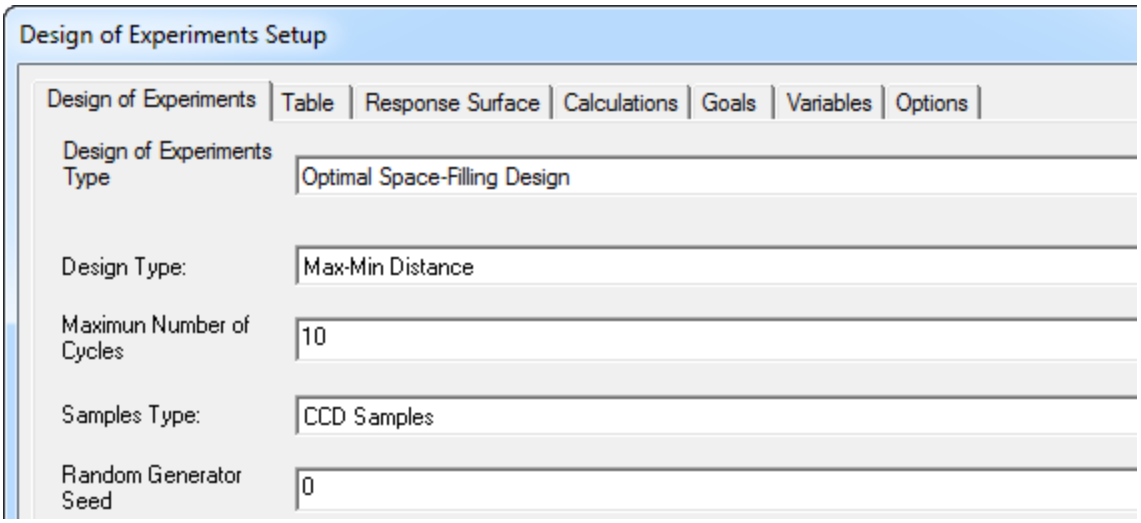
The Design of Experiments tab in the DOE Setup includes selections for defining the sampling points that define your experiment. Each selection for Design of Experiments type has a different set of associated parameters so the appearance of the dialog changes to show the parameters for your selection.



The Design of Experiments Types available in the Desktop include the following:

Design of Experiments Types	Brief Description (click links for more details)
Optimal Space Filling(Default)	An optimized Latin Hypercube Sampling maximizing distance between experiments. Several design type criteria are available: • Max-Min Distance • Centered L2 • Maximum Entropy Several sampling types available which determine the number of samples in the design: • CCD samples (Central Composite Designs are five level factorial designs that are suitable for calibrating the quadratic response model) • Linear model samples • Pure quadratic model samples • Full quadratic model samples • User-Defined samples You also specify a Maximum Number of Cycles and a Random Generator Seed.
Central Composite Design	Several design types available: • Face-Centered • Rotatable • VIF-Optimality • G-Optimality

Design of Experiments Types	Brief Description (click links for more details)
	• Auto-defined You can also choose a Standard or Enhanced Template.
Box-Behnken	Avoids critical configurations in the corner of the design space. Maximum number of input parameters is 12.
Custom	Lets you customize a DOE matrix, by editing values, adding or removing samples, and/or importing samples from a CSV file. Selecting Custom enables an Import button and the **Table** tab, as well as buttons to **Add editable rows** or **Delete selected rows**. If you previously solved the DOE using one of the other algorithms, those design points are retained and you can add new design points to the table. You can also import and export design points into the custom DOE Table from the Parameter Set.
Latin Hypercube Sampling	Statistical design where no two experiments share input parameters of the same value. The samples Type can be: • CCD Samples • Linear Model Samples • Pure Quadratic Model Samples • Full Quadratic Model Samples • User-Defined Samples, for which you also specify the Number of Samples. For each samples type, you also specify a Random Generator Seed.

The Table tab provides a preview view of the design points defined by your selections.

Setting Up Design Of Experiments

Optimal Space Filling Design (OSF)

The goal in Design of Experiments is to determine the smallest sufficient set of points required to calculate a response surface. Therefore, you choose the type depending on the parametric problem and targeted response surface. The number of points depends on the number of input parameters, or is user defined.

Optimal Space-Filling Design (OSF) creates optimal space filling Design of Experiments (DOE) plans according to some specified criteria. Essentially, OSF is a Latin Hypercube Sampling Design (LHS) that is extended with post-processing. It is initialized as an LHS and then optimized several times, remaining a valid LHS (without points sharing rows or columns) while achieving a more uniform space distribution of points (maximizing the distance between points).

To offset the noise associated with physical experimentation, classical DOE types such as CCD focus on parameter settings near the perimeter of the design region. Because computer simulation is not quite as subject to noise, though, the Optimal Space-Filling (OSF) design is able to distribute the design parameters equally throughout the design space with the objective of gaining the maximum insight into the design with the fewest number of points. This advantage makes it appropriate when a more complex meta-modeling technique such as Kriging, Non-Parametric Regression, or Neural Networks is used.

OSF shares some of the same disadvantages as LHS, though to a lesser degree. Possible disadvantages of an OSF design are:

- When the CCD Samples sample type is selected, a maximum of 20 input parameters is supported.
- Extremes, such as the corners of the design space, are not necessarily covered.
- The selection of too few design points can result in a lower quality of response prediction.

The following properties are available for the OSF DOE type.

- **Design Type**: The following choices are available:
  - **Max-Min Distance** (default): Maximizes the minimum distance between any two points. This strategy ensures that no two points are too close to each other. For a small size of sampling (N), the Max-Min Distance design generally lies on the exterior of the design space and fill in the interior as N becomes larger. Generally, this is the faster algorithm.
  - **Centered L2**: Minimizes the centered L2-discrepancy measure. The discrepancy measure corresponds to the difference between the empirical distribution of the sampling points and the uniform distribution. This means that the centered L2 yields a uniform sampling. This design type is computationally faster than the **Maximum Entropy** type.
  - **Maximum Entropy**: Maximizes the determinant of the covariance matrix of the sampling points to minimize uncertainty in unobserved locations. This option often provides better results for highly correlated design spaces. However, its cost increases non-linearly with the number of input parameters and the number of samples to be generated. Thus, it is recommended only for small parametric problems.
- **Maximum Number of Cycles**: Determines the number of optimization loops the algorithm needs, which in turns determines the discrepancy of the DOE. The optimization is essentially combinatorial, so a large number of cycles slows down the process. However, this makes the discrepancy of the DOE smaller. For practical purposes, 10 cycles is generally good for up to 20 variables. The value must be greater than 0. The default is 10.
  - **Samples Type**: Determines the number of DOE points the algorithm should generate. This option is suggested if you have some advanced knowledge about the nature of the metamodel. The following choices are available:
    - **CCD Samples** (default): Supports a maximum of 20 inputs. Generates the same number of samples a CCD DOE would generate for the same number of inputs. You

can use this to generate a space filling design that has the same cost as a corresponding CCD design.

- **Linear Model Samples**: Generates the number of samples as needed for a linear metamodel.
- **Pure Quadratic Model Samples**: Generates the number of samples as needed for a pure quadratic metamodel (no cross terms).
- **Full Quadratic Samples**: Generates the number of samples needed to generate a full quadratic model.
- **User-Defined Samples**: Specify the desired number of samples.

- **Seed Value**: Set the value used to initialize the random number generator invoked internally by the LHS algorithm. Although the generation of a starting point is random, the seed value consistently results in a specific LHS. This property allows you to generate different samplings by changing the value or regenerate the same sampling by keeping the same value. The default is 0.
- **Number of Samples**: Enabled when **Samples Type** is set to **User-Defined Samples**. Specifies the default number of samples. The default is 10.

Setting Up Design Of Experiments

Central Composite Design (CCD)

The goal in Design of Experiments is to determine the smallest sufficient set of points required to calculate a response surface. Therefore, you choose the type depending on the parametric problem and targeted response surface. The number of points depends on the number of input parameters, or is user defined.

Central Composite Design (CCD) provides a screening set to determine the overall trends of the metamodel to better guide the choice of options in Optimal Space-Filling Design. The CCD DOE type supports a maximum of 20 input parameters.

The following properties are available for the CCD DOE type:

- **Design Type**: By specifying the **Design Type** for CCD, you can help to improve the response surface fit for DOE studies. For each CCD type, the alpha value is defined as the location of the sampling point that accounts for all quadratic main effects. The following CCD design types are available:
  - **Face-Centered**: A three-level design with no rotatability. The alpha value equals 1.0. A Template Type setting automatically appears, with Standard and Enhanced options. Choose Enhanced for a possible better fit for the response surfaces.
  - **Rotatable**: A five-level design that includes rotatability. The alpha value is calculated based on the number of input variables and a fraction of the factorial part. A design with rotatability has the same variance of the fitted value regardless of the direction from the center point.

- **VIF-Optimality**: A five-level design in which the alpha value is calculated by minimizing a measure of non-orthogonality known as the Variance Inflation Factor (VIF). The more highly correlated the input variable with one or more terms in a regression model, the higher the VIF.
- **G-Optimality**: Minimizes a measure of the expected error in a prediction and minimizes the largest expected variance of prediction over the region of interest.
- **Auto-Defined**: Design exploration automatically selects the Design Type based on the number of input variables. Use of this option is recommended for most cases as it automatically switches between the G-Optimality if the number of input variables is 5 or VIF-Optimality otherwise.

  However, you can use the Rotatable design if the default option does not provide good values for the Goodness of Fit from the response surface plots. Additionally, you can use the Enhanced template if the default Standard template does not fit the response surfaces well.

- **Template Type**: Enabled for the Rotatable and Face-Centered design types. The following options are available:
  - **Standard**
  - **Enhanced**: Choose this option for a possible better fit for the response surfaces

Related Topics

Setting Up Design Of Experiments

Box Behnken Design (CCD)

The goal in Design of Experiments is to determine the smallest sufficient set of points required to calculate a response surface. Therefore, you choose the type depending on the parametric problem and targeted response surface. The number of points depends on the number of input parameters, or is user defined.

A **Box-Behnken Design** is a three-level quadratic design that does not contain fractional factorial design. The sample combinations are treated in such a way that they are located at midpoints of edges formed by any two factors. The design is rotatable (or in cases, nearly rotatable).

One advantage of a Box-Behnken design is that it requires fewer design points than a full factorial CCD and generally requires fewer design points than a fractional factorial CCD. Additionally, a Box-Behnken Design avoids extremes, allowing you to work around extreme factor combinations. Consider using the Box-Behnken Design DOE type if your project has parametric extremes (for example, has extreme parameter values in corners that are difficult to build). Since the Box-Behnken DOE doesn't have corners and does not combine parametric extremes, it can reduce the risk of update failures.

Possible disadvantages of a Box-Behnken design are:

- Prediction at the corners of the design space is poor and that there are only three levels per parameter.

- A maximum of 12 input parameters is supported.

No additional properties are available for the Box-Behnken Design DOE type.

Related Topics

Setting Up Design Of Experiments

Custom DOE Type

The goal in Design of Experiments is to determine the smallest sufficient set of points required to calculate a response surface. Therefore, you choose the type depending on the parametric problem and targeted response surface. The number of points depends on the number of input parameters, or is user defined.

The **Custom DOE** type allows for definition of a custom DOE Table. You can manually add new design points, entering the input and (optionally) output parameter values directly into the table. If you previously solved the DOE using one of the other algorithms, those design points are retained and you can add new design points to the table. You can also import and export design points into the custom DOE Table from the Parameter Set.

You can change the edition mode of the DOE table to edit the output parameter values. You can also copy and paste data and import data from a CSV file by right-clicking and selecting Import Design Points.

Related Topics

Setting Up Design Of Experiments

Latin Hypercube Sampling

The goal in Design of Experiments is to determine the smallest sufficient set of points required to calculate a response surface. Therefore, you choose the type depending on the parametric problem and targeted response surface. The number of points depends on the number of input parameters, or is user defined.

In the **Latin Hypercube Sampling** Design DOE type, the DOE is generated by the LHS algorithm, an advanced form of the Monte Carlo sampling method that avoids clustering samples. In a Latin Hypercube Sampling, the points are randomly generated in a square grid across the design space, but no two points share the same value. This means that no point shares a row or a column of the grid with any other point.

Possible disadvantages of an LHS design are:

- When the CCD Samples sample type is selected, a maximum of 20 input parameters is supported. For more information, see Number of Input Parameters for DOE Types.
- Extremes, such as the corners of the design space, are not necessarily covered. Additionally, the selection of too few design points can result in a lower quality of response prediction.

Note: The Optimal Space-Filling Design DOE type is an LHS design that is extended with post-processing.

The following properties are available for the LHS DOE type:

- **Samples Type**: Determines the number of DOE points the algorithm should generate. This option is suggested if you have some advanced knowledge about the nature of the metamodel. The following choices are available:
  - **CCD Samples** (default): Supports a maximum of 20 inputs. Generates the same number of samples a CCD DOE would generate for the same number of inputs. You can use this to generate a space filling design that has the same cost as a corresponding CCD design.
  - **Linear Model Samples**: Generates the number of samples as needed for a linear metamodel.
  - **Pure Quadratic Model Samples**: Generates the number of samples as needed for a pure quadratic metamodel (no cross terms).
  - **Full Quadratic Samples**: Generates the number of samples needed to generate a full quadratic model.
  - **User-Defined Samples**: Specify the desired number of samples.
- **Seed Value**: Set the value used to initialize the random number generator invoked internally by the LHS algorithm. Although the generation of a starting point is random, the seed value consistently results in a specific LHS. This property allows you to generate different LHS samplings (by changing the value) or to regenerate the same LHS sampling (by keeping the same value). The default is 0.
- **Number of Samples**: Enabled when **Samples Type** is set to **User-Defined Samples**. Specifies the default number of samples. The default is 10.

6	1in	1mm	0.5mm
7	1in	1mm	1.5mm
8	0.5in	0.5mm	0.5mm
9	1.5in	0.5mm	0.5mm
10	0.5in	1.5mm	0.5mm

Depending on the context, the tables are read-only and filled automatically or they are partially or completely editable. The background color of a cell indicates if it is editable or not:

- A gray background indicates a read-only cell
- A white background indicates an editable cell

Output parameter values calculated from a simulation (a design point update) are displayed in black text.

The Custom Table view also includes an Import button. Import and Export files can be:

- Comma delimited data files, (*.csv)
- Tab delimited data files, (*.tab)
- Ansoft Plot Data files, (.dat)
- Post Processor format data files, (*.txt)

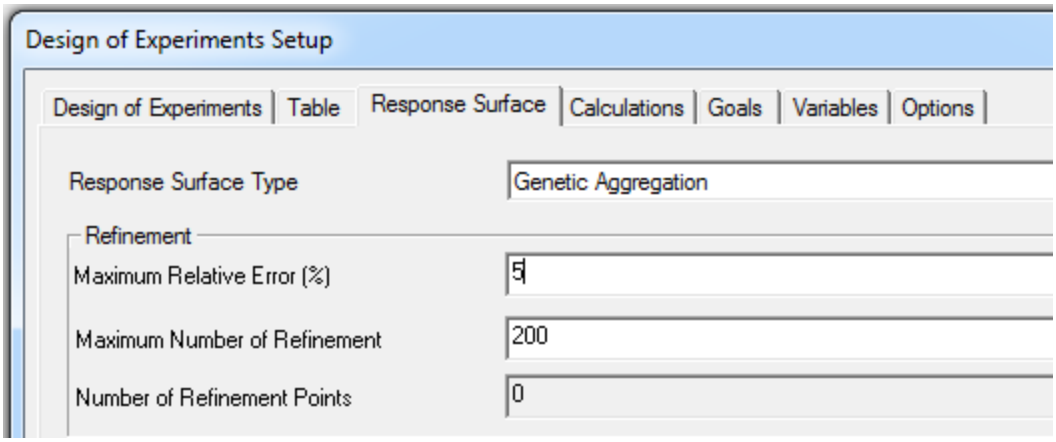
The Table updates automatically when you change your selections on the **Design of Experiments** tab.

Related Topics

Custom DOE Type

Response Surface Tab for Design of Experiments

The Response Surface tab for the **Design of Experiments Setup** dialog lets you select the Response Surface type as Genetic Aggregation or Standard Response Surface.



The selection here specifies the refinement applied to the initial Design of Experiments. The Genetic Aggregation Response Surface finds the best possible response surface for each output automatically by combining

- Metamodels
- Settings

- Kernel Variation
- Polynomial Regression

For each output, a Fitness factor works to minimize error, including cross-validation errors. The automatic refinement adds design points to the DOE until the response surface accuracy meets user requirements. You can specify requirements for:

- **Maximum Relative Error %** – Applies to all output calculations. Empty this field to turn off Auto refinement. (Note: Workbench does not have this field.)
- **Maximum Number of Refinement** attempts
- **Number of Refinement Points** – Read-only property indicating the number of existing refinement points.

If you check **Show Advanced Options** at the bottom of the Setup dialog box, you can also specify the **Crowding Distance Separation Percentage** which determines the minimum allowable distance between new refinement points, implemented as a constraint in the search for refinement points.

You also have the option of selecting **Standard Response Surface- Full 2nd Order Polynomial** as the Response Surface Type.

After you have completed an analysis you can view the generated plot.

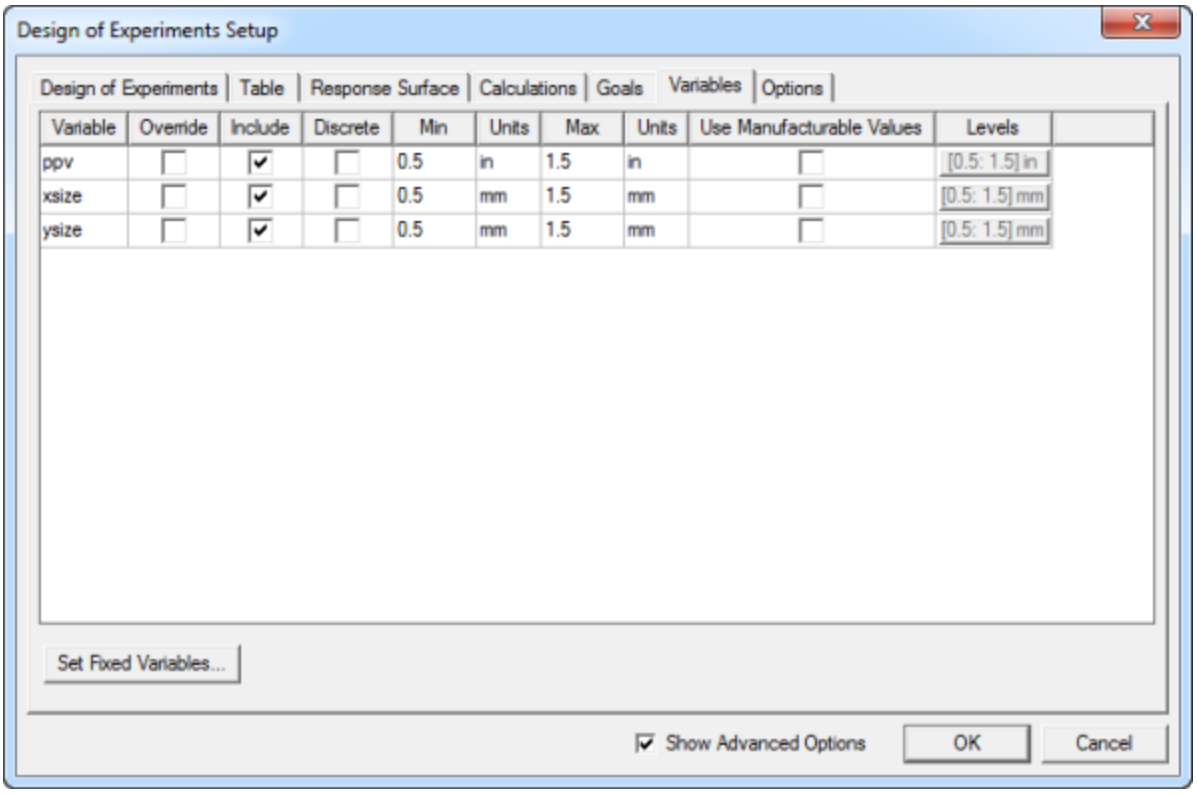
Setting Up Design Of Experiments

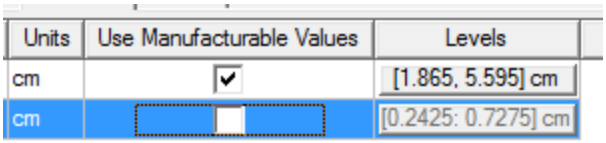
Variables Tab for Design of Experiments

The Variables tab for the **Design of Experiments Setup** dialog displays list of the variables defined for the Design and Project as Optimetrics/Design of Experiments variables.



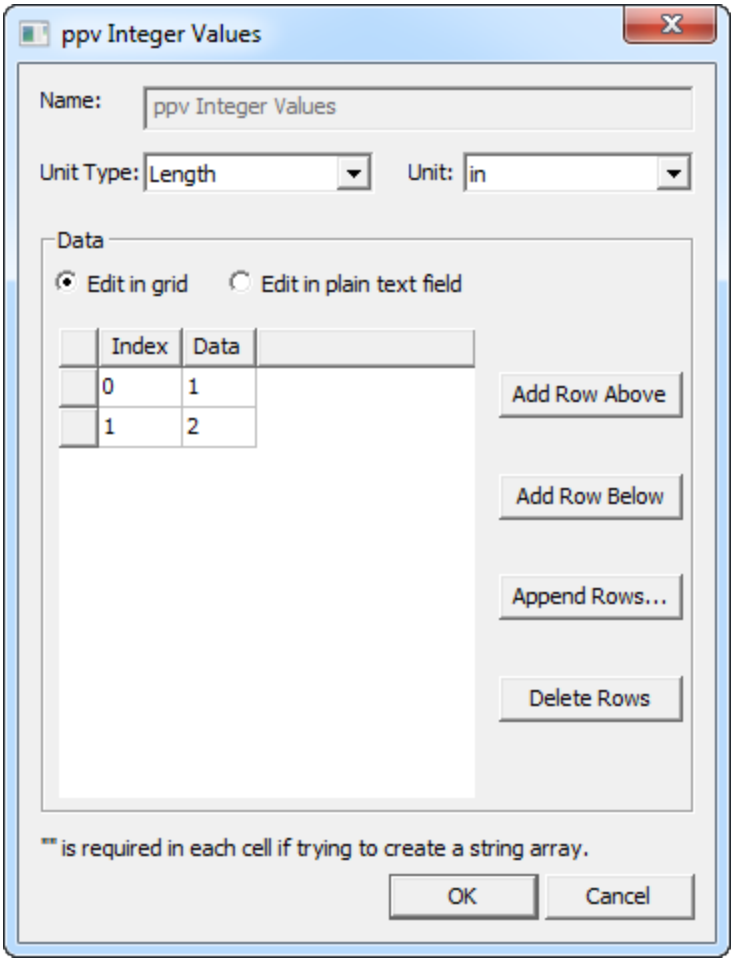
The columns list the Variable names, the current Min and Max Values and Units, and provides options for the following:

- Override--check this to override the current design value. Unchecking this causes a dialog to appear asking you to confirm the return to the design value.
- Include--whether to include the variable in an analysis.
- Discrete--**Discrete Variables** physically represent different configurations or states of the model. When checkbox in the Discrete column is checked the button in the “Levels” column will be enabled.



Levels show the variable values. For continuous variable, Levels is determined by the min/max columns. If you check **Use Manufacturable Values**, Levels lists the Manufacturable values (for example, [min, va, v2, v3, max]). For Integer variables Levels can be a subset of the min/max range. The discrete values can be bounded by a min/man range and/or manufacturable values.

- Click the Levels button for the row to edit the Discrete values. An edit dialog for the variable appears.



- **Continuous Variables** physically vary in a continuous manner between a lower and an upper bound (min/max) defined by the user. With continuous Variables, you can also apply a Manufacturable Values filter to the Variable. Manufacturable Values represent real-world manufacturing or production constraints. The min man values will be upper and lower constraints on the available manufacturable values bounded by the range.
- When check box in the “Use Manufacturable Values” column is checked the button in the “Levels” column is enabled. Click the button to edit the values. An edit dialog for the variable appears.

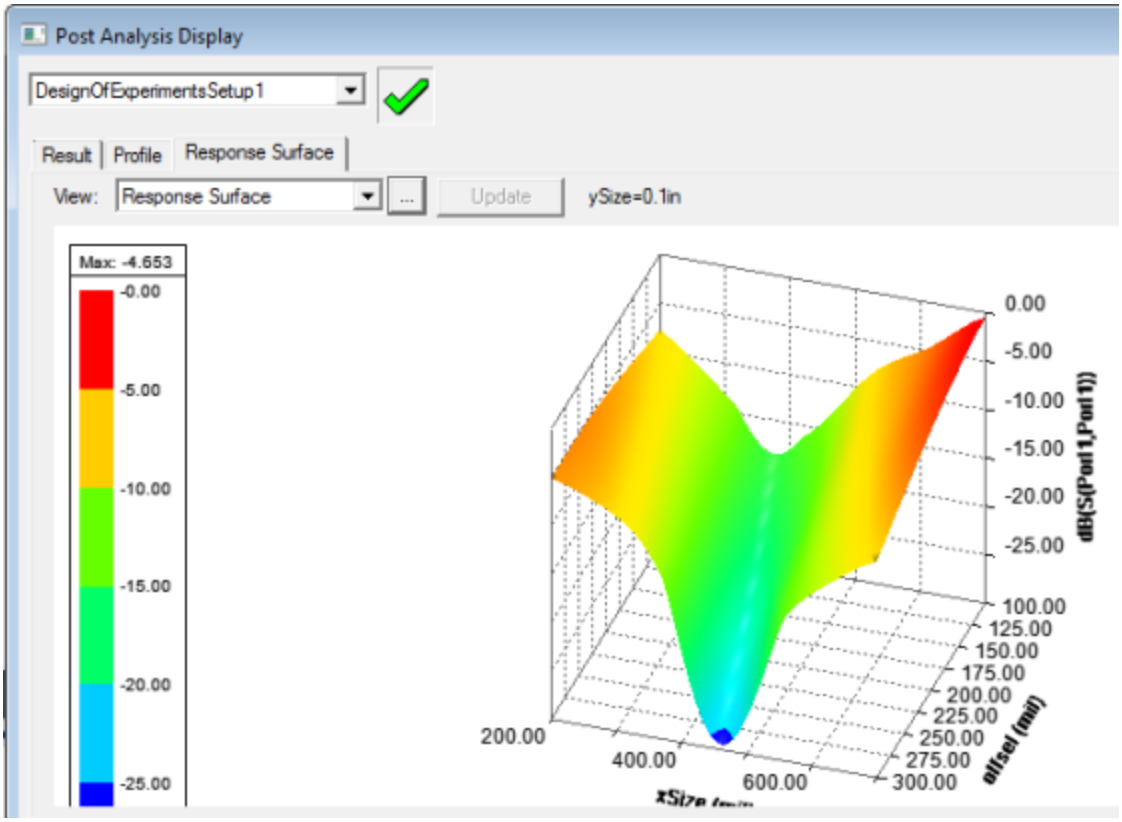
Setting Up Design Of Experiments

View Analysis Result for Design of Experiments

After the Analysis has competed, you can click **View Analysis Result**. This opens a dialog that includes a **Result** tab that lists the variations and variable values, a solution **Profile** tab with start, stop, time elapsed, and machines used, as well as a **Response Surface** tab. When you include more than one variable in the setup, response surface view is available. You can choose any two variables as the X, Y axis, and choose an output calculation as the Z axis, by clicking the "..."

button next to the view list box.



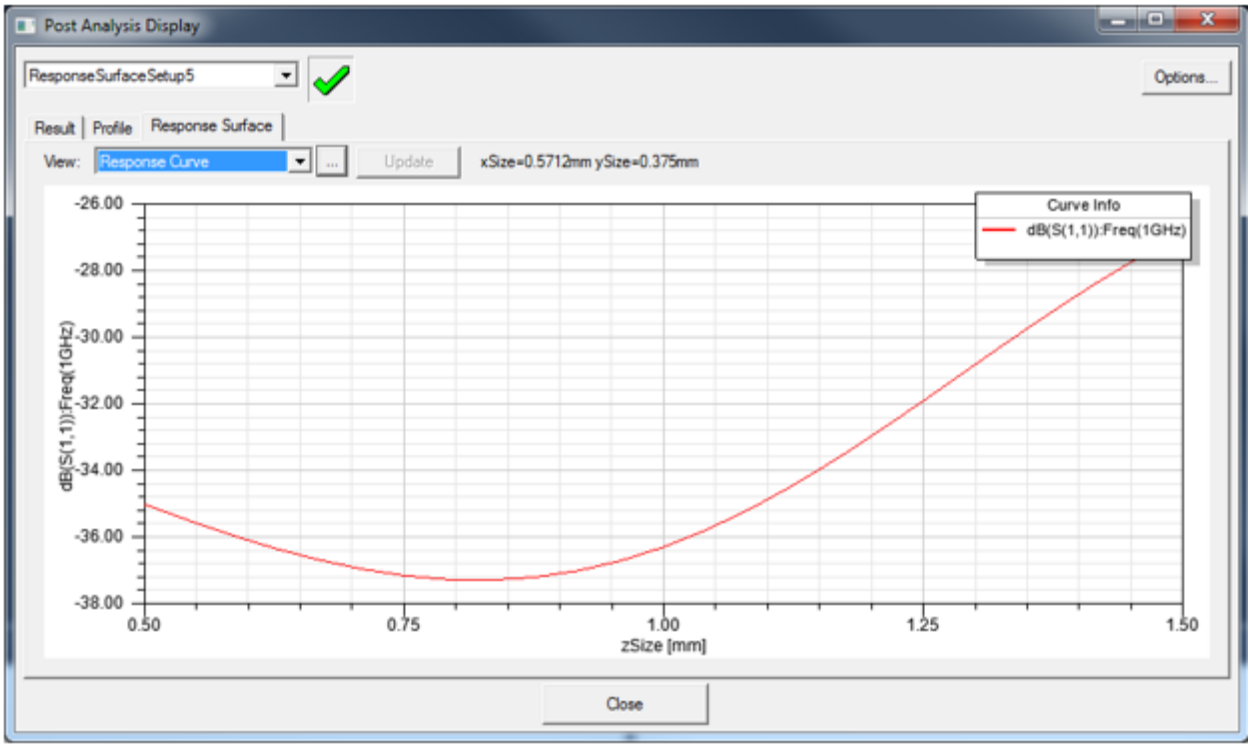
From the Response Surface tab, the “View” list box lets you select all available views of the selected response-surface-setup.

- Min Max Search
- Refinement points table
- Response points table
- Verification points table
- Goodness of Fit
- Response Curve (see below)
- Response Curve (2D Slices, see below)
- Response Surface

The **Update** push button is disabled when the response surface is up to date. After the setup, if you modify a verification point or refinement points, it is enabled. Click this button to re-generate the response-surface with new settings. It may start new simulations if any of the design points in the DOE, refinement points, or verification points has not been solved.

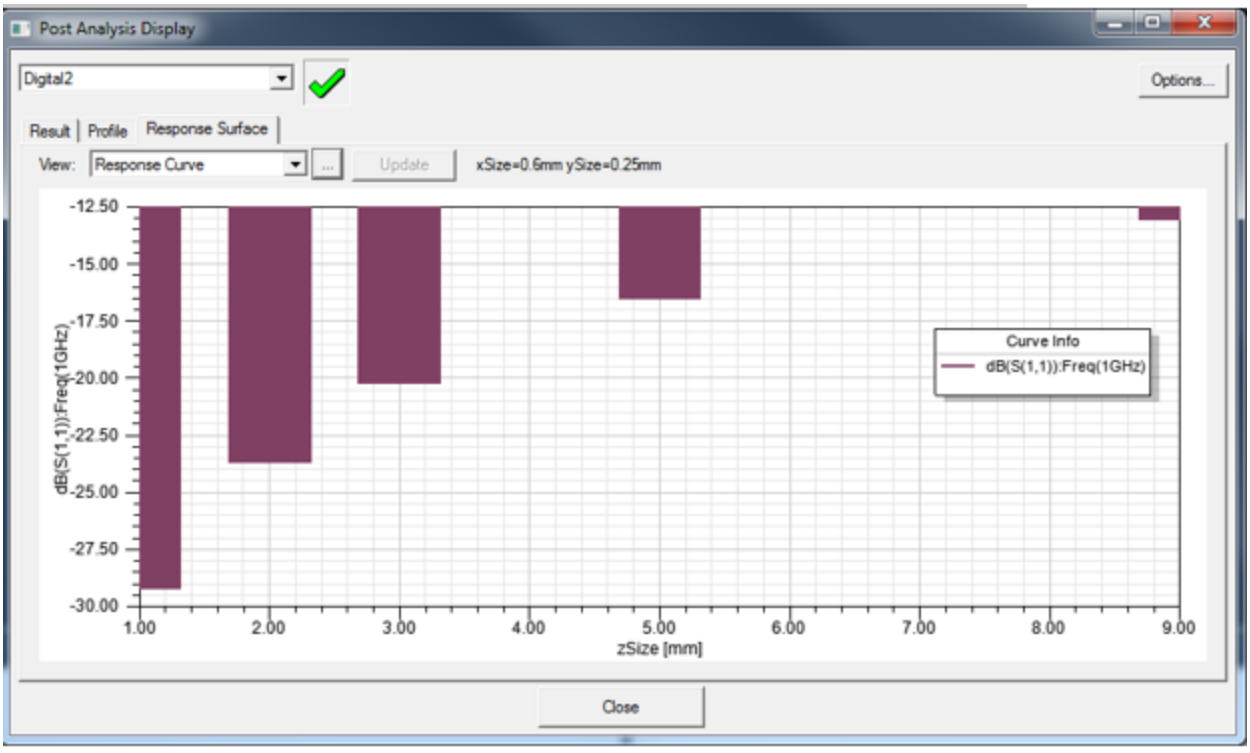
Response Curve

When Continuous Variable is chosen as the X-axis, a Continuous XY plot will be shown.



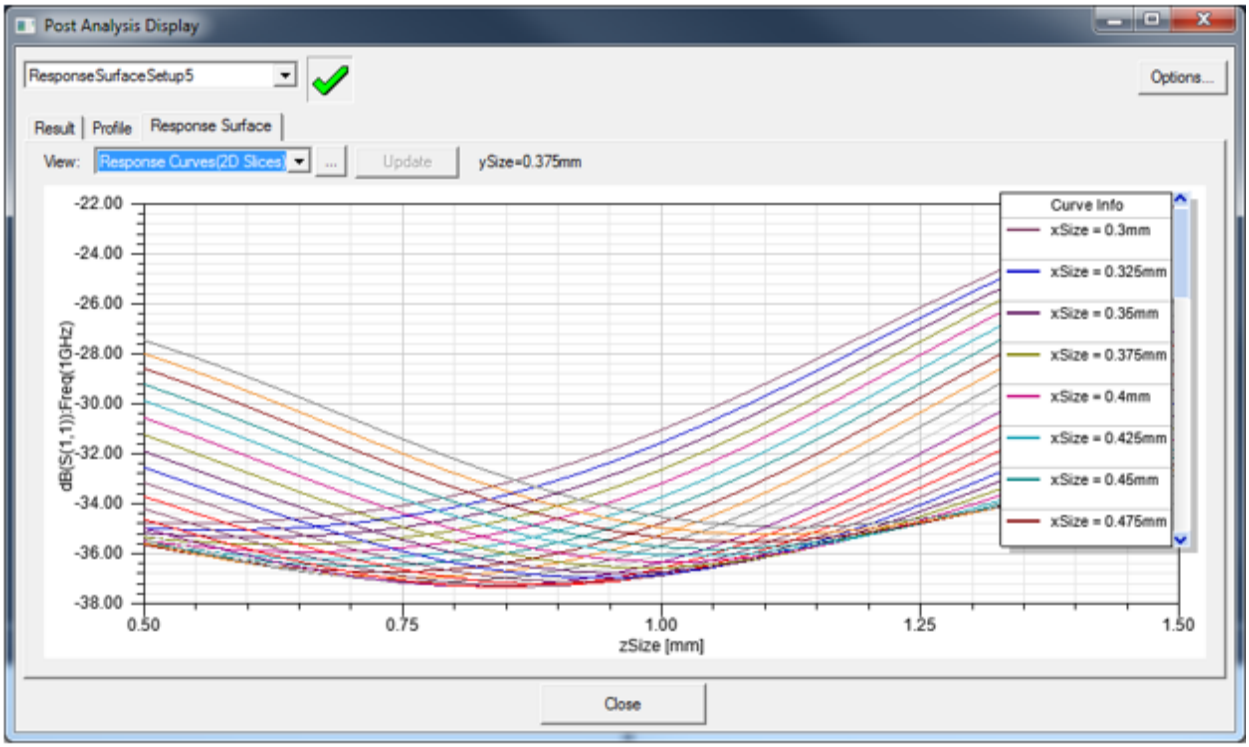
Discrete Variable

If you choose Discrete Variable as the X-axis, a bar chart plot is shown:

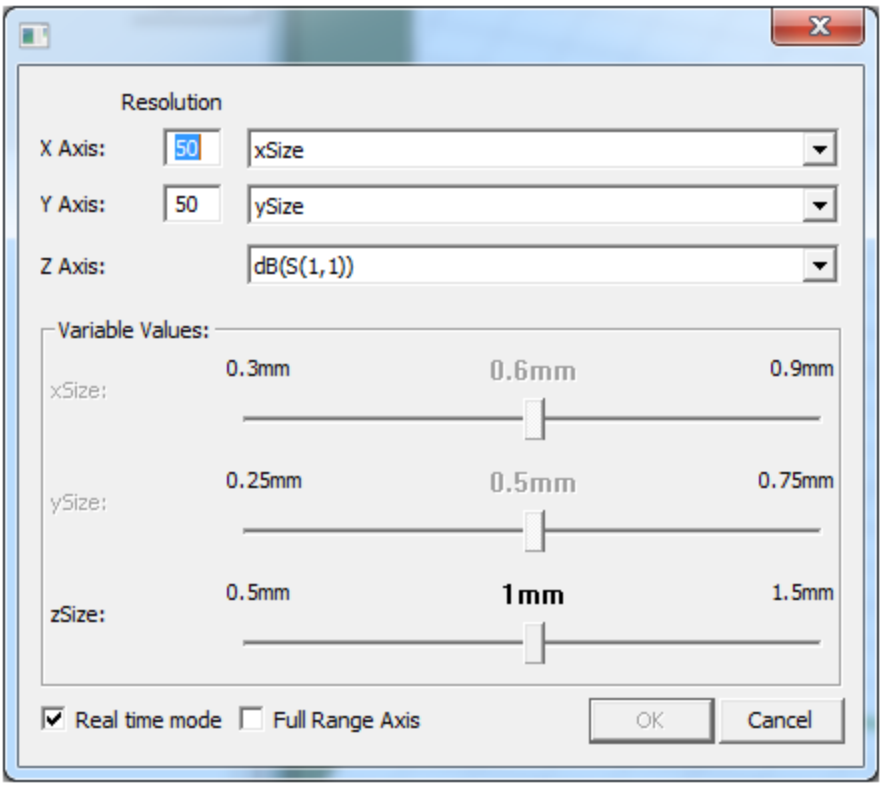


Response Curves (2D Slices)

If you have included more than one variable in the setup, the Response Curves (2D) view is available:



Clicking the ellipsis button [...] by the View for Response Surface opens a dialog that lets you adjust the variables selected and the values applied.



Tuning a Response Curve

For the X Axis and Y Axis, you can specify a Resolution, and the variable to use. For the Z Axis you can select the Cost or calculation. For variables not selected for the X and Y axis, a slider is enabled that lets you adjust the value to see the effect on the response curve plot. You can enable or disable Real time mode by using the check box at the lower left.

Full Range Axis check box

When it is checked all Axes are set to their maximum ranges, and the ranges won't be changed while tuning unless you change the axis variable.

When it is unchecked, the Y(2D)/Z(3D) axis range is auto updated to fit the curve/surface.

Exporting Response Curve Data

You can Export the response curve data as a table in the following formats:

- Comma delimited data files, (*.csv)
- Tab delimited data files, (*.tab)
- Ansoft Plot data files, (*.dat)
- Post Processor format data files, (*.txt)

  Exported files can be imported into a report.

Min-Max Search View for Design of Experiments Result

From the Response Surface tab, the “View” list box lets you select all available views of the selected response-surface-setup.

The **Min-Max Search** view examines the entire output parameter space from a response surface to approximate the minimum and maximum values of each output parameter. When you select a Min/Max row the **Apply** button is enabled, and you can then apply the selected variation variable values to the variables’ nominal values.

	xSize	ySize	zSize	dB(S(1,1)) (P)	Cost (P)
Minimums					
dB(S(1,1))	0.9mm	0.25mm	0.92193882mm	-36.261549	1309.939
Cost	0.3mm	0.30979772mm	1.2109946mm	-20.348505	400.76108
Maximums					
dB(S(1,1))	0.3mm	0.3090939mm	1.1992958mm	-20.34657	400.8617
Cost	0.9mm	0.25mm	0.93275164mm	-36.258197	1310.1544

You can Export the Table in the following formats:

- Comma delimited data files, (*.csv)
- Tab delimited data files, (*.tab)
- Ansoft Plot data files, (*.dat)
- Post Processor format data files, (*.txt)

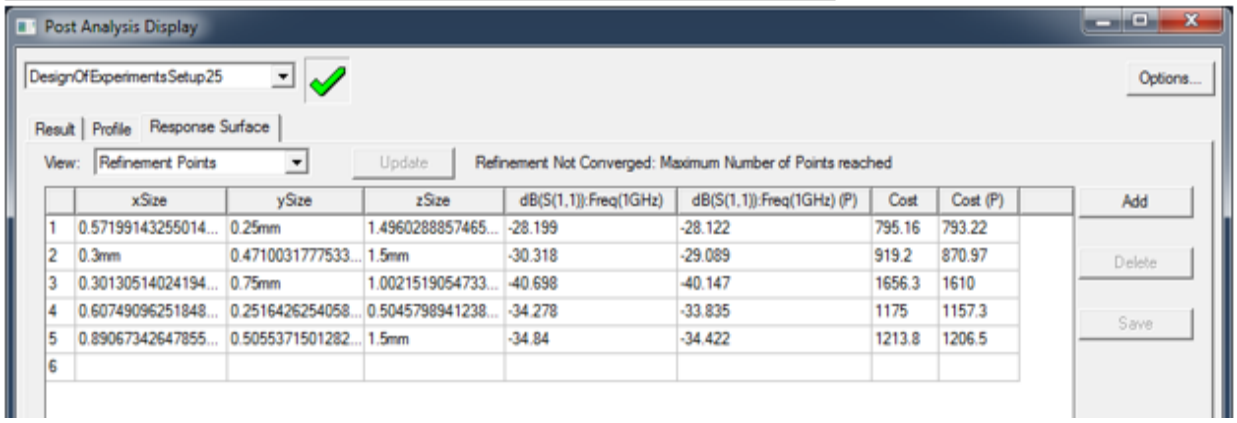
Setting Up Design of Experiments

Using Design of Experiments

Refinement Points Table

From the Response Surface tab, the “View” list box lets you select all available views of the selected response-surface-setup. All refinement points are shown in the Refinement Points table:



Refinement points are points added to your model to enrich and improve your response surface. They can either be generated automatically with the response surface update or added manually, as described in **Performing a Manual Refinement**. As with design points, DesignXplorer must perform a design point update (a "real solve") in order to obtain the output parameters for the refinement points.

Upon update, the refinement points are used to build the response surface and are taken into account for the generation of verification points. Along with DOE points, refinement points are also used as "learning points" for Goodness of Fit calculations.

Performing a Manual Refinement

Manual refinement is a way to force the response surface to take into account points of your choice, in addition to the points already in the Design of Experiments. You can insert a refinement point in the Refinement Points table, and do not need to do an initial solve of the response surface (without the refinement point) before updating your response surface with your manual refinement. Manual refinement is available for all response surface types except for Sparse Grid.

You can add, delete, or modify refinement points by clicking the **Add** or **Delete** buttons, or by modifying point values directly in the grid.

Manual Refinement Point can be inserted from the Response point table and Verification Points Table.

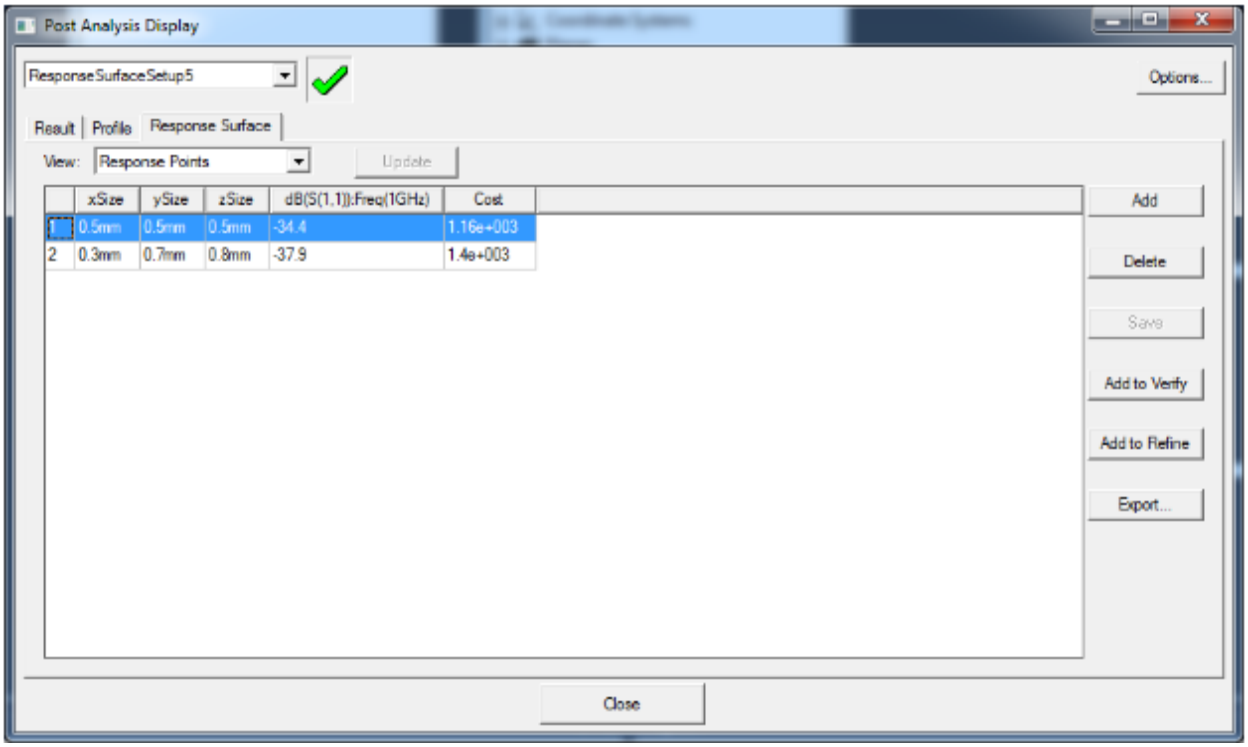
Setting Up Design of Experiments

Using Design of Experiments

Response Points Table

From the Response Surface tab, the “View” list box lets you select all available views of the selected response-surface-setup. All Response points are shown in the Response Points table:



A response point is defined by a snapshot of variable values where output calculation values were calculated in Ansys DesignXplorer from a response surface. As such, the output calculation(or cost) values are approximate and calculated from response surfaces.

You can add, delete, save, or export response points by using the command buttons in the dialog or you can modify response points manually by modifying point values directly in the grid.

Click **Add to Verify** or **Add to Refine** buttons to insert the selected response point to the verification table or refinement table.

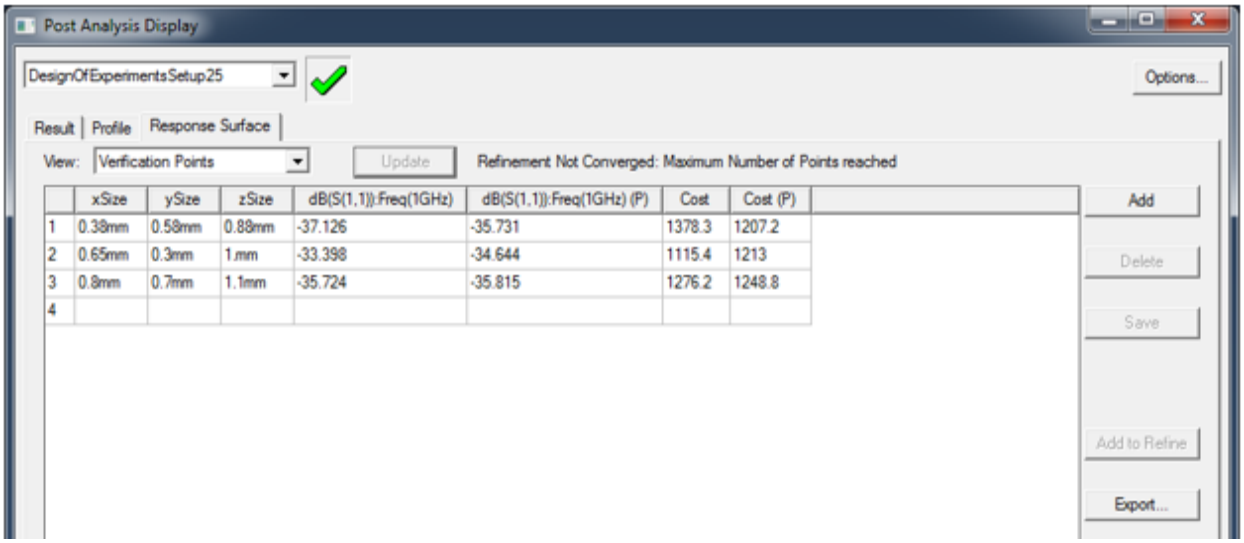
Related Topics

Setting Up Design of Experiments

Using Design of Experiments

Verification Points Table

From the Response Surface tab, the “View” list box lets you select all available views of the selected response-surface-setup. All Verification points are shown in the Verification Points table:



Verification points enable you to verify that the response surface accurately approximates the output parameter values; they compare the predicted and observed values of the output parameters.

You can add, delete and modify Verification points manually.

- Same as add/delete/modify refinement points.
- Insert from Response Points Table.

Click the **Add to Refine** button to insert the selected response point to the refinement table.

A design point update (that is, a "real solve") calculates each verification point. These verification point results are then compared with the response surface predictions and the difference is calculated.

Verification points are useful in validating any type of response surface. In particular, however, you should always use verification points to validate the accuracy of interpolated response surfaces, such as Kriging or Sparse Grid.

You can add, delete, save, or export verification points by using the command buttons in the dialog or you can modify verification points manually by modifying point values directly in the grid.

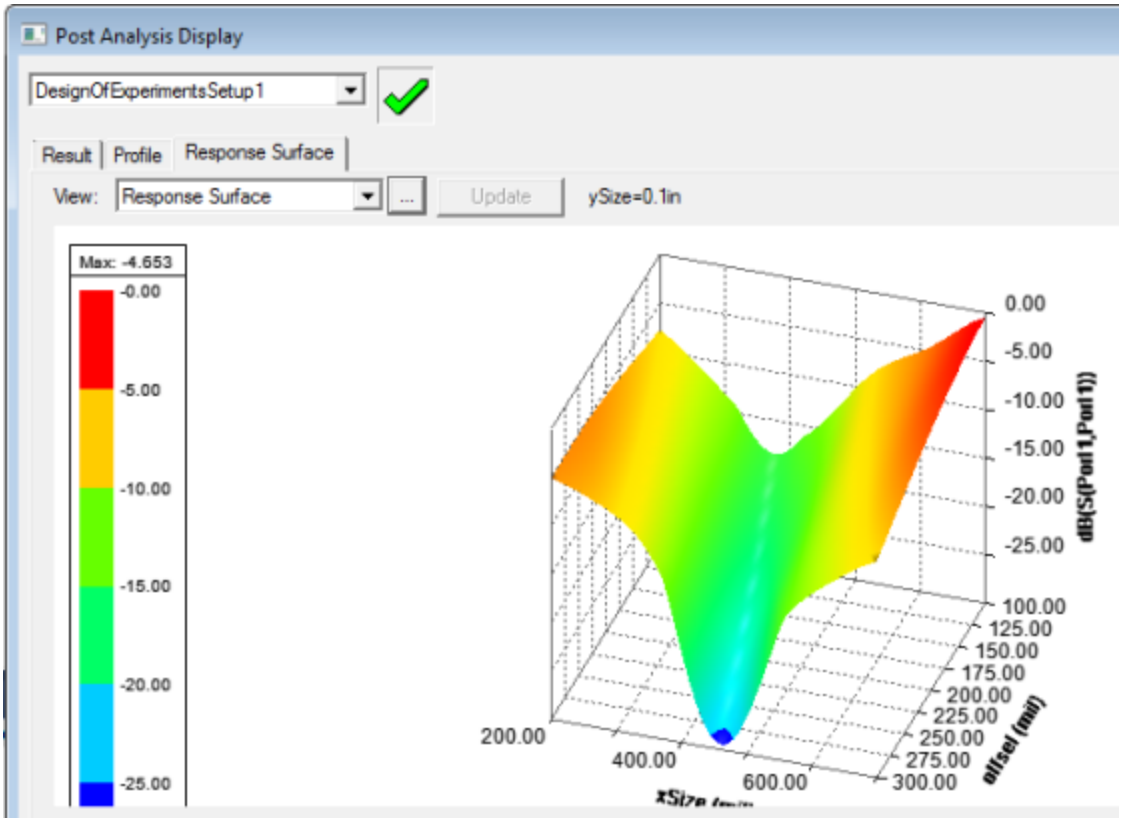
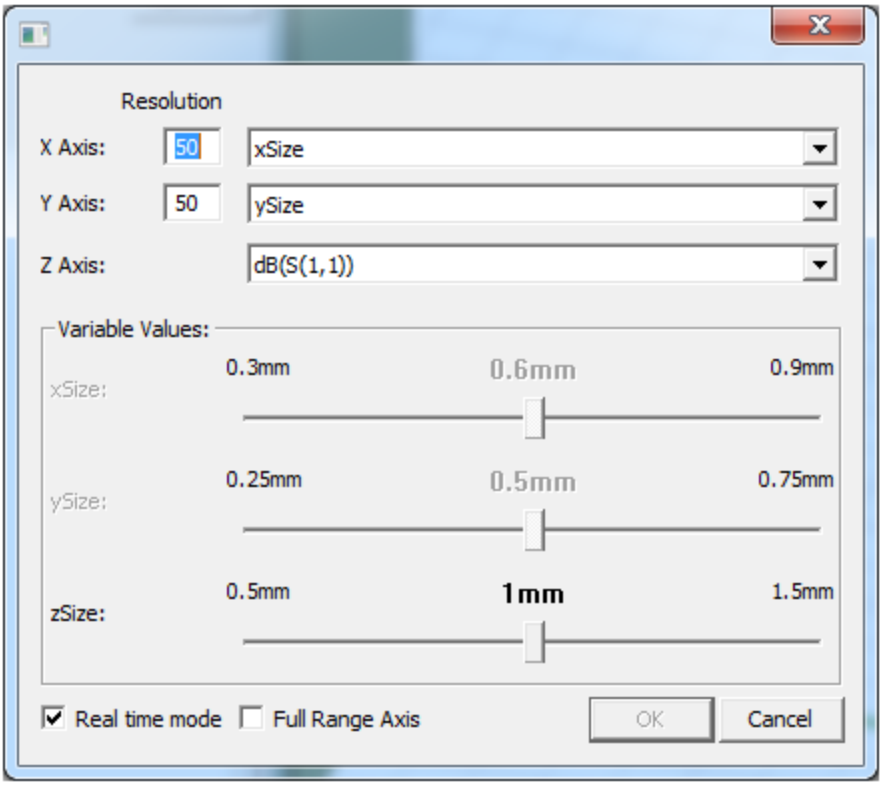
Response Surface Results Design of Experiments Result

When more than one variable is included in the setup, the Response Surface view is available. You can choose any two variables as the X, Y axis, and choose an output calculation as the Z axis, by clicking the "..." button next to the view list box. From the **Response Surface** tab of the Design of Experiments **Post Analysis Display** dialog box, the "View" list box lets you select all available views of the selected response-surface-setup.

Response surfaces are functions of varying natures in which the output parameters are described in terms of the input parameters. Built from the Design of Experiments (DOE), they quickly provide the approximated values of the output parameters throughout the design space without having to perform a complete solution. The accuracy of a response surface depends on several factors: the complexity of the variations of the solution, the number of points in the original DOE, and the response surface type. Once a response surface has been generated, you can create and manage response points and charts. These postprocessing tools help you to understand how each output parameter is driven by input parameters and how you can modify your design to improve its performance.



Clicking the ellipsis button [...] by the View for Response Surface opens a dialog that lets you adjust the variables selected and the values applied.



Tuning a Response Surface

For the X Axis and Y Axis, you can specify a Resolution, and the variable to use. For the Z Axis you can select the Cost or calculation. For variables not selected for the X and Y axis, a slider is enabled that lets you adjust the value to see the effect on the response surface plot. You can enable or disable Real time mode by using the check box at the lower left.

Full Range Axis check box

When it is checked all Axes are set to their maximum ranges, and the ranges won't be changed while tuning unless you change the axis variable.

When it is unchecked, the Y(2D)/Z(3D) axis range is auto updated to fit the curve/surface.

Accumulate Response Curve

It always be unchecked when the tuning dialog started, and won't restore it last check/uncheck state. When it is checked, it will retaining the existing curves, and add new curve to the plot. Uncheck the checkbox won't clear the accumulated curves, just stop to accumulate new curve. When Axis variable is changed all accumulated curves will be cleared.

Exporting Response Surface Data

You can Export the Table in the following formats:

- Comma delimited data files, (*.csv)
- Tab delimited data files, (*.tab)

- Ansoft Plot data files, (*.dat)
- Post Processor format data files, (*.txt)

Setting Up Design of Experiments

Using Design of Experiments

Using the Fast Calculation-Update Algorithm

A fast calculation-update algorithm is available to speed up Optimetrics and report updates during Optimetrics analyses. The fast calculation-update algorithm will generate the same Optimetrics results, only faster, and is available for all Optimetrics analyses *except* Tuning analysis. By default, the fast calculation-update option is automatically enabled whenever it is applicable, but you can configure it manually using the **Options** tab of the Optimetrics **Setup** dialog box. To enable the fast calculation-update algorithm:

1. Click your product, and then **>Optimetrics Analysis >Add** <*OptimetricsType*>.

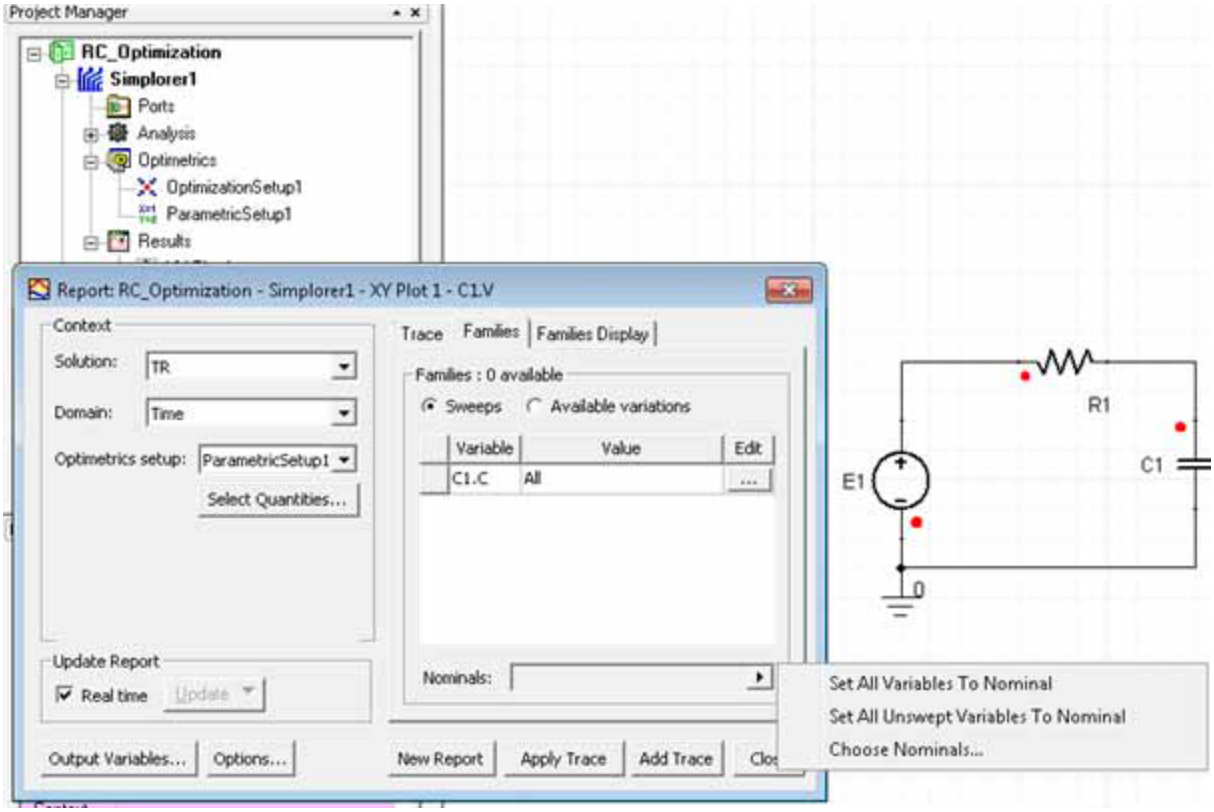
   A typical dialog to **SetupSweep Analysis** is shown below with the **Options** tab selected.

   The **Options** tab is the same for all optimization setups.

2. Check **Use fast calculation-update algorithm** to enable use of the algorithm. (See also, *Fast Calculation-Update Algorithm Limitations*.)

   When the fast calculation-update algorithm is enabled:

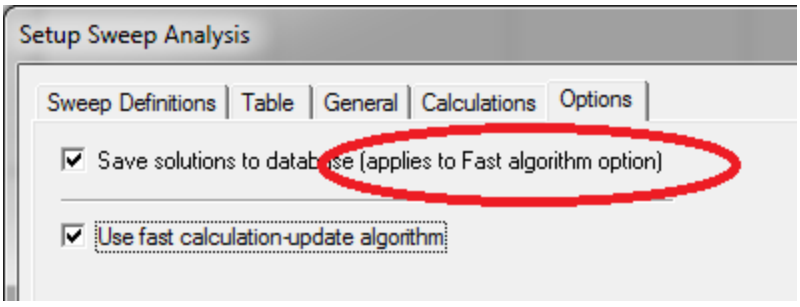
   - You can enable some reports to be updated automatically during the optimetrics analysis if you **Set All Variables To Nominal** in the Report/Trace setup dialog:



- You can see each trace (overwriting the previous), by setting the **Optimetrics setup** in the Report dialog to **None** in addition to having all variables set to Nominal. At the end of the analysis, the user will see the last calculated value.

3. If you have enabled **Use fast calculation-update algorithm** and want to save the solution data for every solved design variation in the Optimetrics analysis, select **Save solutions to database** as shown below. Selecting **Save solutions to database** has no effect without enabling **Use fast calculation-update algorithm**.

Note	Do not select this option when requesting a large number of iterations as the data generated will be very large and the system may become slow due to the large I/O requirements.



- When the **Save solutions to database** option is checked, a plot with traces based on the Optimetrics Setup just run can be updated through a menu command (right-click the desired report in the Project Manager Results folder and select **Update Report**) and will show results as appropriate (family, if chosen).
- Without the **Save solutions to database** option checked, you can examine analysis data in the **Post Analysis Display** dialog box, available by right-clicking on the Optimetrics Setup and choosing **View Analysis Result.**

Fast Calculation-Update Algorithm Limitations

The fast calculation-update algorithm **cannot** be used if **any** optimetrics calculation uses:

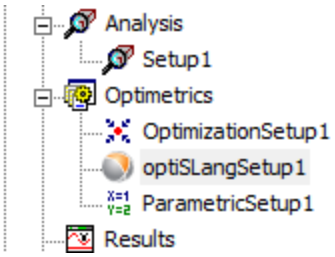
- **Project/Design variables** – If the project/design variable is ***not*** swept in the Optimetrics analysis, and you would like to use it in the expression: You can create an output variable for the Project/Design variable, assign the value of the Project/Design variable to the output variable, and use the output variable in the expression instead.
- **More than one range function** – For example, when range function is not the outermost function or when range function takes arguments.
- **More than one calculation range**, or the calculation range is not for primary sweep.

Similarly, when the fast calculation-update algorithm is enabled, a trace cannot be updated during an analysis if the trace expression uses:

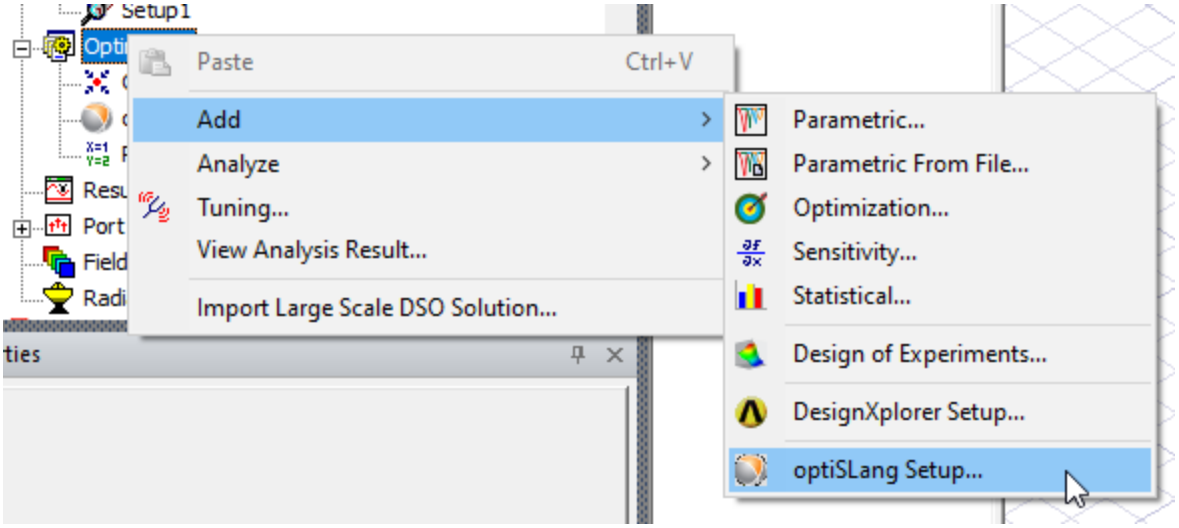
- **Project/Design variables**. (However, you can use the same workaround described above.)
- **Any range function.**

Setting Up optiSLang in Ansys Electronics Desktop

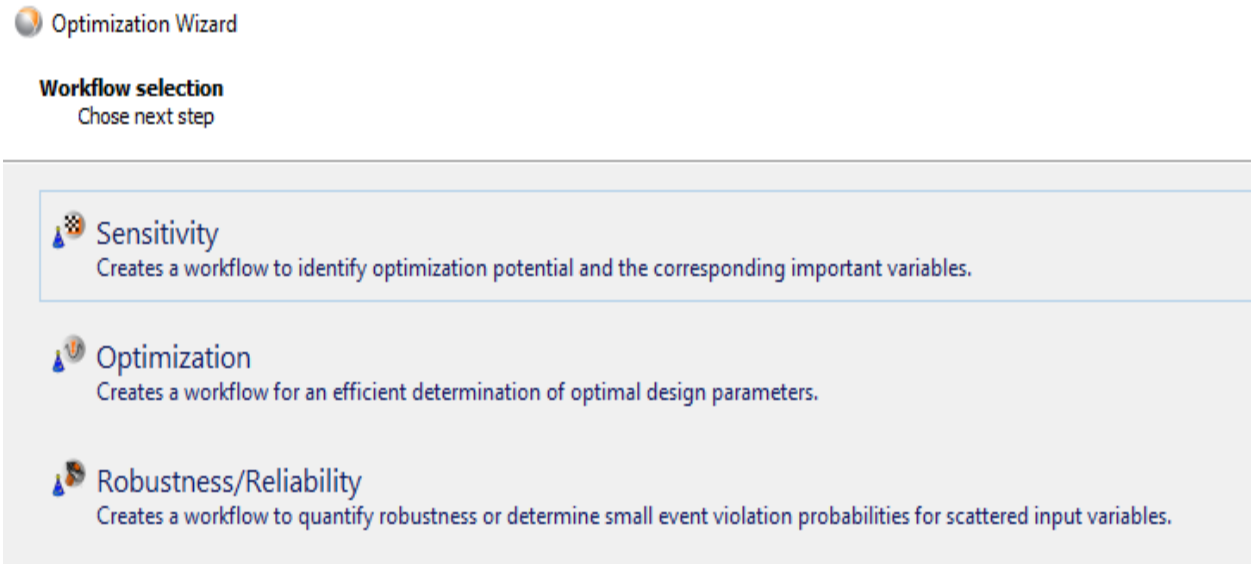
optisLang is a tool that use for graphical programming, process integration and automation that can be integrated with Ansys Electronics Desktop for optimization analysis. It is available at the Ansys Customer Portal as a Downloaded Add-on package. If you have installed optiSLang, and enabled the feature for Ansys Electronics Desktop, you create an optiSLang setup in much the way you would create an Optimetrics setup.



Ansys optiSLang integration then lets you create an optiSLang project from a setup you define in Ansys Electronics Desktop Optimization.



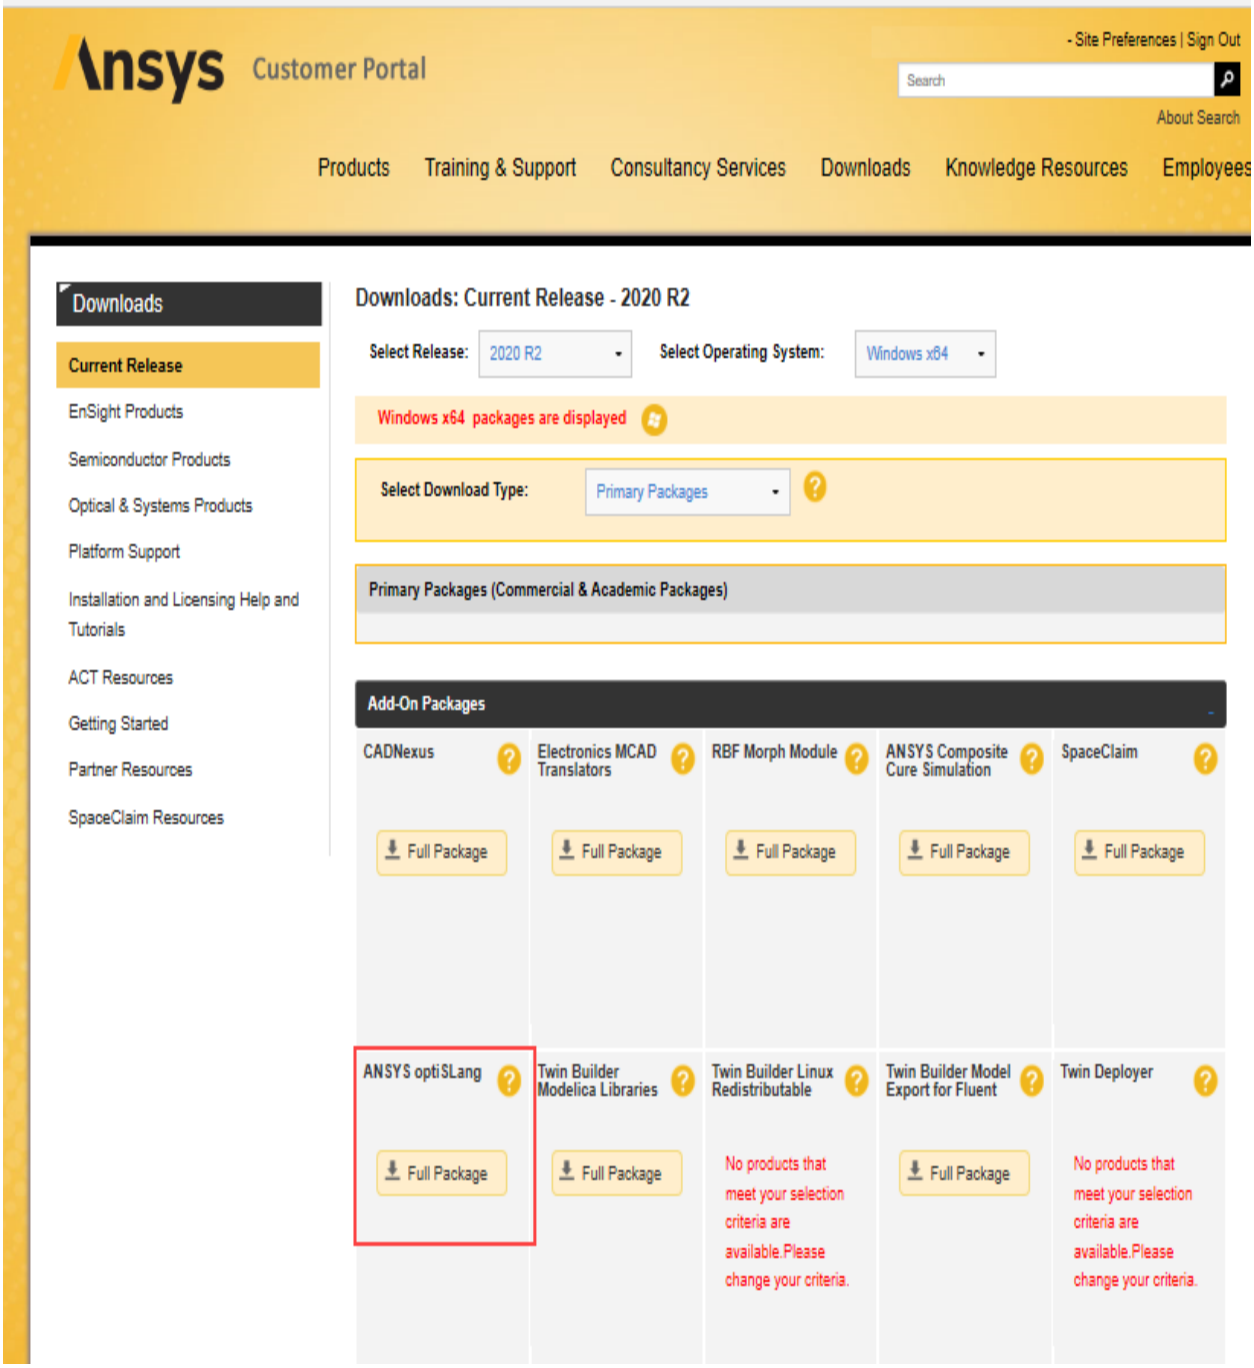
This opens an optiSLang Optimization wizard from which you can define a simulation.



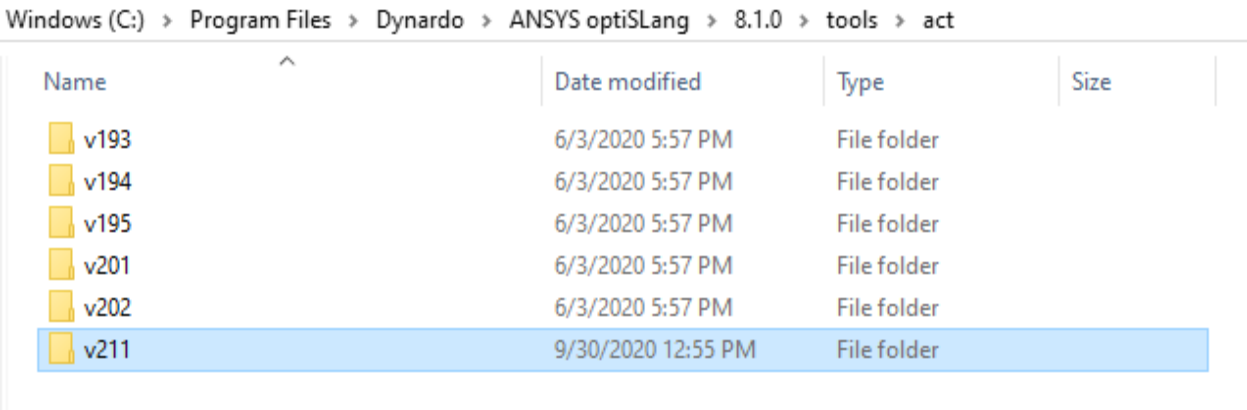
The process for setting up and using optisLang from Ansys Electronics Desktop follows.

Prerequisites

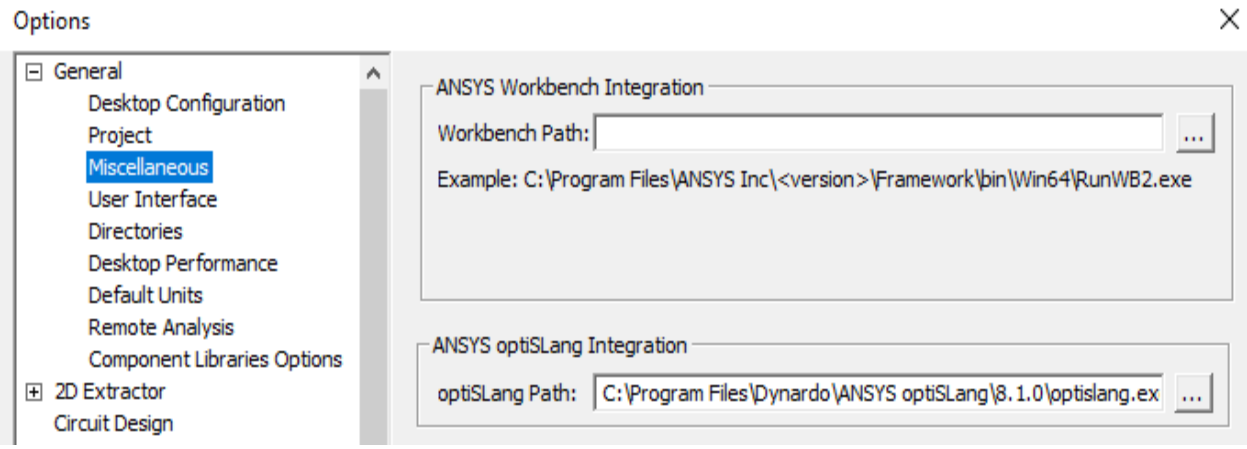
You must obtain optiSLang 8.1.0 or higher from the Ansys Customer Portal as a Downloaded Add-on package and install locally.



You must also install the optiSLang extensions to the scripting folder of the optiSLang installation.

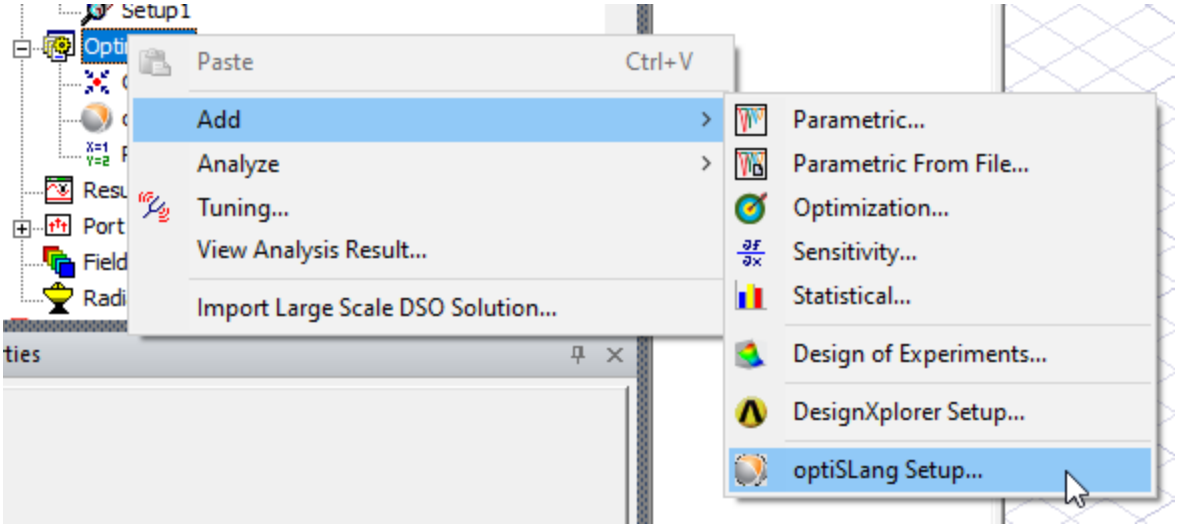


In the **Tools>General Options>Miscellaneous** options, specify the path to the optiSLang installation.

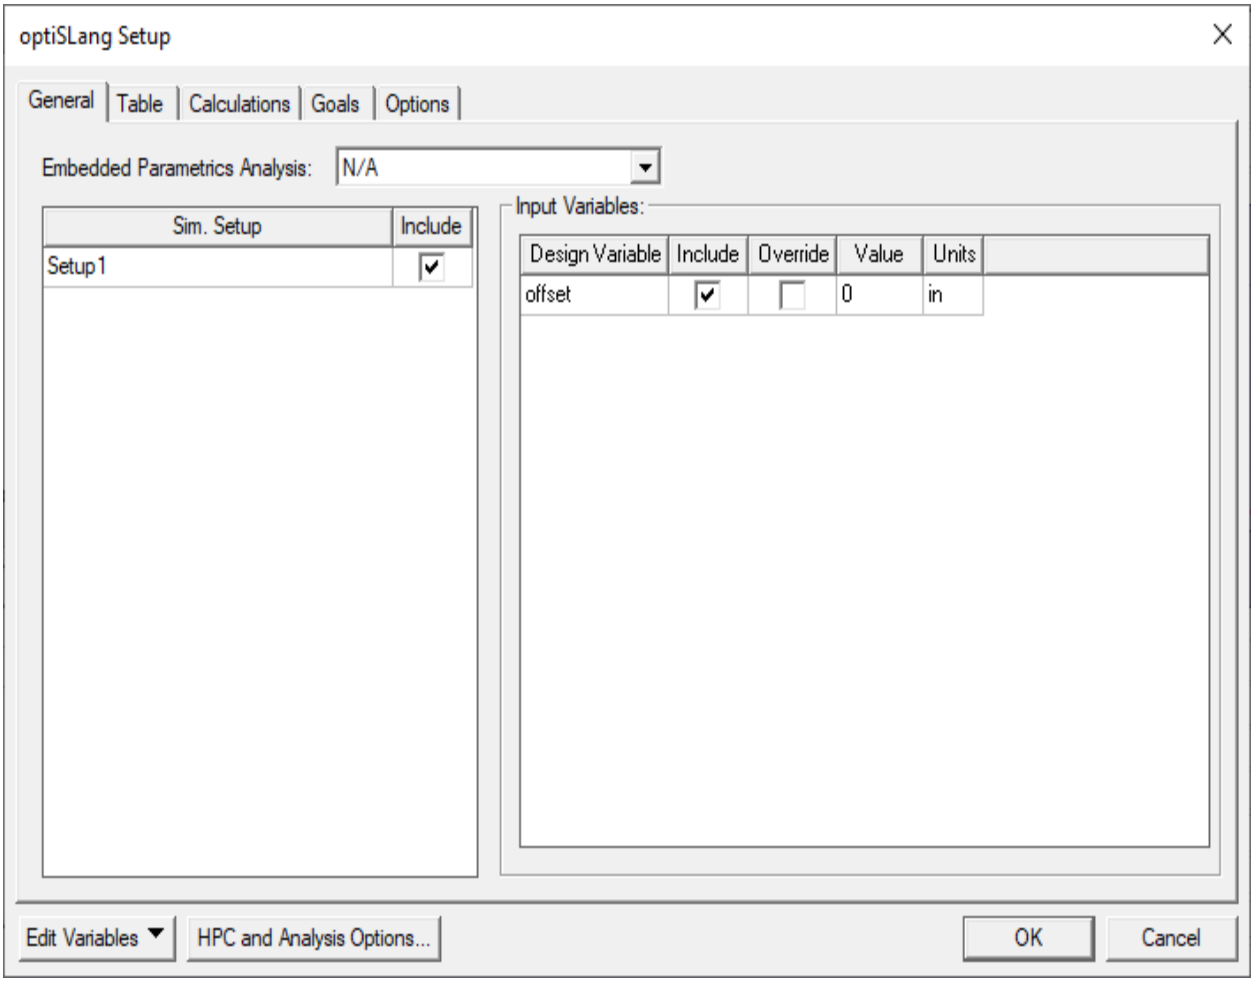


Add the optiSLang Setup

Right-click the Optimetrics icon in the Project tree and select **Add> optiSLang Setup...**. You can also use **Maxwell 2D (or Maxwell 3D)> Optimetrics Analysis> Add optiSLang Setup...**.

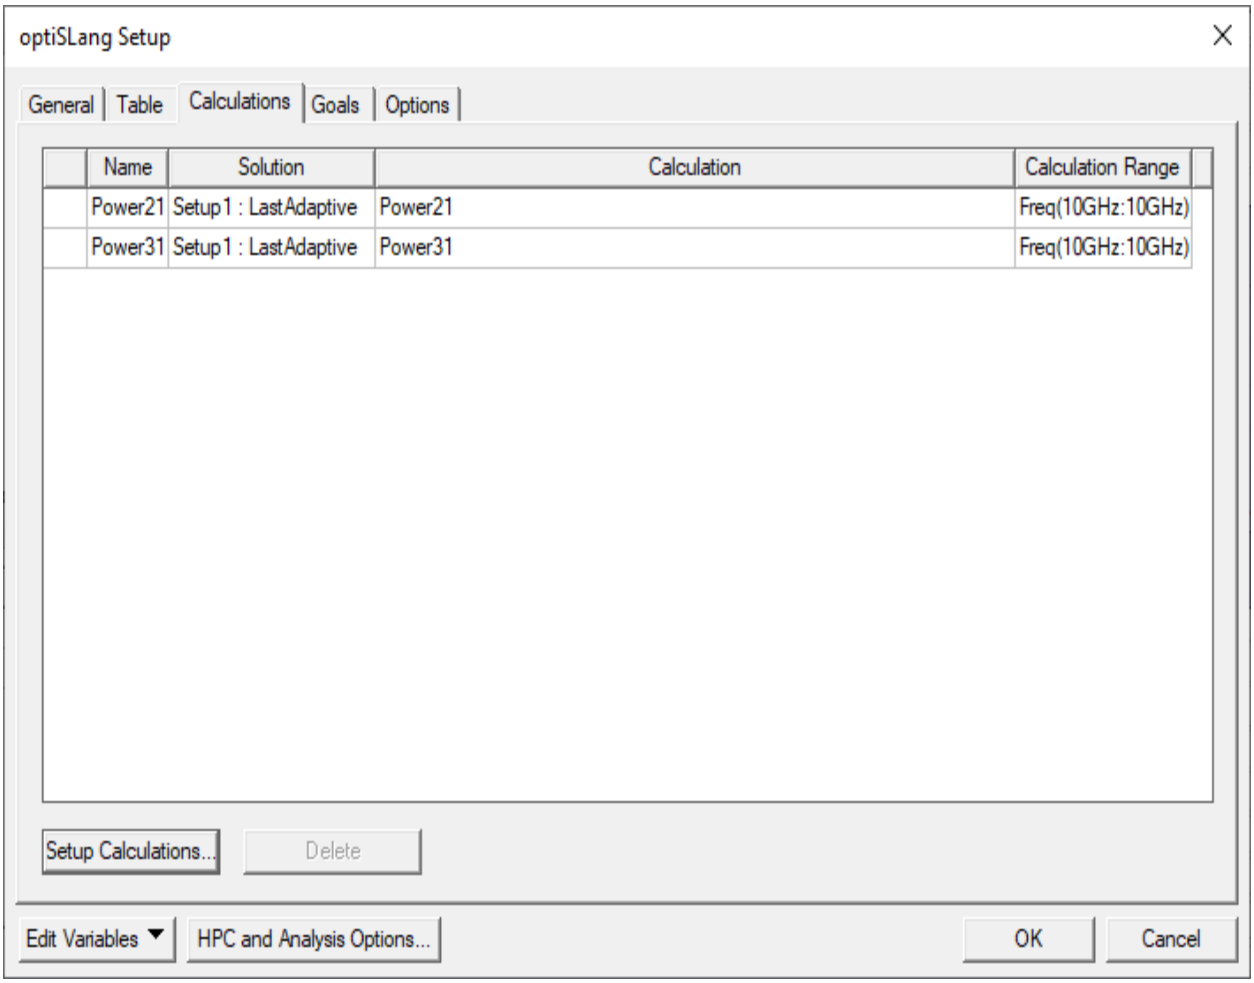


The *optiSLang Setup* dialog box appears. It is very similar to an Optimetrics setup.



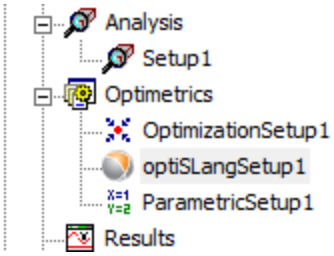
It has tabs for:

- General, which specifies the Setup to include and the Design Variables to use, and whether to include and/or Override the value.
- Table, which shows the values of the included variable.
- Calculations, which accesses Optimetrics calculations.



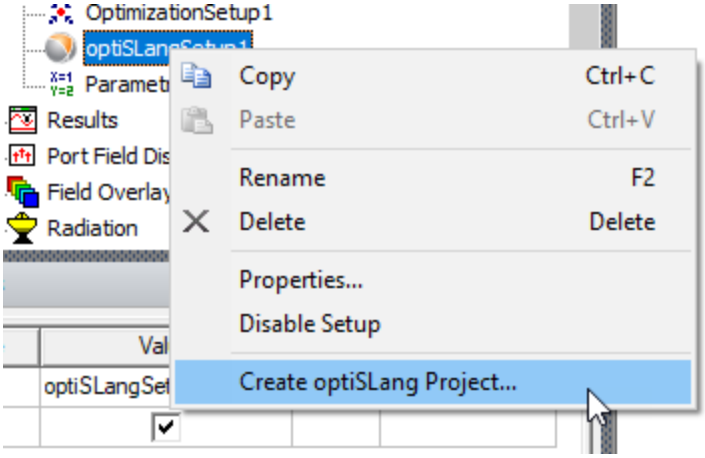
- Goals, including cost functions calculations and norm type.
- Variables, previously defined for Optimization/Design of Experiments as Project or Design variables, and whether to include them, treat as discrete, whether to Use Manufacturable Variables, and the available Levels.
- Options, to Save Fields and Mesh, and whether to copy geometrically equivalent meshes.

Once you have set parameters and click OK, the optiSLang setup appears under the Optimetrics icon in the Project tree.



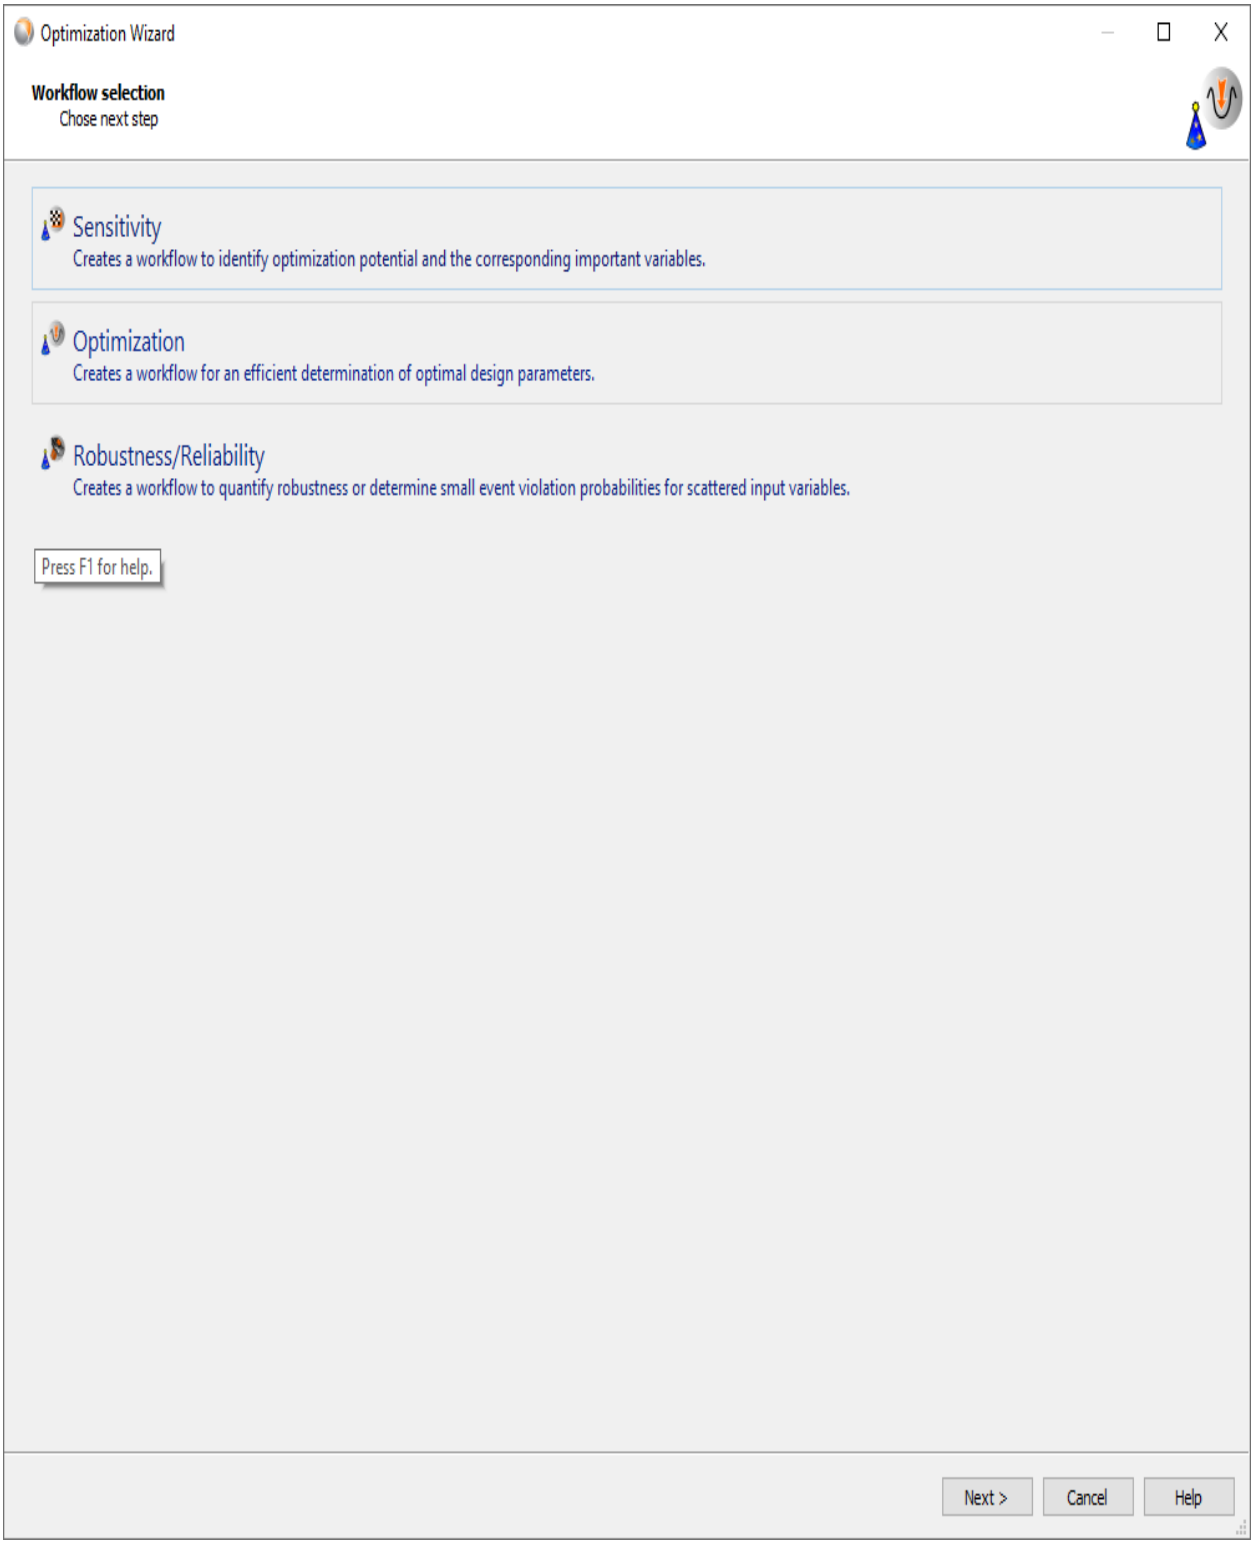
Creating an optiSLang Project

From here you can right-click the optiSLang setup for the shortcut menu.

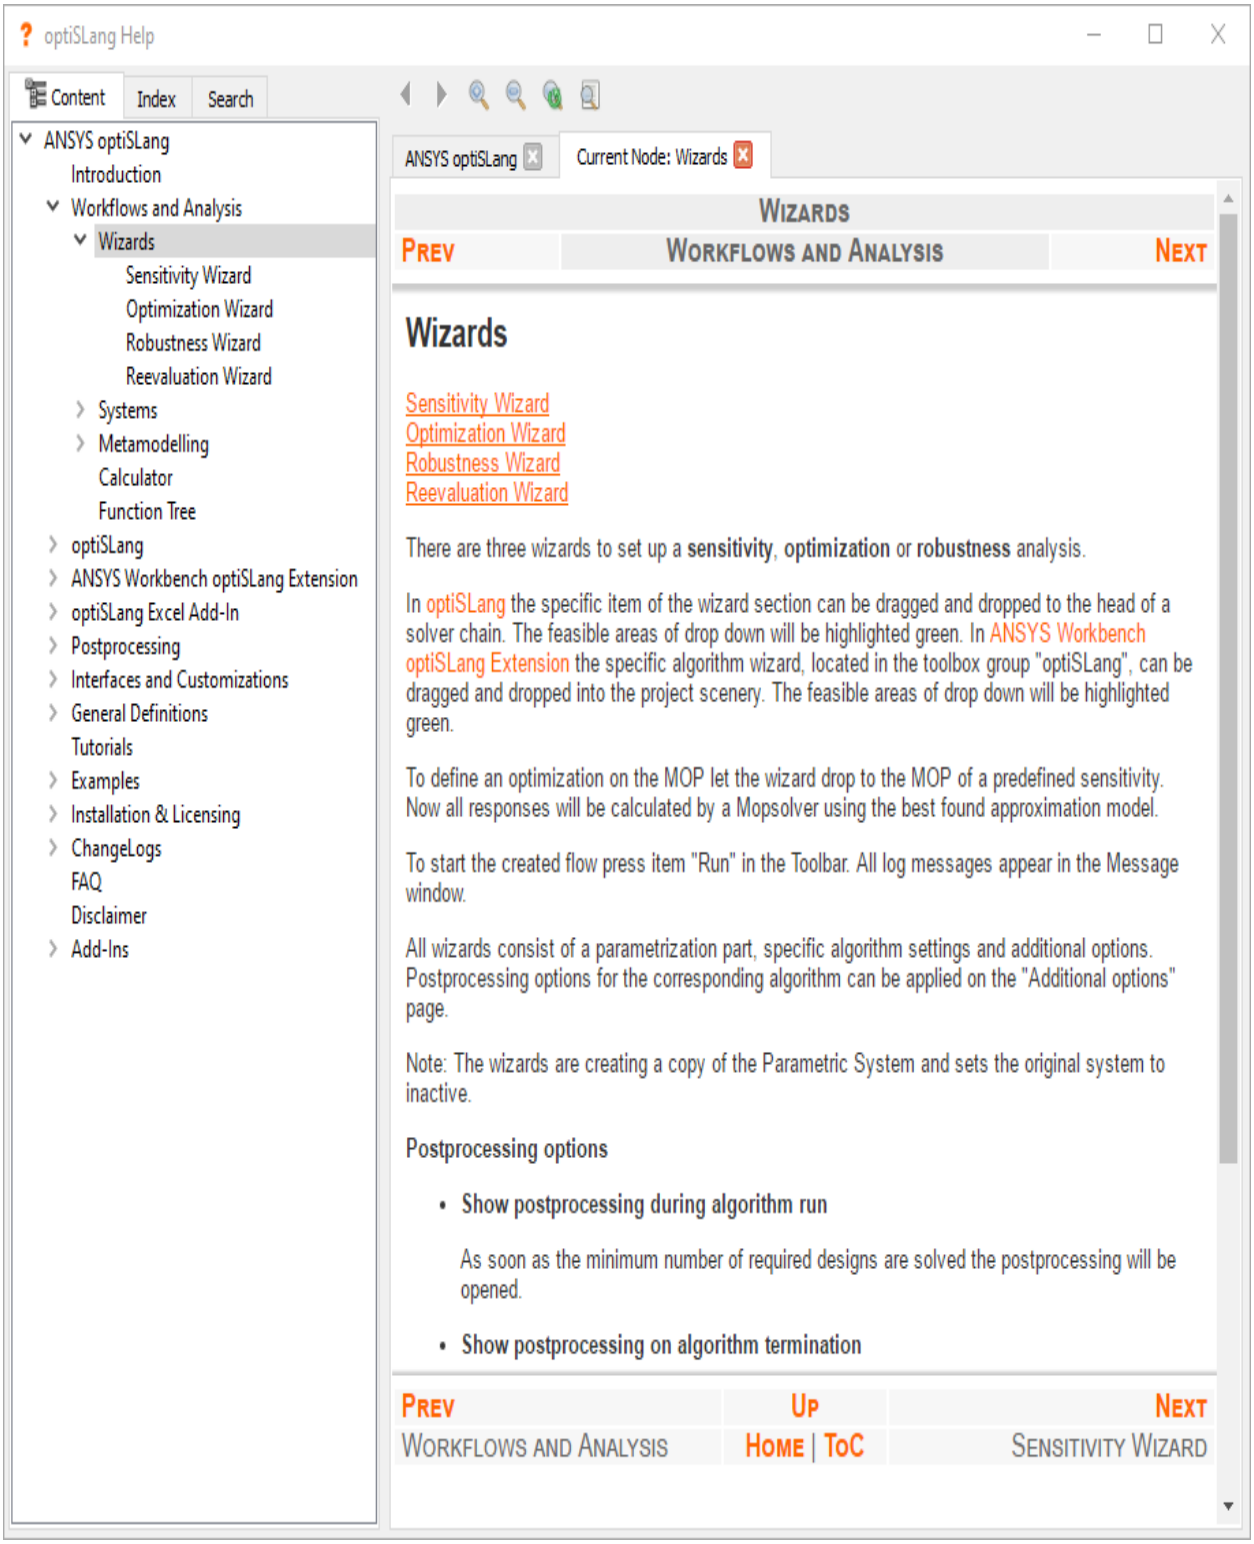


When you select **Create optiSLang Project...**, a progress window opens.

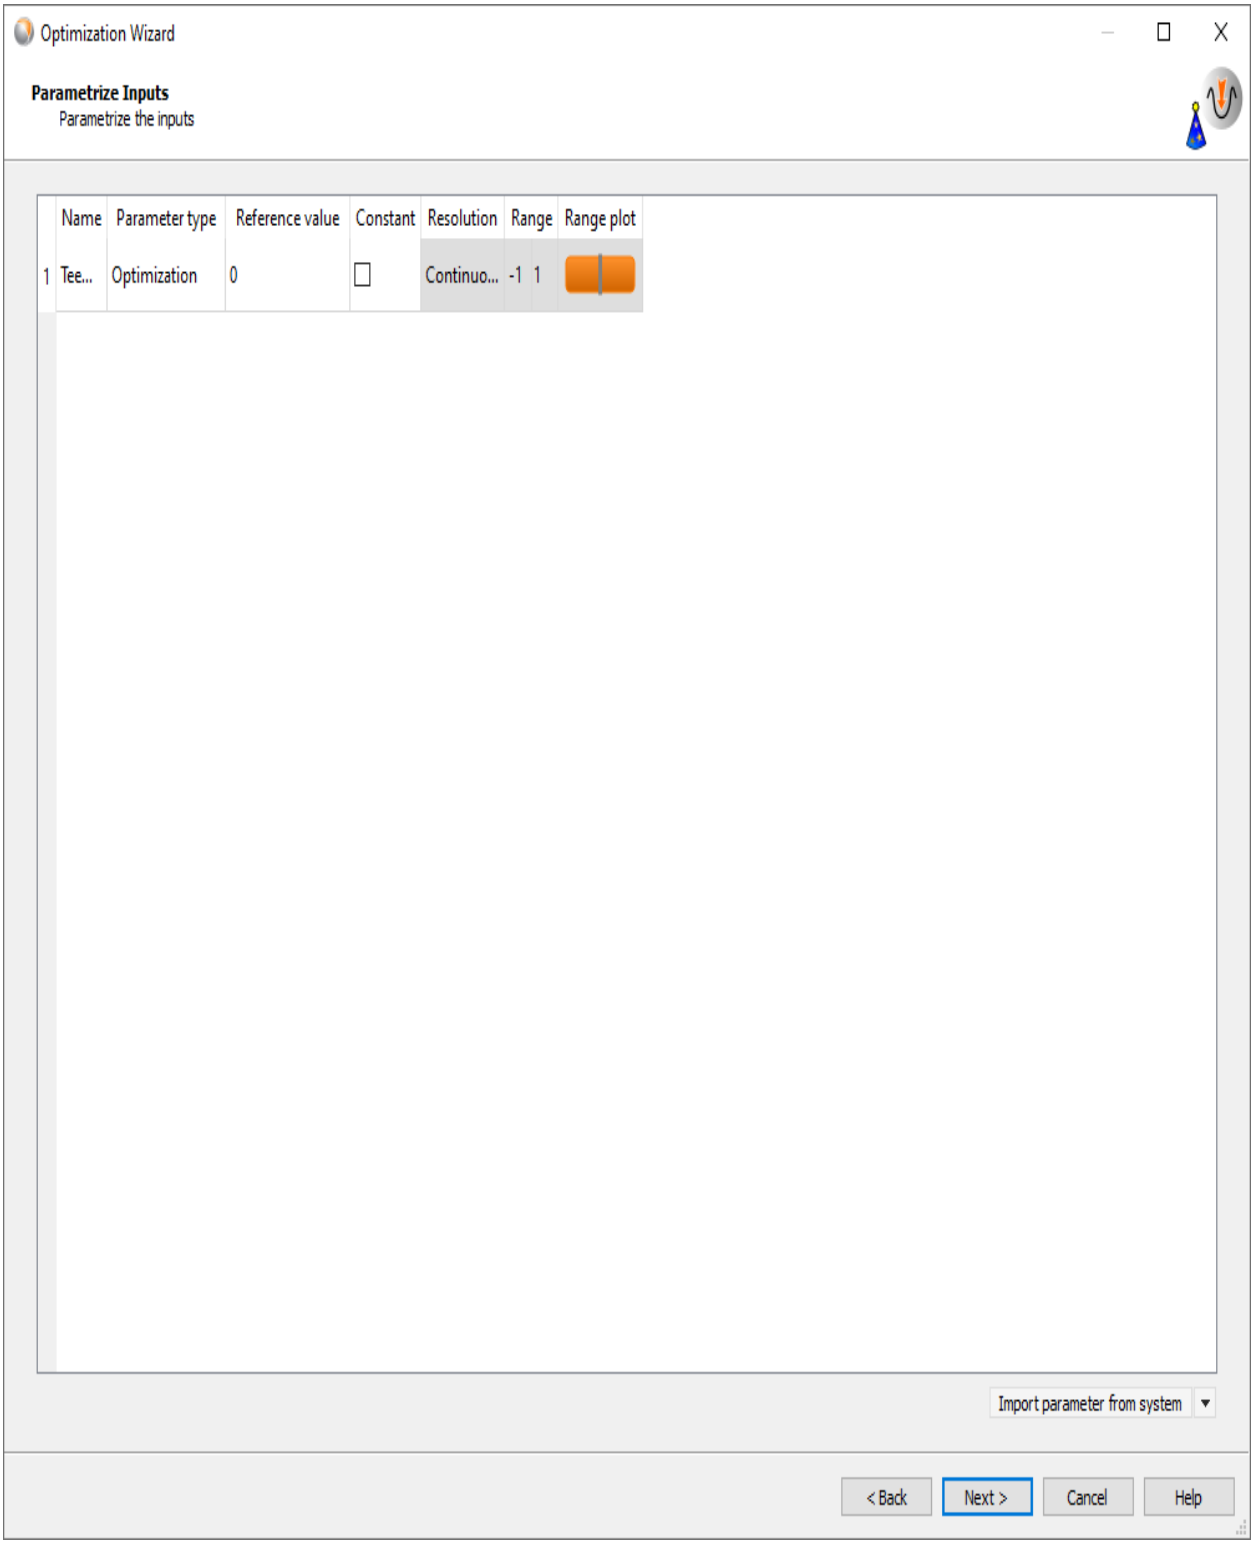
During this progress, the optiSLang **Optimization wizard** displays, where you can select the Workflow as Sensitivity, Optimization, or Robustness/Reliability.



The **Help** button opens a separate **optiSLang Help** window.



Selecting a Workflow and clicking **Next** opens a **Parameterize Input**s page.



Select **Next** for the **Criteria** page.

Optimetrics

Tuning Overview

Tuning a variable is useful when you want to manually modify its value and immediately perform an analysis of the design. For example, it is useful after performing an optimization analysis, in which Optimetrics has determined an optimal variable value, and you want to fine tune the value to see how the design results (for example, traces in a report) are affected.

A design can be updated after a tuning analysis to reflect a design variation solved during a tuning analysis and the results, including field solutions if you select **Save Fields and Mesh on the Options tab of the setup**.

Related Topics

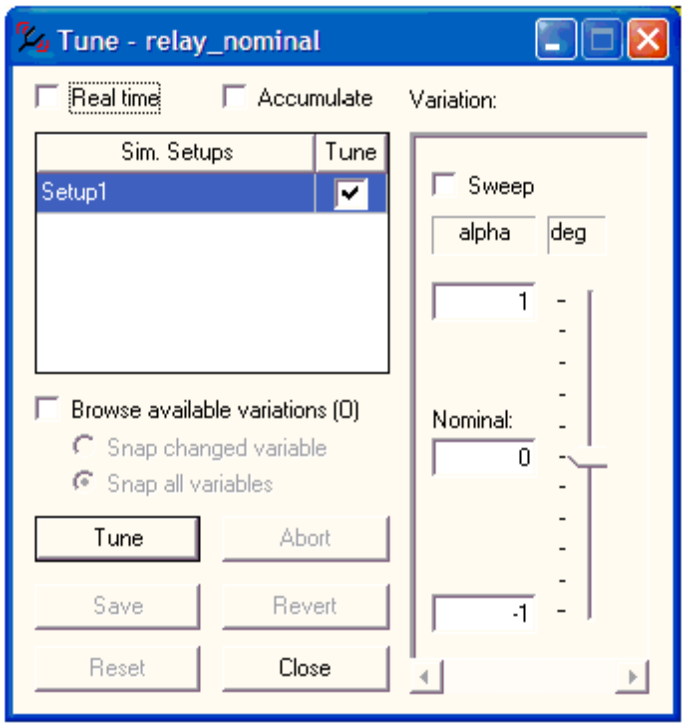
Tuning a Variable

Tuning a Variable

If you want to ensure that tuning does not resolve variations already solved by an optimization setup, you must check **Save Fields and Mesh** in the **Options** tab of that setup.

1. Before a variable can be tuned, you must specify that you intend for it to be used during a tuning analysis in a Project or Design **Properties** dialog box.
2. On the **Maxwell3D or Maxwell2D** menu, click **Optimetrics Analysis>Tune**  .

   The **Tune** dialog box appears, listing the variables which have been included for tuning.



3. Clear the **Real Time** option.

   Clearing the **Real Time** option enables the **Tune** button. If this option is selected, a simulation begins immediately after you move the slider. Otherwise, you use the **Tune** button to apply the current values to a simulation.

4. If you want to see updates to an open Report plot while tuning a post processing variable, you must select the **Browse available variations** check box. Selecting **Browse available variations** disables the sweep check box, and the fields for minimum and maximum variable values. This feature lets you see the effect of changes to the post processing variables on plotted results.

   Clearing **Browse available variations** enables the Sweep check box, the minimum and maximum fields, and changes the Nominal field to Step. See step 6.

5. In the **Sim. Setups** column, select the solution setup you want Maxwell to use when it solves the specified design variation.

   Maxwell solves the analysis using the solution setup you select. If you select more than one, results are generated for all selected solution setups.

   Checking the Tune box for a Sim Setup enables the Real Time check box, the Browse available variations check box, and the Snap radio buttons. Clearing the Tune box disables those selections.

6. In the **Nominal** text box for the variable you want to tune, type the value of the variable you want Maxwell to solve, or drag the slider to increase or decrease its value.

Warning	Variable values must be single real numbers, or expressions that evaluate to single real numbers. Complex numbers cannot be used as the values of variables in any optimetric analysis.

Alternatively, if you want Maxwell to solve a range of values, specify a linear range of values with a constant step size:

a. Select the **Sweep check box**.
b. In the text box below the **Step** value, type the starting value in the variable range.
c. Type the step size, or difference between variable values in the sweep definition, in the **Step** text box. The step size determines the number of design variations between the start and stop values. Maxwell solves the model at each step in the specified range, including the start and stop values.
d. In the text box just below the variable name, type a stopping value in the variable range.

7. If you have cleared the Real Time check box, click **Tune** to apply the changes you have made to the variable values.

Note	Sweeping or using a complex variable is not allowed in any optimetrics setup, including optimization, statistical, sensitivity, and tuning setups.

8. Changing a variable value with the sliders of by typing in the text field enables the **Save** and **Reset** buttons.

   Clicking **Save** opens a **Save As** dialog with a name field, and an **Apply tuned values to design** check box.

   Clicking **Reset** changes the variable values back to what they were originally.

9. If you have changed one or more included variables, clicking **Close** on the **Tuning** dialog opens the **Apply Tuned Variation** dialog box. This lists the included variables and the values for each tuning. If you have tried multiple values, they are listed, and the current value is highlighted. Select another value to change the highlight. Click **OK** to apply the highlighted values to the design, or **Don't Apply** to ignore the changes from the original variable values.

   If you have applied variant values, you should see the new values listed in the relevant Design or Project Properties lists of variables and values, and if the changes affect plots or physical features of a model, those changes should also appear.

   Click **Cancel** to close the dialog and go back to the **Tune** dialog.

Tuning Overview
Resetting Variable Values after Tuning

Applying a Tuned State to a Design

You can apply the variable values solved during a tuning analysis to the nominal design in one of the following three ways:

- When closing the **Tune** dialog box:

1. Click **Close** to exit the **Tune** dialog box.

   The **Apply Tuned Variation** dialog box appears.

2. Click the design variation you want to apply, and then click **OK**.

   The variable values from the solved design variation become the current variable values for the nominal design. If you have applied variant values, you should see the new values listed in the relevant Design or Project Properties lists of variables and values, and if the changes affect plots or physical features of a model, those changes should also be apparent.

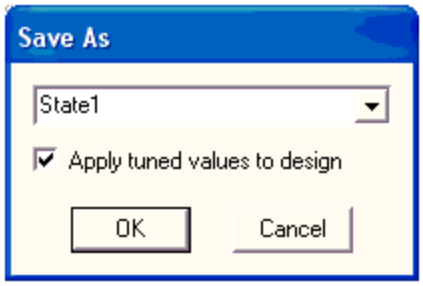
   - When saving a tuned state.
   - When reverting to a tuned state.

Saving a Tuned State

You can save the settings in the **Tune** dialog box, including the variable values you specified for a tuning analysis. Saved states are only available during the current session of the **Tune** dialog box; they are not stored for the next session.

1. After tuning a variable, click **Save** in the **Tune** dialog box.

   A **Save As** dialog box appears.



2. Type a name for the tuned state in the text box.
3. Select **Apply tuned values to design** if you want to update the model to the new variable values.
4. Click **OK** to return to the **Tune** dialog box.

Related Topics

Reverting to a Saved Tuned State

Reverting to a Saved Tuned State

You can revert to a group of saved settings in the **Tune** dialog box, including the variable values you specified for a specific tuning analysis. Saved states are only available during the current session of the **Tune** dialog box; they are not stored for the next session.

1. In the **Tune** dialog box, click **Revert**.

   The **Revert** dialog box appears.
2. Type the name of the tuned state you want to apply or click a name in the pull-down list.
3. Select **Apply tuned values to design** if you want to update the model to the selected tuned state's variable values.
4. Click **OK** to return to the **Tune** dialog box.

Related Topics

Saving a Tuned State

Resetting Variable Values after Tuning

If you want to reset variable values to the values they were set to when you started the current session of the **Tune** dialog box:

- After tuning a variable, click **Reset** in the **Tune** dialog box.

  Solutions for the design variations solved during tuning analyses remain available for post processing.

Saving Field Solutions for Optimetrics Analyses

In order to preserve disk space, by default Maxwell does not save field solution data for every solved design variation in an optimization analysis. It only saves the field solutions for the nominal design when an adaptive analysis is specified in the solution setup or when you request that fields be saved for each solved point in a frequency sweep. If the nominal design is not included in the optimization analysis, all field solutions are deleted.

To save the fields for all design variations, change the default setting for all projects:

1. Select **Tools>Options**, and then select either **Maxwell3D Options or Maxwell2DOption**.

   The appropriate **Options** dialog box appears.
2. Under the **General** tab, select **Save Optimetrics field solutions**.

   Save Fields is selected by default when you create a new Optimetrics setup.

Saving Field Solutions for Optimetrics Analyses

Saving Fields Solutions for a Design of Experiments Setup

In order to preserve disk space, by default Maxwell does not save field solution data for every solved design variation in a Design of Experiments setup. It only saves the field solutions for the nominal design. If the nominal design is not included in the setup, by default field solutions will not be available.

To save the fields for all design variations solved during a Design of Experiments analysis:

1. Open the **Design of Experiments** dialog box.
2. Select the **Options** tab.
3. Click the **Save Fields And Mesh** check box. Optionally, select **Copy geometrically equivalent meshes** and choose whether to **Solve with copied meshes only**, or to **Solve with copied meshes and continue adaptive passes**.

   Maxwell will save the field solution data for every solved design variation in the Design of Experiments setup.

Saving Field Solutions for Optimetrics Analyses

Copying Meshes in Optimetrics Sweeps

An option in the Optimetrics Analysis setups allows you to request Maxwell to copy a mesh that was calculated for one sweep variation for reuse on a geometrically-equivalent sweep variation. For example, with this option selected a sweep on a scan angle would not need to generate meshes for each solution. The option is available on the setups for sweeps on parametrics, optimization, sensitivity, and statistics.

To copy and reuse meshes on geometrically-equivalent parametric variations:

1. Define a variable for the kind of Optimetrics sweep you intent to setup.
2. Select **Maxwell3D or Maxwell2D** and then select the appropriate **Optimetrics>Add** command to display a **Setup** dialog box.
3. Click the **Options** tab in the Setup dialog box.
4. Select **Copy geometrically equivalent meshes**.

   Maxwell will copy the mesh solution calculated for a particular parametric sweep for reuse on each geometrically-equivalent sweep variation.

Note	This option is available with all Optimetrics setups, and is applied when these analyses generate geometrically-equivalent values. However, it is most relevant to parametric sweep, where such equivalences are more likely to occur.

The **Copy geometrically equivalent mesh** option is not recommended for use when the frequency is varying, since meshing is frequency-dependent. You may wish to turn this option off when the first geometrically equivalent variation requires numerous passes after the initial mesh, but the other geometrically-equivalent variations require fewer additional passes, so that it is cheaper to start with the initial mesh each time.

Adding an Expression in the Output Variables Window

When you are in the **Output Variables** window (after clicking **Edit Calculation** from the one of the setup analysis windows), do the following to specify an expression:

1. Type a name for the expression in the **Name** text box.
2. Do the following in the **Calculation** section of the window to insert a quantity into the expression:
   a. Select the **Report Type** and **Solution** from the pull-down lists.
   b. Select a **Category**, **Quantity**, and **Function** from the lists, and click **Insert Quantity Into Expression**.
   c. If you want to insert a specific pre-defined function, select one from the **Function** pull-down list, and click **Insert Function**.
3. You can also type numbers or expression by hand directly into the **Expression** area.

Excluding a Variable from an Optimetrics Analysis

To exclude a variable from being optimized or included in a sensitivity or statistical analysis:

1. Do one of the following:
   - In the **Setup Optimization** dialog box, click the **Variables** tab.
   - In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
   - In the **Setup Statistical Analysis** dialog box, click the **Variables** tab.

   All of the independent variables that were selected for the optimization analysis are listed.
2. Clear the **Include** option for the variable you want to exclude from the analysis.

   The **Override** option is now selected. This indicates that, for this optimization analysis, the variable is not included.

Note	Alternatively, you can select the **Override** option first, and then clear the **Include** option for the variable you want to exclude.

3. Click **OK**.

Modifying the Value of a Fixed Variable

If you are not including a variable in an optimization, sensitivity, or statistical analysis, Optimetrics uses that variable's current value during the analysis.

To override the current value of a fixed variable for an Optimetrics setup:

1. Do one of the following:
   - In the **Setup Optimization** dialog box, click the **Variables** tab.
   - In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
   - In the **Setup Statistical Analysis** dialog box, click the **Variables** tab.
2. Click **Set Fixed Variables**.

   The **Setup Fixed Variables** dialog box appears. Under **Fixed Variables**, all of the current independent variable values are listed.
3. Click the **Value** text box of the variable with the value you want to override.
4. Type a new value in the **Value** text box, and then press **Enter**.

   The **Override** option is now selected. This indicates that the value you entered is used for this Optimetrics setup; the current variable value set for the nominal design is ignored.

Note	Alternatively, you can select the **Override** option first, and then type a new value in the **Value** text box.

5. Optionally, click a new unit system in the **Units** text box.
6. Click **OK**.

To revert to a default variable value, clear the **Override** option.

Linear Constraints

Once the optimization variables are specified, the optimizer handles each of them as an *n*-dimensional vector *x*. Any point in the design space corresponds to a particular *x*-vector and to a design instance. Each design instance may be evaluated via Finite Element Analysis and assigned a cost value; therefore, the cost function is defined over the design space (cos*t*(*x*): $R^n \rightarrow R$), where *n* is the number of optimization variables.

In practice, a solution of the minimization problem is sought only on a bounded subset of the R^n space. This subset is called the feasible domain and is defined via linear constraints.

You may constrain the feasible domain of a design variable by defining linear constraints for the optimization process. The feasible domain is defined as the domain of all design variables that satisfy all upper and lower bounds and constraints. Linear constraints are defined by the following inequalities:

$$\sum_i \alpha_{ij} x_i < c_j \forall j$$

where

- α_{ij} are coefficients.
- c_j is a comparison value for the j^{th} linear constraint.
- x_i is the i^{th} designer parameter.

Related Topics

Setting a Linear Constraint

Setting a Linear Constraint

A linear constraint defines the linear relationship between variables. Setting linear constraints in Optimetrics is useful for establishing limitations involving linear combinations of variable values.

1. Do one of the following:
   - If you are setting up an optimization analysis: In the **Setup Optimization** dialog box, click the **Variables** tab.
   - If you are setting up a sensitivity analysis: In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
2. Click **Linear Constraint**.

   The **Linear Constraint** dialog box appears.
3. Click **Add**.

   The **Edit Linear Constraint** dialog box appears.
4. Click a **Coeff** text box and type a positive or negative coefficient value.
5. Click a condition, **<** (less than) or **>** (greater than), from the pull-down list.

6. Type the inequality value, which should be a constant value, in the text box to the right of the condition.
7. Click **OK**.

   You return to the **Linear Constraint** dialog box. The left-hand side of the constraint appears in the **LHS** (left-hand side) column. The condition is listed in the **Condition** column, and the inequality value is listed in the **RHS** (right-hand side) column.

Linear Constraints

Modifying a Linear Constraint

1. Do one of the following:
   - If you are setting up an optimization analysis: In the **Setup Optimization** dialog box, click the **Variables** tab.
   - If you are setting up a sensitivity analysis: In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
2. Click **Linear Constraint**.

   The **Linear Constraint** dialog box appears.
3. Click the row listing the constraint you want to modify, and then click **Edit**.

   The **Edit Linear Constraint** dialog box appears.
4. Optionally, click a **Coeff** text box and type a new coefficient value.
5. Optionally, click a different condition, **<** (less than) or **>** (greater than), in the pull-down list.
6. Optionally, type a different inequality value in the text box to the right of the condition, and then click **OK**.

   You return to the **Linear Constraint** dialog box. The new coefficient value, the condition, and the inequality value appear in the **LHS** (left-hand side), **Condition**, and **RHS** (right-hand side) columns, respectively.

Deleting a Linear Constraint

1. Do one of the following:
   - If you are setting up an optimization analysis: In the **Setup Optimization** dialog box, click the **Variables** tab.
   - If you are setting up a sensitivity analysis: In the **Setup Sensitivity Analysis** dialog box, click the **Variables** tab.
2. Click **Linear Constraint**.

   The **Linear Constraint** dialog box appears.

3. Click the row listing the constraint you want to delete, and then click **Delete**.

   The constraint is deleted.

Running an Optimetrics Analysis

Once you have created all necessary Optimetrics based analyses, you have several options for running the simulations.

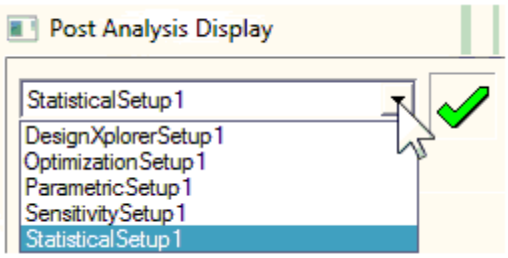
- To use the **Analyze All** command at the Project or design level to simulate the nominal problem and subsequently run all Optimetrics setups, do the following:
  1. In the Project Manager window, right-click on the **project** or **design** name.
  2. Click **Analyze All** from the shortcut menu.
- To use the **Analyze All** command from the Optimetrics menu to simulate only the Optimetrics based setups, do the following:
  1. In the Project Manager window, right-click on **Optimetrics**.
  2. Click **Analyze>All** from the shortcut menu.
- You can choose to analyze only the setups related to a specific Optimetrics type of analysis. In order to simulate setups of a specific type, do the following:
  1. In the Project Manager window, right-click on **Optimetrics**.
  2. Click **Analyze>All{*TYPE*}** from the shortcut menu where *TYPE* is the specific analysis type of interest, Parametric, Optimization, Sensitivity, or Statistical.

Viewing Analysis Results for Optimetrics Solutions

To view data specific to an Optimetrics solution, in general, do the following:

- In the project tree, right-click the Optimetrics setup for which you want to view the results, and then click **View Analysis Result** on the shortcut menu.

  The **Post Analysis Display** dialog box appears.
- Select from available setups by using the dropdown selection menu.



- Select the **Result** tab to view results in plot or table form. When you view results in Table form you can resort the results based on each column. For example, click the Variation column head to invert the sort from lowest to highest setup number. Click the variable name column to resort the results by step value. Click the Cost column head to sort the results from lowest cost to highest cost. Clicking a column again inverts the current sort.

- Click the **Options** button to open a dialog that permits you to specify the Maximum number of significant digits to display when showing the analysis result. The default is 4.
- Select the **Profile** tab to view start, stop, and elapsed times for each variable, and the analysis machine for each variation. You can click the column heads to sort the table by variation number,variable value, start, stop, or elapsed time, or (if you have run a distributed analysis) machine.

See the help topics in this section for more details about viewing optimization analysis results.

Viewing Solution Data for an Optimetrics Design Variation

To view the convergence information, computing resources used, or matrices computed for any design variation solved during an optimization analysis, you must first select the design variation in the **Set Design Variation** dialog box. This dialog box is accessible from the **Solutions** Data window and via the **Results>Apply Solved Variation** command in the **Maxwell3D, Maxwell2D, or RMxprt menu**.

1. Click **Maxwell3D, Maxwell2D, or RMxprt and then select Results>Solution Data**.
   The **Solutions** dialog box appears.
2. Click the browsing dots beside the **Design Variation** box.
   The **Set Design Variation** dialog box appears.
3. Clear the **Use nominal design** option.
4. Click the design variation for which you want to view the solution data, and then click **OK**.
   The solution data is displayed in the table.

Related Topics

Viewing an Optimetrics Solution's Profile Data

Viewing an Optimetrics Solution's Profile Data

At any time during or after the Optimetrics solution process, you can see an overview of the computing resources or profile data that was used by Maxwell as it solved each design variation. The profile data indicates the how long each design variation took to solve.

1. In the project tree, right-click the Optimetrics solution setup of interest, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Click the **Profile** tab.
3. Select the Optimetrics setup with the results you want to view from the pull-down list at the top of the dialog box.
4. Optionally, to examine more detailed profile data for a specific design variation, do the following:
   a. Click a design variation in the table.
   b. Click **Solver Profile**.

The **Solutions** dialog box appears with the profile data for the selected design variation.

The profile line for the matrix solver is in the following format:

```
Solver 123
```

where:

- *1* is the precision type: M (mixed) or D (double)
- *2* is the matrix data type: R (real) or C (complex)
- *3* is the symmetry type: S (symmetric), A (asymmetric), H (hermitian)

Viewing Solution Data for an Optimetrics Design Variation

Viewing Results for Parametric Solution Quantities

1. In the project tree, right-click the parametric setup for which you want to view the results calculated for the solution quantities, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Select the parametric setup with the results you want to view from the pull-down list at the top of the dialog box.
3. If it is not already selected, select **Table** as the view type.

   The results for the selected solution quantities are listed in table format for each solved design variation. The variation column in the table lists the entries in order. Clicking the Vision header inverts the order. Clicking other headers sorts the entries by value, and clicking again inverts the order.
4. Optionally, select **Show complete output name**.

   The complete name of the solution for which the results are being displayed will be listed in the column headings.

5. Optionally, click a design variation in the table, and then click **Apply** (at the far right side of the dialog box).

   The design displayed in the **3D Modeler** window is changed to represent the selected design variation.

Plotting Solution Quantity Results vs. a Swept Variable

Plotting Solution Quantity Results vs. a Swept Variable

To plot solution quantity results versus a swept variable's values on a rectangular (x - y) plot:

1. In the project tree, right-click the parametric setup for which you want to view the results, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. If it is not already selected, select **Plot** as the view type.
3. Select the variable with the swept values you want to plot on the x-axis from the **X** pull-down list.
4. Only one sweep variable at a time can be plotted against solution quantity results. Any other variables that were swept during the parametric analysis remain constant.

   Optionally, to modify the constant values of other swept variables, do the following:

   a. Click **Set Other Sweep Variables Value**.
      The **Setup Plot** dialog box appears. All of the other solved variable values are listed.
   b. Click the row with the variable value you want to use as the constant value in the plot, and then click **OK**.
5. Select the solution quantity results you want to plot on the y-axis from the **Y** pull-down list.

   The xy plot appears in the view window.
6. Right-click in the plot area to get the shortcut menu where you can set modify the plots display properties, print, copy to the clipboard, or export the data to a file.

Viewing Cost Results for an Optimization Analysis

To view cost values versus completed iterations in data table format:

1. In the project tree, right-click the optimization setup for which you want to view the cost results, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Under the **Result** tab, select **Table** as the view type, if it is not already selected.

   The cost value at each solved design variation is listed in table format.
3. Optionally, click a design variation in the table, and then click **Apply**.

Maxwell now points to the selected design variation as the nominal solution and as a result, the design displayed in the **Modeler** window is changed to represent the selected design variation.

Click **Revert** to return the design in the view window to the original value.

Related Topics

To view cost values versus completed iterations in rectangular (x-y) plot format:

1. In the project tree, right-click the optimization setup for which you want to view the cost results, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Under the **Result** tab, select **Plot** as the view type.

   A plot of the cost value at each iteration appears.

Viewing Output Parameter Results for a Sensitivity Analysis

To view actual output parameter values versus design point in data table format:

1. In the project tree, right-click the sensitivity setup for which you want to view the parameter results, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Under the **Result** tab, select **Table** as the view type, if it is not already selected.

   The following values are listed in table format:
   - The regression value of the output parameter at the design point is listed in the **Func. Value** column.
   - The first derivative of the regression is listed in the **1st D** column.
   - The second derivative of the regression is listed in the **2nd D** column.
3. Click **Apply**.

   Maxwell now points to the selected design variation as the nominal solution and as a result, the design displayed in the **Modeler** window is changed to represent the selected design variation.

   Click **Revert** to return the design in the view window to the original value.

Viewing Solution Data for an Optimetrics Design Variation

Plotting Output Parameter Results for a Sensitivity Analysis

To plot output parameter results versus sensitivity variable values on a rectangular (xy) plot:

1. In the project tree, right-click the sensitivity setup for which you want to view the output parameter results, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Under the **Result** tab, select **Plot** as the view type.
3. Select the sensitivity variable with the sweep values you want to plot on the x-axis from the **X** pull-down list.
4. Select the output parameter results you want to plot on the y-axis from the **Y** pull-down list.

   The xy plot appears in the **Post Analysis Display** dialog box.

   The plot displays actual output parameter results for each solved design variation. It also displays a parabola that best fits these results. The parabola is a more accurate representation of sensitivity around the design point than any individual solved design variation.

Viewing Distribution Results for a Statistical Analysis

1. In the project tree, right-click the statistical setup for which you want to view the distribution results calculated for the solution quantities, and then click **View Analysis Result** on the shortcut menu.

   The **Post Analysis Display** dialog box appears.
2. Select the statistical setup with the results you want to view from the pull-down list at the top of the dialog box.
3. To view the results in tabular form, select **Table** as the view type.

   The distribution results for the selected solution quantities are listed in table format for each solved design variation.
4. Optionally, click a design variation in the table, and then click **Apply** (at the far right side of the dialog box).

   The design displayed in the **3D Modeler** window is changed to represent the selected design variation.
5. To view the results in graphic format, select **Plot** as the view type.
6. Type the number of bins you want to plot on the x-axis.
7. Select the solution quantity for which you want to plot distribution results on the y-axis from the **Y** pull-down list.

   A histogram plot appears in the **Post Analysis Display** dialog box. It displays the distribution of the selected solution quantity.
8. Optionally, click a design variation in the table, and then click **Apply** (at the far right side of the dialog box).

Maxwell now points to the selected design variation as the nominal solution and as a result, the design displayed in the **Modeler** window is changed to represent the selected design variation.

Click **Revert** to return the design in the view window to the original value.

   The **Post Analysis Display** dialog box appears.
2. Select the statistical setup with the results you want to view from the pull-down list at the top of the dialog box.
3. If it is not already selected, select **Plot** as the view type.
4. Type the number of bins you want to plot on the x-axis.
5. Select the solution quantity for which you want to plot distribution results on the y-axis from the **Y** pull-down list.

   A histogram plot appears in the **Post Analysis Display** dialog box. It displays the distribution of the selected solution quantity.

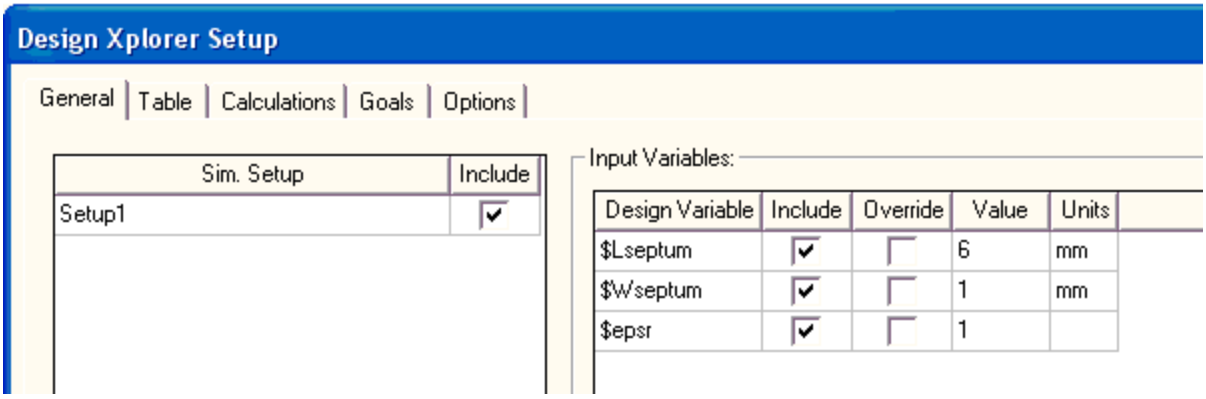
Link to Design Xplorer

You can export a .xml file containing information on a Maxwell setup, optimization variables, and output variables that enables Ansys Design Xplorer to manage Maxwell simulations, for example, for design of experiments and optimization. Design Xplorer will launch Maxwell simulations of design variations and evaluate the Maxwell outputs.

To do so:

1. Click **Maxwell>Optimetrics Analysis>Add Design Xplorer Setup...** or right-click on **Optimetrics** in the **Project** window, and select **Add Design Xplorer Setup...** from the short-cut menu.

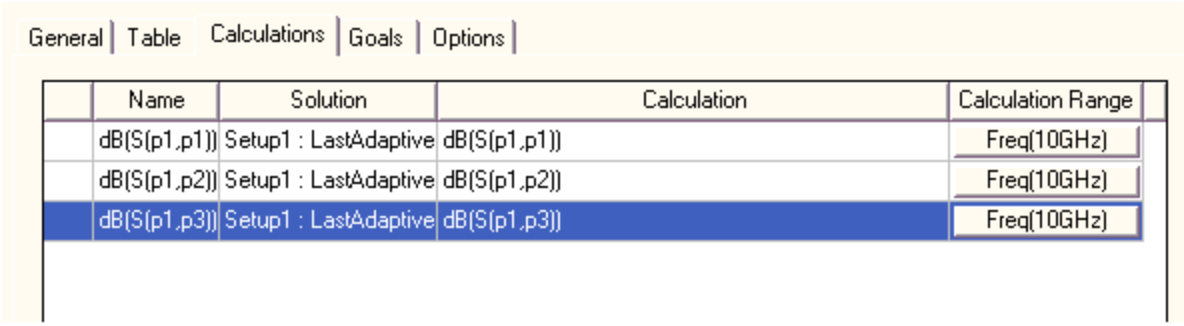
   This opens the **Design Xplorer** dialog with the **General** tab selected. it lists the setups available in the current project, and the input variables it contains.



2. Check Include for the simulation setups you want to use.
3. Check the Design variables to use. You can also chose to Override the value of a design variable. You can edit the Value and Units fields. Unchecking Override returns the values to their original state.
4. To setup any output calculations, click the **Calculation** tab and click the **Setup Calculations** button.

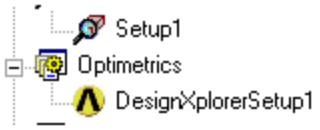
   This opens the **Add/Edit Calculation** dialog. Here you can define the simulation results of interest. The dialog box contains distinct panes and tabs to set the **Context**, the **Calculation Expression**, and the **Calculation Range**. See Setup Calculations for Optimetrics for details.

   Use the **Add Calculation** button to add expressions to the Calculations table of the **Design Xplorer Setup** dialog box, **Calculations** tab.

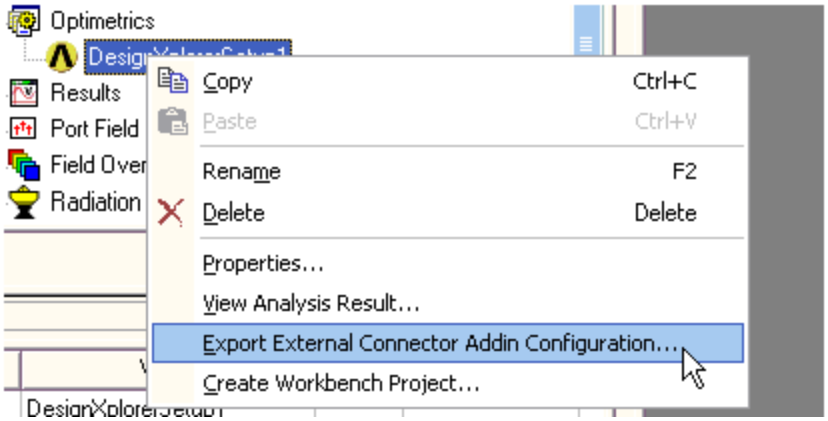


5. When you have added the calculations of interest, click **OK** to save the setup.

   An icon for the Design Xplorer setup appears under Optimization in the Project tree.



6. To create a .xml file with the setup information for Design Xplorer, first Save your project.
7. Then right-click on the setup and select **Export External Connector Addin Configuration.**



This displays a browser dialog that you can use to navigate your file system, and name and saves the .xml file. The .xml file contains information regarding the Maxwell path along with the setup, variables, and simulation results that you specified.

8. If you have an Ansys Workbench installation you can perform additional steps. Ensure that you have provided a path to the Workbench installation in the **Tools>General Options** dialog on the Miscellaneous panel.
9. Then click **Create Workbench Project**.

   This lets you name a Workbench project containing the information in the setup. The Ansys Workbench will be launched with the connection to the Maxwell project established. To this connection, you can add a Design Xplorer Setup. See the documentation of Ansys Workbench for details on Design Xplorer.

26 - Getting Started with RMxprt

RMxprt™ (Rotating Machines expert) is a template-based electrical machine design tool that provides fast, analytical calculations of machine performance and 2-D and 3-D geometry creation for detailed finite element calculations in Ansys® Maxwell®.

Using RMxprt, you can simulate and analyze the following types of machines:

- Three-phase and single-phase induction motors.
- Three-phase synchronous machines.
- Brushless permanent-magnet DC motors.
- Adjust-speed synchronous motors and generators.
- Permanent-magnet DC motors.
- Switched reluctance motors.
- Line-start permanent-magnet synchronous motors.
- Universal motors.
- General DC machines.
- Claw-pole alternators.
- Three-Phase Non-Salient Synchronous Machine
- Generic Rotating Machine

When you start to design a new model in RMxprt, you first select one of the above motor or generator types. You then enter the parameters associated with that machine type in each RMxprt Properties window. The properties windows are accessed by clicking each of the machine elements (for example, stator, rotor, shaft) under **Machine** in the project tree. General options are available directly at the **Machine** level of the project tree. Solution and output options (such as the rated output power) are set when you add a solution setup (by right-clicking **Analysis** in the project tree).

Setting Up A Machine Model

Creating a New RMxprt Project

Specifying RMxprt Machine Data

Creating a Project and Inserting a New RMxprt Design

To create a new project:

1. Click **File>New**.

   A new project is listed in the project tree. It is named Project*n* by default, where *n* is the order in which the project was added to the current session.

Project definitions, such as material assignments, are stored under the project name in the project tree.

2. Click **Project>Insert RMxprt Design** or select **RMxprt** from the **Maxwell** pull-down menu on the **Desktop** ribbon.

   The **Select Machine Type** window appears.

3. Select the machine type you want, and click **OK**.

Specify the name of the project when you save it using the **File>Save** or **File>Save As** commands.

Opening Existing RMxprt Projects and Saving as New

You may also create new projects from existing ones, by saving them under new file names.

To create a new project from an existing one:

1. If you are already in the existing project, click **File>Save As**. The **Save As** window appears. (Otherwise, open the existing project you want to copy first.)
2. Enter a new name for the new project, and click **Save**.

The new project is now saved, with the same information as the existing project.

Opening RMxprt Projects

Open a previously saved project using the **File>Open** command.

1. Click **File**>**Open**.

   The **Open** dialog box appears.

2. Use the file browser to find the RMxprt version 6 project file.

   By default, files that can be opened or translated by RMxprt are displayed.

3. Select the file you want to open.
4. Click **OK**.

   The project information appears in the project tree.

Opening Recent RMxprt Projects

To open a project you recently saved:

- Click the name of the project file at the bottom of the **File** menu.

Saving RMxprt Projects

Use the **File>Save As** command to do the following:

- Save a new project.
- Save the active project with a different name or in a different location.

- Save the active project in another file format for use in another program.

Use the **File>Save** command to save the active project.

Saving RMxprt Project Data Automatically

RMxprt stores recent actions you performed on the active project in an Ansys Electronics Desktop auto-save file in case a sudden workstation crash or other unexpected problem occurs. The auto-save file is stored in the same directory as the project file and is named **Project*n*.aedt.auto** by default, where *n* is the order in which the project was added to the current session. Ansys Electronics Desktop automatically saves all data for the project to the auto-save file, except solution data. By default, Ansys Electronics Desktop automatically saves project data after every ten edits. An "edit" is any action you perform that changes data in the project or the design, including actions associated with project management, model creation, and solution analysis.

With auto-save activated, after a problem occurs, you can choose to re-open the original project file (**Project*n*.aedt**) in an effort to recover the solution data or to open the auto-save file.

To modify the auto-save settings:

1. Click **Tools>Options>General Options**.

   The **Options** dialog box appears.
2. In the **General>Desktop Configuration** panel, verify that **Do Autosave** is selected.

   This option is selected by default.
3. In the **Autosave interval** box, enter the number of *edits* that you want to occur between automatic saves. By default, this option is set at 10.

Note	Auto-save *always* increments forward; therefore, even when you undo a command, Ansys Electronics Desktop counts it as an edit.
4. Click **OK** to apply the specified auto-save settings.

   Once the specified number of edits is carried out, a "model-only" save occurs. This means that Ansys Electronics Desktop does not save solutions data or clear any undo/redo history.

   When Ansys Electronics Desktop auto-saves, an ".auto" extension is appended to the original project file name. For example, **Project1.aedt** will automatically be saved as **Projectn.aedt.auto**.

Warning	When you close or rename a project, Ansys Electronics Desktop deletes the auto-

	save file. Ansys Electronics Desktop assumes that you have saved any desired changes at this point.

Recovering Project Data in an Auto-Save File

Recovering RMxprt Project Data in an Auto-Save File

Following a sudden workstation crash or other unexpected problem, you can recover the project data in its auto-save file.

Warning	When you recover a project's auto-save file you *cannot* recover any solutions data; recovering an auto-save file means you will lose any solutions data that existed in the original project file.

To recover project data in an auto-save file, if Ansys Electronics Desktop containing an RMxprt design has unexpectedly crashed:

1. Launch Ansys Electronics Desktop from your desktop.
2. Click **File>Open**,.
3. Select the original Project*n*.aedt project file for which you want to recover its Project*n*.aedt.auto auto-save file.

   The **Crash Recovery** window appears, giving you the option to open the original project file or the auto-save file.
4. Select **Open project using autosave file** to recover project data in the auto-save file**, and then click OK.** Ansys Electronics Desktop replaces the original project file with the data in the auto-save file.

   Ansys Electronics Desktop immediately overwrites the original project file data with the auto-save file data, removing the results directory (solutions data) from the original project file as it overwrites to the auto-save file.

Warning	If you choose to recover the auto-save file, you cannot recover the original project file that has been overwritten; recovering data in an auto-save file is *not* reversible.

Saving Project Data Automatically

RMxprt Files

When you create any design in the Ansys Electronics Desktop, including an RMxprt design, it is given an **.aedt** file extension and stored in the directory you specify. Any files related to that project are also stored in that directory.

Some common file and folder types are listed below:

.aedt	Maxwell or RMxprt project.
*project_name.***aedtresults**	Folder containing results data for a project.
*design_name.***results**	Folder containing results data for a design. This folder is stored in the *project_name.***aedtresults folder.**
*design_name.***asol**	Results data for a design. This file's contents may be empty if a solution is unavailable. This file is stored in the *project_name.***aedtresults** folder.

Saving Project Notes in RMxprt

You can save notes about a project, such as its creation date and a description of the device being modeled. This is useful for keeping a running log on the project.

To add notes to a project:

1. Click **RMxprt**>**Edit Notes**.

   The **Design Notes** dialog box appears.
2. Click in the window and type your notes.
3. Click **OK** to save the notes with the current project.

To edit existing project notes:

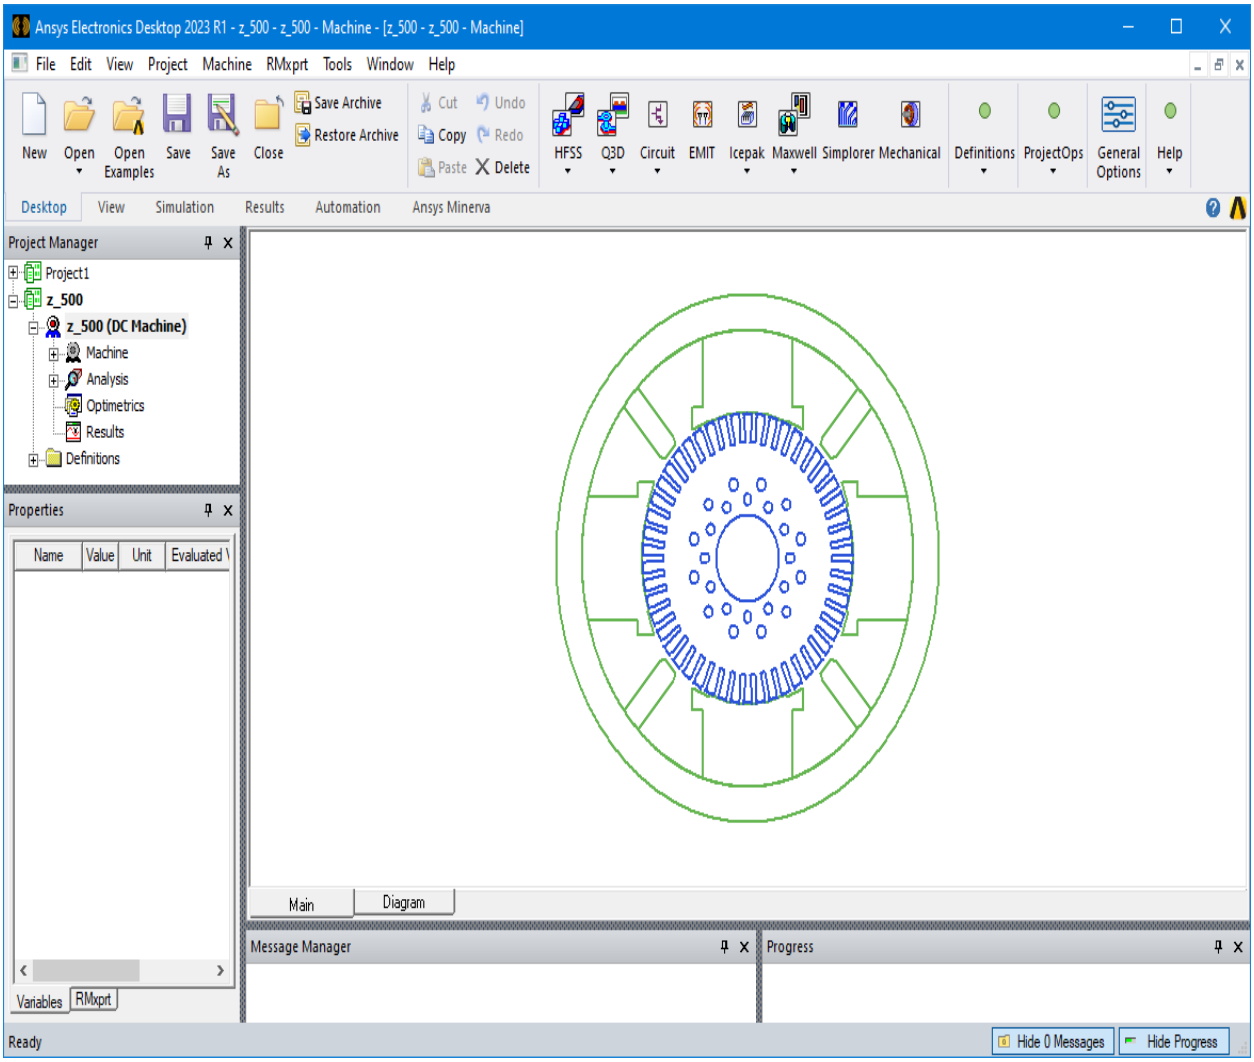
1. Double-click the **Notes** icon in the project tree.
   The **Design Notes** window appears, where you can edit the project's notes.
2. Click **OK** to save any changes, or click **Cancel** to exit without saving edits.

The RMxprt Desktop

RMxprt is integrated within the Maxwell desktop. Consistent with the Maxwell desktop, the RMxprt interface consists of several desktop components: a title bar, a menu bar, ribbons, a status bar, a project manager window, a properties window, a message manager window, a progress window, and a machine editor window. If user-defined rotor or stator slots are used in the design, a slot editor window also displays when a rotor or stator slot is selected in the project tree. The project manager window, the properties window, the message manager window and the progress window are dockable and resizeable.

You can open multiple machine editor windows to display different parts at the same time. One can remain fixed on the winding, one on the diagram, and one on the main desktop window. To open a new window, click **Window>New Window**.

To move back and forth between windows, select the window you want to view from the **Windows**.



RMxprt Title Bar

The title bar is located at the top of the application window. It displays the information of the active design. If a machine editor window is maximized, its title is appended in the title bar within square brackets. The information of the active design includes the desktop name, the project name, the design name and the design type. For an RMxprt design, the design type is **Machine**.

Working with the RMxprt Menu Bar

The menu bar enables you to perform all Maxwell, ePhysics, and/or RMxprt tasks, depending on the software you purchased. Such tasks include managing project files, customizing the desktop, drawing objects, and setting and modifying all project parameters.

RMxprt contains the following menus, which appear at the top of the desktop:

File menu	Use the **File** menu commands to manage RMxprt project files and printing options.
Edit menu	Use the **Edit** menu commands to modify properties in the active design, manage designs in one or more projects, delete projects, and undo and redo actions.
View menu	Use the **View** menu commands to display or hide desktop components, and change the machine editor window view.
Project menu	Use the **Project** menu commands to add a Maxwell 3D, Maxwell2D, or RMxprt design to the active project, analyze all designs of the active project, and define project variables and datasets.
Machine menu	Use the **Machine** menu to work with the machine data, such as edit winding layout, edit wire size, and set dimension unit for the active editor window.
RMxprt menu	Use the **RMxprt** menu commands to validate design input data, analyze designs, set up parameters, add analysis setups, set up Optimetrics, post process solutions, and other design tasks.
Tools menu	Use the **Tools** menu to modify the active project's material library, arrange the material libraries, run and record scripts, update project definitions from libraries, display options, and modify many of the software's default settings.
Window menu	Use the **Window** menu commands to rearrange the application windows.
Help menu	Use the **Help** menu commands to access the help system and view the current software version information.

Working with the RMxprt Shortcut Menus

A variety of shortcut menus — menus that appear when you right-click a selection — are available in the ribbons area of the desktop, in the **Machine Editor** window, in the **Project Manager** window, in the **Properties** window, and in the **Message Manager** window.

In Machine Editor window	Use the shortcut menu in the **Machine Editor** window to edit winding layout, display or hidden coil connection, change the view, and copy to Clipboard.
In the Slot Editor window	Use the shortcut menu in the **Slot Editor** window to insert, append, modify, and remove slot segments.
In the Project Manager window	Use the shortcut menus in the **Project Manager** window (or the project tree) to manage project files and design properties; these commands duplicate menu commands at the top of the screen.
In Properties window	Use the shortcut menus in the **Properties** window to edit (cut, copy, paste or delete) property values.

In Message Manager window	Use the shortcut menus in the **Message Manager** window to clear, copy message, or see message details.

Note	Most of the commands on the shortcut menus are also available on the menu bar.

Undoing RMxprt Commands

Use the **Undo** command on the **Edit** menu to cancel, or undo, the last action you performed on the active project or design.

1. In the **Project Manager** window, do one of the following:
   - To undo the last action you performed on the *active project*, such as inserting a design, click the project icon.
   - To undo the last action you performed on the *active design*, click the design icon.

Note	**You cannot undo an analysis that you have performed on a model, that is, the RMxprt>Analyze command.**

2. Click **Edit>Undo**.

   Your last action is now undone.

Note	When you save a project, RMxprt always clears the entire undo/redo history for the project and its designs.

Related Topics

Redoing Commands

Redoing RMxprt Commands

Use the **Redo** command on the **Edit** menu to reapply, or redo, the last action that was canceled, or undone. **You can redo a canceled action related to project management, model creation, and post-processing.**

1. In the **Project Manager** window, do one of the following:
   - To redo the last action you canceled on the *active project*, such as inserting a design or adding project variables, click the project icon.
   - To redo the last action you canceled on the *active design*, such as drawing an object or deleting a field overlay plot, click the design icon.
2. Click **Edit>Redo**.

   Your last canceled action is now reapplied.

Note	When you save a project, RMxprt always clears the entire undo/redo history for the project and its designs.

Related Topics

Undoing Commands

Working with the RMxprt Status Bar

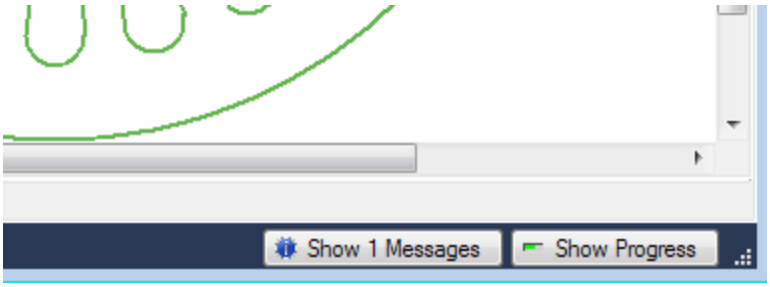
The status bar is located at the bottom of the application window. It displays information about the command currently being performed.

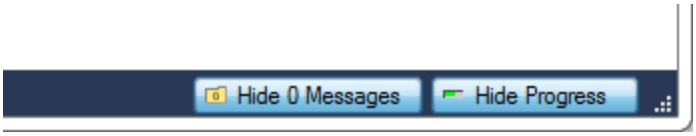
To display or hide the status bar:

- Click **View>StatusBar**.

  A check box appears next to this command if the status bar is visible.

  When visible, the status bar contains buttons to show or hide the message window and progress window.





Working with the RMxprt Machine Editor Windows

You can open multiple machine editor windows in RMxprt. One can remain fixed on the **Winding Editor**, one on the **Diagram** tab, and one on the **Main** tab. To open a new window, click **Window>New Window**. To move back and forth between windows, select the **Windows** menu, and select the window you want to view.

You can cascade all **Machine Editor** windows, tile them horizontally or vertically. You can maximize, minimize or close a **Machine Editor** window by clicking the relevant button on the right-top corner of the window. If no **Machine Editor** window is displayed, you can use **RMxprt>Machine Editor** to bring one window up. When only one **Machine Editor** window is maximized, the window title is displayed within square brackets in the **Title Bar** of the main application window.

As you enter appropriate property values, the **Machine Editor** window dynamically updates the rotor, stator, slots, and windings in the **Main**, **Diagram** and **Winding Editor** tabs. As you provide winding information, the **Winding Editor** tab displays a table of values.

Related Topics

Setting the Window View
Printing in RMxprt

Setting the Window View

To fit the entire diagram in the window:

- Click **View>Fit All**.

To zoom into the diagram in the window:

- Click **View>Zoom In**.

To zoom out of the diagram in the window:

- Click **View>Zoom Out**.

Printing in RMxprt

The printing commands enable you to print the display in the active window.

To print the project:

1. Click **File**>**Print**.
   The **Print** dialog box appears.
2. You can change the print quality (a higher dpi produces a higher quality print but takes more time and printer memory), or you can send the output to a **.prn** file.
3. Do one of the following:
   - Click **OK** to print the project.
   - Click **Cancel** to dismiss the window without printing.
   - Click **Properties** to define printer settings.

Working with the RMxprt Project Manager

The **Project Manager** window displays the open project's structure, which is referred to as the project tree. The **Project Manager** window displays details about all projects open in the Maxwell Desktop, regardless of type.

To show or hide the **Project Manager** window, do one of the following:

- Click **View>Project Manager**.
  A check box appears next to this command if the **Project Manager** window is visible.

Related Topics

Working with the RMxprt Project Tree
Shortcut Menus in the Project Manager Window
"Working with the Project Manager" on page 2-17

Working with the RMxprt Project Tree

The project tree is located in the **Project Manager** window and contains details about all open projects. The top node listed in the project tree is the project name. It is named Project*n* by default, where *n* is the order in which the project was added to the current session of the Maxwell Desktop. Expand the project icon to view all designs and material definitions belonging to the project. For RMxprt projects, the project tree shows where you can select each portion of the machine to open the corresponding tab sheet in the P**roperties** window. The project tree lists options for the general motor characteristics, the stator, the rotor, and other options such as winding data or commutating data. The specific options depend on the machine type you have selected.

Related Topics

Viewing RMxprt Design Details
Automatically Expand the Project Tree

Setting the RMxprt Project Tree to Expand Automatically

You can set the project tree to automatically expand when an item is added to a project.

1. Click **Tools>Options>General Options**.

   The **Options** dialog box appears.

2. Click the **Project Options** tab.
3. Under **Additional Options**, select **Expand Project Tree on Insert**.
4. Click **OK**.

Viewing RMxprt Design Details

Once you insert an RMxprt design into a project, it is listed as the second-level node in the project tree. It is named RMxprtDesign*n* by default, where *n* is the order in which the design was added to the project. Expand the design icon in the project tree to view specific data about the model.

The RMxprtDesign*n* node contains the following project details:

Machine	Allows you to specify parameters for various aspects of the machine. A whole or part geometry will be drawn in the **Main** tab of the **Machine Editor** window

	(based on the values you enter).
Analysis	Displays the solution setups for an RMxprt design. A solution setup specifies how RMxprt computes the solution.
Optimetrics	Displays any Optimetrics setups added to an RMxprt design.
Results	Displays any post-processing reports that have been generated.

Note	To edit a project's design details: • In the project tree, double-click the design setup icon that you want to edit. A dialog box appears with that setup's parameters, which you can then edit.

Working with the RMxprt Properties Window

The **Properties** window displays the attributes, or properties, of an item selected in the project tree and enables you to edit an item's properties. The properties, and the ability to edit them in the **Properties** window vary depending on the type of item selected. The tabs available in the **Properties** window also vary depending the selection.

Single clicking on an item in the Machine section of the project tree displays a docked **Properties** window located under the project tree. A horizontal scroll bar lets you adjust the view of the properties if necessary. Changes to values in the docked properties window apply immediately to the selected object.

Double-clicking on an item in the Machine section of the project tree opens a floating **Properties** window. The floating window can be moved for convenience in viewing the RMxprt **Machine Editor** window. Some objects have tabs on the window to control the properties displayed. Changes to values in the floating window are not applied until you click the **OK** button.

Related Topics

Showing and Hiding the Properties Window

Setting the Properties Window to Open Automatically

Showing and Hiding the RMxprt Properties Window

To show or hide the **Properties** window on the desktop:

- Click **View>Properties**.

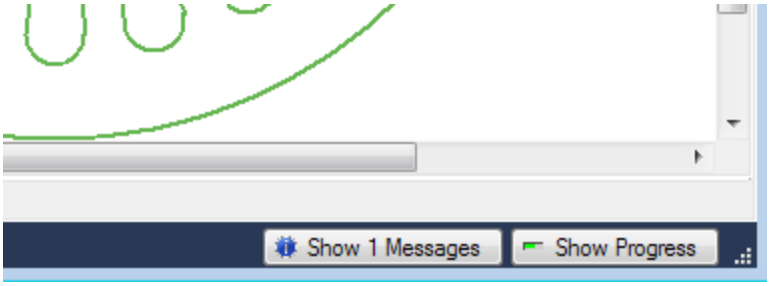
A check box appears next to this command if the **Properties** window is visible.

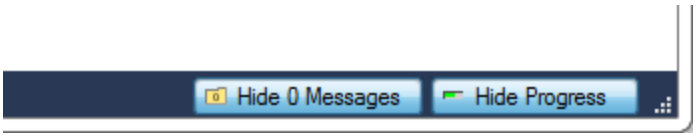
Working with the RMxprt Progress Window

The **Progress** window monitors a simulation while it is running.

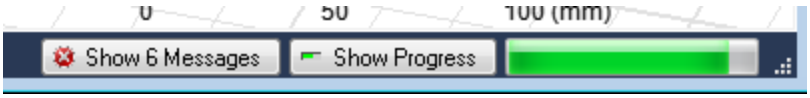
To display or hide the **Progress** window on the desktop, do one of the following:

- Click the **Show Progress** or **Hide Progress** buttons on the status bar:





When more than one progress bar is active, the top progress bar is represented on the status bar with a progress indicator.



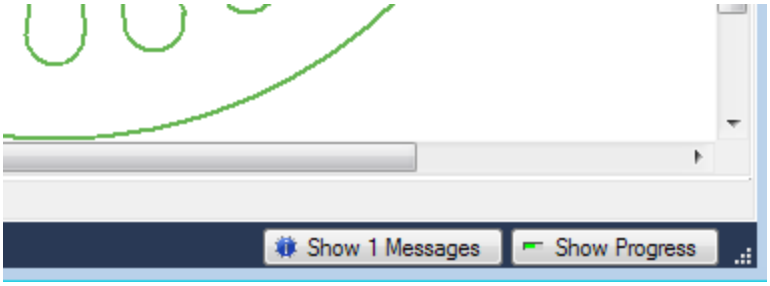
- Click **View>Progress Window**.
  A check box appears next to this command if the **Progress** window is visible.

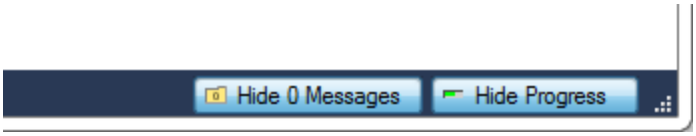
Working with the RMxprt Message Manager

The **Message Manager** displays messages associated with a project's development, such as error messages about the design's setup or informational messages about the progress of an analysis.

To display or hide the **Message Manager** window on the desktop, do one of the following:

- Click the **Show Messages** or **Hide Messages** buttons on the status bar:





- Click **View>Message Manager**.
  A check box appears next to this command if the **Message Manager** is visible.

   A pop-up appears.
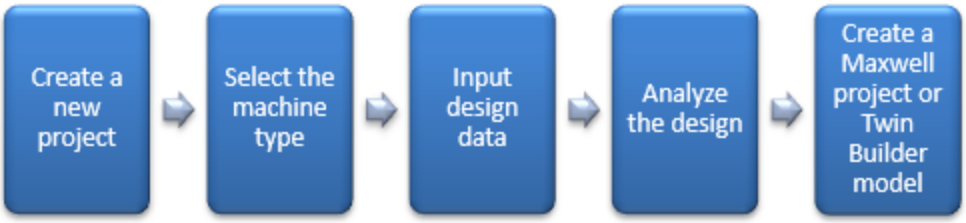
2. Click **Copy messages to clipboard**.

Quick Start for RMxprt

This section briefly introduces how to enter the environment of **RMxprt** and quickly master its main functions by providing a simple example.

The basic process flow chart is shown below.



RMxprt Example Part 1: Create a New Project

To open Ansys Electronics Desktop and create a new project:

1. Double-click the **Ansys Electronics Desktop** icon on your desktop to launch Ansys Electronics Desktop.

   You can also start Ansys Electronics Desktop by clicking **Start** > **All Programs** > **Ansys EM Suite** [version] >**Ansys Electronics Desktop** [version] from Windows.
2. Click **File>New** from the menu bar.

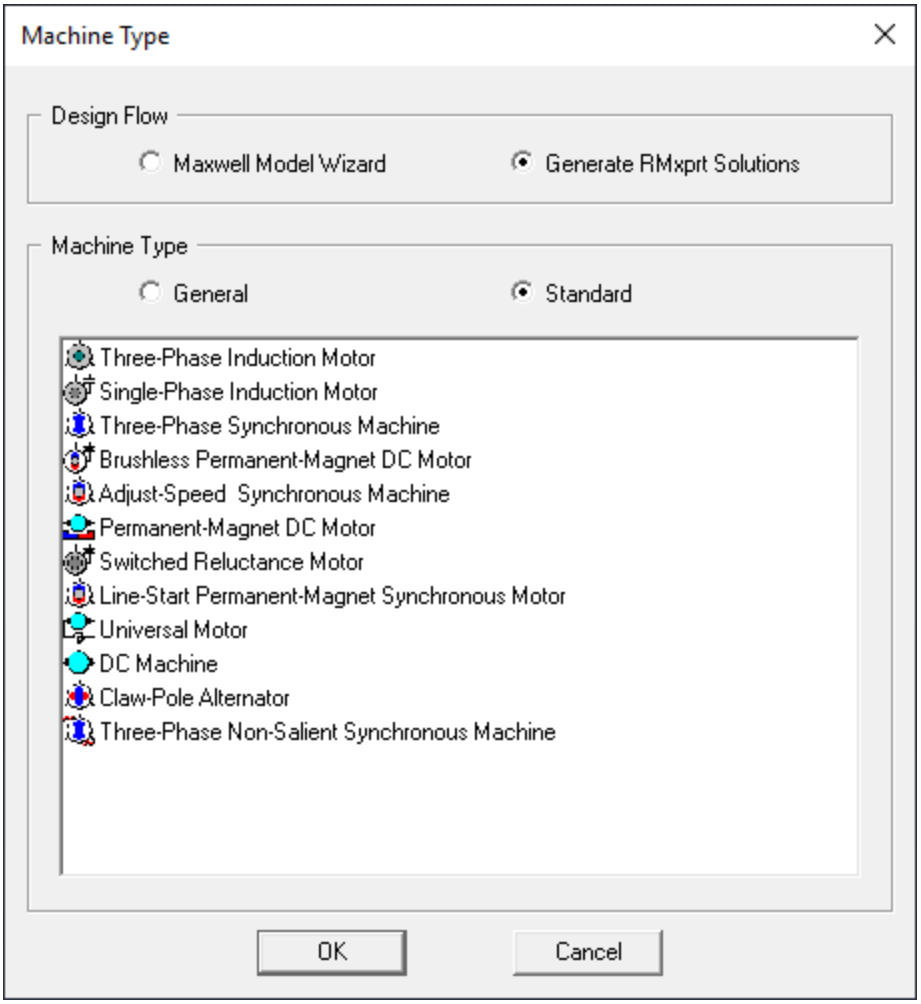
   This creates a new project folder in the project window with the default name of Project*n.*

RMxprt Example Part 2: Select a Machine

To select a machine to insert into the new project:

1. Click **Project>Insert RMxprt Design** or select the RMxprt icon on the Desktop ribbon.

   This displays the **Machine Type** window.



2. For the Design Flow, select the **Generate RMxprt Solutions** radio button; then select **Standard** for Machine Type.From the list of machine types, for this example, select **Brushless Permanent Magnet DC Motor** and click **OK**.

   This closes the window and inserts the Brushless Permanent Magnet DC Motor design in the project.

Continue to Part 3 of the example to Input Design Data.

RMxprt Example Part 3: Input Design Data

In this part of the example, you provide values for the design and for various parts.

1. Click the + symbol by the RMxprt:Design*n* icon in the project tree to view the design hierarchy.

   This displays the Machine Icon.

2. Double-click the icon to view the Machine Properties window.

   Set the values as indicated below.

Machine Type	Brushless Permanent Magnet DC Motor
Number of Poles	Set this to 4
Rotor Position	Set to Inner Rotor
Frictional Loss	Set this to 11 Watts (Frictional and windage loss is typically within the range of 1%~3% of the rated output power, in this example, 2% is estimated.) This value is referred to the given **Reference Speed**. The frictional loss at the computed rated speed will be modified if the computed rated speed is different from the given rated speed.
Windage Loss	0
Reference Speed	Set this to 1500 rpm
Control Type	DC
Circuit Type	Set this to C2. Click the button to display the Select Circuit Type window.  Select the C2 button, and OK to close the window.

3. Click OK to close the Machine properties window.
4. Click the + symbol by the Machine icon to view the design hierarchy of the motor.
5. Double-click the Circuit icon to view the Circuit properties window.

   Set the values as indicated below.

Lead Angle of Trigger	Set this to 0 degrees to obtain the maximum average emf for the following phase in the trigonal period.

	Trigger Pulse Width	Set this to 90 degrees
Transistor Drop	Set this to 2 Volts
Diode Drop	Set this to 2 Volts

6. Click OK to close the circuit properties window.
7. Double-click the Stator icon to view the Stator properties window.

   Set the values as shown below.

Outer Diameter	Set this to 120 mm.
Inner Diameter	Set this to 75 mm.
Length	Set this to 65 mm for the length of the Stator iron core.
Stacking Factor	0.95
Steel Type	Click on the button to display the **Materials** window. Select **RMxprt** library in the **Libraries** box in the upper right corner of the **Materials** window: then select **M19-24G** from the list.

	 Note: If RMxprt is not listed in the libraries box in the upper right corner of the Materials window, quit the Materials window, click **Tools>Configure Libraries**, add **RMxprt** (under materials) and click the **Save as Default** check box. Then click OK.
Number of Slots	Set this to 24.
Slot Type	Select 2 as the Slot type. Click the button on the row cell to display the Select Slot Type window.  Click the 2 button and OK to close the window.
Skew Width	Set this to 1. (To skew one slot pitch.)

8. Click **OK** to close the **Stator Properties** window.

Take a moment to look at the Maxwell Design window. If you click the **Main** tab, you will see two concentric rings that represent the inner and outer diameters you specified. If you click the **Winding Editor** tab, you see a table of the coils, with columns for **Phase**, **Turns**, the **In Slots**, and the **Out Slots**. There is also a drawing showing the placement of the 24 slots of the type that you defined here.

9. Click the + symbol by the **Stator** icon to view the hierarchy under the stator.
10. Click the slot icon to view the **Slot Properties** window.

    Set the values as shown below. Some of the properties will not appear until you disable the **Auto Design** property in the first row.

Auto Design	Uncheck the box to disable auto design. Close the properties window and open it again. Then set the given values for the slot shapes.
Parallel Tooth	Uncheck this box. The Tooth Width property becomes invisible.
Tooth Width	Invisible when Parallel Tooth is unchecked.
Hs0	Set to 0.5 mm
Hs1	Set to 1.0 mm
Hs2	Set to 8.2 mm
Bs0	Set to 2.5 mm
Bs1	Set to 5.6 mm
Bs2	Set to 7.6 mm

11. Click the stator **Winding** icon to view the winding **Properties** window.

    Set the values as shown below.

Winding tab	**Winding Layers**	Set this to 2.
	Winding Type	"Whole-Coiled."
	Parallel Branches	Enter 1 for the number of parallel-connected branches, i.e. the coils in all the slots per phase are in series-connected.
	Conductors per Slot	Set this to 60 for the number of conductors per slot, i.e. the number of turns per coil is equal to 30 for double-layer winding.
	Coil Pitch	Set this to 5. For this example, full pitch = 24 slots / 4 poles = 6. This example uses short coil pitch, *5*, i.e. a coil spans from slot 1 to slot 6.
	Number of Strands	Select *1* for the number of strands (or number of wires per conductor).
	Wire Wrap	Select *0*. This is the total thickness of double side wire insulation. The input value *0* means that **RMxprt** will automatically check into the wire gauge library for the wrap

		thickness relevant to the wire gauge. Different manufacturers produce different **Wire Wrap Thickness** for electromagnetic wire. Typically, **Wire Wrap Thickness** for electromagnetic wire is 7~10% of **Wire Diameter**.
	Wire Size	Click on the Properties field to display the Wire Size window and select *AUTO* for automatic design of wire **Gauge**. Wire Size will be set to 0 in the Wire Size window. This example relies on **RMxprt** to automatically select the optimum diameter and the gauge code for electromagnetic wire.
End/Insulation tab	**Input Half-turn Length**	Uncheck this box.
	Half Turn Length	This item is not shown if **Input Half Turn Length** is unchecked.
	End Extension (End Adjustment)	Set this to 0 mm for the linear overhang of the end part of the coil out of the iron core as shown below. In this example, the coil turns immediately at the slot opening, therefore input 0**.** 	Base Inner Radius	0
	Tip Inner Diameter	0
	End Clearance	0
	Slot Liner	Set this to 0.3 for the single side thickness of slot insulation.
	Wedge Thickness	0
	Layer Insulation	0
	Limited Fill Factor	0.75 (The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.)

13. Click **OK** to close the stator Winding Properties window.
14. Click **Machine>Winding>Connect All Coils** on the menu bar.
    The **Winding** tab in the main window shows all coils connected.
15. Double-click the Rotor Icon to view the **Rotor Properties** window.
    Set the values as shown below.

Outer Diameter	Set this to 74.0 mm. This is the Stator inner diameter - 2* AirGap.
Inner Diameter	Input 26 mm for the inner diameter of the rotor core. This is also the diameter to match the shaft.
Length	Input 65 mm for the length of the rotor core. In this example, the lengths of the iron cores of the stator and the rotor are the same.
Steel Type	Select M19-24G for the material of the silicon-steel sheet for the rotor. In this example, the laminations are punched together on the same sheet; therefore, the material of the silicon-steel sheet and the stacking factors are the same for the stator and the rotor.
Stacking Factor	Input 0.95.
Pole Type	Select 1. Click on the button on the Pole Type field to display the Select Pole Type window.  Click the 1 button and OK to close the window.

16. Click **OK** to close the Rotor Properties window.
17. Click the + symbol by the Rotor icon to open the project hierarchy under the rotor.
18. Double-click the Pole icon to view the Pole Properties window.
    Set the values as shown below.

Embrace	Input 0.7. **Embrace** of the rotor represents the ratio of the rotor central angle corresponding to the arc length along the rotor surface of an arched permanent-magnetic piece to the rotor central angle corresponding to a rotor pole. In a four

	pole machine with **Embrace**, 1, each arched permanent-magnetic piece covers 90 mechanical degrees along the rotor surface. Similarly, **Embrace** 0.667 means 60 mechanical degrees of the coverage of the magnet as shown in the figure. Offset	Input 0. The arched permanent-magnetic pieces to form the magnets of the rotor might not be concentric with the rotor as shown in the figure. In the electric machines with non-uniform air-gap, there exists an offset between the two centers. **RMxprt** terms it as **Pole Arc Offset**. This example uses uniform air-gap; therefore, the offset is set to *0*. Magnet	Select XG196/96. This permanent-magnetic steel possesses residual flux

Type	density 0.96 Tesla, coercive force 690 kA/m, maximum magnetic energy product 183 kJ/m^3, and relative recoil magnetic permeability 1.0.
Magnet Thickness	Input 3.5 mm for the thickness of the permanent-magnetic steel.

19. Click **OK** to close the Pole Properties window.

To continue to Part 4 of the example, go to Analyze the Design.

RMxprt Example Part 4: Analyze the Design.

Before analyzing a design project, a few options should be decided using the following procedures:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Machines** to show the following choice: **Wire Setting**.

   The System Libraries setting should be set to **American**.
2. Click **OK** to close the window.
3. Click **RMxprt>Analysis Setup>Add Solution Setup**.

   This displays the Solution Setup window. Add the following values.

Load Type	Const Power
Rated Output Power	550 W
Rated Voltage	220 V
Rated Speed	1500 rpm
Operating Temperature	75cel

4. Click **OK** to close the dialog to save the Setup.
5. Click **RMxprt>Validation Check** to ensure that all values have been set.

   If any items do not pass validation, use the diagnostic information in the Message Window to resolve any issues.
6. When the design has been validated, click **RMxprt>Analyze All**.

   The progress of the analysis is shown in the Progress window.

To continue to Part 5 of the example, go to Create Reports and View Output.

RMxprt Example Part 5: Create Reports and View Output

After you have run an analysis, you can view the solution data.

1. Click **RMxprt>Results>Solution Data**.

   This opens the **Solutions** window with the **Performance** tab selected, and the FEA Input Data displayed. The **Solutions** window contains tabs for the following:

   - **Performance** – the **Data** field in the **Performance** tab is a drop down menu from which you can select the following:
     - FEA Input Data
     - Full Load Operation
     - Material Consumption
     - No Load Operation
     - Permanent Magnet
     - Rotor Data
     - Stator Slot
     - Stator Winding
     - Steady State Parameters
   - **Design Sheet** – Shows the various design parameter values
   - **Curves** – Selecting the **Curves** tab lets you view predefined graphs.

2. On the **Performance**tab, select **Stator Winding** as the **Data** selection.

   Except for some data corresponding to the wire gauge, this data should be the same as the data input in the Stator Winding Properties window. Since automatic design function for the wire gauge is selected in the input, **RMxprt** calculates the following data:

Wire Diameter (mm):	*0.8118* for the diameter of the electromagnetic wire.
Wire Wrap (mm):	*0* for the insulation thickness of the electromagnetic wire. Because input wire wrap is *0*, RMxprt picks it up from the selected wire library (American wire), but it still *0* based on the wire wrap data in the library.
Stator Slot Fill Factor (%):	*61.6599*.

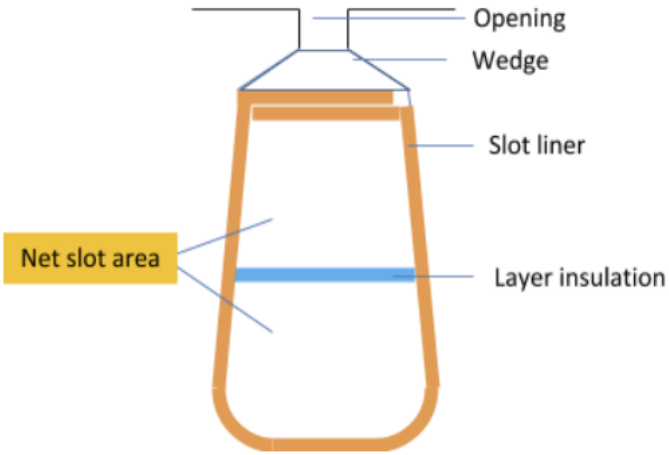
   The electromagnetic wire with **Wire Diameter** of *0.8118* is equivalent to AWG 20. **Stator Slot Fill Factor** represents the percentage of occupation of the slot area, i.e. the ratio of the total square sectional area of wires (including Wire Wrap thickness) in a slot to the total slot area less the slot insulation.

   The slot fill factor is defined as:

$$F_{SF} = \frac{n \cdot d^2}{S_{net}}$$

where:

- n is the total number of wires per slot (the number of conductors per slot times the number of wires per conductor),
- d^2 is the square area of a wire with d being the wire diameter including wire insulation, and
- S_{net} is the net slot area which is obtained from the gross slot area minus opening area, wedge area, liner area, and layer insulation area, as shown below:



a. Now that the **Wire Diameter** of the electromagnetic wire has been calculated by **RMxprt**, you can open the **Winding Properties** window and specify the value.
b. For **Wire Size,** open the Wire Size selection window, select *0.8118* for the electromagnetic wire diameter, which corresponds to *20* for the wire gauge.
c. In the slot **Wire Wrap** field, input *0.08* for the insulation thickness of the electromagnetic wire.
d. Click **OK** to close the properties window.
e. Click **RMxprt>Analyze All**.

   After the second analysis is completed, click **RMxprt>Results>Solution Data** to view the effect of **Wire Wrap Thickness** of the electromagnetic wire on **Stator Slot Fill Factor**.

Wire Diameter (mm):	*0.8118*.
Wire Wrap Thickness (mm):	*0.08*.
Stator Slot Fill Factor (%):	*75.6182*.

3. In the **Solutions** window, change the Data selection to **Rotor Data**.

   The Rotor data is displayed.

   Here most of the data is the same as input in the **Rotor Pole** properties window. The only difference is that the **Pole Arc Radius** replaces **Pole Arc Offset** and, in addition to **MechanicalPole Embrace** which is input based on the physical geometry, **Electrical Pole Embrace** is also given. **Electrical Pole Embrace** is calculated by the ratio of the average

magnetic flux density to the maximum magnetic flux density according to the magnetic flux density distribution along the air-gap.

4. In the **Solutions** window, change the Data selection to **Permanent Magnet**.

   This part displays the characteristic data of the permanent magnets as well as the **Demagnetized Flux Density**, the **Recoil Residual Flux Density**, and the **Recoil Coercive Force** of the recoil line based on the demagnetization flux density, which are used for finite element analysis when a linear PM characteristics must be specified.

5. In the **Solutions** window, change the Data selection to **Steady State Parameters**.

   This part displays the **Stator Winding Factor**, direct- and the quadratic-axis inductances, the **Armature Leakage Inductance**, the **Armature Phase Resistance** of the phase winding, the direct- and the quadratic-axis time constants, the ideal **Start Torque Constant** K_T and the **Ideal Back EMF Constant** K_E.

6. In the **Solutions** window, change the Data selection to **No-Load Operation**.

   This part displays the magnetic flux densities in the teeth and the yoke of the stator, and the yoke of the rotor. The maximum value among the three magnetic flux densities is *1.59* Tesla, which locates at the knee part of the B-H curve, below the saturation situation.

   The mmfs of the teeth and the yoke of the stator, the air-gap, the yoke and the permanent magnet of the rotor are given respectively for half magnetic reluctance path.

   The armature reaction mmf due to the armature current is referred to the demagnetization mmf. The magnetic flux leakage coefficient takes into account the part of the magnetic flux in the rotor not linking with the stator. The correction factors for the yoke lengths of the stator and the rotor to calculate the yoke mmfs of the stator and the rotor are also given here.

   The no-load revolution speed of this machine is approximately *1946* rpm.

7. In the Solutions window, change the Data selection to **Full Load Operation**.

   At **Rated Output Power (kW):***0.550*, the following characteristic parameters of the machine are calculated as:

Parameters	Calculated Values	Units
Average Input Current	*2.93*	A
(of input current waveform in one voltage period)		
RMS Armature Current	*2.45*	A
(of phase current waveform in one voltage period)		
Armature Thermal Load	*70.88*	A^2/mm^3
(product of **Specific Electric Loading** and **Armature Current Density**		)
Specific Electric Load	*14.71*	A/mm
(stator current distribution per circumferential length along air-gap)		

Armature Current Density	*4.65*	A/mm^2
(through cross-sectional area of stator wire)		
Frictional and Wind Loss	*11.42*	W
(at computed **Rated Speed**)		
Iron-Core Loss	*20.02*	W
(due to loss curves of stator and rotor iron-core materials)		
Armature Copper Loss	*47.92*	W
(stator winding ohmic loss)		
Transistor Loss	*9.14*	W
(transistor switching loss)		
Diode Loss	*0.60*	W
(diode power consumption)		
Total Loss	*89.1*	W
(sum of above losses)		
Output Power	*550*	W
(the rated operating point is derived based on **Output Power**)		
Input Power	*639.2*	W
(product of **Rated Voltage** and **Average Input Current**)		
Efficiency	*86.1*	%
(ratio of **Output Power** to **Input Power**)		
Rated Speed	*1557*	rpm
(at **Rated Output Power**)		
Rated Torque	*3.37*	Nm
(at **Rated Output Power**)		
Locked-Rotor Torque	*32.3*	Nm
(starting torque at zero revolution speed)		
Locked-Rotor Current	*52.1*	A
(starting current at zero revolution speed)		

8. In the **Solutions** window, select the **Design Sheet** tab, and scroll down to **Winding Arrangement**.

   This is the layout and the arrangement of the whole two-phase winding of phases A and B, and the short coil pitch factor *5* is taken into account. The 2-phase, 2-layer winding can be arranged in 6 slots as below:

AAABBB

Angle per slot (elec. degrees):	30
Phase-A axis (elec. degrees):	105
First slot center (elec. degrees):	0

9. In the **Solutions** window with the Design Sheet tab selected, scroll down to Transient FEA Input Data. (This is at the very bottom.)

   The following data of the armature winding corresponds to one phase armature winding.

Number of Turns	*360*	
(total number of turns viewed into output terminals)		
Parallel Branches	*1*	
Terminal Resistance	*4.13*	Ohm
(stator winding dc resistance under given operating temperature, 75^{o}C)		
End Leakage Inductance	*1.3*	mH
(of stator winding)		

   The following data is the equivalent values used to 2D electromagnetic field analyses.

Equivalent Model Depth	*65*	mm
Equivalent Stator Stacking Factor	*0.95*	
Equivalent Rotor Stacking Factor	*0.95*	
Equivalent B_r (residual flux density)	*0.87*	Tesla
Equivalent H_c (coercive force)	*690*	kA/m

10. In the **Solutions** window, click the **Curves** tab.

    This displays the Input DC Current Versus Speed graph. If the text is too small to read, you can resize the window. You can view other predefined graphs by selecting from the drop down menu in the Name field.

    Selecting the Curves tab lets you view predefined graphs for the following relations:

    - Input DC Current vs Speed
    - Efficiency vs Speed
    - Ratio of air-gap torque to DC current vs Speed
    - Output Power vs Speed
    - Output Torque vs Speed
    - Cogging Torque in Two Teeth
    - Induced Coil Voltages at Rated Speed

- Air-Gap Flux Density
- Induced Winding Phase Voltage at Rated Speed
- Winding Currents Under Load
- Phase Voltage Under Load

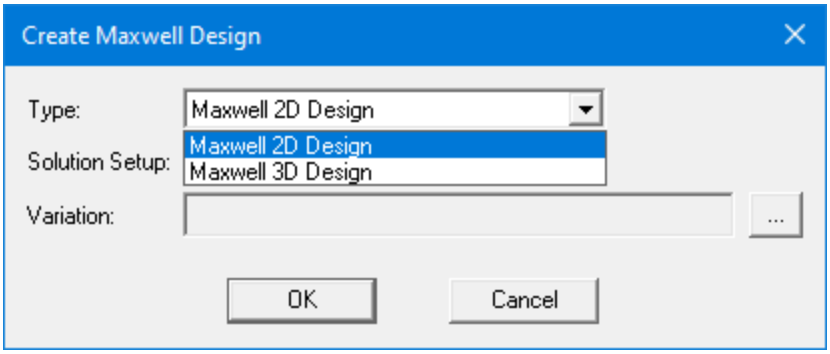
You can also create additional plots with multiple curves.

11. For example, click **RMxprt>Results>Create RMxprt Report>Rectangular Plot**.
    This displays the **Report** dialog box.
12. In the **Traces** tab, for the **Current** category, select **InputDCCurrent**, and click the **New Report** button to generate the report.
13. Then for the **Torque** category select **Output Torque** and click **Add Trace** to add the trace to the report. Click **Close** to close the **Report** window and display the combined graph.

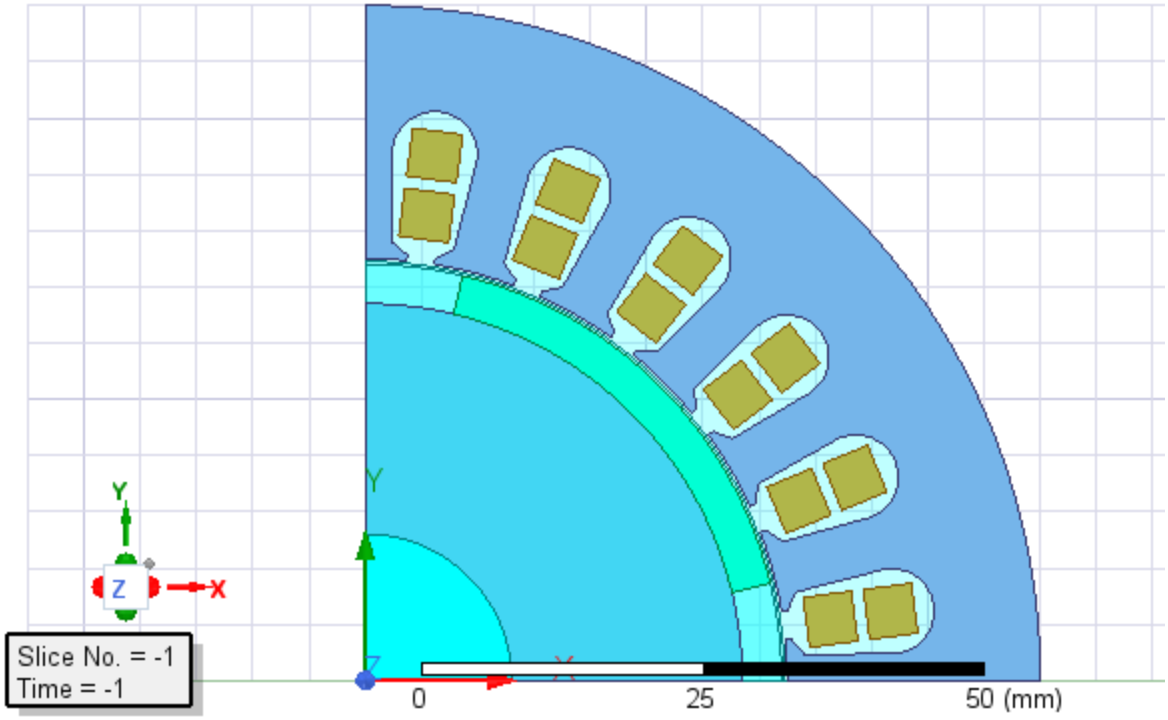
To continue to part Six of the example, go to Output Design Data.

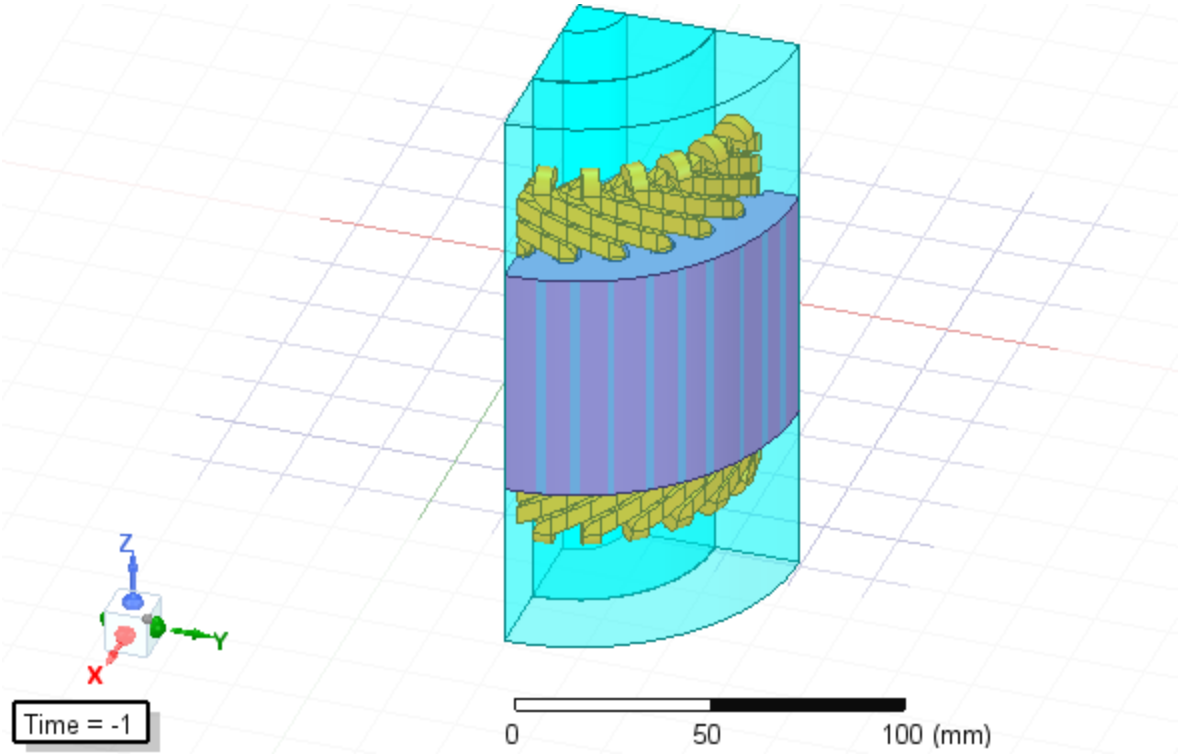
RMxprt Example Part 6: Output Design Data for Further Analysis

To analyze the model further: click **RMxprt>Analysis Setup>Create Maxwell Design**.



In the example design there is only one **Solution Setup** and no design **Variation**. For **Type** choose to create either a **Maxwell 2D Design**, or a **Maxwell 3D Design**. Click **OK** to create the Maxwell design. Examples of the resulting 2D and 3D designs are shown below.





Note	You can also export the model to a Simplorer model, a MotorCAD™project, or

	Customized Design Sheet.

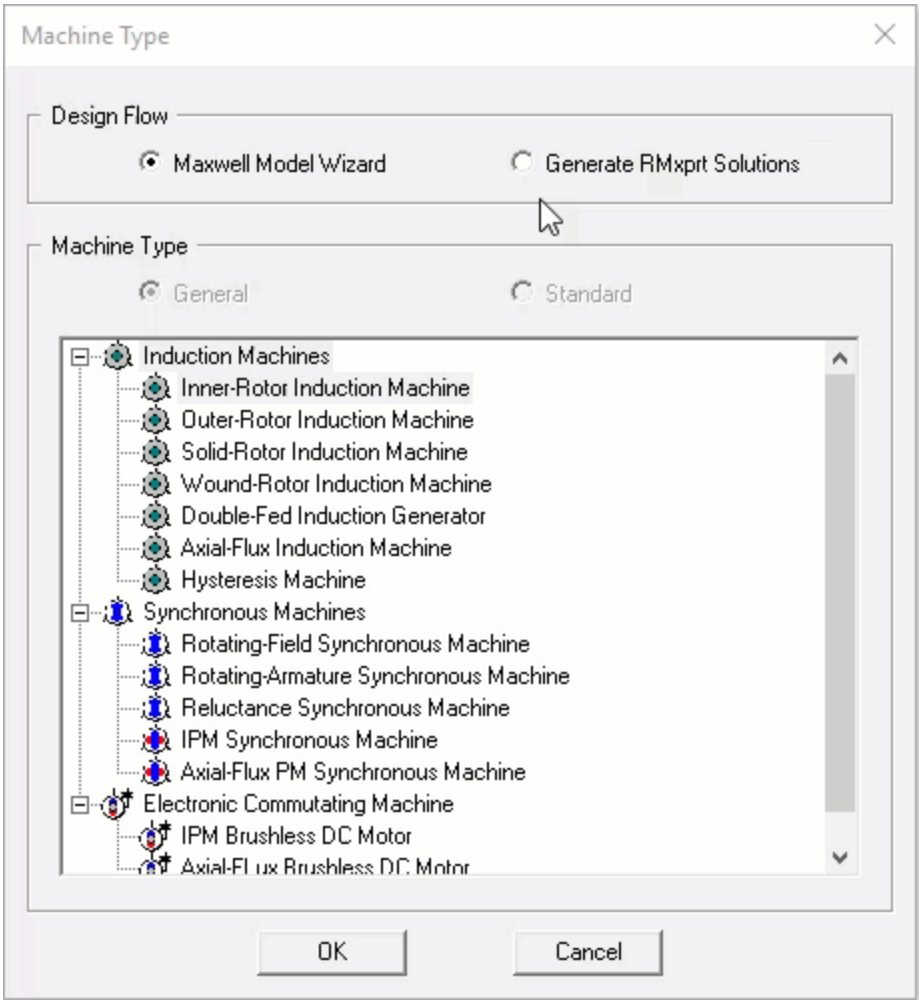
Setting Up RMxprt Projects

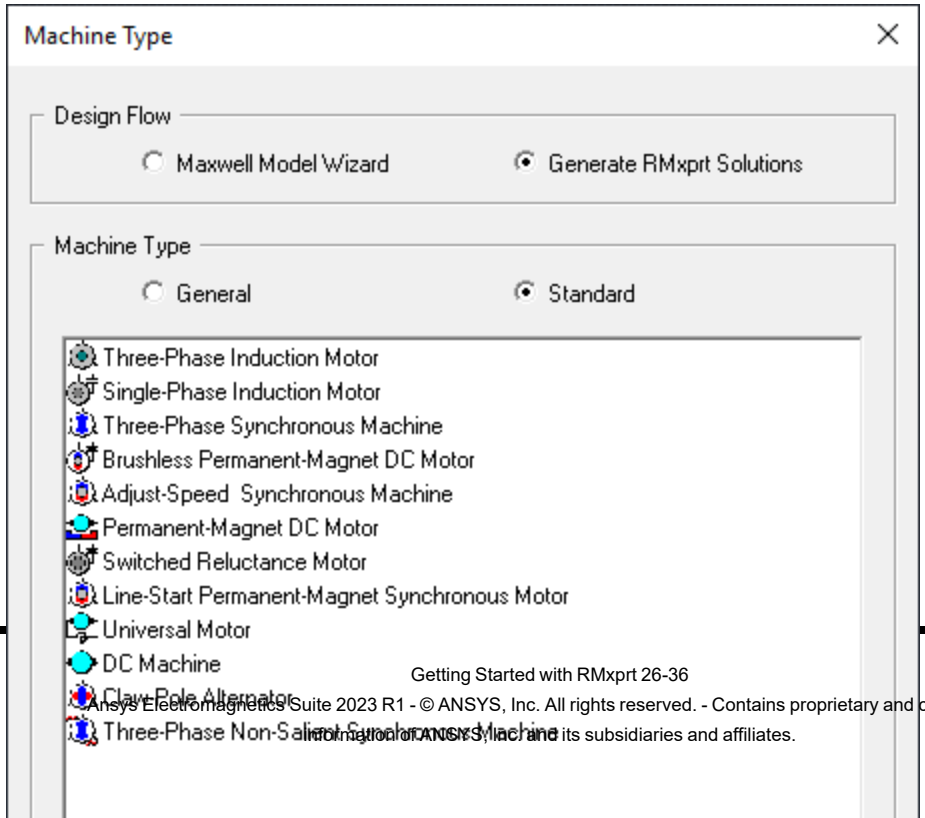
An RMxprt project is a folder that includes one or more models, or *designs*. Each design ultimately includes a geometric model, material assignments, and field solution and post-processing information.

A new project called *Projectn* is automatically created when the software is launched, where *n* is a number. You can also open a new project by clicking **File>New**. In general, use the **File** menu commands to manage projects. If you move or change the names of files without using these commands, the software may not be able to find information necessary to solve the model.

To insert an RMxprt design:

1. Choose the desired **Design Flow** option. You can select either **Maxwell Model Wizard** or **Generate RMxprt Solutions**. If **Maxwell Model Wizard** is selected, you can create an RMxprt design aimed for Maxwell design creation only. You can import your own stator and rotor geometry, with or without material assignment. If **Generate RMxprt Solutions** is selected, you can select either **General** for various pre-defined generic rotating machine types, or **Standard** for other pre-defined machine types.





2. Right-click on the design tree machine item, or pull down the RMxprt main menu, and click on **Machine Type** to open the **Machine Type<*project_name*> - <*design_name*>** dialog box.

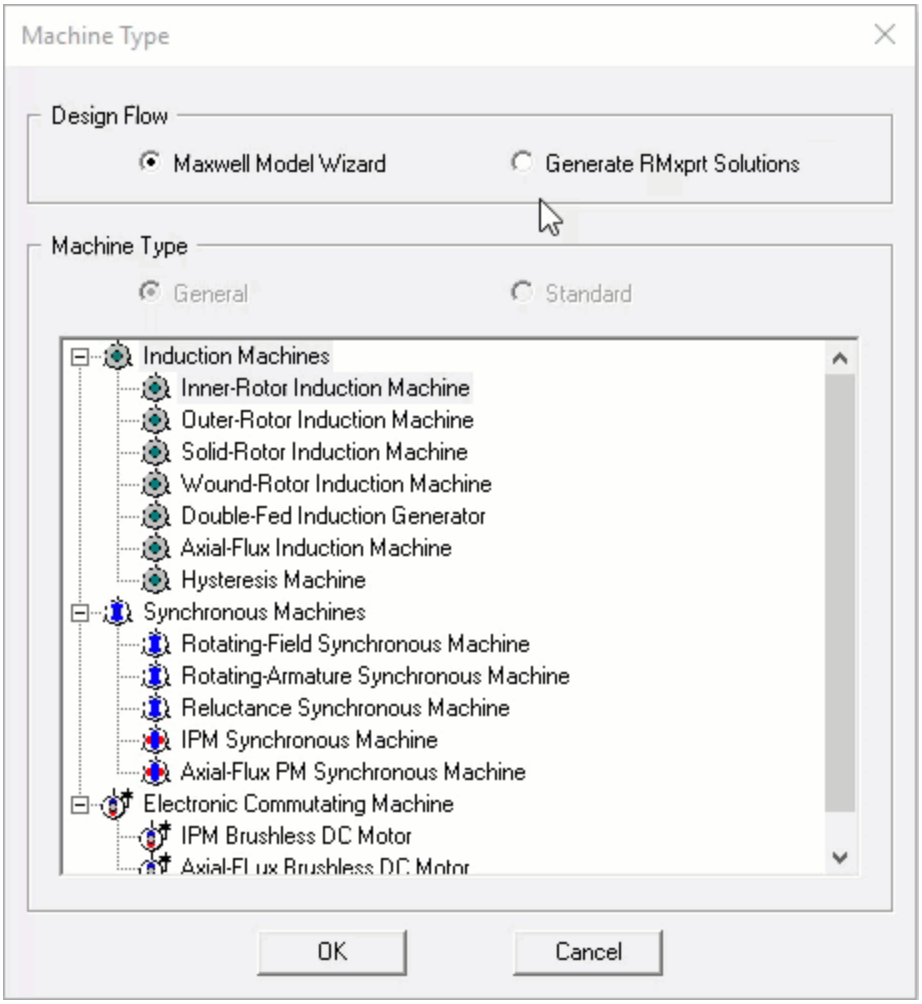
Note	The design flow cannot be changed once it's set, however the machine type can be changed for **Generate RMxprt solutions**.

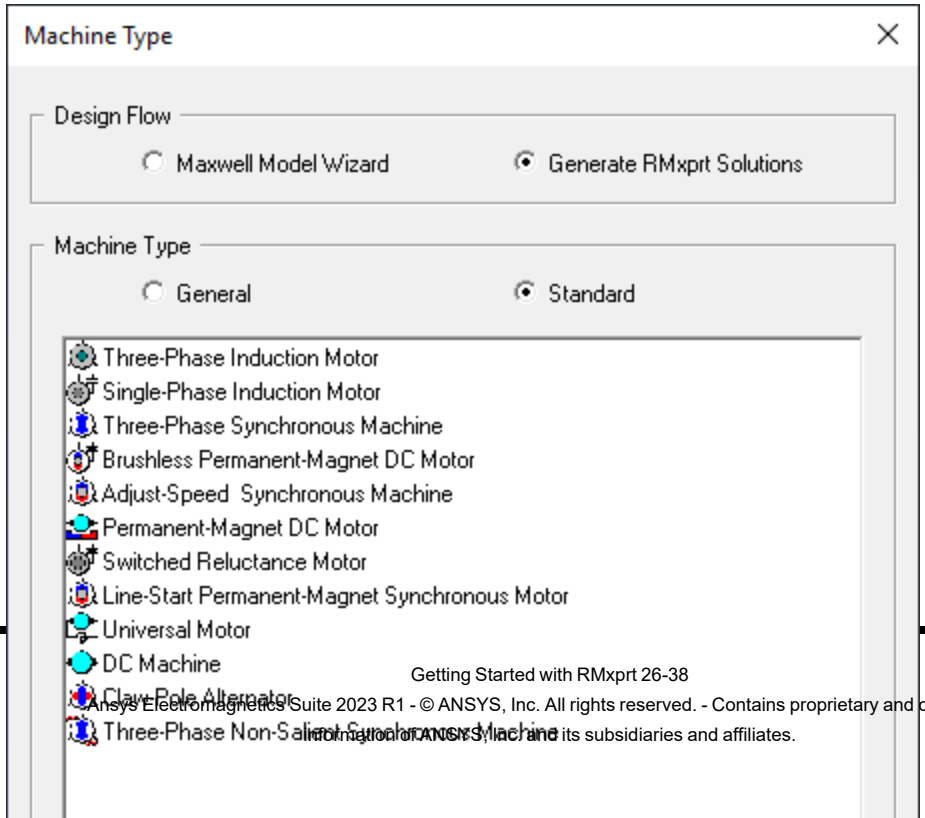
Setting Up A Machine Model

To set up an RMxprt model, follow this general procedure:

1. Insert an RMxprt design. (Click **Project>Insert RMxprt Design**, and specify the machine type from the **Machine Type** window.) For the **Design Flow**, choose either **Maxwell Model Wizard** and select a **Machine Type**; or **Generate RMxprt Solutions**.

   Generate RMxprt Solutions enables the **General** and **Standard** radio buttons. **General** allows you to pick the desired **Generic Rotating Machine** (**GRM**) machine type from the expandable list. **Standard** changes the listing to the basic RMxprt machine templates.





2. Use the **Tools** menu commands to specify general options (such as post-processing and auto-save settings), solver options (such as the default process priority), and specific RMxprt options. Also specify the Machine options (such as the units and the wire setting such as the wire shape and gauge).
3. Double-click the Machine items in the project tree, to specify the settings for the various parts of the selected machine parameters.
4. Under Definitions in the project tree, assign any Materials to the machine parts, setting values such as:
   - Permanent magnet definition, including the coercivity, energy density, and relative recovery permeability.
   - BH-curve parameters.
5. Use the **Setup** commands (either on the RMxprt menu or on the Analysis or Optimetrics submenus via the project tree) to specify variable, parametric, and optimization settings.
6. Use the Validate command to validate the design.
7. Use the Analyze commands to generate a solution, run a parametric analysis, or run an optimization.
8. Use the Results post-processing commands to display the lamination and plot the solutions.

Specifying RMxprt Winding Data

Quick Start for RMxprt

Maxwell Model Wizard

For Maxwell Model Wizard design flow, specify the imported geometry (if any) information through the **Machine** property window to let RMxprt know what parts and attributes to generate in the Maxwell design. Then, click **Create Maxwell Design** in the analysis setup menu to create a new Maxwell design.

You can also change machine type, and design flow in **Maxwell Model Wizard**.

Use the **Machine** property window to describe the general properties and geometry import information of the machine model to be created. It consists of the following:

Name	Description
Source Type	AC or DC source to deliver electrical power
Inner Rotor	Inner rotor, outer rotor, or axial-flux rotor
Use Minimum Setting	Hide input settings not needed for basic Maxwell model creation. Use this option to simplify the RMxprt design process to create the Maxwell model (design).
Import Option	Import geometry or Maxwell design (for geometry with material assignment).

	None: Will not import external geometry file for stator/rotor. **Geometry only**: An external geometry file needs to be imported to the design. Supports third party geometry file as well as Maxwell design(.aedt). RMxprt will add material assignments as well as other Maxwell design setups. **Maxwell design**: Only supports import of Maxwell design. The material of geometry will be retained. RMxprt will not add or change material assignments of the imported geometry.
Core Type	The stator/rotor core type
Core Alignment	Use this option to determine the alignment position of core center. Used for RMxprt to calculate the positions of stator/rotor parts, such as magnets, windings, etc. **Pole or tooth center aligned with x-axis**: When the pole center or tooth center of user's geometry is aligned with x-axis, user should choose this option. **Inter-pole or slot center aligned with x-axis**: When the inter-pole or slot center of user's geometry is aligned with x-axis, user should choose this option. Otherwise, adjust the geometry and then choose either option to prevent incorrect Maxwell design geometry generation.
Import Geometry	The geometry file to be imported. **Note** The imported geometry must be the same dimension as the specified Geometry Mode.
Geometry Mode	Specify the geometry dimension (**2D** or **3D**) so that RMxprt can create other geometry parts of same dimension.
Import Alignment	This option will only be available when fractions value is greater than 1. **Geometry center on x-axis**: When the fraction center is aligned with x-axis, choose this option to let RMxprt know the import alignment. **Independent boundary on x-axis**: When edge (or independent boundary) is aligned with x-axis, choose this option to let RMxprt know the import alignment. Otherwise, adjust the geometry and then choose either option to prevent incorrect Maxwell geometry generation.
Import Fractions	Number of fractions of the import geometry. When the value of **Import Fractions** is 1, the created geometry will have the same fractions as the traditional design without importing cores; when the value of **Import Fractions** is greater than 1, the created geometry will have the same fractions as the Import Fractions.
Z Axis Fractions	Only used when geometry mode is 3D.

	Whole: The center of the geometry model is located at the center of the coordinate and symmetric along x-y plane. **Half**: The geometry only includes half of the motor machine. All parts of the geometry model are located at the positive z axis.
View/Edit Geometry Model	Click this button to load the geometry to be imported and view/edit the content of the geometry.

The following table shows the design settings under different import combinations:

	Import geometry stator core only	Import geometry stator core with material assignments (Maxwell design)	No stator core import
Import geometry rotor core only	Rotor: material assignments and other rotor parts. Stator: material assignments and other stator parts.	Rotor: material assignments and other rotor parts. Stator: other stator parts.	Rotor: material assignments and other rotor parts. Stator: stator core with material assignments and other stator parts.
Import geometry rotor core with material assignments (Maxwell design)	Rotor: other rotor parts. Stator: material assignments and other stator parts.	Rotor: other rotor parts. Stator: material assignments and other stator parts.	Rotor: other rotor parts. Stator: stator core with material assignments and other stator parts.
No rotor core import	Rotor: rotor core with material assignments and other rotor parts. Stator: material assignments and other stator parts.	Rotor: rotor core with material assignments and other rotor parts. Stator: other stator parts.	Rotor: rotor core with material assignments and other rotor parts. Stator: stator core with material assignments and other stator parts.

RMxprt Machine Types
Creating Maxwell Model

Creating Maxwell Model

To generate a Maxwell model:

1. Create or select a solution setup in the project tree.
2. Right-click, and select **Create Maxwell Design** if there is any imported geometry. The geometry mode (2D or 3D) of generated Maxwell design will depend on the your **Geometry Mode** entered in the Machine properties. A Maxwell geometry model is created.
3. If there is no imported geometry, you can select either **Create Maxwell 2D Design** or **Create Maxwell 3D Design** to specify the desired geometry mode to be created.

Changing the Machine Type

RMxprt allows you to change the machine type for an existing design. The original machine data which applies to the new machine type is not retained. Instead, the initial default data for the new machine type is used.

To change the machine type for an existing model:

1. Right-click on the design tree machine item, or pull down the RMxprt main menu, and click on **Machine Type** to open the **Machine Type<*project_name*> - <*design_name*>** dialog box.
2. Choose the desired new machine type and click the **OK** button.
   - The design's machine type label is changed to that of the new machine type. For example, if the original design name and type was **3hp (Single Phase Induction Motor)**, and you change the machine type to a Switched Reluctance Motor, the design name would be **3hp (Switched Reluctance Motor)**. You can **Undo/Redo** the machine type change if you wish to revert to the original machine type and vice-versa.
   - The design tree items (such as the Machine Rotor, Stator, and Shaft data) under the design type will be updated with the default machine data applicable to the new machine type.

RMxprt Machine Types
Maxwell Model Wizard

SetMachineType

Use: Modifies an existing machine type.

Command: **RMxprt>Machine Type** or right-click on a machine model in the Project Manager and select **Machine Type** on the context menu.

Syntax: SetMachineType <MachineType>

Return Value: None

Parameters: <MachineType>

Type: <string>

The desired machine type.

Possible values are: “ASSM”, “BLDC”, “CPSM”, “DCM”, “GRM”, “LSSM”, “PMDC”, “SPIM”, “SRM”, “TPIM”, “NSSM”, “TPSM”, “UNIM”.

representing respectively:

Adjust-Speed Synchronous Machine, Brushless Permanent-Magnet DC Motor, Claw-pole Synchronous Machine, DC Machine, Generic Rotating Machine, Line-Start Permanent-Magnet Synchronous Motor, Permanent-Magnet Synchronous Generator, Single-Phase Induction Motor, Switched Reluctance Motor, Three-Phase Induction Motor", Non-Salient Synchronous Machine, Three-Phase Synchronous Machine, Universal Motor

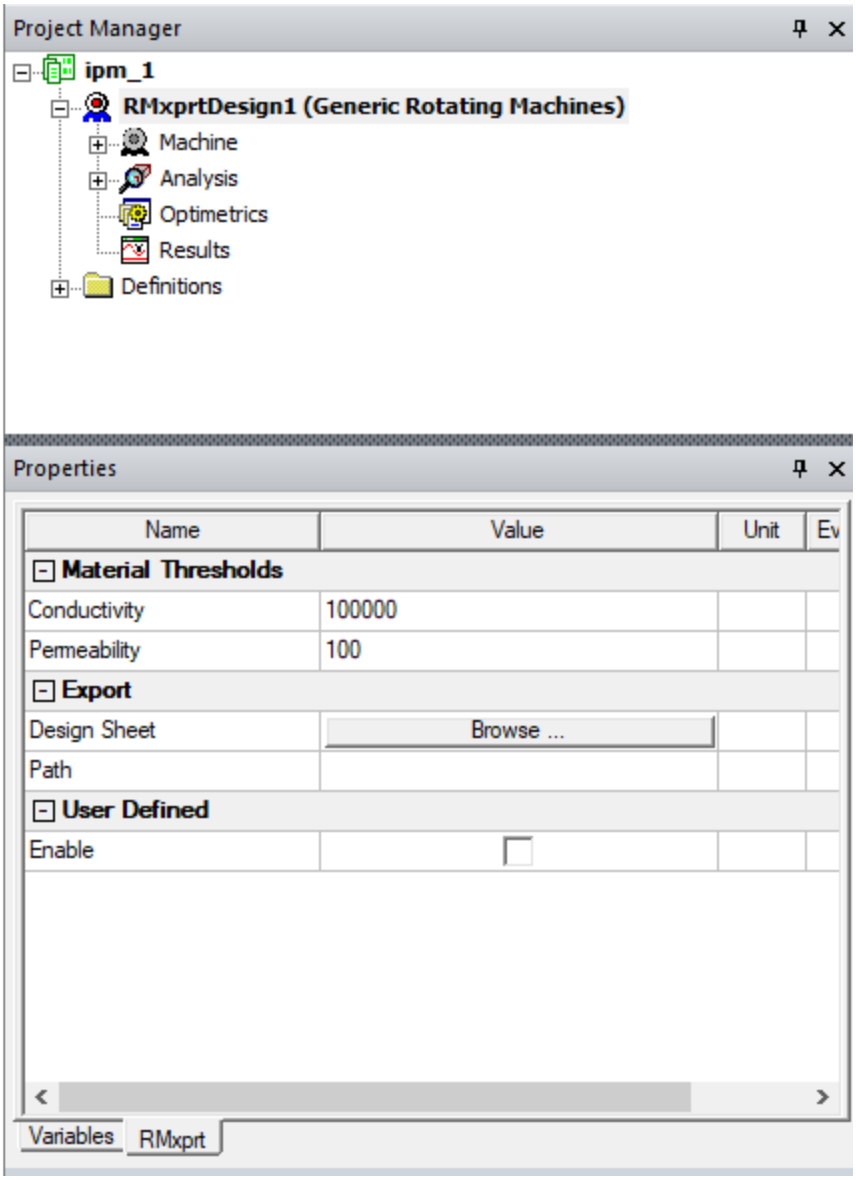
Example: SetMachineType “ASSM”

Design Settings in RMxprt

The Design Settings dialog allows you to specify how the simulator will deal with some aspects of the design.

- Set the Material Threshold for treating materials as conductors/insulators.
- Set Export Options.
- Specify User Defined Data.

You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.



Setting the Material Threshold in RMxprt

1. Click **RMxprt>Design Settings.**
   The **Design Settings** dialog box appears with the **Material Threshold** tab selected. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Type a value in the **Conductivity Threshold** text box (Default=10,000).
3. Type a value in the **Permeability** text box (Default=100).

Note	RMxprt will treat materials with conductivity greater than 10,000 as conductors, and materials with Permeability greater than 100 as steels.

4. If you want these values to be the default, change the values by clicking the **Tools>Options>General Options** menu and setting the material thresholds in the **RMxprt>Threshold** panel.
5. Click **OK**.

Related Topics

Setting RMxprt Options

RMxprt Export Options

To set export options for the project:

1. Click **RMxprt>Design Settings**.

   The **Design Settings** dialog box appears. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. For the **Design Sheet**, type a file name in the **Excel Template** text box.
   - You can also click the **...** button to find and select a file.
3. Click **OK**.

Generating a Custom Design Sheet for RMxprt

Setting User-Defined Data for a Design

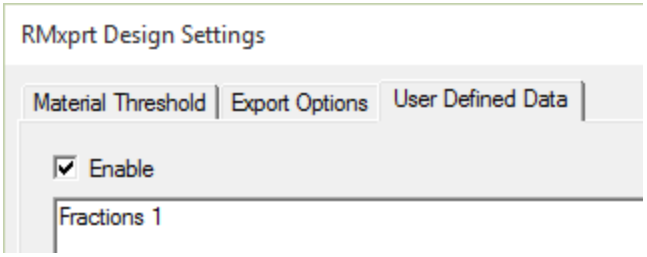
RMxprt allows a user to define some design data in a text file which can be created by a text editor, instead of by RMxprt UI, for the following special circumstances:

- Some special requests from a user which are not necessary to be added to RMxprt UI;
- Some common requests from users which have been implemented in RMxprt solver, but have not been added in RMxprt UI.
- Specifying various calibration factors.
- Specifying Data Based on Design Template Files.

When a user's requests have been implemented in an RMxprt solver but have not been added in the RMxprt UI, the updated solver and the required file format for user defined data will be sent to the user. To use the user defined data feature, the user must first edit the data file using a text editor according to the format provided. Then, select **RMxprt>Design Settings** to display the Design Settings dialog box. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

1. Select the **User Defined Data** tab.
2. Click the **Enable** check box to enable the use of **User Defined Data**.

3. User defined data may be entered directly into the text box. Click in the box and enter the data entries desired.
    - For example: If you want to create a full 360 deg model of the solved RMxprt design, enter **Fractions 1** in the text box and click **OK**. After solving the RMxprt design, if you choose to create a Maxwell 2D or 3D design, a full 360 model is generated.



Similarly, if you want to create a 180 deg half-model of the solved design, enter **Fractions 2** in the text box.

> **Note:** There are template files of file type **.temp** installed with many of the RMxprt examples located in the *<installdir>***Examples\RMxprt** folder. These text files list keywords (such as **Fractions**), default values, and descriptions of supported user defined data for their related machine types. Refer to *Specifying Data Based on Design Template Files* for details of these template files.

4. Alternatively, click **Import File** to import user defined data from an external file.
5. Browse to the directory containing the file.
6. Select the user defined data file which will be displayed in **File** name box.
7. Click **Open** to confirm the selection.
8. The file contents will be imported into the text box. Click **OK** to complete the setup.

User Defined Data is saved in the design file. Changes to **User Defined Data** will cause existing solutions to become invalid.

"Specifying Data Based on Design Template Files" on the facing page

Specifying Calibration Factors via User-Defined Data

Calibration factors for various machine parameters are listed below. These can be used for setting user-defined data for a design.

Keyword	Default Value	Description	Applicable to
KCoreloss	1.0	Calibration factor for core loss	All machines
KE0	1.0	Calibration factor for induced voltages produced by PM or field current excitation	All synchronous machines, BLDC motors
KLad	1.0	Calibration factor for d-axis armature reactive inductance	All machines with AC armature windings
KLaq	1.0	Calibration factor for q-axis armature reactive inductance	All machines with AC armature windings
KLs_Armature	1.0	Calibration factor for armature winding slot leakage inductance	All machines with AC armature windings
KLs_Damper	1.0	Calibration factor for damper, or squirrel-cage, slot leakage inductance	All machines with damper
KLs_Field	1.0	Calibration factor for field winding slot leakage inductance	All machines with field winding
KLe_Armature	1.0	Calibration factor for armature winding end leakage inductance	All machines with AC armature windings
KLe_Damper	1.0	Calibration factor for damper, or squirrel-cage, end leakage inductance	All machines with damper
KLe_Field	1.0	Calibration factor for field winding end leakage inductance	All machines with field winding
KLend_Armature	1.0	Calibration factor for armature winding end-coil length	All machines with AC armature windings
KLend_Field	1.0	Calibration factor for field winding end-coil length	All machines with field winding

Note	
	• For field winding, the spaces between poles are referred to as slots. • Rotor winding is referred to as "Field Winding" for DFIG machines.

Validating RMxprt Projects

Before you run an analysis on a model, it is very important that you first perform a validation check on the project. When you perform a validation check on a project, RMxprt runs a check on all setup details of the active project to verify that the necessary steps have been completed and their parameters are reasonable.

To perform a validation check on the active project:

1. Click **RMxprt**>**Validation Check**. You can also click the **Validate** button on the **Simulation** ribbon.

   RMxprt checks the project setup, and then the **Validation Check** window appears.
2. View the results of the validation check in the **Validation Check** window.

   The following icons can appear next to an item:

	Indicates the step is complete.
	Indicates the step is incomplete.
	Indicates the step may require your attention.

3. View any messages in the **Message Manager** window.
4. If the validation check indicates that a step in your project is incomplete or incorrect, carefully review the setup details for that particular step and revise them as necessary.
5. Click **RMxprt**>**Validation Check** to run a validation check after you have revised any setup details for an incomplete or incorrect project step**.**
6. Click **Close**.

Setting General Options in RMxprt

Default settings for many of the options in RMxprt may be set through the **Tools>Options** menu. To set general options for RMxprt:

1. Click **Tools>Options>General Options**.
   The **General Options** window appears, displaying six available tabs:
   - Project Options
   - Miscellaneous Options
   - Default Units
   - Remote Analysis Options
   - WebUpdate Options
   - Desktop Performance
2. Click each tab, and make the desired selections.
3. Click **OK**.

Related Topics

Setting RMxprt Options

Configuring a Wire Specification Library

In order to be able to select wire size for your design, your need to configure a wire specification library *before* you insert a new design in your project. RMxprt provides the following libraries of wire gauge specifications based on the current widely used standards for bare copper wire gauges (including both round and rectangular wires). These files are stored in the *syslib* directory.

American.wir	File American.wir provides dimensions for all ANSI bare wires.
ANSI_SingleFilm.wir **ANSI_HeavyFilm.wir** **ANSI_TripleFilm.wir** **ANSI_QuadFilm.wir**	Files ANSI*.wir provide dimensions for bare and film insulated copper wires with single, heavy, triple and quad builds of integer and half AWG numbers.
AWG_Int_SingleFilm.wir **AWG_Int_HeavyFilm.wir** **AWG_Int_TripleFilm.wir** **AWG_Int_QuadFilm.wir**	Files AWG_Int*.wir provide dimensions of integer AWG numbers.
Chinese.wir	
IEC_R20Grade1.wir	Files IEC_R20*.wir provide

IEC_R20Grade2.wir **IEC_R20Grade3.wir** **IEC_R40Grade1.wir** **IEC_R40Grade2.wir** **IEC_R40Grade3.wir**	dimensions of enameled copper wires with Grade-1, 2, and 3 insulations of R20 series. Files IEC_R40*.wir provide dimensions of R40 series. In files IEC*.wir, the gauge numbers are equivalent to the AWG numbers according to the nominal diameters.

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Machines** to show the following choice: **Wire Settings**.
2. Select the desired wire library from the drop-down list. In addition to the System Libraries choices listed above, you can also choose wire libraries you may have in either the User or Personal libraries.
3. Edit wire data as needed.

Editing Wire Data

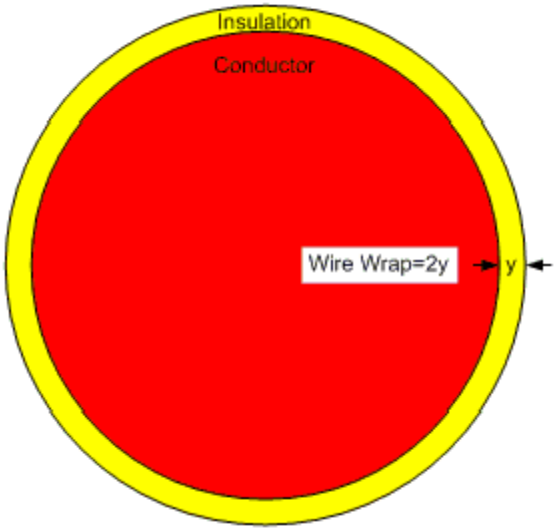
Users must generate their own data files for wire gauges using data for wire gauge and thickness of insulation provided by manufacturers. There are no national standards for insulation thickness, therefore different manufacturers produce electromagnetic wire with different thickness of insulation. The data file **American.wir** does not provide data for thickness of insulation; the data file **Chinese.wir** does provide the data for thickness of insulation, but only for the purpose of reference to users. These files are stored in the file folder *syslib* along with several other wire data reference libraries.

To define or edit wire data:

1. Click **Machine>Wire** to open the **Edit Wire Data** dialog box
2. Select the units from the **Unit System** pull-down list.

   English Unit System stands for British unit system, **Metric Unit System** stands for the metric unit system. When changing the unit system, the message box **Note** pops up to inform changing in unit system is only for specifying input data unit, but not for transferring data between two unit systems
3. Optionally, click **Import** to import wire data from a file. Provide the file name to import in the **File name:** edit box (or by browsing) and use the default file type *Wire Size File (*.wir)*. Several standard wire libraries are provided in the *syslib* directory.
4. Click the **Round** or **Rectangle** tab for the wire shape you want to edit.

   For **Round**:



a. Specify the desired values for Gauge No., Diameter, and/or Wrap.

Gauge No.	wire gauge index number.
Diameter	diameter of bare copper wire, in mm or inch.
Wrap	thickness of insulation wrap, in mm or inch.

b. Modify the wire data as needed.

c. Optionally, Add or Delete Rows for wire values.

For **Rectangle**:

		1	2	3	4	5	6	7	8	9	10	11	12	
1	->A	1.02	1.15	1.29	1.45	1.63	1.83	2.05	2.3	2.59	2.91	3.26	3.66	4.1
2	B ->R	0.5	0.5	0.5	0.5	0.5	0.5	0.5	0.5	0.67	0.67	0.8	0.8	1
3	2.05	1.876	2.143	2.430	2.758									
4	2.18	2.009	-	2.598	-									
5	2.3	2.131	2.430	2.752	3.120	3.534								
6	2.44	2.274	-	2.933	-	3.763								

a. Specify the desired values to limit ratios of the two sides.

Wire Shape Limit (B/A) max	the maximum ratio between the wide and the narrow sides.
Wire Shape Limit (B/A) min	the minimum ratio between the wide and the narrow sides.

b. Use the radio buttons to specify whether to consider priority factors.
All Size – for No Consideration of Priority Factors

Select the radio button **All Size**, and then click the **Calculate** button. All the sectional areas of wire gauge with the ratio B/A between the wide and the narrow sides satisfying the condition **(B/A) max** > B / A > **(B/A) min** appear in the table.

Skip One – for Consideration of Priority Factors

Select the radio button **Skip One**, and then click the **Calculate** button. All the sectional areas of wire gauge with the ratio B/A between the wide and the narrow sides satisfying the condition **(B/A) max** > B / A > **(B/A) min** appear in three different modes in the table **Rectangular Wire Data**.

- At the intersection of the odd columns and the odd rows, the sectional areas appear in black numbers (recommended to use).
- At the intersection of the odd columns and the even rows or the even columns and the odd rows, the sectional areas appear in blue numbers (rarely used).
- At the cross of the even columns and the even rows, the sectional areas do not show (generally not used).

c. Optionally, Add or Delete rows or columns for wire values.

4. Optionally, click **Export** to export the data you entered to a file. Provide the file name to import in the **File name:** edit box (or by browsing) and use the default file type *Wire Size File (*.wir)*. The default directory for an exported wire data file is *userlib*.
5. When you are finished, click **Save** to save the data, and click **Close** to close the window.

Note	Saving wire data only updates the wire data in the active design.

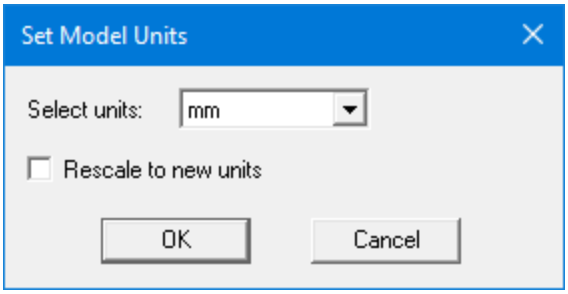
Setting RMxprt Machine Model Units

To set the machine model's units of measurement:

1. Click **Machine** > **Units**.

   The **Set Model Units** dialog box appears.



2. Select the new units for the model from the **Select units** drop-down menu.
3. Specify how the change in units affects the model:
   - Select the **Rescale to new units** option to rescale the dimensions to the new units. For example, selecting centimeters (cm) as the new unit of measurement results in a dimension of 10 millimeters (mm) becoming 10 cm.
   - Clear the **Rescale to new units** option (the default) to convert the dimensions to the new units without changing their scale. For example, selecting cm as the new unit of measurement results in a dimension of 10 mm becoming 1 cm.

Click **OK** to apply the new units to the model.

Edit AC Windings

RMxprt can automatically arrange almost all commonly used single- or double-layer poly-phase ac windings provided all coils have the same number of turns. Users do not need to define coils one by one. For a double-layer winding, RMxprt can also handle the coils with half turns which are arranged in the order of even, odd, even, odd, …, as long as it is physically possible.

RMxprt also provides a very flexible tool, the **Winding Editor**, to allow users to design a variety of special winding types according to their own needs, such as compound single- and double-layer

winding, big- and small-phase-spread variable-pole multiple-speed winding, sine-wave three-phase winding, and so forth. The **Winding Editor** is available to the following types of electric machines:

1. Three-phase induction motors
2. Single-phase induction motors
3. Three-phase synchronous motors and generators
4. Line-start permanent-magnet synchronous motors
5. Claw-pole alternators
6. Adjustable-speed permanent-magnet synchronous motors and generators
7. Brushless permanent-magnet DC motors

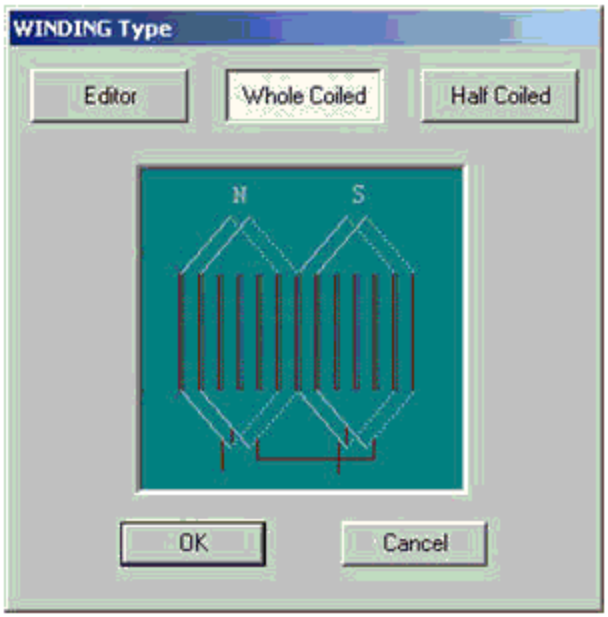
When you edit the AC winding of a new design for the first time, RMxprt creates a default winding arrangement based on the basic winding specifications: **Number of Phases**, **Number of Poles**, **Number of Slots**, **Winding Layers**, **Conductors per Slot**, and **Coil Pitch**. Then you can edit the winding configuration based on the default arrangement.

Enable Winding Editor

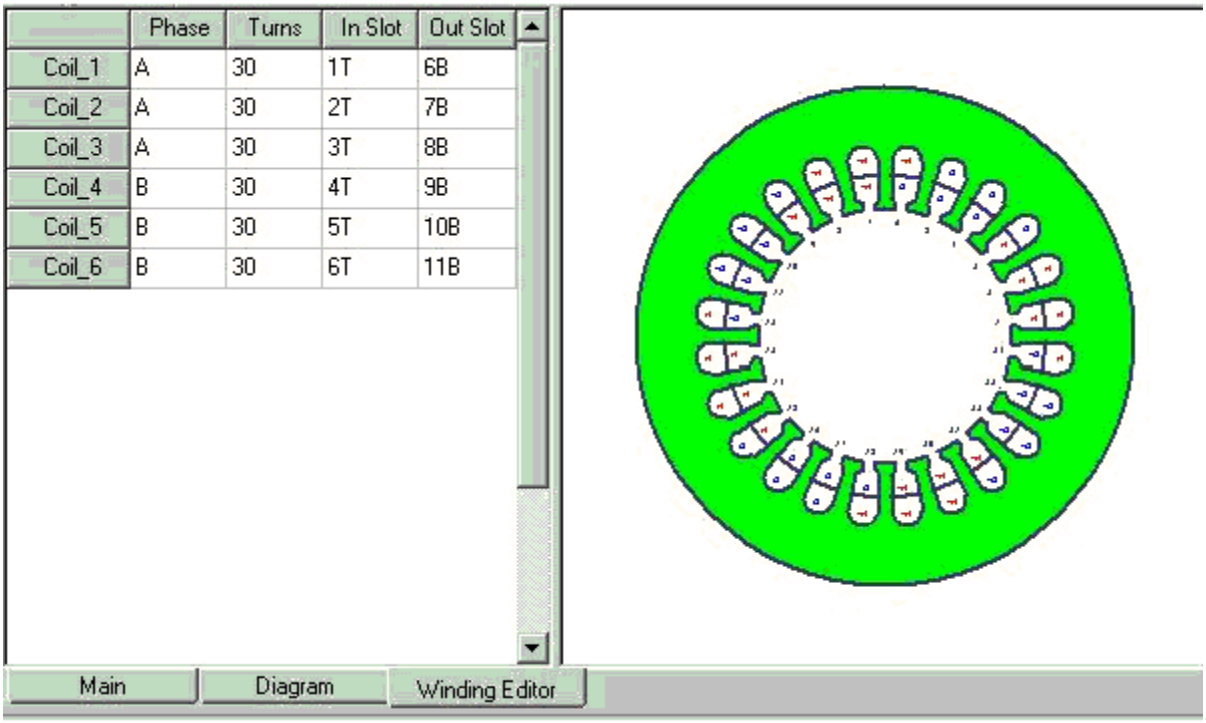
Setting the **Winding Type** property to **Editor** enables the command **Machine>Edit Layout** on the menu bar.

To display the dialog box **Winding Editor**:

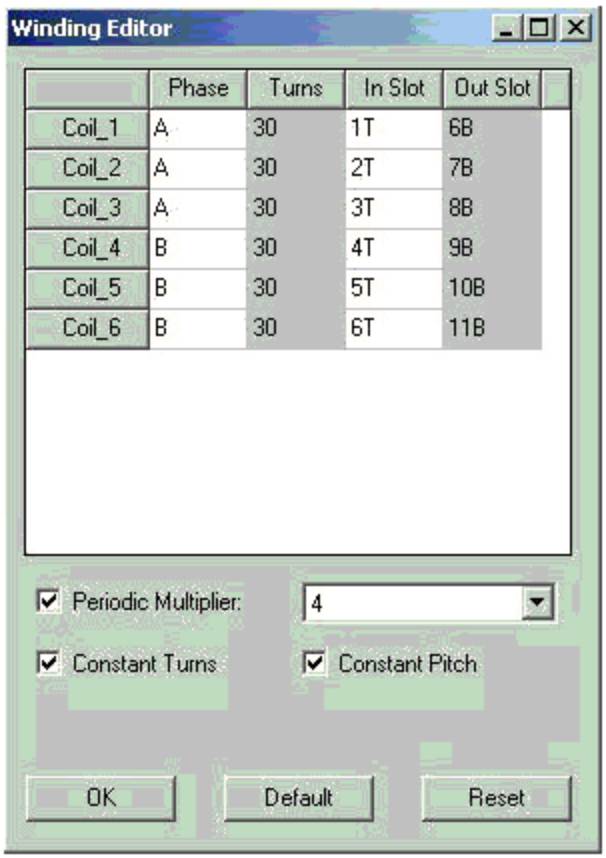
1. Select **Winding** in the Project Tree. In the Properties window, set the Winding Type Value to **Editor**. To do this, click on the button Winding Type Value to display the WINDING Type selection window, as shown:



2. Select **Editor** as the Winding Type and click **OK**.
   This closes the WINDING Type selection window and sets the Winding Type Value to Editor. It also enables the command **Machine>Winding>Edit Layout** on the menu bar. Now the Machine Editor window displays the default winding arrangement, as shown:



3. Click **Machine>Winding>Edit Layout**.
   This displays the **Winding Editor** dialog as shown. The Winding Editor dialog box includes functions that do not appear in the Winding Editor tab sheet in the RMxprt Machine Editor window.
   In addition, right-clicking in the data table section of the Winding Editor tab in the Machine Editor displays a shortcut menu where you may also select **Edit Layout**.



Edit Winding Configuration

Each row of the winding data table in the Winding Editor dialog box is identified with the coil index in the column Coil. This information is displayed in the tab sheet Winding Editor in the RMxprt Machine Editor window as well, but it is editable in the dialog box Winding Editor.

The winding data table contains four columns:

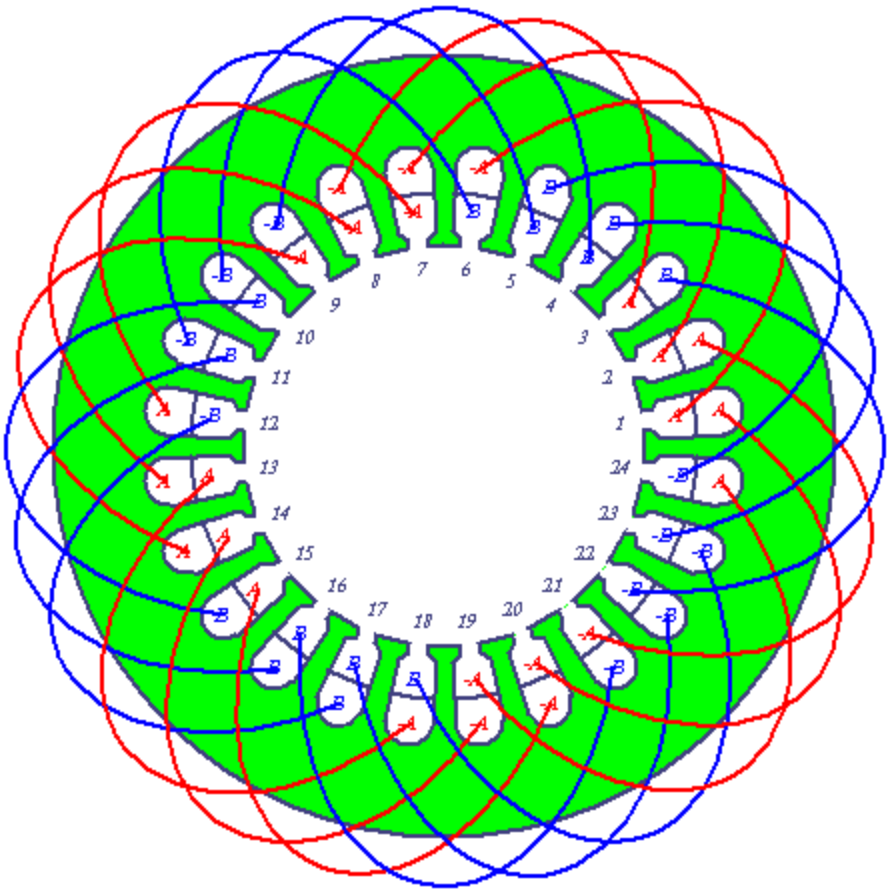
Phase	is for the phase to which the coil belongs.
Turns	is for the number of turns of the coil.
In Slots	is for the slot number with the coil side current flowing in ('flow-in-side' for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "T" to show the top layer.
Out Slots	is for the slot number with the coil side current flowing out ("flow-out-side" for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "B" to show the bottom layer.

View Winding Connections

When you have specified the winding data, you can execute the following commands to display or hide the winding connections.

1. Click the menu command **Machine>Winding>Connect All Coils**.

   Upon executing, the graphical display in the Machine Editor window shows the connections as shown:



2. To remove the connections in the graphical display in the Machine Editor window, select **Machine>Winding>Disconnect All Coils**.
3. Winding connections may also be viewed by shortcut menu. **Right-click** on the **winding layout** section of the Machine Editor window, a shortcut menu pops up. Select **Connect All Coils** or **Disconnect All Coils** to toggle the coils display on or off.

   If you right-click on a slot layer, commands related to that slot layer will be enabled, and you will be able to view or hide only one coil or one phase connection related to the slot layer. You may copy the connection drawing to clipboard from the shortcut menu as well.

Working with the Slot Editor

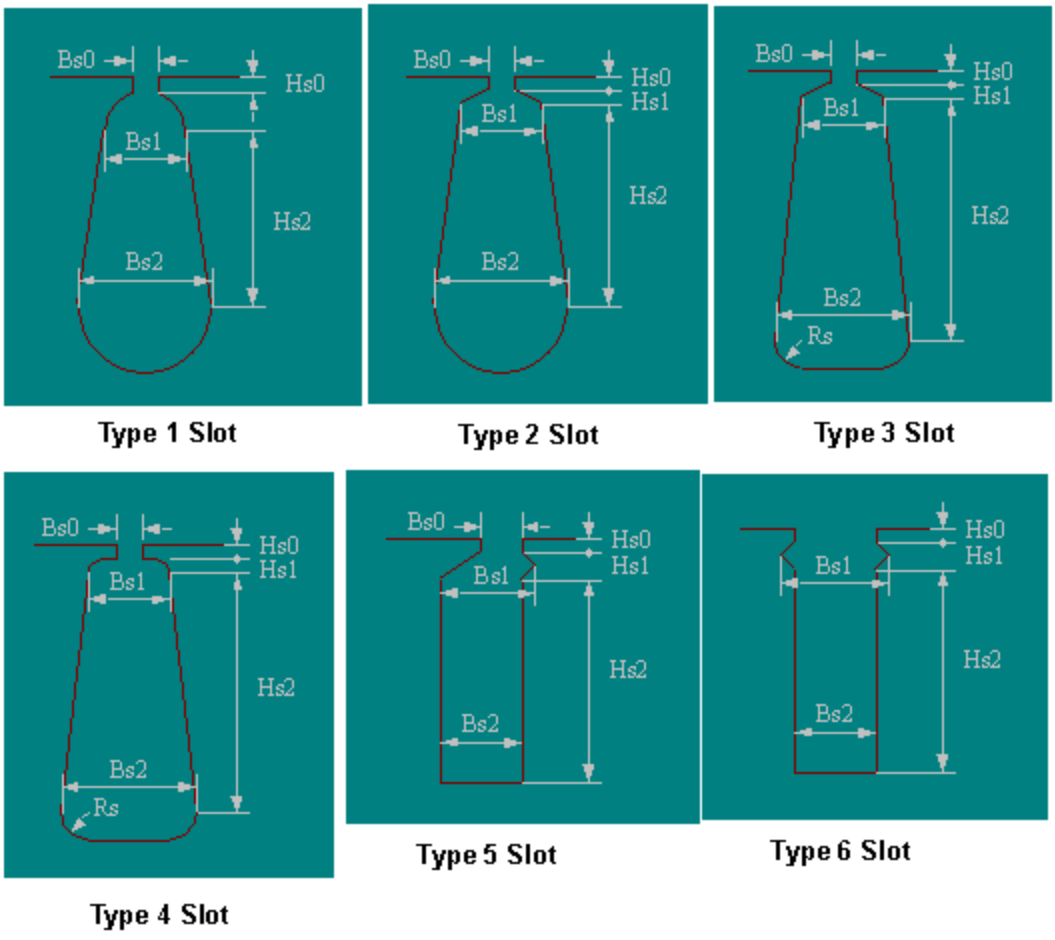
RMxprt provides a flexible tool, the **Slot Editor**, to enable users to edit user-defined slots easily.

Standard slot types in a project can be converted to equivalent user-defined versions that can be edited in the RMxprt Slot Editor tool as follows:

1. In the Project tree, select the Rotor or Stator whose slot is to be converted.
2. In the Rotor or Stator Properties Window, click the **Slot Type Value** button to open the **Select Slot Type** dialog box.
3. Check **User Defined Slot**, and click **OK**.

   The slot label in the Project tree changes to one of the following:

   UserDefSymmetricSlot (user-defined symmetric slot), **UserDefUnsymmetricSlot** (user-defined unsymmetric slot), or **UserDefHalfSlot** (user-defined half slot), depending on the standard Slot Type on which it is based.



Standard Slot Types 1, 2, 3, 4, and 6 are symmetric. Standard slot Type 5 is unsymmetric. Half slots are present if the machine's Rotor or Stator Properties Window includes a Half Slot property that has been enabled.

The Slot Editor Window

When you select a user-editable slot in the Project tree, the Slot Editor window appears on the desktop. The slot editor window is split into two frames. The left frame is the data editing view, which contains an expandable tree view of the slot and its constituent segments. The right frame shows a graphical view of the slot geometry formed by its segments.

Slot geometry types that can be edited are: *symmetric*, *unsymmetric*, and *half-slot*. A symmetric slot is shown in the following figure.

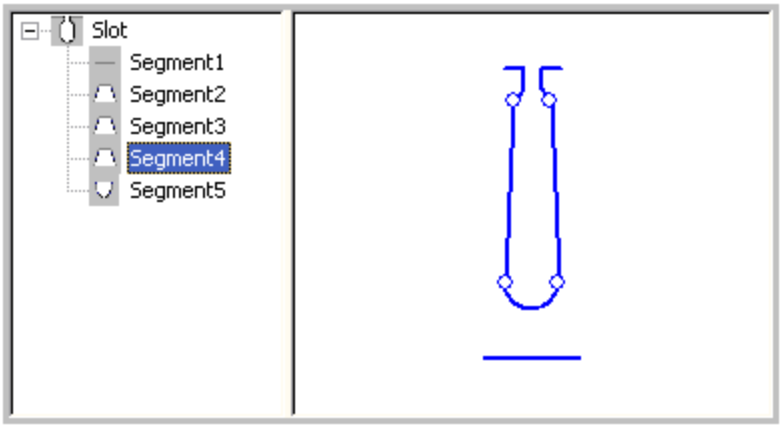
The Edit Slot Segments Dialog Box

Slot Editor Data Editing View

In the tree view, the **Slot** root tree item is predefined and cannot be modified. The top segment in the tree, **Segment1**, cannot be deleted. In the slot data edit view, the slot segment tree items always follow in order from top to bottom of the slot. Segment names also follow this top-to-bottom order, **Segment1**, **Segment2**, **Segment3**, etc., regardless of any operations that are made. Adjacent segments viewed in the tree are geometrically connected to each other as viewed on the slot graph. The data of neighboring segments are tightly coupled due to this geometry connection.

Selecting a segment in the tree highlights the corresponding segment (and its mirror image for symmetric slots) in the Slot Editor Graphic view – indicated by small open circles at the endpoints of the segments.



The Properties Window is also updated to show the selected segment's properties. Changing segment values in the slot editor updates the Properties Window, and vice-versa.

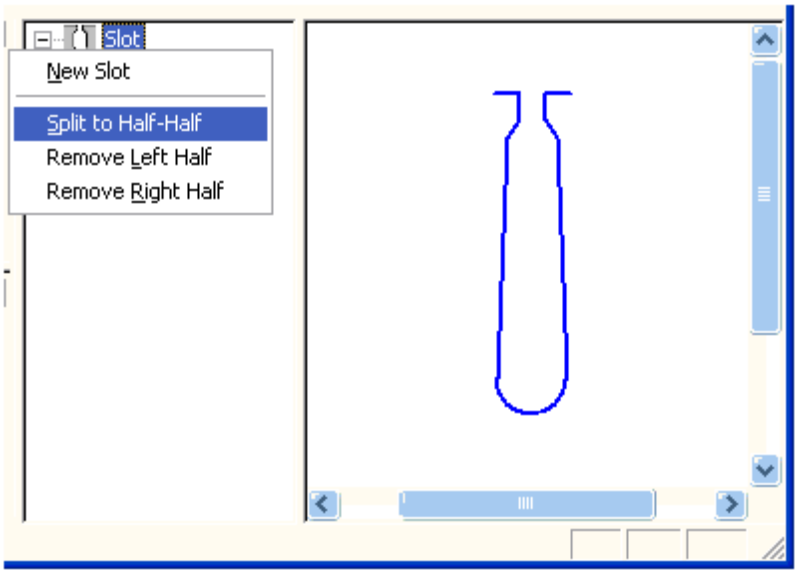
Editing Slot Segments
Editing Unsymmetric Slots
Editing Half Slots
The Edit Slot Segments Dialog Box

Editing Symmetric Slots

For a *symmetric* slot, right-clicking the **Slot** tree item pops up a context menu displaying the following choices:



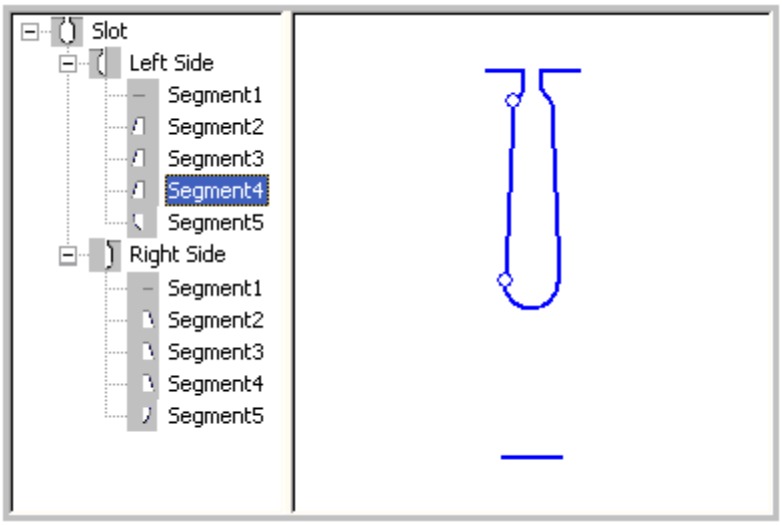
- **New Slot** - opens the **New Slot** dialog box in which the user can select a new standard slot.
- **Split to Half-Half** - splits the slot into a **Left Side** and a **Right Side** transforming it into an *unsymmetric* slot. Each side then can be edited independently.
- **Remove Left** (or **Right**) **Half**, **Remove Right Half** - removes the segments for the left (or right) half of the symmetric slot, transforming the slot into a *half-slot*.

Related Topics

The New Slot Dialog Box
Editing Slot Segments
Editing Unsymmetric Slots
Editing Half Slots

Editing Unsymmetric Slots

For an *unsymmetric* (i.e., split) slot type, two additional expandable sub-branches, **Left Side** and **Right Side**, are present in the slot tree. The segments in each side can be edited independently.



Right-clicking the **Slot** tree item pops up a context menu with the following choices:

- **New Slot** - opens the **New Slot** dialog box in which the user can select a new standard slot.
- **Merge Left** (or **Right**) **to Symmetric** - the left (or right) side segments are mirrored and merged to form a *symmetric* slot.
- **Left Right Flip** - the left side and right side segments are flipped (reflected and interchanged). The slot remains unsymmetric.
- **Remove Left Half**, **Remove Right Half** - removes the segments for the left (or right) half of the symmetric slot, transforming the slot into a *half-slot*.

Right-clicking either the **Right Side** or **Left Side** sub-branch tree item opens a context menu on which you can choose either: **Merge to Symmetric**, which mirrors the selected side's segments and merges the segments into a *symmetric* slot; or **Remove**, which removes the selected side and all of its segments, resulting in a right or left half-slot.

Related Topics

The New Slot Dialog Box

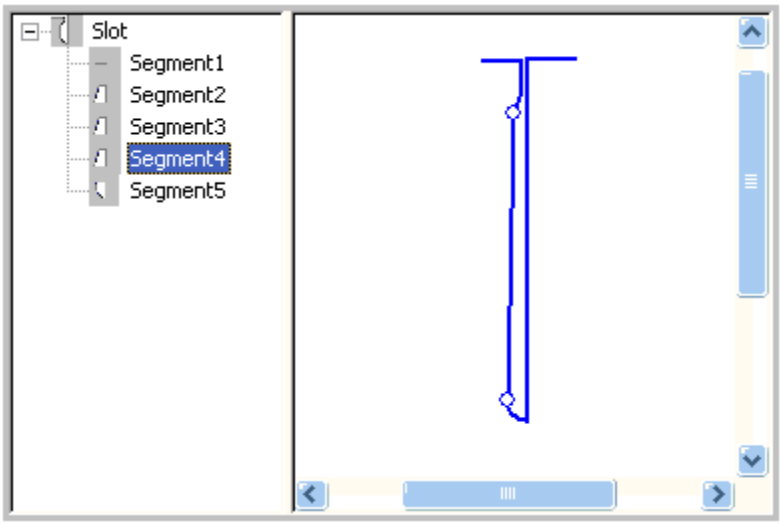
Editing Slot Segments

Editing Symmetric Slots

Editing Half Slots

Editing Half Slots

For a *half slot*, only the segments on one side of the slot can be edited.



Right-clicking the **Slot** tree item pops up a context menu displaying the following choices:

- **New Slot** - opens the **New Slot** dialog box in which the user can select a new standard slot.
- **Merge to Symmetric** - the left (or right) half-slot segments are mirrored and merged to form a symmetric slot.
- **Left Right Flip** - the left (or right) half-slot segments are flipped (reflected). The slot remains unsymmetric.
- **Mirror** - the left (or right) half-slot segments are mirrored (reflected and copied), transforming the slot into an *unsymmetric* slot.

Related Topics

The New Slot Dialog Box
Editing Slot Segments

Editing Unsymmetric Slots

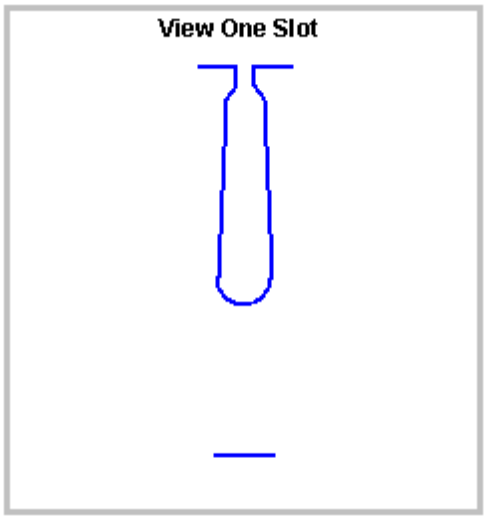
The New Slot Dialog Box

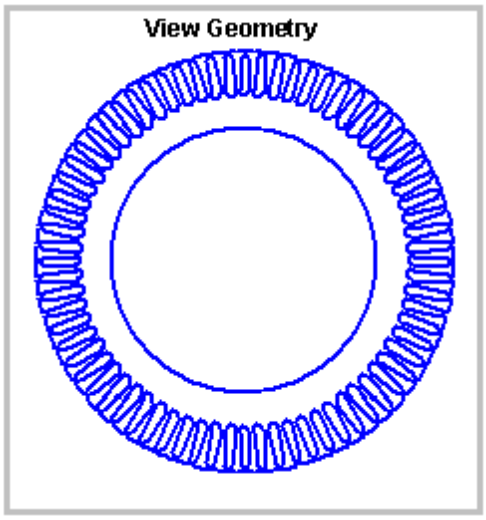
Selecting **New Slot** in any of the **Slot** tree item context menus opens the **New Slot** dialog box.

Radio buttons allow the user to select a **Symmetric Slot**, **Unsymmetrical Slot**, **Left Half Slot**, or **Right Half Slot** as the type to be added. Clicking **OK** confirms the choice and replaces the existing slot type in the editor with a slot of the selected type. The new slot has only **Segment1** present. The user must then edit the slot segments to form the desired slot geometry.

Slot Editor Graphical View

The slot editor graphic view allows users either to **View One Slot** of the type currently being edited, or to **View** the **Geometry** of the machine stator or rotor with all of the slots in place.





Right-clicking anywhere in the graphic view pops up a context menu. In addition to changing the view, the menu provides commands to **Zoom In** and **Zoom Out**, to **Fit All** the view in the frame, as well as commands to **Insert**, **Append**, **Modify**, and **Remove** slot segments. These commands are discussed more fully in the section on *Editing Slot Segments*.

The Edit Slot Segments Dialog Box

Editing Slot Segments

The RMxprt Slot Editor allows users to edit the segments that form the geometry of slots. In the slot data edit view, selecting a slot segment item on the tree, then right-clicking on it displays a context menu with commands that allow users to **Insert**, **Append**, **Modify**, and **Remove** segments.

Alternatively, users can select a slot segment directly in the graphic view, then right-click to bring up a context menu containing the same segment editing commands.

When a slot segment is selected, users can also modify the segment data directly in the desktop property window. Each edit triggers immediate validation. If edited values are improper, warning message windows are displayed describing the problem. Editing operations support Undo/Redo. Scripting functions are also available.

- **Insert Segment** -adds a segment *before* the currently selected segment. The added segment is defined by the user in the **Edit Slot Segment** dialog box.

NOTE: You cannot insert a segment before **Segment1**.

- **Append Segment** - adds a segment *after (i.e., below)* the currently selected segment. The appended segment is defined by the user in the **Edit Slot Segment** dialog box.
- **Modify Segment** - modifies the currently selected segment. The segment is modified by the user in the **Edit Slot Segment** dialog box.
- **Remove Segment** - removes the currently selected segment. The ends of the segments on either side of the removed segment are joined when the segment is removed.

NOTE: **Segment1** cannot be removed.

The Edit Slot Segment Dialog Box

In the **Edit Slot Segment** dialog box, user can define the shape and dimension(s) of the segment to be added, inserted, or appended relative to the currently selected segment in the slot data edit view. As shown below, eight basic geometric shapes are provided for defining the slot segment. The **Selected Shape** panel shows dimensional parameters that affect the segment shape such as: height, starting and ending width, and radius. Parameters that determine the shape of the segment can be edited in the **Segment Data** panel.

	• **Start width** - sets the starting width and unit of measure. The value shown depends on the ending width of the previous segment and thus is not editable. • **End width** - sets the ending width and unit of measure. A drop-down box provides three additional options for controlling the segment shape: • **Line edge** (the default) - makes the segment a straight line. • **Arc offset on slot center** - makes the segment an

	arc whose radius is determined by a user-specified offset from the rotor/stator center with respect to the slot center. • **Arc offset on tooth center** - makes the segment an arc whose radius is determined by a user-specified offset from the rotor/stator center with respect to the tooth center. 	• **Start width** - sets the starting width and unit of measure. The value shown depends on the ending width of the previous segment and thus is not editable. • **Height** -sets the height and unit of measure for the segment. A drop-down box provides three options for controlling the segment shape: • **End width** (the default)- sets the ending width and unit of measure.

	•  **Parallel slot** - effectively sets the segment end width to the same value as the start width resulting in the slot sides being parallel to each other. •  **Parallel tooth** - sets the segment end width to a value such that the slot side is parallel to the adjacent slot side of the tooth formed between them.
	• **Start width** - sets the starting width and unit of measure. The value shown depends on the ending width of the previous segment and thus is not editable. • **End width** - sets the ending width and unit of measure.
	• **Start width** - sets the starting width and unit of measure. The value shown depends on the ending width of the previous segment and thus is not editable. • **Radius** - sets the radius and unit of measure for the segment.

Validation of the entered data is done when either the **OK** or **Preview** is clicked. If edited values are improper, warning message windows are displayed describing the problem. The **Preview** button allows users to preview the current changes in the slot graph window without confirming the changes.

Clicking the **OK** button confirms the changes and closes the dialog box.

Clicking the **Cancel** button cancels the changes and closes the dialog box.

Working with Variables in RMxprt

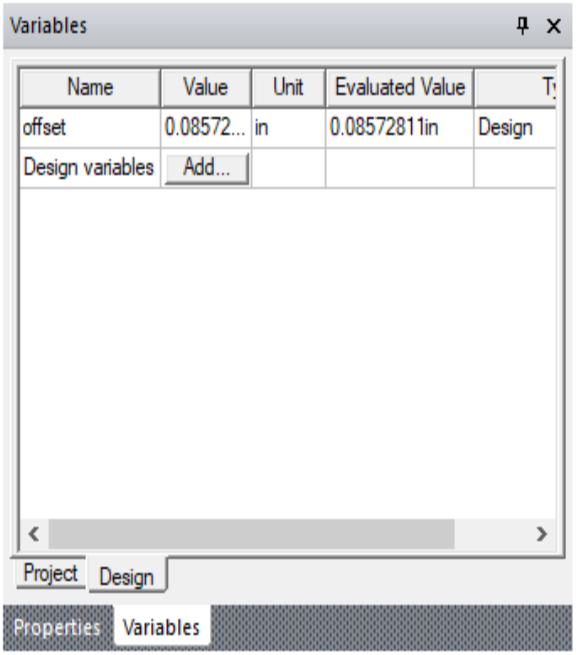
A variable is a numerical value, mathematical expression, or mathematical function that can be assigned to a design parameter in RMxprt. Variables are useful in the following situations:

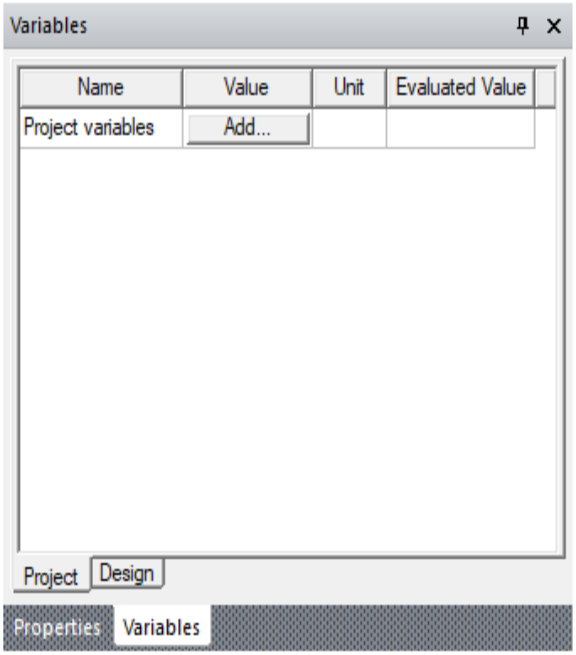
- When you expect to change a parameter often.
- When you expect to use the same parameter value often.
- When you intend to run a parametric analysis in which you specify a series of variable values within a range to solve.
- When you intend to optimize a parameter value by running an optimization analysis.

There are two types of variables in RMxprt:

Project Variables	A project variable can be assigned to any parameter value in the project in which it was created. RMxprt differentiates project variables from other types of variables by prefixing the variable name with the $ symbol. You can manually include the $ symbol in the project variable's name, or RMxprt can automatically append the $ after you define the variable.
Design Variables	A design variable can be assigned to any parameter value in the RMxprt design in which it was created.

Clicking **View** > **Variables** brings up a dockable variable window that is associated with the active project and/or design. When there is an active project, there will be a corresponding project variable tab. When there is an active design, there will be a corresponding design variable tab. Each tab contains an **Add...** button allowing creation of new variable of this type. If variables exist for the Project or Design, they are shown in the corresponding tab.





Related Topics

Setting up an Optimization Analysis

Adding a Project Variable in RMxprt

A project variable can be assigned to a parameter value in the RMxprt project in which it was created. RMxprt differentiates project variables from other types of variables by prefixing the variable name with the following symbol: **$**. You can manually include the symbol **$** in the project variable's name when you create it, or RMxprt will automatically append the project variable's name with the symbol after you define the variable. Project variables can be used in any design within the project.

1. Click **Project>Project Variables**.
   - Alternatively, right-click the project name in the project tree, and then click **Project Variables** on the shortcut menu.

   The **Properties** dialog box appears.
2. Under the **Project Variables** tab, click **Add**.

   The **Add Property** dialog box appears.
3. In the **Name** box, type the name of the variable.

   Project variable names must start with the symbol **$** followed by a letter. Variable names may include alphanumeric characters and underscores (_). The names of intrinsic functions and the predefined constant pi (π) cannot be used as variable names.

You can sort the project variables by clicking on the Name column header. By default, variables are sorted in original order. Clicking once sorts them in ascending order, noted by a triangle pointing up. Clicking against sorts in descending order, noted by a triangle pointing down. Clicking a third time sorts in original order, with no triangle.

4. Select a radio button for the variable use:

Selected Use	Setable Properties
Variable	Unit Type, Units, Value.
Separator	Value
Array Index Variable	Associate Array variable, Value

Each selection affects the settable options.

5. For Project Variables in the **Unit Type** text box you can use the drop down menu to select from the list of available unit types. “None” is the default.

   When you select a Unit Type, the choices in drop-down menu for the Units text box adapt to that unit type. For example, selecting Length as the Unit Type causes the **Unit** menu to show a range of metric and english units for length. Similarly, if you select the Unit Type as Resistance, the Units drop down lists a range of standard Ohm units.

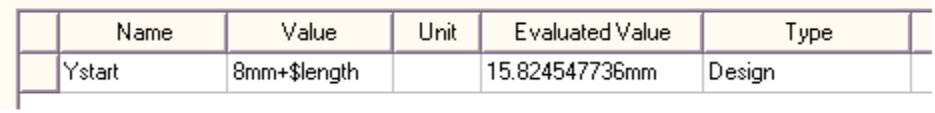
6. In the **Value** box, type the quantity that the variable represents. Optionally, include the units of measurement.

Warning	If you include the variable's units in its definition (in the **Value** box), do not include the variable's units when you enter the variable name for a parameter value.

   The quantity can be a numerical value, a mathematical expression, or a mathematical function. The quantity entered will be the *current,* or *default, value* for the variable.

7. Click **OK**.

   You return to the **Properties** dialog box. The new variable and its value are listed in the table. If the value is an expression, the evaluated value is shown. Updating the expression also changes the evaluated value display. The evaluated values of any dependent variables also are changed.



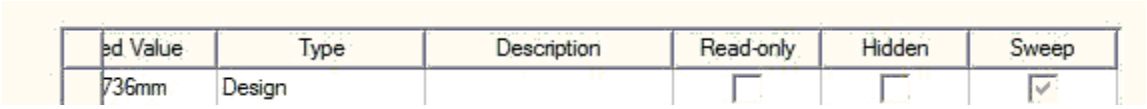
Name	Value	Unit	Evaluated Value	Type
Ystart	8mm+$length		15.82454773 6mm	Design

8. Optionally, type a description of the variable in the **Description** box.
9. Optionally, select **Read-Only**. The variable's name, value, unit, and description cannot be modified when **Read-only** is selected.

10. Optionally, select **Hidden**. If you clear the **Show Hidden** option, the hidden variable will not appear in the **Properties** dialog box.
11. You can also designate a variable as Sweep. You may need to use the scroll bar or resize the dialog to view the check boxes.

The Sweep check box lets you designate variables to include in solution indexing as a way to permit faster post processing. Variables with Sweep unchecked are not used in solution indexing. If a solution exists, checking or unchecking a variable's Sweep setting produces a warning that the change will invalidate existing solutions. To continue, click **OK** to dismiss the warning dialog.

If a variable has dependent variables, the Sweep check box is disabled and cannot be changed.



12. Click **OK**.

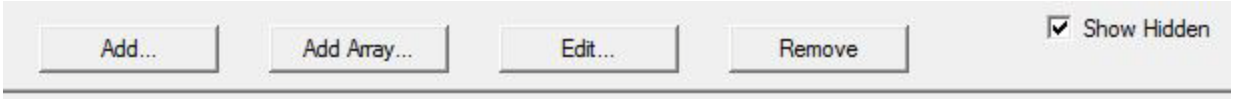
The new variable can now be assigned to a parameter value in the project in which it was created.

Adding a Design Variable in RMxprt

A design variable is associated with an RMxprt design. A design variable can be assigned to a parameter value in the RMxprt design in which it was created.

1. Click **RMxprt>Design Properties**.
   - Alternatively, right-click the design name in the project tree, and then click **Design Properties** on the shortcut menu.

   The **Properties** dialog box appears opened on the **Local Variables** tab. From the Properties dialog you can Add, Add Array, Edit, or Remove variables.



Any existing Design variables are listed in the **Properties** dialog with the name followed by cells for Value, Unit, Evaluated Value, Type, Description, and Read-only and Hidden check boxes. A Show Hidden check box on the lower right of the Properties dialog controls the appearance of any Hidden variables.

Initially, leave the radio button with Value selected until you have defined a variable. The other radio buttons let you enable defined variables for Optimization/Design of Experiments, Tuning, Sensitivity or Statistics. Selecting one of these radio buttons adds a new column to the Variable definition row for which you can check or uncheck Include for regular variables for that kind of Optimetrics simulation.

2. Click **Add**.

   The **Add Property** dialog box appears.

3. In the **Name** box, type the name of the variable.

   Variable names must start with a letter, and may include alphanumeric characters and underscores (_). The names of intrinsic functions and the predefined constant pi (π) cannot be used as variable names.

   You can sort the variables by clicking on the Name column header. By default, variables are sorted in original order. Clicking once sorts them in ascending order, noted by a triangle pointing up. Clicking against sorts in descending order, noted by a triangle pointing down. Clicking a third time sorts in original order, with no triangle.

4. Select a radio button for the variable use:

Selected Use	Setable Properties
Variable	Unit Type, Units, Value
Array Index Variable	Associate Array variable, Value
Separator	Value
Post Processing Variable	Unit Type, Units, Value

   Each selection affects the settable options.

5. In the **Unit Type** text box you can use the drop-down menu to select from the list of available unit types. “None” is the default.

   When you select a Unit Type, the choices in drop-down menu for the Units text box adapt to that unit type. For example, selecting Length as the Unit Type causes the Unit menu to show a range of metric and english units for length. Similarly, if you select the Unit Type as Resistance, the Units drop down lists a range of standard Ohm units.

6. In the **Value** box, type the quantity that the variable represents. Optionally, include the units of measurement.

Note	If you include the variable's units in its definition (in the **Value** box), do not include the variable's units when you enter the variable name for a parameter value.

   The quantity can be a numerical value, a mathematical expression, or a mathematical function. The quantity entered will be the *current* (or *default value)* for the variable. If the mathematical expression includes a reference to an existing variable, this variable is treated as a dependent variable. The units for a dependent variable will automatically change to

those of the independent variable on which the value depends. Additionally, dependent variables, though useful in many situations, cannot be the direct subject of optimization, sensitivity analysis, tuning, or statistical analysis.

Note	Complex numbers are not allowed for variables to be used in an Optimetrics sweep, or for optimization, statistical, sensitivity or tuning setups.

7. Click **OK**.

   You return to the **Properties** dialog box. The new variable and its value are listed in the table. If the value is an expression, the evaluated value is shown. Updating the expression also changes the evaluated value display. The evaluated values of any dependent variables also are changed.

	Name	Value	Unit	Evaluated Value	Type
	Ystart	8mm+$length		15.824547736mm	Design

8. Optionally, type a description of the variable in the **Description** box.
9. You can designate a variable as Read-only, Hidden, or Sweep. You may need to use the scroll bar or resize the dialog to view the check boxes.

	ated Value	Type	Description	Read-only	Hidden	Sweep
		Design		☐	☐	☑

   The Sweep check box lets you designate variables to include in solution indexing as a way to permit faster post processing. Variables with Sweep unchecked are not used in solution indexing. If a solution exists, checking or unchecking a variable's Sweep setting produces a warning that the change will invalidate existing solutions. To continue, click **OK** to dismiss the warning dialog.

   If a variable has dependent variables, the Sweep check box is disabled and cannot be changed.

	ed Value	Type	Description	Read-only	Hidden	Sweep
	736mm	Design		☐	☐	☑

10. Click **OK**.

The new variable can now be assigned to a parameter value in the design in which it was created.

Add Array of Values for an RMxprt Design Variable

A design variable is associated with an RMxprt design. You can also add a variable defined with an array of values.

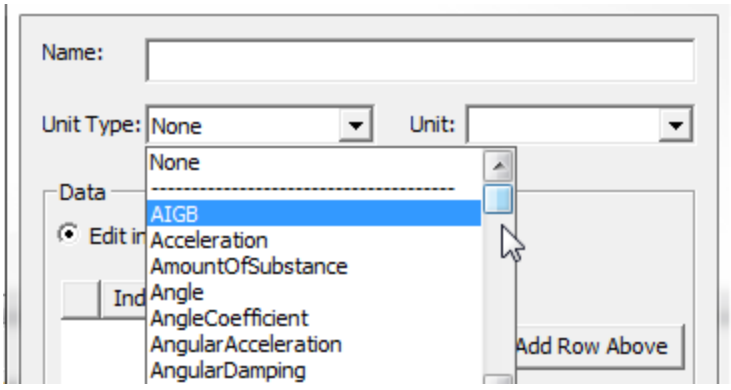
1. Click **RMxprt**>**Design Properties**.
   - Alternatively, right-click the design name in the project tree, and then click **Design Properties** on the shortcut menu.

     The Local Variables **Properties** dialog box appears. From the Properties dialog you can Add, Add Array, Edit... or Remove variables. This section describes Add Array. Use the links for descriptions of Add,.Edit and Remove,

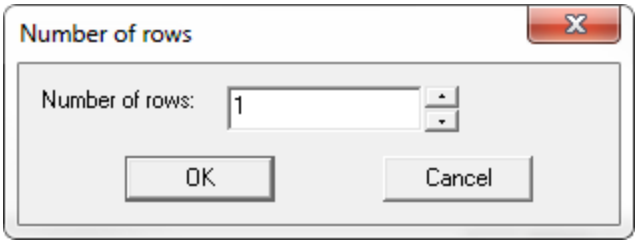
     Any existing Design variables are listed in the **Properties** dialog with the name followed by cells for Value, Unit, Evaluated Value, Type, Description, and Read-only and Hidden check boxes. A Show Hidden check box on the lower right of the Properties dialog controls the appearance of any Hidden variables.

     Initially, leave the radio button with Value selected until you have defined a variable. The other radio buttons let you enable regular variables for Optimization/Design of Experiments, Tuning, Sensitivity or Statistics. Array variables cannot be enabled for Optimetrics use.
2. Click the **Add Array...**. button.

   The **Add Array** dialog displays.
3. Specify a variable Name in the text field.
4. Select a Unit Type and Units from the drop-down menus.



5. To specify the array with Edit in Grid Selected, you can begin by clicking the **Append Rows...** button to display the **Number of Rows** dialog box. (For Edit in plain text field, see below.)



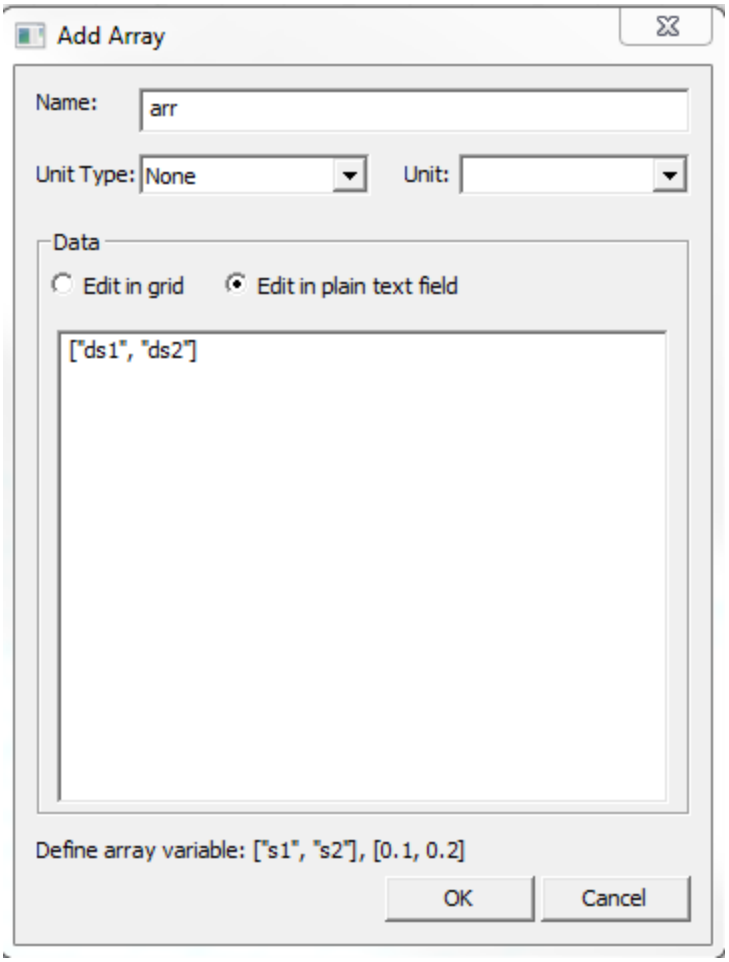
6. Specify a value and click OK.

   This displays a list of indexed data rows in the **Add Array** dialog box. You can type any data value in the cells. If you enter alphanumeric text in a cell it must be delimited by double quotes. You can edit the rows relative a row selection by clicking buttons to Add Row Above, Add Row Below, or Remove Row. All cells must contain a value.

7. When you have completed the array, click **OK** to close the dialog,

   The Array variable is listed in the **Design Properties** dialog as a Local Variable. The array variable value field includes the array contents in brackets with the unindexed data values delimited by commas.

   If you elected to edit the array Edit in plain text field in the **Add Array** dialog, the bracketed and comma delimited format is used.



Defining Mathematical Functions in RMxprt

A mathematical function is an expression that references another defined variable. A function's definition can include both expressions and variables.

The following mathematical functions may be used to define expressions:

Basic functions	**/**, **+**, **-**, *, mod (modulus), **** (exponentiation), **-** (Unary minus), **==** (equals), **!** (not), **!=** (not equals), **>** (greater than), **<** (less than), **>=** (greater than equals), **<=** (less than equals), **&&** (logical and), **||** (logical or)
Intrinsic functions	**if**, **sqn**, **abs**, **exp**, **pow**, **ln** (natural log), **sqrt**
Trigonometric expressions	**sin**, **cos**, **tan**, **asin**, **acos**, **atan**, **sinh**, **cosh**, **tanh**

The predefined variables X, Y, Z, Phi, Theta, R, and Rho must be entered as such. X, Y, and Z are the rectangular coordinates. Phi, Theta, and Rho are the spherical coordinates. R is the cylindrical radius, and Rho is the spherical radius.

If you do not specify units, all trigonometric expressions expect their arguments to be in radians, and the inverse trigonometric functions' return values are in radians. If you want to use degrees, you must supply the unit name **deg**. When the argument to a trigonometric expression is a variable, the units are assumed to be radians. These function names are reserved and may not be used as variable names.

Defining an Expression in RMxprt

Expressions are mathematical descriptions that typically contain intrinsic functions, such as sin(x), and arithmetic operators, such as +, -, *, and /, as well as defined variables. For example, you could define: x_size = 1mm, y_size = x_size + sin(x_size).

The symbol, pi (π), is the only available predefined constant. It may not be reassigned a new value.

Numerical values may be entered in Ansys' shorthand for scientific notation. For example, $5x10^7$ could be entered as **5e7**.

Using Valid Operators for Expressions in RMxprt

The operators that can be used to define an expression or function have a sequence in which they are performed. The following list shows both the valid operators and the sequence in which they are accepted (listed in decreasing precedence):

( )	parenthesis	1
!	not	2
^ (or **)	exponentiation (If you use "**" for exponentiation, as in previous software versions, it is automatically changed to "^".)	3
-	unary minus	4
*****	multiplication	5
/	division	5
+	addition	6
-	subtraction	6
==	equals	7
!=	not equals	7
>	greater than	7

<	less than	7
>=	greater than or equal to	7
<=	less than or equal to	7
&&	logic and	8
||	logic or	8

Using Intrinsic Functions in Expressions in RMxprt

RMxprt recognizes a set of intrinsic trigonometric and mathematical functions that can be used to define expressions. Intrinsic function names are reserved and may not be used as variable names.

The following intrinsic functions may be used to define expressions:

Function	Description	Syntax
abs	Absolute value (|x|)	**abs(x)**
sin	Sine	**sin(x)**
cos	Cosine	**cos(x)**
tan	Tangent	**tan(x)**
asin	Arcsine	**asin(x)**
acos	Arccosine	**acos(x)**
atan	Arc tangent. Takes a tangent value as an argument. Because there are two angles in a circle that can have the same tangent value, and atan can return only one value, it returns a value in the range between -90 degrees and +90 degrees (or between -pi/2 and pi/2 in radians).	**atan(x)**
atan2	A two-argument version of the **atan** function. Takes the y and x coordinates (including sign information) of a point as arguments and returns the angle from the X-axis. Can return angle values for the full circle (-180 degrees to +180 degrees or -pi to +pi in radians).	**atan2(y,x)**
asinh	Hyperbolic Arcsine	asinh(x)
atanh	Hyperbolic Arctangent	atanh(x)
sinh	Hyperbolic Sine	**sinh(x)**
cosh	Hyperbolic Cosine	**cosh(x)**
tanh	Hyperbolic Tangent	**tanh(x)**
even	Returns 1 if integer part of the number is even; returns 0 otherwise.	even(x)
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise.	odd(x)
sgn	Sign extraction	sgn(x)
exp	Exponential ($\mathbf{e}^{x}$)	**exp(x)**

pow	Raise to power (x^y)	pow(x,y)
if	If	**if(cond_exp,true_exp, false_exp)**
pwl	Piecewise Linear with linear extrapolation on x. (pwl can be used with datasets for Design Variables but not for Project variables).	pwl **(dataset_exp, variable)**
pwlx	Piecewise Linear x with linear extrapolation on x	pwlx **(dataset_exp, variable)**
pwl_periodic	Piecewise Linear with periodic extrapolation on x	pwl_periodic **(dataset_exp, variable)**
sqrt	Square Root	**sqrt(x)**
ln	Natural Logarithm (The "log" function has been discontinued. If you use "log(x)" in an expression, the software automatically changes it to "ln(x)".)	**ln(x)**
log10	Logarithm base 10	log10(x)
int	Truncated integer function	int(x)
nint	Nearest integer	nint(x)
max	Maximum value of two parameters	max(x,y)
min	Minimum value of two parameters	min(x,y)
mod	Modulus	mod(x,y)
rem	Returns the fractional part of a decimal number such that rem(x) = x-int(x)	rem(x)
clp	Closest point interpolation. Note: If used with a large 3D dataset, clp function will degrade.	clp (*datasetName*, X,Y,Z)

Note	If you do not specify units, all trigonometric functions interpret their arguments as radians. Likewise, inverse trigonometric functions' return values are in given in radians. When the argument to a trigonometric expression is a variable, the units are assumed to be radians. If you want values interpreted in degrees, supply the argument with the unit name **deg**

Using Piecewise Linear Functions in Expressions in RMxprt

The following piecewise linear intrinsic functions are accepted in expressions:

```
pwl (dataset_expression, variable)
pwlx (dataset_expression, variable)
pwl_periodic (dataset_expression, variable)
```

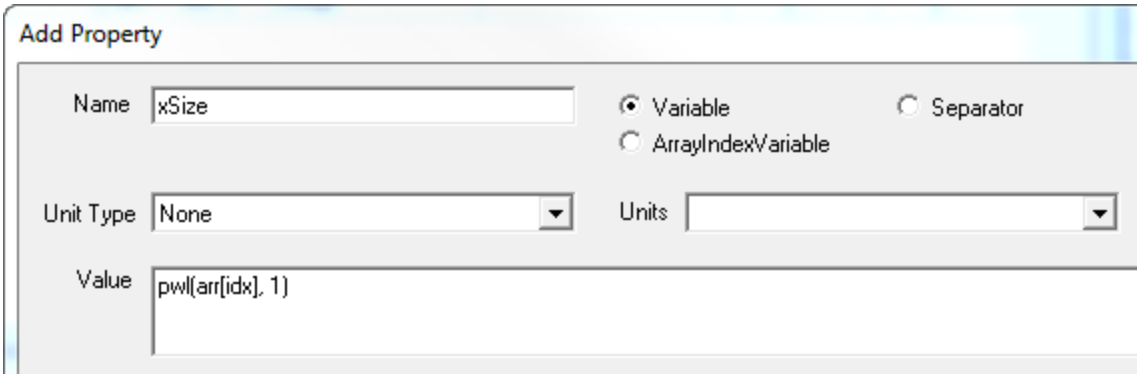
The **pwl** and **pwlx** functions interpolate along the x-axis and returns a corresponding y value. The **pwl_periodic** function also interpolates along the x-axis but periodically.

You can use **pwl** in an expression that uses array variables and datasets for uses such as a frequency dependent material property. For example, you specify BulkConductivity as:

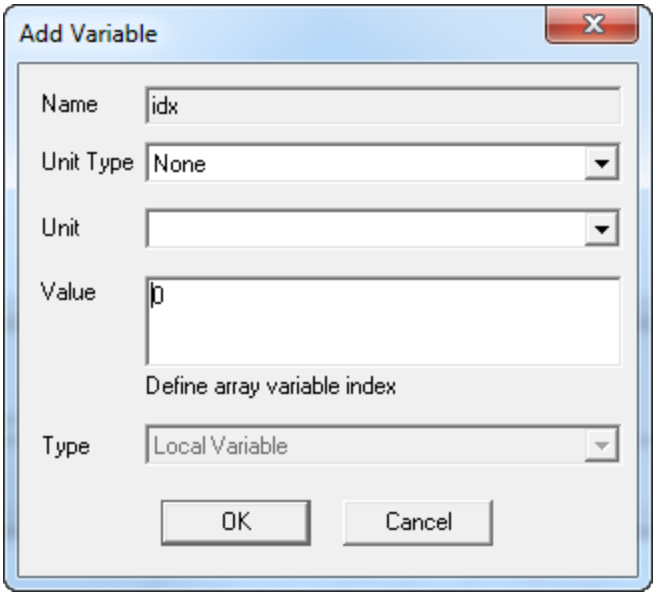
`pwlx($dsArr[$dsIndex], Freq)` where `$dsArr=["$ds1", "$ds2"]`

You can create a Design Variable representing dimension `xSize` as `pwl(arr[idx], 1)` where "`arr`" is an array variable and `idx` is an array index variable.

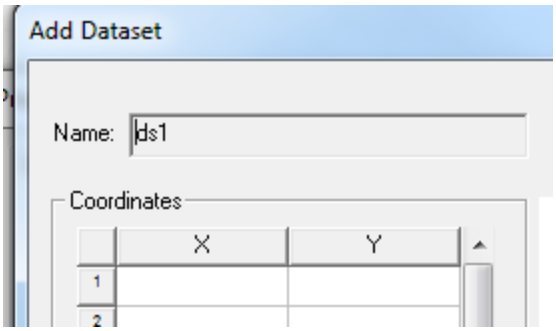
In this case, creating a variable named xSize with pwl(arr[idx], 1) like this:



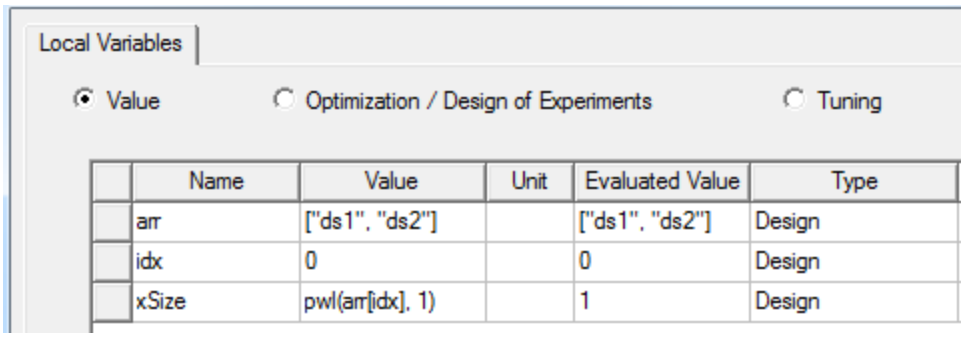
This value for xSize automatically opens a dialog first for the idx index variable:



And then dialogs automatically open for each dataset variable implicit for the predefined array variable:



Then the **Design Properties** dialog shows as follows:



Note: While you can use pwl for a design variable dataset, it does not work for a project variable dataset.

Using Dataset Expressions in RMxprt

Dataset expressions take the following form:

$$dset((x_0,y_0), \ldots, (x_n,y_n))$$

These expressions may be used as the first parameter to piecewise linear (**pwl**, **pwlx** and **pwl_periodic**) functions, and may also be assigned to variables, in which case the variable may be used as the second parameter to **pwl**, **pwlx** and **pwl_periodic** functions.

Dataset expressions are derived from a series of points in a plot created in the **Datasets** dialog box. (Refer to Adding Datasets for related information on working with datasets.) Each plot consists of straight line segments whose vertices represent their end points. A curve is fitted to the segments of the plot, and an expression is derived from the curve that best fits the segmented plot. The created expression is then used in the piecewise linear intrinsic functions.

Assigning Variables in RMxprt

To assign a variable to a parameter in RMxprt:

- Type the variable name or mathematical expression in place of a parameter value in a **Value** box.

  If you typed a variable name that has not been defined, the **Add Variable** dialog box appears, enabling you to define the design variable.

  If you typed a variable name that included the **$** prefix, but that has not been defined, the **Add Variable** dialog box appears, enabling you to define the project variable.

  You can assign a variable to nearly any design parameter assigned a numeric value in RMxprt.

Choosing a Variable to Optimize in RMxprt

Before a variable can be optimized, you must specify that you intend for it to be used during an optimization analysis in the **Properties** dialog box.

1. If the variable is a design variable, click **RMxprt>Design Properties**. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   If the variable is a project variable, click **Project>Project Variables**. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

   The **Properties** dialog box appears.

2. Click the tab that lists the variable you want to optimize.
3. Click the row containing the variable you want to optimize.

Note	Dependent variables cannot be optimized.

4. Select the **Optimization/Design of Experiments** option.
5. For the variable you want to optimize, select **Include**.

   The selected variable is now available for optimization in an optimetrics setup defined in the current design or project.
6. Optionally, override the default minimum and maximum values that Optimetrics will use for the variable in every optimization analysis. During optimization, the optimizer does not consider variable values that lie outside of this range.
7. Click **OK**.

Related Topics

Setting up an Optimization Analysis

Including a Variable in a Sensitivity Analysis in RMxprt

Before a variable can be included in a sensitivity analysis, you must specify that you intend for it to be used during a sensitivity analysis in the **Properties** dialog box.

1. If the variable is a design variable, click **RMxprt>Design Properties**. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   If the variable is a project variable, click **Project>Project Variables**. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

   The **Properties** dialog box appears.
2. Click the tab that lists the variable you want to include in the sensitivity analysis.
3. Click the row containing the variable you want to include in the sensitivity analysis.

Note	Dependent variables cannot be included in a sensitivity analysis.

4. Select the **Sensitivity** option.
5. For the variable you want to include in the sensitivity analysis, select **Include**.

   The selected variable is now available for sensitivity analysis in a sensitivity setup defined in the current design or project.

6. Optionally, override the default minimum and maximum values that Optimetrics will use for the variable in every sensitivity analysis. During sensitivity analysis, Optimetrics will not consider variable values that lie outside of this range.
7. Optionally, override the default initial displacement value that Optimetrics will use for the variable in every sensitivity analysis. During sensitivity analysis, Optimetrics will not consider a variable value for the first design variation that is greater than this step size away from the starting variable value.
8. Click **OK**.

Related Topics

Setting up a Sensitivity Analysis

Choosing a Variable to Tune in RMxprt

Before a variable can be tuned, you must specify that you intend for it to be tuned in the **Properties** dialog box.

1. If the variable is a design variable, click **RMxprt>Design Properties**.

   If the variable is a project variable, click **Project**>**Project Variables**.

   The **Properties** dialog box appears.
2. Click the tab that lists the variable you want to tune.
3. Click the row containing the variable you want to tune.

Note	Dependent variables cannot be tuned.
4. Select the **Tuning** option.
5. For the variable you want to tune, select **Include**.
6. Click **OK**.

   The selected variable is now available for tuning in the **Tune** dialog box.

Related Topics

Tuning a Variable

Including a Variable in a Statistical Analysis in RMxprt

Before a variable can be included in a statistical analysis, you must specify that you intend for it to be used during a statistical analysis in the **Properties** dialog box.

1. If the variable is a design variable, click **RMxprt>Design Properties**. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and

Design Xplorer Setup. Click **Edit Variables** and from the menu select **Edit Design Variables**.

If the variable is a project variable, click **Project**>**Project Variables**. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

The **Properties** dialog box appears.

2. Click the tab that lists the variable you want to include in the statistical analysis.
3. Click the row containing the variable you want to include in the statistical analysis.

Note	Dependent variables cannot be included in a statistical analysis.

4. Select the **Statistics** option.
5. For the variable you want to include in the statistical analysis, select **Include**.

   The selected variable is now available for statistical analysis in a statistical setup defined in the current design or project.
6. Optionally, override the distribution criteria that Optimetrics will use for the variable in every statistical analysis.
7. Click **OK**.

Working with Materials in RMxprt

RMxprt shares many common functions related to materials and material handling with **Maxwell3D** and **Maxwell2D**. For general topics such as, Assigning Materials, Searching for Materials, Adding New Materials, and Viewing and Modifying Material Attributes, see the topics in Maxwell help under **Assigning Materials**.

RMxprt includes a material library containing common materials used in motor design. However, this library needs to be configured so that it is automatically loaded for any new **RMxprt** design. Once the library is configured, you can add, remove, and edit RMxprt materials in two main ways:

- Using the **Tools>Edit Libraries>Materials** menu command.
- Right-clicking **Materials** in the project tree and selecting **Edit Library**.

Editing definitions from the project window does not modify the configured libraries for any particular design. To consider the current design, use the **Tools>Edit Libraries** option. Doing so ensures that new libraries are added to the configured list for the current design. If you edit materials from this command for the current and then export them, they will also be available to assign to objects in other designs.

Material Library Management for RMxprt

Material Library Management for RMxprt

The three most crucial electromagnetic materials in the electric machine are soft-magnetic material (silicon steel sheet), hard-magnetic material (permanent magnet) and electromagnetic wire. It is convenient to create a data file library for them for quick selection while inputting design data.

Soft-Magnetic Materials

The stator and the rotor iron cores in the electric machine are generally laminated with punched sheets of nonlinear soft-magnetic silicon steel. Some special types of electric machines, such as moment motor, turbo-generator etc., use integrated solid rotor iron core of soft-magnetic material. For magnetic field analysis and core loss analysis of the electric machine, the magnetization characteristics (**B-H Curve**) and the loss characteristics (**B-P Curve**) of the iron-core material must be defined. The dialog boxes to do so are accessed from the **View/Edit Material** window, which, in turn is accessed from the **Edit Libraries** window. Access to the window for editing the B-H curve is enabled when you set the Magnetic Permeability value to nonlinear (rather than simple or Anisotropic). When you set the value to nonlinear, the value field changes to a B-H Curve button. Click the B-H curve button to open the window.

For the loss characteristics (B-P Curve), you first set the **Core Loss Model** of the material to **Electrical Steel** (rather than **None** or **Power Ferrite**) as a material property in the **View/Edit Material** window. When you do so, this enables the **Calculate Properties** selection for drop down

at the bottom of the window. Select **Core Loss Coefficient** from the drop down menu to open the B-P Curve window.

Adding New Materials to an RMxprt Project

You can add a new material to a project or to the global user-defined material library. To make the new project material available to all projects, you must export the material to a global user-defined material library.

To assign a material to an object:

1. Click **Tools>Edit Libraries>Materials**.
   - In the project tree, you can also right-click **Materials**, and select **Edit Library**.

   The **Edit Libraries** dialog box appears.
1. Click **Add Material**.

   The **View/Edit Material** dialog box appears.
2. Type a name for the new material in the **Material Name** text box.
3. In the **View/Edit Material for** section, select whether this material should be available for the **Active Design** only, for **This Product** only or for **All Products**. The selection makes a difference in the properties displayed.

Note	When you select certain **Type** or **Value** options, additional parameters appear beneath some properties in the same way that **Magnitude** appears beneath **Magnetic Coercivity**. As necessary, specify values for any additional parameters that appear.

4. In the **Properties of the Material** table, specify the **Type** and the **Value** for the following material properties, displayed when **Active Design** is selected:
   - Relative Permeability.
   - Bulk Conductivity
   - Magnetic Coercivity (including the Magnitude of the vector)

- Core Loss Model - model selections for this property may enable access to coefficient calculation windows, and enable additional properties.
- Mass Density

If you select **This Product**, additional fields are displayed.

- Relative Permittivity
- Dielectric Loss Tangent
- Magnetic Loss Tangent
- Composition

5. Optionally, change the **Units** for any of the properties.
6. Click **Validate Material** to verify the settings you have specified are valid for the existing properties.
   If the material setup is valid, a green check mark appears below the **Validate Material** button.
7. Click **OK** to save the new material.
   The **Edit Libraries** dialog box reappears, with the new material added to the list of materials.
8. Click **OK** to close the **Edit Libraries** dialog box.

Relative Permittivity for an RMxprt Material

Specify the following for Relative Permittivity and specify the units.

Type	Value
Simple	Type a value for the **Relative Permittivity**.
Anisotropic	The following two parameters appear: • T(1,1) • T(2,2) Type a simple value for each.
Nonlinear	The material's relative permittivity varies according to its associated D-E curve. **Note** Not valid in RMxprt.

Note	This property is not used in RMxprt design analysis, but it will be transferred to Maxwell 3D Design automatically when the design is created by RMxprt.

Relative Permeability for a Maxwell or RMxprt Material

Select one the following for relative permeability and specify the units:

Type	Value
Simple	Type a value for the **Relative Permeability**.
Anisotropic	The following parameters appear: • T(1,1) • T(2,2) • T(3,3) Select either a **Simple** or **Nonlinear** Type for each of these parameters.
Nonlinear	Click **BH Curve**, and specify the coordinates for the BH-curve (or curves if multiple temperature dependencies are used) in the BH Curve dialog box. Also enables X, Y, and Z Component unit vector fields for Magnetic Coercivity.

Note	The Anisotropic type is not used in RMxprt design.

Specifying BH Curves for Nonlinear Relative Permeability

For Maxwell 2D and 3D eddy current, magnetostatic and transient solution types, when you define a new material or edit an existing material with a nonlinear relative permeability in the **View/Edit Materials** window, you need to specify the magnetization characteristics using BH curves.

You can also model temperature dependencies of the nonlinear material property by providing two or more temperature-dependent BH curves. For temperature dependencies of permanent magnetic materials, refer to *Interpolation of Temperature-Dependent Demagnetization Curves*.

Note	The thermal modifier for permeability is disabled when temperature-dependent BH curves are specified.

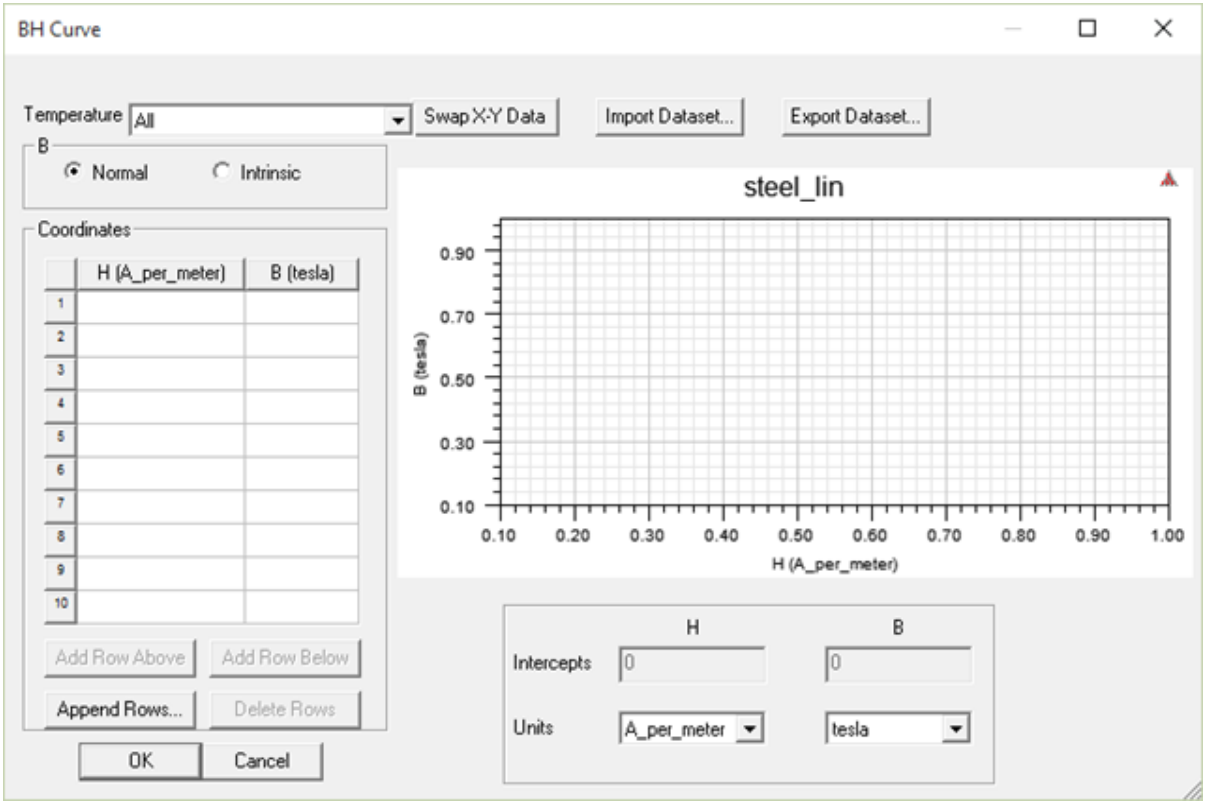
If a user-input BH curve is used without smoothing, the non-smoothed BH curve is treated as piece-wise linear between user-input data points inside the software, which may cause nonlinear convergence issues. However, if you chose to use a smoothed BH curve constructed by the software, the operating point may not exactly reside on the user-input BH curve. **Smooth BH curve** is not selected by default. You can select it from the **Solve Setup**, on the **Solver** panel. For isotropic nonlinear materials, you can force Maxwell to use the original user-input data points without smoothing by software by clearing the **Smooth BH Curve** option.

1. Open the **View / Edit Materials** dialog from the **Edit Materials** window either by:
   - Selecting an existing material that you need to edit, and click **View / Edit Material**.
   - Clicking **Add Material.**

   Either of these actions open the **View/ Edit Materials** dialog box.
2. For the **Relative Permeability** property do one of the following (depending on the type of material you are defining):
   - Select **Nonlinear** as the **Type**. A **B-H Curve** button appears in the **Value** column.
   - Select **Anisotropic** as the **Type** to display the additional parameters: **T(1,1)**, **T(2,2)**,

T(3,3). Selecting **Nonlinear** for any of these additional parameters also causes a **B-H Curve** button to appear in the **Value** columns.

3. You can Input BH curve(s) by clicking a **B-H Curve** button to open the **BH Curve** dialog box.



4. Set the **Units** for **H** and **B** by selecting from the drop down menus. If temperature-dependent BH curves are used, the selection of units applied to all of the temperature-dependent curves
5. Choose the type of curve you want to define by selecting either **Normal** or **Intrinsic**.

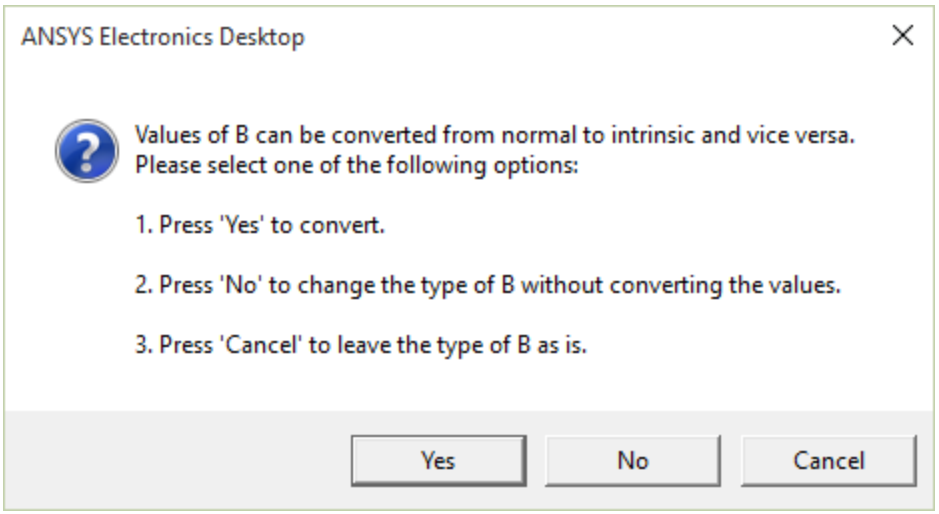
Note	Selection between **Normal** or **Intrinsic** BH curve is not supported when temperature-dependent BH curves are used. Temperature-dependent curves are restricted to the type **Normal**.

For a material property without an existing BH curve definition, the dialog opens with an empty list of coordinates and the default type will be **Normal**. For a property with existing BH curve definition, the selected radio button corresponds to the existing B type.

Note	• The **Intrinsic** BH curve is supported only in Maxwell 2D/3D magnetostatic, eddy current, and transient design types. A material property defined using an Intrinsic BH curve will fail validation check in all the other product/design types. • When an **Intrinsic** BH curve is added, the **Relative Permeability Value**

	button label in the **View/Edit Material** dialog box changes to **Bi-H Curve** as visual indication of the type of curve currently defined for the material.

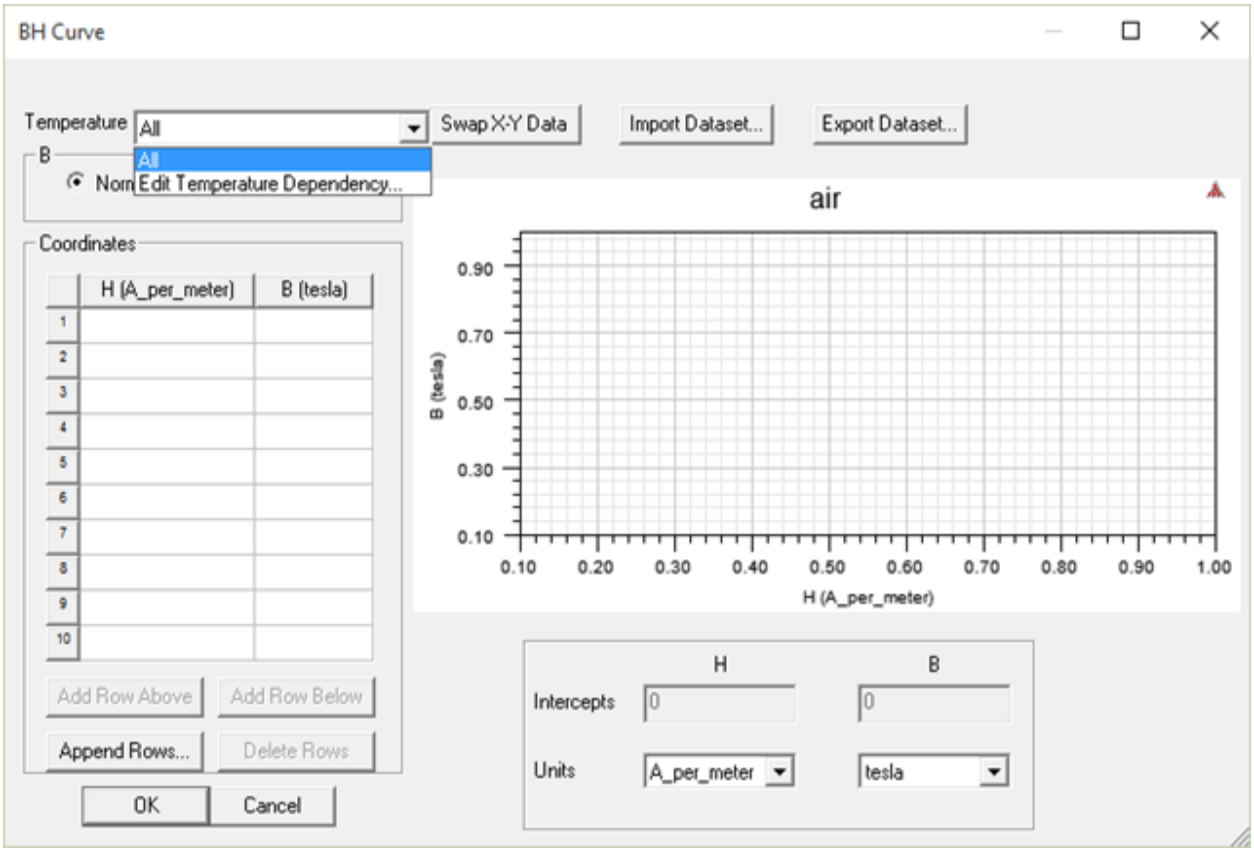
You can change the type at any time. For an existing curve, validation checks are performed on the coordinate list when you attempt to change the type. If the data is not valid, an error message will be displayed and the type of B will not be changed. If data is valid, a query dialog box displays asking if the coordinates should be converted.



Pressing **No** can be used, fer example, when users have specified the BH coordinates and then realize they haven't select the desired type.

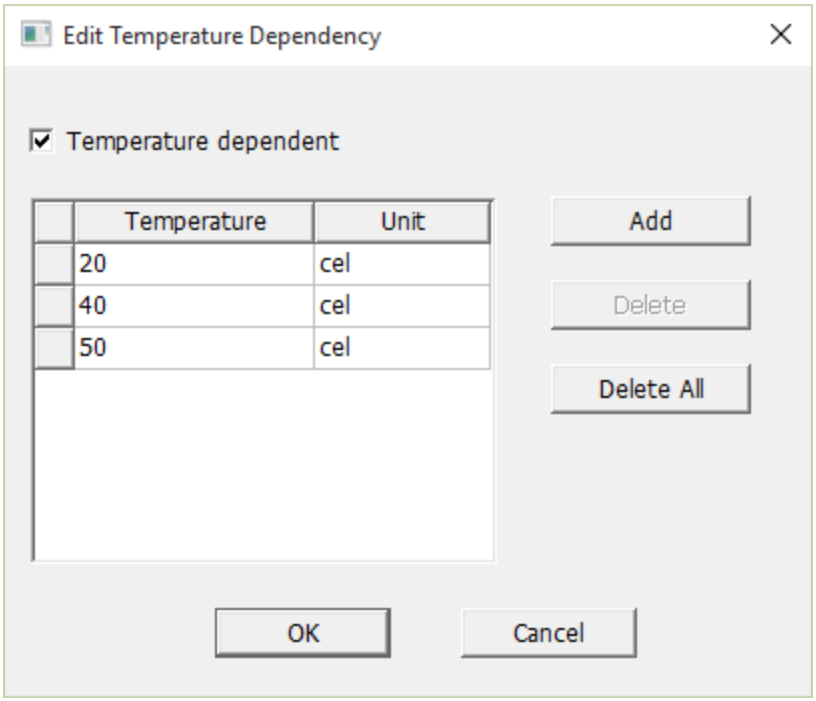
Note	Changing the type of the BH curve invalidates all solution data

6. The initial selections in the **Temperature** drop-down menu include **All** and **Edit Temperature Dependency…**.



The default selection is **All**, which means the BH curve applies to all temperatures – in other words, the BH curve is *not* temperature dependent. For this case, continue with step 8.

7. Optionally, for Maxwell 2D and 3D eddy current, magnetostatic and transient solution types, you can model temperature dependencies of the nonlinear material property by providing multiple temperature-dependent BH curves. At least two BH curves must be defined when using this feature. If you want to change the **Temperature** setting to specify temperature-dependent BH curves:
    a. Select **Edit Temperature Dependency** to open the Edit Temperature Dependency dialog box.



b. Use the **Add** button to add rows to the table. In each row, enter the desired **Temperature**, and select the appropriate **Unit**. The **Delete** button can be used to remove selected rows from the table. **Delete All** removes all of the rows.

c. Check **Temperature dependent** to enable temperature-dependent BH curves to be added.

d. Click OK to return to the **BH Curve** dialog box.

The **Temperature** drop-down now lists all of the temperatures you specified above. Select the one for which you want to enter B and H coordinate values in the following step. Also, a **Show all curves** check box is now present. Checking this enables all of the BH curves to be displayed simultaneously.

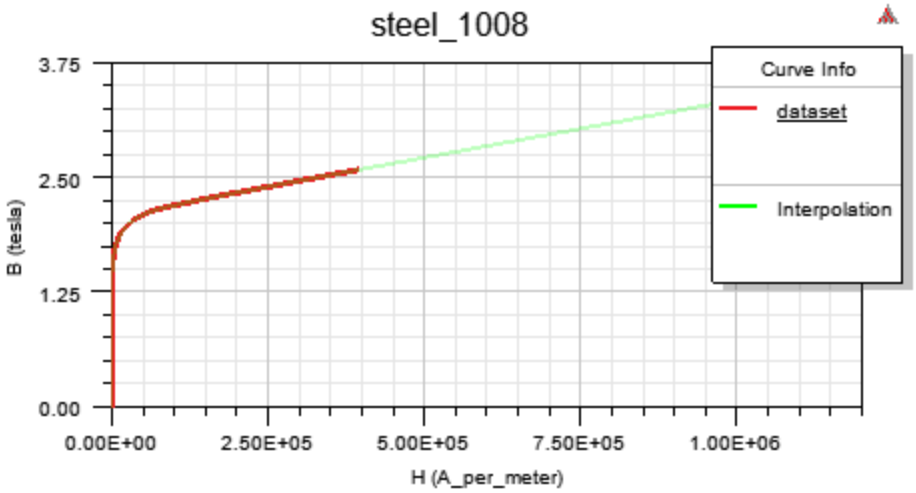
e. Select the temperature for which you want to add (or edit) BH curve values, then continue with the next step.

8. Enter B and H values in each row of the **Coordinates** table. Placing the cursor in a table cell enables the **Add Row Above**, **Add Row Below**, and **Delete Rows** buttons. **Append Rows** allows you to specify the number of rows to append to the table.

Note	• When using temperature-dependent BH curves, the settings in the BH Curve dialog apply to the currently selected temperature value. • When adding (or editing) temperature-dependent BH curves, repeat this step for each specified temperature as needed.

Note the following requirements for creating a valid curve:

- For a **Normal** BH curve, the slope of the curve can not be less than that of free space anywhere along the curve.
- For an **Intrinsic** BH curve, the slope of the curve can not be less than 0.
- The value of B must increase along the curve.
- The initial value of B must be 0 (zero).
- Since BH operating points in the FEA solution may extend beyond the input BH data set, the BH data set is extrapolated in Maxwell. The slope of the last two user-defined data points is used to extrapolate the BH curve, and thus should be as close to μ_0 as possible.
- The data points representing the BH curve should have enough points for accurate representation of the curve. Twenty (20) or more points should be specified with increased representation on the "knee" of the curve.
- Normal BH curves with a positive B value at the first point will be extrapolated (interpolation). Intrinsic curves are not extrapolated.



As you enter values, the graph is updated. If you are using multiple temperature-dependent BH curves, a **Show all curves** check box is present. Checking this box enables all of the temperature-dependent BH curves to be displayed simultaneously.

- Optionally, click **Import Dataset** to import BH curve data from a file, and if they are in the wrong columns, click **Swap X-Y Data** to switch the B values and H values in the graphics display. You can also use the SheetScan tool to extract curve data from sources such as manufacturer datasheets to a dataset, which can then be exported to a tab-delimited file, and imported via **Import Dataset**. (Refer to *Adding Datasets* and *Exporting Datasets* for related information on working with datasets. Refer to *Using SheetScan* for working with the SheetScan tool.)

Note	When using temperature-dependent BH curves, selecting **Import Dataset** will import a single curve for the currently selected temperature.

9. When finished entering data, click **OK** to close the window.

   An error message displays if a slope is out of tolerance, identifying the data points between which the slope is less than that of free space. Out of tolerance data points must be corrected before you can successfully exit the dialog box. If the slope of the last two points is more than twice the permeability of free space, a warning message is issued during the solution. The slope of the last 2 points should be as close to μ_0 as possible to represent a fully saturated material.

The BH curve (or curves if multiple temperature dependencies are used) you have defined is associated with the Relative Permeability property of the material.

Note	When an **Intrinsic** BH curve is added, the **Relative Permeability Value** button label changes to **Bi-H Curve** as visual indication of the type of curve currently defined for the material.

Assigning Material Property Types

Temperature-Dependent BH Curves

Temperature-Dependent BH Curves

While a material's temperature dependency can be specified via the thermal modifier, which is described in terms of a mathematical expression, this might not be good enough for applications where it is difficult to describe the temperature dependency in terms of an expression. For such cases, an alternative method is available to let users directly input data for multiple, temperature-dependent, BH curves. Maxwell uses this data to derive a corresponding BH curve for each specified temperature using an interpolation algorithm as follows:

Suppose there are m temperature dependent curve inputs in the form of:

$$T_0 :: \quad (0,0), (h_{01},\ b_{01}) \cdots\cdots (h_{0i},\ b_{0i}) \cdots\cdots (h_{0N_0},\ b_{0N_0})$$

$$\cdots\cdots\cdots\cdots\cdots$$

T_k :: $(0,0), (h_{k1},\ b_{k1}) \cdots\cdots (h_{ki},\ b_{ki}) \cdots\cdots (h_{kN_k},\ b_{0N_k})$

$\cdots\cdots\cdots\cdots\cdots$

T_m : : $(0,0), (h_{m1},\ b_{m1}) \cdots\cdots (h_{mi},\ b_{mi}) \cdots\cdots (h_{mN_m},\ b_{mN_m})$

Where T_0 , T_k *and* T_m ... $(T_0 < T_k < T_m)$ are reference temperatures at which BH curves were measured.

The number of *(b,h)* pairs in each BH curve can be different.

In Maxwell, if the local temperature of temperature-dependent nonlinear magnetic material is *T*.. $(T_k < T < T_{k+1})$, the local BH curve can be obtained by interpolation:

If $T \le T_0$, BH curve input at temperature T_0 is applied.

If $T \ge T_m$, BH curve input at temperature T_m is applied.

If $T_k < T < T_{k+1}$, $(h_i,\ b_i)$ pairs are calculated as:

For a given h_i , $b_{k,i}$ *and* $b_{k+1,\ i}$ are magnetic flux densities obtained from inputted BH curves at temperatures T_k *and* T_{k+1} , and b_i is obtained by interpolation:

$$b_i = b_{k,i} + \frac{T - T_k}{T_{k+1} - T_k}(b_{k+1,i} - b_{k,i})$$

Note	Thermal modifier for permeability is disabled when temperature-dependent BH curves are specified.

Set Ambient Temperature

Interpolation of Temperature-Dependent Demagnetization Curves

For an intrinsic demagnetization curve at reference temperature T_0 expressed by a data set (h_i, b_i), the demagnetization curve at temperature *T* can be derived by scaling *h* and *b* independently as (h_i•*Q*(*T*), b_i•*P*(*T*)), where temperature dependent scaling factors *P*(*T*) and *Q*(*T*) can be specified via the thermal modifier. This algorithm, called shape preserving algorithm, can be found in *Temperature Dependent Nonlinear Permanent Magnets.* However, this mathematical expression might not be good enough for applications where it is difficult to describe the temperature dependency in terms of an expression. In addition, the measured multiple temperature-dependent intrinsic demagnetization curves might not be shape-preserved in some materials. For such cases, an alternative method is available to let users directly input data for multiple temperature-

dependent demagnetization curves. Maxwell uses this data to derive a corresponding demagnetization curve for a specified temperature using an interpolation algorithm as follows.

Suppose there are *m* inputs of temperature-dependent intrinsic demagnetization curve in the form of:

$$T_0 :: (h_{ci\_0},\ 0), (h_{01},\ b_{01}) \cdots\cdots (h_{0i},\ b_{0i}) \cdots\cdots (0,\ b_{0N_0})$$

$$\cdots\cdots\cdots\cdots\cdots$$

$$T_k :: (h_{ci\_k},\ 0), (h_{k1},\ b_{k1}) \cdots\cdots (h_{ki},\ b_{ki}) \cdots\cdots (0,\ b_{kN_k})$$

$$\cdots\cdots\cdots\cdots\cdots$$

$$T_m :: (h_{ci\_m},\ 0), (h_{m1},\ b_{m1}) \cdots\cdots (h_{mi},\ b_{mi}) \cdots\cdots (0,\ b_{mN_m})$$

Where T_0 , T_k *and* T_m ... $(T_0 < T_k < T_m)$ are reference temperatures at which demagnetization curves were measured. The flux density of the end point b_{kN_k} is the residual b_{r_k} for curve *k*.

The number of (h_{ki}, b_{ki}) points, N_k +1, in each demagnetization curve can be different.

In Maxwell, if the local temperature of temperature-dependent nonlinear magnetic material is *T*.. $(T_k < T < T_{k+1})$, the local demagnetization curve can be obtained by interpolation:

If $T \le T_0$, the demagnetization curve at temperature T_0 is returned as the interpolated demagnetization curve.

If $T \ge T_m$, the demagnetization curve at temperature T_m is returned as the interpolated demagnetization curve.

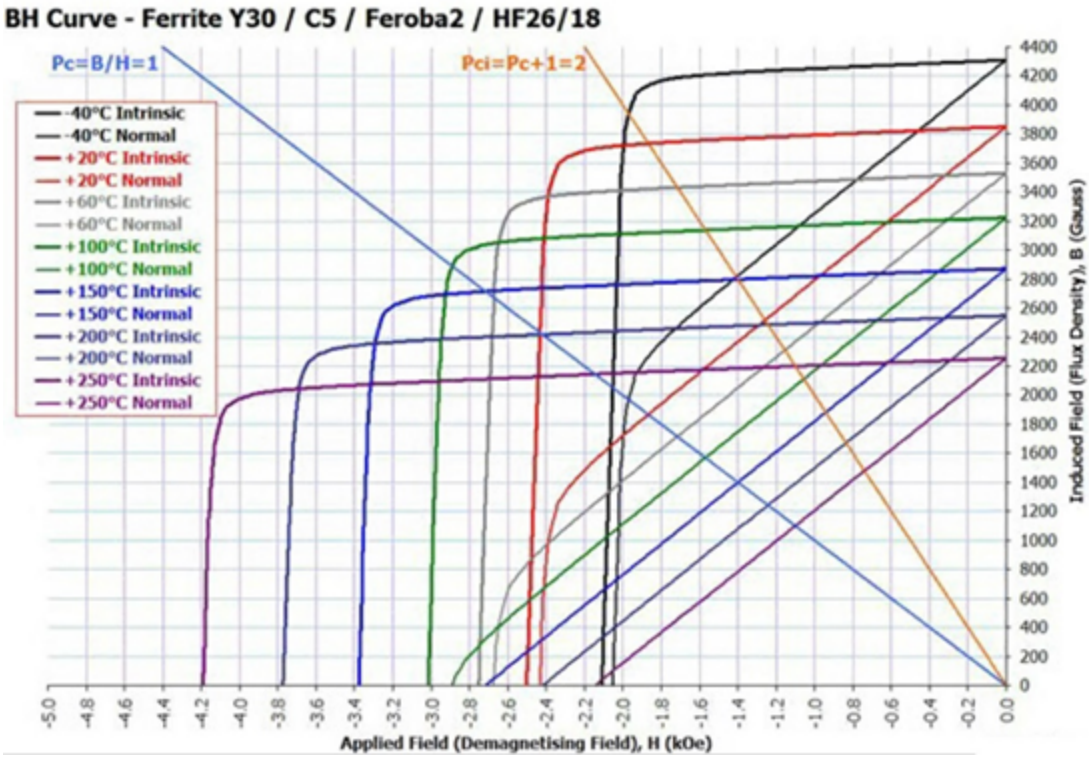
If $T_k < T < T_{k+1}$, the interpolated demagnetization curve at temperature T can be derived by following steps:

1. Get temperature interpolating coefficient: $c_T = (T - T_k) / (T_{k+1} - T_k)$.
2. Get interpolated intrinsic coercivity: $h_{ci} = (1 - c_T)\ h_{ci\_k} + c_T\ h_{ci\_k+1}$.
3. Get interpolated residual: $b_r = (1 - c_T)\ b_{r\_k} + c_T\ b_{r\_k+1}$.
4. Derive demagnetization curve at temperature *T* using shape preserving algorithm based on the curve at T_k, which is expressed as $(h_{ki} \cdot Q_0,\ b_{ki} \cdot P_0)$, where $Q_0 = h_{ci} / h_{ci\_k}$, and $P_0 = b_r / b_{r\_k}$.
5. Derive demagnetization curve at temperature *T* using shape preserving algorithm based on the curve at T_{k+1}, which is expressed as $(h_{k+1\_i} \cdot Q_1,\ b_{k+1\_i} \cdot P_1)$, where $Q_1 = h_{ci} / h_{ci\_k+1}$, and $P_1 = b_r / b_{r\_k+1}$.
6. Derive the weighted average curve from the curve expressed by $(h_{ki} \cdot Q_0,\ b_{ki} \cdot P_0)$ and the curve expressed by $(h_{k+1\_i} \cdot Q_1,\ b_{k+1\_i} \cdot P_1)$ with weighting factors of $(1 - c_T)$ and c_T, respectively.

We can input temperature-dependent demagnetization curves in both normal and intrinsic formats. When normal demagnetization curves are input, we will transfer them to intrinsic curves

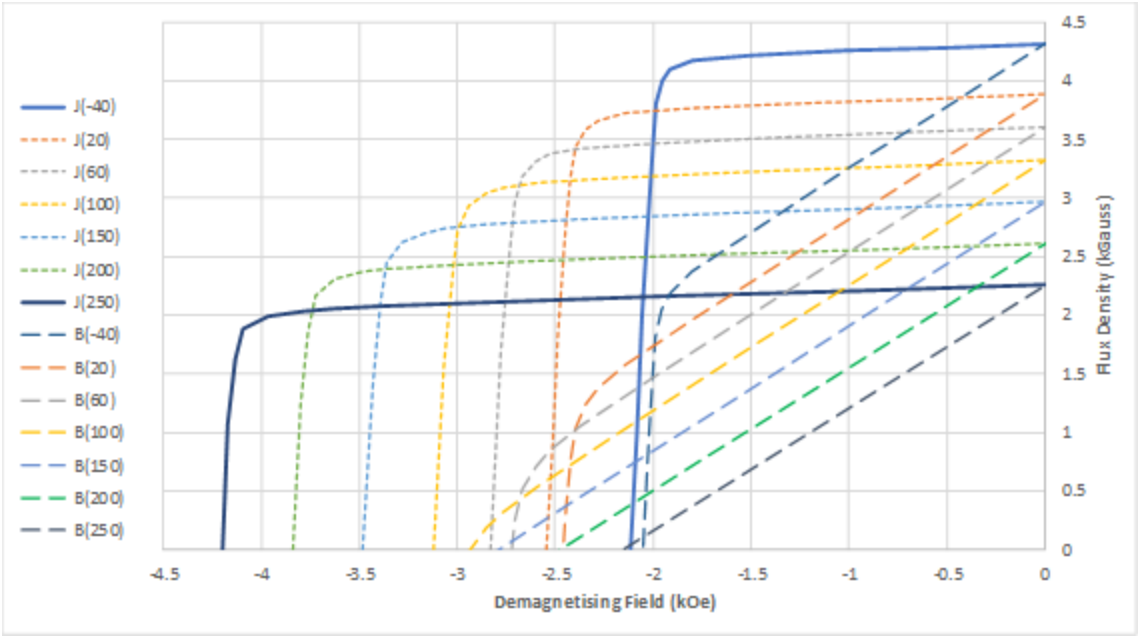
and extend them with additional estimated data sets. Since the extended curve parts are approximated, it is suggested to directly input intrinsic curves with different temperatures as basic curves for interpolation, if they are available.

For example, the material Ferrite Y30 has BH curves with Br decreasing and Hci increasing as temperature increasing, as shown below.



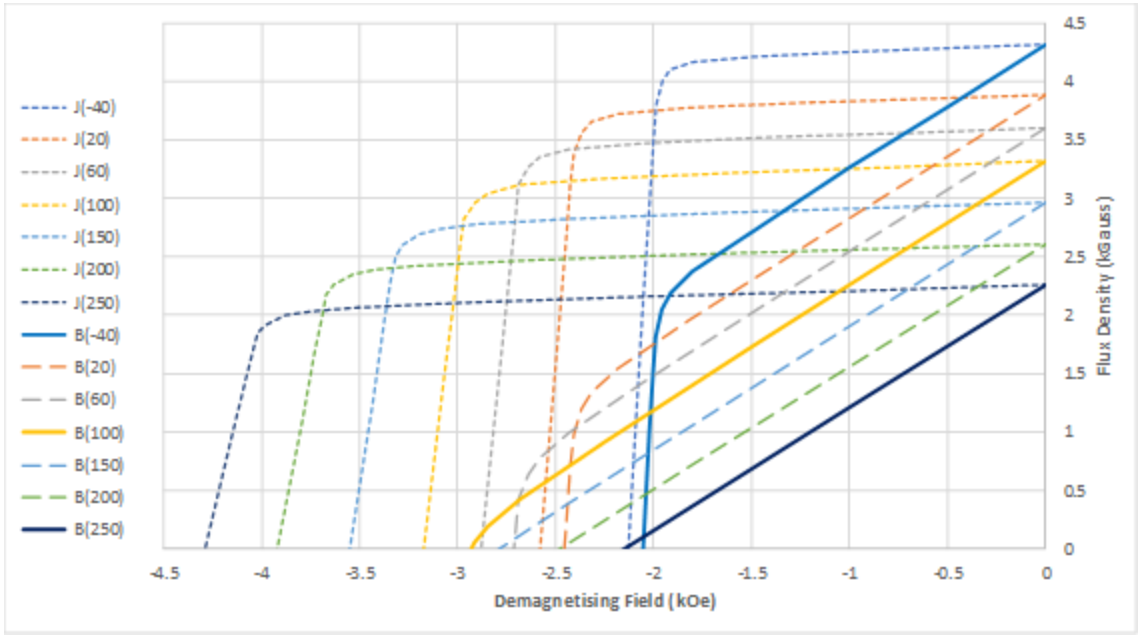
Temperature-dependent BH curves for Ferrite Y30

If we input two intrinsic curves of the minimum and maximum temperatures, we can interpolate the intrinsic curves of other temperatures, and derive normal curves, as shown below.



Input two intrinsic curves in (solid lines)
Interpolated intrinsic curves (short-dashed lines)
Derived normal curves (long-dashed lines)

If intrinsic curves are not available, we need to input three normal curves with minimum and maximum temperatures, as well as the curve with maximum Hc. In such cases, the estimated and interpolated intrinsic curves, and derived normal curves, are as shown below.



Input three normal curves (solid lines) Estimated and interpolated intrinsic curves (short-dashed lines) Derived normal curves (long-dashed lines)

Note: Thermal modifier for permeability is disabled when temperature-dependent BH curves are specified.

Temperature Dependent Nonlinear Permanent Magnets

Bulk Conductivity for an RMxprt Material

Specify the following for bulk conductivity and specify the units:

Type	Value
Simple	Type a value for the **Bulk Conductivity**.
Anisotropic	The following parameters appear: • T(1,1) • T(2,2) You can enter a simple value for each of these parameters. **Note** The Anisotropic type is not used in RMxprt designs.
Nonlinear	The material's bulk conductivity varies according to its associated J-E curve. **Note** The Nonlinear type is not used in RMxprt designs.

Dielectric Loss Tangent for RMxprt Material

Specify the following for dielectric loss tangent.

Type	Value
Simple	Type a value for the**Dielectric Loss tangent**.
Anisotropic	The following two parameters appear: • T(1,1) • T(2,2) Type a simple value for each.

Note	This property is not used in RMxprt design analysis, but it will be transferred to Maxwell 3D Design automatically when the design is created by RMxprt.

Magnetic Loss Tangent for RMxprt Material

Type	Value
Simple	Type a value for the **Bulk Conductivity**.
Anisotropic	The following two parameters appear: • T(1,1) • T(2,2) Type a simple value for each.

Note	This property is not used in RMxprt design analysis, but it will be transferred to Maxwell 3D Design automatically when the design is created by RMxprt.

Magnetic Coercivity for Maxwell and RMxprt Materials

Specify the following for magnetic coercivity and specify the units:

Type	Value
Vector	Appears by default. • If the Relative Permeability Type is either **Simple** or **Anisotropic**, enter a **Value** for the **Magnitude**. • If the Relative Permeability Type is Nonlinear, Magnitude becomes uneditable, and three additional fields of Type **Unit Vector**: **X Component**, **Y Component**, and **Z Component** appear in which you can enter values or specify functions.

Core Loss Model for an RMxprt Material

Specify the following for core loss type and specify the units:

Name	Value
None	No core loss is to be calculated for this material.
Electrical Steel	The following parameters appear: • **Kh** • **Kc**

	• **Ke** **Note** Selecting **Electrical Steel** also enables the Calculate Properties for Core Loss Coefficient pull-down list item at the bottom of the dialog box.
Power Ferrite	The following parameters appear: • **Cm** • **X** • **Y** **Note** Selecting **Power Ferrite** also enables the Calculate Properties for Core Loss versus Frequency pull-down list item at the bottom of the dialog box.

Calculating Properties for Core Loss in RMxprt (BP Curve)

To be able to extract parameters from the loss characteristics (B-P Curve), you first set the **Core Loss Model** of the material to Electrical Steel as a material property in the **View / EditMaterial** window.

To calculate core loss properties for an electrical steel material:

1. Click **Tools>Edit Libraries>Materials**.
   - Or in the project tree, you can also right-click **Materials**, and select **Edit Library**.

   The **Edit Libraries** window appears.
1. Click **Add Material**.

   The **View/Edit Material** window appears.
2. In the **Core Loss Type** row, select **Electrical Steel** from the **Value** pull-down list.

   This enables the **Calculate Properties for** pull-down menu at the bottom of the dialog box with the following two choices:
   - **Calculate Properties for: Core Loss at One Frequency**
   - **Calculate Properties for: Core Loss versus Frequency**

   It also displays parameters associated with Electrical Steel materials.

Electrical Steel Core Loss from a Single-Frequency Loss Curve

With the **Core Loss Type** set to Electrical Steel:

1. Select **Core Loss at One Frequency** from the **Calculate Properties for:** pull-down menu.

   The **BP Curve** window appears.
2. Do one of the following to specify a BP curve:

- Import the curve from a saved file.
- Enter the coordinates manually.

Note	The accuracy in inputting the data for B-P Curve for the electrical steel material has significant effect on the correctness of the analyses to the electromagnetic characteristics of the electric machine. You should input the data for B-P Curve according to the accurate data provided by the manufacturers of materials.

3. Select the units in which the B-P curve is measured from the **Core Loss Unit** pull-down list.
4. Type values and select units for the following:
   - Mass Density
   - Frequency
   - Thickness
   - Conductivity

   The following parameters are dynamically updated with both the specified unit and the standard unit (w/m^3) as the input data changes.
   - **Kh** -Hysteresis
   - **Kc** - Classical Eddy
   - **Ke** - Excess
5. Click **OK**.

   The **View/Edit Material** dialog box reappears. The property values fro **Kh**, **Kc**, and **Ke** are updated as new default values.

Computation of Core Loss from a Single-Frequency Loss Curve

The principles of the computation algorithm are summarized as follows.

The iron-core loss is expressed as:

$$p_v = p_h + p_c + p_e$$

$$= K_1 B_m^2 + K_2 B_m^{1.5}$$

where the eddy-current loss is

$$p_c = k_c (f B_m)^2$$

the hysteresis loss is

$$p_h = k_n f B_m^2$$

and the excessive loss is

$$p_e = k_e (f B_m)^{1.5}$$

Therefore

$$K_1 = k_h f + K_c f^2$$
$$K_2 = k_e f^{1.5}$$

The classical eddy-current loss coefficient is calculated directly as

$$k_c = \pi^2 \sigma \frac{d^2}{\delta}$$

where σ is the conductivity and *d* is the thickness of one lamination sheets.
Minimize the quadratic form to obtain K_1 and K_2.

$$err(K_1, K_2) = \sum_i \left[p_{vi} - \left(K_1 B_{mi}^2 + K_2 B_{mi}^{1.5} \right) \right]^2 = min$$

where P_{vi}, B_{mi} – the i-th point of the data on the loss characteristics curve.

The other two loss coefficients are obtained as

$$k_h = \frac{K_1 - k_c f_0^2}{f_0}$$

$$k_e = \frac{K_2}{f_0^{1.5}}$$

where f_0 is the testing frequency for **B-H Curve**.

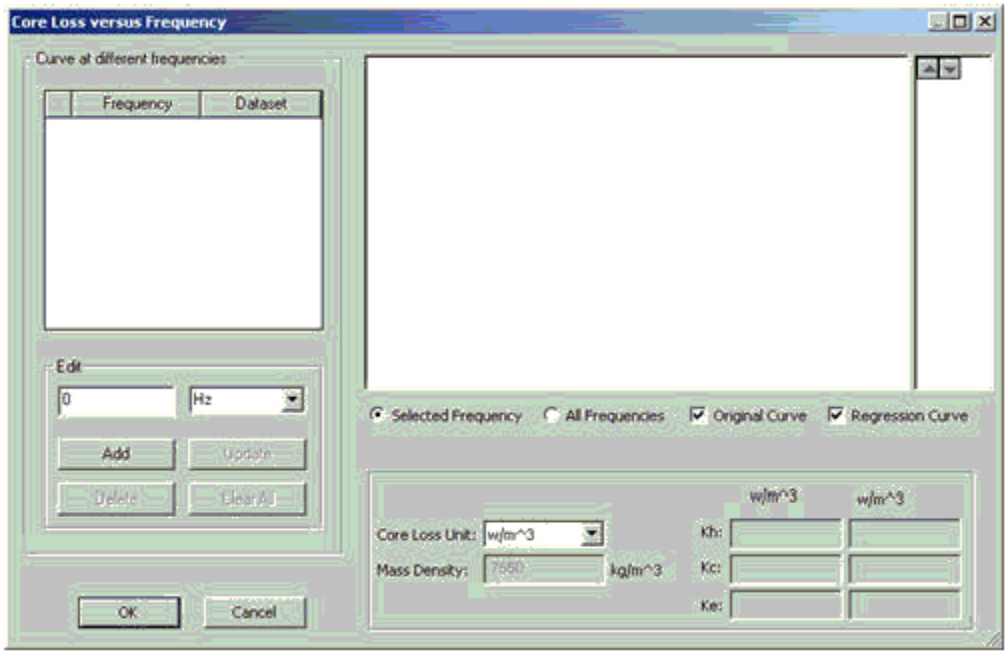
Electrical Steel Core Loss from Multi-Frequency Loss Curves

With the **Core Loss Type** set to Electrical Steel:

1. Select **Core Loss versus Frequency** from the **Calculate Properties for:** pull-down menu.

   The **Core Loss versus Frequency** window appears as shown:



2. Using the Edit area, **Add** frequency points at which a dataset is available for the Core Loss.
3. For each Dataset added, click the **Edit Dataset** button to launch the Edit Dataset dialog.
4. Add Dataset information for the frequency by manually entering the data or importing the data from a table. Click **OK** to accept the dataset and return to the **Core Loss versus Frequency** dialog box. Continue adding dataset information until all frequencies have datasets defined.
5. Click **OK** when all frequencies have valid data to complete the core loss calculation and return to the **View/Edit Material** dialog.

Computation of Core Loss from Multi-Frequency Loss Curves

The principles of the computation algorithm are summarized as follows.

The iron-core loss is expressed as:

$$p_v = p_h + p_c + p_e$$

$$= k_h f B_m^2 + k_c (f B_m)^2 + k_e (f B_m)^{1.5}$$

Minimize the quadratic form to obtain k_h , k_c and k_e directly.

$$err(k_h, k_c, k_e) = \sum_{i=1}^{m} \sum_{j=1}^{n_i} \left[p_{vij} - \left(k_h f_i B_{mij}^2 + k_c f_i^2 B_{mij}^2 + k_e f_i^{1.5} B_{mij}^{1.5} \right) \right]^2 = min$$

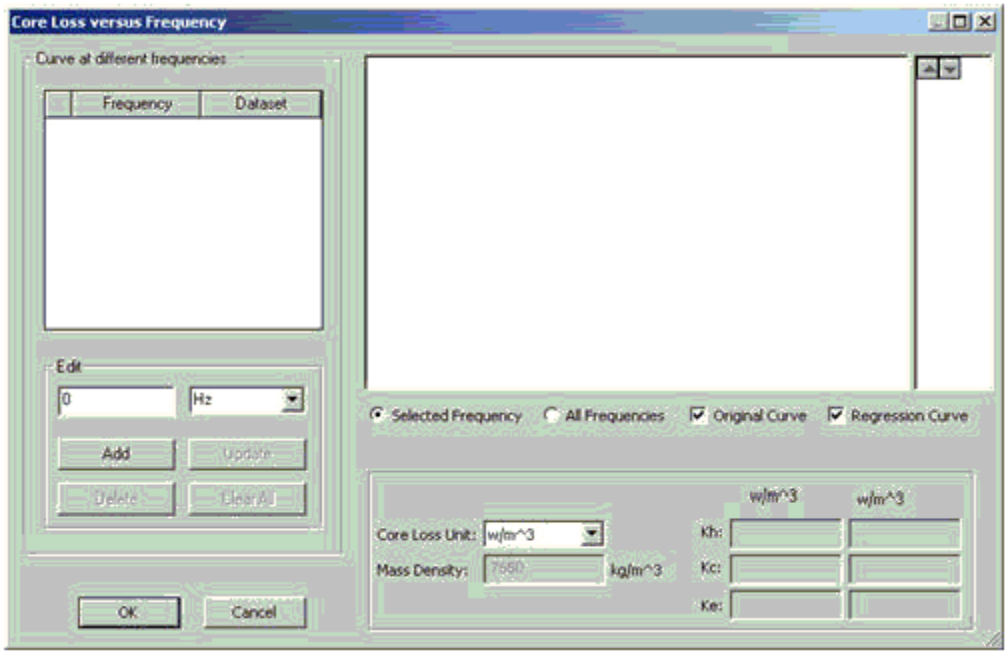
where m - the number of loss curves, n_i - the number of points of the i-th loss curve, and $P_{vij} = f(f_i, B_{mij})$ - two dimensional lookup table for multi-frequency loss curves.

Power Ferrite Core Loss from Multi-Frequency Loss Curves

With the **Core Loss Type** set to Power Ferrite:

1. Select **Core Loss versus Frequency** from the **Calculate Properties for:** pull-down menu.

   The **Core Loss versus Frequency** window appears as shown:



2. Using the Edit area, **Add** frequency points at which a dataset is available for the Core Loss.
3. For each Dataset added, click the **Edit Dataset** button to launch the Edit Dataset dialog.
4. Add Dataset information for the frequency by manually entering the data or importing the data from a table. Click **OK** to accept the dataset and return to the **Core Loss versus Frequency** dialog box. Continue adding dataset information until all frequencies have datasets defined.

5. Click **OK** when all frequencies have valid data to complete the core loss calculation and return to the **View/Edit Material** dialog.

Computation of Power Ferrite Core Loss from Loss Curves

The principles of the computation algorithm are summarized as follows.
The iron-core loss is expressed as:

$$p_v = C_m f^x B_m^y$$

or

$$\log(p_v) = c + x \cdot \log(f) + y \cdot \log(B_m)$$

where

$$c = \log(C_m)$$

Minimize the quadratic form to obtain *c*, *x* and *y*.

$$err(c,x,y) = \sum_{i=1}^{m} \sum_{j=1}^{n_i} [\log(p_{vij}) - (c + x \cdot \log(f_i) + y \cdot \log(B_{mij}))]^2 = min$$

where m - the number of loss curves, n_i - the number of points of the i-th loss curve, and $P_{vij} = f(f_i, B_{mij})$ - two dimensional lookup table for multi-frequency loss curves. Then C_m is calculated from the equation above.

Mass Density for RMxprt Material

Provide a Simple value for Mass density in kg/m^3.

Composition for RMxprt Material

Specify whether the composition is Solid or Lamination.

If Lamination, specify the:

- Stacking Factor - takes a simple value
- Stacking Direction - a drop down menu lets you select V(1), V(2), or V(3).

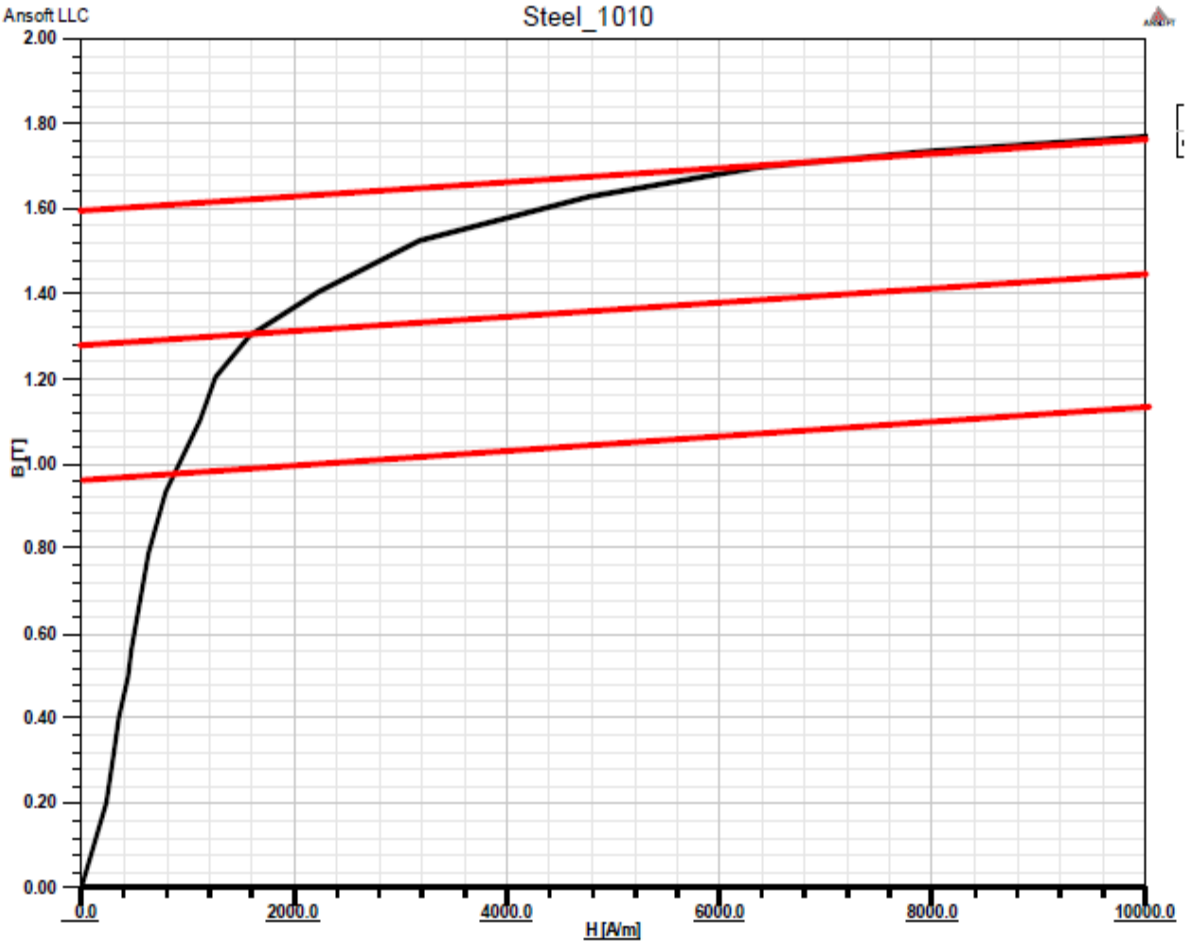
Note	This property is not used in RMxprt design analysis, but it will be transferred to Maxwell 3D Design automatically when the design is created by RMxprt.

Permanent Magnet Materials in RMxprt

A permanent magnet is defined as a material that generates a magnetic flux due to permanent magnetic dipoles in that material.

Compute Remanent Br from B-H curve

The value of the remanent Br of the individual element after the magnetization field is computed is determined in such a way: after having located the operating point on the original non-remanent B-H curve, draw a line which is parallel to the original recoil curve with the slope of $\mu_0\mu_r$ and passes the operating point, the intersection of this line with B-axis is the remanent Br as the result of the applied magnetization field.



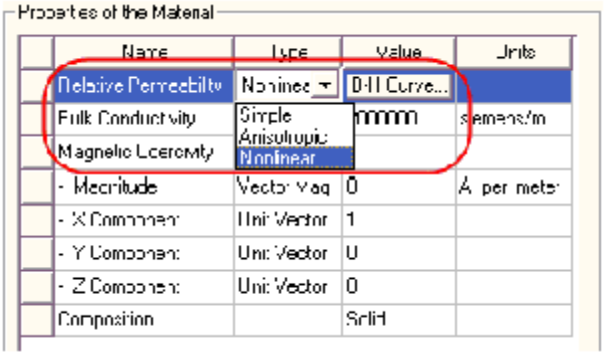
Calculating the Properties for a Non-Linear Permanent Magnet in RMxprt

Non-linear permanent magnet properties may be specified in one of two ways.

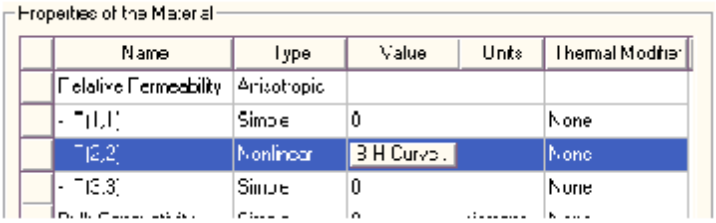
First, a BH curve may be input directly as follows:

1. Click the **View/Edit Materials…** button in the **Edit Libraries** dialog box.

   The **View/Edit Material** dialog box appears.
2. The nonlinear BH curve is defined by setting the **Relative Permeability** **Type** either to **Nonlinear** or **Anisotropic.**



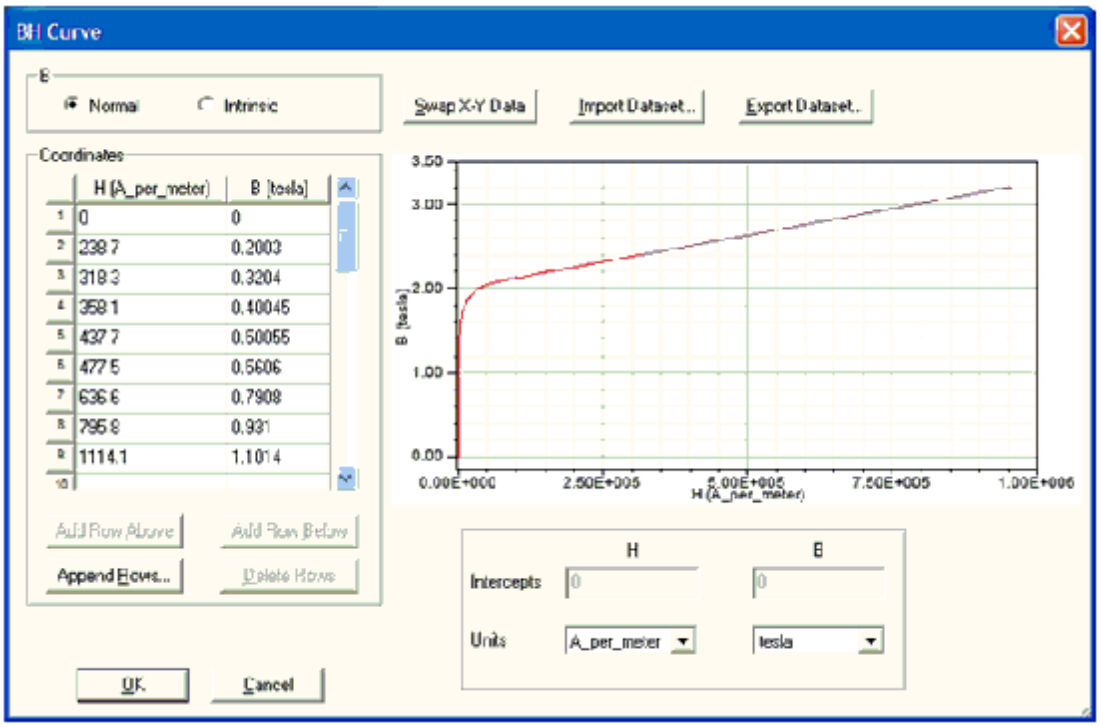
If you select Anisotropic, each of its components can be selected **Nonlinear** and can be specified by a **BH Curve**.



A **B-H Curve** button appears in the nonlinear property's **Value** column

3. Input the BH curve by clicking the **B-H Curve** button in the property **Value** column.

   This opens the **BH Curve** dialog box in which you can input (or modify) curve data. (Refer to *Adding Datasets* for general information on working with datasets.



- For a **Normal** BH curve, the slope of the curve can not be less than that of free space anywhere along the curve.
- For an **Intrinsic** BH curve, the slope of the curve can not be less than 0.

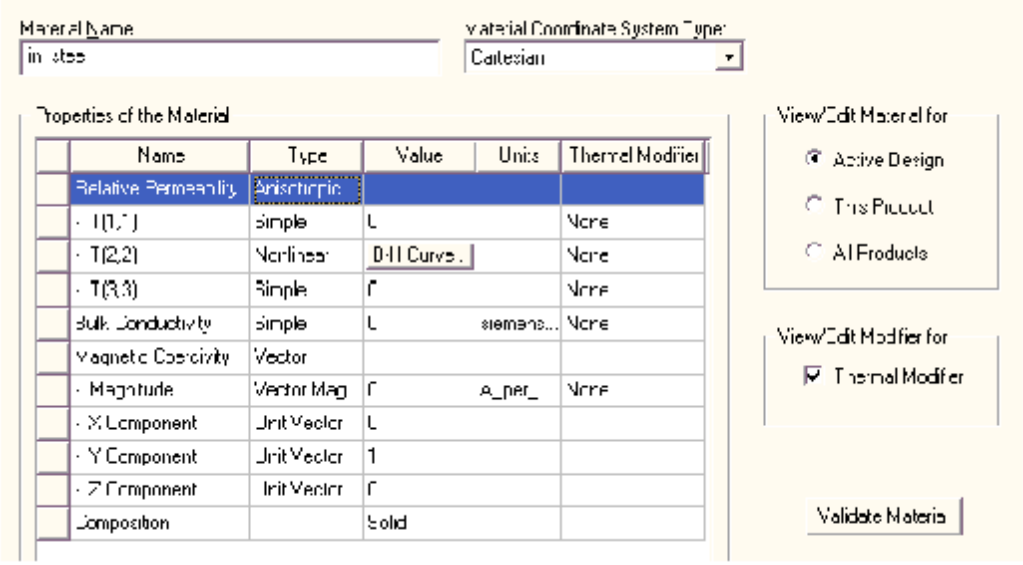
Note	• The **Intrinsic** BH curve is supported only in Maxwell 2D/3D magnetostatic and transient design types. A material property defined using an Intrinsic BH curve will fail validation check in all the other product/design types. • When an **Intrinsic** BH curve is added, the **Relative Permeability Value** button label changes to **Bi-H Curve** as visual indication of the type of curve currently defined for the material.

When you **OK** the dialog box, an error message displays if a slope is out of tolerance, identifying the data points between which the slope is less than that of free space.

The operations to input a nonlinear demagnetization curve are the same as entering a BH curve for Steel material. When a BH curve goes through the second quadrant or third quadrant, the curve is treated as a demagnetization curve.

4. To model *temperature dependency* for a nonlinear permanent magnet you must:
   - Use an **Intrinsic** BH curve to model the **Relative Permeability**
   - Specify a Thermal Modifier for both **Relative Permeability** and the **Magnitude** of **Magnetic Coercivity**. Apply a thermal Modifier by selecting the **Thermal Modifier** check box. Checking this box causes the **Thermal Modifier** column to display at the right side of the **Properties of the Material** table. Selecting **Edit** rather than **None** causes display

of the **Edit Thermal Modifier** dialog.



Alternatively, a non-linear BH curve can be modeled by the following four parameters:

- residual flux density B_r
- coercive field force H_c
- maximum energy product $(BH)_{max}$
- relative recoil permeability μ_r

From the V**iew/Edit Materials** window:

1. Set the **Relative Permeability** to **Nonlinear**.

   This enables the **Calculate Properties for...** drop down menu at the bottom of the window.
2. Click **Non-Linear Permanent Magnet** from the drop down menu.

   This displays the **Properties for Non-Linear Permanent Magnet** dialog box, which contains the following fields into which you enter the appropriate values.

Mur	Provide a value for relative permeability.
Hc	Coercive field force H_c in the units specified. Provide a value and select units from the drop down menu.
Br	Residual flux density B_r, in Tesla. If enabled, provide a value and select units from the drop down menu.
BH max	Maximum magnetic energy product $(BH)_{max}$ If enabled, provide a value and select units form the drop down menu.

3. Click **OK** to close the dialog and return to the **View/Edit Materials** window.

The values for **Relative Permeability** and **Magnitude** under **Magnetic Coercivity** are updated as new default values. Maxwell will create a lookup table based on the Four-Parameter Curve Fitting algorithm, and update the coordinates of the BH curve automatically as long as the input data of four parameters pass the validation check.

Calculating the Properties for a Linear Permanent Magnet
Temperature Dependent Nonlinear Permanent Magnets
Irreversible Demagnetization Due to Temperature Change

Calculating the Properties for a Linear Permanent Magnet

Edit a linear demagnetization curve is simple. From the V**iew/Edit Materials** window:

1. Set the **Relative Permeability** to **Simple**.
   This enables the **Calculate Properties for Permanent Magnet** drop down menu at the bottom of the window.
2. Click **Permanent Magnet** from the drop down menu.
   This displays the **Properties for Permanent Magnet** window. This contains the following fields.

Mu (enabled by default)	Provide a value.
Hc (enabled by default)	Coercive field force H_c in the units specified. Provide a value and select units from the drop down menu.
Br/Mp (disabled by default)	Checking this enables the radio buttons that let you specify either Br or Mp.
Br	Residual flux density B_r, in Tesla. If enabled, provide a value and select units from the drop down menu.
Mp	If enabled, provide a value and select units form the drop down menu.

3. Click **OK** to close the dialog and return to the **View/Edit Materials** window.

The values for **Relative Permeability** and **Magnitude** under **Magnetic Coercivity** are updated as new default values.

Note	The accuracy in inputting the characteristic parameters for the permanent-magnetic material has significant effect on the correctness of the analyses to the electromagnetic characteristics of the electric machine. It is suggested that users should input the characteristic parameters of the permanent-magnetic material according to the accurate data provided by the manufacturers of materials. **RMxprt** provides a few

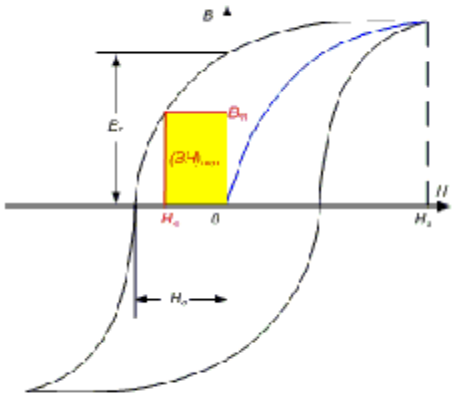
	characteristic parameters of permanent-magnetic materials for reference.

Using Demagnetization Curves

Many permanent magnet manufactures directly provide demagnetization curves for their products, but in most cases, manufactures provide some main parameters, such as residual flux density *Br*, coercive field force *Hc* and maximum magnetic energy product $(BH)_{max}$, and relative recoil magnetic permeability μ_r. This section and the next section describe the basic parameters for the demagnetization curve of permanent magnets and the curve fitting based on these parameters.

Hysteresis Loop

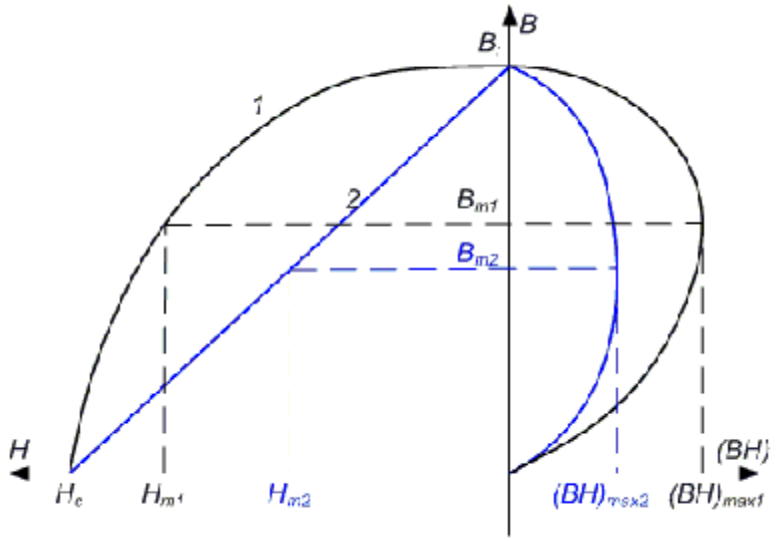
The permanent-magnetic material belongs to hard-magnetic material. It is characterized with "fat" hysteresis loop, which encloses large area as shown in the figure. When magnetized, it keeps high magnetic property with the external magnetic field removed, therefore is used in the permanent-magnet electric machine to produce magnetic field. The characteristics of the permanent-magnetic material are represented with its main parameters: residual flux density B_r, coercive field force H_c and maximum magnetic energy product $(BH)_{max}$.



Demagnetization Curve

The part of the maximum hysteresis loop of the permanent-magnetic material in the second quadrant is called the demagnetization curve as shown in the next figure. It is the basic characteristics curve of the permanent-magnetic material. On the demagnetization curve, the magnetic flux density has positive values, but the magnetic field intensity has negative values. It means that the permanent-magnetic material is applied with demagnetization magnetic field

intensity. Since H_m and B_m are in opposite directions, when the magnetic flux goes through the permanent-magnetic material, the magnetic potential difference along the direction of the magnetic flux does not drop, but rises. Therefore, the permanent-magnetic material is a magnetic source, similar to the electric source in the electric circuit.

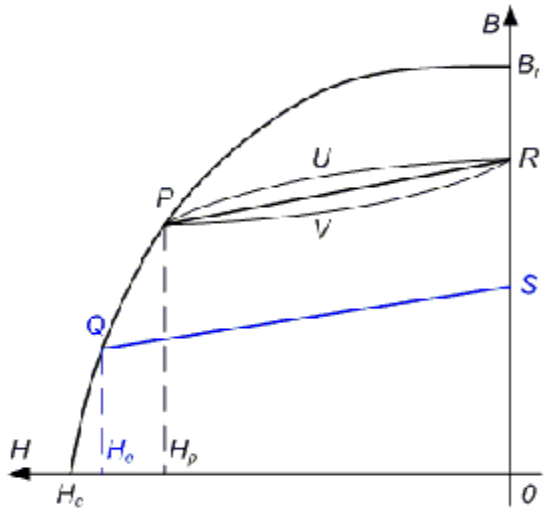


The two extreme positions on the demagnetization curve are the two significant parameters to represent the magnetic characteristics of the permanent-magnetic material. On the demagnetization curve, the value of the magnetic flux density corresponding to zero magnetic field intensity H is termed residual flux density B_r, on the other hand, the value of the magnetic field intensity corresponding to zero magnetic flux density B is termed coercive field force H_c. The produce of the magnetic flux density and the magnetic field intensity at any point on the demagnetization curve is termed magnetic energy product (BH), which is proportional to the magnetic energy density possessed by the permanent magnet at the given operating situation. At the two extreme positions ($B = B_r$, $H = 0$) and ($B = 0$, $H = H_c$), the magnetic energy product is equal to zero. Somewhere at an intermediate position, the magnetic energy reaches its maximum value and is termed maximum magnetic energy product $(BH)_{max}$, which is another significant parameter to represent the magnetic characteristics of the permanent-magnetic material. To some permanent-magnetic materials with linear demagnetization curve, it is obvious that at ($B = B_r / 2$, $H = H_c / 2$), the magnetic energy product reaches its maximum value, i.e. $(BH)_{max} = B_r H_c / 4$.

Recoil Lines

The relationship between the magnetic flux density and the magnetic field intensity represented by the demagnetization curve only exists when the magnetic field intensity varies in the same direction. In fact, when the permanent magnet electric machine is working, the demagnetization field intensity varies repeatedly in both directions. When demagnetization field is applied to the

magnetized permanent magnet, the magnetic flux density decreases along the curly segment B_rP on the demagnetization curve as shown in the figure



If the external demagnetization field intensity H_p is removed when the magnetic flux density reaches the point *P*, the magnetic flux density will increase not along the original demagnetization curve, but along another curve *PVR*. If the external demagnetization field intensity is reapplied, the magnetic flux density will decrease along the new curve *RUP*. By repeatedly applying the demagnetization field intensity, a localized loop is formed and is termed local hysteresis loop. On the local hysteresis loop, the rising segment and the dropping segment are quite close to each other, therefore can be approximated by the straight line *PR*, which is termed recoil line with *P* as the starting point. If demagnetization field with intensity H_q not exceeding the original value H_p is applied thereafter, the magnetic flux density will vary reversibly along the recoil line *PR*. If $H_q > H_p$, the magnetic flux density drops to a new starting point *Q*. It will vary along the new recoil line *QS*, but not the previous one *PR*. This sort of irreversible variation in magnetic flux density causes instability in the characteristics of electric machines and complicates the design computation of permanent magnet electric machines, therefore should be avoided as possible.

Recoil Magnetic Permeability

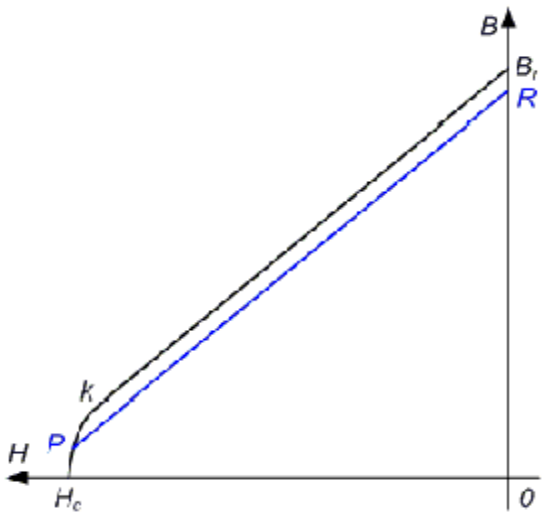
The ratio of the average slope of the recoil line to the magnetic permeability in vacuum μ_0 ($\mu_0 = 4 \times 10^{-7}$ H/m) is termed relative recoil magnetic permeability or recoil magnetic permeability for short, μ_r:

$$\mu_r = \frac{1}{\mu_0}\left|\frac{\Delta B}{\Delta H}\right|$$

If the demagnetization curve is curly, the value of μ_r depends on the location of the starting point and is a variable, but typically varies within a small range. Therefore, it is approximated as a constant and is taken as the slop of the tangent to the point (B_r, 0) on the demagnetization curve. In other words, the recoil lines at different starting points are approximated as a family of parallel lines, which are all parallel to the tangent to the point (B_r, 0) on the demagnetization curve.

Inflection Point

Some permanent-magnetic materials, such as some ferrite permanent-magnetic materials, show straight upper segment on the demagnetization curve. When the demagnetization field intensity drops to a given value, the demagnetization curve turns to decrease rapidly. The turning point is termed inflection point. If the demagnetization field intensity does not exceed the inflection point *k*, the recoil line coincides with the straight segment on the demagnetization curve. If the demagnetization field intensity exceeds the inflection point *k*, the new recoil line *RP* no longer coincides with the straight segment on the demagnetization curve.



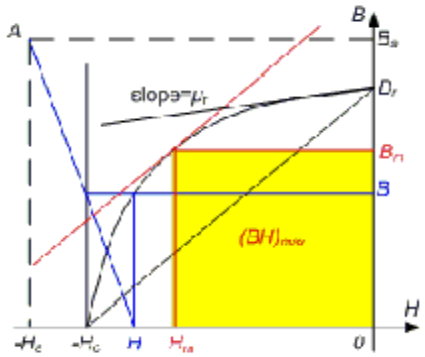
Some permanent-magnetic materials, such as most of the rare-earth permanent-magnetic materials, show straight demagnetization curve in the whole range. In those cases, the recoil line coincides with the demagnetization curve. This makes the magnetic property keep stable while the permanent-magnet electric machine is working. This is the best ideal demagnetization curve for electric machine applications.

Curve Fitting of Demagnetization Curves

RMxprt fits the demagnetization curve according to the given characteristic parameters B_r, H_c, $(BH)_{max}$ and μ_r.

Three Parameter Curve Fitting

Given the three characteristic parameters *Br*, *Hc* and $(BH)_{max}$, the principles of the three-parameter curve fitting algorithm are summarized as follows.Using the following figure as a reference:



$$H_a = \frac{H_c}{a}$$

and

$$B_a = \frac{B_r}{a}$$

where a<1.

Any magnetic flux density *B* in the interval

$$0 \le B \le B_r$$

corresponds to the magnetic field intensity *H*:

$$H = -H_c + \frac{H_a - H_c}{B_a - B} B = -H_c + \frac{H_c(1-a)}{B_r - aB} B = -H_c \frac{B_r - B}{B_r - aB}$$

The tangent at any point is given by:

$$\frac{dB}{dH} = \left(\frac{dH}{dB}\right)^{-1} = \frac{\left(1 - a\frac{B}{B_r}\right)^2}{1-a} \frac{B_r}{H_c}$$

The magnetic flux density B_m and the magnetic field intensity H_m corresponding to the maximum magnetic energy product satisfy the following relationship:

$$\left.\frac{dB}{dH}\right|_{B = B_m} = \frac{B_r}{H_c}$$

Solving yields:

$$B_m = \frac{B_r}{1 + \sqrt{1-a}} \qquad and \qquad H_m = -\frac{H_c}{1 + \sqrt{1-a}}$$

Let the magnetic energy product at the point equal to $(BH)_{max}$ be:

$$\left|B_m H_m\right| = \frac{B_r H_c}{(1 + \sqrt{1-a})^2} = (BH)_{max}$$

Solving yields:

$$a = 2\sqrt{\left|\frac{B_r H_c}{(BH)_{max}}\right|} - \left|\frac{B_r H_c}{(BH)_{max}}\right|$$

The relative recoil magnetic permeability μ_r is calculated as:

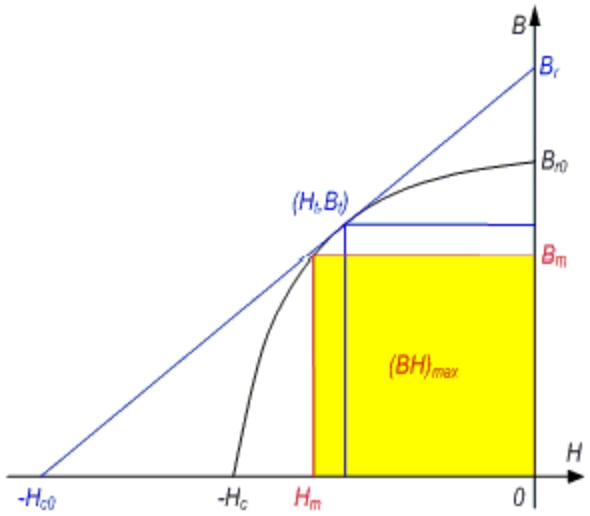
$$\mu_r = \frac{1}{\mu_0}\frac{dB}{dH}\bigg|_{B=B_r} = (1-a)\frac{B_r}{\mu_0 H_c}$$

Four Parameter Curve Fitting

The three-parameter curve fitting technique fits the demagnetization curve well. For the nonlinear permanent-magnetic material, the real operating point lies often not on the demagnetization curve, but on the recoil line. The relative recoil magnetic permeability calculated with the three-parameter curve fitting technique will cause deviation, therefore RMxprt employs a more accurate fitting technique: four-parameter curve fitting technique, as introduced below.

Given the four characteristic parameters B_r, H_c, $(BH)_{max}$ and μ_r, the principles of the four-parameter curve fitting algorithm are summarized as follows:

1. Draw a line through the point (0, B_r) with the slope equal to $-\mu_r\mu_o$ as shown in the Figure. The segment of this line in the second quadrant is termed the ideal recoil line.



2. Find the virtual magnetic flux density B_{r0}.
3. With B_{r0}, H_c, and $(BH)_{max}$, draw the demagnetization curve with the three-parameter curve fitting technique. The curve should touch the ideal recoil line at the tangent point (H_t, B_t).
4. Any magnetic flux density B in the interval

$$0 \le B \le B_r$$

corresponds to the magnetic field intensity H:

$$H = \begin{cases} -H_c \dfrac{B_{r0} - B}{B_{r0} - a_o B} & B \le B_t \\ H_t + \dfrac{B - B_t}{\mu_r \mu_o} & B \ge B_t \end{cases}$$

The virtual magnetic flux density B_{r0} is found by iteration:

1. Start from the initial guess for the lower and the upper bounds for the virtual magnetic flux density B_{r0}:

$$B_0 = max\left(\mu_r \mu_o H_c, \frac{(BH)_{max}}{H_c}\right)$$

$$B_1 = B_r$$

2. Let:

$$B_{r0} = \frac{B_0 + B_1}{2}$$

3. With B_{r0}, H_c, and $(BH)_{max}$, draw the demagnetization curve with the three-parameter curve fitting technique.

$$a_0 = 2\sqrt{\left|\frac{B_{r0}H_c}{(BH)_{max}}\right|} - \left|\frac{B_{r0}H_c}{(BH)_{max}}\right|$$

4. The curve should touch a line parallel to the ideal recoil line at the tangent point (H_t, B_t).

$$B_t = \begin{cases} B_{r0} & a_0 = 0 \\ \dfrac{B_{r0} - \sqrt{\mu_r \mu_0 H_c (1 - a_0) B_{r0}}}{a_0} & a_0 > 0 \end{cases}$$

and

$$H_t = -H_c \frac{B_{r0} - B_t}{B_{r0} - a_0 B_t}$$

1. For any magnetic flux density B in the interval

$$0 \le B \le B_r$$

the corresponding magnetic field intensity H will be calculated by:

$$H = \begin{cases} -H_c \dfrac{B_{r0} - B}{B_{r0} - a_o B} & B \le B_t \\ H_t + \dfrac{B - B_t}{\mu_r \mu_o} & B \ge B_t \end{cases}$$

1. Calculate the value of H_r corresponding to B_r using:

$$H_r = H_t + \frac{B_r - B_t}{\mu_r \mu_0}$$

2. If H_r>0, the assumed virtual B_{r0} is too small, the lower bound of the interval needs to be increased, so let B_0=B_{r0}. If, however, H_r<0, the assumed B_{r0} is too big, the upper bound of the interval needs to be decreased, so let B_1=B_{r0}.
3. Repeat steps (2) through (7) until H_r converges to 0 within satisfactory precision.

Conductor Data

When a material is assigned to a machine part, RMxprt checks that the material is appropriate for the machine part based upon whether it is a conductor or other material type. RMxprt distinguishes conductors based on material threshold settings. RMxprt's treatment of conductors may be set by the used by adjusting the **Material Threshold**.

Setting the Material Threshold for RMxprt

1. Click **RMxprt>Design Settings.**

   The **Design Settings** dialog box appears with the **Material Threshold** tab selected.
2. Type a value in the **Conductivity Threshold** text box (Default=100,000).
3. Type a value in the **Permeability** text box (Default=100).

Note	RMxprt will treat materials with conductivity greater than 100,000 as conductors, and materials with Permeability greater than 100 as steels.

4. If you want these values to be the default, change the values by clicking the **Tools>Options>RMxprt Options** menu and setting the material thresholds in the **RMxprt Options** dialog.
5. Click **OK**.

Editing Conductivity Properties in RMxprt

1. Click **Tools>Edit Libraries>Materials** to open the **Edit Libraries** dialog box.
2. Select the material in the list whose conductivity properties you wish to edit and click the **View/Edit Materials** button.
3. In the **View/Edit Materials** dialog, **Bulk Conductivity** has two property types in the **Type** pull-down list.

- **Simple**: For this type, you must enter a simple value for the property value.
- **Anisotropic**: For this type, you must specify material properties for three principal directions:

a. **T(1,1)**

b. **T(2,2)**

c. **T(3,3)**

Note	The Anisotropic type is not used in RMxprt design analysis, but it will be transferred to Maxwell 3D Design automatically when the design is created by RMxprt.

4. **Mass Density** is a Simple parameter.

Specifying RMxprt Solution Settings

Specify how RMxprt computes a solution by adding a *solution setup* to the design. You can define more than one solution setup per design.

To add a solution setup to a design:

1. Select a design in the project tree.
2. Click **RMxprt**>**Analysis Setup>Add Solution Setup**.
   - Alternatively, right-click **Analysis** in the project tree, and then click **Add Solution Setup** on the shortcut menu.

   The **Solution Setup** dialog box appears. It is divided among the following tabs:

General	Includes general solution settings, including rated output power, speed, operating temperature, etc.
<machine type>	Includes settings specific to the selected machine type.
Defaults	Includes settings to save and clear user-defined default values.

3. Click the**General** tab.
4. If available for the machine you are using, select an **Operation Type** from the pull-down list.

   This may be Motor or Generator.

Note	To enable selection of **Generator** for Adjust-Speed Synchronous Machines, the machine **Control Type** must be set to **AC** in its Properties window.

   When you make the selection, this makes a difference in the **Load Type** available.
5. Select a **Load Type** from the pull-down list. For **Motor** operation, the options are:
   - **Const Speed**
   - **Const Power**
   - **Const Torque**
   - **Linear Torque**
   - **Fan Load**

   If the model has an **Operation Type**, and you select **Generator**, the **Load Type** options are:
   - **Infinite Bus**
   - **Independent Generato**r
6. Type the **Rated Output Power**, and select the units.
7. Type the **Rated Voltage**, and select the units.
8. Type the **Rated Speed**, and select the units.
9. Type the **Operating Temperature**, and select the units.
10. Click the **<machine type>** tab (if any for this machine).

The options vary depending on the machine. For example, the 3 Phase Induction Motor includes options for:

- Frequency and Units
- Winding Connection (Wye or Delta).

The 3 Phase Synchronous Machine includes options for:

- Rated Power Factor
- Winding Connection (Wye or Delta)
- Exciter Efficiency
- Input Exciting current and units

The Brushless DC Motor does not use the <**machine type**> tab.

11. Specify the desired settings, based on the machine type you have selected.
12. Click **OK**.

Note	To edit a setup after it has been created, right-click the specific setup (for example, **Setup1**), under **Analysis** in the project tree, and then click **Properties** on the shortcut menu.

Generating a Custom Design Sheet for RMxprt

RMxprt allows users to import all the data items of **Design Output** into a **Microsoft Excel** worksheet in order for users to design **Design Sheet** of their own styles according to their own requirements using **Microsoft Excel**.

Before you can specify a design sheet, you first need to customize a template in Microsoft Excel and set the export options.

To set the export options:

1. Click **RMxprt>Design Settings**.
   The **Design Settings** dialog box appears. Select the **Export Options** tab.
2. In the **Design Sheet** section, specify an **Excel Template** by clicking the **...** button, selecting the template you want to use, and clicking **Save**.
3. Click **OK**.

To create a design sheet based on a previously-customized template after the design has been analyzed:

1. Click **RMxprt>Analysis Setup>Export**.
   The **Export** dialog box appears.
2. Select **Customized Design Sheet** from the **Type** pull-down menu.
3. Choose the **Solution Setup** from the drop-down menu.
4. In the **Path** field, enter the location to export the files to, or use the ellipsis (...) button to browse to the desired location.
5. Click **OK**.

RMxprt will connect to **Microsoft Excel** according to the set path and automatically import the relevant data from **Design Output** into a copy of the customized **Design Sheet Template**.

Specific data not available in **Design Output** is shown as **N/A**, for instance, **RS** in **Slot Sizes** is *N/A* **(mm)** when stop type is 1. The post-processing of data is automatically performed, for instance, **Winding Weight** is *0.947* **(kg)**.

Note	Several **Design Sheet** examples are shipped with RMxprt in the examples subdirectory of your installation.

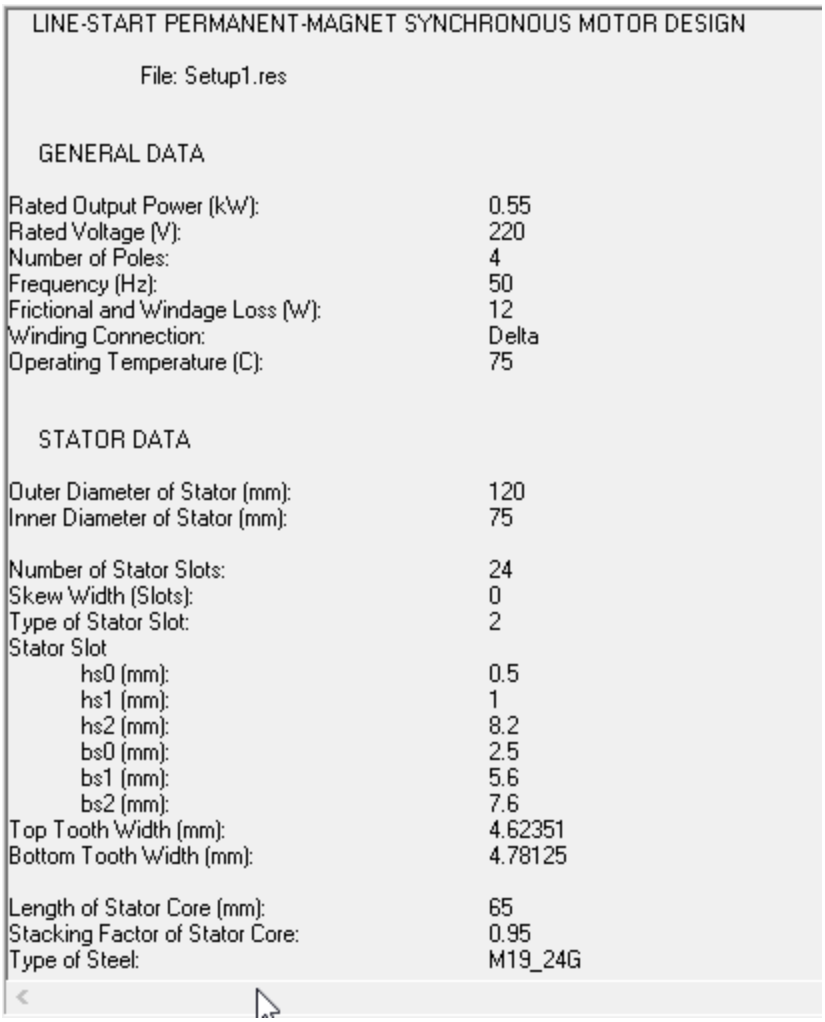
Key Words in Output Data for RMxprt

In **Design Output** of **RMxprt**, the literal expressions for various parameters are termed key words of output data. For example, the **Design Output** for Line-start Permanent-magnet Synchronous Motor (*lssm*) example project sm-1.aedt is shown below.



LINE-START PERMANENT-MAGNET SYNCHRONOUS MOTOR DESIGN

File: Setup1.res

GENERAL DATA

Rated Output Power (kW):	0.55
Rated Voltage (V):	220
Number of Poles:	4
Frequency (Hz):	50
Frictional and Windage Loss (W):	12
Winding Connection:	Delta
Operating Temperature (C):	75

STATOR DATA

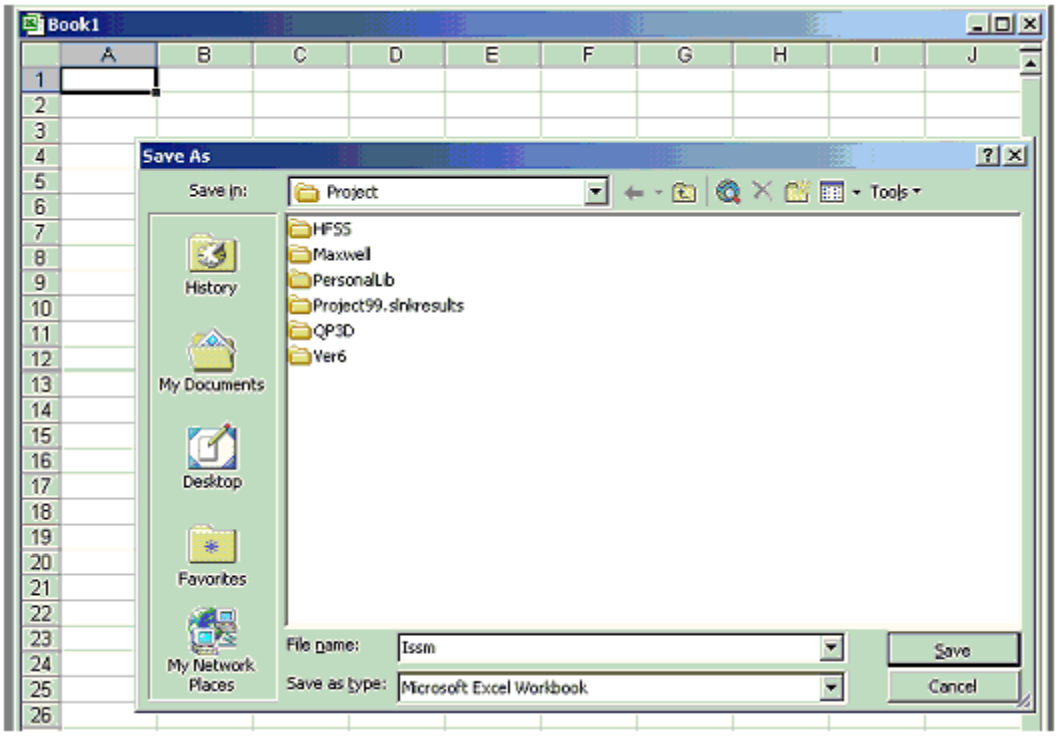
Outer Diameter of Stator (mm):	120
Inner Diameter of Stator (mm):	75
Number of Stator Slots:	24
Skew Width (Slots):	0
Type of Stator Slot:	2
Stator Slot	
hs0 (mm):	0.5
hs1 (mm):	1
hs2 (mm):	8.2
bs0 (mm):	2.5
bs1 (mm):	5.6
bs2 (mm):	7.6
Top Tooth Width (mm):	4.62351
Bottom Tooth Width (mm):	4.78125
Length of Stator Core (mm):	65
Stacking Factor of Stator Core:	0.95
Type of Steel:	M19_24G

In the **Design Sheet**, "Rated Output Power", "Rated Voltage", "Number of Poles", "Frequency", "Frictional and Windage Loss", etc. are all key words of output data.

Creating RMxprt Customized Design Sheet Template

As a sample example, the Line-start Permanent-magnet Synchronous Motor (*lssm*) is used to demonstrate the process for creating a **CustomizedDesign Sheet template**.

Start **Microsoft Excel**, rename the blank worksheet file as "*lssm*" and save it under the path *ansoft\rmxprt5* as shown below.



Design Template of Microsoft Excel Worksheet in Preferred Styles

According to special requirements and preferences, select relevant parameters, arrange the page formats of worksheet. Taking as example a part of the parameters of the **Design Sheet** of the Line-start Permanent-magnet Synchronous Motor (*lssm*), the designed worksheet template is shown below.

Set Boundary for Data Imported into Worksheet for RMxprt

RMxprt automatically searches for matching key words while importing data into the **Microsoft Excel** worksheet. To reduce the searching space, and therefore the searching time, it is possible to set the searching boundary. **RMxprt** defines = "" as identification of boundary. In the following figure, for instance, the cells in the green-colored area are all keyed in with = "" to form boundary. While importing data, **RMxprt** will not search below or to the right of the boundary for matching key words.

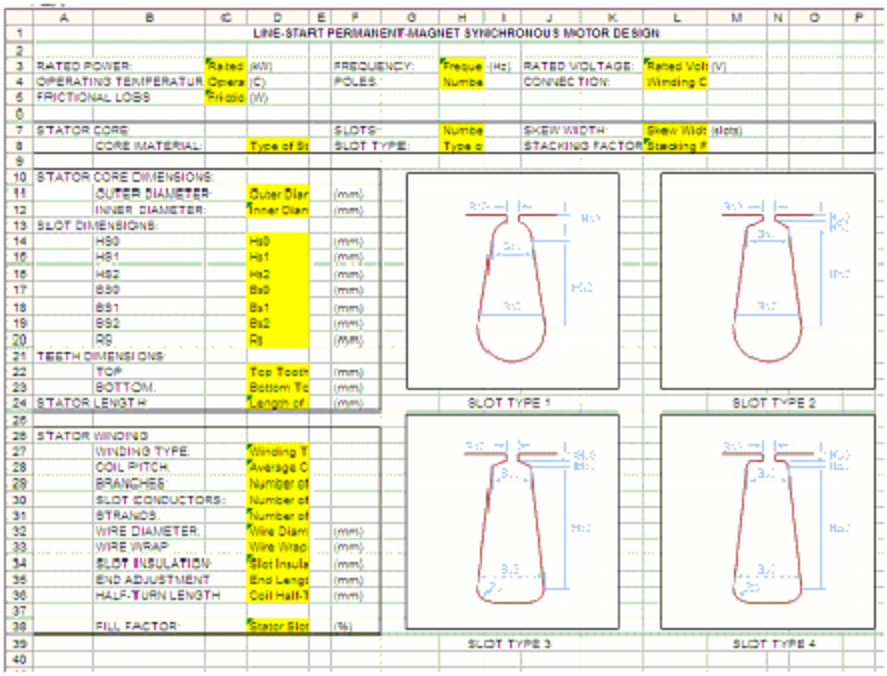
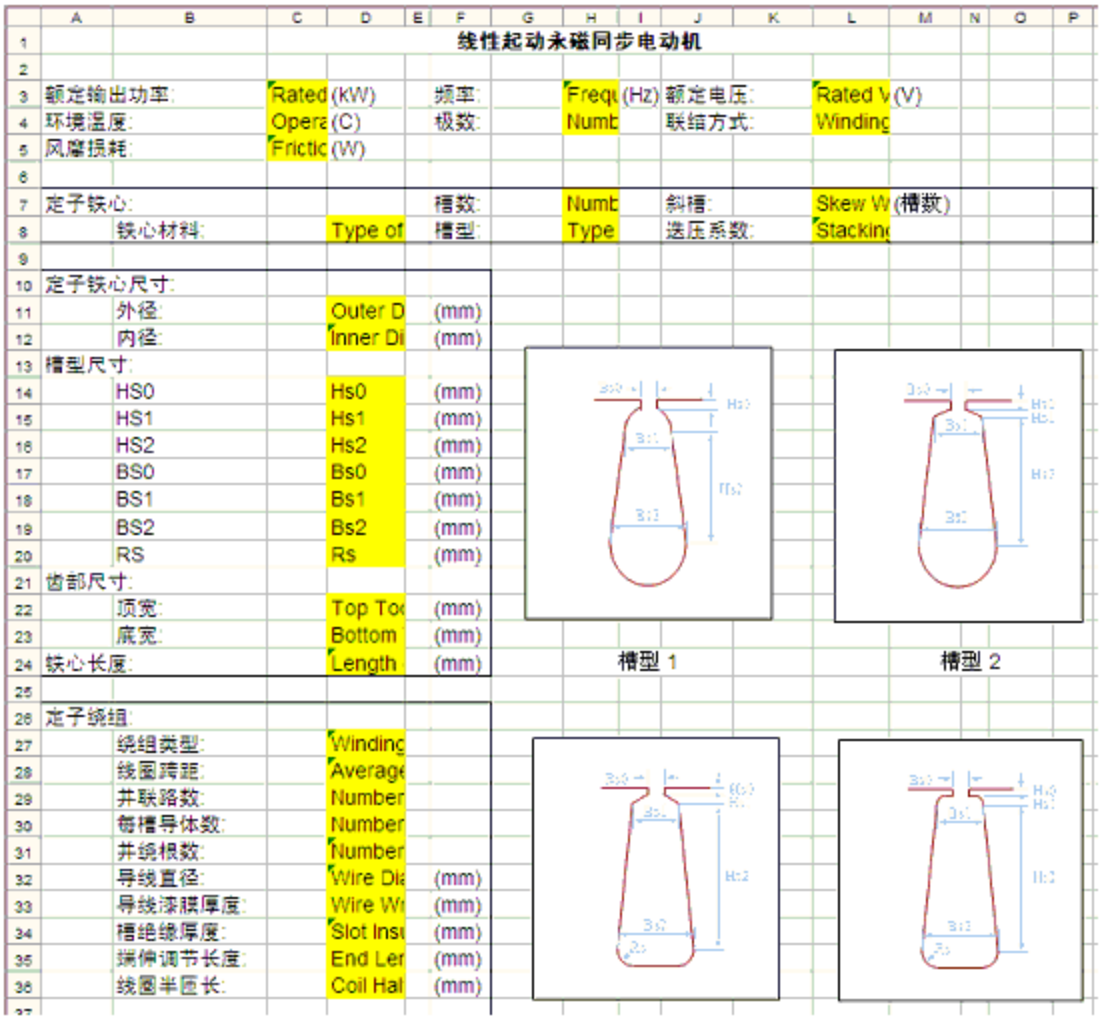
Insert Figures into Template for RMxprt

With resort to function **Paste**, it is possible to insert desired figures into the worksheet template. In the following example, for instance, four figures of slot types are inserted.



Use Different Languages for RMxprt Design Sheets

It is possible to use a preferred language other than English in the **Microsoft Excel** worksheet template. In the following example, for instance, Simplified Chinese is used.



Note	Key words are not allowed to be expressed in other languages.

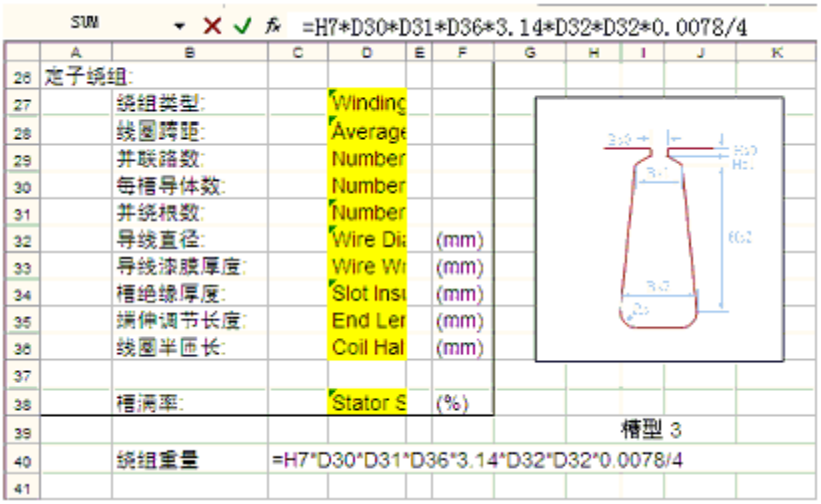
Post-process Data for RMxprt

Using the relevant functions of **Microsoft Excel**, it is possible to post-process data in the worksheet template. For example, calculate the weight of a winding using the following formula:

$$\begin{aligned} winding weight = {} & number\ of\ slots \times number\ of\ conductors\ per\ slot \\ & \times number\ of\ parallel\ wires \times length\ of\ half\ turns\ of\ coil \\ & \times sectional\ area\ of\ wire \times specific\ weight\ of\ wire \end{aligned}$$

In the following figure, the formula is entered into the relevant cell as:

=H7*D30*D31*D36*3.14*D32*D32*0.0078/4



Running an RMxprt Simulation

After you specify how RMxprt will compute the solution, begin the solution process.

1. Select a solution setup in the project tree.
2. Click **RMxprt>Analyze**.

To run more than one analysis at a time, follow the same procedure while a simulation is running. The next solution setup will be solved when the previous solution is complete.

To solve *every solution setup in a design*:

1. In the project tree, under the design you want to solve, select **Analysis**.
2. Click **RMxprt>Analyze All.**

   Each solution setup is solved in the order it appears in the project tree.

Aborting RMxprt Analyses

To end the solution process before it is complete:

- Right-click in the **Progress** window, and select **Abort** from the shortcut menu.

  The analysis stops immediately.

If you aborted the solution in the middle of an adaptive pass, the data for that pass or current frequency point is deleted. Any solutions that were completed prior to the one that was aborted are still available.

Re-solving an RMxprt Problem

If you modify a design after generating a solution, the solution in memory will no longer match the design. The solution setup with the invalid solution is marked with an *X* in the project tree and in the **Results** window.

To generate a new solution after modifying a design, follow the procedure for running a simulation:

1. Select a solution setup in the project tree.
2. Click **RMxprt>Analyze**.

Post Processing and Generating Reports in RMxprt

When RMxprt has completed a solution, you can display and analyze the results in the following ways:

- View solution data.
- Specify output variables.
- Export a model to be used in Maxwell 2D, Maxwell 3D, Twin Builder, or Motor-CAD™.
- Create a Customized Design Sheet
- Create Reports

Viewing RMxprt Solution Data

To access the **Solutions** dialog box, do one of the following:

- Click **RMxprt**>**Results>Solution Data**.
- Right-click **Results** in the project tree, and then click **Solution Data** on the shortcut menu.
- Right-click **Setup1** in the Project tree, and then click **Performance** on the shortcut menu.
- Click the **Solution Data** icon on the **Results** ribbon.

The **Solutions** dialog contains three tabs:

- **Performance** – this contains a Data field with a drop-down menu that allows you to view many different data tables, which vary with the machine type. Some examples are:
  - Aux Winding
  - Full Load Operation
  - Material Consumption
  - No Load Operation
  - Permanent Magnet
  - Rotor Data
  - Rated Parameters
  - Stator Slot
  - Stator Winding
  - Steady State Parameters
- **Design Sheet** – this displays the contexts of the **.res** file for the current setup. The file contains tables with information for such things as (depending on the machine type):
  - General Data
  - Stator Data
  - Rotor Data
  - Permanent Magnet Data
  - Material Consumption
  - Rated Operation
  - No-Load Operation
  - Steady State Parameters
  - No Load Magnetic Data
  - Full Load Data

- Winding Arrangement
- Transient FEA Input Data

To print the design sheet:

1. Right-click the design sheet to display the context menu.
2. Select **Print** from the shortcut menu.

   The **Print** dialog box appears.

3. Select the printer, and click **OK** to print.

- **Curves** – this displays the plots that were automatically generated by the solver. You can select these from a drop-down menu (menu contents vary with the machine type):
  - Input DC Current vs Speed
  - Efficiency vs Speed
  - Output Power vs Speed
  - Output Torque vs Speed
  - Cogging Torque in Two Teeth
  - Induced Coil Voltage at Rated Speed
  - Air Gap Flux Density
  - Induced Winding Phase Voltage at Rated Speed
  - Winding Currents Under Load
  - Phase Voltage Under Load

Note	You can also open the **Solution Data** dialog box directly by clicking the **Solution Data** icon on the Results ribbon.

  To print plots from the **Curve** tab:

1. Right-click on the desired plot to display the context menu.
2. Click **Print** on the menu to display the **Print** dialog.
3. Select the printer, and click **OK** to print.

Note	The context menu also provides commands that allow the user to change various plot characteristics such as: trace type and properties such as color; add/edit data markers and labels; edit axis, legend, and title properties. The plot image can also be copied to the clipboard for pasting in another application. Plot data can also be exported to various formatted text files that can then be imported into spreadsheets, etc. Refer to *Modifying the Background Properties of a Report* for additional information.

Browse Solutions in RMxprt

If you have run different solutions on a design, you can use the **RMxprt>Results>Browse Solutions** to look through and manage them.

1. Click **RMxprt>Results>Browse Solutions**

This displays the **Solutions** dialog with the **Browse** tab selected.

From here you can select a design, and view the Setup, Solution and State tables.

2. Click the **Properties** button to view the **Solution Browser** properties dialog box.

   This contains radio buttons for you to select the tree view. It can be organized as:

   - **Variation / Setup / Solution**
   - **Setup / Solution / Variation**
   - **Setup /Variation / Solution**

   Click **OK** to accept your selection and close the dialog.

3. From the **Solutions** dialog box, you can also select and delete solutions.

Creating a Maxwell Design from RMxprt

RMxprt provides a way to export solved models as either a Maxwell 2D or Maxwell 3D design.

- All the RMxprt machine types are supported.
- Setups for boundaries, excitations, parameters, etc. are automatically created.
- Variable definitions and assignments are automatically mapped from the solved RMxprt design to the Maxwell design.

Note	Creating a Maxwell2D/3D design from an old version (version 15 or older) of a solved RMxprt design results in the Maxwell2D/3D design being created *without* any variables even if the original RMxprt design uses variables. In such cases, the **Message Manager** displays a warning message informing the user that the Maxwell design being created does not contain any variable assignments from the RMxprt design; and recommends re-solving the setup to get the variable assignments.

To export the model to a Maxwell 2D Design or Maxwell 3D Design:

1. Click **RMxprt>Analysis Setup>Create Maxwell Design**

   The **Create Maxwell Design** dialog box appears.

2. Select one of the following from the **Type** drop-down list:
   - **Maxwell 2D Design**
   - **Maxwell 3D Design**
3. Select the setup you want to export from the **Solution Setup** drop-down list.
4. Optionally, click the **[...]** button to specify a **Variation** in the **Set Design Variation** dialog box. This allows the user to choose the default variable values to be used in the Maxwell design being created with variables.
5. Click **OK** to create the Maxwell design.

You can now work with the model in the Maxwell2D or Maxwell3D design, add boundaries and excitations, perform analyses, and analyze results.

Note	• For Maxwell 2D/3D designs for motor applications, the computed output mechanical power at a given constant speed may not reach the desired rated power. Therefore, it is useful to apply constant power as the mechanical load. In

	Maxwell 2D/3D designs created by RMxprt, the mechanical transient is setup according to the rated mechanical output power, and equivalent damping is added to accelerate the process approaching to the rated output power. This setup is visible when **Consider Mechanical Transient** on the Mechanical tab of the Motion Setup dialog box is checked. • For Maxwell 2D/3D designs of AC machines, RMxprt automatically enables an alternating flux (AF) model in the voltage definition for each winding to reduce transient solution time to reach steady-state when the Maxwell 2D or 3D model is created. • For Maxwell 2D designs of double-cage induction machines with separate end rings, and of synchronous machines with separate dampers for each pole, RMxprt automatically creates multiple end connection excitations in the Maxwell 2D design. For synchronous machines, if the created geometry model has only one pole, it is changed to two poles, with two separate end connection excitations. This enables simulation of double-cage induction machines with separate rings, as well as synchronous machines with separate dampers for each pole.

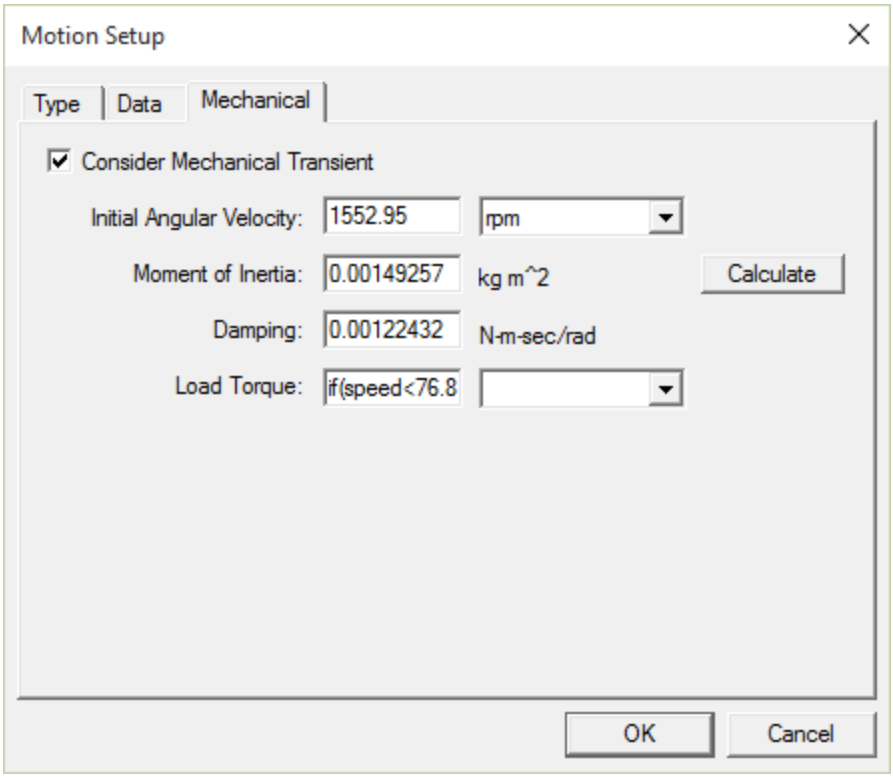
Speed Adjustment to Achieve to Rated Output Power

Speed Adjustment to Achieve to Rated Output Power

The speed setup in all RMxprt created Maxwell designs is the estimated rated speed which is computed based on the rated output power using Equivalent Magnetic Circuit (EMC) method in RMxprt. The EMC method may not be very accurate in some cases, especially when some part of the magnetic circuit is highly saturated. In order to obtain the correct rated performance in Maxwell designs, the speed setup by RMxprt based on the estimated rated speed should be adjusted so that the simulated mechanical output power matches the specified rated output power. *All rated performance data, such as torque, speed and current, must be obtained at the rated output power!* For this purpose, all RMxprt created Maxwell designs have an initial mechanical transient setup to automatically adjust the speed to approach the rated mechanical output power. This initial transient mechanical setup will be lost if you close the project without checking the **Consider Mechanical Transient** check box as shown in the following example.



However, using the mechanical transient to reach to the rated output power may need much longer simulation time especially when the rotor Moment of Inertia is large. Reducing the value of the Moment of Inertia may cause speed oscillation.

The following two methods may be used to adjust the speed to achieve to the rated output power:

- Using the initial mechanical transient setup by RMxprt
- Adjusting speed manually for a constant speed setup

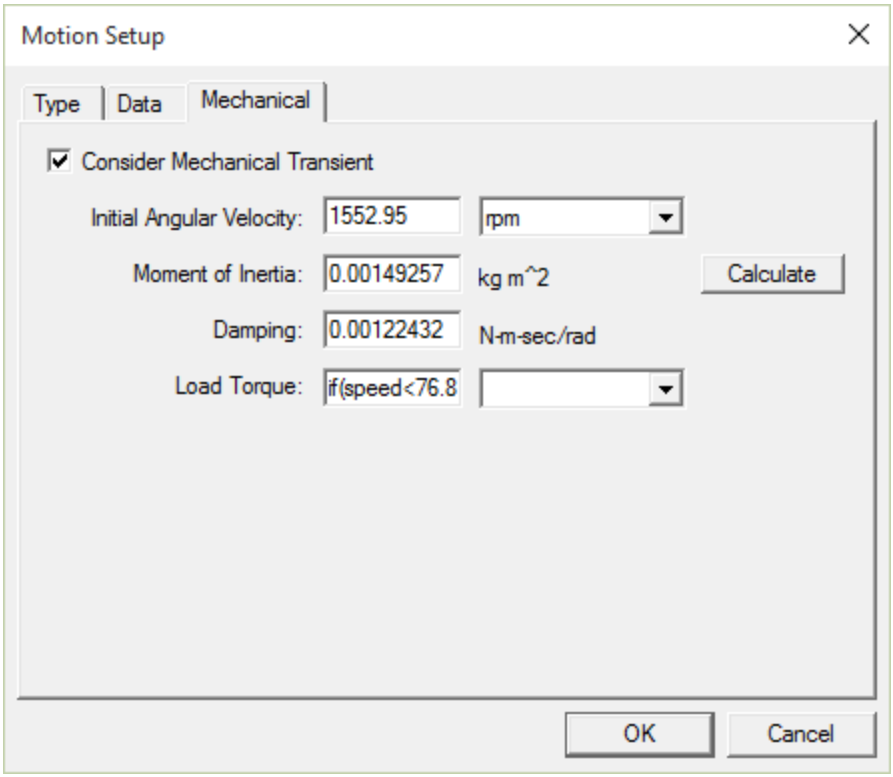
Related Topics

Using the Initial Mechanical Transient Setup by RMxprt

Adjusting Speed Manually for a Constant Speed Setup

Using the Initial Mechanical Transient Setup by RMxprt

To use this method, you need to check **Consider Mechanical Transient** in the **Mechanical** tab of the **Motion Setup** dialog box immediately after the design is created from RMxprt. An example showing the initial values for mechanical transient setup is shown below.



Note that if you close the design without checking it, and open the design later, this initial mechanical transient setup will loss.

The method for using the mechanical transient setup is as follows:

In the Mechanical tab of the Motion Setup panel, when **Consider Mechanical Transient** is checked, the displayed **Load Torque** is actually the "Driving Torque" because the positive torque is defined in the positive speed direction. Therefore, the real positive Load Torque must be defined with a negative value. In order to automatically adjust the speed for the motor to generate the specified output power, you need to set the load torque curve with Constant Power, that is:

Tload = – Pspec / speed

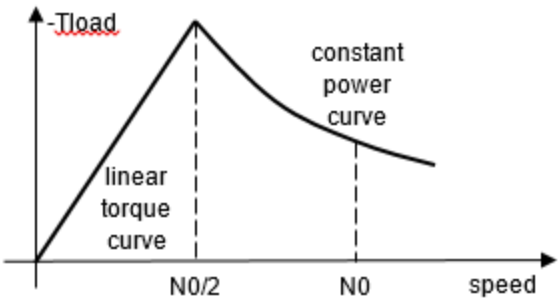
where **speed** is the real rotor speed, and **Pspec** is a constant value.

In order to apply this load torque curve for any initial speed, the load torque curve is defined as:

Tload = if(speed<N0/2, -4*Pspec/N0/N0*speed, -Pspec/speed)

where **N0** is the *synchronous speed* for synchronous motors, or the *rated speed* for other motor types in (rad/s).

The load torque is shown below, which is applicable for all motor types excluding synchronous motors.



For synchronous motors, the motor driving torque varies with torque angle which is the difference between the phase angles of the applied and the induced voltages. If the initial speed is set as the synchronous speed, and the initial torque angle is set smaller than the real value, the motor driving torque will be smaller than the specified load torque. With mechanical transient, the speed will decrease, which makes the torque angle and driving torque increase. When the driving torque equals the load torque, the speed, which is lower than the synchronous speed, will stay constant temporarily. Since the speed is lower than the synchronous speed, the torque angle continues to increase, which makes the driving torque greater than the load torque, and therefore the speed increases. When the speed reaches the synchronous speed, the torque angle will be too large, which will increase the speed to exceed the synchronous speed. Therefore, the speed will oscillate about the synchronous speed. This oscillation will decay to zero if the synchronous motor has a damper cage winding. The decaying time depends on the strength of the damping effects.

In order to speed up the decaying process, an additional load torque component to model the damping effects around the synchronous speed is set for all types of synchronous motors, as expressed below:

Tdamp = - Tst * (speed/N0 - 1)

where **Tst** is set as the rated torque. You may increase **Tst** to increase the damping effects. The damping torque curve is shown below.

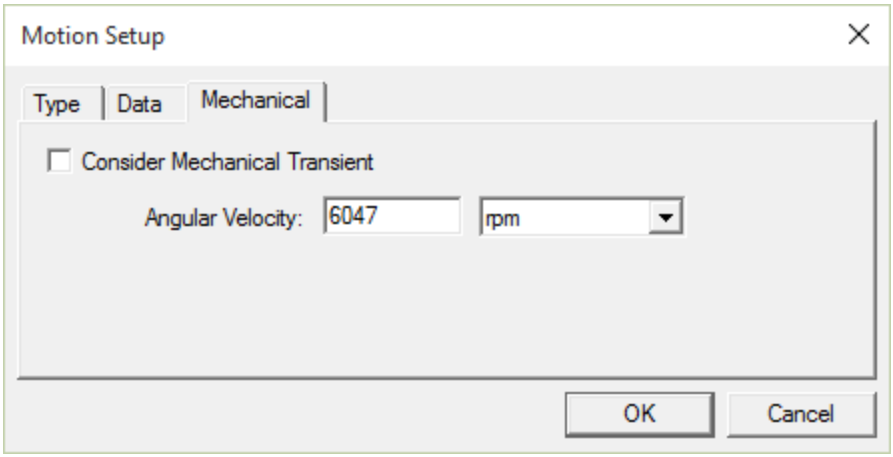
Speed Adjustment to Achieve to Rated Output Power

Adjusting Speed Manually for a Constant Speed Setup

The specified rated output power can be reached by manually adjusting the input speed without checking **Consider Mechanical Transient**.



This adjustment method may require iteration, as described below:

Determine the solution at the RMxprt setting speed.

Using a Permanent Magnet DC motor as an example, assume that the solution data for the Maxwell 2D design originally created by RMxprt are:

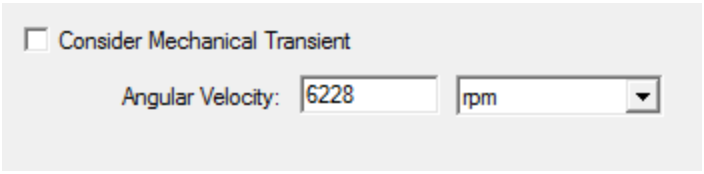
- The period is 4.96 ms based on the original setting speed n0 = 6047rpm for a 4-pole motor.
- The average torque in the last period, from 5.04 ms to 10 ms, is T0 = 1.4044 Nm
- The simulated output power is 889.3 W.

If the specified rated output power is 200 W, in order to reduce the motor driving output power, we need to increase the motor speed.

For the next iteration, try increasing the speed by 3%, that is: n1 = n0 * (1+3%) = 6228 rpm.

First Iteration – Determine the solution at the first adjusted speed.

When the speed is set to be n1 = 6228 rpm:



- The period for this speed is 4.82 ms.
- The new simulated average torque in the last period is T1 = 0.7276 Nm
- The output power is P1 = 0.7276 * 6228 * 2*pi/60 = 474.5 W.

If the output power of 474.5 W is acceptable, you can stop here. Otherwise, you need to continue to adjust the speed as described below.

Second Iteration – Determine the solution at the second adjusted speed.

Now, we have two solutions of (n0, T0) = (6047 rpm, 1.4044 Nm) and (n1, T1) = (6228 rpm, 0.7276 Nm). Assuming the motor driving torque **T** at any speed **n** can be obtained from linear interpolation and extrapolation, the motor driving torque can be expressed as:

T = T0 + (T1-T0) / (n1-n0) * (n-n0) = 1.4044 – 0.003739 * (n – 6047) = 24.0155 – 0.003739 * n

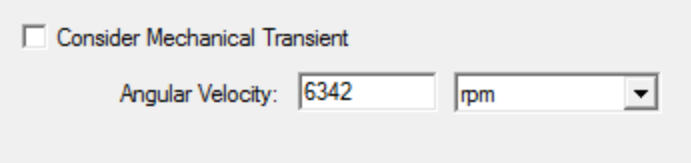
In order to obtain the specified rated output power, the load torque can expressed as:

T = 200 / n * 60/(2 pi) = 1910 / n

The new adjusted speed **n2** can be obtained by solving the above two equations, the resulting value being:

n2 = 6342 rpm

Thus, if we set the speed to be n2 = 6342 rpm.



- The period for this speed is 4.73 ms.
- The new simulated average torque in the last period is T2 = 0.3065 Nm.
- Now, the output power is: P2 = 0.3065 * 6342 * 2*pi/60 = 203.6 W, which is very close to the specified rated output power of 200 W.

Comparing the discrepancy between RMxprt and Maxwell 2D results after this second iteration:

	RMxprt	Maxwell 2D	Error
Speed	6047 rpm	6342 rpm	-4.65%
Torque	0.3216 Nm	0.3065 Nm	4.93%
Output Power	200 W	203.6 W	-1.77%

The above table shows that for a small change of speed in Maxwell setup, the torque change may be significant. In the example, the Maxwell 2D result of torque at n0 = 6047 rpm is T0 = 1.4044 Nm, while the torque at n2 = 6342 rpm is T2 = 0.3065Nm. The speed change of 4.65% results in a torque change of 358%.

In the above method, the algorithm for the speed adjustment is suitable for most motor types including (PM)DC motors, BLDC motors, universal motors, induction motors, and switched reluctance motors. For induction motors, the first adjusted speed can be obtained by increasing or decreasing the speed slip with certain percentage.

Note	• The speed setup by RMxprt is just an initial setup. Users must adjust the speed if the output power is far away from the specified rated output power.

	• This method is suitable for all (PM)DC motors, BLDC motors, universal motors, induction motors, and switched reluctance motors. For all synchronous machines, users must adjust the power angle or the torque angle if the output power is far away from the rated output power.

Speed Adjustment to Achieve to Rated Output Power

Exporting a Simplorer Model, MotorCAD Project, or Customized Design Sheet

To export the model to a Simplorer model, a MotorCAD™ project, or Customized Design Sheet:

1. First, solve the design for the specific solution setup from which the export is desired.

Note	Attempting to export without the requisite files present automatically launches simulation to generate them.

2. Click **RMxprt>Analysis Setup>Export** to open the **Export** dialog box.

   You can also right-click on **Analysis** or **Analysis>Setup** in the Project Manager and select **Export**.

3. Select one of the following from the Type drop-down list:
   - **Simplorer Model**
   - **Customized Design Sheet**
   - **MotorCAD Project**
4. Select the setup you want to export from the **Solution Setup** drop-down list.
5. Optionally, click the Variation ellipsis [**...**] button to specify a design **Variation to use during export**.
6. Specify the **Path** to store the exported files in by clicking the Path ellipsis [...] button and browsing to the desired directory. You can also create a new directory, if desired.
7. Click **OK**.

   – For **MotorCAD Project**, a <*project_name*>**.mot** file that includes all machine and housing data will be generated. You can then open the project in Motor-CAD for analysis.

   – For **Customized Design Sheets**, a <*design_sheet_name*>**.xls** file will be generated.

   – For **Simplorer** models, three files will be exported:
   - <*project name*>_<*design name*>_<*setup name*>.sml
   - <*project name*>_<*design name*>_<*setup name*>_*signals*.sml
   - <*project name*>_<*design name*>_<*setup name*>_*SimCkt*.vbs

   You can now use the Twin Builder **Tools>Run Script** command to run the .vbs script to generate the components on the Twin Builder schematic. (Refer to the Twin Builder help for detailed information on running scripts.)

You can now work with the model in the product to which you exported it, and perform other kinds of analyses.

Generating a Custom Design Sheet for RMxprt

Creating an Icepak Design

RMxprt provides a way to export solved models as Icepak designs.

To export the model as an Icepak Design:

1. Click **RMxprt>Analysis Setup>Create Icepak Design**; or right-click on the analysis setup in the Project tree and select **Create Icepak Design** from the context menu.

   The **Create Icepak Design** dialog box appears.
2. Select the setup you want to export from the **Solution Setup** drop-down list.
3. Optionally, click the **[...]** button to specify a **Variation** in the **Set Design Variation** dialog box. This allows the user to choose either the nominal design or to choose the variation to be used in the Icepak design being created.
4. Enter or choose the **Path** where the Icepak project is to be output.
5. Do one of the following:
   a. Click **OK** without selecting **Launch Icepak application** to generate the Icepak project and put it in the designated folder.
   b. Select **Launch Icepak application** and click **OK** to generate the Icepak project in the designated folder, and automatically open the Icepak design in the Icepak application.

Note	• If you want to launch the Icepak application, ensure that the Workbench path is set in the Tools/Options/General Option/Miscellaneous tab. • Refer to the Icepak documentation for information on working with Icepak designs.

Creating Reports in RMxprt

After RMxprt has generated a solution, all of the results for that solution are available for analysis. One of the ways you can analyze your solution data is to create a report, or graphical representation, that displays the relationship between a design's values and the corresponding analysis results. Reports are created using the **RMxprt>Results>Create RMxprt Report>**<*report_type*> command. The available options in the resulting **Reports** dialog box depend on the report type you create and the available solution data. You can also create reports using the **RMxprt>Results>Create Quick Report** command. The **Quick Report** feature lets you select from a list of predefined categories (such as coil voltage or torque) from which to create a rectangular plot.

If you have created custom report templates (for example, including your company name or other format changes), you can also create a report based on that template by selecting **RMxprt>Results>Report Templates>***<templateName>*.

You can also Create a Report from a Report Data (`.rdat`) file by selecting **RMxprt>Results>Create Report from File**, then browse to the desired `.rdat` file and open it. (Refer to *Performance Computation Based on FEA Created ROM for Induction Machines for an example.*)

The report appears in the view window and is listed in the project tree.

Selecting the Display Type in RMxprt

Modifying Reports in RMxprt

To modify the data that is plotted in a report:

1. In the project tree, right-click the report you want to modify.
2. Select **Modify Report** from the shortcut menu.
3. Modify the selections in the Report dialog box as needed.
4. Click **Close** when you are finished modifying the report.

   The updated report appears in the view window.

To update all modified reports:

Click **RMxprt>Results>Update Reports**.

Opening All Reports in RMxprt

To open all reports for a project:

Click RMxprt>Results>Open All Reports.

This opens all reports.

To simplify viewing and comparisons, it may be helpful to use **Window>Cascade** or **Window>Tile Horizontally** or **Window>Tile Vertically** commands.

To close all open reports:

Click **Window>Close All**.

Deleting All Reports in RMxprt

To delete all reports for a project:

Click **RMxprt>Results>Delete All Reports**.

This deletes all reports for the project.

Selecting the Display Type in RMxprt

The information in a report can be displayed in several formats. Select from the following **Display Type** formats in the **Create Report** dialog box:

Rectangular Plot	A 2D rectangular (x-y) graph.
Rectangular Stacked Plot	A series of 2D rectangular (x-y) graphs stacked vertically, sharing a common x-axis scale, but with each trace having its own y-axis scale.
3D Rectangular Plot	A 3D rectangular (x-y-z) graph.
3D Rectangular Bar Plot	A 3D rectangular (x-y-z) bar graph.
3D Polar Plot	A 3D circular plot divided by spherical coordinates.
Data Table	A grid with rows and columns that displays, in numeric form, selected quantities against a swept variable or another quantity.
Rectangular Contour Plot	A rectangular (x-y-z) graph. Contour plots are useful to visualize surfaces (for e.g. Directivity as a function of phi/theta).

Creating 2D Rectangular Plots in RMxprt

A rectangular plot is a 2D, x-y graph of results.

1. Click **RMxprt>Results>Create RMxprt Report>Rectangular Plot**.

   The **Report** dialog appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a pull down selection list containing options for plotting vs ElectricDegree, Speed, or a user-selected Parameter.
3. Under the **Trace** tab, **Y** component section, specify the information to plot along the y-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. Value field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

4. On the **Trace** tab, **X** (Primary sweep) line, specify the quantity to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop down list.
   - If sweeps are available, you can select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The function of the selected quantity will be plotted against the swept variable values or quantities you specified on an x-y graph. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.

10. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.

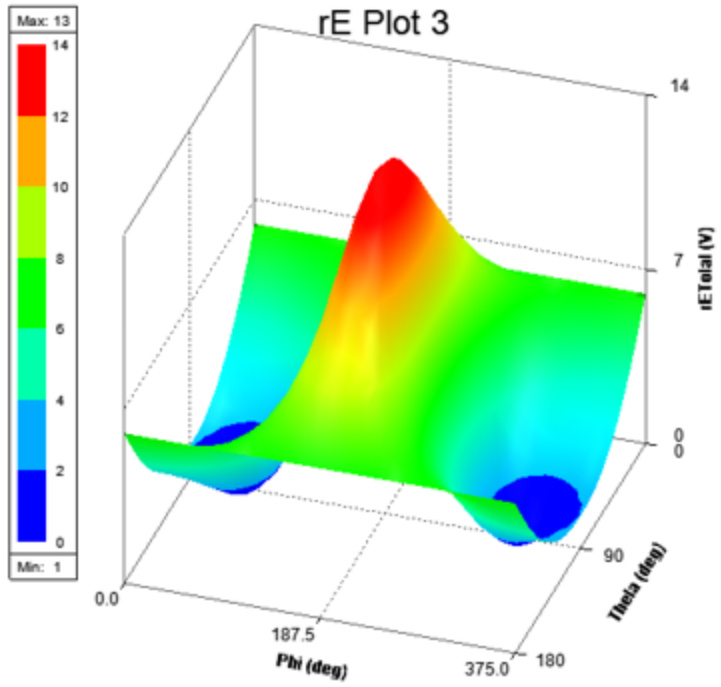
Working with Traces

Creating 3D Rectangular Plots in RMxprt

Below is an example of a 3D rectangular plot.



Working with a 3D Rectangular Plot

You can Rotate, Zoom and Pan a plot. When you rotate, the Cartesian grid responds so that the curve always remains in front and the grids behind.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the Properties dialog box. the properties are grouped appropriately under various tabs, which correspond to plot entities:

- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title.
- Axis [X|Y|Z]: Properties related to the 3 axes
- Grid [XY|YZ|ZX]: Properties related to the 3 grids
- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Plot" on page 26-159.

Creating a 3D Rectangular Plot

1. Click **RMxprt>Results>Create RMxprt Report>3D Rectangular Plot** .
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a pull down selection list containing options for plotting vs ElectricDegree, Speed, or a user-selected Parameter.
3. Under the **Z** tab, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **Y** (**Secondary Sweep**) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the Secondary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab, **X** (**Primary Sweep**) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the Primary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

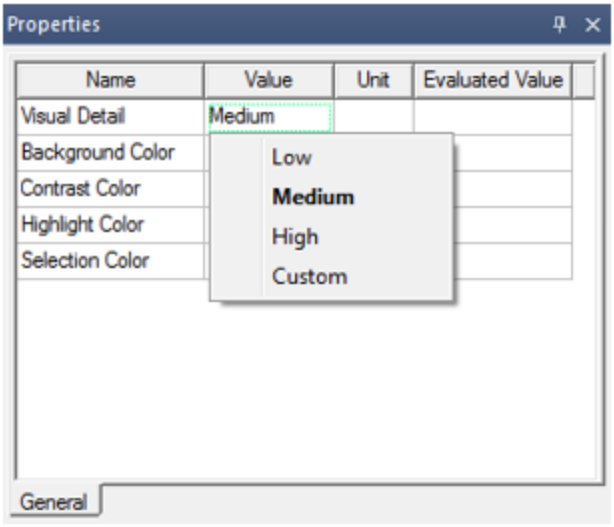
   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the project tree.When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their

properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.

8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Controlling Visual Detail in a 3D Plot

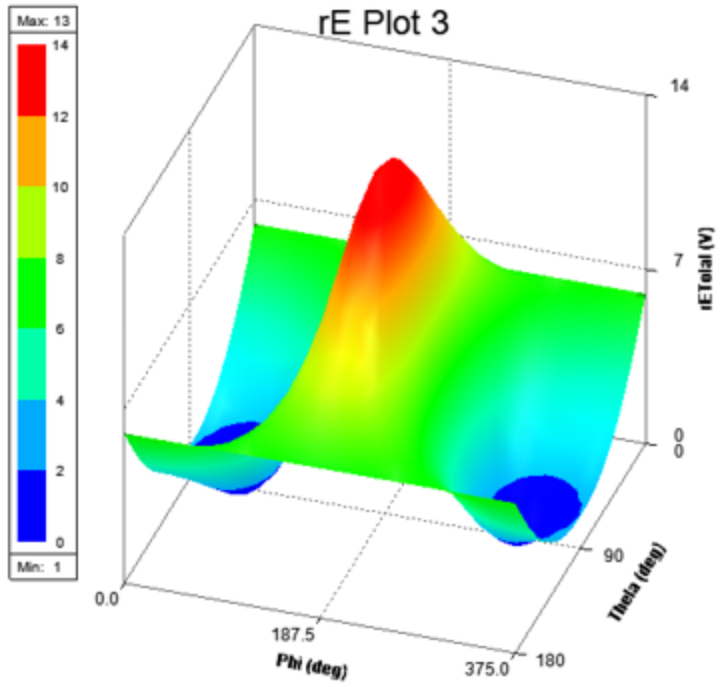
If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.



The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

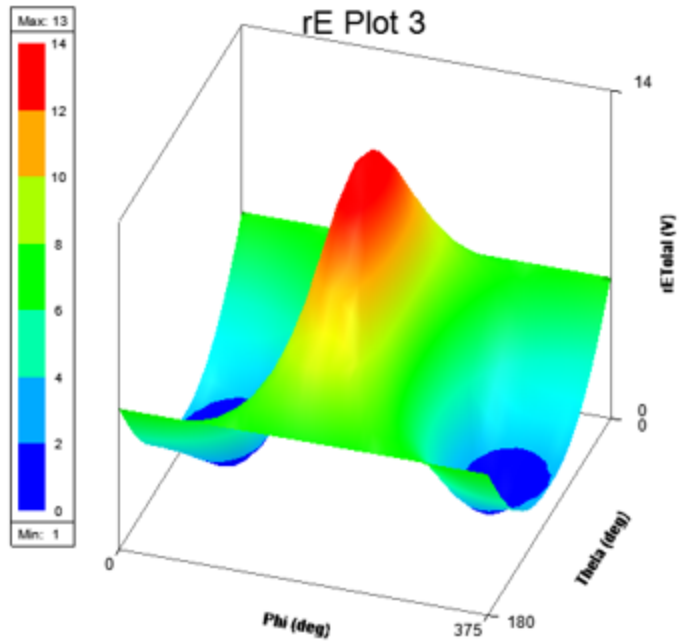
You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Rectangular Plot with Medium Visual Detail



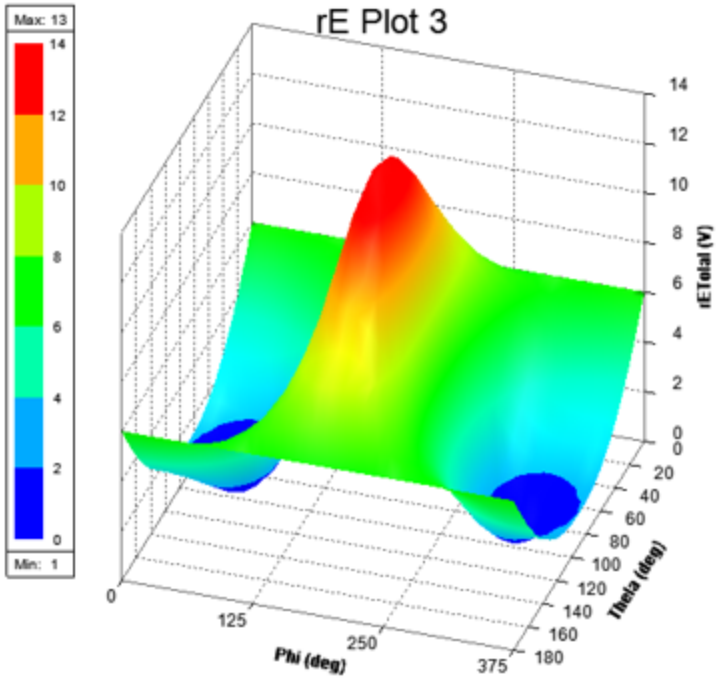
On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

3D Rectangular Plot with Low Visual Detail



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

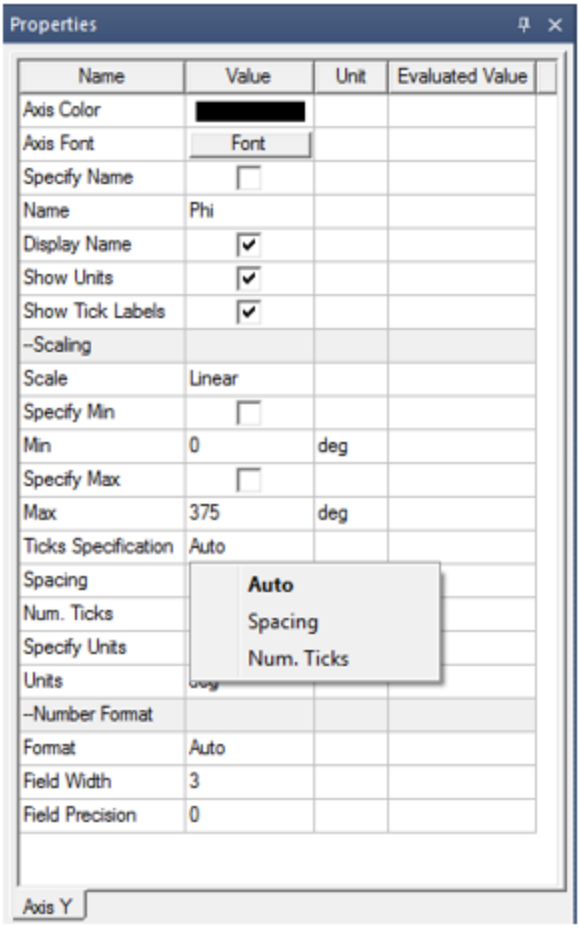
3D Rectangular Plot with High Visual Detail



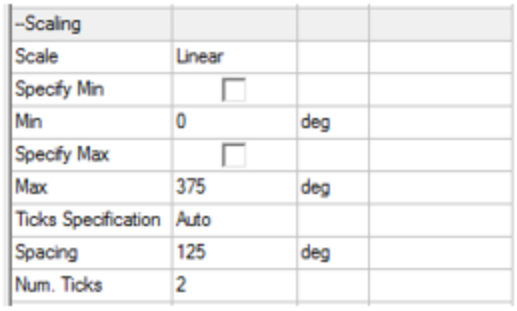
With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:



You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

Note	With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

- ColorKey: Properties related to ColorKey, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all surfaces

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Rectangular Bar Plot" on page 26-169.

Creating a 3D Rectangular Bar Plot

1. On the **Results** menu (under the **Maxwell** menu or right-click **Results** in the Project Manager), click **Create *<type>* Report**, and select **3D Rectangular Bar plot** from the report type menu, or select the Results tab of the ribbon, and select the 3D Rectangular Bar icon for the Report type you want to create.

   The *Report* dialog box appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop-down selection list. This lists the available solutions, whether sweeps or adaptive passes.

b. Geometry field with a drop-down selection list. For field and radiated field reports, this applies the quantity to a geometry or radiated field setup.

3. Under the **Trace** tab **Z** Component area, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot. The category you select provides the default plot name.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

      > **Note:**
      >
      > Color shows valid expression.

   e. **Range Function** button -- opens the *Set Range Function* dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab **Y** (Secondary sweep) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab **X** (Primary sweep) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the drop-down list.
   - If sweeps are available, you can select the browse button to display a dialog that lets you select particular values. The quantity will be plotted against the primary sweep variable listed.
6. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables **Add Trace** on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, S Parameter Plot *n* or rE Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

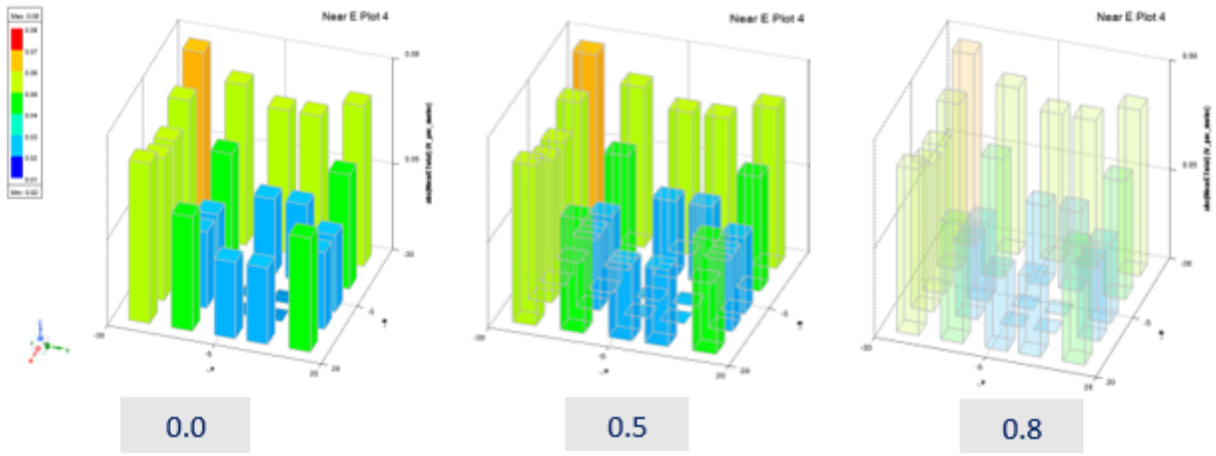
   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the Project Manager. When you select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.
7. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

3D Rectangular Bar Customization

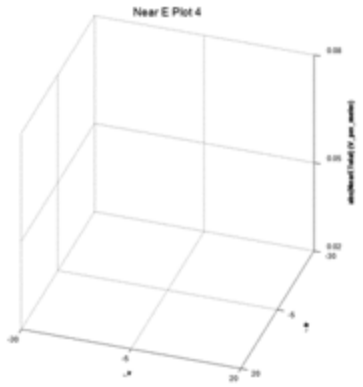
Selecting a bar in the plot shows the customizable attributes of bars in a 3D Rectangular Bar plot.

The customizable attributes of the bars in a 3D Rectangular Bar plot include:

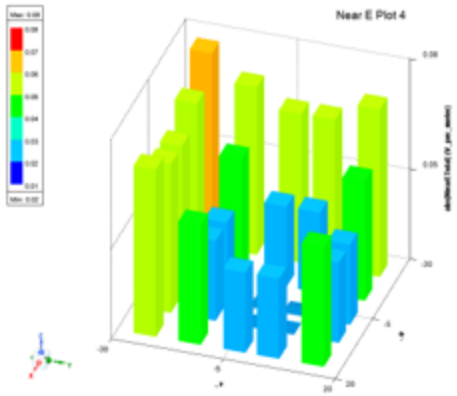
- Transparency



- Filled

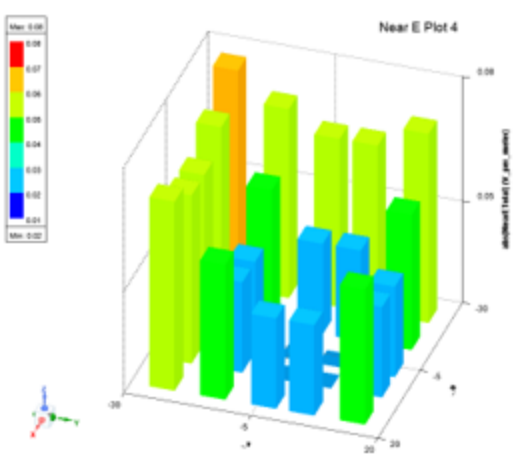


Filled [ ]

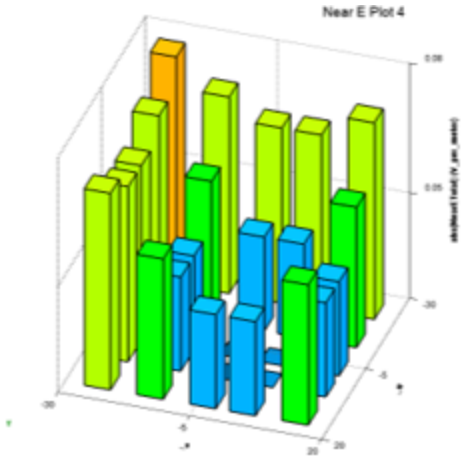


Filled [√]

- Show Outline



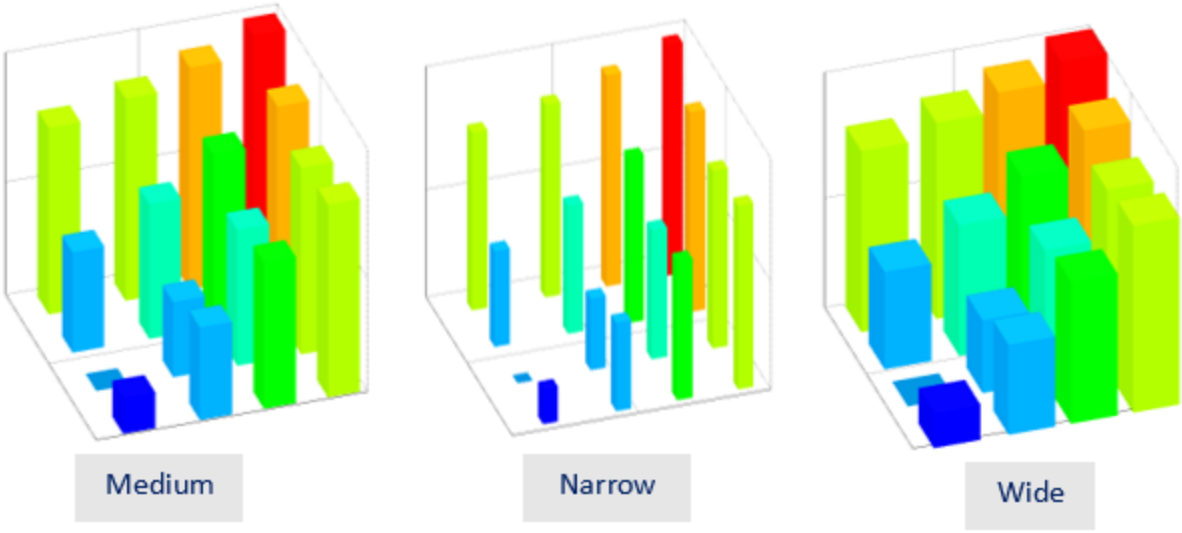
Show Outline []



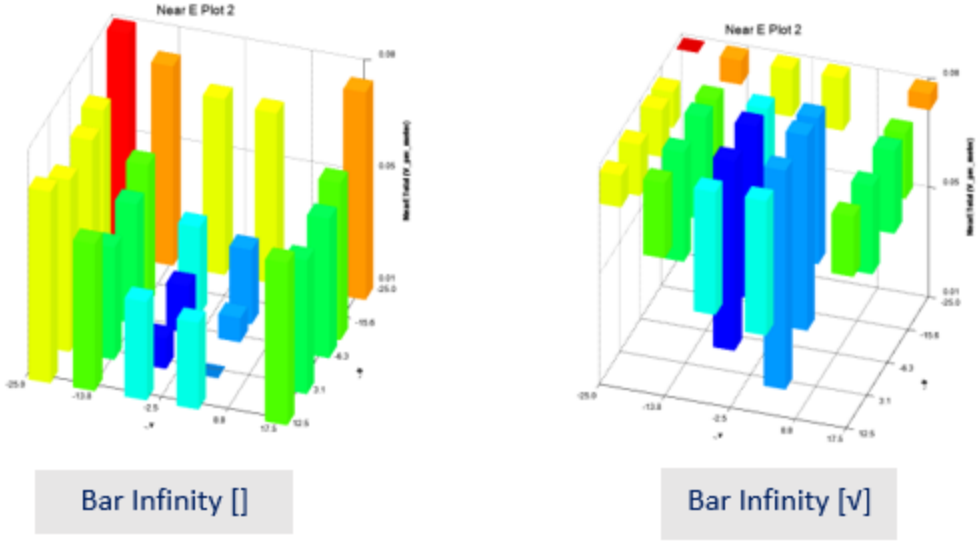
Show Outline [√]

- Outline Color (customizable, see plot above)
- Outline Width (customizable, see plot above)

- Bar Width, controls the thickness of the bar. Medium (default), Wide and Narrow are the width that equals to ½, ¾ and ¼ of the min spacing between adjacent points respectively.

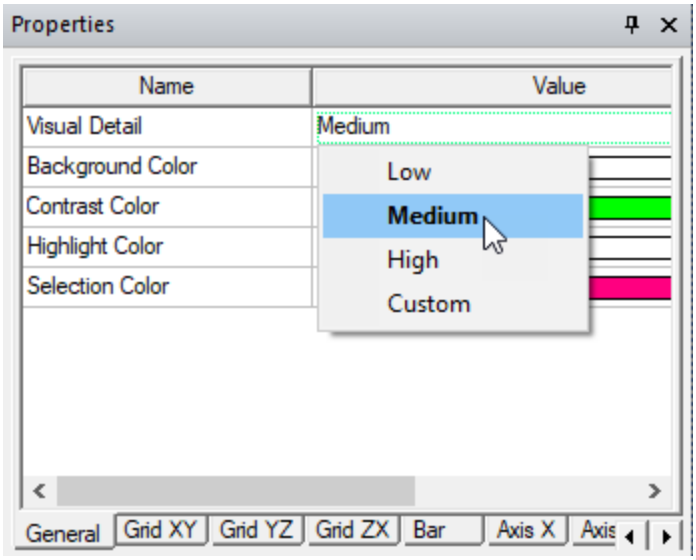


- Bar Infinity represents the third coordinate (z) using the bottom of the bar.



Controlling Visual Detail in a 3D Rectangular Bar Plot

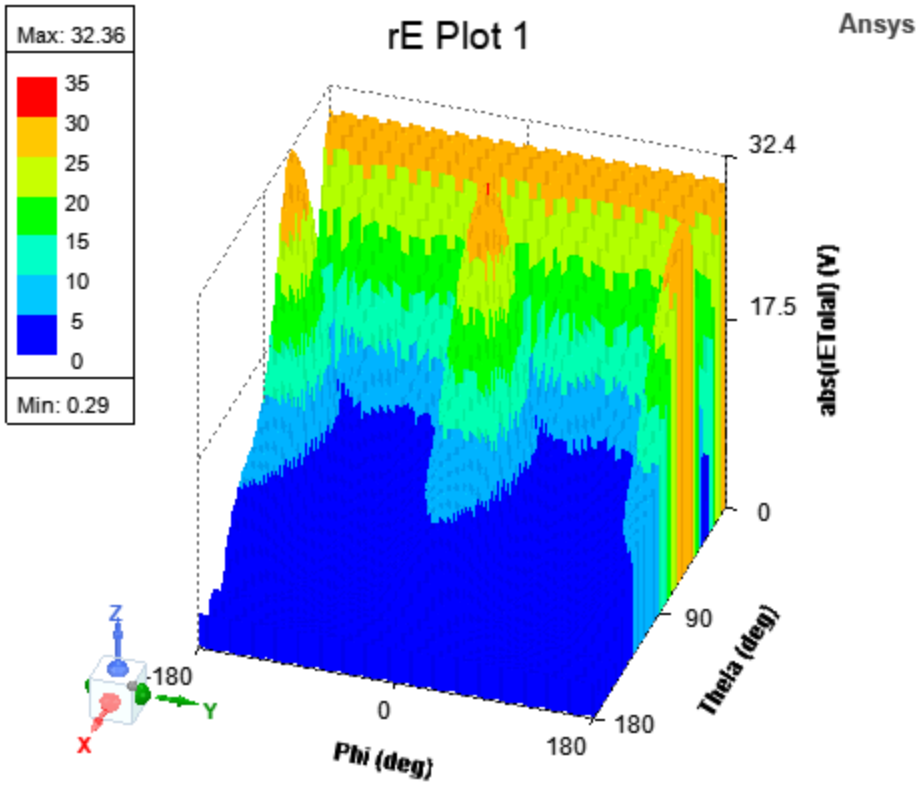
If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.



The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

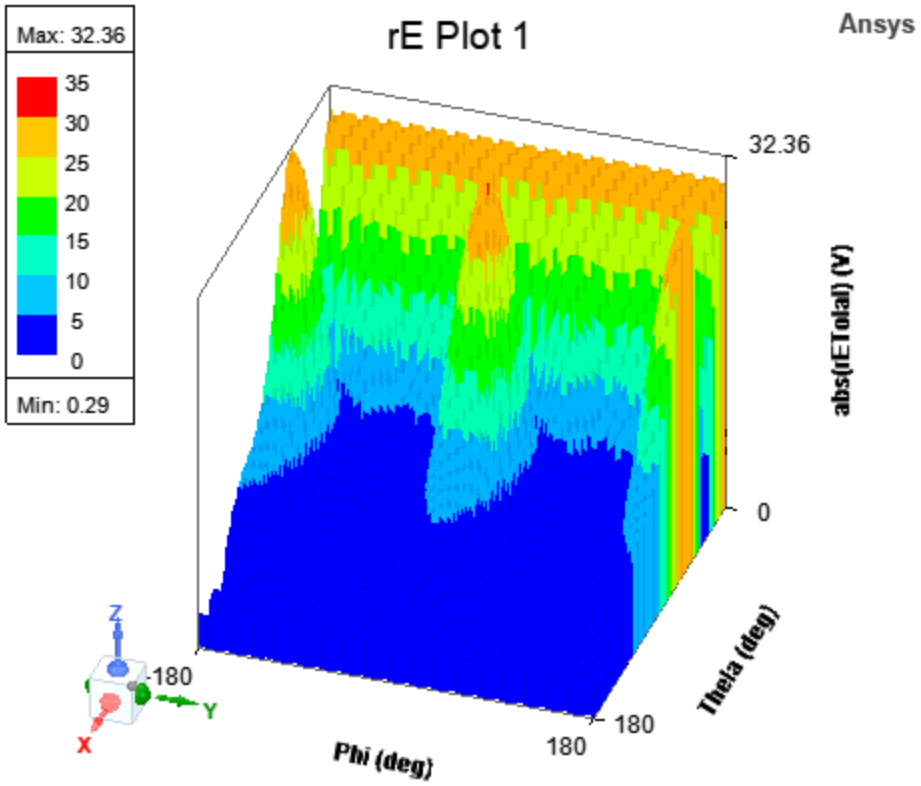
You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Rectangular Plot with Medium Visual Detail



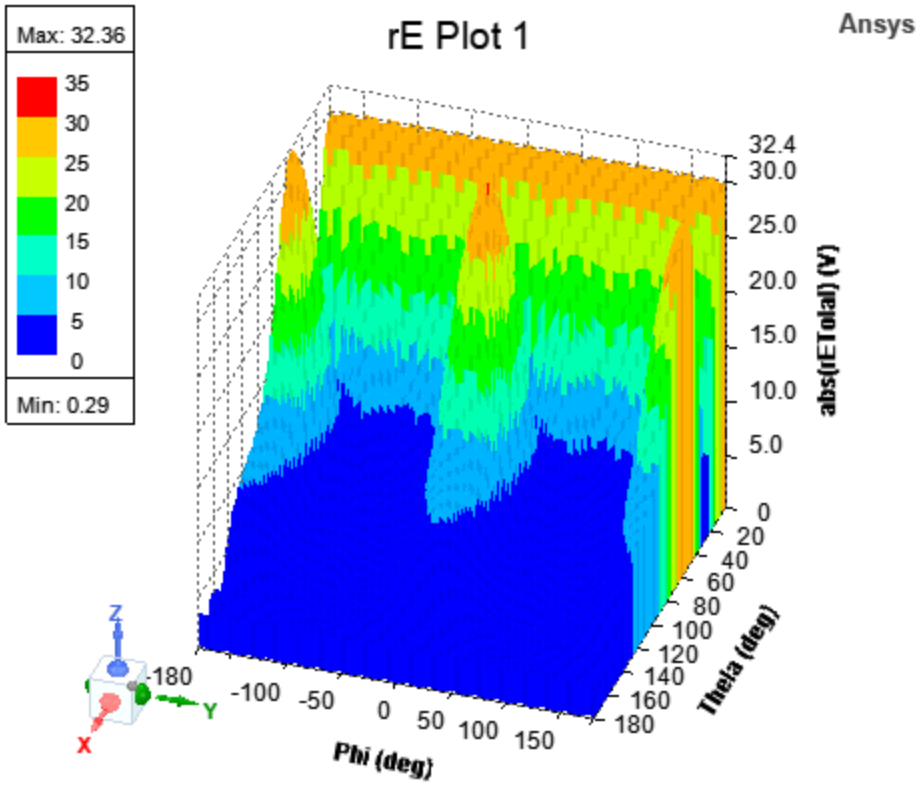
On creation, a 3D Rectangular Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under Medium Visual Detail level, a 3D Rectangular Plot has 3 ticks per axis (X, Y, Z axis) which will show min, max and middle value. This setting also shows axes labels.

3D Rectangular Bar Plot with Low Visual Detail



With Visual Detail set to Low, a 3D Rectangular Plot shows axes with 2 ticks corresponding to min and max values. It also shows axes labels and grid borders.

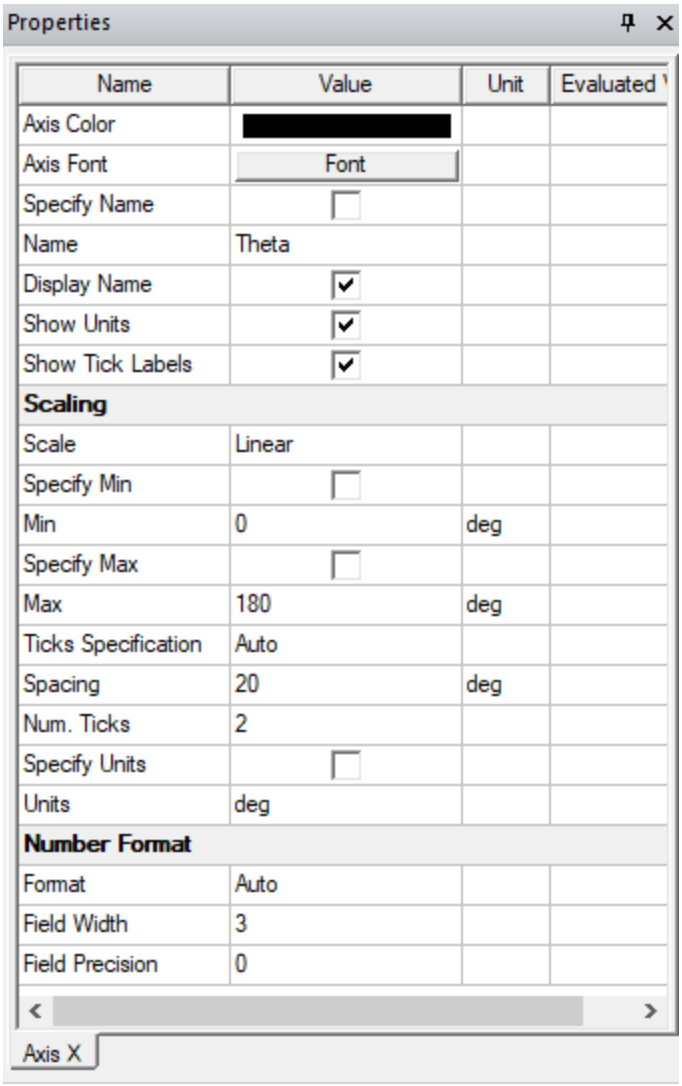
3D Rectangular Bar Plot with High Visual Detail



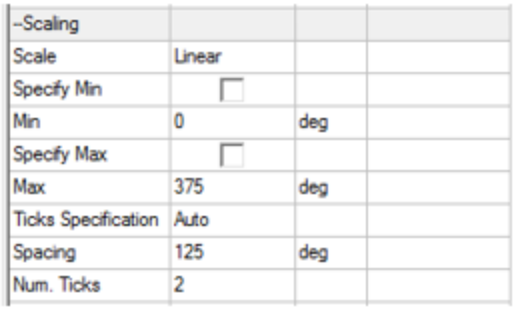
With Visual Detail set to High, a 3D Rectangular Plot shows all Cartesian axes and grids together with all ticks and axes labels.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:



You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

> **Note:**
>
> With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property.
>
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto.
> - If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

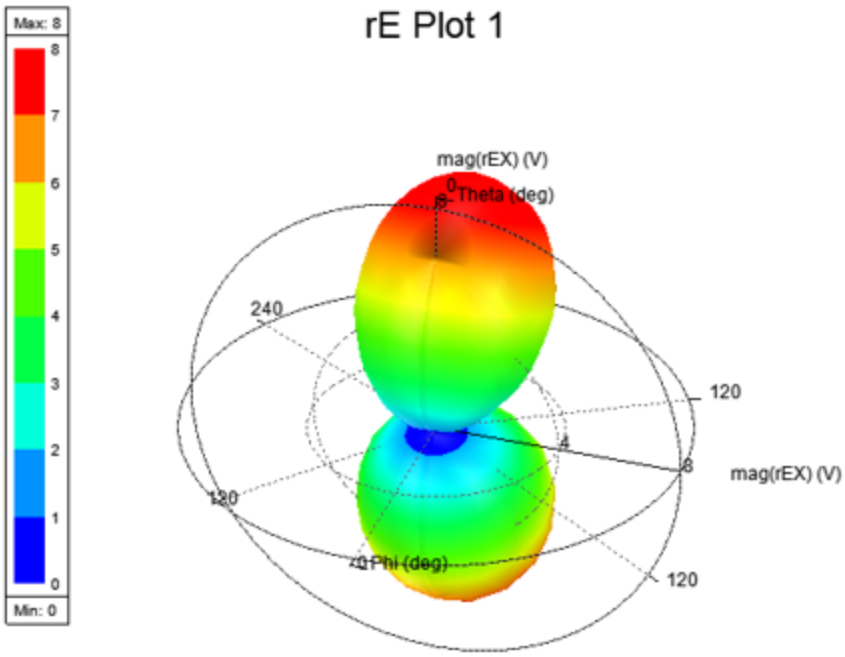
Creating 3D Polar Plots in RMxprt

A 3D polar plot is a 3D circular chart divided by the spherical coordinates R, theta, and phi, where R is the radius, or distance from the origin, theta is the angle from the x-axis, and phi is the angle from the origin in the z direction.



Interacting with 3D Polar Plots

You can Rotate, Zoom and Pan a plot.

Clicking on a plot entity selects it, highlighting the selected entity in bold.

Double-clicking anywhere in the plot brings up the Properties dialog box. The properties are grouped appropriately under various tabs, which correspond to plot entities:

- General: For general plot properties such as Visual Detail level and background color
- Header: Properties related to plot Header/Title
- Axis Phi: Properties related to the circular axis which is in XY plane
- Axis Theta: Properties related to the circular axis which is in YZ plane
- Axis Rho: Properties related to the radial axis
- Grid phi-rho-theta(0): Properties related to phi-rho grid at theta = 0 (XY plane)
- Grid theta-rho-phi(90): Properties related to theta-rho grid at phi = 90 (YZ plane)
- Color Key: Properties related to the color key, including borders, background, Min and Max, as well as number format and precision.
- Contour: Properties related to contouring of all curves/surfaces
- Surface: Properties related to the curve

Selecting a property also displays its properties in the Property window. You can edit the properties to customize the appearance of the plot. See "Controlling Visual Detail in a 3D Plot" on page 26-178.

Creating a 3D Rectangular Plot

1. Click **RMxprt>Results>Create RMxprt Report>3D Rectangular Plot** .
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a pull down selection list containing options for plotting vs ElectricDegree, Speed, or a user-selected Parameter.
3. Under the **Z** tab, specify the information to plot along the z-axis:
   a. In the **Category** list, click the type of information to plot.
   b. In the **Quantity** list, click the value to plot.
   c. In the **Function** list, click the mathematical function of the quantity to plot.
   d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

   e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.
4. On the **Trace** tab, **Y** (**Secondary Sweep**) lines, specify the information to plot along the y-axis in one of the following ways:
   - Select the sweep variable to use from the Secondary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
5. On the **Trace** tab, **X** (**Primary Sweep**) lines, specify the information to plot along the x-axis in one of the following ways:
   - Select the sweep variable to use from the Primary Sweep drop down list.
   - If sweeps are available, you can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting). The quantity will be plotted against the primary sweep variable listed.
6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report.**

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, (for example, Force Plot *n* or Output Variables Plot *n*). You can edit the plot names in the project tree and the plot header text in the report synchronizes.

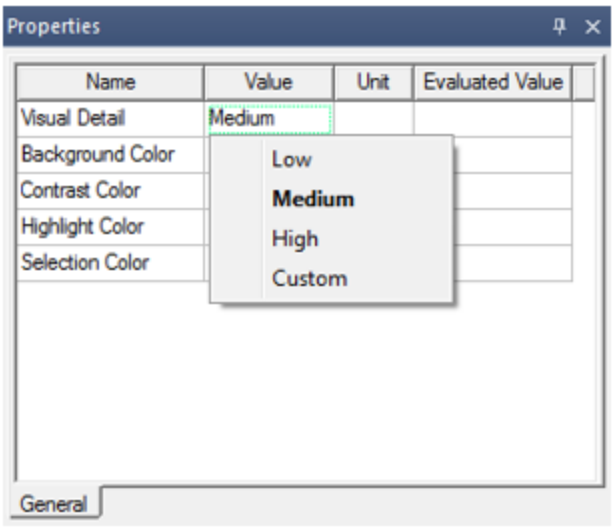
   The function of the selected quantity or quantities will be plotted against the values you specified on an x-y-z graph. The plot is listed under **Results** in the project tree.When you

select the traces or plots, axis or grid labels, plot header, color key, or variable labels, their properties are displayed in the Properties window. The properties for each plot element can be edited directly to modify the plot content and appearance. See Modifying the Background Properties of a Report.

8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace rather than New Report**.

Controlling Visual Detail in a 3D Plot

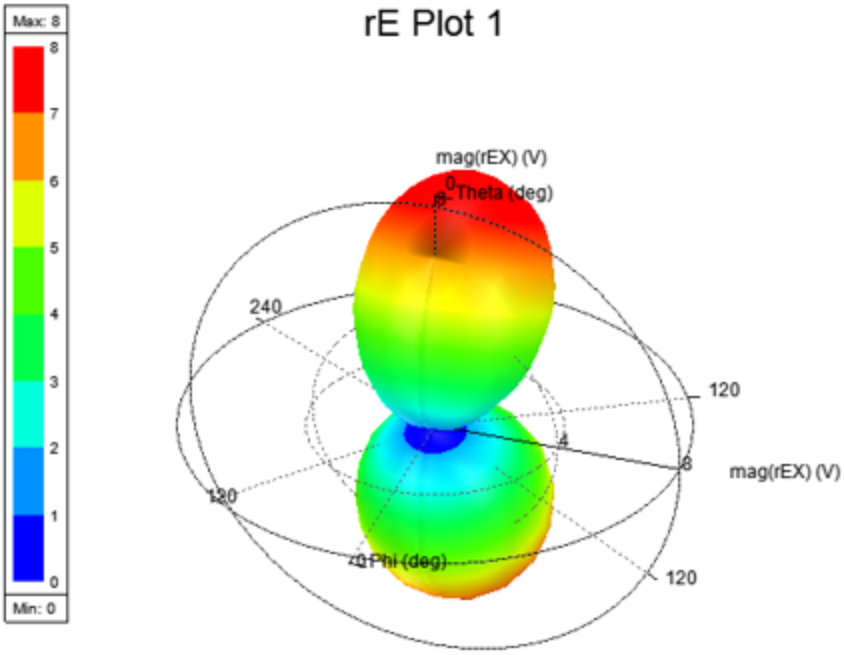
If a particular plot seems busy with information, you can edit plot properties, such as Axis and Grid Attributes for discrete levels of visual detail to improve readability. Double-click anywhere on a plot to display the Properties dialog box. The Visual Detail property on the General tab also provides control suited to different screen and plot sizes.



The Visual Detail menu has four options: Low, Medium (the default), High, and Custom. If you select any Visual Detail, the 3D plot is rendered according to the selected Visual Detail level and the properties reflect the values chosen for the selected visual detail level. From this predefined visual detail level, if you modify any properties, Visual Detail is automatically set to Custom (or to another predefined visual detail level if the edits happen to match the settings for that level).

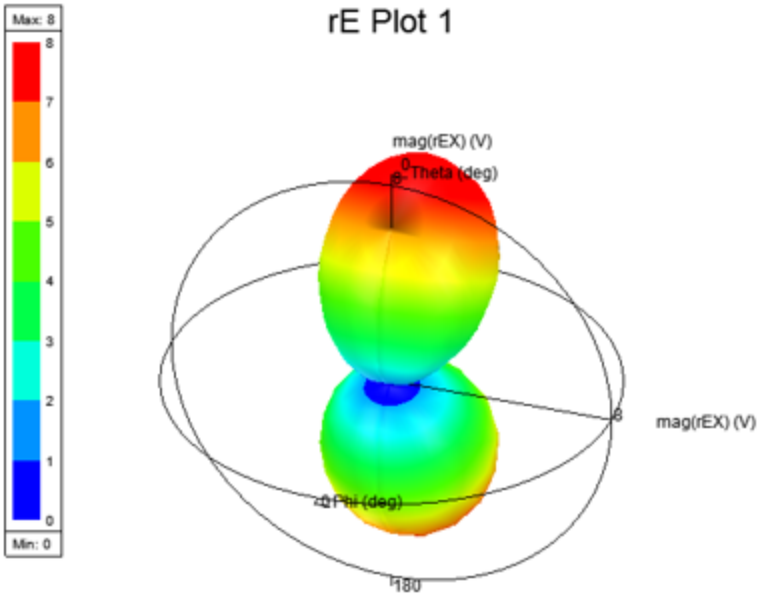
You can also manually set Visual Detail to Custom. In such a case, Custom will inherit property values corresponding to the previous level. This ensures that you can customize settings starting from a baseline provided by the preconfigured Low, Medium or High Visual Detail levels.

3D Polar Plot with Medium Visual Detail



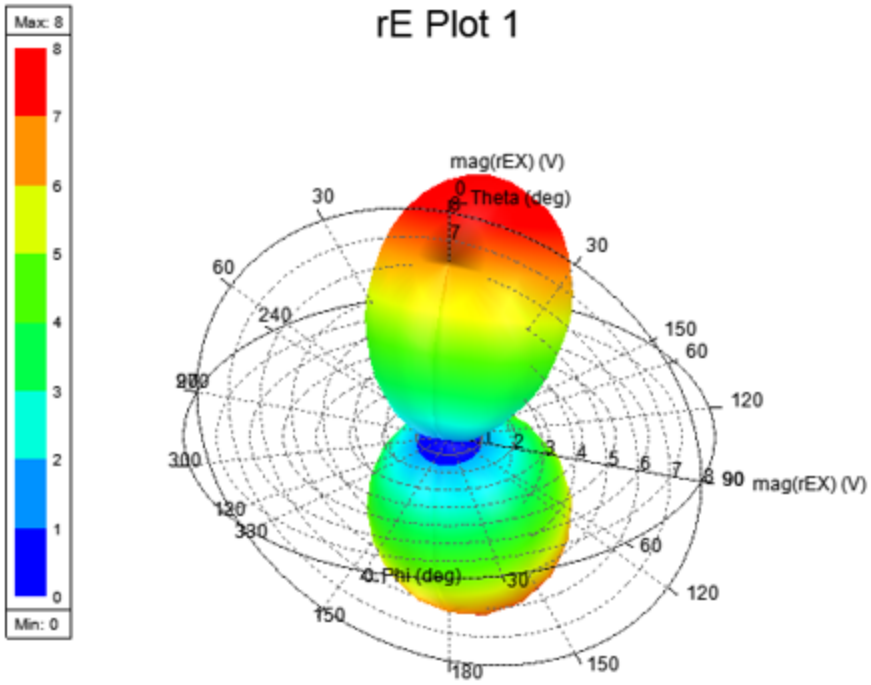
On creation, a 3D Polar Plot has Visual Detail set to Medium and looks and feels as shown above. Specifically, under the Medium Visual Detail level, 3D Polar Plot has 3 ticks per axis (phi, theta and rho axis) which show min, max and middle value. This setting also shows axes labels.

3D Polar Plot with Low Visual Detail



With Visual Detail set to Low, 3D Polar Plot does not show polar grids or grid lines. It only shows axes with 2 ticks corresponding to min and max values. This setting also renders axis labels.

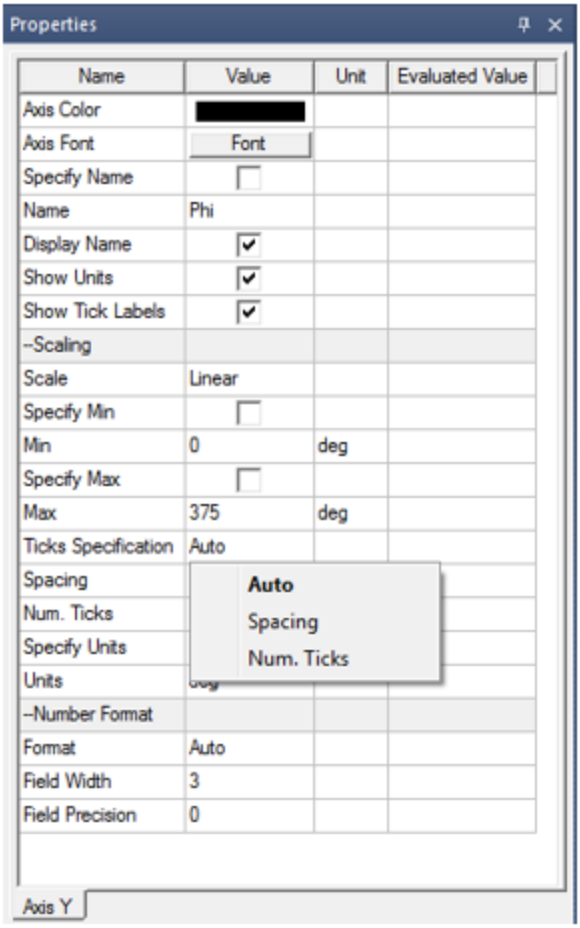
3D Polar Plot with High Visual Detail



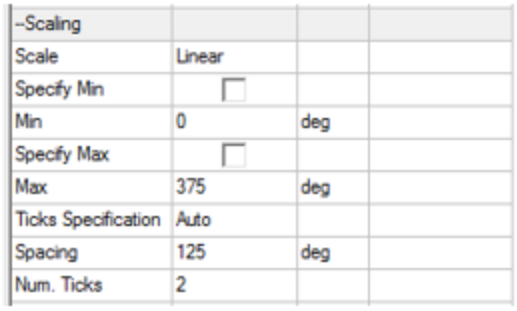
With Visual Detail set to High, a 3D Polar Plot shows all polar axes and grids together with all ticks and axes labels. This is ideal for large plot sizes.

Axis Properties: Ticks Specification and Num. Ticks

Ticks Specification is available on Axis properties, as shown below:



Ticks Specification is a menu with possible values as Auto, Spacing, and Num. Ticks, with Auto being the default value. If Ticks Specification is Auto, then a spacing value is automatically calculated and used to calculate and display the tick labels. **Spacing** shows the calculated value, and Num. Ticks shows the number of ticks based on this spacing value, as shown below:



You can edit the **Spacing** field when Ticks Specification is set to Spacing; otherwise, it is read only.

You can edit the **Num. Ticks** field when Ticks Specification is Num. Ticks; otherwise, it is read only.

Valid Num. Ticks are between 0 and 100, including 0 and 100. If you enter an invalid value, an error message is shown. If you enter a spacing value that results in number of ticks greater than 100, then an appropriate value is shown.

- If Num. Ticks is 0, then no ticks are shown on the axis.
- If Num. Ticks is 1, then only the max value tick is shown on the axis.
- If Num. Ticks is 2, then only the min and max value ticks are shown on the axis.
- If Num. Ticks is greater than 2, then evenly spaced ticks (including min and max) are shown on the axis.

Note	With the addition of the Ticks Specification property to Axis properties, the **Specify Spacing** property was removed as an Axis property. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Unchecked, Ticks Specification is set to Auto. • If an R18.0 or R18.1 project is opened with **Specify Spacing** as Checked, Ticks Specification is set to Spacing.

Creating Data Tables in RMxprt

A data table is a grid with rows and columns that displays, in numeric form, selected quantities against a swept variable or other quantities.

1. Click **RMxprt>Results>Create RMxprt Report>Data Table**.

   The **Report** dialog box appears.
2. In the **Context** section make selections from the following field or fields, depending on the design and solution type.
   a. Solution field with a drop down selection list. This lists the available solutions, whether sweeps or adaptive passes.
   b. Domain field with a drop down selection list.
3. Under the **Trace** tab, **Y** component section, select the quantity you are interested in and its associated function:
4. Under the **Y** tab, select the quantity you are interested in and its associated function:
   a. On the **Category** drop down list, click the type of information to plot.
   b. On the **Quantity** list, click the values to plot. Use CTRL-click to make multiple selections.
   c. In the **Function** list, click the mathematical function to use for the quantity.

d. The **Value** field displays the currently specified Quantity and Function. You can edit this field directly.

Note	Color shows valid expression.

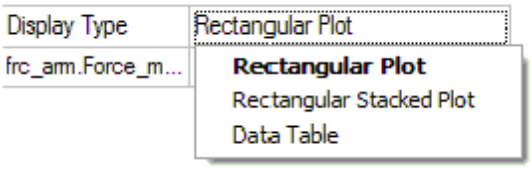
e. **Range Function** button -- opens the **Set Range Function** dialog box. This applies currently specified Quantity and Function.

5. On the **Trace** tab, **X (Primary Sweep) line,** select the sweep variable from the drop down list. By default **All** of the chosen sweep's values are used. You can also select the browse [...] button to display a dialog box that lets you select particular sweep values, specify a range of sweep values (for Time sweeps), or **Use all values** (the default setting).
6. On the **Families** tab, confirm or modify the sweep variables that will be plotted.
7. Click **New Report**.

   This creates a new report in Project tree, displays the report with the defined trace, and enables the **Add Trace** button on the **Report** dialog box. The default name is based on the Report Category you selected, for example, Force Plot *n* or Output Variables Plot *n*. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

   The Y quantity will be listed at each variable value or additional quantity value you specified. The data table is listed under **Results** in the project tree. The plot is listed under **Results** in the project tree and the traces are listed under the plot. When you select the traces or plots, their properties are displayed in the Properties window. These properties can be edited directly to modify the plot.
8. Optionally, add another trace to the plot by following the procedure above, using **Add Trace** rather than **New Report**.

You can also modify the display type of an existing plot from the Properties dialog for that plot. Select the Report icon in the Project tree to display the Properties dialog box. Selecting the Display Type field displays a menu with selections available for that plot.



Once you make a selection, the plot display updates for the current selection.

If you choose to print a data table:

- Selecting print "All" prints the whole table for current data page (if there is more than one data page).
- Selecting print "Pages" prints user-specified pages.
- If the table is bigger than the screen view (that is, it has a scroll bar), printing first scrolls right, prints until no more scrolling occurs, and then scrolls down.
- The Page number appears at the bottom of the page, aligned at center.

- The table layout of each page follows the screen, but without the scroll bar being printed, and no data page bar as on screen.

Sweeping a Variable
Working with Traces

Working with Traces in RMxprt

A trace in a 2D or 3D report defines one or more curves on a graph. A trace in a data table defines part of the displayed matrix of text values.

The values used for a plot's axes can be variables in the design or functions and expressions based on the design's solutions. If you have solved one or more variables at several values, you can "sweep" over some or all of those values, resulting in a curve in 2D or 3D space.

A report can include any number of traces and, for rectangular graphs, up to four independent y-axes.

In general, to add a trace to a report:

1. In the **Traces** dialog box, specify the information you want to plot along the appropriate axes.
2. Click **Add Trace**.
