   A trace is added to the traces list at the top of the **Traces** dialog box. The trace represents the function of the quantity you selected and will be plotted against other quantities or swept variable values. Each column lists an axis on the report and the information that will be plotted on that axis.

   You can modify the information to be plotted by typing the name of the quantity or sweep variable to plot along an axis directly in the boxes.

   The trace will be visible in the report when you click **Done**.

Note	• The **Traces** dialog box can be accessed via the **Create Report**dialog box**.** • You can also Add Trace Characteristics to 2D reports.

Removing Traces in RMxprt

You can traces from the traces list in the following ways:

To *remove one trace* from the report:

- Select the trace you want to remove from the traces list, and then click **Remove Trace**.

To *remove all traces* from the report:

- Click **Remove All Traces**.

Working with Traces

Replacing Traces in RMxprt

To replace a trace in the traces list with a different trace definition:

1. Select the trace you want to remove from the traces list.
2. In the **Traces** dialog box, specify the information you want to plot along the appropriate axes.
3. Click **Replace Trace**.

   The trace you selected is removed, and the new trace information you specified replaces it in the traces list.
4. Click **Done**.

Adding Blank Traces in RMxprt

To add a blank trace to the traces list:

- Click **Add Blank Trace**.

You can now type the quantities to plot in the appropriate axes boxes.

Sweeping a Variable in a Report in RMxprt

In RMxprt, a swept variable is an intrinsic, project, or design variable that typically has more than one value. From the **Traces** dialog box, you can plot any calculated or derived quantity against one or more of the swept variable's values.

When you click the Sweeps tab in the **Traces** dialog box, the first sweep variable listed is the "primary sweep". If you are creating a 3D report, the second sweep variable listed is the "secondary sweep". Any additional sweep variables are represented as additional curves on the graph.

To modify which variable is the primary sweep variable:

- Click the **Name** box for the primary sweep variable, and then click the variable name you want to be the primary sweep variable.

To modify the secondary sweep variable or any additional sweep variable, follow the same procedure.

To modify the values that will be plotted for a variable:

1. Click a variable in the table.

   To the right, all of the possible values for the selected variable are listed.
2. Select **All Values**.

   All of the selected variable's values are plotted.
   - Alternatively, clear **All Values** and select the specific values to plot against the selected quantity.

Selecting a Function in RMxprt

The value of a quantity being plotted depends upon its mathematical function, which you select from the **Function** list in the **Report** dialog box. The available, valid functions depend on the type of quantity (real or complex) that is being plotted. The function is applied to the quantity which is implicitly defined by all the swept and current variables. For example, "Volume(Stator)" is the volume of the model object named Stator for every swept combination of variables ("height" and so forth).

These functions can also be applied to previously specified Quantities and Functions as **Range Functions** when using the Set Range Function dialog.

Some of these functions can operate along an entire curve. These are: min, max, integ, rms, pk2pk, cang_deg and cang_rad.

You can select from the following functions in the **Trace** tab **Function** list, or type them directly into the Y or X field, if necessary:

abs	Absolute value of the simulation quantity which results in a number that is always positive.
acos	Arc cosine i.e. the inverse function of a cosine.
acosh	Inverse hyperbolic arc cosine.
ang	Magnitude of an angle.
ang_deg	Angle (phase) of a complex number, cut at +/-180.
ang_rad	Angle in radians.
arg	Argument of a complex number. It is the angle the complex number makes with the positive x axis. Same as **ang_deg**.
asin	Arc sine i.e. inverse function of sine.
asinh	Inverse hyperbolic sine.
atan	Arc tangent. Takes a tangent value as an argument. Because there are two angles in a circle that can have the same tangent value, and atan can return only one value, it returns a value in the range between -90 degrees and +90 degrees (or between -pi/2 and pi/2 in radians).

atanh	Inverse hyperbolic tan.
atan2	A two-argument version of the **atan** function. Takes the y and x coordinates (including sign information) of a point as arguments and returns the angle from the X-axis. Can return angle values for the full circle (-180 degrees to +180 degrees or -pi to +pi in radians).
avg	Returns the average of the values of the selected quantity. avg = (Area between the curve and the X-axis) / (X length of the curve)
avgabs	Returns the mean of the absolute value of the selected quantity.
bandwidth	Returns the 3dB bandwidth of the selected simulation quantity. For bandwidth, the calculation is based on 3dB below the maximum peak.
cang_deg	Cumulative angle (phase) of the first parameter (a complex number) in degrees, along the second parameter (typically sweep variable). Returns a double precision value cut at +/-180.
cang_rad	Cumulative angle of the first parameter in radians along a second parameter (typically a sweep variable). Returns a double precision value.
cmplx(*re*, *im*)	A complex number, where *re* is the real part and *im* is the imaginary part.
conjg	Conjugate of the complex number.
cos	Cosine.
cosh	Hyperbolic cosine.
crestfactor	Returns the crest factor (peak/RMS) for the selected quantity.
cum_integ	The cumulative integral function returns a set of values that have the same length as the original set of points (the first element will always be zero). Element *I* of the set returned by cum_integ is the integral of elements 1 through *I* of the original data set.
cum_sum	The cumulative sum function returns a data set that has the same length as the original set of points. Element *I* of the set returned by cum_sum is the sum of elements 1 through *I* of the original data set.
dB(x)	20*log10(|x|) to base 10.
dBc	Decibels relative to the carrier. It is the power ratio of the signal to a carrier signal. Gives the relative signal strength.
dBm(x)	10*log10(|x|) +30.
dBW(x)	10*log10(|x|).
dB10	10*log(|x|) to base 10.
dB10normalize	10*log [normalize(mag(x))].
dB20	20*log(x) to base 10.
dB20normalize	20*log [normalize(mag(x))].
deadtime	Obtains the latest time when the qtyl is within a tolerance of zero.

delaytime	Obtains the time from zero to 50% of the target point.
degel	Conversion from degrees electrical to seconds with respect to Hz.
deriv	Derivative of a given parameter.
distortion	Returns the total distortion for the selected simulation quantity and an additional argument frequency, which is the frequency in Hz at which to calculate the fundamental RMS of the simulation quantity.
even	Returns 1 if integer part of the number is even; returns 0 otherwise.
exp	Exponential function (the natural anti-logarithm) of the simulation quantity.
formfactor	Returns the form factor (RMS/Mean Absolute Value) for the selected quantity.
fundamentalmag	Returns the RMS value of the fundamental frequency for the selected quantity, and an additional argument, Frequency, which specifies the fundamental frequency.
gaincrossover	Returns the gain crossover frequency (where the gain is 0 dB) of the selected simulation quantity in Hz.
gainmargin	Returns the gain margin in dB at the phase crossover frequency of the selected simulation quantity. It also requires a reference simulation quantity to which the measured quantity is compared and the AC magnitude and phase angle of the reference quantity. These are entered as the arguments Reference Channel, Base Source Magnitude, and Base Source Angle.
iae	Returns the integral of the absolute deviation of the selected quantity from a target value that is entered via the additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.
if	if(cond_exp,true_exp, false_exp).
im	Imaginary part of the complex number.
int	Truncated integer function.
integ	Integral of the selected quantity. Uses trapezoidal area.
integabs	Absolute value of integral.
ise	Returns the integral of the squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.
itae	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and select the Error category.
itse	Returns the time-weighted squared deviation of the selected quantity from a target value that is entered via an additional argument. To use this function, you need to open the Add Trace Characteristics dialog and

	select the Error category.
j0	Bessel function of the first kind (0^{th} order).
j1	Bessel function of the first kind (1^{st} order).
jn	Bessel function of the first kind (nth order).
ln	Natural logarithm.
log	Natural logarithm (same as ln).
log10	Logarithm base 10.
lowercutoff	Returns the lower 3dB frequency of the selected simulation channel in Hertz.
lsidelobeX	The 'x' value for the left side lobe: the next highest value to the left of the max value.
lsidelobeY	The 'y' value for the left side lobe: the next highest value to the left of the max value.
mag	Magnitude of the complex number.
max	Returns maximum value of the simulation quantity.
max_swp	Returns maximum value of a sweep.
max2	Maximum value of the two simulation quantities. For example, **max2(a,b)** will plot maximum of **a** and **b** for a particular instance.
mean	Returns the average in the set of quantities selected. mean = sum(all y-value) / (number of y-values)
min	Returns the minimum value of the simulation quantity.
min_swp	Returns the minimum value of a sweep.
min2	Minimum value of the two simulation quantities. For example, **min2(a,b)** will plot minimum of **a** and **b** for a particular instance.
mod	Returns the modulus or absolute value of the simulation quantity.
nint	Nearest integer.
none	Returns null value.
normalize	Divides each value within a trace by the maximum value of the trace. ex. normalize(mag(x)).
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise.
overshoot	Calculates peak overshoot given a threshold value and number of evenly spaced points over entire time range.
peakgain	Returns the peak value of gain of the selected simulation quantity in dB.
peakgainfreq	Returns the frequency in Hz at which the peak gain of the selected simulation quantity occurs.
polar	Coverts the complex number in rectangular co-ordinates to polar co-ordinates.
per	Returns the period of a simulation quantity.

phasecrossover	Returns the phase crossover frequency, at which the phase is -180 degrees, in Hz for the selected simulation quantity.
phasemargin	Returns the phase angle in degrees at the gain crossover frequency of the selected simulation quantity.
pk2pk	Peak to peak. Difference between max and min of the first parameter over the second parameter. Returns the peak-to-peak value for the selected simulation quantity.
pkavg	Returns the ratio of the peak to peak-to-average for the selected quantity.
pmax	Maximum period of the selected simulation quantity.
pmin	Minimum period of the selected simulation quantity.
pow	Raises x to the power of y; pow(x,y).
prms	Period Root Mean Square.
pulsefall9010	Returns the pulse fall time of the selected quantity according to the 90%-10% estimate.
pulsefront1090	Returns the pulse front time of the selected quantity according to the 10%-90% estimate.
pulsefront3090	Returns the pulse front time of the selected quantity according to the 30%-90% estimate.
pulsemax	Returns the pulse maximum from the front and tail estimates for the selected quantity.
pulsemaxtime	Returns the time at which the maximum pulse value of the selected quantity is reached.
pulsemin	Returns the pulse minimum from the front and tail estimates for the selected quantity.
pulsemintime	Returns the time at which the minimum pulse value of the selected quantity is reached.
pulsetail50	Returns the pulse tail time of the selected quantity from the virtual peak to 50%.
pulsewidth5050	Returns the pulse width of the selected quantity as measured from the 50% points on the pulse front and pulse tail.
pwl	Piecewise Linear.
pwl_periodic	Piecewise Linear for periodic extrapolation on x.
pwlx	Piecewise Linear x with linear extrapolation on x.
pw_minus	Pulse width of the first negative pulse.
pw_minus_avg	Returns the average of the negative pulse width input stream.
pw_minus_max	Returns the maximum pulse width of the negative pulse of input stream.
pw_minus_min	Returns the minimum pulse width of the negative pulse of input stream.
pw_minus_rms	RMS of the negative pulse width input stream.
pw_plus	Pulse width of the first positive pulse.

pw_plus_avg	Average of the positive pulse width input stream.
pw_plus_max	Max. Pulse width of the positive pulse of input stream.
pw_plus_min	Min. Pulse width of the positive pulse of input stream.
pw_plus_rms	RMS of the positive pulse width input stream.
re	Real part of the complex number.
rect	Converts the complex number in polar to rectangular co-ordinates.
rem	Fractional part of the selected simulation quantity i.e. remainder.
ripple	Returns the ripple factor (AC RMS/Mean) for the selected quantity.
risetime	Obtains the time taken to go from 10% to 90% of target point.
rms	Returns the root mean square value of the selected quantity.
rmsAC	Returns the AC RMS for the selected quantity.
root	nth root function.
rSidelobeX	Returns the X value of right side-lobe occurrence.
rSidelobeY	Returns the Y value of right side-lobe occurrence.
settlingtime	Returns the latest time at which the value of the selected simulation quantity fell outside its tolerance band. The target value of the quantity and the +/- bandwidth of the tolerance band are the additional args.
sgn	Sign extraction.
sin	Sine.
sinh	Hyperbolic sine.
slidingmean	Returns the moving average value of the selected simulation quantity (specified by the first argument). The average is calculated over a period (specified by the second argument).
slidingrms	Returns the moving RMS value of the selected simulation quantity (specified by the first argument). The RMS value is calculated over a period (specified by the second argument).
sqr	Square of the selected simulation quantity.
sqrt	Square root of the selected simulation quantity.
stddev	Returns the standard deviation of given values.
sum	Returns the sum of the given values.
tan	Tangent.
tanh	Hyperbolic tangent.
undershoot	Calculates peak undershoot given a threshold value and number of evenly spaced points over entire time range.
uppercutoff	Returns the upper 3dB frequency of the selected simulation channel in Hz.
variance	Calculates the variance of the given values.
XAtYMax	Threshold crossing time: report first time (x value) at which an output

	quantity crosses YMax.
XAtYMin	Threshold crossing time: report first time (x value) at which an output quantity crosses a user definable threshold.
XAtYVal	Returns the X value at the first occurrence of Y value.
XWidthAtYVal	Returns the X width between the first 2 occurrence of Y value.
xdb10beamdwidth	Width between left and right occurrences of values 'x' db10 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
xdb20beamwidth	Width between left and right occurrences of values 'x' db20 from max. Takes 'x' as argument (3.0 default). To use this function, you need to open the Add Trace Characteristics dialog and select the Radiation category.
YAtXMax	Returns the X value at maximum value of Y.
YAtXMin	Returns the Y value at minimum value of X.
YAtXVal	Returns the Y value at the first occurrence of X value.
y0	Bessel function of the second kind (0^{th} order).
y1	Bessel function of the second kind (1^{st} order).
yn	Bessel function of the second kind (nth order).

Selecting a Parameter, Variable, or Quantity to Plot in RMxprt

Each trace in a report includes a quantity that is plotted along an axis. The quantity being plotted can be a value that was calculated by RMxprt, such as L_{11}, a value from a calculated expression.

To select a parameter, variable, or quantity to plot:

1. In the **Traces** dialog box, select one of the following categories:

Variables	User-defined project or design variables.
Output Variables	Derived quantities RMxprt project or design variables, parameters or solution curves.

2. Select a quantity to plot from the **Quantity** list. The available quantities depend on the selected category and the setup of the design.

Creating Quick Reports in RMxprt

Following is the procedure for creating a quick report.

1. On the Project tree, select a **setup** or **sweep icon** of interest.
2. Right-click to display the shortcut menu and select **Quick Report**.
   The **Quick Report** dialog appears.
3. Select the one or more categories for the report from the list and click OK.

A rectangular plot for each selected category displays. The new plot or plots appear in the Project tree under the Results icon. The default Report Name that appears is derived from the report category specified in the **Quick Report** dialog box. You can edit the plot names in the project tree and the plot header text in the report synchronizes.

Related Topics

Creating Reports
Modifying Reports
RMxprt Quick Report Categories

RMxprt Quick Report Categories

When using the Quick Reports function for Solutions, the following report categories may be available depending upon the solution parameters requested, solution type, etc:

Category	Description
Coil Voltage	Report voltages in the machine coil.
Current	Report currents for each line or phase of the machine, source current, line current, armature current.
Flux Density	Report flux density in the machine air gap, flux linkages.
Induced Voltage	Report Induced Line and Phase voltages.
Misc.	Report miscellaneous quantities specific to the machine type such as power factor, torque to current ratio.
Percentage	Report machine efficiency.
Power	Report air gap power, output power.
Torque	Report cogging torque, output torque, magnet generated torque, induction torque.
Voltage	Report Line and Phase voltage.
Angle	Reports power factor angle.
Angular Speed	Reports angular speed.
Inductance	Reports air gap permeance.

Specifying RMxprt Winding Data

To define the winding data for an RMxprt machine

1. In the project tree, under **Machine**, open the folder that requires a winding, and double-click **Winding** to open the winding **Properties** dialog box.
   - For some machine types this would be **Machine>Rotor>Winding**, for others, **Machine>Stator>Winding**.
   - You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Specify the desired settings.
3. Click **OK** to close the **Properties** dialog box.

The specific properties available depend on the specific machine.

The following machine types have winding data available:

- Three-Phase Induction Motors (stator winding) and (rotor winding)
- Three-Phase Synchronous Machines (stator winding) and (rotor winding)
- Brushless PMDC Motors (stator winding)
- Adjust-Speed Synchronous Machines (stator winding)
- PMDC Motors (rotor winding)
- Switched Reluctance Motors (stator winding)
- Line-Start Permanent-Magnet Synchronous Motors (stator winding)
- Universal Motors (stator winding) and (rotor winding)
- General DC Machines (rotor winding)
- Claw-Pole Alternators (stator winding)
- Generic Rotating Machines

Setting the Winding Type

RMxprt can automatically arrange almost all commonly used single- or double-layer poly-phase ac windings provided all coils have the same number of turns. Users do not need to define coils one by one. For a double-layer winding, **RMxprt** can also handle the coils with half turns which are arranged in the order of even, odd, even, odd, …, as long as it is physically possible.

RMxprt also provides a very flexible tool **Winding Editor** in order for the users to design a variety of special winding types according to their own needs, such as compound single- and double-layer winding, big- and small-phase-spread variable-pole multiple-speed winding, sine-wave three-phase winding, and so forth. The **Winding Editor** is available to the following types of electric machines:

1. Three-phase induction motors
2. Single-phase induction motors
3. Three-phase synchronous motors and generators
4. Line-start permanent-magnet synchronous motors
5. Claw-pole alternators

6. Adjustable-speed permanent-magnet synchronous motors and generators
7. Brushless permanent-magnet DC motors

When you edit the AC winding of a new design for the first time, RMxprt creates a default winding arrangement based on the basic winding specifications: **Number of Phases**, **Number of Poles**, **Number of Slots**, **Winding Layers**, **Conductors per Slot**, and **Coil Pitch**. Then you can edit the winding configuration based on the default arrangement.

Winding Types Available for Machines

Use the **Winding Type** dialog to set the Winding type.

1. To display the **Winding Type** dialog double-click on the Winding property button.

   Passing the cursor over the buttons for the Winding types changes the graphic to show the available windings for the motor in the design. Choices differ depending on the motor. A Winding Editor selection does not have a graphic.

   Selections for the Three Phase Induction Motor (stator winding) and (rotor winding), Three-Phase Synchronous Machine (stator winding) and (rotor winding), Brushless Permanent Magnet DC Motor (stator winding), Adjust Speed Synchronous Machine (stator winding), Line Start PM Synchronous Motor (stator winding), and Claw Pole alternator (stator winding) include:

   - Editor - enable the Winding Editor
   - Whole Coiled
   - Half Coiled

   Selections for the DC Permanent Magnet Motor (rotor winding) and Universal Motor include (stator winding) and (rotor winding):

   - Lap
   - Wave

   Selection for the General DC Machines (rotor winding) include:

   - Lap
   - Wave
   - Frogleg

   Selections for single-phase induction motor include:

   - Editor - enable the Winding Editor
   - Lap - 90 deg phase belt 2-layer coil for both single and double layer
   - Sin_1 - first class sinusoidal coil for double layer only
   - Sin_2 - second class sinusoidal coil for double layer only

   The Switched Reluctance motor does not involve winding selections.

2. Select the **Winding Type** and click OK.

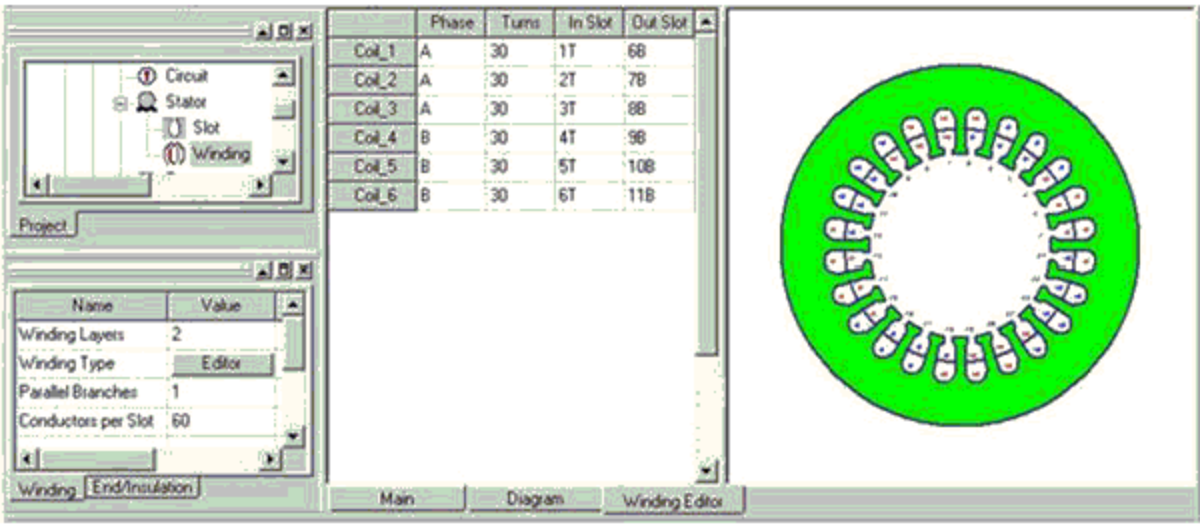
   This closes the window and sets the Winding Type property. If you select the Editor type, It also enables the **Machine>Edit Layout** command on the menu bar.

Enable the Winding Editor

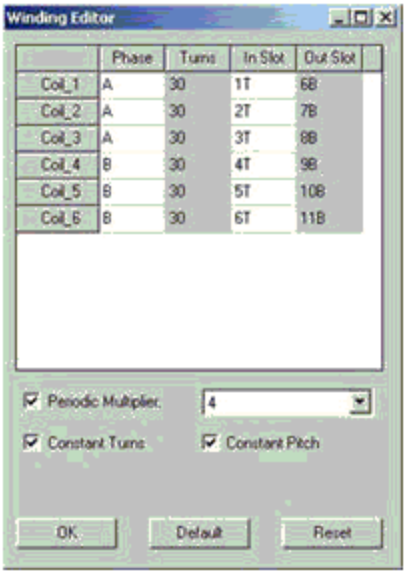
Setting the **Winding Type** property to **Editor** enables the command **Machine>Edit Layout** on the menu bar. To display the dialog box Winding Editor:

1. Open the Winding Properties window and set the Winding Type value to Editor. To do this, double-click on the button Winding Type value to display the Winding Type selection window.

2. Select Editor as the Winding Type and click OK. This closes the Winding Type selection window and sets the Winding Type Value to Editor. It also enables the command Machine>Winding>Edit Layout on the menu bar. Now the Machine Editor window displays the default winding arrangement.



3. Click **Machine>Winding>Edit Layout**. This displays the dialog box Winding Editor as shown. The dialog box Winding Editor includes functions that do not appear in the tab sheet Winding Editor in the RMxprt Machine Editor window.



4.

Edit Winding Configuration

Each row of the winding data table in the Winding Editor dialog box is identified with the coil index in the column Coil. This information is displayed in the tab sheet Winding Editor in the RMxprt Machine Editor window as well, but it is editable in the dialog box Winding Editor.

The winding data table contains four columns:

Phase	is for the phase to which the coil belongs.
Turns	is for the number of turns of the coil.
In Slots	is for the slot number with the coil side current flowing in ('flow-in-side' for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "T" to show the top layer.
Out Slots	is for the slot number with the coil side current flowing out ("flow-out-side" for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "B" to show the bottom layer.

Setting the Number of Winding Layers

To set the number of winding layers:

1. Open the **Winding Properties** window by double-clicking on the Winding icon in the properties window.
2. Use the drop-down menu in the Winding Layers field to set the number as 1 or 2.

   This sets the winding layers used in the winding.

   The number of layers selected makes a difference in the display of data in the **Winding Editor**.

Connecting and Disconnecting Windings

When you have specified the winding data, you can execute the following commands to automatically connect or disconnect the windings.

- **Machine>Winding>Connect All Coils**

  Upon executing, the graphical display in the main window shows the connections.
- **Machine>Winding>Disconnect All Coils**

  Upon executing, the graphical display in the main window updates to remove the connection.

View Winding Connections

Poly-phase Winding Editor

RMxprt provides a **Winding Editor** in order for users to design variety of special winding types according to their own needs, such as compound single- and double-layer winding, big- and small-phase-spread variable-pole multiple-speed winding, sine-wave three-phase winding, and so forth. The **Winding Editor** is available to the following types of electric machines:

- Three-phase Induction Motor
- Three-phase Synchronous Motor
- Three-phase Synchronous Generator
- Permanent-magnet Synchronous Generator
- Line-start Permanent-magnet Synchronous Motor
- Adjustable-speed Permanent-magnet Synchronous Motor
- Brushless Permanent-magnet DC Motor
- Claw-pole Alternator

You input data for **Number of Poles** in **the Machine Properties** window and data for the **Number of Slots** and Slot Type in the **StatorProperties** window. You set the **Number of Slots** in the **Winding Properties** window. **RMxprt** automatically arranges the winding layout and display the relevant information that has been specified in the **Winding Editor** tab of the **RMxprt** main window. As long as the edited winding data have been saved, the **Winding Editor** tab will display the last saved winding data whenever **Winding Editor** dialog is launched. The left top part of the **Winding Editor** tab shows the winding data, as does the Winding Editor dialog box. In this area, the total number of rows equals half the number of slots.

Enabling the Winding Editor Dialog

Setting the **Winding Type** property to Editor enables the **Machine>Edit Layout** command on the menu bar. To display the **Winding Editor** dialog:

1. Open the **WindingProperties** window and set the **Winding** property to Editor.

   To do this, double-click on the Winding property button to display the **Winding Type** selection window.
2. Select **Editor** as the **Winding Type** and click OK.

   This closes the **Winding Type** window and sets the Winding Type property to Editor. It also enables the **Machine>Edit Layout** command on the menu bar.
3. Click **Machine>Edit Layout**.

   This displays the **Winding Editor** dialog. The **Winding Editor** dialog box includes functions that do not appear in the **RMxprt** main window **Winding Editor** tab.

   You can also invoke the Winding Editor dialog by:

   a. Right-click on the data table section of the Winding Editor tab of the main window.
   b. This displays an Edit Layout button.
   c. Click the Edit Layout button to display the Winding Editor dialog.

   You can also display the **Winding Editor** dialog by:

   a. Right click in the **Winding Editor** tab main window display.

This displays a shortcut menu.

b. Click **Edit Layout** from the shortcut menu.

Each row of the winding data is identified with coil index in the **Coil** column. This information is displayed in the **Winding Editor** tab in the RMxprt Main window, and it editable in the **Winding Editor** dialog.

- Column **Phase** is for the phase to which the coil belongs.
- Column **Turns** is for the number of turns of coil.
- Column **In Slots** is for the slot number with the coil side current flowing in ('flow-in-side' for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "T" to show the top layer.
- Column **Out Slots** is for the slot number with the coil side current flowing out ('flow-out-side' for short). If 2 Layers are specified in the Winding Properties window, the slot number ends with a "B" to show the bottom layer.

By changing the belonging phase in column **Phase**, the number of turns in column **Turns**, the flow-in-side slot number in column **In Slot**, the flow-out-side slot number in column **Out Slot** for each coil, it is possible to arrange the distribution of coils of single and double layer winding of any type required.

The **Winding Editor** dialog also includes three check boxes:

- **Periodic Multiplier:** indicates the possibility to select the number of unit machines for editing winding arrangement. It has a drop-down menu to show the possible numbers for the periodic multiplier.

  When checked, the pull-down list box to the right displays the numbers of unit machines for selection. Selecting *1* means whole slots are considered as one unit machine, and all coils is listed in the table of the edit window. Selecting *2* lists half of the total coils in the table, and whole slots are divided into two unit machines, etc. When the check box **Periodic Multiplier:** is unchecked, the pull-down list box to the right is grayed (enabled); all the coils are listed in the table.

- Constant Turns.

  Checking the check box (multiple choices) **Constant Turns** indicates that the number of turns keeps constant and the column **Turns** in the table is grayed (disabled). If the check box **Constant Turns** is unchecked, the column **Turns** in the table is brightened allowing for editing and modifying the number of turns.

- Constant Pitch

  Checking this box grays the Out Slots column to the values cannot be edited. It means that the coil pitch is constant. For two-layer windings, all flow-in-side slots are defined as top layer, and all flow-out-side slots as bottom layer. The flow-out-side slot number is automatically computed based on the input in the edit box Coil Pitch in Stator2 page in RMxprt window, and Out Slot column is disabled.

  When the check box Constant Pitch is unchecked, the column Out Slot is enabled to allow arbitrarily changing slot pitch for each coil.

The **Winding Editor** dialog includes three command buttons.

- Click the command button **Default** in the window **Winding Editor**, all the data in the table resumes to the situation of data from automatic arrangement by **RMxprt**.
- Click the command button **Reset** in the window **Winding Editor**, all the data in the table resumes to the situation of data when the window **Winding Editor** was first opened, or resumes to the data that you have saved.
- Click OK to accept the current values and close the **Winding Editor** dialog.

Windings Basic Terminology

Conductor

A conductor refers to a half turn of a coil. A conductor may be formed with one insulated wire, or with several strands of insulated wires.

Strands

A conductor may consist of several wires of same or different sizes stranded together. The number of strands is also called **number of wires per conductor**. The conductor current may not uniformly distribute among all wires, but the current density is uniformly distributed.

Coil

A coil is wound with several **turns**, each turn consisting of two conductors. Coils are generally wound with insulation-wrapped electromagnetic wire continuously on a winding mould. However, coils with single-turn for heavy current are often formed with two separate thick conductors. A thick conductor is hammered onto the winding mould to form a half-coil. The linear part of a conductor imbedded into a slot of iron core is termed **effective side**.

Coil Pitch

The number of slots of the armature iron core spanned by the two effective sides of a coil is termed coil pitch, denoted by y. For instance, if the side of a coil in the 1-st slot spans 8 slots and is connected to the side of the coil in the 9-th slot, the coil pitch of the coil is y = 8.

Full coil pitch:	coil pitch = pole pitch
Short coil pitch:	coil pitch < pole pitch
Long coil pitch:	coil pitch > pole pitch, usually used in variable-pole multiple-speed machines
Pole pitch:	distance between two contiguous poles measured in number of slots. $polepitch = \frac{totalnumberofslots}{numberofpoles}$

Coil Set

The coils belonging to the same phase under one pole are connected in series as a coil set.

Winding

The coils or coil sets of a phase are connected according to certain rules to form a phase winding. A phase may consist of several **branches** connected in parallel. Every branch must produce exactly the same back emf and must have the same resistance. As a result, the phase winding current is uniformly distributed among all branches.

In summary, a **winding** may be connected with several branches in parallel; each **branch** consists of one or more coil sets connected in series; a **coil set** may have several series coils; a **coil** is wound with a number of turns; a **turn** is formed by two conductors; a **conductor** may be stranded by one or more same- or different-size wires.

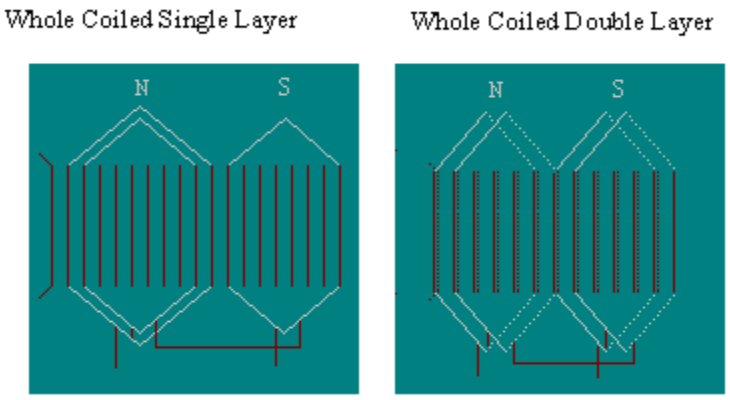
Poly Phase AC Winding

The common armature winding of poly-phase ac machines is catalogued and classified as shown in the following table.

Polyphase AC Winding	
Double layer	Variable-pole multiple speed type
	Fractional slot number type
	Wave-type
	Concentric type
	Lap Type
Single Layer	Crossed Concentric type (whole coiled or half coiled)
	Crossed Chain-type (whole coiled or half coiled)
	Concentric type (whole coiled or half coiled)
	Lap-type (whole coiled or half coiled)
	Chain-type (whole coiled or half coiled)
Compound layer	

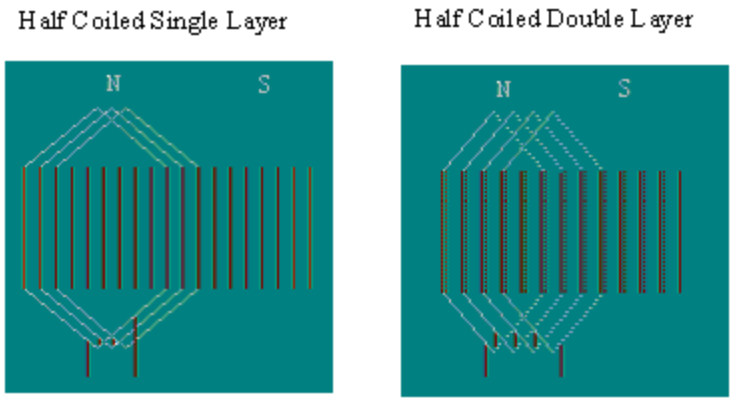
Whole-coiled Windings

When the coils of an AC winding are connected so that there are as many coil sets per phase as there are poles, the winding is called "whole-coiled."



Half-coiled Windings

When the coils are connected so that there is only one coil set per phase per pair of poles, the winding is called "half-coiled."



Single-Layer Windings

All the conductors in one slot are connected in series with all the conductors in another slot to form a single-layer coil. You set the number of winding layers in the Winding properties window, Winding tab. Comparing to double-layer type, this type is characterized by

- Number of coils halved;
- No need for insulation between layers, therefore higher slot filling factor;
- Coil pitch depends on the connection, and is not adjustable;
- Being widely used in small capacity electric machines.

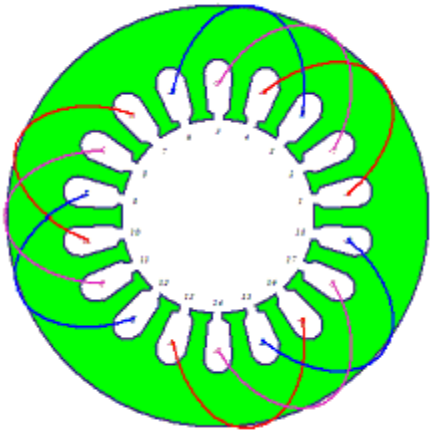
According to different layouts of the end winding, single-layer windings are classified as chain-, lap-, concentric- and crossed-types.

Chain-type Windings

The name single-layer chain-type is from the linked chain-like developed winding diagram. For a chain-type winding, every coil set has only one coil.

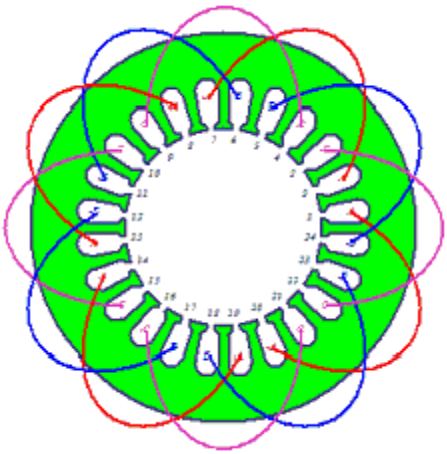
Half-coiled Chain-type Winding

An example of three-phase 6-pole 18-slot single-layer half-coiled chain-type winding is shown in the following figure.



Whole-coiled Chain-type Winding

An example of three-phase 4-pole 24-slot single-layer whole-coiled chain-type winding is shown in the following figure.

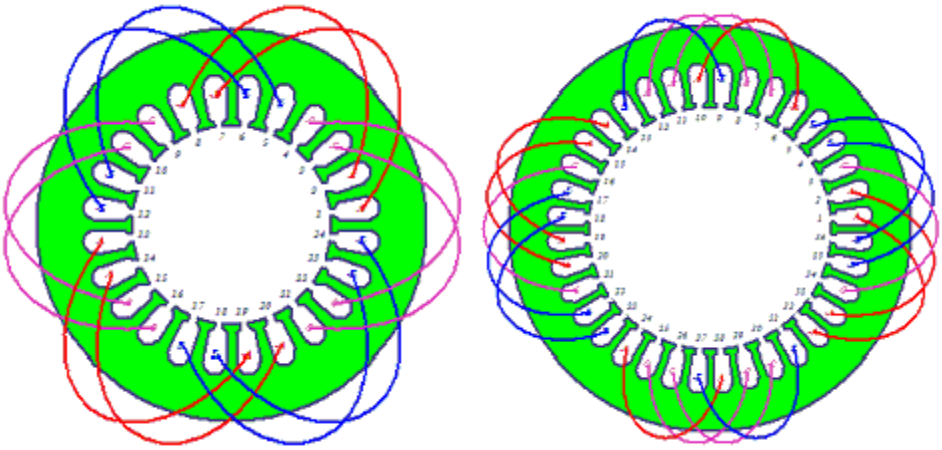


Lap-type Windings

The name single-layer lap-type is from the lapped layout of end connection. In a lap-type winding, at least one coil set has 2 or more coils which are overlapped each other. If some coil sets have only one coil, this winding type is also called "crossed lap-type".

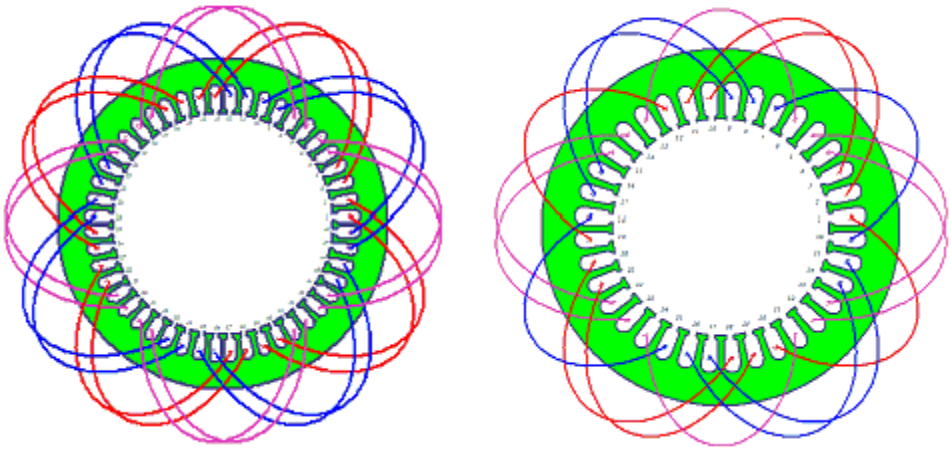
Half-coiled Lap-type Winding

An example of three-phase 4-pole 24-slot single-layer half-coiled lap-type winding is shown in the figure on the left, and an example of three-phase 8-pole 36-slot single-layer half-coiled crossed lap-type windings is shown in the following figure on the right.



Whole-coiled Lap-type Winding

An example of three-phase 4-pole 48-slot single-layer whole-coiled lap-type winding is shown on the left, and an example of three-phase 4-pole 36-slot single-layer whole-coiled crossed lap-type winding is shown on the right1



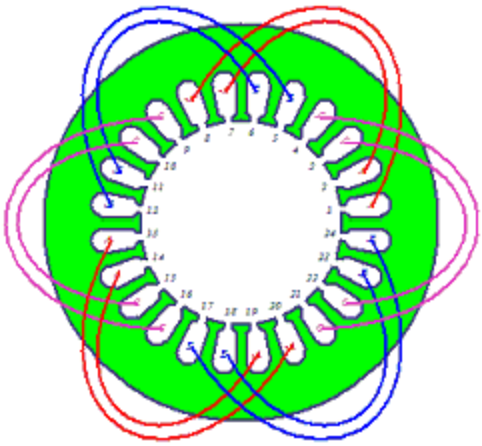
Concentric-type Windings

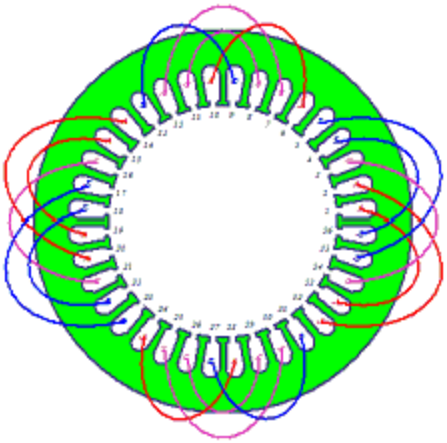
In a concentric-type winding, at least one coil set has 2 or more coils and non coils are overlapped each other. If some coil sets have only one coil, this winding type is also called "crossed concentric-type".

The single-layer concentric-type is formed of coils with different coil pitch, but with the same central line and of concentric-circle-like, therefore is named concentric-type. Its end connection can be arranged in layers, and therefore is convenient to imbed into slots. Nevertheless, the end magnetic leakage is a bit bigger.

Half-coiled Concentric-type Winding

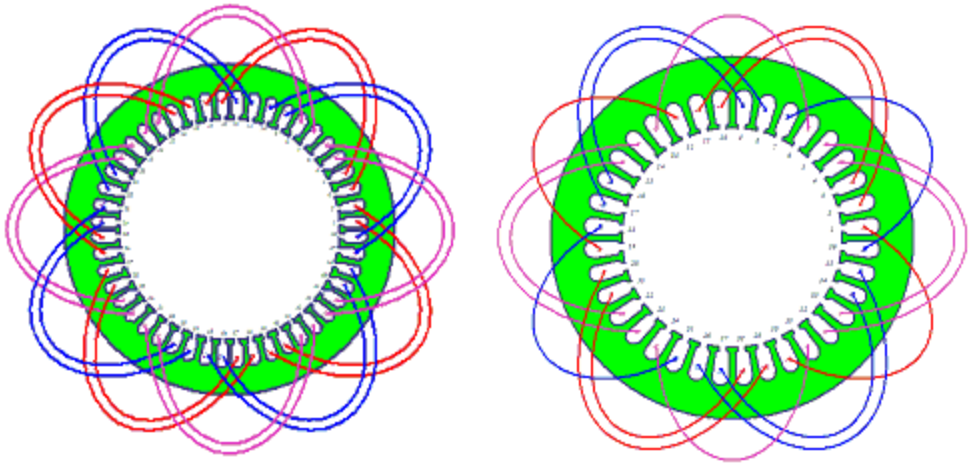
An example of three-phase 4-pole 24-slot single-layer half-coiled concentric-type winding is shown on the left, and an example of three-phase 8-pole 36-slot single-layer half-coiled crossed concentric-type winding is shown on the right.





Whole-coiled Concentric-type Winding

An example of three-phase 4-pole 48-slot single-layer whole-coiled concentric-type winding is shown on the left, and an example of three-phase 4-pole 36-slot single-layer whole-coiled crossed concentric-type winding is shown on the right.



Double-Layer Windings

In this type, the conductors in a slot are arranged in upper and lower layers. One side of each coil is imbedded in the upper layer in one slot and the other side is imbedded in the lower layer in another slot. You set the number of winding layers in the Winding properties window, Winding tab. Comparing to single-layer-type, this type is characterized by:

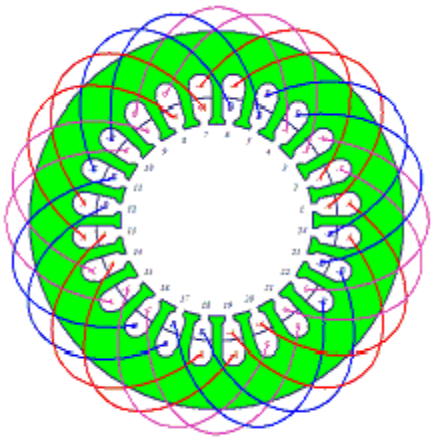
- Number of coils doubled;
- Need for insulation between layers, therefore lower slot filling factor, and danger in electric breakdown between phases;
- Adjustable coil pitch, therefore possible weakening of harmonic emfs with proper short pitch factor to improve electromagnetic properties of electric machines;
- Being widely used in electric machines with capacity over 10 kW.

For the single speed electric machine, the double-layer winding typically adopts whole-coiled type. For the double speed electric machine with doubling number of poles, the double-layer winding is whole-coiled in high speed, half-coiled in low speed.

According to different coil shapes, double-layer windings are classified as lap-, concentric- and wave-types.

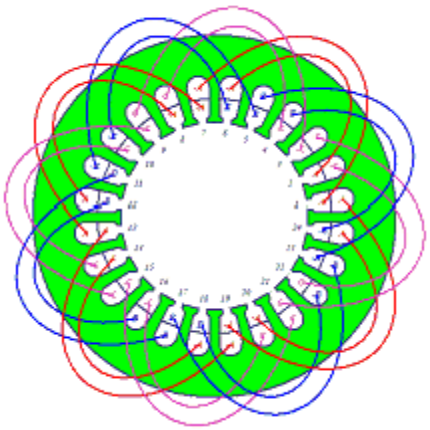
Double-layer Lap-type Winding

An example of three-phase 4-pole 24-slot whole-coiled double-layer lap-type windings (short pitch $y = 5$) is shown below.



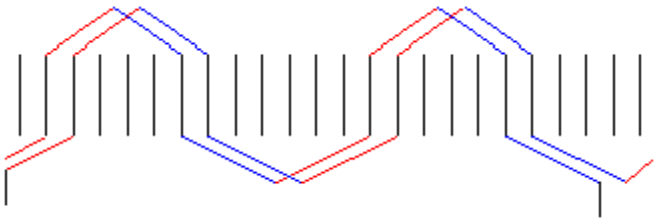
Double-layer Concentric-type Winding

An example of three-phase 4-pole 24-slot whole-coiled double-layer concentric-type windings (short pitch $y = 5$) is shown below.



Double-layer Wave-type Winding

The name double-layer wave-type is from the wave-like developed winding diagram as shown below.



Compared to lap-type:

- The winding of each phase connects the coils under different poles in series in one round, and returns to the left to the first coil, then winds the next round, and so on so forth until all the coils belonging to this phase are connected.
- This type is usually used in single-turn preformed hard coil for low voltage high current electric machines.
- This type needs less connection wire between poles.

Fractional-Pitch Winding

First, introduce a number *q*, called **number of slots per pole per phase**, which is defined as

$$q = \frac{total\,number\ of\ slots}{number\ of\ poles \times number\ of\ phases}$$

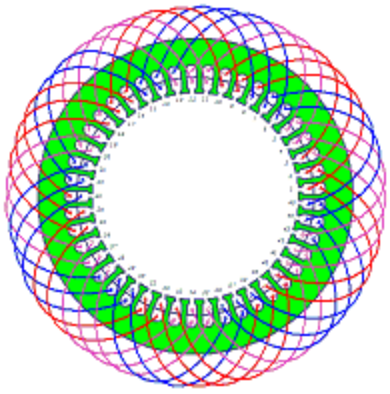
$$q = b\frac{c}{d}$$

A fractional-pitch winding has a fractional number .

An example of three-phase 6-pole 45-slot fractional-pitch double-layer winding

$q = 2\frac{1}{2}$ $\tau = 7\frac{1}{2}$

(, short pitch *y* = 7, pole pitch) is shown here.



Auto-arrangement of AC Windings

RMxprt can arrange these windings automatically if all coils have the same number of turns. This section describes the process to automatically arrange the coil distribution.For winding layout display in **RMxprt**, the lap-type is default if windings are automatically arranged. If a concentric-

type layout display is desired, the winding can be defined by winding editor, as described in the next section.

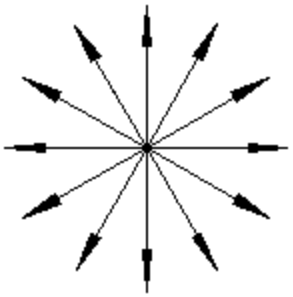
The wave-type winding is effective to a lap-type winding, and is also displayed as a lap-type winding.

Star Vector Diagram

The conductors (or coils) in slots produce emf (or mmf), which can be expressed with unit vector. When the electric machine has number of pole *p*, and number of slots *Z*, the angular phase difference in electric degrees between two contiguous slots is

$$\alpha = \frac{p \times 180^{\circ}}{Z}$$

Drawing the vectors of emfs (or mmfs) in all the slots according to their phase angles forms the star vector diagram of the winding. The following figure shows an example of the star vector diagram of 4-pole 24-slot winding.



If there exists the greatest common factor *t* between the number of slots *Z* and the number of pole pairs *pp* (= *p/2*), the star vector diagram repeats *t* times, i.e. the winding has *t* periods. Let

$$Z_0 = \frac{Z}{t}$$

,

and

$$p_0 = \frac{p}{t}$$

,
then Z_0 and p_0 construct a complete star vector diagram and form a unit electric machine. For the whole-pitch winding electric machine (q, as shown later, is an integer), $t = p/2$. For the fractional-pitch winding electric machine,

$$q = \frac{Z}{mp} = b + \frac{c}{d}$$

where m is the number of phases. If $t > 1$, the angular phase difference between two contiguous vectors is

$$\alpha = \frac{360°}{Z_0}$$

and the difference between the ordinal numbers of the slots of two contiguous vectors is

$$y_0 = \frac{m(bd + c)G - 1}{d}$$

where G is a minimum integer to make y_0 equal to an integer (y_0 should take into account the possible reverse connection of coils under the contiguous pole).

Phase Spread

In the star vector diagram of a unit electric machine, the range occupied by the vectors of each phase under one pole is termed phase spread, expressed in electric degrees or number of slots. For a single-layer winding, the phase spread is 180°/m (m – the number of phases). The phase spread of a double-layer half-coiled winding is 360°/m, and the phase spread of a double-layer full-coiled winding is 180°/m.

The phase spread of a 2-phase winding is always 90° (= 180°/m). Therefore, a 2-phase winding cannot take the double-layer half-coiled winding type. The windings for single-phase induction motor are also considered as 2-phase windings.

When the number of phases is an even number of greater than or equal to 4, the phase spread is always 360°/m. Therefore, a winding with even number of phases (4, 6, …) can take only the double-layer half-coiled winding type.

When the number of phases is an odd number of greater than or equal to 3, the phase spread can be either 360°/m or 180°/m. Therefore, a winding with odd number of phases (3, 5, …) can take any winding types.

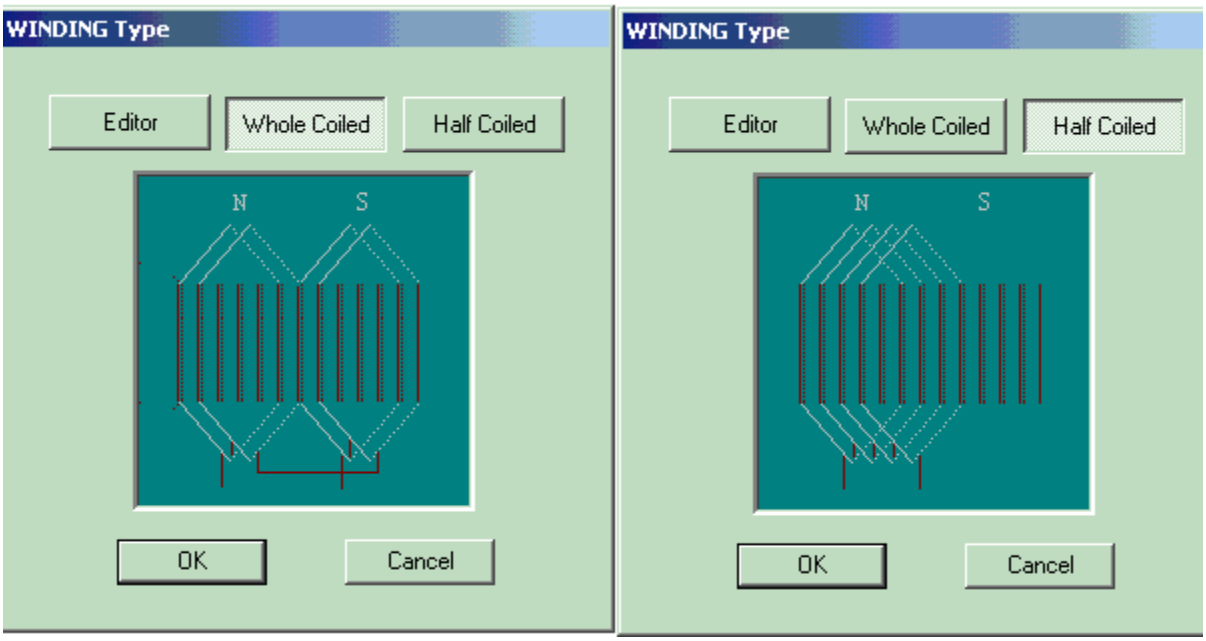
Coil Arrangement

Coil arrangement is completed by the following processes. First, draw the star vector diagram based on number of slots and number of poles. Then divide the whole region (360 electric degrees) to several phase spreads, which is derived from the number of phases and the winding type. Finally, assign all phase spreads to each phase in such a way that the axis of each succeeded phase lags by 360/*m* electric degrees (90 electric degrees for 2 phases).

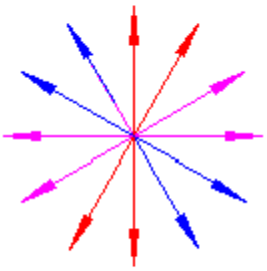
Double-layer Windings

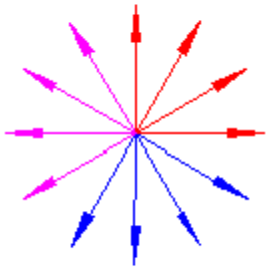
Take a three-phase winding as an example. The width of phase spread of half-coiled winding is $360^o / 3 = 120^o$, the sequence of the phase spread is A, B, C. For whole-coiled winding, the width of phase spread is $180^o / 3 = 60^o$, the sequence of phase spread is A, –C, B, –A, C, –B, where the phase spread with negative sign is termed negative phase spread.

The winding types can be set in the Winding Type panel for a machine that includes these options (in this case, a brushless permanent magnetic DC motor), for double-layer whole-coiled windings as shown in on the left and double-layer half-coiled windings as shown on the right.



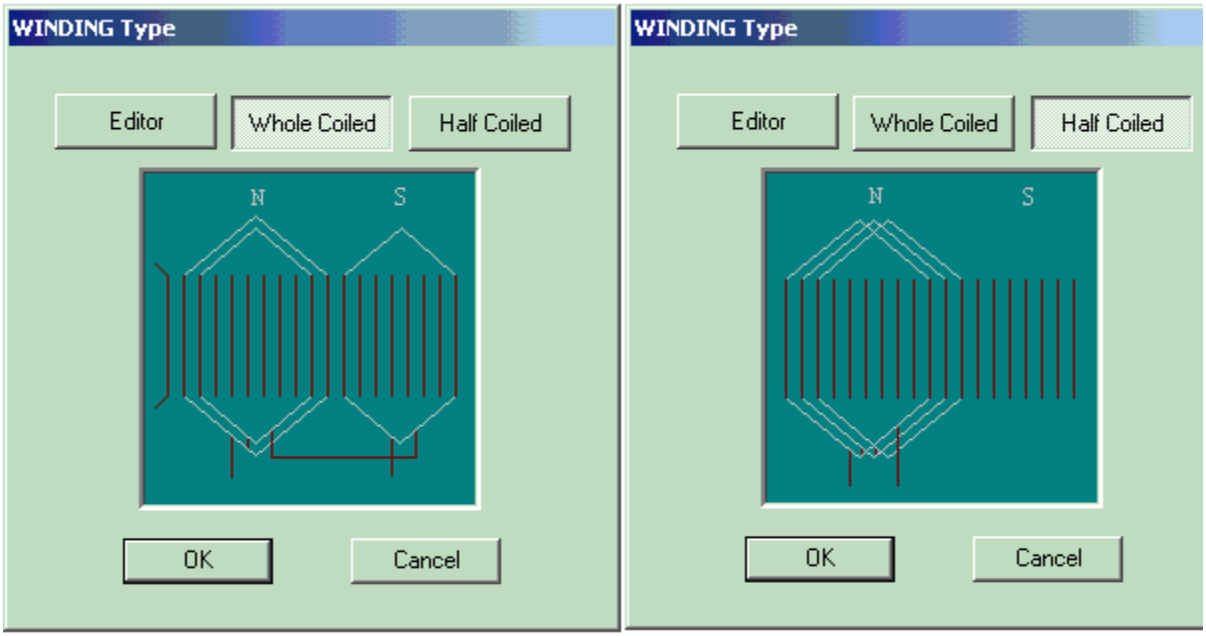
The star vector diagram of a three-phase whole-coiled (60^o-phase-spread) winding is shown below on the left, and that of a half-coiled (120^o phase spread) winding is shown below on the right.





Single-layer Windings

The winding layers can be set in the properties window for the winding, for single-layer whole-coiled windings as shown on the left and single-layer half-coiled windings as shown on the right.



The phase spread of a three-phase single-layer whole-coiled or half-coiled winding is 60^{o}, and the star vector diagram is the same as the double-layer whole-coiled winding.

Fractional-pitch Windings

The number of slots per pole per phase of fractional-pitch winding is a mixed number.

$$q = b\frac{c}{d}$$

In the unit electric machine, the numbers of slots occupied by phase spread are not all the same, but repeat with the radix *d*. In each *d* poles, there are *c* poles with the slot number of phase spread equal to *b* + 1 (big phase spread), *d* – *c* poles with the slot number of phase spread equal to *b* (small phase spread).

Take as an example a three-phase 10-pole 36-slot fractional-pitch winding with phase spread of 60°. The number of slots per pole per phase of fractional-pitch winding is

$$q = \frac{36}{3 \times 10} = 1\frac{1}{5}$$

the greatest common factor between the number of slots 36 and the number of pole pairs 5 is *t* = 1, the angular phase difference between two contiguous vectors in the star vector diagram is

$$\alpha = \frac{360^{\circ}}{36} = 10^{\circ}$$

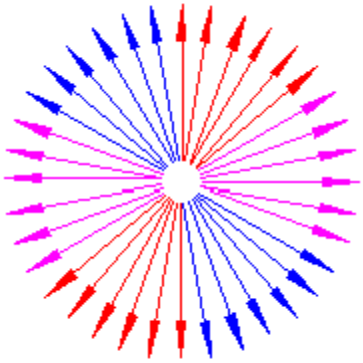
the difference between the ordinal numbers of the slots of two contiguous vectors is (*G* = 2)

$$y_0 = \frac{3(1 \times 5 + 1) \times 2 - 1}{5} = 7$$

the repetition radix *d* = 5. In each 5 pole region, each phase has big phase spread of 1 + 1 = 2 slots under 1 pole, and small phase spread of 1 slot under 4 poles. The repeating format is 2 1 1 1 1 for phase A. The repetition of phase spread distribution for all phases is shown in the following table.

Slot number	1~2	3	4	5	6	7~8	9	10	11	12	13~14	15	16	17	18
Phase spread	A	–C	B	–A	C	–B	A	–C	B	–A	C	–B	A	–C	B
Slot number	19~20	21	22	23	24	25	27	28	29	30	31	33	34	35	36
Phase spread	–A	C	–B	A	–C	B	–A	C	–B	A	–C	B	–A	C	–B

The star vector diagram of winding is shown below.



Asymmetric Windings

Whole-pitch windings (*q* is integer) are always symmetric. Fractional-pitch windings with

$$q = b\frac{c}{d}$$

becomes asymmetric if the denominator *d* is a multiple of the number of phases *m*. In general, it is avoid using asymmetric windings as possible. Nevertheless, it is sometime possible to design poly-phase windings with little asymmetry in order to use existing punching tools.

If *d* is a multiple of the number of phases *m*, but the total number of slots *Z* can be divided by *m*, it is possible to construct poly-phase winding with little asymmetry. **RMxprt** can perform automatic arrangement for this sort of windings and obtain the phase-spread in electric degrees for each phase.

Take as an example a three-phase 6-pole 66-slot fractional-pitch winding electric machine. Since

$$q = \frac{66}{3 \times 6} = 3\frac{2}{3}$$

d = *m* = 3, the winding is asymmetric. The output in the window **Design Output** is shown below.

The information for WINDING ARRANGEMENT is displayed as follows:

The distribution of coil slots to phases:

The 3-phase, 2-layer winding can be arranged in 66 slots as below:

AAAAZZZZBBBXXXXCCCCYYYAAAZZZZBBBBXXXCCCCYYYYAAAAZZZBBBBXXXX CCCYYYY

X, Y and Z stands for –A, -B and –C, respectively. For asymmetric windings, additional information is output, as shown below.

The winding factors of each phase are:

Phase A	0.954119
Phase B	0.954119
Phase C	0.949042

The angles between two-phase winding axes are:

Phase A & B	119.082
Phase B & C	120.459
Phase C & A	120.459

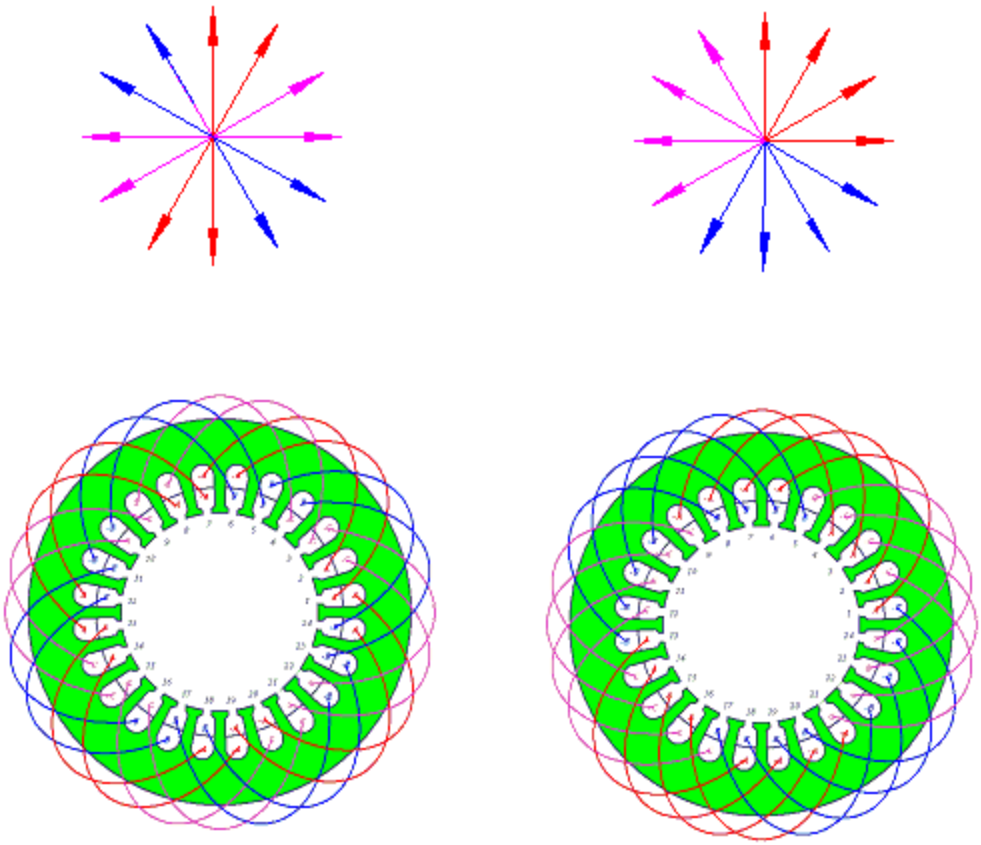
If a sinusoidal rotating field links the winding, the fundamental induced-voltage components will be:

Positive-sequence component	100%
Negative-sequence component	0.286577%
Zero-sequence component	0.639823%

Coil Connections

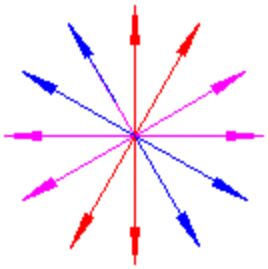
Connection of Double-layer Lap Windings

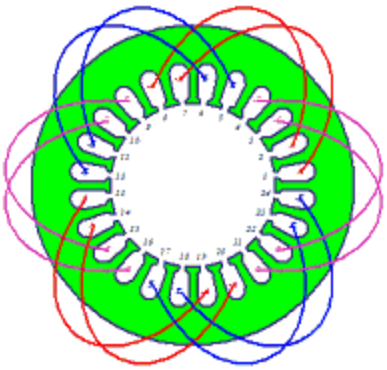
Every vector represents the top-layer effective side of a coil. The bottom effective side of the coil is determined based on the coil pitch, and is not displayed in the diagrams. Therefore, every vector in the diagrams can also stand for a coil. Connect all coils in phase spread of A in positive direction, and all coils in phase spread of –A in negative direction to form the phase A winding. In this way, phase B and C windings can also be connected. The winding connection layouts for the vector diagrams are shown below.

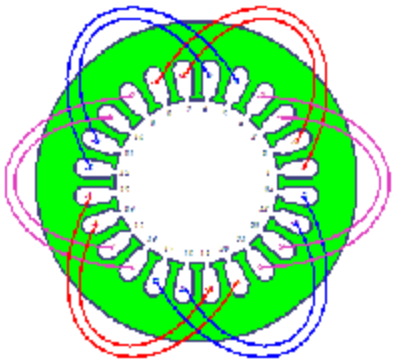


Connection of Single-layer Half-coiled Windings

Every vector in A, B and C phase spread represents "go" effective side of a coil, the "return" effective side of the coil is located in –A, –B and –C phase spread. For the lap type connection, all coils are with full coil pitch. The connection layouts of the lap type and the concentric type, with respect to the same vector drawing are shown below.



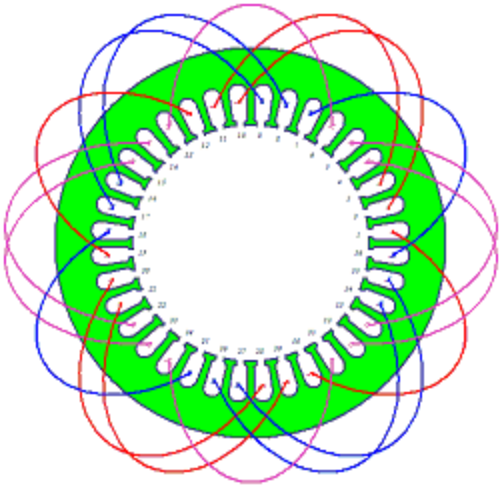




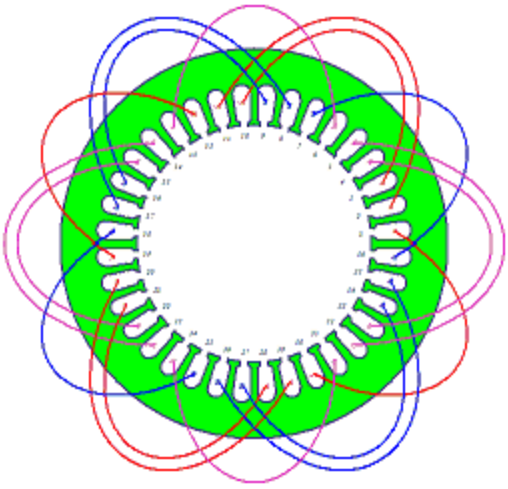
Connection of Single-layer Whole-coiled Windings

In the previous example, for the concentric type (lower right in the diagram), if coil 1 is not connected from slot 1 to slot 8 (long coil pitch: coil pitch = 7 > pole pitch = 6), but connected from slot 1 to slot 20, and slot 8 to slot 13, all coils of phase A winding have coil pitch of 5. In this way, the winding becomes single-layer whole-coiled type with the same star vector diagram and phase spread, and has much shorter average coil pitch. Therefore, single-layer whole-coiled windings consume less electromagnetic wire than single-layer half-coiled windings. **RMxprt** can optimize connections to minimize the average coil pitch to form a single-layer whole-coiled winding.

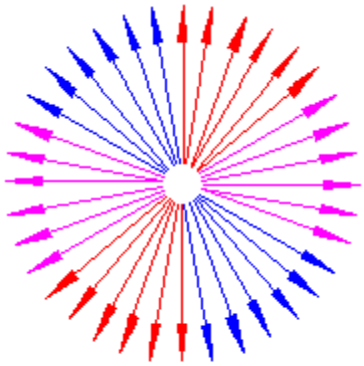
An example of three-phase 4-pole 36-slot single-layer whole-coiled crossed lap-type winding (q = 3, 60^o phase-spread) is shown below.



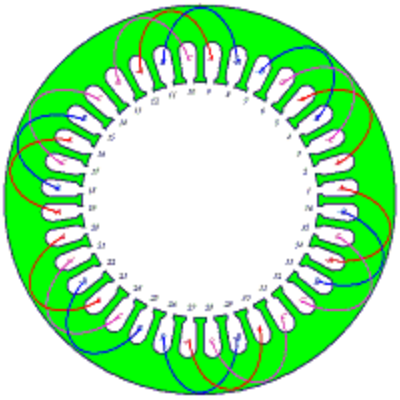
An example of three-phase 4-pole 36-slot single-layer whole-coiled crossed concentric-type winding (q = 3, 60^o phase-spread) is shown below.



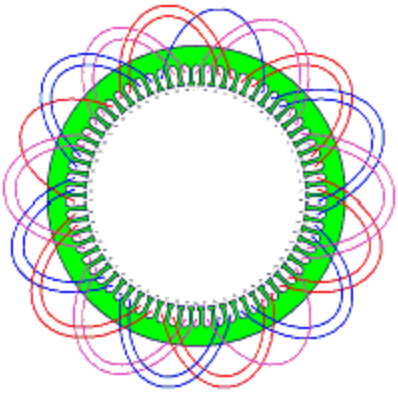
A star vector diagram with fractional coil pitch can also be connected with single-layer whole-coiled type. When the number of slots per pole per phase q <2, as shown in the following vector diagram, the number of coil sets per phase may not equal to the number of poles (6 coils vs 10 poles), but the algorithm to connect coils is the same (minimize the average coil pitch), and therefore, it is still referred as whole coiled windings.



The winding connection layout for the previous vector diagram is shown below.



Another example is an asymmetric three-phase winding. The connection layout is shown below.



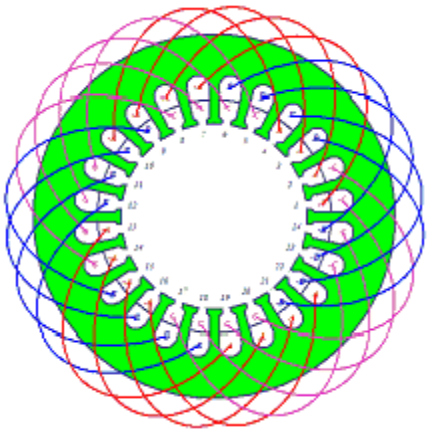
Connection of Double-pole Dual-speed Windings

Commonly used for coils of double-layer windings are lap- and concentric-types. Single-speed double-layer winding electric machine is usually connected as whole-coiled winding. Double-pole dual-speed electric machine is connected as double-layer whole-coiled winding at high speed and as double-layer half-coiled winding at low speed.

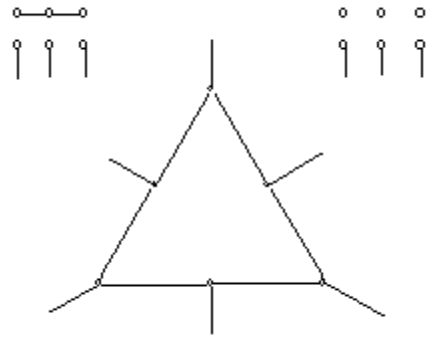
Take as an example a three-phase dual-speed 2/4-pole 24-slot double-layer winding. The arrangement of coils is shown in the Table and in the following figure.

Slot number	1	2	3	4	5	6	7	8	9	10	11	12
Two poles	A	A	A	A	–C	–C	–C	–C	B	B	B	B
Four poles	A	A	A	A	C	C	C	C	B	B	B	B

Slot number	13	14	15	16	17	18	19	20	21	22	23	24
Two poles	–A	–A	–A	–A	C	C	C	C	–B	–B	–B	–B
Four poles	A	A	A	A	C	C	C	C	B	B	B	B



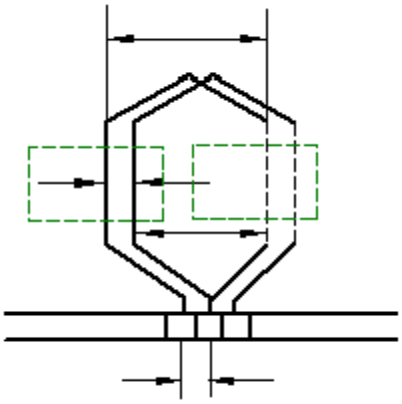
The connection for variation of number of poles is shown in the next figure. On the top-left is the 2-pole 2Y-connection at high speed, on the top-right is the 4-pole -connection at low speed.



DC Windings

Lap Winding

The winding layout of a lap-type winding for dc machines is as shown below.



A lap-type winding has the following relationships:

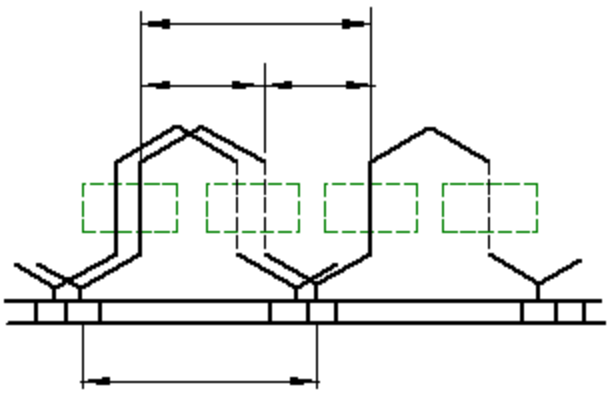
Coil pitch	$y_1 = \frac{Z}{p} \mp \varepsilon = \text{integer}$
Commutator pitch	$y_k = \pm m$
Number of branches in parallel	$a = mp$

where

Z	number of slots
p	number of poles
m	number of multiplex

Wave Winding

The winding layout of a wave-type winding for dc machines is as shown below.

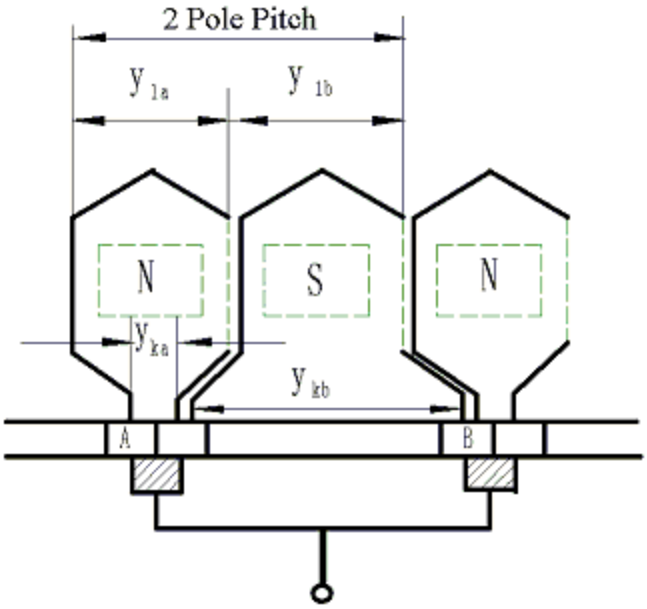


A wave-type winding has the following relationships:

Coil pitch	$y_1 = \frac{Z}{p} \mp \varepsilon = \text{integer}$
Commutator pitch	$y_K = \frac{K \mp m}{p/2} = \text{integer}$
Number of branches in parallel	$a = m$

Frog-leg Winding

A frog-leg winding consists of a lap winding and a wave winding. Assume the lap winding has *m* multiplex number. In order to connect the wave winding in parallel with the lap winding, the wave winding should have the same branch bake emf as the lap winding. Therefore, the number of branches in parallel of the wave winding has to be the same as that of the lap winding, or the multiplex number of the wave winding must be *mp/2*. The winding layout of a frog-leg-type winding with *m=1* for dc machines is as shown below.



A frog-leg-type winding has the following relationships:

Coil pitch	$y_{1a} + y_{1b} = \frac{2K}{p} = \text{integer}$
Commutator pitch	$y_{Ka} + y_{Kb} = \frac{2K}{p} = \text{integer}$ $y_{Ka} = \pm m$

	$y_{k2} = \frac{2K}{p} \mp m$
Number of branch in parallel	$a = pm$

where

m	number of multiplex (of the lap winding)

Virtual Slots

Windings of the dc machine are usually double-layer type. In many cases, often a number of coil sides are imbedded into one slot for simplification of structure. Therefore, the number of slots Z is less than the number of coils S. There exists the relationship

$$Z = \frac{S}{\mu}$$

where μ is the number of coil sides in each layer in one slot and is termed virtual slot factor. Therefore, the number of conductors per slots is equal to multiple of 2μ.

Equipotential Connectors

The points ideally possessing the same electric potential in armature winding are often wholly or partly connected by short copper wire, which is termed equipotential connector.

Equipotential Connector Class A of Simplex-lap Winding

Asymmetry in magnetic circuit, such as eccentric air-gap, causes circulating current in lap winding, increases losses and affects commutation in order. The equipotential connector Class A on the commutator of simplex-lap winding can solve this problem. The connection pitch of equipotential connector Class A of simplex-lap winding y_p is equal to the number of commutator segments per pole pair.

$$y_p = \frac{K}{p} = \frac{K}{a} = \text{integer}$$

Winding with y_p = integer is termed symmetric winding. Only symmetric winding can have equipotential connector Class A.

No need for Equipotential Connector for Simplex-wave Winding

Simplex-wave winding does not possess electrically equipotential points, therefore, can not have equipotential connector. On the other hand, simplex-wave winding does not need equipotential connector.

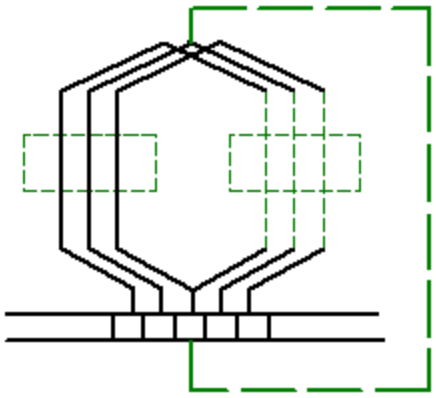
Equipotential Connector Class B of Multiplex-wave Winding

There are electric equipotential points among different sets of simplex-wave windings of multiplex-wave winding. They can be connected to eliminate the nonuniform distribution of electric potential on commutator segments due to inequality of brush resistances. This is termed equipotential connector Class B. The connection pitch of equipotential connector Class B of multiplex-wave winding y_p is equal to the number of commutator segments per branch pair in parallel.

$$y_p = \frac{K}{a} = \text{integer}$$

Equipotential Connector of Multiplex-lap Winding

For multiplex-lap winding, equipotential connector Class A is needed for each set of simplex-lap windings, equipotential connector Class B is needed among different sets of simplex-lap windings. There exist no electrically equipotential points among different sets of simplex-lap windings on the commutator side of armature, however, there exist electrically equipotential points among different sets of simplex-lap windings on different sides of armature as points A and B in the following figure.



Those points can be connected by conductors passing through inside armature.

No Need for Equipotential Connector for Frog-leg Winding

For frog-leg winding, each pair of electrically equipotential points on commutator is connected by a lap coil and a wave coil in series. The connection acts as equipotential connector Class A for lap winding and as equipotential connector Class B for wave winding. Therefore there is no need for extra equipotential connectors.

Pole Windings

The following two types of electric machines possess similar pole winding structure:

- DC machine (motor and generator)
- Three-phase synchronous machine (motor and generator)

RMxprt adopts the same arrangement procedure for pole windings of the two types of electric machines. There are three types of structure as shown in the following figure:

Round Wire	pole winding with round wire. Cylinder Coil	pole winding with rectangular wire wound in standing way. Edgewise Coil	pole winding with rectangular wire wound in flatting way.

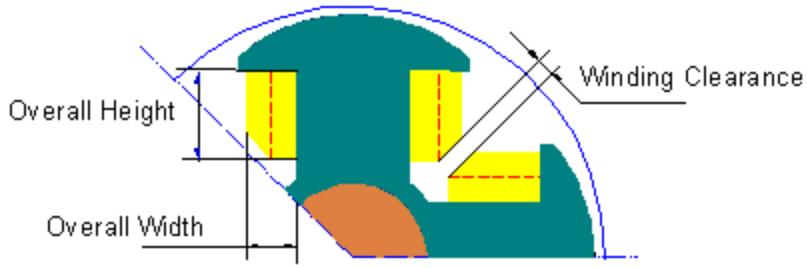
	
Limited Space for Wire Arrangement

Before completing a winding arrangement, **RMxprt** needs to determine the limited space sizes for the winding. The limited sizes include: limited **Overall Height**, limited **Overall Width** and **Winding Clearance** (the clearance between two adjacent pole windings), as shown below.

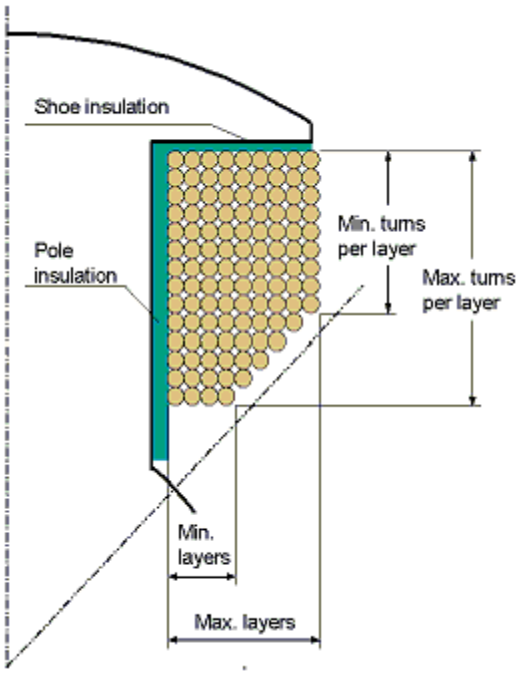


Overall Height, **Overall Width** and **Winding Clearance** can be input from RMxprt panel. If either **Overall Height** or **Overall Width** is set to *0*, **RMxprt** perform automatic space optimization to obtain the maximum space for pole winding arrangement in the condition to guarantee the clearance between pole windings.

If the space from input or determined by space optimization is not sufficient to arrange for the input number of turns per pole, a message of "The rotor/shunt/series/commutating winding control dimension is not big enough." is displayed in **Design Output** window.

Round Wire Winding

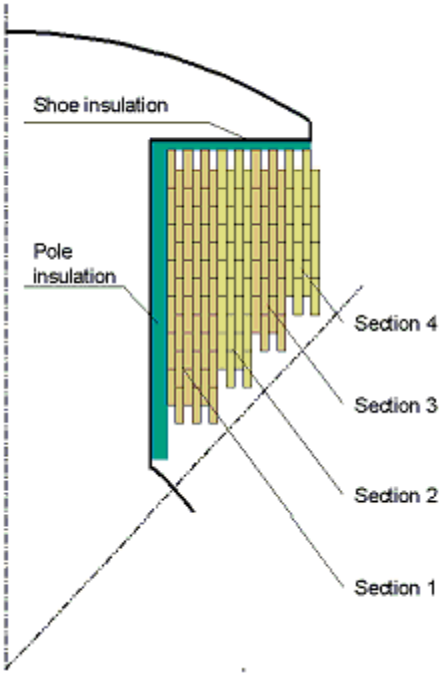
The arrangement of pole winding with round wire is shown below.



With auto-arrangement of pole windings, **RMxprt** calculates maximum number of layers, minimum number of layers, maximum number of turns per layer, minimum number of turns per layer, and the maximum number of turns per pole that is available from the limited space, and so forth.

Cylinder Coil

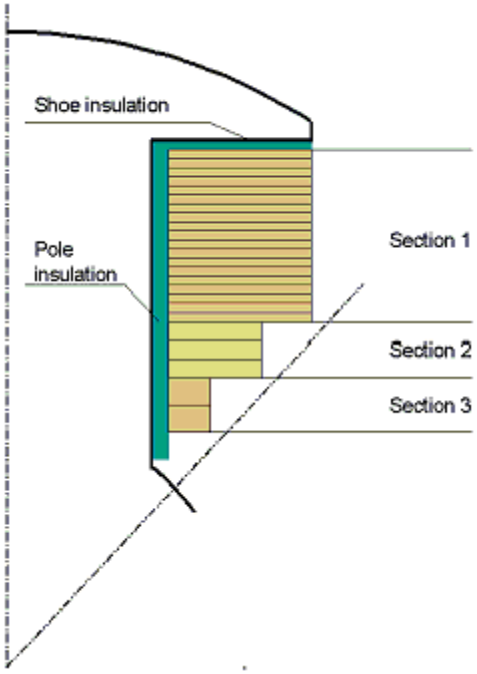
The arrangement of magnetic-pole winding with rectangular wire wound in standing way by **RMxprt** is shown below.



The cylinder coil is wound with half-turn over lapped layer by layer. Layers with the same number of turns constitute a section. The output window **Design Output** displays the number of layers and the number of turns per layer of each section, and the maximum number of turns per pole that is available from the limited space.

Edgewise Coil

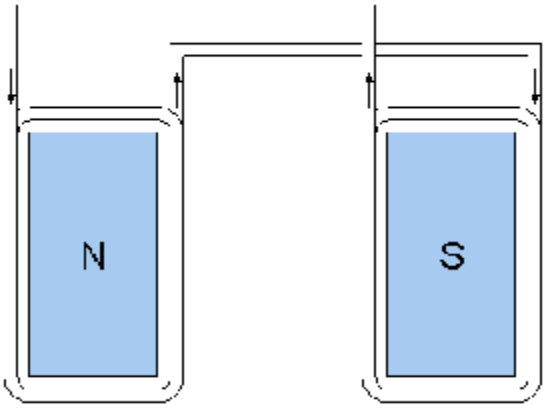
The arrangement of magnetic-pole winding with rectangular wire wound in flatting way by **RMxprt** is shown below.



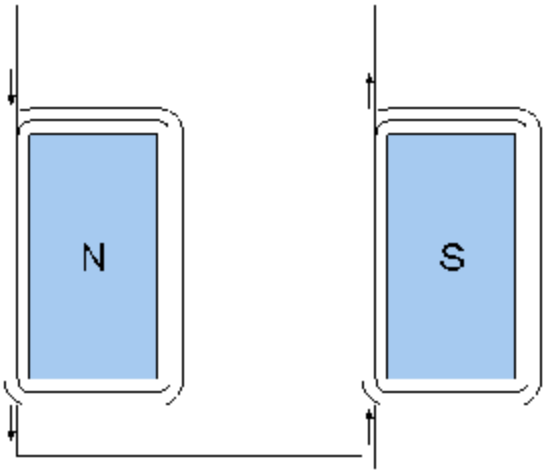
To guarantee the clearance between two adjacent pole windings, the wire width of the lower parts is decreased, while the wire thickness is increased to keep the sectional area of wire invariant as possible. The turns with the same wire gauge constitute a section (maximum three sections are allowed). The output window **Design Output** displays the number of turns of each section and the sizes of wire gauge, and the maximum number of turns per pole that is available from the limited space.

Pole Winding with Half Turns

For some large machines, a half turn may be included due to too few turns per pole. When the number of turns per pole is an integer number, the number of conductors per pole is an even number with equal conductor number at both pole sides. Therefore, the two terminal leads of one pole coil are at the same axial side (or at different pole sides), as shown below.



When the number of turns per pole includes a half turn, the number of conductors per pole is an odd number. In this case, one pole side has one more conductor than the other pole side, and the two terminal leads of one pole coil are at different axial sides (or at the same pole side), as shown below.



Exporting Winding Data

Winding data may be export to a table:

1. Select the **Machine>Winding>Export Layout** command from the menu. You may also right-click in the **Winding Editor** window and select **Export Layout** from the shortcut menu.

2. Browse to the location to save the file and enter a filename.
3. Click **Save** to export the winding data to a file and dismiss the dialog.

Note	The winding must be editable for the Export Layout command to be available. If you are using a standard winding, you can switch to the Winding Editor by: 1. Click on the **winding** in the Project Tree window. 2. In the Properties Window, click on the button next to **Winding Type**. The **Winding Type** dialog is displayed. 3. Select **Editor** as the winding type and click **OK**.

RMxprt Machine Types

Using Ansys RMxprt, you can simulate and analyze the following standard machine types:

- Adjust-Speed Synchronous Machine
- Brushless Permanent-Magnet DC Motor
- Claw-Pole Alternator
- General DC Machine
- Generic Rotating Machine
- Line-Start Permanent-Magnet Synchronous Motor
- Permanent-Magnet DC Motor
- Single-Phase Induction Motor
- Switched Reluctance Motor
- Three-Phase Induction Motor
- Three-Phase Non-Salient Synchronous Machine
- Three-Phase Synchronous Machine
- Universal Motor

Three-Phase Induction Motors

After you have selected **Three-Phase Induction Motors** as your model type, you must define the following:

- General data, such as the voltage, speed, and materials.
- Stator data, such as the slot types, diameter, and wire dimensions.
- Rotor data, such as the slot dimensions, skew, and ventage holes.
- Solution data, such as rated output voltage and frequency.

By option, you can:

- Add a machine housing.
- Add vents to and remove an existing vent from the stator and rotor.

Analysis Approach for Three-Phase Induction Motors

For a three-phase induction motor, the stator winding (with a sinusoidal spatial distribution and *p* pairs of poles) is connected to a three-phase symmetric voltage power supply. The resulting currents in the stator produce a rotating magnetic field. The rotor winding is often a squirrel cage type with the number of poles dictated by the number of poles in the stator. Currents are induced in the rotor bars and produce, in turn, a second rotating magnetic field. The two rotating fields produce a resultant rotating magnetic field in the air gap of the machine. The interaction of this field in the air gap with the rotor bar currents produces an electromagnetic torque, which acts on the rotor in the direction of the rotation of the field in the air gap. A torque of equal value acts upon the stator in the opposite direction.

The stator winding, which is connected to a phase of the supply system, has *p* coils, each with a symmetric spatial distribution and an opening of $\pi D/2p$, where *D* is the diameter of the winding. In this case, the magnetic field in the air gap has *p* periods, and the winding has *p* pairs of poles.

The performance of three-phase induction motors (IndM3) is analyzed based on the equivalent circuit of one phase in the frequency domain as shown in Figure 1.

In the figure, R1 is the stator resistance, X1 is stator leakage reactance, which consists of stator slot leakage reactance, end-winding leakage reactance, and differential leakage reactance. X2 and R2 are rotor leakage reactance and rotor resistance, respectively. X2 includes rotor slot leakage reactance, end-ring leakage reactance, differential leakage reactance, and skewing leakage reactance. Due to the saturation of the leakage field, X1 and X2 are nonlinear. The parameters in the equivalent circuit are dependent on the stator and rotor currents. Due to the skin effects, X2 and R2 are the equivalent values from a distributed-parameter circuit, as shown in Figure 2.

They vary with the rotor slip s. All rotor parameters have been referred to the stator side.

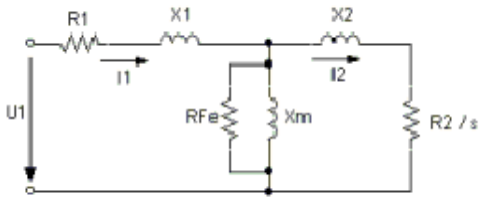


Figure 1

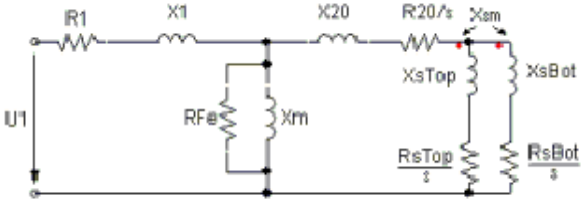

Figure 2

In the exciting branch, Xm is the magnetizing reactance, and RFe is the resistance corresponding to iron-core losses. Xm is a linearized nonlinear parameter that varies with the saturation of the main field.

After a phase voltage U1 is applied to the phase terminals, stator phase current I1 and rotor current I2, which has been referred to the stator, can be easily computed by the circuit analysis. The electromagnetic power Pm, or air-gap power, is computed by the following:

```
Pm = 3 * I2^2 * R2/s
```

The electromagnetic torque Tm is:

$$Tm = Pm/\omega$$

where w is the synchronous speed in rad/s.

The output mechanical shaft torque T2 is:

```
T2 = Tm - Tfw
```

where Tfw is the frictional and wind torque.

The output power is:

$$P2 = T2 * \omega_2$$

where $\omega_2 = \omega * (1 - s)$ and is rotor speed in rad/s.

The input power is:

$$P1 = P2 + Pfw + Pcu2 + PFe + Pcu1 + Ps$$

where Pfw, Pcu2, PFe, Pcu1, and Ps are frictional and wind loss, rotor copper loss, iron-core loss, stator copper loss, and stray loss, respectively.

The power factor is derived from:

$$PF = P1/(m * U1 * I1)$$

The efficiency is computed by:

$$eff = P2/P1 * 100\%$$

Defining a Three-Phase Induction Motor

The general procedure for defining a three-phase induction motor is as follows:

1. Insert a three-phase induction motor into an existing or new project.
2. Double-click the **Machine** entry in the project tree to define the general data, such as the number of poles and machine losses.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
7. Double-click the **Machine-Rotor-Slot** entry in the project tree to define the rotor slot dimensions.
8. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor conductor, ventage hole dimensions, and skew.
9. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
10. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
11. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.

12. Choose **File>Save** to save the project.
13. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once the design is analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Please refer to the *Three-Phase Induction Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example of a three-phase induction motor problem.

Defining the General Data for a Three Phase Induction Motor

Use the **General Data Properties** window to define the basic parameters of the induction motor, such as the number of poles, and frictional loss.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the stray loss factor in the **Stray Loss Factor** field. The stray load loss consists of the losses arising from non-uniform current distribution in the copper and additional core losses produced in the iron by distortion of the magnetic flux by the load current. The IEEE Standard provides different assumed stray load loss values for AC motors rated less than 2500 hp, as follows:
   - 1) 1-125 HP = 1.8% of rated output power
   - 2) 126-500 HP = 1.5%
   - 3) 501-2499 HP = 1.2%
4. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
5. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
6. Enter the given speed in the **Reference Speed** field.
7. Click **OK** to close the **Properties** window.

General Data for Three-Phase Induction Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Three Phase Induction Motor).
Number of Poles	The number of poles the machine contains.
Stray Loss Factor	The stray loss factor: the ratio of stray loss to rated output power.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a Three-Phase Induction Motor

The stator is the outer lamination stack where the three-phase windings reside. In the project tree, double-click **Machine>Stator**, **Machine-Stator-Slot**, and **Machine-Stator-Winding** to define the physical dimensions, slot data, wires, and conductors for the stator.

TTo define general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.

   The **Select Slot Type** window appears.

   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.

c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.

9. Enter the number of sectors in the **Lamination Sectors** field.
10. Enter the thickness of the magnetic end pressboard in the **Pressboard Thickness** field. Enter **0** for a non-magnetic end pressboard.
11. Enter the skew width, measured in slot number, in the **Skew Width** field.
12. Click **OK** to close the **Properties** window.

Stator Data for Three-Phase Induction Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Lamination Sectors	The number of lamination sectors.
Pressboard Thickness	The magnetic press board thickness (0 for a non-magnetic press board).
Skew Width	The skew width measured in slot number.

Defining the Stator Slots for a Three-Phase Induction Motor

Note	If you chose **User Defined Slot** in the **Select Slot Type** window, you must define the slot dimensions using the **Slot Editor**.

To define the stator slots:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.

3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.
4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

5. Click **OK** to close the **Properties** window.

Stator Slot Data for Three-Phase Induction Motors

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-**

	Stator-Slot is selected). Rs is added when the slot type is 3 or 4.

Defining the Stator Windings for a Three-Phase Induction Motor

Define the wires, conductors, insulation, and windings of the stator.

To define the wires and windings:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the six types of windings that are possible (three for one-layer and three for two-layer):

Type	Description
One layer winding Editor	A user-defined one-layer winding arrangement. You need to set up the winding arrangement for each slot.
Whole Coiled	A one-layer whole-coiled winding: Half Coiled	A one-layer concentric half-coiled winding:

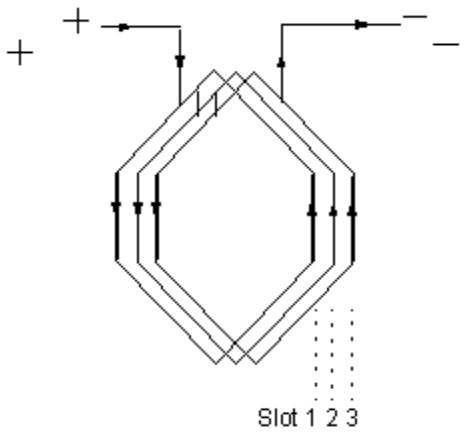
	Two Layer Winding Editor	A user-defined two-layer winding arrangement. When you select for winding layers the you can specify a different winding arrangement for each slot in the Winding Editor.
Whole Coiled	A two-layer whole coiled winding:  The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
Half Coiled	A two-layer half-coiled winding:



There is only one coil per phase per pair of poles.

Note	For a two-layer winding, if you check **Constant Pitch** in the **Winding Editor**, only the top layer needs to be defined; the bottom layer will be determined according to the coil pitch. Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** window and return to the **Properties** window.

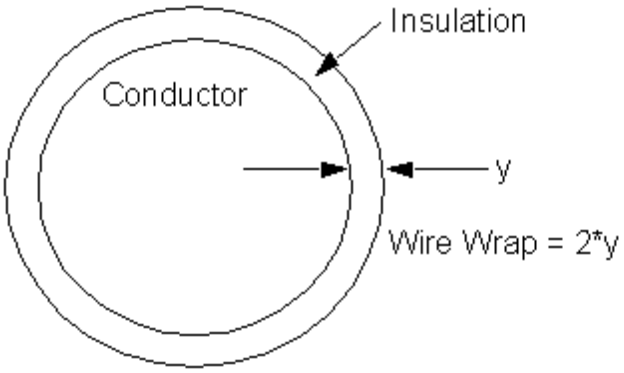
a. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.

b. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.

c. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.

d. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.

e. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



f. Select the **Wire Size**: Click the button for **Wire Size**. The **Wire Size** window appears.
g. Select a value from the **Wire Diameter** pull-down list.
h. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

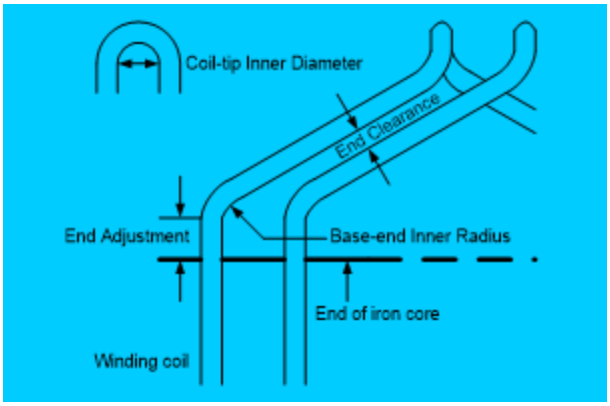
<number>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21 mm and 2 with a diameter of 0.13 mm.

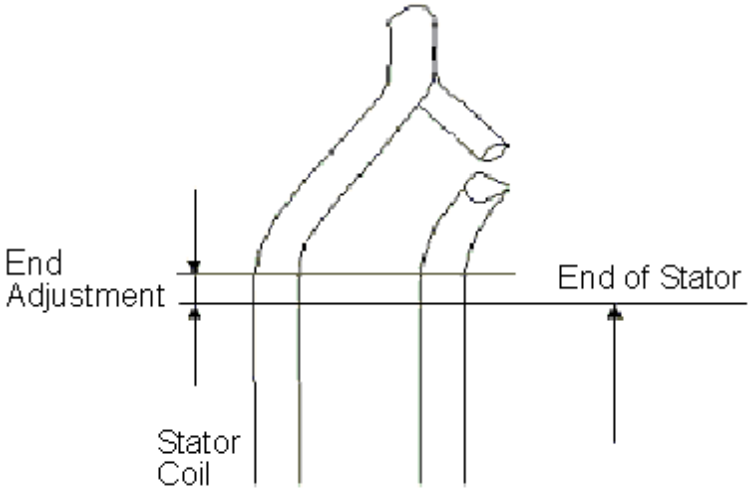
The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

a. Click the **End/Insulation** tab.
b. Select or clear the **Input Half-turn Length** check box.
c. Do one of the following:
   - If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
   - If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the

conductor extends vertically beyond the end of the stator.





5. Enter the inner radius of the base corner in the **Base Inner Radius** field.
6. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
7. Enter the distance between two stator coils in the **End Clearance** field.
8. Enter the thickness of the slot liner insulation in the **Slot Liner** field.
9. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
10. Enter the thickness of the insulation layer in the **Layer Insulation** field.
11. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
12. Click **OK** to close the **Properties** window.

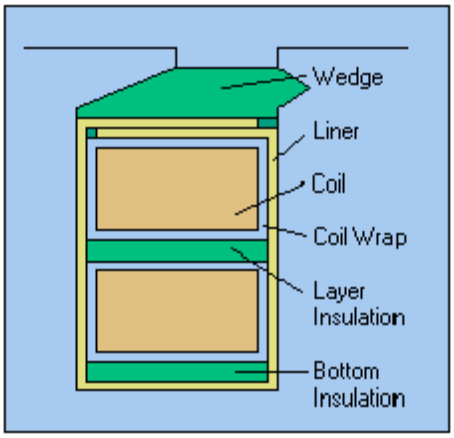
Stator Winding Data for Three-Phase Induction Motors

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the stator winding.
	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.

	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.



Winding Editor for a Three-Phase Induction Motor

For a three-phase induction motor, you may want to specify a different number of conductors for each stator slot. The **Winding Editor** makes this possible by enabling you to specify the number of turns for each coil. To enable the **Winding Editor**, you must have set the **Winding Property** for the **Winding Type** to **Editor**.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.

4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Three-Phase Induction Motor

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Choose **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Stator Vent Data for Three-Phase Induction Motors

By option, you can add a vent to a three-phase induction motor. To add a vent to stator in a three-phase induction motor.

1. Select the stator icon in the project tree.
2. Right-click to display the pop-up menu and select **Insert Vent**.

   The vent icon appears in the project tree under the stator.

To remove a vent to stator in a three-phase induction motor.

1. Select the stator icon in the project tree.
2. Right-click to display the pop-up menu and select **Remove Vent**.
   The vent icon disappears in the project tree under the stator.

The Vent data for the stator includes the following fields.

Vent Ducts	Number of radial vent ducts
Duct Width	Width of radial vent ducts
Magnetic Spacer Width	Width of magnetic spacer which holds vent ducts. 0 for non magnetic spacer
Duct Pitch	Center-to-Center distance between two adjacent Vent ducts

Defining the Rotor Data for a Three-Phase Induction Motor

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine-Rotor**, **Machine-Rotor-Slot**, and **Machine-Rotor-Winding** to define the rotor slots and vents.

To define general stator data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
3. Enter the **Number of Slots** in the rotor.
4. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
5. Enter the outer diameter of the rotor in the **Outer Diameter** field.
6. Enter the inner diameter of the rotor in the **Inner Diameter** field.
7. Enter the length of the rotor core in the **Length** field.
8. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.

9. Enter the **Skew Width**, measured in rotor slot pitch. This value defines by how much the rotor bars are skewed.
10. Optionally, select **Cast Rotor** to allow the conductor to fill all the space available in the slot. Otherwise, RMxprt assumes the slot wedge that fixes the bars is filled with insulator material in a 2D/3D geometry model.
11. Optionally, select **Half Slot** to draw only half of the rotor slots.
12. Optionally, select **Double Cage** to specify the winding as a double-squirrel-cage winding.

    If you select Double Cage, another line appears in the properties to let you specify the Bottom Slot type.

    a. Click on the Custom button on the Double Cage row. This displays the Select Slot Type window.
    The **Select Slot Type** window appears.
    b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

13. Click **OK** to close the **Properties** window.

Rotor Data for Three-Phase Induction Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Stacking Factor	The stacking factor of the rotor core.
Number of Slots	The number of slots the rotor core contains.
Slot Type	The type of slots in the rotor core. Click the button to open the **Select Slot Type** window.
Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Skew Width	The skew width measured in slot number.
Cast Rotor	Select or clear this to specify whether the rotor squirrel-cage winding is cast or not.
Half Slot	Select this to specify a half-shaped unsymmetrical slot.
Double Cage	Select this to specify the winding as double-squirrel-cage.

Defining the Rotor Slots for a Three-Phase Induction Motor

To define the type and dimensions of the rotor's slots:

1. To open the **Rotor Data Slot Properties** window, double-click the **Machine-Rotor-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the slot dimensions in the following fields: **Hs0**, **Hs01**, **Hs2**, **Bs0**, **Bs1**, **Bs2**, **Rs**.
3. Click **OK** to close the **Properties** window.

Rotor Slot Data for Three-Phase Induction Motors

To access the rotor slot data, double-click the **Machine-Rotor-Slot** entry in the project tree.

The **Rotor Slot Data Properties** window contains the following fields:

Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs01	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Rotor Winding for a Three-Phase Induction Motor

To define the rotor winding data:

1. To open the **Rotor Data Slot Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select a **Bar Conductor Type** for the rotor winding bar:
   a. Click the button for **Bar Conductor Type**.
   The **Select Definition** window appears.
   b. Select a conductor type from the list, or define a new conductor type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.

3. Enter the length of the gap between the end ring and the iron core in the **End Length** field. This field specifies the value for only one end of the gap, not both.
4. Enter the end ring dimension in the axial direction in the **End-Ring Width** field. The end ring connects the bars of the rotor to one another.
5. Enter the end ring dimension in the radius direction in the **End-Ring Height** field. The end ring's height covers at least the cross-section of the rotor conductor.
6. Select an **End Ring Conductor Type** for the rotor winding end ring:
   a. Click the button for **End Ring Conductor Type**.
      The **Select Definition** window appears.
   b. Select a conductor type from the list, or define a new conductor type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Click **OK** to close the **Properties** window.

Rotor Winding for Three-Phase Induction Motors

To access the rotor winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Bar Conductor Type	The type of bar conductor used in the winding. Click the button to open the **Select Definition** window.
End Length	The length of the single-side end of the extended bar.
End Ring Width	The width of one side of the end rings in the axial direction. The end ring connects the bars of the rotor to one another.
End Ring Height	The height of the end rings in the radian direction. The end ring connects the bars of the rotor to one another.
End Ring Conductor Type	The type of end ring conductor used in the winding. Click the button to open the **Select Definition** window.

Rotor Vent Data for Three-Phase Induction Motors

By option, you can add a vent to a rotor in a three-phase induction motor.

To add a vent to rotor:

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Insert Vent**.
   The vent icon appears in the project tree under the rotor.

To remove a vent to stator in a three-phase induction motor.

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Remove Vent**.
   The vent icon disappears in the project tree under the stator.

The Vent data for the rotor includes the following fields.

Vent Ducts	Number of radial vent ducts
Duct Width	Width of radial vent ducts
Magnetic Spacer Width	Width of magnetic spacer which holds vent ducts. 0 for non magnetic spacer
Duct Pitch	Center to center distance between vent ducts
Holes per row	Number of axial vent holes per row.
Inner hole diameter	Diameter of vent holes in inner row.
Outer hole diameter	Diameter of vent holes in outer row.
Inner hole location	Center to center diameter of inner hole vents
Outer hole location	Center to center diameter of outer hole vents.

Defining the Shaft Data for a Three-Phase Induction Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Three-Phase Induction Motors

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Three-Phase Induction Motor

To define the solution data:

1. To open the Solution Setup window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.

3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired rotor speed in the **Rated Speed** field. When input Rated Speed is less than the Synchronous Speed, the machine operates as a motor. When input Rated Speed is greater than the Synchronous Speed, the machine operates as a generator. For an induction generator, the rated performance will be calculated at the input Rated Speed with the three-phase windings connecting to infite bus.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **Three-Phase Induction Motor** tab.
9. Enter the electrical line frequency in the **Frequency** field, and select the units.
10. Select the **Winding Connection** from the following options:
    - **Wye** (Y)
    - **Delta**
11. Click **OK** to close the **Solution Setup** window.

Setting Up Analysis Parameters for a Three-Phase Induction Motor

Single-Phase Induction Motors

After you have selected **Single-Phase Induction Motors** as your model type, you must define the following:

- General data, such as the voltage, speed, and materials used in the motor.
- Stator data, such as the slot types, diameter, and wire dimensions.
- Rotor data, such as the slot dimensions, skew width, and ventage holes.
- Solution data, such as rated output voltage and frequency.

By option, you can:

- Add a machine housing.
- Add a vent or remove a vent from the rotor.

Analysis Approach for Single-Phase Induction Motors

The construction of a single-phase induction motor is structurally similar to the poly-phase squirrel-cage induction motors. The primary difference is that the stator windings, which consist of a main winding and an auxiliary winding, have axes of these that are displaced 90 electrical degrees in space. To produce a starting torque, the currents in the two windings must be out of phase. Usually a capacitor is connected in series with the auxiliary winding so that the auxiliary winding current is forced to lead the main winding current by about 90 electrical degrees. Two parallel capacitors can also be used: one for starting, and one for running, so that both a starting and running performance are obtained.

An algorithm called symmetric component method is applied to analyze single-phase induction motors (IndM1). Both voltages and currents of the main-phase and auxiliary-phase windings are decomposed to positive- and negative-sequence components. The equivalent circuits for main-phase positive-sequence components, auxiliary-phase positive-sequence components, main-

phase negative-sequence components, and auxiliary-phase negative-sequence components are shown in (a), (b), (c), and (d) of Figure 3, respectively.

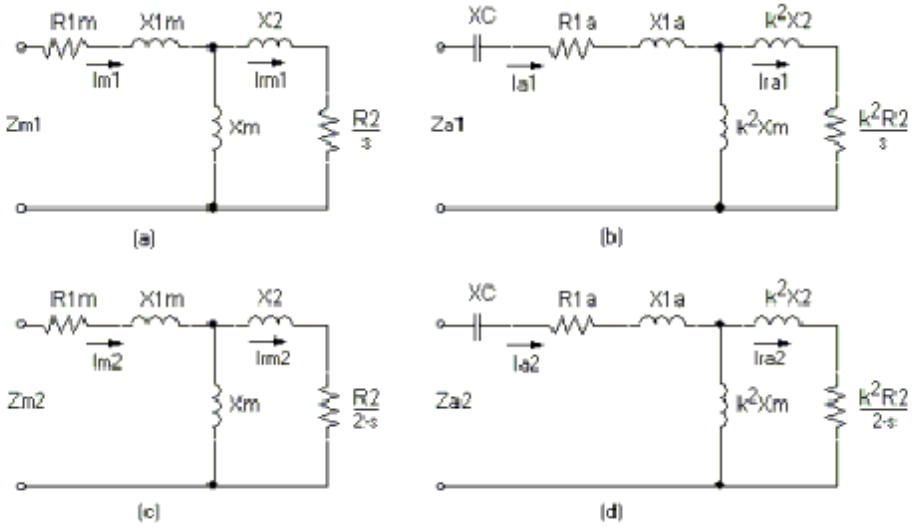

Figure 3

In the figures, R1m, X1m, R1a, X1a, R2, X2, and Xm are main-phase stator resistance, main-phase stator leakage reactance, auxiliary-phase stator resistance, auxiliary-phase stator leakage reactance, rotor resistance, rotor leakage reactance, and magnetizing reactance, respectively. XC is the reactance of the capacitor connected in series with the auxiliary winding, and the coefficient k is the ratio of effective turns of the auxiliary winding to that of the main winding. R2, X2, and Xm have been referred to the main winding. The equivalent impedance of the four circuits is Z_{m1}, Z_{a1}, Z_{m2}, and Z_{a2}, as shown in the figures.

According to the symmetric component method, the positive and negative components of auxiliary-phase currents can be expressed in the form of a phasor as the following:

$$\mathbf{I}_{a1} = (j / k)\mathbf{I}_{m1}$$

$$\mathbf{I}_{a2} = ((j / k)\mathbf{I}_{m2}$$

Because the main winding and the auxiliary winding have the same applied terminal voltage U1, the voltage equations for both windings become the following:

$$\mathbf{U}_1 = \mathbf{U}_{m1} + \mathbf{U}_{m2} = \mathbf{I}_{m1}\mathbf{Z}_{m1} + \mathbf{I}_{m2}\mathbf{Z}_{m2}$$

$$\mathbf{U}_1 = \mathbf{U}_{a1} + \mathbf{U}_{a2} = \mathbf{I}_{a1}Z_{a1} + \mathbf{I}_{a2}Z_{a2} = (j / k)(\mathbf{I}_{m1}Z_{a1} - \mathbf{I}_{m2}Z_{a2})$$

The positive and negative components of main-phase current are calculated by the following:

$$\mathbf{I}_{m1} = \mathbf{U}_1(Z_{a2} - jkZ_{m2}) / (Z_{m1}Z_{a2} + Z_{m2}Z_{a1})$$

$$\mathbf{I}_{m2} = \mathbf{U}_1(Z_{a1} + jkZ_{m1}) / (Z_{m1}Z_{a2} + Z_{m2}Z_{a1})$$

The total input current is:

$$\mathbf{I}_1 = \mathbf{I}_m + \mathbf{I}_a = (\mathbf{I}_{m1} + \mathbf{I}_{m2}) + (\mathbf{I}_{a1} + \mathbf{I}_{a2})$$

Based on these two components of main-phase current, all current components shown in Figure 3 can be obtained by simple computation.

Then the total input current is:

$$\mathbf{I}_1 = \mathbf{I}_m + \mathbf{I}_a = (\mathbf{I}_{m1} + \mathbf{I}_{m2}) + (\mathbf{I}_{a1} + \mathbf{I}_{a2})$$

The positive- and negative-sequence air-gap power can be computed in the following way:

```
Pm1 = 2 * Irm1^2 * R2 / s
Pm2 = 2 * Irm2^2 * R2 / (2 - s)
```

The total air-gap power is:

```
Pm = Pm1 - Pm2
```

Tm, T2, P2, P1, and eff are computed in the same way as for three-phase induction motors.

The power factor is derived from:

```
PF = P1 / (U1 * I1)
```

Defining a Single-Phase Induction Motor

The general procedure for structurally defining a single-phase induction motor is as follows:

1. Insert a single-phase induction motor design in an existing or newly created project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
7. Double-click the **Machine-Rotor-Slot** entry in the project tree to define the rotor slot dimensions.
8. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor conductor, ventage hole dimensions, and skew.
9. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
10. Optionally, for Inner Rotor machines only, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
11. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
12. Choose **File>Save** to save the project.
13. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once the design is analyzed, the model can be imported into the Maxwell 2D Modeler, or can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Please refer to the *A Capacitor-Run Single-Phase Induction Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example of a single-phase induction motor problem.

Defining the General Data for a Single-Phase Induction Motor

Use the **General Data Properties** window to define the basic parameters of the induction motor, such as the number of poles, frictional loss, and operation mode.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Select one of the following for the **Rotor Position**:
   - **Inner Rotor**
   - **Outer Rotor**
4. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
5. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
6. Enter the given speed in the **Reference Speed** field.
7. Select the **Operation Mode**:
   a. Click the button.
   The **Select Operation Mode** window appears.
   b. Select from one of the following:

C-Run	Capacitance-run mode. The capacitor is in series with the auxiliary winding. In the Capacitor run mode, the capacitor will be designed (if the auto-design mode is selected) to minimize the backward magnetomotive force.
C-Start	Capacitance-start mode. The auxiliary winding is in series with the capacitor and is disconnected when the rotor reaches the switching speed.
C-R&S	Capacitance-run and start mode. Two capacitors are in series with the auxiliary winding; one for starting, one for running.
R-Start	Resistor-start mode. The auxiliary winding is disconnected when the rotor reaches the switching speed.

   c. Click **OK** to close the **Select Operation Mode** window and return to the **Properties** window.

8. Enter values in the following capacitance, resistance, and switching speed fields:

Run Capacitance	Available for C-Run, C-R&S
Run Resistance	Available for C-Run, C-R&S
Start Capacitance	Available for C-Start, C-R&S
Start Resistance	Available for C-Start, C-R&S
Switching Speed	Available for C-Start, C-R&S, R-Start

9. If the start winding needs to be optimized, select the **Objective Type** from the following three options:
   - **(Tst/Ist)max**. Accept the defaults. This is the ratio of the maximum starting torque to the starting current ratio.
   - **(Tst)max**. Enter the given start current ratio. This is the maximum starting torque
   - **(Ist)min (minimum starting current). Enter the given start torque ratio.**

Note	The start-winding optimization goal is disabled for the **C-Run** operation mode. In capacitor-run mode, the capacitor is designed to minimize the backward magnetomotive force. For other modes, if the auto-design function is active, the capacitor and the resistance are designed according to the start goal, selected from the following: • The maximum value of (Starting Torque/Starting Current). • The maximum starting torque. • The minimum starting current.

10. Click **OK** to close the **Properties** window.

General Data for Single-Phase Induction Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Single Phase Induction Motor).
Number of Poles	The number of poles the machine contains.
Rotor Position	Select whether the rotor is an **Inner Rotor** or **Outer Rotor**.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Operation Mode	Click the button to select from the following four modes: **C-Run**, **C-Start**, **C-R&S**, and **R-Start**.
Run Capacitance	The capacitance of the run capacitor. Available for C-Run and C-R&S operation modes.
Run Resistance	The resistance of the run capacitor. Available for C-Run and C-R&S operation modes. See **Note** below.
Start Capacitance	The resistance of the start capacitor. Available for C-Start and C-R&S operation modes.
Start Resistance	The resistance of the start capacitor. Available for C-Start and C-R&S operation modes.
Switching Speed	The switching speed of the capacitor or resistor. Available for C-Start, C-R&S, and R-Start operation modes.
Objective Type	If the start winding needs to be optimized, select from the following three objective types: **(Tst/Ist)max**, **(Tst)max**, or **(Ist)min**. • For **(Tst/Ist) max**, accept the defaults. This is the ratio of the maximum starting torque to the starting current ratio. • For **(Tst) max**, enter the **Given Start Current Ratio**. This is the maximum starting torque. • For **(Ist) min** (minimum starting current), enter the **Given Start Torque Ratio**. The start-winding optimization goal is disabled for the **C-Run** operation mode.

Note	When exporting the RMxprt model to Maxwell: • If the value of the **Run Resistance** is **zero** in RMxprt, the value of the **Run Resistance** will be autocomputed in Maxwell to a value of 1% of the capacitor reactance. • To neglect the **Run Resistance** in Maxwell, set the value to a small non-zero number in RMxprt.

Defining the Stator Data for a Single-Phase Induction Motor

The stator is the outer lamination stack where the three-phase windings reside. In the project tree, double-click **Machine-Stator**, **Machine-Stator-Slot**, and **Machine-Stator-Winding** to define the physical dimensions, slot data, wires, and conductors for the stator.

To define general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.

5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
   The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
   The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the overall width of the stator outer profile in the **Overall Width** field.
10. Click **OK** to close the **Properties** window.

Stator Data for Single-Phase Induction Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Overall Width	The overall width of the stator outer profile.

Defining the Stator Slots for a Single-Phase Induction Motor

Use the **Stator1** window to define the physical dimensions of the stator slots.

To define the stator slots:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.
4. Enter the available slot dimensions.

Hs0	Always available.
Hs1	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

5. Click **OK** to close the **Properties** window.

	Parallel Branches	The number of parallel branches in the series winding.
	Number of Strands	The number of wires per conductor in the series winding (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 for auto-pickup from the wire library).
	Wire Size	The wire diameter (0 for auto-design).

Stator Slot Data for Single-Phase Induction Motors

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.

Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

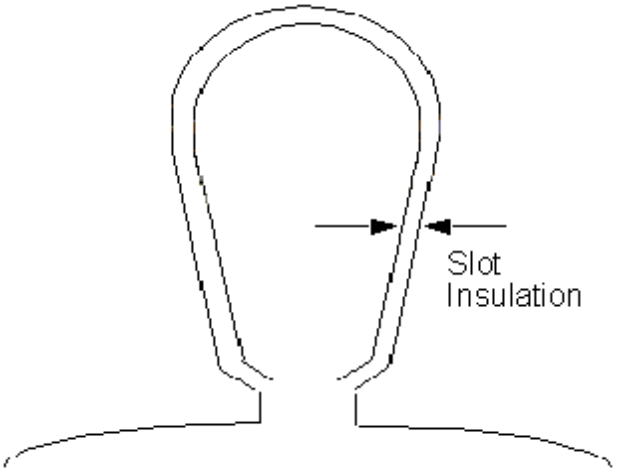
Defining the Stator Windings for a Single-Phase Induction Motor

Define the wires, conductors, insulation, and windings of the stator.

To define the wires and windings:

1. To open the **Stator Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Click the **Winding** tab.

3. Enter the thickness of the slot liner in the **Slot Liner** field.



4. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
5. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
6. Select or clear the **Include Series Winding** check box. This option sets whether or not to include the series winding in the speed adjustment. When this option is selected, a third tab, **Series (C)**, appears in the **Properties** window.
7. Enter the number of layers in the **Winding Layers** field.
8. Enter the number of slots in the **Coil Pitch** field.
9. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following types of winding:
      - **Lap**
      - **Sin_1**
      - **Sin_2**
      - **Editor**

   When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the four types of windings that are possible:

Editor	A user-defined one or two-layer winding arrangement, determined by your **Winding Layers** selection. Enables the Winding Editor, where you can specify a different winding arrangement for each slot.
Lap	90 deg phase belt 2-layer coil for both single and double layer

	Sin_1	A first-class sinusoidal coil for double layer only. The **Conductors per Layer** field defines the maximum number of conductors in the slot. The software will determine the winding distribution in the slots to get the sinusoidal current distribution. Sin_2	A second-class sinusoidal coil for double layer only. The **Conductors per Layer** field defines the maximum number of conductors in the slot. The software will determine the winding distribution in the slots to get the sinusoidal current distribution. 
c. Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** window and return to the **Properties** window.

10. Click the **Main (A)** tab.
    a. Enter the end length adjustment of the main stator coil in the **End Extension** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.

    b. Enter the number of conductors per layer of main winding in the **Conductors per Layer** field.
    c. Enter the number of parallel branches in the main stator winding in the **Parallel Branches** field.
    d. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design the value.
    e. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.

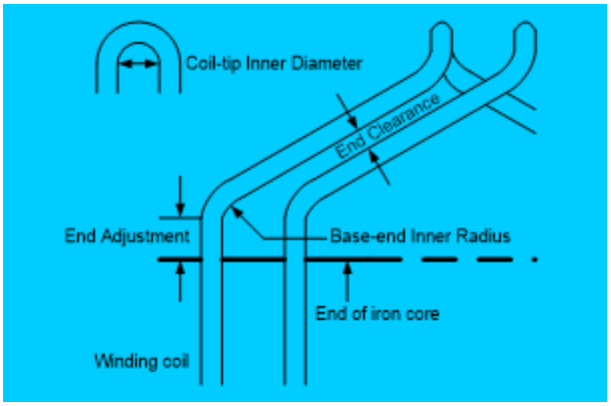
    f. To select the **Wire Size**: Click the button for **Wire Size**.
    The **Wire Size** window appears.

g. Select a value from the **Wire Diameter** pull-down list.

h. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

<*number*>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.



i. Enter the inner radius of the base corner in the **Base Inner Radius** field.

j. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.

k. Enter the distance between two stator coils in the **End Clearance** field.

l. Enter the thickness of the slot liner insulation in the **Slot Liner** field.

m. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.

n. Enter the thickness of the insulation layer in the **Layer Insulation** field.

o. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.

p. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

11. Click the **Aux (B)** tab.

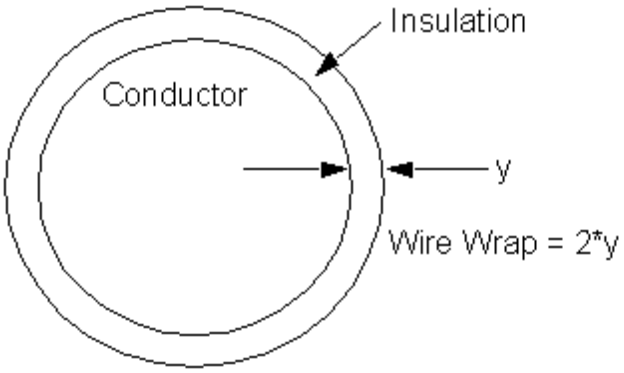
a. Enter the end length adjustment of the auxiliary stator coil in the **End Extension** field.

b. Enter the number of conductors per layer of auxiliary winding in the **Conductors per Layer** field.

c. Enter the number of parallel branches in the auxiliary stator winding in the **Parallel Branches** field.

d. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design the value.

e. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



f. To select the **Wire Size**: Click the button for **Wire Size**.
The **Wire Size** window appears.

g. Select a value from the **Wire Diameter** pull-down list.

h. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

< ***number*****>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.

AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

i. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

12. Click **OK** to close the **Properties** window.

Stator Winding Data for Single-Phase Induction Motors

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Slot Liner**	The thickness of the slot liner.
	Wedge Thickness	The thickness of the wedge insulation
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
	Winding Layers	The number of winding layers. Not visible if the **Winding Type** is either **Sin_1** or **Sin_2**.
	Coil Pitch	The coil pitch measured in number of slots. Not visible if the **Winding Type** is either **Sin_1** or **Sin_2**.
	Winding Type	The type of stator winding for the main phase. Click the button to open the **Winding Type** window and choose from **Lap**, **Sin_1**, **Sin_2**,and **Editor**.
Main (A)	**End Extension**	The end length adjustment of the stator coils.
	Conductors per Layer	The number of conductors per layer in the main winding.
	Parallel Branches	The number of parallel branches in the main stator winding.

	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 for auto-pickup from the wire library).
	Wire Size	The wire diameter (0 for auto-design).
Aux (B)	**End Extension**	The end length adjustment of the auxiliary winding.
	Conductors per Layer	The number of conductors per layer in the auxiliary winding.
	Parallel Branches	The number of parallel branches in the auxiliary stator winding.
	Number of Strands	The number of wires per conductor in the auxiliary winding (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 for auto-pickup from the wire library).
	Wire Size	The wire diameter (0 for auto-design).

Winding Editor for a Single-Phase Induction Motor

For a single-phase induction motor, you may want to specify a different number of conductors for each stator slot. The Winding Editor makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.
4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Single-Phase Induction Motor

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.

3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Choose **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Defining the Rotor Data for a Single-Phase Induction Motor

The rotor consists of copper bars in which current is induced from the stator windings. The rotor rotates at a slightly slower speed than the stator electromagnetic field. In the project tree, double-click **Machine>Rotor**, **Machine-Rotor-Slot**, and **Machine-Rotor-Winding** to define the physical dimensions, slot data, wires, and conductors for the rotor.

To define the general rotor data:

1. To open the **Rotor Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
3. Enter the **Number of Slots** in the rotor.
4. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
   The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.

5. Enter the outer diameter of the rotor in the **Outer Diameter** field.
6. Enter the inner diameter of the rotor in the **Inner Diameter** field.
7. Enter the length of the rotor core in the **Length** field.
8. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
   The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
9. Enter the **Skew Width**, measured in rotor slot pitch. This value defines by how much the rotor bars are skewed.
10. Optionally, select **Cast Rotor** to allow the conductor to fill all the space available in the slot. Otherwise, RMxprt assumes the slot wedge that fixes the bars is filled with insulator material in a 3D/3D geometry model.
11. Click **OK** to close the **Properties** window.

Rotor Data for Single-Phase Induction Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Stacking Factor	The stacking factor of the rotor core.
Number of Slots	The number of slots the rotor core contains.
Slot Type	The type of slots in the rotor core. Click the button to open the **Select Slot Type** window.
Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Skew Width	The skew width measured in slot number.
Cast Rotor	Select or clear this to specify whether the rotor squirrel-cage winding is cast or not.

Defining the Rotor Slots for Single-Phase Induction Motors

To define the rotor's slots:

1. To open the **Rotor Slot Properties** window, double-click the **Machine-Rotor-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the slot dimensions in the following fields: **Hs0**, **Hs01**, **Hs2**, **Bs0**, **Bs1**, **Bs2, Rs**.
3. Click **OK** to close the **Properties** window.

Rotor Slot Data for Single-Phase Induction Motors

To access the rotor slot data, double-click the **Machine-Rotor-Slot** entry in the project tree.

The **Rotor Slot Data Properties** window contains the following fields:

Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs01	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Rotor Windings for Single-Phase Induction Motors

To define the rotor windings:

1. To open the **Rotor Winding Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select a **Bar Conductor Type** for the rotor winding bar:
   a. Click the button for **Bar Conductor Type**.
   The **Select Definition** window appears.
   b. Select a conductor type from the list, or define a new conductor type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
3. Enter the length of the gap between the end ring and the iron core in the **End Length** field. This field specifies the value for only one end of the gap, not both.

4. Enter the end ring dimension in the axial direction in the **End-Ring Width** field. The end ring connects the bars of the rotor to one another.
5. Enter the end ring dimension in the radius direction in the **End-Ring Height** field. The end ring's height covers at least the cross-section of the rotor conductor.
6. Select an **End Ring Conductor Type** for the rotor winding end ring:
   a. Click the button for **End Ring Conductor Type**.
   The **Select Definition** window appears.
   b. Select a conductor type from the list, or define a new conductor type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Click **OK** to close the **Properties** window.

Rotor Winding Data for Single-Phase Induction Motors

To access the rotor winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Bar Conductor Type	The type of bar conductor used in the winding. Click the button to open the **Select Definition** window.
End Length	The length of the single-side end of the extended bar.
End Ring Width	The width of one side of the end rings in the axial direction.
End Ring Height	The height of the end rings in the radian direction.
End Ring Conductor Type	The type of end ring conductor used in the winding. Click the button to open the **Select Definition** window.

Defining the Shaft Data for a Single-Phase Induction Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Single-Phase Induction Motors

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Adding or Removing a Vent from a Single-Phase Induction Motor

By option, you can add a vent to a single-phase induction motor. To add a vent:.

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Insert Vent**.
   The vent icon appears in the project tree under the rotor.

To remove a vent from a rotor in a three-phase induction motor.

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Remove Vent**.
   The vent icon disappears in the project tree under the rotor.

The Vent data for the stator includes the following fields.

Holes per row	Number of axial vent holes per row.
Inner hole diameter	Diameter of vent holes in inner row.
Outer hole diameter	Diameter of vent holes in outer row.
Inner hole location	Center to center diameter of inner hole vents
Outer hole location	Center to center diameter of outer hole vents.

Setting Up Analysis Parameters for a Single-Phase Induction Motor

To define the solution data:

1. To open the **Solution Setup** window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.

Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **Single-Phase Induction Motor** tab.
9. Enter the electrical line frequency in the **Frequency** field, and select the units.
10. Click **OK** to close the **Solution Setup** window.

Setting Up Analysis Parameters for a Single-Phase Induction Motor

Adjust-Speed Synchronous Machines

After you have selected **Adjust-Speed Synchronous Machines** as your model type, you need to define the following:

- General data, such as the voltage, speed, and circuit type of the model.
- Circuit data, such as trigger pulse width, transistor drop, and control circuit information.
- Stator data, such as the diameter, slot dimensions, and skew width of the stator.
- Stator Winding
- Rotor pole data, such as the associated permanent-magnet dimensions, air gap, and stacking factor.
- Solution data, such as rated output voltage and frequency.

By option, you can:

- Add a machine housing.

Analysis Approach for Adjust-Speed Synchronous Machines

In adjustable-speed permanent-magnet synchronous machines, the rotor speed is controlled by adjusting the frequency of the input voltage. Unlike standard brushless permanent-magnet DC motors, this type of machine does not utilize position sensors.

Permanent magnets are mounted on the rotor of a permanent-magnet synchronous machine, which could be either inner or outer rotor type. The poly-phase armature winding is embedded in the stator, whose number of poles is the same as that of the rotor. The machine can operate as a generator or as a motor. When the machine operates as a motor, the stator poly-phase winding can be fed either by a sinusoidal AC source or by a DC source via a DC to AC inverter. When the machine operates as a generator, the stator poly-phase winding supplies an AC source for electric loads.

Stator Winding Connected to a Sinusoidal AC Source

In this case, the performance of the machine can be analyzed in the frequency domain based on the phasor diagrams, as shown in Figure 6.1 for the generators and Figure 6.2 for the motors.

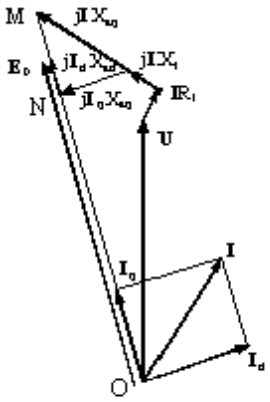

Figure 6.1 The phasor diagram for generators

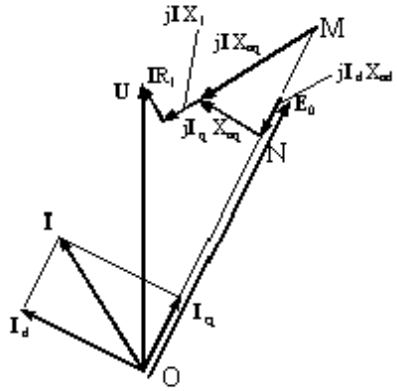

Figure 6.2 The phasor diagram for motors

In the figures, R_1 and X_1 are the resistance and the leakage reactance of the armature winding, X_{ad} and X_{aq} are the d-axis armature reactance and the q-axis armature reactance, respectively. In the phasor diagram, X_{ad} is a linearized nonlinear parameter, and X_{aq} is a linear parameter. The d-axis synchronous reactance X_d and q-axis synchronous reactance X_{aq} are calculated directly from

Let ? denote the power angle for a generator (the angle that U lags E_0), or the torque angle for a motor (the angle that E_0 lags U), then we have

$$X_d = X_1 + X_{ad}$$

$$X_q = X_1 + X_{aq}$$

$$I_d X_d + I_q R_1 = \pm(U\cos\theta - E_0)$$

$$-I_d R_1 + I_q X_q = U\sin\theta$$

where the plus sign + is for the motor and the minus sign - is for the generator.
Solving for I_d and I_q yields

$$I_d = \frac{\pm X_q(U\cos\theta - E_0) - R_1 U\sin\theta}{R^2_1 + X_d X_q}$$

$$I_q = \frac{\pm R_1(U\cos\theta - E_0) - X_d U\sin\theta}{R^2_1 + X_d X_q}$$

where the plus sign + is for the motor and the minus sign - is for the generator.

Let the angle that *I* lags E_0 be ψ, we have

$$\psi = \tan^{-1}\frac{I_d}{I_q}$$

The power factor angle φ (the angle that *I* lags *U*) is

$$\varphi = \psi \pm \theta$$

where the plus sign + is for the motor and the minus sign - is for the generator.

For the motor operation, the input electric power is

$$P_1 = 3UI\cos\varphi$$

The output mechanical power is

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_{Fe})$$

where P_{fw}, P_{Cua}, and P_{Fe} denote the frictional and wind, the armature copper and the iron-core losses, respectively.

The output mechanical torque is

$$T_2 = \frac{P_2}{\omega}$$

where ω denotes the synchronous speed in rad/s.

The efficiency of the motor is

$$\eta = \frac{P_2}{P_1} \times 100\,\%$$

For the generator operation, the output electric power is

$$P_2 = 3UI\cos\varphi$$

The input mechanical power is

$$P_1 = P_2 + P_{fw} + P_{Cua} + P_{Fe}$$

where P_{fw}, P_{Cua}, and P_{Fe} denote the frictional and wind, the armature copper and the iron-core losses, respectively.

The input mechanical torque is

$$T_1 = \frac{P_1}{\omega}$$

where ω denotes the synchronous speed in mechanical rad/s.

The efficiency of the generator is

$$\eta = \frac{P_2}{P_1} \times 100\ \%$$

Stator Winding Fed by a DC to AC Inverter

In this case, this adjustable-speed synchronous machine (ASSM) operates as a motor, and the analysis approach is similar to that of a brushless DC (BLDC) motor. The stator poly-phase armature winding is connected to a DC power supply through a DC to AC inverter to produce the rotational magnetic field in the air-gap. The main difference between ASSM and BLDC motor is: in BLDC motor, trigger time exactly **depends on** the rotor position; but in ASSM, the trigger time is **independent of** the rotor position. If the mechanical load of a BLDC motor increases, the rotor speed and the induced voltage decreases, causing the armature current and torque increase to balance the increased mechanical load. However, for an ASSM, if the mechanical load increases, the rotor speed decreases temporarily, which causes the torque angle (the same as lead angle of trigger for a BLDC motor) increase and then torque increase to retain the synchronous speed.

Therefore, the speed of a BLDC motor varies with input voltage and mechanical load, while the speed of an ASSM does not. The speed of an ASSM can be changed by adjusting the frequency of the controlling signal, which explains why it is called *Adjustable-Speed Permanent-Magnet Synchronous Machine*.

Using the time-domain mathematical model to analyze the characteristics of the electric machine, Park's voltage equation in the matrix form is as follows

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} - \begin{bmatrix} e_d \\ e_q \\ e_0 \end{bmatrix} = \begin{bmatrix} R_1 + L_d\rho & -L_q\omega_e & 0 \\ -L_d\omega_e & R_1 + L_q\rho & 0 \\ 0 & 0 & R_1 + L_0\rho \end{bmatrix} \cdot \begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix}$$

where R_1 is the armature winding resistance, L_d, L_q and L_0 are the d-, the q- and the 0-axis inductances respectively, ω_e is the revolution speed in electric radians per second, the differential operator is

$$\rho = \frac{\mathrm{d}}{\mathrm{d}t}$$

The coordinate transformation equations for the terminal voltage, the induced emf and the armature winding current are

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} = C^T \begin{bmatrix} v_a \\ v_b \\ \vdots \end{bmatrix} \qquad \begin{bmatrix} e_d \\ e_q \\ e_0 \end{bmatrix} = C^T \begin{bmatrix} e_a \\ e_b \\ \vdots \end{bmatrix} \qquad \begin{bmatrix} i_a \\ i_b \\ \vdots \end{bmatrix} = C \begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix}$$

The transformation matrices for the two-, the three- and the four-phase systems are C_2, C_3 and C_4, respectively, as follows

$$C_2 = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \end{bmatrix}$$

$$C_3 = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\theta & \sin\theta & \frac{1}{\sqrt{2}} \\ \cos(\theta-\alpha) & \sin(\theta-\alpha) & \frac{1}{\sqrt{2}} \\ \cos(\theta-2\alpha) & \sin(\theta-2\alpha) & \frac{1}{\sqrt{2}} \end{bmatrix}$$

$$C_4 = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ \sin\theta & -\cos\theta & 0 \\ -\cos\theta & -\sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \end{bmatrix}$$

where

$$\alpha = \frac{2}{3}\pi$$

The input electric power is obtained from the voltage and the current as:

$$P_1 = \frac{1}{T}\int_0^T (v_d i_d + v_q i_q + v_0 i_0)dt$$

The output mechanical power is:

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_{Fe})$$

where P_{fw}, P_{Cua}, P_t and P_{Fe} denote the frictional and wind, the armature copper, the switching and the iron-core losses, respectively.

The output mechanical torque is

$$T_2 = \frac{P_2}{\omega}$$

where ω denotes the revolution speed in mechanical radians per second.

The efficiency of the electric machine is

$$\eta = \frac{P_2}{P_1} \times 100\ \%$$

Defining an Adjustable-Speed Synchronous Machine

The general procedure for defining a adjust-speed synchronous machine is as follows:

1. Insert the adjust-speed synchronous machine into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine>Circuit** entry in the project tree to define the control circuit.
4. Double-click the **Machine>Stator** entry in the project tree to define the stator geometry.
5. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
6. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
7. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
8. Double-click the **Machine-Rotor-Pole** entry in the project tree to define the pole, embrace, offset, and air gap data for the rotor pole.
9. Double-click the **Machine>Shaft** entry in the project tree to define the magnetism of the shaft.
10. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
11. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
12. Choose **File>Save** to save the project.
13. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Defining the General Data for an Adjust-Speed Synchronous Machine

Use the **General** window to define the basic parameters of the motor, such as the motor's rated output power, rated voltage, losses, and circuit types.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
4. Enter the wind loss due to air resistance measured at the reference speed in the **Windage Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Select one of the following from the **Control Type** pull-down list:
   - **DC**: Switched DC voltage at the given input frequency.
   - **PWM**: Pulse width modulation. When you select this source type, you must enter the following values in the **Circuit Data Properties** window: **Modulation Index** (the ratio of the sine wave amplitude to the triangular amplitude) and **Carrier Frequency Times** (the ratio of the triangular frequency to the sine wave frequency).
   - **AC**: An AC excitation.
7. Select a **Circuit Type** from the following types:

Y3	Y-connected, three-phase.
L3	Loop-type, three-phase.
S3	Star-type, three-phase.
C2	Cross-type, two-phase.
L4	Loop-type, four-phase.
S4	Star-type, four-phase.

   The circuit types are based on industry standards. By default, type **Y3**, a three-phase, six-status circuit, is selected as the circuit type.

Note	When you place the mouse cursor over a circuit type, an outline schematic of the circuit appears.

8. Click **OK** to close the **Properties** window.

General Data for Adjust-Speed Synchronous Machines

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Adjust-Speed Synchronous Machine).
Number of Poles	The number of poles the machine contains.
Rotor Position	Select whether the rotor is an **Inner Rotor** or **Outer Rotor**.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Windage Loss	The windage loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.
Control Type	The way the circuit is controlled. Select from **DC**, **PWM** (pulse-width modulation), or **AC**.
Circuit Type	The drive circuit type. Click the button to open the **Circuit Type** window and select from the following six types: • **Y3**: Y-Type, 3-Phase • **L3**: Loop-Type, 3-Phase • **S3**: Star-Type, 3-Phase • **C2**: Cross-Type, 2-Phase • **L4**: Loop-Type, 4-Phase • **S4**: Star-Type, 4-Phase

Defining the Circuit Data for an Adjust-Speed Synchronous Machine

Use the **Circuit Data Properties** window to define the circuit properties for an adjustable-speed synchronous machine.

Note	No circuit data properties exist when **AC** is selected as the **Control Type**.

1. To open the **Circuit Data Properties** window, double-click the **Machine>Circuit** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. If you selected DC as the **Control Type**, enter the period from on-status to off-status of a transistor, in electrical degrees, in the **Trigger Pulse Width** field.

3. Enter the voltage drop across one transistor when the transistor is turned on in the **Transistor Drop** field. Refer to the figures of the different circuit types in step 2.
4. Enter the voltage drop of one diode in the discharge loop in the **Diode Drop** field. If you selected a star-type circuit (**S3** or **S4**) as the **Circuit Type**, enter the total discharge voltage in this field.
5. If you selected PWM as the **Control Type**, then enter values in the following two fields:
   - **Modulation Index**: The ratio of the sine-wave amplitude to the triangular amplitude. (PWM circuits only.)
   - **Carrier Frequency Times**: The ratio of the triangular frequency to the sine-wave frequency. (PWM circuits only.)
6. Click **OK** to close the **Properties** window.

Circuit Data for Adjust-Speed Synchronous Machines

To access the **Circuit Data Properties** window, double-click the **Machine>Circuit** entry in the project tree. No circuit data properties exist when **AC** is selected as the **Control Type**.

Trigger Pulse Width	The period from on-status to off-status for a transistor, in electrical degrees. (DC circuits only.)
Transistor Drop	The voltage drop across one transistor when the transistor is turned on.
Diode Drop	The voltage drop across one diode in the discharge loop.
Modulation Index	The ratio of the sine-wave amplitude to the triangular amplitude. (PWM circuits only.)
Carrier Frequency Times	The ratio of the triangular frequency to the sine-wave frequency. (PWM circuits only.)

Defining the Stator Data for an Adjust-Speed Synchronous Machine

Use the **Stator Properties** windows to define the stator dimensions, slots, windings, and conductors.

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.

5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the skew width, measured in slot number, in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Defining the Stator Dimensions and Slots

To define the stator slots:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.

4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

5. Click **OK** to close the **Properties** window.

Stator Data for Adjust-Speed Synchronous Machines

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Skew Width	The skew width measured in slot number.

Stator Slot Data for Adjust-Speed Synchronous Machines

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Stator Windings and Conductors for an Adjust-Speed Synchronous Machine

To define the stator windings and conductors:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the six types of windings that are possible (three for one-layer and three for two-layer):

Type	Description
One Layer Winding Editor	A user-defined one-layer winding arrangement. You need to set up the winding arrangement for each slot.
Whole Coiled	A one-layer whole-coiled winding: Whole Coiled	A two-layer wave winding:  The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
Half Coiled	A two-layer half-coiled winding:

	 There is only one coil per phase per pair of poles.

Note	**For a two-layer winding**, if you click **Constant Pitch** in the **Winding Editor**, only the top layer needs to be defined; the bottom layer will be determined according to the coil pitch.

Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** window and return to the **Properties** window. Select the **Winding Type** for the stator.

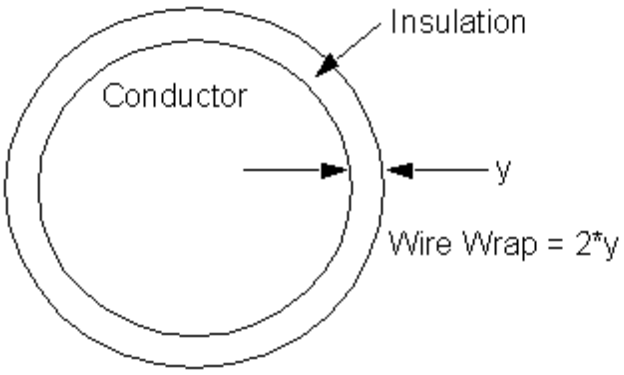
Note	When you place the mouse cursor over the winding type, a schematic of the selected winding appears.

Winding types **10** and **20** are user-defined. If you select either of these, a window appears, asking you to define the name of the winding arrangement. The window closes when the user-defined winding is entered.

Select from the following winding types:

One-Layer Winding Editor	
	A user-defined single-layer winding arrangement. When you select this type, enter the winding arrangement, and choose **OK**.
11	A one-layer whole-coiled winding: 
20	A user-defined winding arrangement. When you select this type, enter the winding arrangement, and choose **OK**.
21	A two-layer wave winding:  The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
22	A two-layer winding: 
5. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.
6. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.

8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



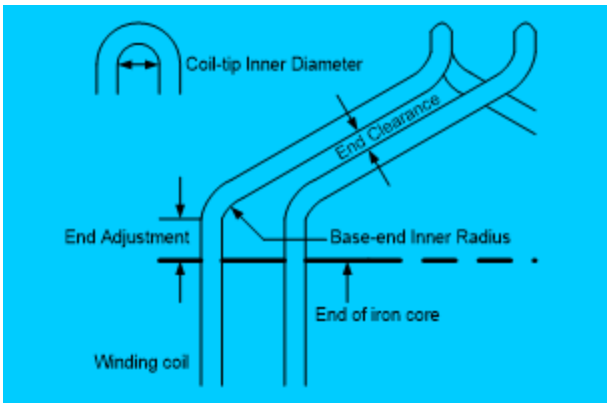
10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

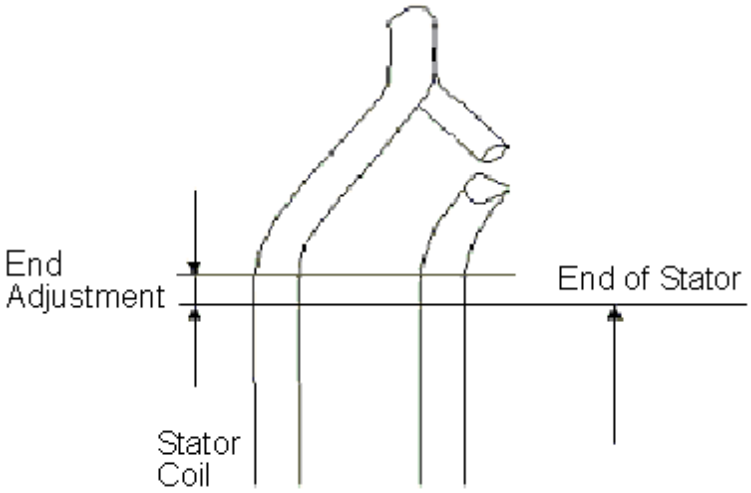
< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

11. Click the **End/Insulation** tab.
12. Select or clear the **Input Half-turn Length** check box.
13. Do one of the following:

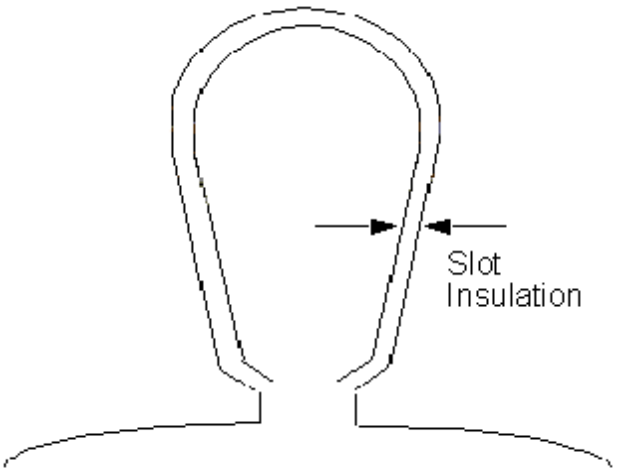
- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.





14. Enter the inner radius of the base corner in the **Base Inner Radius** field.
15. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
16. Enter the distance between two stator coils in the **End Clearance** field.

17. Enter the thickness of the slot liner insulation in the **Slot Liner** field.



18. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
19. Enter the thickness of the insulation layer in the **Layer Insulation** field.
20. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
21. Click **OK** to close the **Properties** window.

Winding Editor for an Adjustable-Speed Synchronous Machine

For a adjustable-speed synchronous machine, you may want to specify a different number of conductors for each stator slot. The Winding Editor makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.
4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for an Adjustable Speed Synchronous Machine

Use the **Gauge** option in the **Wire Size** dialog if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

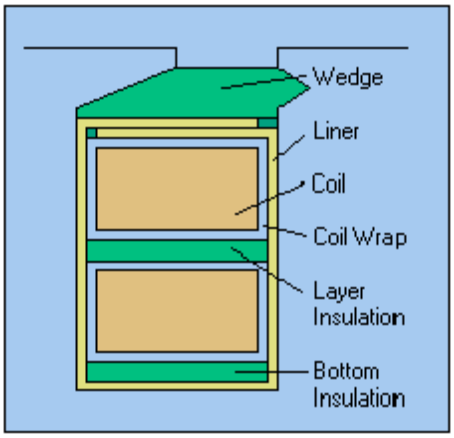
Stator Winding Data for Adjust-Speed Synchronous Machines

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the stator winding.

	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.



Defining the Rotor Data for an Adjust-Speed Synchronous Machine

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine>Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general stator data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the outer diameter of the rotor in the **Outer Diameter** field.
3. Enter the inner diameter of the rotor in the **Inner Diameter** field.
4. Enter the length of the rotor core in the **Length** field.
5. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
6. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
7. Select a **Pole Type**:
   a. Click the button.
      The **Select Pole Type** window appears.
   b. Click a button to select the desired pole type (1, 2, 3, 4, or 5). TIP: When you run the mouse over each option, the diagram changes to show that pole type.

Note	When you place the mouse cursor over a rotor type, an outline of the selected circuit type appears.

   c. Click **OK** to close the **Select Pole Type** window and return to the **Properties** window.

8. Click **OK** to close the **Properties** window.

Rotor Data for Adjust-Speed Synchronous Machines

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Stacking Factor	The stacking factor of the rotor core.
Pole Type	The pole type for the rotor. Click this button to open the **Select Pole Type** window and select from the following types: **1**, **2**, **3**, **4**, *5*.

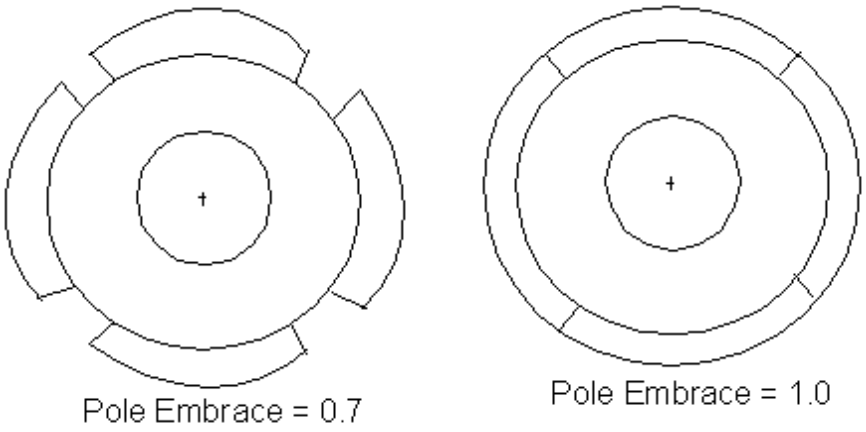
Defining the Rotor Pole for an Adjust-Speed Synchronous Machine

The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **Rotor Pole Data Properties** window to define the rotor pole.

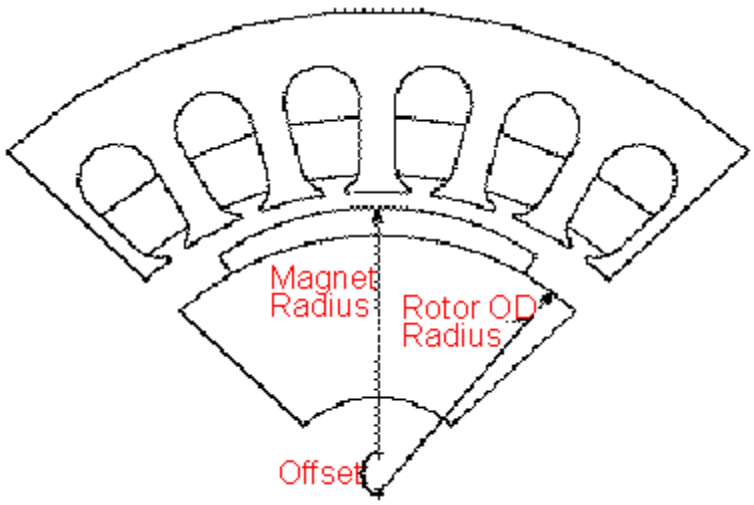
Note	Some of the fields in the **Rotor Pole** window change, or are inactive, depending on the **Rotor Type** you select.

To define the rotor pole:

1. To open the **Rotor Pole Data Properties** window, double-click the **Machine-Rotor-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. For all pole types except type **4**, enter the ratio of the actual arc distance in relation to the maximum possible arc distance in the **Embrace** field. This value is between 0 and 1.



3. For pole type **4**, enter the shaft diameter of the rotor in the **Shaft Diameter** field.
4. For pole types **1**, **2**, and **3**, enter the distance from the center of the rotor to the polar arc center in the **Offset** field. Enter 0 for a uniform air gap.



5. For pole type **5**, enter the thickness of the bridge across the two poles in the **Bridge** field.
6. For pole type **5**, enter the width of the rib supporting the bridge in the **Rib** field.
7. Select the type of magnet to use in the rotor pole from the **Magnet Type** pull-down menu.
8. For pole types **4** and **5**, enter the width of the magnet in the **Magnet Width** field.
9. Enter the maximum radial thickness of the magnet in the **Magnet Thickness** field.
10. Click **OK** to close the **Properties** window.

Rotor Pole Data for Adjust-Speed Synchronous Machines

To access the pole rotor data, double-click the **Machine-Rotor-Pole** entry in the project tree.

The **Rotor Pole Data Properties** window contains the following fields:

Embrace	The pole embrace. For pole types **1**, **2**, **3**, and **5**.
Shaft Diameter	The shaft diameter of the rotor. For pole type **4**.
Offset	The pole-arc center offset from the rotor center (0 for a uniform air gap). For pole types **1**, **2**, and **3**.
Bridge	The thickness of the bridge across two adjacent poles. For pole type **5**.
Rib	The width of the rib at the center of two adjacent poles that support the bridge. For pole type **5**.
Magnet Type	The type of magnet. Click the button to open the **Select Definition** window. For all pole types.
Magnet Width	The maximum width of the magnet. For pole types **4** and **5**.
Magnet Thickness	The maximum thickness of the magnet. For all pole types.

Defining the Shaft Data for an Adjust-Speed Synchronous Machine

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Adjust-Speed Synchronous Machines

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for an Adjust-Speed Synchronous Machine

To define the solution data:

1. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to open the Solution Setup window.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.

Note	To enable selection of **Generator** for Adjust-Speed Synchronous Machines, the machine **Control Type** must be set to **AC** in its Properties window.

   a. If Motor was selected for the Operation Type, select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

   b. If Generator was selected for the Operation Type, select the **Load Type** used in the generator from the following options: Infinite Bus or Independent Generator.

Infinite Bus	When the generator is connected to an infinite bus of the power system, the terminal voltages remain constant and the output power is determined by the output currents.
Independent Generator	The generator supplies electrical power to a load inductor. For an AC generator, the resistance and inductance of the load inductor are determined by the rated output power, the rated voltage, and the rated power factor. For a DC generator, the resistance of the load resistor is determined by the rated output power and the rated voltage.

3. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
4. Enter either the RMS line-to-line voltage (for AC control type), or the DC voltage (for DC and PWM control types) in the **Rated Voltage** field.
5. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.

6. Enter the temperature at which the system functions in the **Operating Temperature** field.
7. Click the **Adjust-Speed Synchronous Machine** tab and select either **Time** or **Frequency** as the **Domain** for the solution.
8. Click **OK** to close the **Solution Setup** window.

Related Topics

Solution Data for Adjust-Speed Synchronous Machines

Solution Data for Adjust-Speed Synchronous Machines

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	The operation type is automatically set to **Motor** for this machine type.
Load Type	Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	Type a value for the rated output voltage, and select the units.
Rated Voltage	Type a value for the rated voltage, and select the units.
Rated Speed	Type a value for the rated speed, and select the units.
Operating Temperature	Type a value for the operating temperature, and select the units.

Setting Up Analysis Parameters for an Adjust-Speed Synchronous Machine

Permanent-Magnet DC Motors

After you have selected **Permanent-Magnet DC Motors** as your model type, you need to define the following:

- General data, such as the voltage, speed, and circuit type of the model.
- Stator data, such as the diameter, slot dimensions, and skew width of the stator.
- Stator pole data, such as its associated pole dimensions, type of steel, and pole magnet specifications.
- Rotor data, such as the slot types and dimensions, slot data, and windings.

- Commutator and brush data, such as the commutator dimensions and brush length.
- Shaft data
- Solution data, such as rated output voltage and frequency.

By option, you can:

- Add a machine housing.

Analysis Approach for PMDC Motors

For a permanent-magnet DC motor, the stator is equipped with P pairs of permanent magnets, creating P pairs of alternating north and south poles. The distribution of the magnetic field produced by the permanent magnet's field flux is fixed with respect to the stator. The rotor is equipped with a distributed winding connected to a commutator that revolves together with the rotor.

A system of brushes is kept in permanent electrical contact with the commutator. When DC current is applied to the rotor winding (via the brushes and commutator), a torque is produced by the interaction of the rotor (armature) currents and the field produced by the permanent magnets.

The commutator causes the armature to create a magnetic flux distribution that is fixed in space and whose axis is perpendicular to the axis of the field flux produced by the permanent magnets. For these motors, the commutator acts as a mechanical rectifier.

The performance of a permanent-magnet DC (PMDC) motor is computed by DC analysis only. The voltage equation of a PMDC motor is:

$$U = Ub + R1 * I + E$$

where Ub is the voltage drop of one-pair brushes, R1 is the armature resistance, $E = Ke * \omega$ is the back emf with *Ke* the back-emf constant in Vs/rad, and ω is the speed in rad/s. For a given speed ω, armature current can be computed based on the applied voltage *U*, as shown below:

$$I = (U - Ub - Ke * \omega)/R1$$

The shaft torque T2 is computed by:

$$T2 = Kt * I - Tfw$$

where *Kt* is the torque constant in Nm/A, which is numerically the same as *Ke*, and *Tfw* is the frictional torque.

The output power (mechanical power) is:

$$P2 = T2 * \omega$$

The input power (electrical power) is:

$$P1 = P2 + Pfw + Pcua + Pb + PFe$$

where *Pfw*, *Pcua*, *Pb*, and *PFe* are frictional and wind loss, armature copper loss, brush drop loss, and iron-core loss, respectively.

The efficiency is:

$$eff = P2/P1 * 100\%$$

Defining a Permanent-Magnet DC Motor

The general procedure for defining a permanent-magnet DC motor is as follows:

1. Insert the permanent-magnet DC motor into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine>Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Pole** entry in the project tree to define the stator pole dimensions.
5. Double-click the **Machine>Rotor** entry in the project tree to define the rotor geometry.
6. Double-click the **Machine-Rotor-Slot** entry in the project tree to define the rotor slot dimensions.
7. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor windings and conductors.
8. Double-click the **Machine>Commutator** entry in the project tree to define the commutator and brush data.
9. Double-click the **Machine>Shaft** entry in the project tree to define the magnetism of the shaft.
10. Optionally, for Inner Rotor machines only, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
11. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
12. Choose **File>Save** to save the project.
13. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D project.

Refer to the *Permanent-Magnet DC Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example of a permanent-magnet DC motor problem.

Defining the General Data for PMDC Motors

Use the **General** window to specify the rated output power, voltage values, circuit type, and speed of the DC motor.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.

Note	To use the **Brush Press** and **Frictional Coefficient** fields when you define the commutator and brush later in the **Commutator/Brush Data** window, enter **0** here for the **Friction Loss**.

4. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

General Data for PMDC Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (DC Permanent Magnet Motor).
Number of Poles	The number of poles the machine contains.
Rotor Position	Select whether the rotor is an **Inner Rotor** or **Outer Rotor**.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a PMDC Motor

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the stacking factor for the stator core in the **Stacking Factor** field. This value is a ratio of the effective magnetic length of the core, and ranges from 0 to 1. It is defined as the total length minus the total insulation from the laminations, divided by the total length. A value of 1 indicates that the stator is not laminated.
6. Click **OK** to close the **Properties** window.

Stator Data for PMDC Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.

Defining the Stator Pole for a PMDC Motor

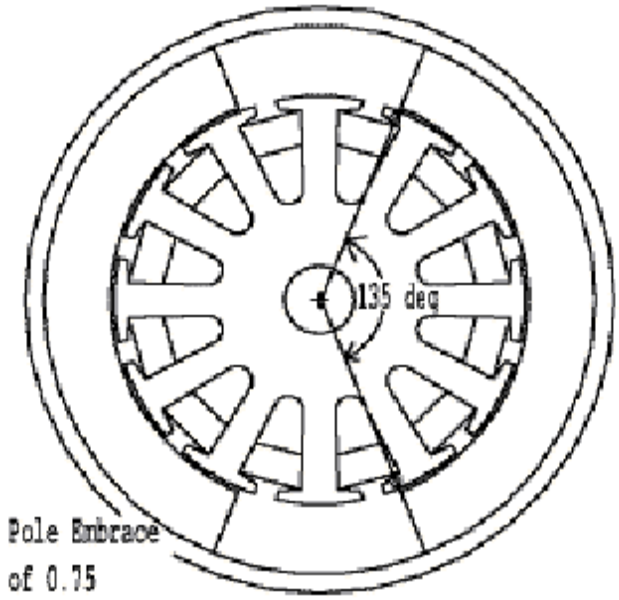
The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **s Stator Pole Data Properties** window to define the stator pole.

To define the rotor pole:

1. To open the **Stator Pole Data Properties** window, double-click the **Machine-Stator-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)

Note	For a two-pole machine, a pole embrace of 0.75 yields a magnet with a span of 135 degrees (based on 0.75*180 degrees).

2. Enter the ratio of the actual arc distance in relation to the maximum possible arc distance in the **Embrace** field. This value is between 0 and 1.



3. Enter the distance from the center of the stator to the magnet arc center in the **Offset** field. Enter 0 for a uniform air gap.
4. To select the type of magnet to use in the rotor pole:
   a. Click the **Magnet Type** button.
      The **Select Definition** window appears.
   b. Select or define a material for the magnet type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
5. Enter the length of the magnet in the axial direction in the **Magnet Length** field.
6. Enter the maximum radial thickness of the magnet at the center of the pole in the **Magnet Thickness** field. To control the flux, the magnet's thickness may vary.
7. Click **OK** to close the **Properties** window.

Stator Pole Data for PMDC Motors

To access the stator pole data, double-click the **Machine-Stator-Pole** entry in the project tree.

The **Stator Pole Data Properties** window contains the following fields:

Embrace	The pole embrace.
Offset	The pole-arc center offset from the stator center (0 for a uniform air gap).
Magnet Type	The type of magnet. Click the button to open the **Select Definition** window.
Magnet Length	The maximum length of the magnet.
Magnet Thickness	The maximum thickness of the magnet.

Defining the Rotor Data for a PMDC Motor

The rotor is equipped with slots containing copper conductors that are connected to the commutator. The commutator acts as a mechanical rectifier in the motor.

Use the **Rotor Data Properties**, **Rotor Slot Data Properties**, and **Rotor Winding Data Properties** windows to define the rotor slots, windings, and dimensions.

To define general rotor data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
3. Enter the **Number of Slots** in the rotor.
4. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
   The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic outline of the slot appears.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
5. Enter the outer diameter of the rotor in the **Outer Diameter** field.
6. Enter the inner diameter of the rotor in the **Inner Diameter** field.
7. Enter the length of the rotor core in the **Length** field.
8. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
   The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
9. Enter the skew width, measured in slot number, in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Rotor Data for PMDC Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Stacking Factor	The stacking factor of the rotor core.
Number of Slots	The number of slots the rotor core contains.
Slot Type	The type of slots in the rotor core. Click the button to open the **Select Slot Type** window.

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Skew Width	The skew width measured in slot number.

Defining the Rotor Slots for a PMDC Motor

To define the physical dimensions of the rotor slots:

1. To open the **Rotor Slot Data Properties** window, double-click the **Machine-Rotor-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

4. Click **OK** to close the **Properties** window.

Rotor Slot Data for PMDC Motors

To access the stator slot data, double-click the **Machine-Rotor-Slot** entry in the project tree.

The **Rotor Slot Data Properties** window contains the following fields:

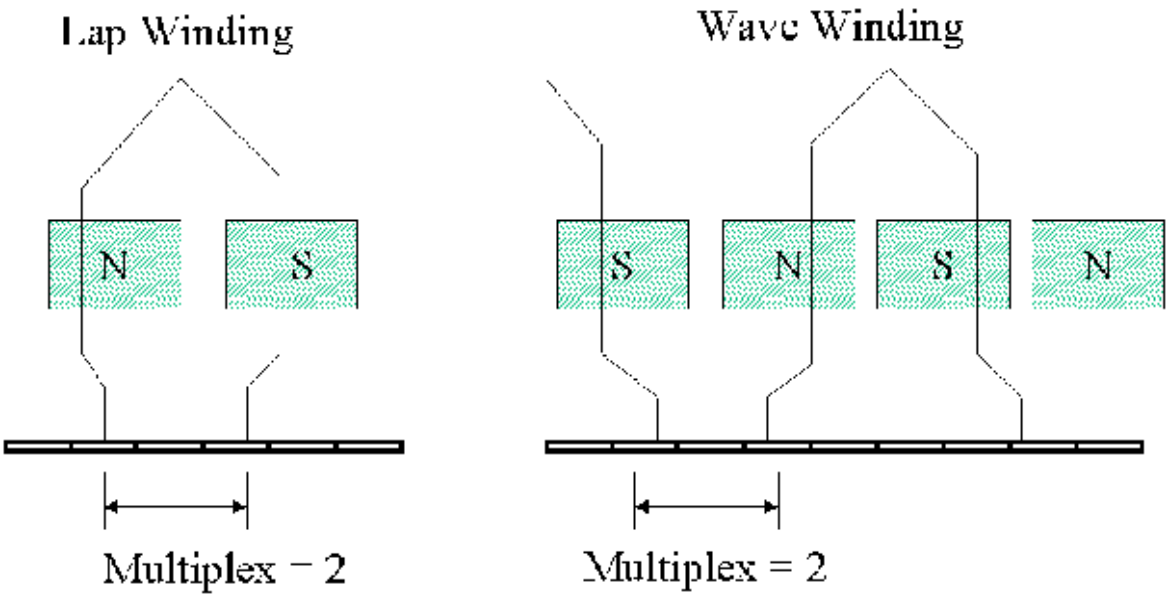
Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-**

	Rotor-Slot is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Rotor Windings and Conductors for a PMDC Motor

To define the rotor windings, wires, and conductors:

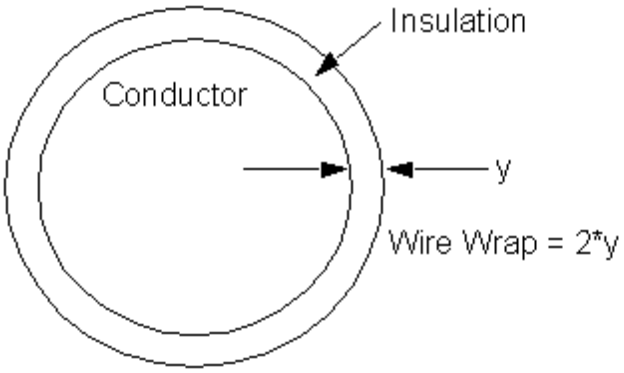
1. To open the **Rotor Slot Winding Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Lap**
      - **Wave**
      - **Frog Leg**
4. Enter the number of windings in the **Multiplex Number** field (1 for a single winding, 2 for double windings, 3 for triple windings). For a lap winding, the multiplex number is the number of commutators between the start and end of one winding, and the number of parallel branches is equal to the number of poles multiplied by the multiplex number. For a wave winding, the number of parallel branches equals the multiplex number multiplied by two.



5. Enter the number of virtual slots per each real slot in the **Virtual Slots** field. The rotor is assumed to have two layers of conductors, an upper and a lower layer. Each layer of conductors can have a number of windings, which are referred to as virtual slots.

Note	For example, the upper and lower layer can have two windings each, which would yield a virtual slot number of two; for a 12 slot machine, this would yield 24 commutation segments.

6. Enter the total number of conductors in each rotor slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers. This value is the total number of conductors in one real full rotor slot.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



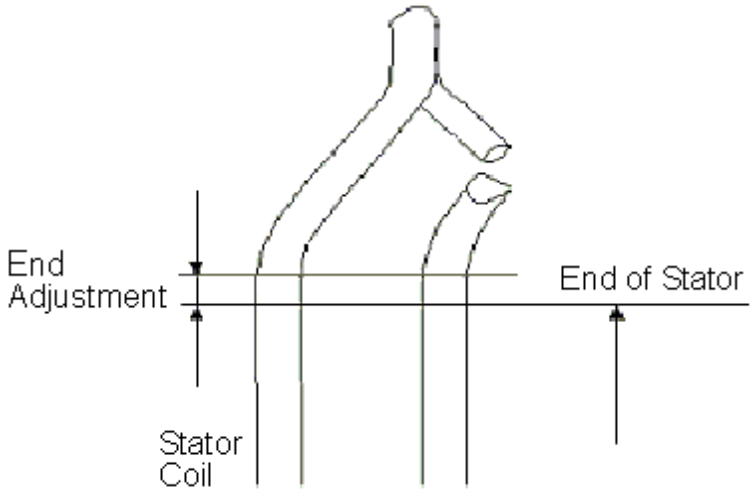
10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

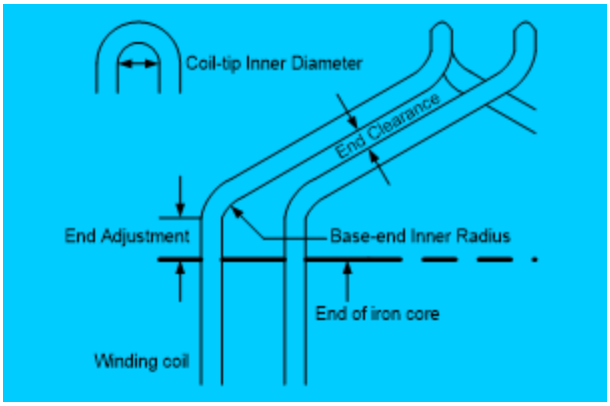
<*number*>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

11. Click the **End/Insulation** tab.
12. Select or clear the **Input Half-turn Length** check box.
13. Do one of the following:
    - If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.

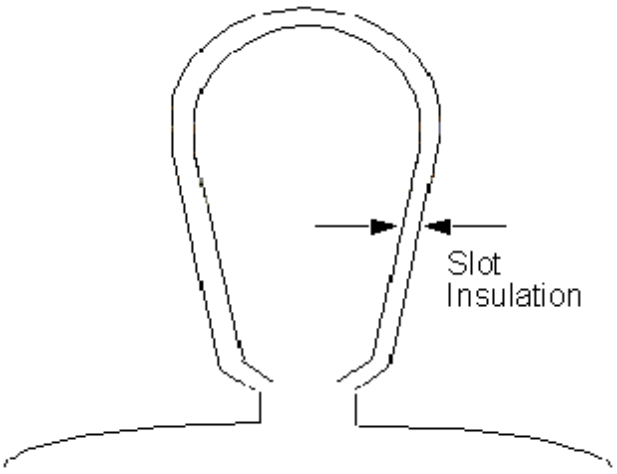
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.





14. Enter the inner radius of the base corner in the **Base Inner Radius** field.
15. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
16. Enter the distance between two rotor coils in the **End Clearance** field.

17. Enter the thickness of the slot liner insulation in the **Slot Liner** field.



18. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
19. Enter the thickness of the insulation layer in the **Layer Insulation** field.
20. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
21. Select the type of equalizer connection from the **Equalizer Connection** pull-down menu. Select from **None**, **Half**, or **Full**.
22. Click **OK** to close the **Properties** window.

Defining Different Size Wires for a PMDC Motor

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.

- Enter a **Number** in the table to specify how many of the conductor's wires have this data.

4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

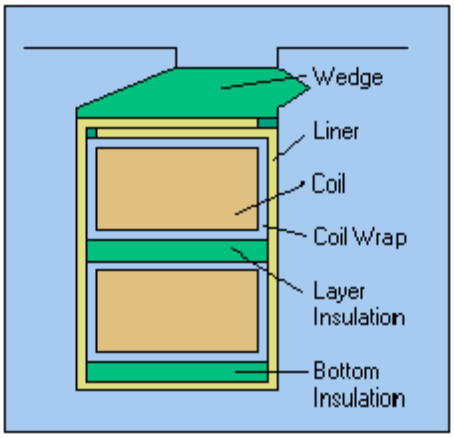
Rotor Winding Data for PMDC Motors

To access the stator winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Winding tab	**Winding Type**	The type of rotor winding. Click the button to open the **Winding Type** window and choose from **Lap**, **Wave**, and **Frog Leg**.
	Multiplex Number	Single, double, or triple windings (1, 2, or 3).
	Virtual Slots	The number of virtual slots per real slot.
	Conductors per Slot	The number of conductors per rotor slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.

End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
	Equalizer Connection	The connection type of the equalizer. Select from **None**, **Half**, or **Full**.



Defining the Commutator and Brush for a PMDC Motor

The commutator allows current transfer between DC terminals or brushes and the rotor coils, providing the current to the system as a function of rotation. Due to the action of the commutator, the corresponding magnetic field has a fixed distribution with respect to the stator.

To define the commutator and brush pairs:

1. To open the **Commutator Data Properties** window, double-click the **Machine>Commutator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Commutator** tab.
3. Select **Cylinder** or **Pancake Type** as the **Commutator Type**.

Note	When you place the mouse cursor over the commutator type, an outline of the commutator appears.

4. For **Cylinder** commutators, do the following:
   a. Enter the **Commutator Diameter**.
   b. Enter the **Commutator Length**.
5. For **Pancake** commutators, do the following:
   a. Enter the **Outer Diameter**.
   b. Enter the **Inner Diameter**.
6. Enter the thickness of the insulation between two consecutive commutator segments in the **Commutator Insulation** field.
7. Click the **Brush** tab.
8. Enter the **Brush Width**.
9. Enter the **Brush Length**.
10. Enter the number of brush pairs when using a wave armature winding in the **Brush Pairs** field.
11. Enter the angle of displacement from the neutral axis, in mechanical degrees, in the **Brush Displacement** field.

Note	The brush displacement is positive for the counter-clockwise direction. For example, if the rotor turns clockwise and the brush displacement is also clockwise, then the angle is negative; if the rotor turns clockwise but the brush displacement is counter-clockwise, then the angle is positive.

12. Enter the voltage drop across one brush pair in the **Brush Drop** field.
13. Enter the mechanical pressure of the brushes as they press against the commutator in the **Brush Press** field.

14. Enter the **Frictional Coefficient** of the brush.

Note	If the **Friction Loss** field is used in the **General** window, the **Brush Press** and **Frictional Coefficient** fields will be hidden in the **Commutator/Brush** window. These fields are shown only when the **Friction Loss** field in the **General** window is set to zero.

15. Click **OK** to close the **Properties** window.

Commutator and Brush Data for PMDC Motors

To access the commutator and brush data, double-click the **Machine>Commutator** entry in the project tree.

The **Commutator Data Properties** window contains the following fields:

Commutator tab	**Commutator Type**	The type of commutator. Click the button to open the **Select Commutator Type** window and select from **Cylinder** or **Pancake**.
	Commutator Diameter	For a **Cylinder** commutator type, the diameter of the commutator.
	Commutator Length	For a **Cylinder** commutator type, the length of the commutator.
	Outer Diameter	For a **Pancake** commutator type, the outer diameter of the commutator.
	Inner Diameter	For a **Pancake** commutator type, the inner diameter of the commutator.
	Commutator Insulation	The thickness of the insulation between the two commutator bars.
Brush tab	**Brush Width**	The width of the brush.
	Brush Length	The length of the brush.
	Brush Pairs	The number of brush pairs.
	Brush Displacement	The displacement of the brush from the neutral position, in mechanical degrees (positive for anti-rotating direction).
	Brush Drop	The voltage drop across a one-pair brush.
	Brush Press	The brush press per unit area. (Available only when **Frictional Loss** is set to zero for the machine.)
	Frictional Coefficient	The frictional coefficient of the brush. (Available only when **Frictional Loss** is set to zero for the machine.)

Defining the Shaft Data for a PMDC Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for PMDC Motors

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a PMDC Motor

To define the solution data:

1. To open the **Solution Setup** window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.

7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click **OK** to close the **Solution Setup** window.

Solution Data for PMDC Motors

Solution Data for PMDC Motors

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	The operation type is automatically set to **Motor** for this machine type.
Load Type	Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	Type a value for the rated output voltage, and select the units.
Rated Voltage	Type a value for the rated voltage, and select the units.
Rated Speed	Type a value for the rated speed, and select the units.
Operating Temperature	Type a value for the operating temperature, and select the units.

Setting Up Analysis Parameters for a PMDC Motor

Three-Phase Synchronous Machines

After you have selected **Three-Phase Synchronous Machines** as your model type, you need to define the following:

- General data, such as the unit system, power, and voltage.
- Stator data, such as the slot types and dimensions, stator diameter, skew width, and laminations.
- Optional stator Vent data.
- Winding data, such as the parallel branches, conductors, and wire dimensions.
- Rotor pole data, such as its associated pole-body dimensions and air gaps.
- Optional Rotor damper data, such as the damper dimensions, rings, and material properties.
- Rotor winding data and the winding control parameters.
- Shaft Data

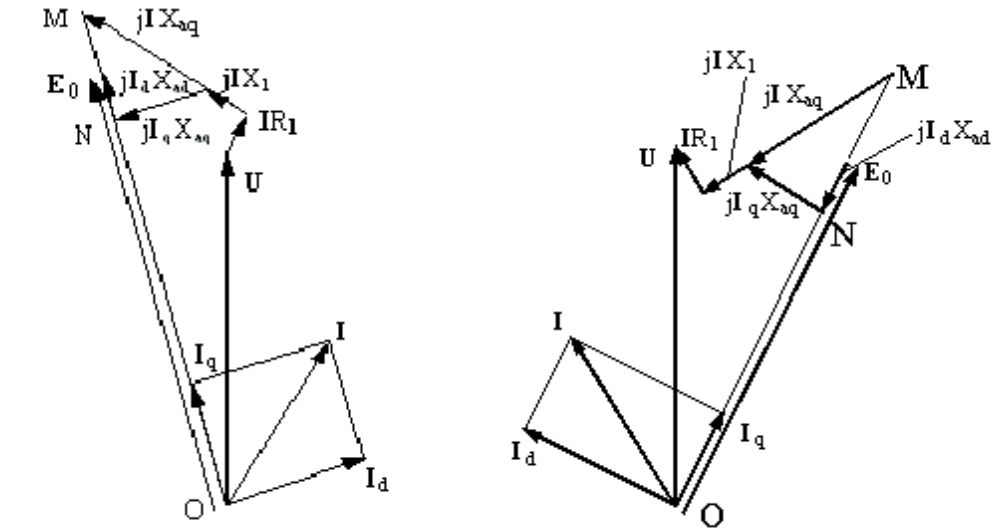
- Optional machine housing.
- Solution data, such as specifying motor or generator application, and rated output voltage and frequency.

Also see the Analysis Approach for Three-Phase Synchronous Machines.

Analysis Approach for Three-Phase Synchronous Machines

The three-phase salient-pole synchronous electric machine has two types: the generator and the motor. Their basic structures are the same. Three-phase synchronous generators are the main source of electrical energy for industrial, commercial, and private use. They receive mechanical energy at the shaft and transform it into electrical energy. The rotor is equipped with a multi-pole winding excited by a DC source. The stator is equipped with a three-phase winding that has a sinusoidal spatial distribution. The spinning rotor produces a rotating magnetic field in the air gap of the machine. The frequency of the voltage induced in the stator is given by $f=pv$, where p is the number of pairs of poles, and v is the velocity of the rotor. The machine is capable of producing both active and reactive power as required by the load connected at the stator phasor.

The three-phase salient-pole synchronous electric machine has two types: the generator and the motor. Their basic structures are the same. Usually the frequency-domain phasor diagram is adopted to analyze the characteristics. The phasor diagram for a generator is shown on the left and that for a motor is shown on the right.



In the figure, R1, X1, Xad, and Xaq are armature resistance, armature leakage reactance, d-axis armature reactance, and q-axis armature reactance, respectively. Xad is nonlinear, while a linearized value is used in the phasor diagram. Taking the input voltage **U** as the reference phasor, for a given current:

$$\mathbf{I} = I\angle -\varphi$$

where φ is the power factor angle, a phasor represented by OM can be derived by:

U + **I**(R1 + jX1 + jXaq)

The direction of $\mathbf{E}_0$ can, therefore, be obtained. Taking the power angle, the angle that **U** legs $\mathbf{E}_0$, as θ, then the angle that **I** legs $\mathbf{E}_0$ is:

$$\psi = \theta + \varphi$$

The d- and q-axis currents are then represented by the following:

$$Id = I * \sin(\psi)$$

$$Iq = I * \cos(\psi)$$

The phasor length ON represents the d-axis back EMF from d-axis resultant flux linkage and is used to determine the d-axis field saturation. Then a frozen method is applied to derive $\mathbf{E}_0$, X_{ad}, and exciting current I_f.

The output power (electric power) is directly computed from voltage and current as:

$$P2 = 3*U*I*\cos(\varphi)$$

The input power (mechanical power) is defined as:

$$P1 = P2 + Pfw + Pcua + PFe + Padd + Pcuf + Pex$$

where Pfw, Pcua, PFe, Padd, Pcuf and Pex are frictional and wind loss, armature copper loss, iron-core loss, additional loss, field winding copper loss, and exciter loss, respectively.

The input mechanical shaft torque is:

$$T1 = P1/\omega$$

where SYMBOL is synchronous speed in rad/s.

The efficiency is computed by:

```
eff = P2/P1 * 100%
```

Main Features

- Adapted to both Synchronous Motor and Generator

  The structures of the salient-pole synchronous motor and the generator are basically the same, but their phasor relationships and the computation methods are slightly different, their output characteristics data are also different. This is specified in the solution setup.

- Auto Arrangement of Three-phase Windings

  Almost all commonly used three-phase single- and double-layer, half- and whole-type ac windings (including fractional-pitch windings) can be automatically arranged. Users do not need to define coils one by one. RMxprt also supports a double-layer winding with half-turn coils which are auto-arranged in the order of even, odd, even, odd, …, and even, odd, as long as it is physically possible.

  When a designer adopts single-layer whole-coiled windings, RMxprt will perform winding arrangement optimization to minimize the average coil pitch. When asymmetric three-phase windings are used, winding arrangement is optimized in such a way that minimum negative-sequence and zero-sequence components are achieved.

- Winding Editor Supporting Any Single- and Double-Layer Windings

  Besides taking advantage of the winding auto-arrangement function in RMxprt, users can also specify any special winding by using of the Winding Editor function.

  In Winding Editor, through modification of phase belonging, number of turns, in-slot and out-slot number of each coil, it is possible to design single- and double-layer winding arrangement for any purposes.

- Analyze Air-Gap Magnetic Field Distribution

  For both uniform and non-uniform air gaps, Schwarz-Christopher Transformation is adopted to solve for the air-gap magnetic field distribution.

- Analyze EMF Waveform and Total Harmonic Distortion (THD)

  Based on the analysis of the air-gap magnetic field waveform, taking into account coil short pitch, winding distribution, skew slot, winding connection, load effects and other factors, the emf waveforms in the coils and the windings are analyzed to solve for the emf distortion factors.

- Analyze Dynamic Parameters of Damping Winding

  Different from the squirrel-cage winding of the induction machine, the damping winding of the salient-pole synchronous machine is located in the surface of magnetic field poles, which deviates greatly along the d- and the q-axes. Furthermore, the connection of damping bars has several forms. The bars under each pole could be connected, but not connected with those under other poles. All the bars could be connected together. The bars could be connected through end-plate. RMxprt can deal with all those complicated situations and give the dynamic parameters for the damping winding.

Defining a Three-Phase Synchronous Machine

The general procedure for defining a three-phase synchronous machine is as follows:

1. Insert a three-phase synchronous machine into a existing or new project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
5. Optionally, you can add a vent to, or remove an existing vent from the stator. To add a vent, select the stator, and right-click to display the pop-up menu for **Insert Vent**.
6. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings, conductors, and insulation data.
7. Double-click the **Machine-Rotor** entry in the project tree to define the general rotor geometry, the pole data, and the insulation data.
8. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor conductors and windings.
9. Optionally, you can add a damper to the design or remove an existing damper. To add a damper, use **Machine-Insert Damper**. This inserts the damper in the project tree under the rotor. You must then specify the slot type and other properties for the damper.
10. Optionally, you can add a vent to, or remove an existing vent from the rotor. To add a vent select the rotor, and right-click to display the pop-up menu. Use **Insert Vent**.
11. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
12. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
13. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define this solution data.
14. Choose **File>Save** to save the project.
15. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once the design is analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a Maxwell 3D design.

Defining the General Data for a Three-Phase Synchronous Machine

Use the **General Data Properties** window to define the power settings, speed, and efficiency of the generator. This window allows you to define the basic parameters of the synchronous generator, such as power, voltage, winding connections, and losses.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)

2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the power lost through frictional forces in the **Frictional Loss** field.
4. Enter the wind loss measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

General Data for Three-Phase Synchronous Machines

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Three Phase Synchronous Machine).
Number of Poles	The number of poles the machine contains.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator for a Three-Phase Synchronous Machine

Use the **Stator** windows to define the slot dimensions, stacking factors, air ducts, and insulation of the stator. The stator is the outer lamination stack where the three-phase windings reside.

To define general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.

7. Enter the **Number of Slots** in the stator.
8. Select the**Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 6). Slot types **1** though **4** are filled with round wire. Slot types **5** and **6** are filled with rectangular wire. If **Auto Design** is enabled, the software designs an optimum slot geometry; in this case, you can input the tooth width dimension, and the software determines the slot width accordingly.

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the number of sectors in the **Lamination Sectors** field.
10. Enter the thickness of the magnetic pressboard in the **Pressboard Thickness** field. Enter **0** for a non-magnetic pressboard.
11. Enter the skew width, measured in slot number, in the **Skew Width** field.
12. Click **OK** to close the **Properties** window.

Stator Data for Three-Phase Synchronous Machines

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Lamination Sectors	The number of lamination sectors.
Pressboard Thickness	The magnetic press board thickness (0 for a non-magnetic press board).
Skew Width	The skew width measured in slot number.

Defining Stator Slots for a Three-Phase Synchronous Machine

To define the slot dimensions:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.
4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.

5. Click **OK** to close the **Properties** window.

Stator Slot Data for Three-Phase Synchronous Machines

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

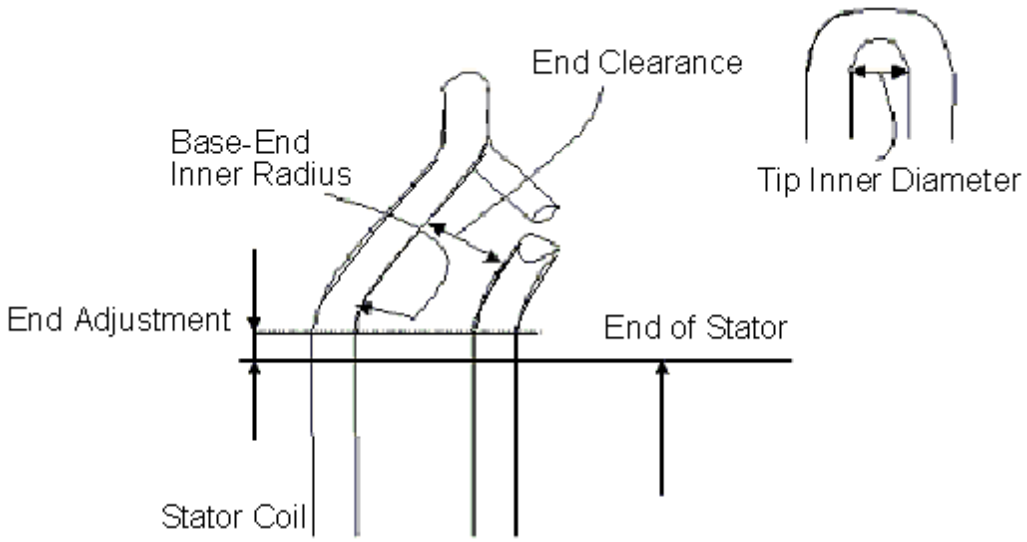
The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-**

	Stator-Slot is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining Stator Windings and Insulation for a Three-Phase Synchronous Machine

Use the **Stator Winding** window to define the stator winding data, such as the coils, wires, insulation, number of parallel branches, and physical dimensions of the windings.



The stator winding data defines the configuration of one phase of the three-phase windings.

To define the stator windings and insulation:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the six types of windings that are possible (three for one-layer and three for two-layer):

Type	Description
Editor	A user-defined one-layer winding arrangement. You need to set up the winding arrangement for each slot. For this winding type, the following letters are used for the phase windings: • Phase A/A return uses A/X. • Phase B/B return uses B/Y. • Phase C/C return uses C/Z.
Whole Coiled	A one-layer whole-coiled winding: Half Coiled	A one-layer concentric half-coiled winding: Editor	A user-defined two-layer winding arrangement. When you select **20**, the Winding Editor opens, where you can specify a different winding arrangement for each slot.

Whole Coiled	A two-layer wave winding:  The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
Half Coiled	A two-layer half-coiled winding:  There is only one coil per phase per pair of poles.

Note	**Example 1:** A one layer winding arranged in 12 slots should be defined as type **10**, with the following arrangement: **AAZZBBXXCCYY** **Example 2:** A two layer winding arranged in 12 slots should be defined as type **20**, with the following arrangement: **AAZZBBXXCCYY** Only the top layer needs to be defined; the bottom layer will be determined according to the coil pitch.

Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** window and return to the **Properties** window. Select a **Winding Type**. When you place the mouse cursor over a winding, an outline of the selected winding appears. The following winding types are available:

10	A user-defined single-layer winding arrangement. When you select it, enter the winding arrangement, and choose **OK**. For this winding type, the following letters are used for the phase windings: • phase A/A return uses A/X. • phase B/B return uses B/Y. • phase C/C return uses C/Z.
11	A one-layer whole-coiled winding: 12	A one-layer concentric half-coiled winding: 20	A user-defined winding arrangement. When you select this type, enter the winding arrangement, and choose **OK**.
21	A two-layer wave winding:

	 The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
22	A two-layer winding: Note	**Example 1:** A one layer winding arranged in 12 slots should be defined as type **10**, with the following arrangement: **AAZZBBXXCCYY** **Example 2:** A two layer winding arranged in 12 slots should be defined as type **20**, with the following arrangement: **AAZZBBXXCCYY** Only the top layer needs to be defined; the bottom layer will be determined according to the coil pitch.

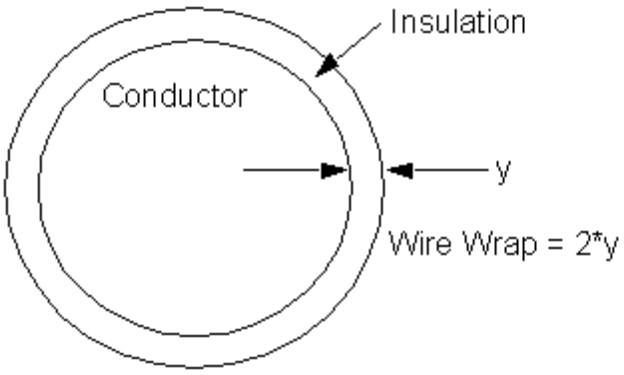
a. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.

b. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.

c. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.

d. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.

e. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



f. Select the **Wire Size**: Click the button for **Wire Size**. The **Wire Size** window appears. Select a value from the **Wire Diameter** pull-down list. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

g.

<*number*>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

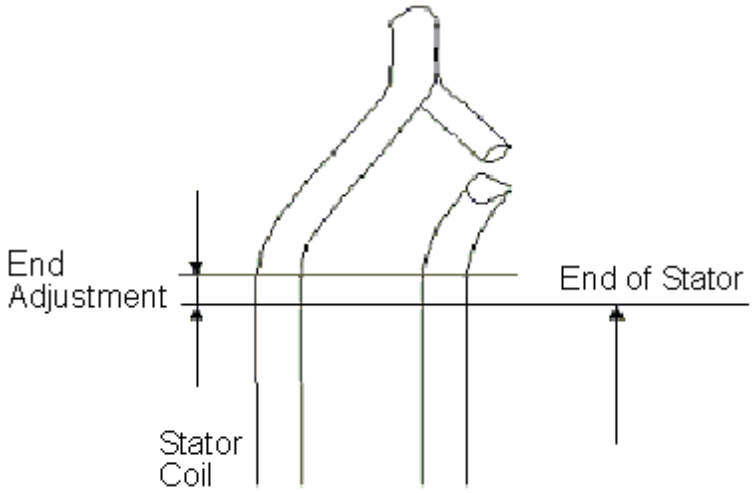
The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

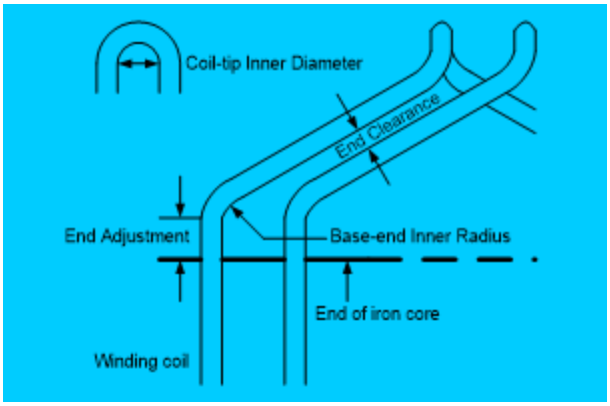
a. Click the **End/Insulation** tab.

b. Select or clear the **Input Half-turn Length** check box.

c. Do one of the following:

- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.





5. Enter the inner radius of the base corner in the **Base Inner Radius** field.
6. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
7. Enter the distance between two stator coils in the **End Clearance** field.
8. Enter the thickness of the slot liner insulation in the **Slot Liner** field.
9. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
10. Enter the thickness of the insulation layer in the **Layer Insulation** field.
11. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
12. Click **OK** to close the **Properties** window.

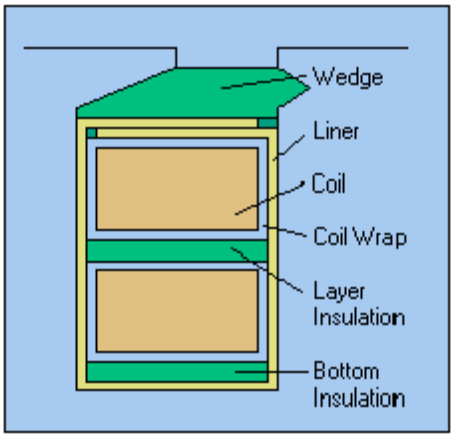
Stator Winding and Insulation for Three-Phase Synchronous Machines

To access the stator winding and insulation data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the stator winding.
	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length7**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.

	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.



Winding Editor for a Three-Phase Synchronous Machine

For a three-phase synchronous machine, you may want to specify a different number of conductors for each stator slot. The Winding Editor makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.

4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Three-Phase Synchronous Machine

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Choose **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Stator Vent Data for Three-Phase Synchronous Machines

To insert a vent on a stator for a three phase synchronous machine:

1. Right click on the stator icon in the project tree to display the shortcut menu.
2. Click **Insert Vent**.

   The vent icon appears in the project tree under the stator.

To remove an existing vent item,

1. Right-click on the stator icon in the project tree to display the shortcut menu.
2. Click **Remove Vent**.

   This removes the vent item from the project tree.

To access the Vent properties for a vent, double click on a vent item. The **Vent Properties** window contains the following fields.

Vent Ducts	The number of radial vent ducts.
Duct Width	The width of the radial vent ducts.
Magnetic spacer width	Width of magnetic spacer which holds vent ducts. O for non-magnetic spacer.
Duct pitch.	Center-to-Center distance between two adjacent Vent ducts

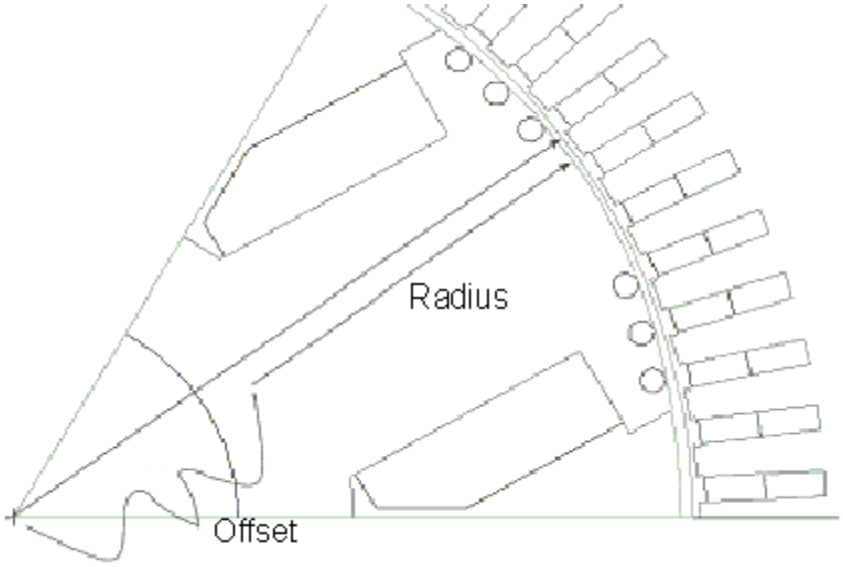
Defining the Rotor for a Three-Phase Synchronous Machine

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine-Rotor** and **Machine-Rotor-Winding** to define the rotor.

To define the general rotor data:

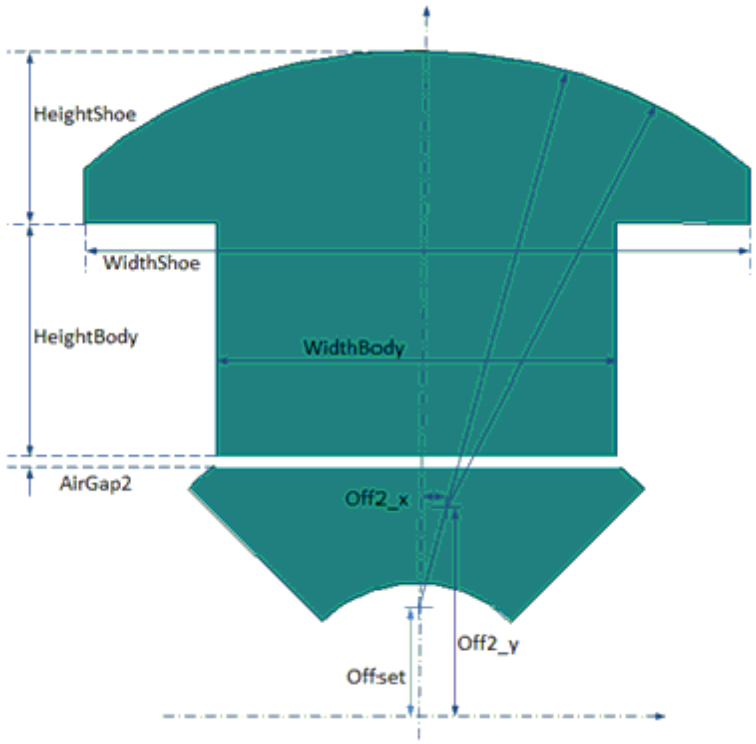
1. To open the **Rotor Data Properties** window, double-click the **Machine-Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Rotor** tab.
3. Enter the outer diameter of the rotor in the **Outer Diameter** field.
4. Enter the inner diameter of the rotor in the **Inner Diameter** field.
5. Enter the length of the rotor core in the **Length** field.
6. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
8. Click the **Pole** tab.

9. Enter the pole-arc center offset from the rotor center in the **Pole Arc Offset** field.



10. Enter the width of the pole shoe in the **Pole Shoe Width** field.
11. Enter the height of the pole shoe in the **Pole Shoe Height** field.
12. Enter the width of the pole body in the **Pole Body Width** field.
13. Enter the height of the pole body in the **Pole Body Height** field.
14. Enter the width between the rotor pole and rotor yoke in the **Second Air Gap** field.
15. To include the two arcs in the half-pole range, do the following:
    a. Select the **Select Pole Arc** check box.
    b. Enter the offset of the second arc perpendicular to the pole-center line in the **Off2_x** field.
    c. Enter the offset of the second arc parallel with the pole-center line in the **Off2_y** field.

Note	If the Off2_x and Off2_y parameters for the second arc are invalid, the second arc is ignored and the pole includes only the first arc defined by Pole Arc Offset.



1. Select or clear the **Magnetic PressBoard** check box to specify whether or not the press board is made of magnetic material.
2. Enter the thickness of the press board in the **Press Board Thickness** field.
3. Click the **Insulation** tab.
4. Enter the thickness of the insulating material beneath the shoe pole in the **Shoe Insulation** field.
5. Enter the thickness of the insulating material on the side of the pole body in the **Pole Insulation** field.
6. Enter the clearance distance between the windings in the **Winding Clearance** field.
7. Click **OK** to close the **Properties** window.

Rotor, Rotor Pole, and Insulation for Three-Phase Synchronous Machines

To access the general rotor data, pole data, and insulation data double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

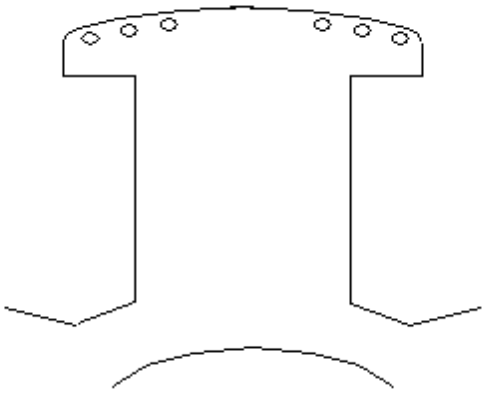
Rotor tab	**Outer Diameter**	The outer diameter of the rotor core.
	Inner	The inner diameter of the rotor core.

	Diameter	
	Length	The length of the rotor core.
	Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
	Stacking Factor	The stacking factor of the rotor core.
Pole tab	**Pole Arc Offset**	The pole-arc center offset from the rotor center.
	Pole Shoe Width	The width of the pole shoe.
	Pole Shoe Height	The height of the pole shoe.
	Pole Body Width	The width of the pole body.
	Pole Body Height	The height of the pole body.
	Second Air Gap	The width of the second air gap, between the rotor pole and rotor yoke.
	Second Pole Arc	Select or clear this option to specify whether or not the pole surface includes the two arcs in the half-pole range. When you select this check box, two additional fields appear: **Off2_x** and **Off2_y**.
	Off2_x	The offset of the second arc perpendicular to the pole-center line. This field is only available when **Second Pole Arc** is selected. **Note:** If **Off2_x** for the second arc is invalid, the second arc is ignored and the pole includes only the first arc defined by **Pole Arc Offset**.
	Off2_y	The offset of the second arc parallel with the pole-center line. This field is only available when **Second Pole Arc** is selected. **Note:** If **Off2_y** for the second arc is invalid, the second arc is ignored and the pole includes only the first arc defined by **Pole Arc Offset**.
	Magnetic PressBoard	Select or clear this option to specify whether or not the press board is made of magnetic material.
	Press Board Thickness	The thickness of the press board.
	Steel Type	The steel type of the rotor pole. Click the button to open the **Select Definition** window. Default value is the same as the rotor core.
	Stacking Factor	The stacking factor of the rotor pole. Default value is the same as the rotor core.

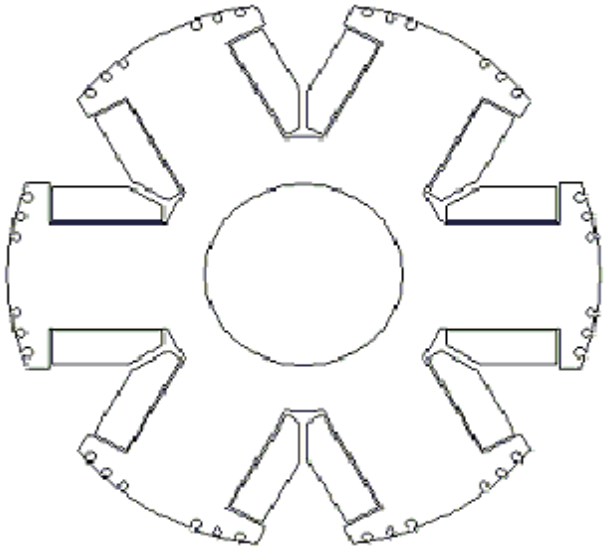
Insulation tab	**Shoe Insulation**	The thickness of the insulating material beneath the pole shoe.
	Pole Insulation	The thickness of the insulating material on the side of the pole body.
	Winding Clearance	The clearance distance between the windings.

Defining the Rotor Pole for a Three-Phase Synchronous Machine

The rotor pole drives the electromagnetic field that is coupled with the stator windings.
The following figure shows a partial diagram of a rotor pole:

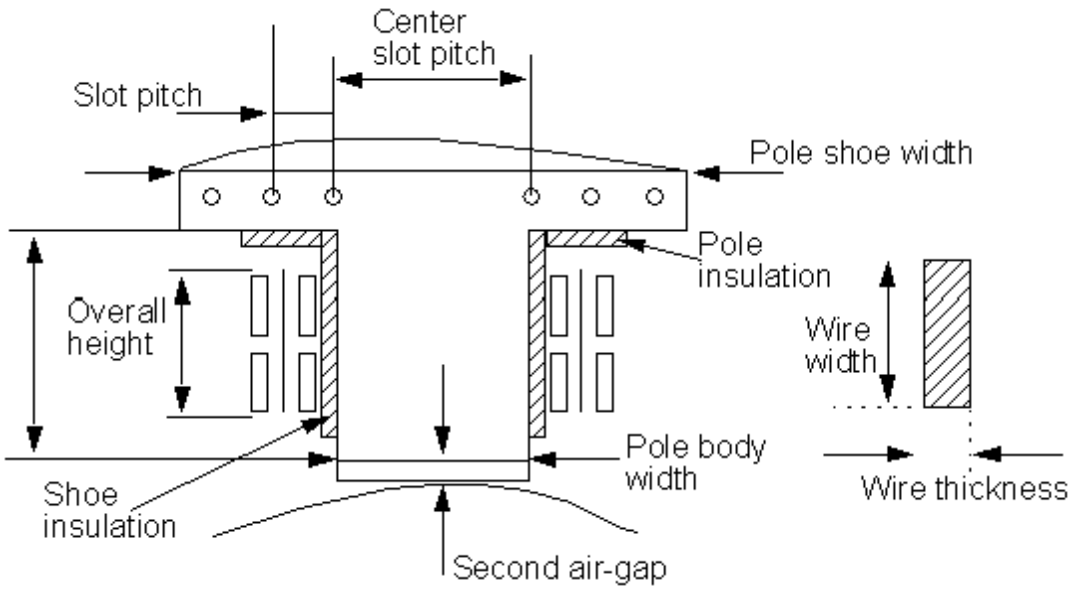


The following figure shows a diagram of an entire rotor:



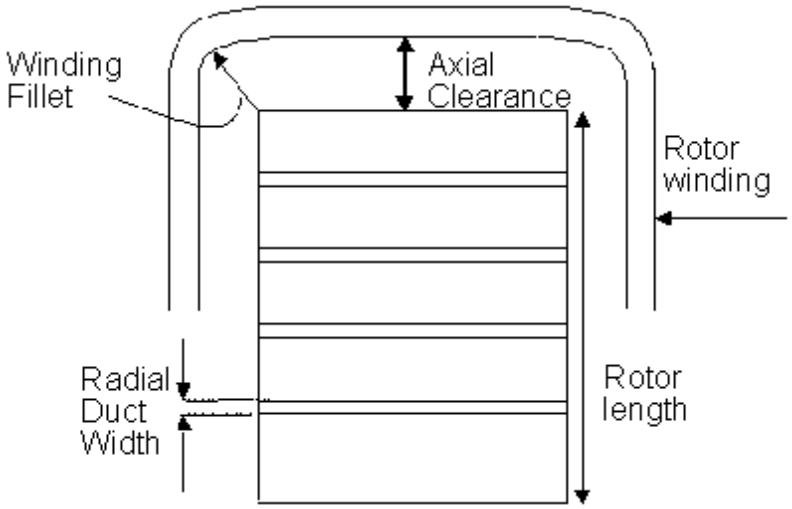
Defining the Rotor Winding Data for a Three-Phase Synchronous Machine

Use the **Rotor Winding** window to define the wires and physical dimensions of the rotor winding. The rotor winding provides the excitation for the electromagnetic field that produces the rotor pole.



To define the rotor windings:

1. To open the **Rotor Winding Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select the **Winding Type** for the rotor:
   a. Click the button.
      The **Winding Type** window appears.
   b. Click to select the type of winding, from **Round**, **Cylinder**, or **EdgeWise**.
      When you place the mouse cursor over the winding type, a schematic of the selected winding appears
   c. Click **OK** to return to the **Properties** window.
3. Enter the number of parallel branches for the winding in the **Parallel Branches** field.
4. Conductors per Pole
5. Enter the number of wires in each conductor in the **Number of Strands** field.
6. Enter the width of the insulating wire wrap in the **Wire Wrap** field.
7. Interturn Insulation
8. Enter the gauge of the wire in the **Wire Size** field.
9. Enter the **Axial Clearance** to specify the axial distance between the core and the coil at the end of the lamination stack.



10. Limited Cross Width
11. Limited Cross Height
12. Winding Fillet
13. Click **OK** to close the **Properties** window.

Rotor Winding Data for Three-Phase Synchronous Machines

To access the rotor winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Winding Type	The type of rotor winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
Parallel Branches	The number of parallel branches in the rotor winding.
Conductors per Pole	The number of conductors per rotor pole (0 for auto-design).
Number of Strands	The number of wires per conductor (0 for auto-design).
Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
Interturn Insulation	The thickness of the inter-turn insulation of an edgewise winding. This field only appears when **EdgewiseCoil** is selected as the **Winding Type**.
Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
Axial Clearance	The axial gap between the field winding and the pole body or inner coil.

Limited Cross Width	The limited cross-section width for the winding design or arrangement (0 for available maximum area).
Limited Cross Height	The limited cross-section height for the winding design or arrangement (0 for available maximum area).
Winding Fillet	The size of the winding fillet.

Defining the Rotor Damper Data

To define a rotor damper for a machine that permits one:

1. Click **Machine>Insert Damper.**

   The Damper icon appears in the project tree under the rotor icon. A slot icon appears in the hierarchy under the damper.
2. Double click on the Damper icon to display the properties window for the damper.
3. Enter the appropriate values for the damper. The slot type, the bar conductor type, and end conductor type are entered by clicking on buttons that open other windows.
4. Click OK to close the properties window.

Damper Data for Three-Phase Synchronous Machines

By option, you can add a damper to or remove damper from the rotor of a three phase machine.

To add a damper:

1. Right-click on the rotor icon in the project tree to display the short cut menu.
2. Click **Insert Damper** on the menu.

   The damper appears in the project tree under the rotor. The damper also includes an associated slot.

1. To remove a damper, right-click on the rotor icon in the project tree to display the short cut menu.
2. Click **Remove Damper** on the menu.

   The damper and associated slot are removed from the project tree.

The damper data contains the following fields.

Damper slots per pole	Number of damper slots per pole.
Slot type	Damper slot type. Specify this by clicking the button in the properties field and selecting from the Select Slot Type window.
Cast Rotor	Whether the rotor squirrel cage winding is cast.

Bar conductor type	Specify this by clicking the button in the properties field, and using the Select Definition window to find and assign materials.
End length	Single side end extended bar length/
End ring width	Axial width of end ring.
End ring height	Radial height of end ring.
End ring conductor type	Specify this by clicking the button in the properties field and using the Select Definition window to find and assign the material.
End Ring type	Type of end ring for the damper. Specify this by clicking the button in the properties field and use the Select Pole type window to select from the available types.
Slot pitch	Slot pitch in mechanical degrees in reference to the offset center.

Defining the Shaft Data for a Three-Phase Synchronous Machine

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Three-Phase Synchronous Machines

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Three-Phase Synchronous Machine

To define the solution data:

1. To open the **Solution Setup** window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab.

3. Select **Motor** or **Generator** from the **Operation Type** pull-down list.
4. Select the **Load Type** used in the motor from the following options:

Infinite Bus	When the generator is connected to an infinite bus of the power system, the terminal voltages remain constant and the output power is determined by the output currents.
Independent Generator	The generator supplies electrical power to a load inductor. For an AC generator, the resistance and inductance of the load inductor are determined by the rated output power, the rated voltage, and the rated power factor. For a DC generator, the resistance of the load resistor is determined by the rated output power and the rated voltage.
Const Speed	*For Motors.* The speed remains constant in the motor.
Const Power	*For Motors.* The output power remains constant in the motor.
Const Torque	*For Motors.* The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	*For Motors.* The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	*For Motors.* The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

5. Enter the output power developed at the shaft of the machine in the **Rated Output Power** field.
6. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
7. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
8. Enter the temperature at which the system functions in the **Operating Temperature** field.
9. Click the **Three-Phase Synchronous Machine** tab.
10. Enter a value in the **Rated Power Factor** field.
11. Select **Wye** or **Delta** from the **Winding Connection** pull-down list.
12. In the **Exciter Efficiency** field, enter the efficiency of the exciter used to supply the rotor winding with DC current if it is mechanically connected to the shaft of the generator. The efficiency value ranges between 0 and 1 and will only affect the total efficiency result.
13. To enter an **Input Exciting Current**, select the check box, enter a value, and select the units.
14. Click **OK** to close the **Solution Setup** window.

Setting Up Analysis Parameters for a Three-Phase Synchronous Machine

Brushless Permanent-Magnet DC Motors

After you have selected **Brushless Permanent-Magnet DC Motors** as your model type, you need to define the following:

- General data, such as the voltage, speed, and circuit type of the model.
- Circuit data, such as lead trigger angle, transistor drop, and control circuit information.
- Stator data, such as the diameter, slot dimensions, winding data, and skew width of the stator.
- Rotor data
- Rotor pole data, such as the magnet dimensions and stacking factor.

- Shaft data
- Optional machine housing.
- Solution data, such as rated output voltage and frequency.

Analysis Approach for Brushless PMDC Motors

The stator of a brushless DC motor is equipped with a polyphase winding. The phases are connected to the DC bus through a switching circuit. The switching sequence is controlled so that it is synchronized with the position of the rotor. As a result, the stator produces a rotating magnetic field.

The rotor is equipped with permanent magnets, creating a structure with the same number of poles at the stator. The stator switches act like a commutator in a classic DC motor.

In brushless permanent-magnet DC (BLDC) motors, the armature currents are commutated exactly according to rotor position. The signal of rotor position may be obtained from a position sensor, or from induced voltages for sensor-less control system.

The performance of BLDC motors is analyzed via a time-domain simulation. The voltage equation in the time domain is:

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} - \begin{bmatrix} e_d \\ e_q \\ e_0 \end{bmatrix} = \begin{bmatrix} R_1 + L_d p & -L_q \omega_e & 0 \\ -L_d \omega_e & R_1 + L_q p & 0 \\ 0 & 0 & R_1 + L_0 p \end{bmatrix} \cdot \begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix}$$

where R_1, L_d, L_q, and L_0 are armature resistance, d-axis synchronous inductance, q-axis synchronous inductance, and 0-axis inductance, respectively. ω_e is rotor speed in electrical rad/s, and p represents for *d/dt*.

The transformations for terminal voltages, induced voltages, and winding currents are given by the following three equations:

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} = C^T \cdot \begin{bmatrix} v_a \\ v_b \\ ? \end{bmatrix} : \quad \begin{bmatrix} e_d \\ e_q \\ e_0 \end{bmatrix} = C^T \cdot \begin{bmatrix} e_a \\ e_b \\ ? \end{bmatrix} \quad : \begin{bmatrix} i_a \\ i_b \\ ? \end{bmatrix} = C \cdot \begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix}$$

The transformation matrices for 2-phase, 3-phase, and 4-phases systems, noted as C_2, C_3, and C_4, are as follows:

$$C_2 = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \end{bmatrix}$$

$$C_3 = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos\theta & \sin\theta & 1/(\sqrt{2}) \\ \cos(\theta-\alpha) & \sin(\theta-\alpha) & 1/(\sqrt{2}) \\ \cos(\theta-2\alpha) & \sin(\theta-2\alpha) & 1/(\sqrt{2}) \end{bmatrix}$$

$$C_4 = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ \sin\theta & -\cos\theta & 0 \\ -\cos\theta & -\sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \end{bmatrix}$$

where $\alpha = 2\pi/3$.

The input power (electric power) can now be computed from the voltage and current as:

$$p_1 = \frac{1}{t}\int_0^T (v_d i_d + v_q i_q + v_0 i_0)dt$$

The output power (mechanical power) is:

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_t + P_{Fe})$$

where P_{fw}, P_{Cua}, P_t, and P_{Fe} are frictional and wind loss, armature copper loss, transistor/diode loss, and iron-core loss, respectively.

The output mechanical shaft torque T_2 is:

$$T_2 = P_2 / \omega$$

where ω is the rotor speed in mechanical rad/s.

The efficiency is computed by:

$$eff = P_2/P_1 * 100\%$$

Defining a Brushless Permanent-Magnet DC Motor

The general procedure for defining a brushless permanent-magnet DC motor is as follows:

1. Insert the permanent magnet brushless DC motor into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Circuit** entry in the project tree to define the control circuit.
4. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
5. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
6. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
7. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
8. Double-click the **Machine-Rotor-Pole** entry in the project tree to define the pole, embrace, offset, and air gap data for the rotor pole.
9. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
10. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
11. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.

12. Choose **File>Save** to save the project.
13. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design

Please refer to the *Brushless Permanent-Magnet DC Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example of a brushless permanent-magnet DC motor problem.

Defining the General Data for a Brushless PMDC Motor

Use the **General** window to specify the rated output power, voltage values, circuit type, and speed of the brushless DC motor.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
4. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Select **DC** or **CCC** from the **Control Type** pull-down list.
7. Select a **Circuit Type** from the following types:

Y3	Y-connected, three-phase.
L3	Loop-type, three-phase.
S3	Star-type, three-phase.
C2	Cross-type, two-phase.
L4	Loop-type, four-phase.
S4	Star-type, four-phase.

   The circuit types are based on industry standards. By default, type **Y3**, a three-phase, six-status circuit, is selected as the circuit type.

Note	When you place the mouse cursor over a circuit type, an outline schematic of the circuit appears.

8. Click **OK** to close the **Properties** window.

General Data for Brushless PMDC Motors

To access the general data, double-click the **Machine** entry in the project tree.

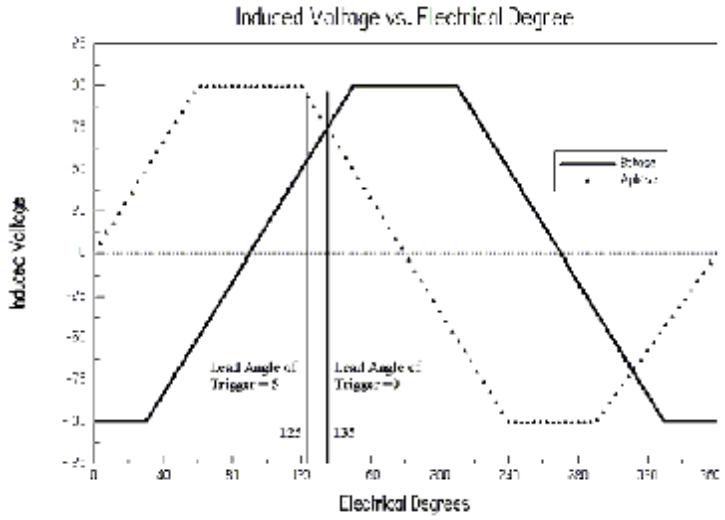
The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Brushless Permanent-Magnet DC Motor).
Number of Poles	The number of poles the machine contains.
Rotor Position	Select whether the rotor is an **Inner Rotor** or **Outer Rotor**.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.
Control Type	The way the circuit is controlled. Select from **DC** or **CCC** (chopped current control).
Circuit Type	The drive circuit type. Click the button to open the **Circuit Type** window and select from the following six types: • **Y3**: Y-Type, 3-Phase • **L3**: Loop-Type, 3-Phase • **S3**: Star-Type, 3-Phase • **C2**: Cross-Type, 2-Phase • **L4**: Loop-Type, 4-Phase • **S4**: Star-Type, 4-Phase

Defining the Circuit Data for a Brushless PMDC Motor

Use the **Circuit Data Properties** window to define the circuit data for a brushless PMDC Motor.

1. To open the **Circuit Data Properties** window, double-click the **Machine>Circuit** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the trigger's lead angle in electrical degrees in the **Lead Angle of Trigger** field. The trigger's lead angle is shown in the following plot of the open circuit induced voltage versus position. An angle of 0 means that the induced voltage in the triggered phase is at a maximum:



Note	A positive value represents a lead angle, and a negative value represents a lag angle.

3. Enter the period from on-status to off-status of a transistor, in electrical degrees, in the **Trigger Pulse Width** field.
4. Enter the voltage drop across one transistor when the transistor is turned on in the **Transistor Drop** field. Refer to the figures of the different circuit types in step 2.
5. Enter the voltage drop of one diode in the discharge loop in the **Diode Drop** field. If you selected a star-type circuit (**S3** or **S4**) as the **Circuit Type**, enter the total discharge voltage in this field.
6. If you selected CCC (chopped current control) as the **Control Type**, then enter the maximum and minimum current values in the **Maximum Current** and **Minimum Current** fields.
7. Click **OK** to close the **Properties** window.

Circuit Data for Brushless PMDC Motors

To access the **Circuit Data Properties** window, double-click the **Machine>Circuit** entry in the project tree.

Lead Angle of Trigger	The trigger's lead angle, in electrical degrees.
Trigger Pulse Width	The period from on-status to off-status for a transistor, in electrical degrees.
Transistor Drop	The voltage drop across one transistor when the transistor is turned on.
Diode Drop	The voltage drop across one diode in the discharge loop.
Maximum	The maximum current for the chopped current control. This field is not

Current	available for a DC circuit.
Minimum Current	The minimum current for the chopped current control. This field is not available for a DC circuit.

Defining the Stator Data for a Brushless PMDC Motor

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the skew width, measured in slot number, in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Stator Data for Brushless PMDC Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.

Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Skew Width	The skew width measured in slot number.

Defining the Stator Slots for a Brushless PMDC Motor

To define the physical dimensions of the stator slots:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.
4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.

5. Click **OK** to close the **Properties** window.

Stator Slot Data for Brushless PMDC Motors

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Stator Windings and Conductors for a Brushless PMDC Motor

To define the stator windings, wires, and conductors:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the six types of windings that are possible (three for one-layer and three for two-layer):

Type	Description
Editor	A user-defined one-layer winding arrangement. You need to set up the winding arrangement for each slot. For this winding type, the following letters are used for the phase windings: • Phase A/A return uses A/X. • Phase B/B return uses B/Y. • Phase C/C return uses C/Z.
Whole Coiled	A one-layer whole-coiled winding: Half Coiled	A one-layer concentric half-coiled winding: Editor	A user-defined two-layer winding arrangement. When you select **20**, the Winding Editor opens, where you can specify a different winding arrangement for each slot.
Whole Coiled	A two-layer wave winding:

	 The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
Half Coiled	A two-layer half-coiled winding:  There is only one coil per phase per pair of poles.

Note	**For a two layer winding,** if you check Constant Pitch in the Winding Editor, only the top layer needs to be defined; the bottom layer will be determined according to the coil pitch.

Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** window and return to the **Properties** window.

Select a **Winding Type**. The following winding types are available:

Note	When you place the mouse cursor over a winding, an outline of the selected winding appears.

10	A user-defined single-layer winding arrangement. When you select this type, enter the winding arrangement, and choose **OK**. For this winding type, the following letters are used for the phase windings: • Phase A/A return uses A/X. • Phase B/B return uses B/Y. • Phase C/C return uses C/Z.
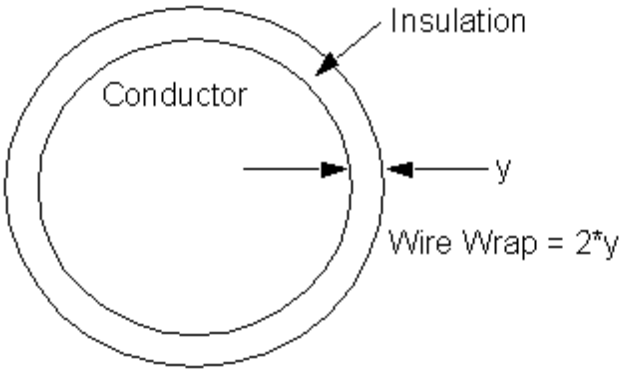
11	A one-layer whole-coiled winding: 12	A one-layer concentric half-coiled winding: 20	A user-defined two-layer winding arrangement. When you select this type, enter the winding arrangement, and choose **OK**.
21	A two-layer wave winding:

	 The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
22	A two-layer winding: 
a. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.
b. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.
c. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
d. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
e. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



f. Select the **Wire Size**:
   g. Click the button for **Wire Size**.
   The **Wire Size** window appears.
   h. Select a value from the **Wire Diameter** pull-down list.
   i. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

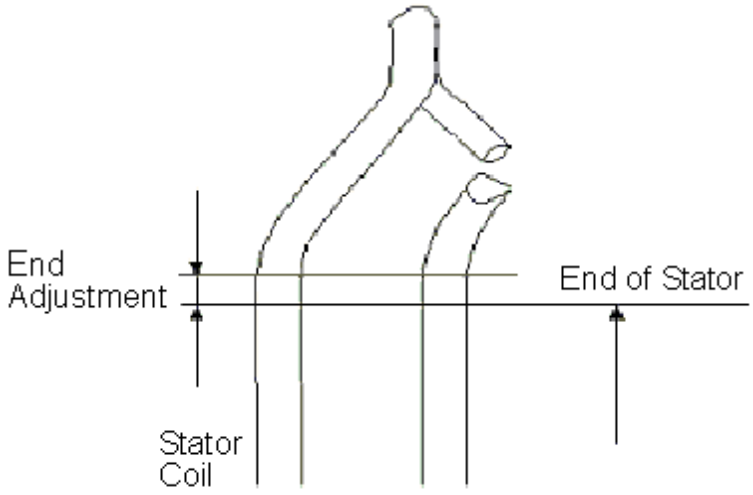
< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

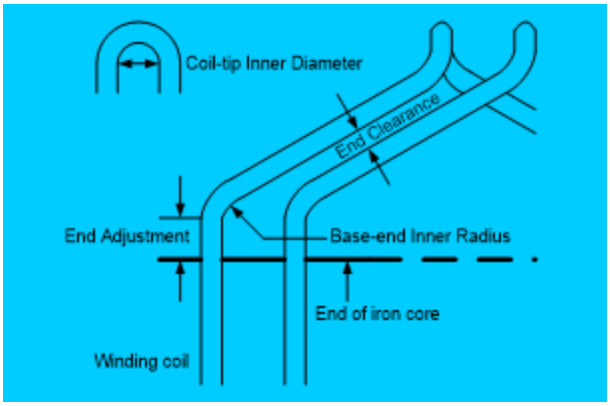
The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

a. Click the **End/Insulation** tab.
b. Select or clear the **Input Half-turn Length** check box.
c. Do one of the following:
   - If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.

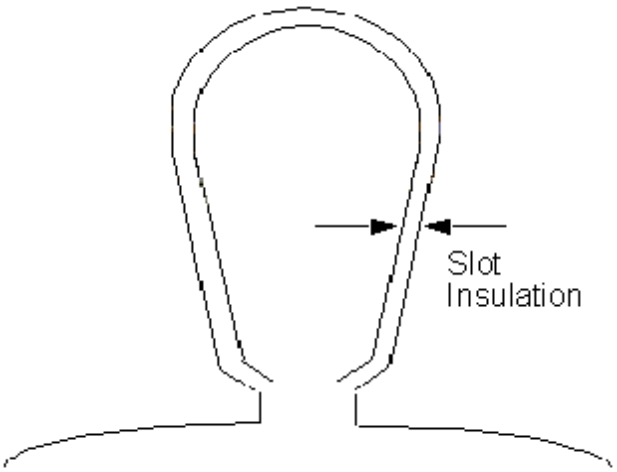
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.





5. Enter the inner radius of the base corner in the **Base Inner Radius** field.
6. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
7. Enter the distance between two stator coils in the **End Clearance** field.

8. Enter the thickness of the slot liner insulation in the **Slot Liner** field.



9. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
10. Enter the thickness of the insulation layer in the **Layer Insulation** field.
11. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
12. Click **OK** to close the **Properties** window.

Winding Editor for a Brushless DC Motor

For a brushless DC motor, you may want to specify a different number of conductors for each stator slot. The Winding Editor makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.
4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the conductor settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Brushless DC Motor

Use the **Gauge** option in the **Wire Size** dialog if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Stator Winding Data for Brushless PMDC Motors

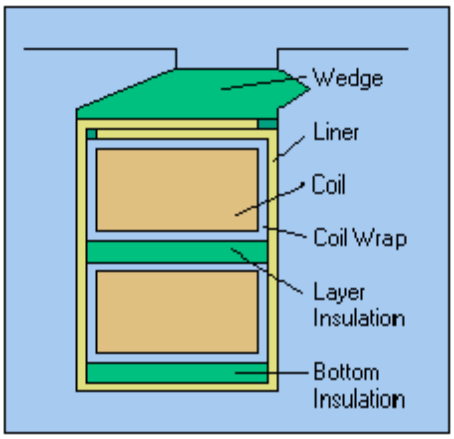
To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the

		stator winding.
	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire

		slot area.



Defining the Rotor Data for a Brushless PMDC Motor

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine>Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general rotor data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the outer diameter of the rotor in the **Outer Diameter** field.
3. Enter the inner diameter of the rotor in the **Inner Diameter** field.
4. Enter the length of the rotor core in the **Length** field.
5. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
6. Enter the stacking factor for the rotor core in the **Stacking Factor** field.
7. Select a **Pole Type**:
   a. Click the button.
      The **Select Pole Type** window appears.
   b. Click a button to select the desired pole type (1, 2, 3, 4, or 5). TIP: When you run the mouse over each option, the diagram changes to show that pole type.

Note	When you place the mouse cursor over a pole type, an outline of the selected circuit type appears.

c. Click **OK** to close the **Select Pole Type** window and return to the **Properties** window.

8. Click **OK** to close the **Properties** window.

Rotor Data for Brushless PMDC Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Stacking Factor	The stacking factor of the rotor core.
Pole Type	The pole type for the rotor. Click this button to open the **Select Pole Type** window and select from the following types: **1**, **2**, **3**, **4**, *5*.

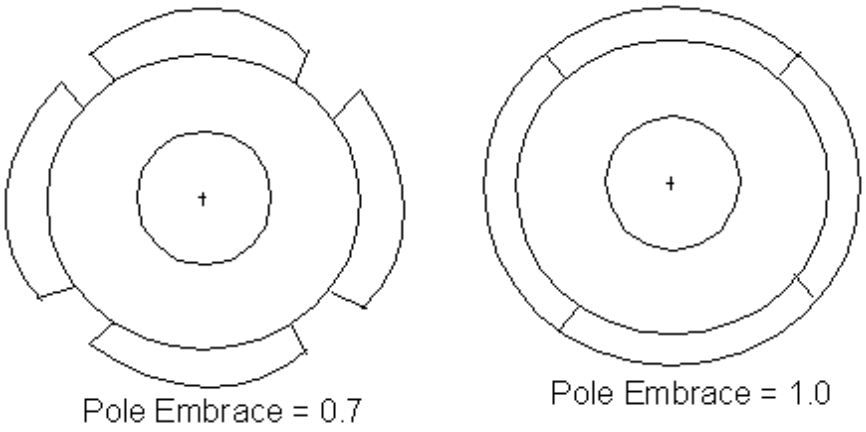
Defining the Rotor Pole for a Brushless PMDC Motor

The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **Rotor Pole Data Properties** window to define the rotor pole.

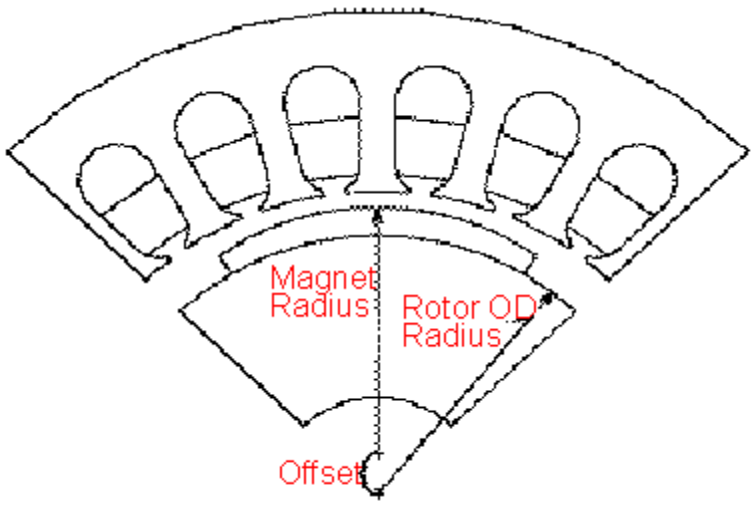
Note	Some of the fields in the **Rotor Pole** window change, or are inactive, depending on the **Rotor Type** you select.

To define the rotor pole:

1. To open the **Rotor Pole Data Properties** window, double-click the **Machine-Rotor-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. For all pole types except type **4**, enter the ratio of the actual arc distance in relation to the maximum possible arc distance in the **Embrace** field. This value is between 0 and 1.



3. For pole type **4**, enter the shaft diameter of the rotor in the **Shaft Diameter** field.
4. For pole types **1**, **2**, and **3**, enter the distance from the center of the rotor to the polar arc center in the **Offset** field. Enter 0 for a uniform air gap.



5. For pole type **5**, enter the thickness of the bridge across the two poles in the **Bridge** field.
6. For pole type **5**, enter the width of the rib supporting the bridge in the **Rib** field.
7. Select the type of magnet to use in the rotor pole from the **Magnet Type** pull-down menu.
8. For pole types **4** and **5**, enter the width of the magnet in the **Magnet Width** field.
9. Enter the maximum radial thickness of the magnet in the **Magnet Thickness** field.
10. Click **OK** to close the **Properties** window.

Rotor Pole Data for Brushless PMDC Motors

To access the pole rotor data, double-click the **Machine-Rotor-Pole** entry in the project tree.

The **Rotor Pole Data Properties** window may contain the following fields, depending on the pole type specified.

Embrace	The pole embrace. For pole types **1**, **2**, **3**, and **5**.
Shaft Diameter	The shaft diameter of the rotor. For pole type **4**.
Offset	The pole-arc center offset from the rotor center (0 for a uniform air gap). For pole types **1**, **2**, and **3**.
Bridge	The thickness of the bridge across two adjacent poles. For pole type **5**.
Rib	The width of the rib at the center of two adjacent poles that support the bridge. For pole type **5**.
Magnet Type	The type of magnet. Click the button to open the **Select Definition** window. For all pole types.
Magnet Width	The maximum width of the magnet. For pole types **4** and **5**.
Magnet Thickness	The maximum thickness of the magnet. For all pole types.

Defining the Shaft Data for a Brushless PMDC Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Brushless PMDC Motors

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Brushless PMDC Motor

To define the solution data:

1. To open the Solution Setup window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is **Motor** for this machine type.

3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, T_{load} = T_{rated}, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click **OK** to close the **Solution Setup** window.

Solution Data for Brushless PMDC Motors

Analysis Offered

Analysis Offered

- Adapted to both Synchronous Motor and Generator

  The structures of the salient-pole synchronous motor and the generator are basically the same, but their phasor relationships and the computation methods are slightly different, their output characteristics data are also different. Therefore, RMxprt divides the synchronous machine into two design modules: Synchronous Motor and Synchronous Generator.
- Auto Arrangement of Three-phase Windings

  Almost all commonly used three-phase single- and double-layer, half- and whole-type ac windings (including fractional-pitch windings) can be automatically arranged. Users do not need to define coils one by one. RMxprt also supports a double-layer winding with half-turn coils which are auto-arranged in the order of even, odd, even, odd, …, and even, odd, as long as it is physically possible.

  When a designer adopts single-layer whole-coiled windings, RMxprt will perform winding arrangement optimization to minimize the average coil pitch. When asymmetric three-phase windings are used, winding arrangement is optimized in such a way that minimum negative-sequence and zero-sequence components are achieved.

- Winding Editor Supporting Any Single- and Double-Layer Windings

  Besides taking the great advantage of the winding auto-arrangement function in RMxprt, users can also specify any special winding by using of the Winding Editor function.

  In Winding Editor, through modification of phase belonging, number of turns, in-slot and out-slot number of each coil, it is possible to design single- and double-layer winding arrangement for any purposes.
- Analyze Air-Gap Magnetic Field Distribution

  For both uniform and non-uniform air gaps, Schwarz-Christopher Transformation is adopted to solve for the air-gap magnetic field distribution.
- Analyze EMF Waveform and Total Harmonic Distortion (THD)

  Based on the analysis of the air-gap magnetic field waveform, taking into account coil short pitch, winding distribution, skew slot, winding connection, load effects and other factors, the emf waveforms in the coils and the windings are analyzed to solve for the emf distortion factors.
- Analyze Dynamic Parameters of Damping Winding

  Different from the squirrel-cage winding of the induction machine, the damping winding of the salient-pole synchronous machine is located in the surface of magnetic field poles, which deviates greatly along the d- and the q-axes. Furthermore, the connection of damping bars has several forms. The bars under each pole could be connected, but not connected with those under other poles. All the bars could be connected together. The bars could be connected through end-plate. RMxprt can deal with all those complicated situations and give the dynamic parameters for the damping winding.

Setting Up Analysis Parameters for a Brushless PMDC Motor

Solution Data for Brushless PMDC Motors

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	The operation type is automatically set to **Motor** for this machine type.
Load Type	Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	Type a value for the rated output voltage, and select the units.
Rated Voltage	Type a value for the rated voltage, and select the units.
Rated Speed	Type a value for the rated speed, and select the units.

Operating Temperature	Type a value for the operating temperature, and select the units.

Setting Up Analysis Parameters for a Brushless PMDC Motor

Switched Reluctance Motors

After you have selected **Switched Reluctance Motors** as your model type, define the following:

- General data, such as the power, voltage, and speed of the motor.
- Circuit data.
- Stator core data, such as the number of poles, diameter, and yoke thickness.
- Stator coil data, such as the slot liner thickness, number of parallel branches, and number of wires in each conductor.
- Rotor core data, such as the air gap dimensions and number of poles in the rotor.
- Shaft data.
- Optional machine housing.
- Solution data.

Analysis Approach for Switched Reluctance Motors

This motor type operates with shaft position feedback to synchronize the commutation of the phase currents with precise rotor position. Typically, both the stator and the rotor are salient to increase the torque-producing characteristics of the motor. The rotor has no windings; the torque is produced by the alignment tendency of the rotor to the stator so that the stator flux linkage is maximized.

In these motors, the stator and rotor have different numbers of poles. The stator phase windings are energized at precise moments synchronized with the position of the rotor. The task of energizing the stator windings is performed by a complex electronic system.

The number of phases in the winding is the ratio of the stator number of poles to the smallest common divider of the stator and the rotor number of poles.

In switched reluctance motors (SRM), the stator and the rotor have a different number of poles, and the stator currents are commutated exactly according to rotor position. The signal of the rotor position is obtained from a position sensor. The stator windings are triggered one by one, and normally the current in a winding has finished or almost finished freewheeling when the next winding is triggered. Therefore, the mutual effects between two phases can be neglected. The voltage equation of one phase is:

$$u = u_T + R_S \cdot i + \frac{d\Psi(\theta, i)}{dt}$$

where u_T is the transistor or diode voltage drop, and R_s is the stator winding resistance. $\Psi(\theta, i)$ is the flux linkage of the winding at rotor position θ and winding current i, as is shown in Figure 8, where the rotor position when the center of the rotor slot is aligned to the winding axis is defined as 0.

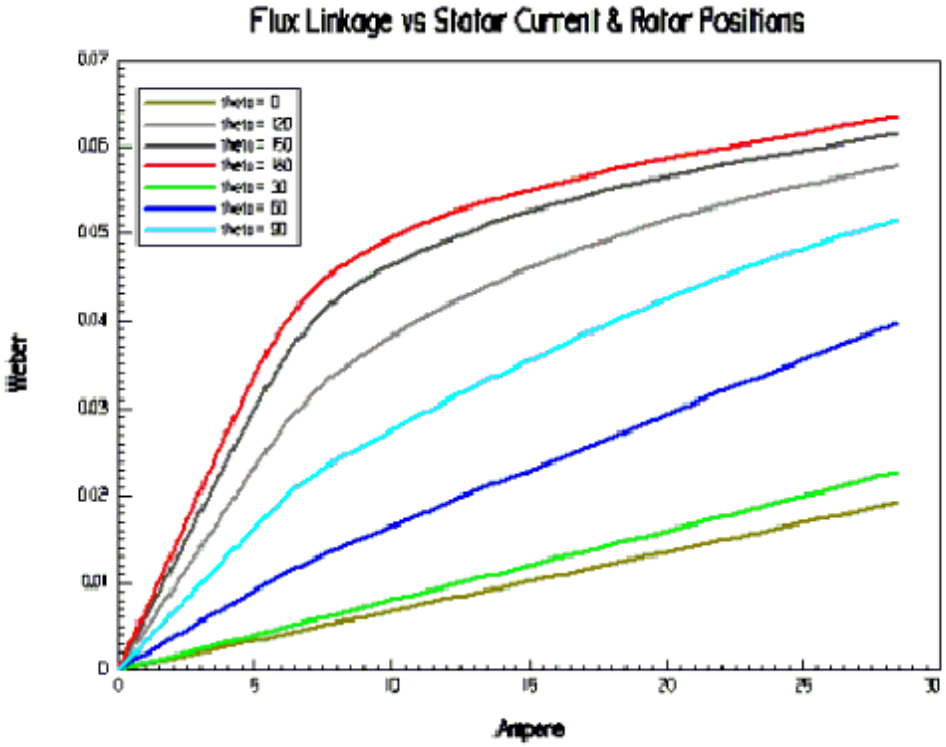

Figure 8

Let

$$L_{\theta} = \frac{\partial\Psi(\theta, i)}{\partial i}$$

and

$$G = \frac{\partial(\Psi / i)}{\partial\theta} = \frac{\partial L}{\partial\theta}$$

Then

$$u = u_T + R_S \cdot i + L\,p\,i + G\omega_e i$$

where ω_e is the rotor speed in electrical rad/s, and *p* is the differential operator as given by:

$$p = \frac{\mathbf{d}}{\mathbf{d}t}$$

The instant electromagnetic torque t_2 is:

$$t_2 = \frac{1}{2} G i^2$$

The input electric power is computed from voltage and current as:

$$P_1 = \frac{1}{T}\int_0^T (u \cdot i \cdot dt)$$

The output mechanical power is:

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_t + P_{Fe})$$

where P_{fw}, P_{Cua}, P_t, and P_{Fe} are frictional and wind loss, armature copper loss, transistor/diode loss, and iron-core loss, respectively.

The average output mechanical shaft torque T_2 is:

$$T_2 = \frac{P_2}{\omega}$$

where ω is the rotor angular speed in mechanical rad/s.

The efficiency of the electric machine is computed by:

$$\eta = \frac{P_2}{P_1} \times 100\ \%$$

Defining a Switched Reluctance Motor

The general procedure for defining a switched reluctance motor is as follows:

1. Insert a Switched Reluctance motor into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Circuit** entry in the project tree to define the control circuit.
4. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
7. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
8. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
9. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
10. Choose **File>Save** to save the project.
11. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D project.

Please refer to the *Switched Reluctance Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example.

Defining the General Data for a Switched Reluctance Motor

Use the **General** window to define the power settings, speed, and period of the motor.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
3. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
4. Enter the given speed in the **Reference Speed** field.
5. Select **DC** or **CCC** from the **Control Type** pull-down list.
6. Select a **Circuit Type** from the following types:

• **Full-Voltage**
• **Half-Voltage**
• **Coupled-Coil**

   The circuit types are based on industry standards. By default, type **Full-Voltage**, is selected as the circuit type.

Note	When you place the mouse cursor over a circuit type, an outline schematic of the circuit appears.

7. Click **OK** to close the **Properties** window.

General Data for Switched Reluctance Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Switched Reluctance Motor).
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

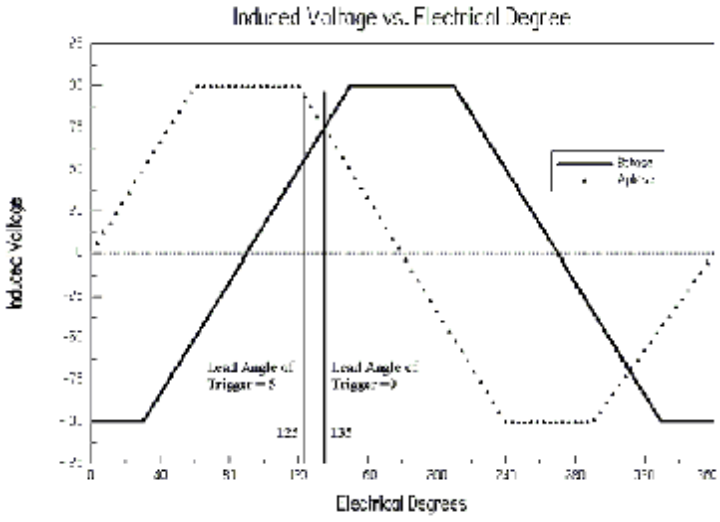
Control Type	The way the circuit is controlled. Select from **DC** or **CCC** (chopped current control, which forces the current to fall between the minimum and maximum values specified).
Circuit Type	The drive circuit type. Click the button to open the **Circuit Type** window and select from the following three types: • **Full-Voltage** • **Half-Voltage** • **Coupled-Coil**

Defining the Circuit Data for a Switched Reluctance Motor

Use the **Circuit Data Properties** window to specify the rated output power, voltage values, circuit type, and speed of the brushless DC motor.

To define the general data:

1. To open the **Circuit Data Properties** window, double-click the **Machine-Circuit** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the trigger's lead angle in electrical degrees in the **Lead Angle of Trigger** field. The trigger angle is the point at which the magnetic poles interact to begin the motion of the motor. An angle of 0 means that each phase is triggered when its axis is aligned with the rotor slot center. The trigger's lead angle is shown in the following plot of the open circuit induced voltage versus position. An angle of 0 means that the induced voltage in the triggered phase is at a maximum:



Note	A positive value represents a lead angle, and a negative value represents a lag angle.

3. Enter the period from on-status to off-status of a transistor, in electrical degrees, in the **Trigger Pulse Width** field. The trigger pulse width is the width of the energizing pulse applied to the winding, or the period for an ‘on’ status of the transistors. The maximum ‘on’ period is given by 180 degrees plus the value for the lead angle of trigger.
4. Enter the voltage drop across one transistor when the transistor is turned on in the **Transistor Drop** field. Refer to the figures of the different circuit types in step 2. This value is over one conduction path when the transistors are triggered.
5. Enter the voltage drop on all anti-parallel diodes in the discharge path in the **Diode Drop** field. If you selected a star-type circuit (**S3** or **S4**) as the **Circuit Type**, enter the total discharge voltage in this field.
6. If you selected CCC (chopped current control) as the **Control Type**, then enter the maximum and minimum current values in the **Maximum Current** and **Minimum Current** fields.
7. Click **OK** to close the **Properties** window.

Circuit Data for Switched Reluctance Motors

To access the **Circuit Data Properties** window, double-click the **Machine>Circuit** entry in the project tree. When **AC** is selected at the **Control Type**, now circuit data properties exist.

Lead Angle of Trigger	The trigger’s lead angle, in electrical degrees.
Trigger Pulse Width	The period from on-status to off-status for a transistor, in electrical degrees.
Transistor Drop	The voltage drop across one transistor when the transistor is turned on.
Diode Drop	The voltage drop across one diode in the discharge loop.
Maximum Current	The maximum current for the chopped current control. This field is not available for a DC circuit.
Minimum Current	The minimum current for the chopped current control. This field is not available for a DC circuit.

Defining the Stator Data for a Switched Reluctance Motor

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the total length of the stator core in the **Length** field.

5. Enter the effective magnetic length of the core in the **Stacking Factor** field. This value typically ranges from between 0.93 and 1.0, and is defined as the total length minus the total lamination insulation, divided by the total length.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the number of poles the stator core contains in the **Number of Poles** field.
8. Enter the pole embrace in the **Embrace** field. The pole embrace is the ratio of the actual pole arc angle to the maximum possible pole angle in the field. This value ranges from between 0 and 1.
9. Enter the thickness of the stator coil yoke in the **Yoke Thickness** field.
10. Click **OK** to close the **Properties** window.

Stator Data for Switched Reluctance Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Poles	The number of poles the stator core contains.
Embrace	The stator pole embrace.
Yoke Thickness	The thickness of the yoke at the stator core.

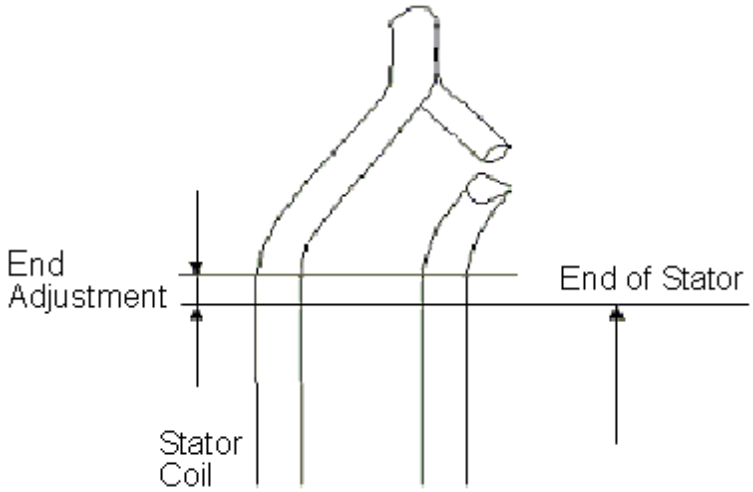
Defining the Stator Winding Data for a Switched Reluctance Motor

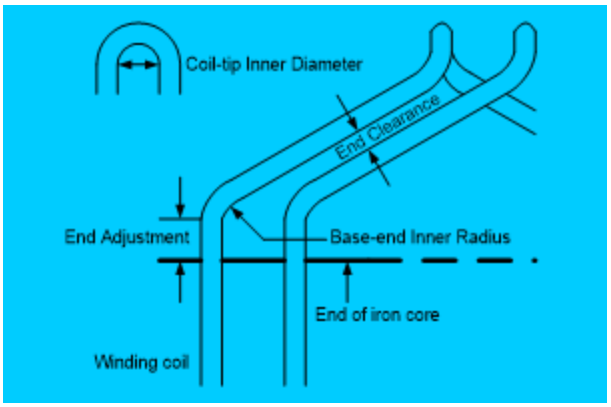
The stator coils provide the excitation for the rotating magnetic poles.

Use the **Stator Coil** window to define the parallel branches, wire specifications, and slot liner for the stator coil.

To define the stator coils:

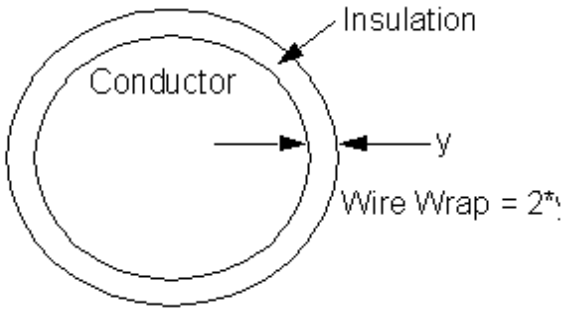
1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Enter the thickness of the insulation between the stator core and the field winding in the **Insulation Thickness** field.
3. Enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.





4. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.
5. Enter the number of turns per stator pole in the **Turns per Pole** field.
6. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
7. Enter the inner radius of the base corner in the **Base Inner Radius** field.

8. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
9. Enter the distance between two stator coils in the **End Clearance** field.
10. Enter the thickness of the slot liner insulation in the **Slot Liner** field.
11. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
12. Enter the thickness of the insulation layer in the **Layer Insulation** field.
13. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
14. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



15. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

<number>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

d. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.
e. Enter the conductor area ratio of the coupled circuit to the main circuit in the **Coupled Ratio** field.
f. Click **OK** to close the **Properties** window.

Defining Different Size Wires for a Switched Reluctance Motor

Use the **Gauge** option in the **Wire Size** window if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Stator Winding Data for Switched Reluctance Motors

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Insulation Thickness	The thickness of the insulation between the stator core and the field winding.
End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
Parallel Branches	The number of parallel branches in the stator winding.
Turns per Pole	The number of turns per stator pole (0 for auto-design).
Number of Strands	The number of wires per conductor (0 for auto-design).
Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
Coupled Ratio	The conductor area ratio of the coupled circuit to the main circuit.

Defining the Rotor Data for a Switched Reluctance Motor

The rotor core channels the flux generated by stator windings and provides shaft torque. The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. Use the **Rotor Data Properties** window to define the air gaps, rotor dimensions, and type of steel used in the rotor core. In the project tree, double-click **Machine>Rotor** to define the rotor.

To define general rotor data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the outer diameter of the rotor in the **Outer Diameter** field.
3. Enter the inner diameter of the rotor in the **Inner Diameter** field.
4. Enter the length of the rotor core in the **Length** field.
5. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.

b. Select a steel type from the list, or define a new steel type.
c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.

6. Enter the effective magnetic length of the core in the **Stacking Factor** field. This value ranges from 0 to 1, and is defined as the total length minus the total lamination insulation, divided by the total length.
7. Enter the number of poles the rotor core contains in the **Number of Poles** field.
8. Enter the ratio of the actual pole angle in relation to the maximum possible pole angle in the **Embrace** field. The value ranges from 0 to 1.
9. Enter the thickness of the rotor yoke in the **Yoke Thickness** field.
10. Click **OK** to close the **Properties** window.

Rotor Data for Switched Reluctance Motors

To access the general rotor data, double-click the **Machine-Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Stacking Factor	The stacking factor of the rotor core.
Number of Poles	The number of poles the rotor core contains.
Embrace	The rotor pole embrace.
Yoke Thickness	The thickness of the rotor core yoke.

Defining the Shaft Data for a Switched Reluctance Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Switched Reluctance Motors

To access the shaft data, double-click the **Machine-Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Switched Reluctance Motor

To define the solution data:

1. To open the Solution Setup window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click **OK** to close the **Solution Setup** window.

Solution Data for Switched Reluctance Motors

Solution Data for Switched Reluctance Motors

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	The operation type is automatically set to **Motor** for this machine type.
Load Type	Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	Type a value for the rated output voltage, and select the units.
Rated Voltage	Type a value for the rated voltage, and select the units.
Rated Speed	Type a value for the rated speed, and select the units.
Operating Temperature	Type a value for the operating temperature, and select the units.

Setting Up Analysis Parameters for a Switched Reluctance Motor

Line-Start Permanent-Magnet Synchronous Motors

Once you have selected **Line-Start Permanent-Magnet Synchronous Motors** as your motor type, you can define the following:

- General data, such as the frequency, winding connection, number of poles, and voltage.
- Stator data, such as the slot type and dimensions, stator diameter, and winding data.
- Rotor pole data, such as its associated dimensions, stacking factor, and magnet type.
- Shaft data.
- Solution data.

By option, you can:

- add a machine housing.
- from a stator,
- from a rotor.

Analysis Approach for Line-Start PM Synchronous Motors

Synchronous motors use a three-phase sinusoidal voltage source to induce a rotating magnetic field in the stator. Applying this three-phase sinusoidal voltage source to the stator winding of a synchronous motor yields the rotational magnetic field in the air gap. The permanent magnet poles mounted on the rotor try to align in this rotating field, producing a synchronous torque on the rotor. Upon starting, the damping winding on the rotor generates the asynchronous starting torque, creating a self-starting feature.

The phasor diagram for the line-start permanent-magnet synchronous motor (LSSM) in the frequency domain is shown in Figure 6.

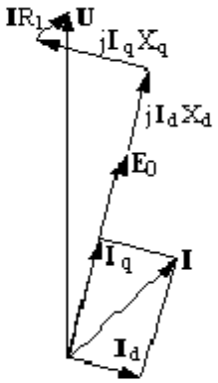

Figure 6

In Figure 6, R_1, X_d, and X_q are armature resistance, d-axis synchronous reactance, and q-axis synchronous reactance, respectively. X_d is the sum of leakage reactance, X_1 and d-axis armature reactance X_{ad}, and X_q is the sum of X_1 and q-axis armature reactance X_{aq}:

$$X_d = X_1 + X_{ad}$$

$$X_q = X_1 + X_{aq}$$

For a given torque angle θ, the angle that $\mathbf{E}_0$ lags $\mathbf{U}$, we have the following:

$$I_d X_d + I_q R_1 = U\cos\theta - E_0$$

$$-I_d R_1 + I_q X_q = U\sin\theta$$

Solving for I_d and I_q yields:

$$I_d = \frac{X_q(U\cos\theta - E_0) - R_1 U\sin\theta}{R^2_1 + X_d X_q}$$

$$I_q = \frac{R_1(U\cos\theta - E_0) - X_d U\sin\theta}{R^2_1 + X_d X_q}$$

The angle that **I** legs $\mathbf{E}_0$ is:

$$\Psi = \tanh\frac{I_d}{I_q}$$

The power factor angle (or torque angle) that **I** legs **U**, is:

$$\varphi = \Psi + \theta$$

The input power (electric power) can now be computed from voltage and current as:

$$P_1 = 3UI\cos\varphi$$

The output power (mechanical power) is:

$$P_2 = P_1 - (P_{fw} + P_{Cu} + P_{Fe})$$

where P_{fw}, P_{Cu}, and P_{Fe} are frictional and wind loss, armature copper loss, and iron-core loss, respectively.

The output mechanical power (torque) T_2 is:

$$T_2 = \frac{P_2}{\omega}$$

where ω is the synchronous speed in rad/s.

The efficiency is computed by:

$$\eta = \frac{P_2}{P_1} \times 100\,\%$$

The motor is started the same way as for an induction motor, by using a squirrel-cage-type winding -- called a damper winding in this case -- that is mounted on the rotor, producing the starting torque.

Defining a Line-Start Permanent Magnet Synchronous Motor

The general procedure for defining a line-start synchronous motor is as follows:

1. Insert a line-start synchronous motor into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
7. Double-click the **Machine-Rotor-Pole** entry in the project tree to define the pole, embrace, offset, and air gap data for the rotor pole.
8. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
9. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
10. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.

11. Choose **File>Save** to save the project.
12. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Defining the General Data for a Line-Start PM Synchronous Motor

Use the **General** window to define the basic parameters of the motor, such as the motor's rated output power, rated voltage, losses, and connection type.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
4. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

General Data for Line-Start PM Synchronous Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Line-Start PM Synchronous Motor).
Number of Poles	The number of poles the machine contains.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a Line-Start PM Synchronous Motor

The stator is the outer lamination stack where the polyphase voltage windings reside.

Use the **Stator Data**, **Stator Slot Data**, and **Stator Winding Data** windows to define the stator data, such as physical dimensions of the lamination, windings, and conductors.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the effective magnetic length of the core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the skew width, measured in slot number, in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Stator Data for Line-Start PM Synchronous Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.

Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Skew Width	The skew width measured in slot number.

Defining the Stator Slots for a Line-Start PM Synchronous Motor

To define the slot type:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.
4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

5. Click **OK** to close the **Properties** window.

Stator Slot Data for Line-Start PM Synchronous Motors

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0**

	and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Stator Windings and Conductors for a Line-Start PM Synchronous Motor

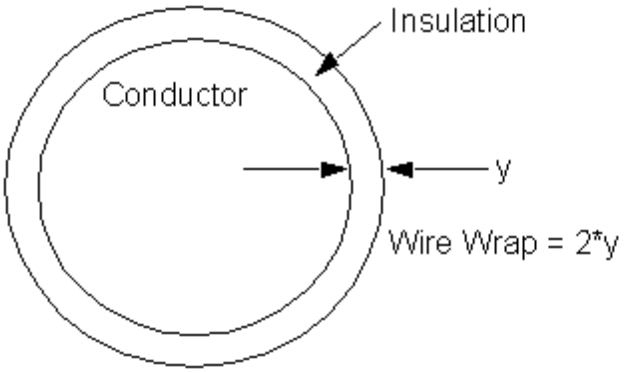
To define the stator windings and conductors:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. You can also enter values in the **Properties** section of the desktop without opening a separate window.
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select the **Winding Type** for the stator:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

Note	When you place the mouse cursor over the winding type, a schematic of that type appears.

   c. Click **OK** to close the **Winding Type** window and return to the **Properties** window.
5. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.

6. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

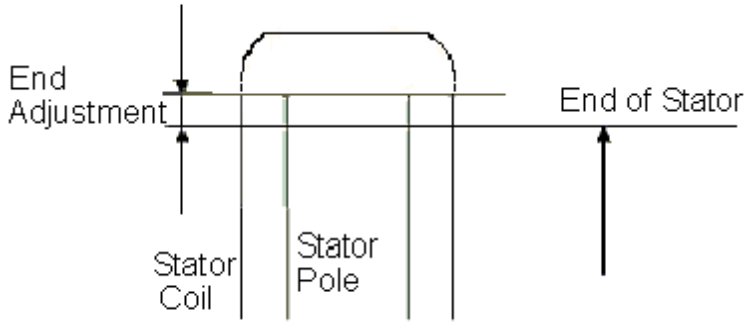
d. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

e. Click the **End/Insulation** tab.

f. Select or clear the **Input Half-turn Length** check box.

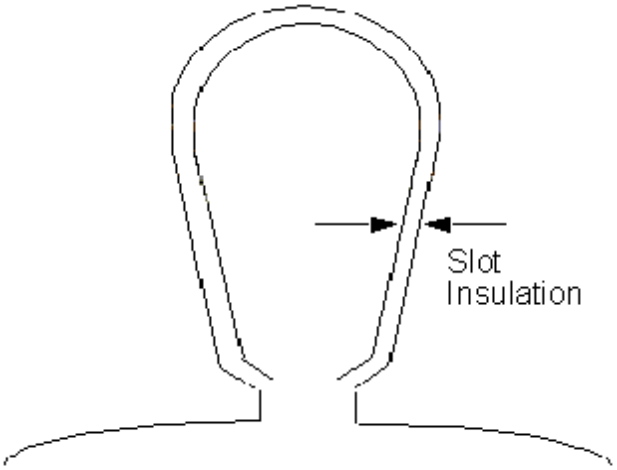
g. Do one of the following:

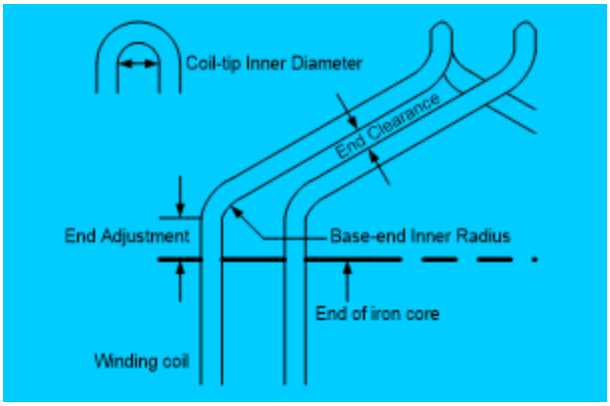
- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of the stator.



11. Enter the inner radius of the base corner in the **Base Inner Radius** field.
12. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
13. Enter the distance between two stator coils in the **End Clearance** field.

14. Enter the thickness of the slot liner insulation in the **Slot Liner** field.





15. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
16. Enter the thickness of the insulation layer in the **Layer Insulation** field.
17. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
18. Click **OK** to close the **Properties** window.

Winding Editor for a Line-Start Synchronous Motor

For a line-start synchronous motor, you may want to specify a different number of conductors for each stator slot. The Winding Editor makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.
4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Line-Start Synchronous Motor

Use the **Gauge** option in the **Wire Size** window if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor’s wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor’s wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

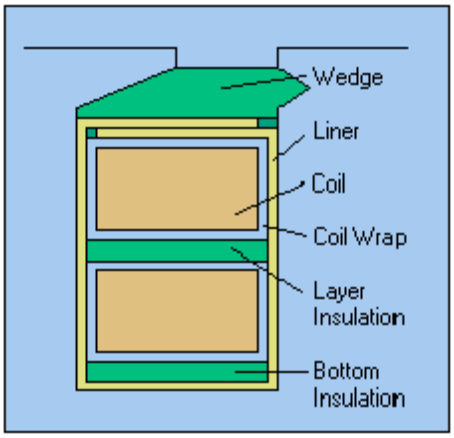
Stator Winding Data for Line-Start PM Synchronous Motors

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the stator winding.
	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.

	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.



Optional Vent for Line-Start PM Synchronous Motor Stator

To add a Vent to the stator, select the stator icon and right-click to display the pop-up menu with **Insert Vent**.

The vent is shown in the project tree under the stator.

To remove an existing Vent, select the stator and right-click to display the up-up menu with **Remove Vent**.

The Vent Data properties window contains the following fields.

Vent Ducts	Number of radial vent ducts
Duct Width	Width of radial vent ducts
Magnetic spacer width	Width of magnetic spacer which hold vent ducts. 0 for non-magnetic spacer.
Duct pitch	Vent ducts.

Defining the Rotor Data for a Line-Start PM Synchronous Motor

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine-Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general rotor data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the outer diameter of the rotor in the **Outer Diameter** field.
3. Enter the inner diameter of the rotor in the **Inner Diameter** field.
4. Enter the length of the rotor core in the **Length** field.
5. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
6. Enter the effective magnetic length of the rotor core in the **Stacking Factor** field. This value ranges from 0 to 1 and is defined as the total length minus the total lamination insulation, divided by the total length. A value of 1 indicates that the rotor is not laminated.
7. Select a **Pole Type**:
   a. Click the button.
      The **Select Pole Type** window appears.
   b. Click a button to select the desired pole type (1, 2, 3, 4, 5, 6, 7, or 8). TIP: When you run the mouse over each option, the diagram changes to show that pole type.

Note	When you place the mouse cursor over a pole type, an outline of the selected circuit type appears.

   c. Click **OK** to close the **Select Pole Type** window and return to the **Properties** window.
8. Click **OK** to close the **Properties** window.

Rotor Data for Line-Start PM Synchronous Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.

Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Stacking Factor	The stacking factor of the rotor core.
Pole Type	The pole type for the rotor. Click this button to open the **Select Pole Type** window and select from the following types: **1**, **2**, **3**, **4**, **5**, **6**, **7**, **8**. When you mouse over each button, a diagram appears for that pole type, showing the arrangement and dimensions.

Defining the Rotor Pole for a Line-Start PM Synchronous Motor

The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **Rotor Pole Data Properties** window to define the rotor pole.

Note	Some of the fields in the **Rotor Pole** window change, or are inactive, depending on the **Rotor Type** you select.

To define the rotor pole:

1. To open the **Rotor Pole Data Properties** window, double-click the **Machine-Rotor-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the limited diameter for the magnet ducts in the **D1** field.
3. Enter one or more of the following magnet duct dimensions, depending on the pole type selected: **O1**, **O2**, **B1**.
4. For all pole types except number **8**, enter the width of the rib supporting the bridge in the **Rib** field.
5. Select the type of magnet to use in the rotor pole:
   a. Click **Magnet Type** button.
      The **Select Definition** window appears.
   b. Select a material.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
6. Enter the total width of all magnets per pole in the **Magnet Width** field.
7. Enter the maximum radial thickness of the magnet in the **Magnet Thickness** field.
8. Click **OK** to close the **Properties** window.

Rotor Pole Data for Line-Start PM Synchronous Motors

To access the pole rotor data, double-click the **Machine-Rotor-Pole** entry in the project tree.

The **Rotor Pole Data Properties** window contains the following fields:

D1	The limited diameter for the magnet ducts. See the diagrams in the **Select Pole Type** window for the location of each dimension and which pole types require which dimensions.

O1	A magnet duct dimension. See the diagrams in the **Select Pole Type** window for the location of each dimension and which pole types require which dimensions.
O2	A magnet duct dimension. See the diagrams in the **Select Pole Type** window for the location of each dimension and which pole types require which dimensions.
B1	A magnet duct dimension. See the diagrams in the **Select Pole Type** window for the location of each dimension and which pole types require which dimensions.
Rib	The width of the rib at the center of two adjacent poles that support the bridge. For pole types except number **8**.
Magnet Type	The type of magnet. Click the button to open the **Select Definition** window. For all pole types.
Magnet Width	The maximum width of the magnet. For all pole types.
Magnet Thickness	The maximum thickness of the magnet. For all pole types.

Optional Rotor Damper for Line-Start PM Synchronous Motor

- To add a damper, right-click on the rotor item in the project tree to display the pop-up menu with **Insert Damper**.
- To remove an existing damper, right-click on the rotor icon in the project tree to display the shortcut menu with **Remove Damper**.

The **Damper Data** properties window contains the following fields.

Damper Slots per Pole	Number of damper slots per pole.
Slot Type	Damper slot type. Click the field button open the Slot selection window and select one of the four types.
Cast Rotor.	Specify whether the rotor squirrel cage winding is cast.
Bar conductor type	Click the field button to open the Materials Selection window to specify the material for the bar conductor.
End Length	Single side end extended bar length
End Ring Width	Axial width of end ring.
End Ring Height	Radial height of end ring
End Ring Conductor type	Click the field button to open the Materials Selection window to specify the material for the end ring conductor.

Defining the Shaft Data for a Line-Start PM Synchronous Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine-Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Line-Start PM Synchronous Motors

To access the shaft data, double-click the **Machine-Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Line-Start PM Synchronous Motor

To define the solution data:

1. To open the Solution Setup window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **Line-Start PM Synchronous Motor** tab.

9. Select **Wye** or **Delta** from the **Winding Connection** pull-down list.
10. Click **OK** to close the **Solution Setup** window.

Solution Data for Line-Start PM Synchronous Motors

Solution Data for Line-Start PM Synchronous Motors

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	***General** tab*. The operation type is automatically set to **Motor** for this machine type.
Load Type	***General** tab*. Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	***General** tab*. Type a value for the rated output voltage, and select the units.
Rated Voltage	***General** tab*. Type a value for the rated voltage, and select the units.
Rated Speed	***General** tab*. Type a value for the rated speed, and select the units.
Operating Temperature	***General** tab*. Type a value for the operating temperature, and select the units.
Winding Connection	***Line-Start PM Synchronous Motor** tab.* Select **Wye** or **Delta** from the **Winding Connection** pull-down list.

Setting Up Analysis Parameters for a Line-Start PM Synchronous Motor

Universal Motors

After you have selected **Universal Motors** as your model type, enter the motor data to define the following:

- General data, such as the number of poles, frictional loss, and reference speed.
- Stator pole and winding data, such as its associated pole dimensions, type of steel, and wire definitions.
- Rotor data, such as the slot types and dimensions, rotor diameter, laminations, and windings and conductors.
- Commutator and brush data, such as the commutator dimensions and brush length.
- Shaft data.

- Optional machine housing.
- Solution data.

Analysis Approach for Universal Motors

For a DC motor, if its field winding is connected in series with its armature winding, it becomes a series motor. When the polarity of the terminal voltage changes, the direction of the produced electromagnetic torque does not change because the armature and the exciting currents alternate their directions at the same time. That means the motor can operate not only with a DC source but also with an AC source. Because it can operate with both DC and AC sources, a series motor is also called universal motor (UniM).

For a universal motor, the stator is equipped with *p* pairs of coil-wound poles, creating *P* pairs of alternating north and south poles. The coil excitation may be either AC or DC. The rotor is equipped with a distributed winding connected to a commutator that revolves together with the rotor.

A system of brushes is kept in permanent electrical contact with the commutator. When AC or DC current is applied to the rotor winding (via the brushes and commutator) a torque is produced by the interaction of the rotor (armature) currents and the field produced by the stator poles.

The commutator causes the armature to create a magnetic flux distribution whose axis is perpendicular to the axis of the field flux produced by the permanent magnets. For these motors, the commutator acts as a mechanical rectifier.

The performance of a universal motor is analyzed in the frequency domain. The voltage equation of a universal motor is:

$$U = ZI = (R_a + R_f + R_b)I + j\omega(L_a + L_f + 2M_{af})I + \omega_e(G_{aa} + G_{af})I$$

where, R_a, R_f, and R_b are the armature resistance, field winding resistance, and the brush contact resistance, respectively. L_a, L_f, and M_{af} are the armature self inductance, field winding self inductance, and their mutual inductance, respectively, and are linearized nonlinear parameters. Gaa and Gaf are the coefficients of motion induced voltages by the armature and field winding currents, respectively, and are also linearized nonlinear parameters. ω is the radian frequency, and ω_e the rotor speed in electric rad/s. Z is equivalent input impedance. When the brush axis is aligned with q-axis:

$$M_{af} = G_{aa} = 0$$

For a given rotor speed ω_e, armature current can be computed based on the applied voltage *U*, as:

$$I = \frac{U}{Z}$$

The input power (electric power) is directly computed from voltage and current as:

$$P_1 = UI\cos\varphi$$

The output power (mechanical power) is:

$$P_2 = P_1 - (P_{fw} + P_b + P_{cuf} + P_{Fe})$$

where P_{fw}, P_b, P_{cua}, P_{cuf}, and P_{Fe} are frictional and wind loss, brush drop loss, armature copper loss, field winding copper loss, and iron-core loss, respectively.

The output mechanical shaft torque T_2 is:

$$T_2 = \frac{P_2}{\omega}$$

The efficiency is computed by:

$$eff = \frac{P_2}{P_1} \times 100\ \%$$

Defining a Universal Motor

The general procedure for defining a universal motor is as follows:

1. Insert a universal motor into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Pole** entry in the project tree to define the stator pole dimensions.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.
7. Double-click the **Machine-Rotor-Slot** entry in the project tree to define the rotor slot dimensions.
8. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor windings and conductors.
9. Double-click the **Machine-Commutator** entry in the project tree to define the commutator and brush data.
10. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
11. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
12. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
13. Choose **File>Save** to save the project.
14. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Refer to the *Universal Motor Problem* application note, on the technical support page of the Ansys web site, for a specific example.

Defining the General Data for a Universal Motor

Use the **General** window to define the basic parameters of the universal motor such as the power settings, speed, and rated voltage.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
4. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

General Data for Universal Motors

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Switched Reluctance Motor).
Number of Poles	Number of poles for this machine.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a Universal Motor

Use the **Stator Properties** windows to define the stator dimensions, slots, windings, and conductors.

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the overall width of the stator outer profile in the **Overall Width** field.
4. Enter the **Inner Diameter** of the stator.
5. Enter the length of the stator core in the **Length** field.
6. Enter the stacking factor for the stator core in the **Stacking Factor** field.
7. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
8. Click **OK** to close the **Properties** window.

Stator Data for Universal Motors

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Overall Width	The overall width of the stator outer profile.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The effective magnetic length of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.

Defining the Stator Pole for a Universal Motor

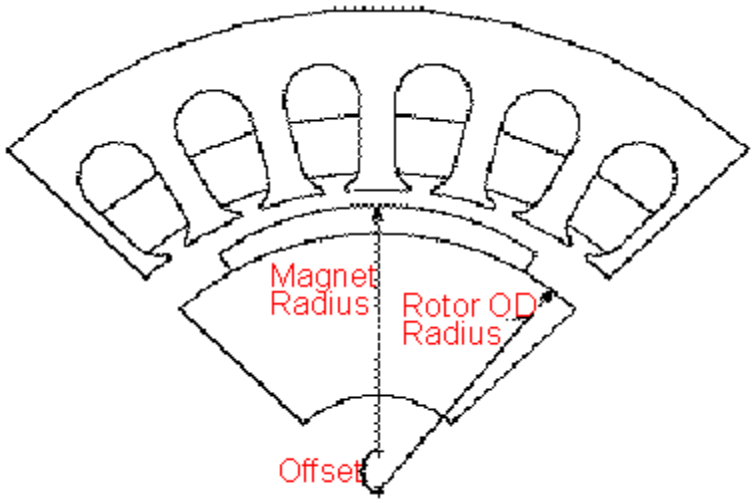
The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **s Stator Pole Data Properties** window to define the stator pole.

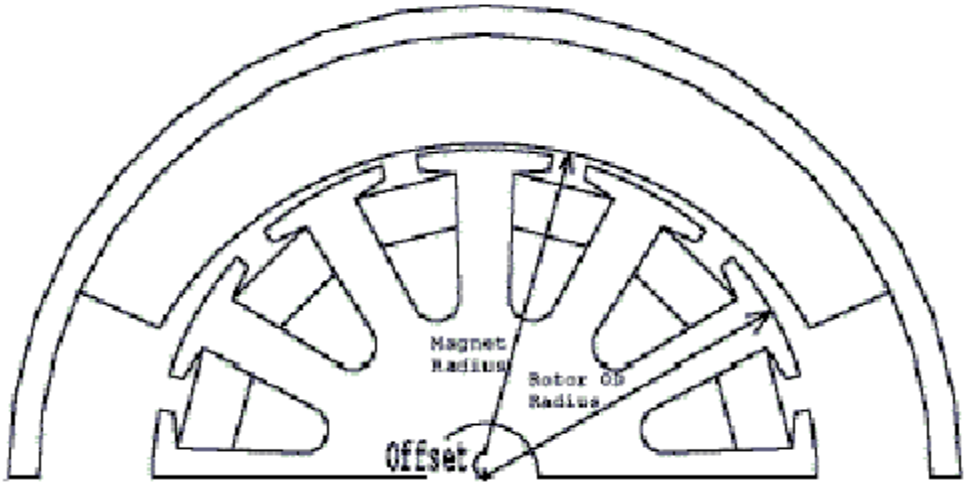
To define the rotor pole:

1. To open the **Stator Pole Data Properties** window, double-click the **Machine-Stator-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)

Note	For a two-pole machine, a pole embrace of 0.75 yields a magnet with a span of 135 degrees (based on 0.75*180 degrees).

2. Enter the ratio of the actual arc distance in relation to the maximum possible arc distance in the **Embrace** field. This value is between 0 and 1.
3. Enter the distance from the center of the stator to the magnet arc center in the **Offset** field. Enter 0 for a uniform air gap.





4. Enter the minimum pole width in the **PoleWidth** field.
5. Enter the yoke thickness in the **Ty** field.

6. Enter the shoe-tip thickness in the **Ts** field.
7. Enter the pole's hole radius in the **R1** field. If there is no hole in the design, enter **0**.
8. Enter the pole's side fillet radius in the **R2** field.
9. Enter the radius of the pole's center side fillet arcs in the **R3** field.
10. Enter the radius of the shoe connecting arc in the **R4** field. To auto-design this dimension, enter **0**. For a linear connection, enter **0**.
11. Enter the inner radius of the screw hole between the two poles in the **R5** field. If there is no hole in the design, enter **0**.
12. Enter the outer radius of the screw hole between the two poles in the **R6** field. If there is no hole in the design, enter **0**.
13. Click **OK** to close the **Properties** window.

Stator Pole Data for Universal Motors

To access the stator pole data, double-click the **Machine-Stator-Pole** entry in the project tree.

The **Stator Pole Data Properties** window contains the following fields:

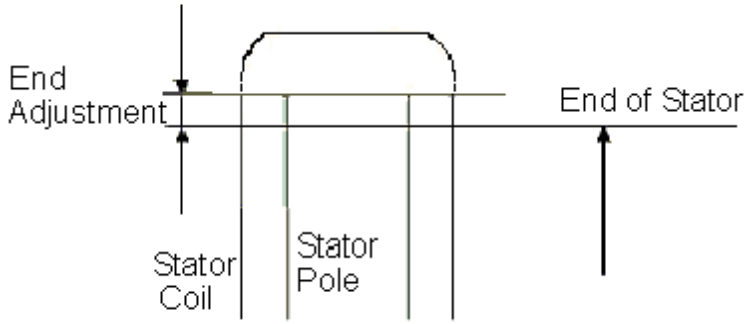
Embrace	The pole embrace.
Offset	The pole-arc center offset from the stator center (0 for a uniform air gap).
PoleWidth	The minimum pole width.
Ty	The yoke thickness.
Ts	The shoe-tip thickness.
R1	The hole radius in the pole (0 for no hole).
R2	The radius of the pole side fillet.
R3	The radius of the center of the pole side fillet arcs.
R4	The radius of the shoe connecting arc (0 for auto-design or for a linear connection).
R5	The inner radius of the screw hole between two poles (0 for no hole).
R6	The outer radius of the screw hole between two poles (0 for no hole).

Defining the Stator Windings and Conductors for a Universal Motor

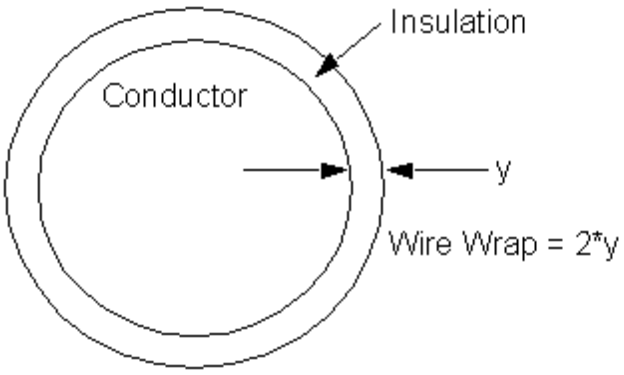
To define the stator windings and conductors:

1. To open the **Stator Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the thickness of the insulation between the stator core and the field winding in the **Insulation Thickness** field.
3. Enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the conductor extends vertically beyond the end of

the stator.



4. Enter the number of parallel branches in the stator winding in the **Parallel Branches** field.
5. Enter the number of turns per stator pole in the **Turns per Pole** field. To auto-design the number of turns, enter **0**.
6. Enter the number of wires per conductor in the **Number of Strands** field. Enter **0** to have RMxprt auto-design this value.
7. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



8. Select the **Wire Size**:
   a. Click the button for **Wire Size**.
      The **Wire Size** window appears.
   b. Select a value from the **Wire Diameter** pull-down list.
   c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.

USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

a. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

b. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.

c. Enter the thickness of the insulation layer in the **Layer Insulation** field.

d. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.

e. Click **OK** to close the **Properties** window.

Defining Different Size Wires for a Universal Motor Stator Winding

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.

6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Stator Winding Data for Universal Motors

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Insulation Thickness	The thickness of the insulation between the stator core and the field winding.
End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
Parallel Branches	The number of parallel branches in the stator winding.
Turns per Pole	The number of turns per stator pole (0 for auto-design).
Number of Strands	The number of wires per conductor (0 for auto-design).
Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.

Defining the Rotor Data for a Universal Motor

The rotor is equipped with slots containing copper conductors that are connected to the commutator. The commutator acts as a mechanical rectifier in the motor.

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine>Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general stator data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)

2. Enter the stacking factor for the rotor core in the **Stacking Factor** field. This value relates to the effective magnetic length of the core, and ranges from 0 to 1. It is defined as the total length minus the total insulation from the laminations, divided by the total length. A value of 1 indicates that the rotor is not laminated.
3. Enter the number of slots in the rotor core in the **Number of Slots** field.
4. Select a **Slot Type**:
   a. Click the button.
      The **Select Slot Type** window appears.
   b. Click a button to select the desired pole type (1, 2, 3, 4, 5, or 6). Though slots **3** and **4** are visually similar, they differ in how the edges are constructed. Slot **3** has a tapered edge leading from the slot opening to the main slot body. Slot **4** has a rounded edge at the same location, where the quantity **Hr1** defines the radius of the corner slot. TIP: When you run the mouse over each option, the diagram changes to show that pole type.
   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.

   Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.
5. Enter the outer diameter of the rotor core in the **Outer Diameter** field.
6. Enter the inner diameter of the rotor core in the **Inner Diameter** field.
7. Enter the length of the rotor core in the **Length** field.
8. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
9. Enter the number of slots in the skew width in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Rotor Data for Universal Motors

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Stacking Factor	The effective magnetic length of the rotor core.
Number of Slots	The number of slots in the rotor core.
Slot Type	The rotor core slot type. Click the button to open the **Select Slot Type** window and select from the following types: **1**, **2**, **3**, **4**, **5**, **6**.
Outer Diameter	The outer diameter of the rotor core.

Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Skew Width	The skew width measured in slot number.

Defining the Rotor Slots for Universal Motors

To define the physical dimensions of the rotor slots:

1. To open the **Rotor Slot Data Properties** window, double-click the **Machine-Rotor-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box. Using this option causes the software to converge to a flux density value of 1.5 Tesla in the rotor teeth.
3. Enter the available slot dimensions. The following dimensions may be listed, depending on the **Slot Type** selected and depending on whether or not **Auto Design** is selected.:

Hs0	Always available.
Hs1	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Always available. Rs is added when the slot type is 3 or 4.

4. Click **OK** to close the **Properties** window.

Rotor Slot Data for Universal Motors

To access the rotor slot data, double-click the **Machine-Rotor-Slot** entry in the project tree.

The **Rotor Slot Data Properties** window contains the following fields:

Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.

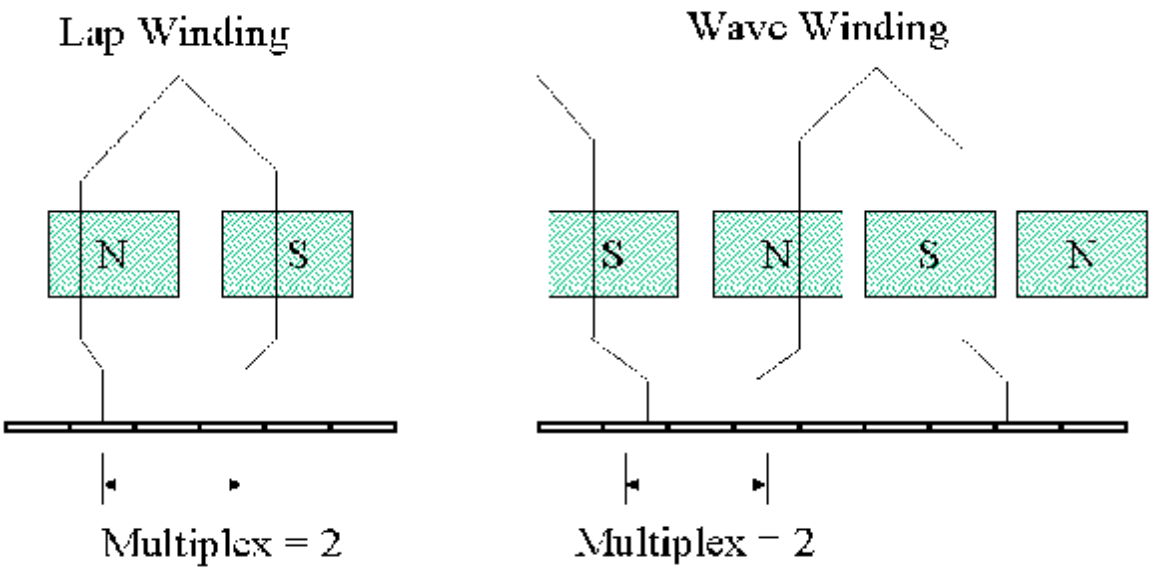
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Rotor Windings and Conductors for a Universal Motor

To define the rotor windings, wires, and conductors:

1. To open the **Rotor Slot Winding Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Lap**
      - **Wave**
      - **Frog Leg**
4. Enter the number of windings in the **Multiplex Number** field (1 for a single winding, 2 for double windings, 3 for triple windings). For a lap winding, the multiplex number is the number of commutators between the start and end of one winding, and the number of parallel branches is equal to the number of poles multiplied by the multiplex number. For a wave winding, the number of parallel branches equals the multiplex number multiplied by

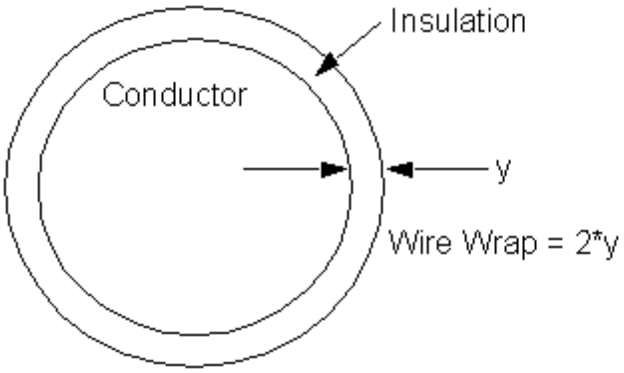
two.



5. Enter the number of virtual slots per each real slot in the **Virtual Slots** field. The rotor is assumed to have two layers of conductors, an upper and a lower layer. Each layer of conductors can have a number of windings, which are referred to as virtual slots.

Note	For example, the upper and lower layer can have two windings each, which would yield a virtual slot number of two; for a 12 slot machine, this would yield 24 commutation segments.

6. Enter the total number of conductors in each rotor slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers. This value is the total number of conductors in one real full rotor slot.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



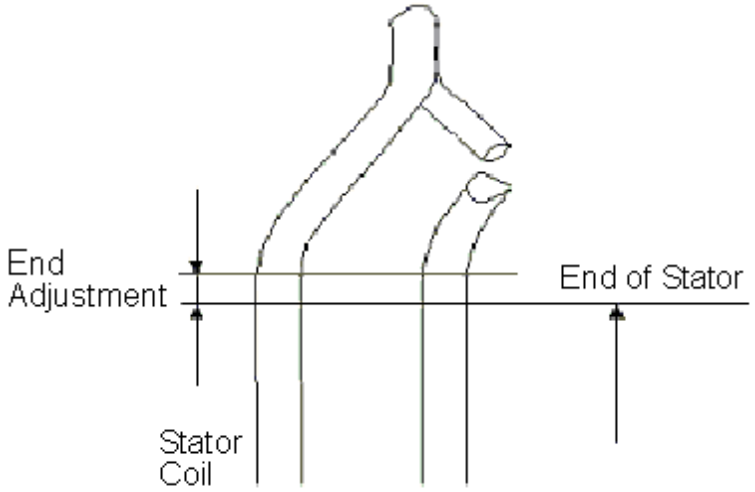
10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

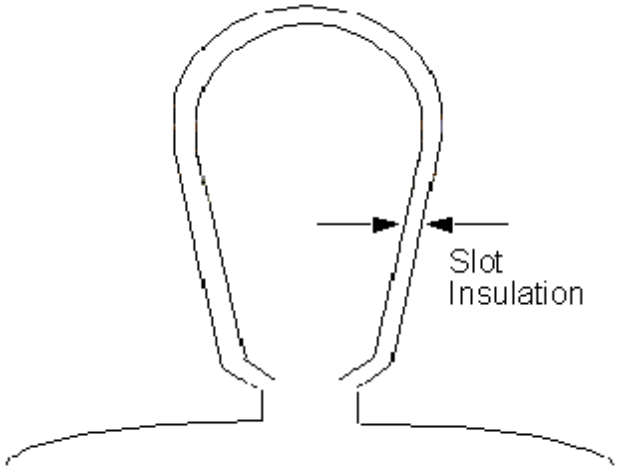
The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window. Click the **End/Insulation** tab. Select or clear the **Input Half-turn Length** check box. Do one of the following:

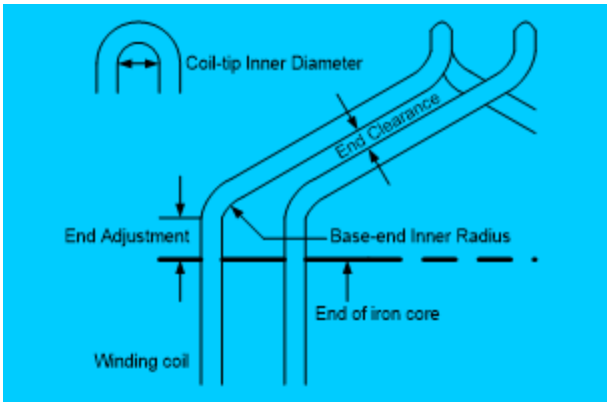
- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the

conductor extends vertically beyond the end of the stator.



11. Enter the inner radius of the base corner in the **Base Inner Radius** field.
12. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
13. Enter the distance between two rotor coils in the **End Clearance** field.
14. Enter the thickness of the slot liner insulation in the **Slot Liner** field.





15. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
16. Enter the thickness of the insulation layer in the **Layer Insulation** field.
17. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
18. Select the type of equalizer connection from the **Equalizer Connection** pull-down menu. Select from **None**, **Half**, or **Full**.
19. Click **OK** to close the **Properties** window.

Defining Different Size Wires for a Universal Motor Rotor Winding

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.

6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

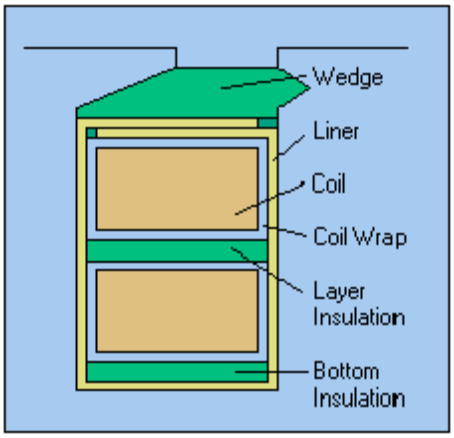
Rotor Winding Data for Universal Motors

To access the stator winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Winding tab	**Winding Type**	The type of rotor winding. Click the button to open the **Winding Type** window and choose from **Lap**, **Wave**, and **Frog Leg**.
	Multiplex Number	Single, double, or triple windings (**1**, **2**, or **3**).
	Virtual Slots	The number of virtual slots per real slot.
	Conductors per Slot	The number of conductors per rotor slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you

		open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the rotor coils.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
	Equalizer Connection	The connection type of the equalizer. Select from **None**, **Half**, or **Full**.



Defining the Commutator and Brush for a Universal Motor

The commutator allows current transfer between DC terminals or brushes and the rotor coils, providing the current to the system as a function of rotation. Due to the action of the commutator,

the corresponding magnetic field has a fixed distribution with respect to the stator.

To define the commutator and brush pairs:

1. To open the **Commutator Data Properties** window, double-click the **Machine>Commutator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Commutator** tab.
3. Select **Cylinder** or **Pancake Type** as the **Commutator Type**.

Note	When you place the mouse cursor over the commutator type, an outline of the commutator appears.

4. For **Cylinder** commutators, do the following:
   a. Enter the **Commutator Diameter**.
   b. Enter the **Commutator Length**.
5. For **Pancake** commutators, do the following:
   a. Enter the **Outer Diameter**.
   b. Enter the **Inner Diameter**.
6. Enter the thickness of the insulation between two consecutive commutator segments in the **Commutator Insulation** field.
7. Click the **Brush** tab.
8. Enter the **Brush Width**.
9. Enter the **Brush Length**.
10. Enter the number of brush pairs when using a wave armature winding in the **Brush Pairs** field.
11. Enter the angle of displacement from the neutral axis, in mechanical degrees, in the **Brush Displacement** field.

Note	The brush displacement is positive for the counter-clockwise direction. For example, if the rotor turns clockwise and the brush displacement is also clockwise, then the angle is negative; if the rotor turns clockwise but the brush displacement is counter-clockwise, then the angle is positive.

12. Enter the voltage drop across one brush pair in the Brush Drop field.
13. Enter the mechanical pressure of the brushes as they press against the commutator in the **Brush Press** field.
14. Enter the **Frictional Coefficient** of the brush.

Note	If the **Friction Loss** field is used in the **General** window, the **Brush Press** and **Frictional Coefficient** fields will be hidden in the **Commutator/Brush** window. These fields are shown only when the **Friction Loss** field in the **General** window is set to zero.

15. Click **OK** to close the **Properties** window.

Commutator and Brush Data for Universal Motors

To access the commutator and brush data, double-click the **Machine>Commutator** entry in the project tree.

The **Commutator Data Properties** window contains the following fields:

Commutator tab	**Commutator Type**	The type of commutator. Click the button to open the **Select Commutator Type** window and select from **Cylinder** or **Pancake**.
	Commutator Diameter	For a **Cylinder** commutator type, the diameter of the commutator.
	Commutator Length	For a **Cylinder** commutator type, the length of the commutator.
	Outer Diameter	For a **Pancake** commutator type, the outer diameter of the commutator.
	Inner Diameter	For a **Pancake** commutator type, the inner diameter of the commutator.
	Commutator Insulation	The thickness of the insulation between the two commutator bars.
Brush tab	**Brush Width**	The width of the brush.
	Brush Length	The length of the brush.
	Brush Pairs	The number of brush pairs.
	Brush Displacement	The displacement of the brush from the neutral position, in mechanical degrees (positive for anti-rotating direction).
	Brush Drop	The voltage drop across a one-pair brush.
	Brush Press	The brush press per unit area. (Available only when **Frictional Loss** is set to zero for the machine.)
	Frictional Coefficient	The frictional coefficient of the brush. (Available only when **Frictional Loss** is set to zero for the machine.)

Defining the Shaft Data for a Universal Motor

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Universal Motors

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Universal Motor

To define the solution data:

1. To open the **Solution Setup** window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power developed at the shaft of the motor in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the motor at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **Universal Motor** tab.
9. Enter the **Frequency**, and select the units.
10. Click **OK** to close the **Solution Setup** window.

Solution Data for Universal Motors

Solution Data for Universal Motors

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	***General** tab*. The operation type is automatically set to **Motor** for this machine type.
Load Type	***General** tab*. Select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**.
Rated Output Power	***General** tab*. Type a value for the rated output voltage, and select the units.
Rated Voltage	***General** tab*. Type a value for the rated voltage, and select the units.
Rated Speed	***General** tab*. Type a value for the rated speed, and select the units.
Operating Temperature	***General** tab*. Type a value for the operating temperature, and select the units.
Frequency	***Universal Motor** tab.* Enter a frequency in the **Frequency** field, and select the units.

Setting Up Analysis Parameters for a Universal Motor

General DC Machines

After you have selected **DC Machine** as your model type, enter the motor data to define the following:

- General data, such as the output power, rated voltage, speed, and machine type (motor or generator).
- Stator data, such as its associated pole dimensions, type of steel, and pole magnet specifications.
- Stator field data, such as shoe and pole insulation, dimensions, and winding information.
- Rotor data, such as the slot types and dimensions, rotor diameter, lamination, and wire specifications.
- Commutator and brush data, such as the commutator type and dimensions and brush length.
- Shaft data.
- Solution data.

By option you can insert or remove the following for a DC machine.

- Add a machine housing.
- Compensating data, added under the stator

- Commutating data, added under the stator
- Vent data, added under the rotor
- Shunt data, added under the stator field.
- Series data, added under the stator field.

Analysis Approach for General DC Machines

For a Direct-Current (DC) Electric Machine Design, either a generator or motor, the rotor is equipped with a distributed winding -- called armature winding -- that is connected to a commutator revolving together with the rotor.

The stator is equipped with *p* pairs of poles, which are excited by *p* pairs of shunt and/or series windings. A shunt winding may be separately excited or self-excited. The separately excited shunt winding is excited by a separate DC voltage source. The self-excited shunt winding is excited by the terminal voltage of the armature winding and is connected in parallel with the armature winding. A series winding is connected in series with the armature winding. If both self-excited shunt and series windings are mounted on the stator poles, RMxprt assumes that the armature winding connects the series winding in series first, then connects the shunt winding in parallel.

A system of brushes is kept in permanent electrical contact with the commutator. When DC current is applied to the rotating armature winding via the brushes and commutator, a stationary magnetic field distribution is created with the axis electrically perpendicular to the axis of the field produced by the shunt and/or series windings. As a result, a torque is produced by the interaction of the fields produced by the armature and exciting currents. For these brush commutating machines, the commutator together with the brushes acts as a mechanical rectifier.

The field produced by the armature current is called armature reaction field. The armature reaction field causes poor commutating and poor voltage distribution along commutator bars. In order to improve commutating, commutating poles and winding can be equipped between two adjacent main poles and compensating winding can be equipped under main poles.

The performance of a DC machine is computed by DC analysis.

DC Machine Operating as a Motor

The voltage equation of a DC motor is

$$U = E + (U_b + R_1 \cdot I_a)$$

where, U_b is the voltage drop of one-pair brushes, R_1 is the total series resistance of the armature branch, E is the back emf as given below:

$$E = C_{Ef} \cdot \omega \cdot I_f + C_{Es} \cdot \omega \cdot I_a$$

where C_{Ef} and C_{Es}, which depend on the saturation of the magnetic field, are the back-emf coefficients in ohm.s/rad, is the rotor speed in mechanical rad/s, and I_f and I_a are the exciting currents of the shunt and series windings, respectively.

For a given speed, armature current can be computed based on the terminal voltage U, as shown below:

$$I_a = \frac{U - U_b - C_{Ef} \cdot \omega \cdot I_f}{R_1 + C_{Es} \cdot \omega}$$

The shaft torque is computed from:

$$T_2 = (C_{Tf} \cdot I_f + C_{Ts} \cdot I_a) \cdot I_a - T_{fw}$$

where C_{Tf} and C_{Ts} are the torque coefficients in Nm/A^2 which are numerically the same as C_{Ef} and C_{Es}, respectively. T_{fw} is the frictional and wind torque. The output power (mechanical power) is

$$P_2 = T_2 \cdot \omega$$

The input power (electrical power) is

$$P_1 = P_2 + (P_{fw} + P_{Cua} + P_b + P_{Fe})$$

where P_{fw}, P_{Cua}, P_b, and P_{Fe} are the frictional and wind loss, armature branch copper loss, brush drop loss, iron-core loss and shunt winding copper loss, respectively. The efficiency is:

$$\eta = \frac{P_2}{P_1} \times 100\ \%$$

DC Machine Operating as a Generator

For a DC generator, the voltage equation is

$$U = E - (U_b + R_1 \cdot I_a)$$

$$E = C_{Ef} \cdot \omega \cdot I_f + C_{Es} \cdot \omega \cdot I_a$$

The performance is analyzed as follows

$$I_a = -\frac{U + U_b - C_{Ef} \cdot \omega \cdot I_f}{R_1 - C_{Es} \cdot \omega}$$

$$T_1 = ((C_{Tf} \cdot I_f + C_{Ts} \cdot I_a) \cdot I_a) + T_{fw}$$

$$P_1 = T_1 \cdot \omega$$

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_b + P_{Fe})$$

$$\eta = \frac{P_2}{P_1} \times 100\,\%$$

Defining a General DC Machine

The general procedure for defining a general DC machine is as follows:

1. Insert a DC machine into a new or existing project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Pole** entry in the project tree to define the stator pole dimensions.
5. Double-click the **Machine-Stator-Field** entry in the project tree to define the stator windings, conductors, and insulation data.
6. Double-click the **Machine-Rotor** entry in the project tree to define the general rotor geometry, the pole data, and the insulation data.
7. Double-click the **Machine-Rotor-Slot** entry in the project tree to define the rotor slot dimensions.
8. Double-click the **Machine-Rotor-Winding** entry in the project tree to define the rotor conductors and windings.
9. Double-click the **Machine-Commutator** entry in the project tree to define the commutator and brush data.
10. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
11. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
12. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.

13. Choose **File>Save** to save the project.
14. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and a new Maxwell 3D design.

Refer to the *DC Machine* application note, on the technical support page of the Ansys web site, for a specific example of a problem using a DC machine.

Defining the General Data for a General DC Machine

Use the **General** window to define the basic parameters of the DC motor, such as the power settings, speed, and rated voltage.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
4. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
5. Enter the given speed in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

General Data for General DC Machines

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (DC Machine).
Number of Poles	The number of poles the machine contains.
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Wind Loss	The wind loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a General DC Machine

Use the **Stator Properties** windows to define the stator dimensions, slots, windings, and conductors.

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the maximum diameter for a polygon-type frame in the **Frame Outer Diameter** field.
3. Enter the minimum outer width for a polygon-type frame in the **Frame Overall Width** field.
4. Enter the **Frame Thickness**.
5. Enter the **Frame Length**.
6. Select a steel type for the frame:
   a. Click the button for **Frame Material**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Select a **Pole Type**:
   a. Click the button.
      The **Select Pole Type** window appears.
   b. Click a button to specify the desired field type (either 1 or 2).
   c. Click **OK** to close the **Select Pole Type** window and return to the Properties window.
8. Enter the length of the stator main pole in the **Pole Length** field.
9. Enter the effective magnetic length for the stator main pole in the **Pole Stacking Factor** field.
10. Select a steel type for the stator main pole:
    a. Click the button for **Pole Material**.
       The **Select Definition** window appears.
    b. Select a steel type from the list, or define a new steel type.
    c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
11. Enter the thickness of the pole press boards in the **Press Board Thickness** field.
12. If the pole press board is made of magnetic material, then select the **Magnetic Press Board** check box.
13. Click **OK** to close the **Properties** window.

Stator Data for General DC Machines

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Frame Outer Diameter	The maximum diameter for a polygon-type frame.
Frame Overall Width	The minimum outer width for a polygon-type frame.
Frame Thickness	The thickness of the frame.
Frame Length	The length of the frame.
Frame Material	The steel type of the frame. Click the button to open the **Select Definition** window.
Pole Type	The pole type of the stator. Click the button to open the **Select Pole Type** window and select from the following two types: **1** and **2**.
Pole Length	The length of the stator main pole.
Pole Stacking Factor	The stacking factor of the stator main pole.
Pole Material	The steel type of the stator main pole. Click the button to open the **Select Definition** window.
Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Whether or not the pole press board is made of magnetic material.

Defining the Stator Pole for a General DC Machine

The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **s Stator Pole Data Properties** window to define the stator pole.

To define the rotor pole:

1. To open the **Stator Pole Data Properties** window, double-click the **Machine-Stator-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)

Note	For a two-pole machine, a pole embrace of 0.75 yields a magnet with a span of 135 degrees (based on 0.75*180 degrees).

2. Enter the inner diameter at the pole center in the Dmin field.
3. Enter the diameter at the pole tip in the Dmax field.
4. Enter the width of the pole arc with a uniform air gap in the Bp0 field. For an eccentric air gap, enter 0.
5. Enter the width of the pole tip in the Bp1 field.

6. Enter the maximum width of the pole shoe in the Bp2 field. This field is only available for a Pole Type of 1.
7. Enter the minimum width of the pole shoe in the Bp3 field. This field is only available for a Pole Type of 1.
8. Enter the size of the pole shoe fillet in the Rp0 field. THis field is only available for a Pole Type of 2.
9. Enter the fillet between the pole shoe and the pole body in the Rp1 field. THis field is only available for a Pole Type of 2.
10. Enter the pole shoe height in the Hp field.
11. Enter the pole body width in the Bm field.
12. Click **OK** to close the **Properties** window.

Stator Pole Data for General DC Machines

To access the stator pole data, double-click the **Machine-Stator-Pole** entry in the project tree.

The **Rotor Pole Data Properties** window contains the following fields:

Dmin	The inner diameter at the pole center.
Dmax	The diameter at the pole tip.
Bp0	The width of the pole arc with a uniform air gap (0 for an eccentric air gap).
Bp1	The width of the pole tip.
Bp2	The maximum width of the pole shoe. For pole type 1.
Bp3	The minimum width of the pole shoe. FOr pole type 1.
Rp0	The pole shoe fillet. For pole type 2.
Rp1	The fillet between the pole shoe and the pole body. For pole type 2.
Hp	The height of the pole shoe.
Bm	The width of the pole body.

Defining the Stator Field Data for a General DC Machine

To define the stator windings and insulation data:

1. To open the **Stator Field Properties** window, double-click the **Machine-Stator-Field** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the thickness of the insulation under the pole shoe in the **Shoe Insulation** field.
3. Enter the thickness of the insulation at the pole body side in the **Pole Insulation** field.
4. Enter the minimum gap in the **Winding Clearance** field. The winding clearance is one of the following: the minimum gap between two field windings, or the minimum gap between a field winding and a commutating winding.

5. Enter the thickness of the insulation between the shunt winding and the series winding in the **Winding Insulation** field.
6. Select the type of exciting of the series winding to the shunt winding from the **Compound Exciting Mode** pull-down list. The options are **Cumulative** and **Differential**.
7. Click **OK** to close the **Properties** window.

Stator Field Data for General DC Machines

To access the stator field data, double-click the **Machine-Stator-Field** entry in the project tree.

The **Stator Field Data Properties** window contains the following fields:

Shoe Insulation	The thickness of the insulation under the pole shoe.
Pole Insulation	The thickness of the insulation at the pole body side.
Winding Clearance	The minimum air gap between two field windings, or the minimum gap between a field winding and a commutating winding.
Winding Insulation	The thickness of the insulation between the shunt winding and the series winding.
Compound Exciting Mode	The cumulative exciting or differential exciting of the series winding to the shunt winding. Select **Cumulative** or **Differential** from the pull-down list.

Shunt Data for General DC Machines

By option you can insert or remove a shunt from a General DC Machine. If you insert a shunt, it appears in the project tree under the stator field data.

To insert a shunt.

1. Right click on the Field icon under the stator in the project tree to display the popup menu.
2. Click **Insert Shunt**.

   The Shunt icon appears under the field icon.

To Remove an existing shunt:

1. Right click on the Field icon under the stator in the project tree to display the popup menu.
2. Click **Remove Shunt**.

   The shut is removed from the project tree.

The Shunt data for a General DC Machine contains the following fields.

Winding type	Specified as Round, Cylinder coil, or Edgewise coil, by clicking the button to display the Winding Type selection window.
Parallel	Number of parallel branches.

branches	
Conductors per pole	Number of conductors per pole. 0 for auto-design. Odd number of strands for the case where the input and output leads are on different sides.
Number of strands	Number of strands (number of wires per conductor). 0 for auto-design.
Wire wrap	Double side wire wrap thickness. 0 for auto-pickup in the wire library.
Wire size.	Click the button to display the Wire Size selection window.
Axial Clearance	Axial gap between field winding and pole body on the inner coil.
Limited cross width	Limited cross-section width for winding design or arrangement. 0 for available maximum area.
Limited cross height	Limited cross-section height for winding design or arrangement. 0 for available maximum area.
Winding fillet.	

Series Data for General DC Machines

By option, you can insert or remove a series from a General DC Machine. If you insert a series, it appears in the project tree under the stator field data.

To insert a series:

1. Right click on the Field icon under the stator in the project tree to display the popup menu.
2. Click **Insert Series**.

   The Series icon appears under the field icon.

To Remove an existing series:

1. Right click on the Field icon under the stator in the project tree to display the popup menu.
2. Click **Remove Series**.

   The series is removed from the project tree.

The Series data for a General DC Machine contains the following fields.

Winding type	Specified as Round, Cylinder coil, or Edgewise coil, by clicking the button to display the Winding Type selection window.
Parallel branches	Number of parallel branches.
Conductors per pole	Number of conductors per pole. 0 for auto-design. Odd number of strands for the case where the input and output leads are on different sides.
Number of	Number of strands (number of wires per conductor). 0 for auto-design.

strands	
Wire wrap	Double side wire wrap thickness. 0 for auto-pickup in the wire library.
Wire size.	Click the button to display the Wire Size selection window.
Axial Clearance	Axial gap between field winding and pole body on the inner coil.
Limited cross width	Limited cross-section width for winding design or arrangement. 0 for available maximum area.
Limited cross height	Limited cross-section height for winding design or arrangement. 0 for available maximum area.
Winding fillet.	

Compensating Data for General DC Machines

By option, you can insert or remove Compensating for a General DC Machine.

To insert compensating:

1. Right-click on the Stator icon to display the pop-up menu.
2. Click **Insert Compensating**.

To remove an existing Compensating:

1. Right click on the Stator icon to display the pop-up menu.
2. Click **Remove Compensating**.

To access the data for compensating inserted to a General DC Machine, double click on the **Machine-Rotor-Compensating** item in the project tree.

The **Compensating** properties window contains the following fields.

Slots per pole	Number of slots per pole for the compensating winding.
Bc0	Opening width of the compensating slots.
Hc0	Opening height of the compensating slots.
Bc2	Width of the compensating slots.
Hc2	Height of the compensating slots.
Parallel branches	Number of parallel branches.
Conductors per slot	Number of conductors per slot for the compensating windings
Number of strands	Number of strands (number of wires per conductor), 0 for auto-design.

Wire wrap	Double-side wire wrap thickness, 0 for auto pickup in the wire library
Rectangle wire	Whether to use round (the default) or rectangle wire.
Wire size	Click the button to display the Wire Size window to specify the wire diameter and gauge.
Slot liner	Insulation slot liner thickness
End adjustment	one side end length adjustment of a conductor.

Commutating Data for General DC Machines

Commutating must be inserted under the stator by right-clicking on the stator icon to display the pop-up menu, and click **Insert Commutating** command. This command also inserts an icon in the project tree for an associated winding.

To remove an existing Commutating (and associated winding), right-click on the stator icon to display the pop-up menu and click **Remove Commutating**. This removes the commutating and the associated winding.

Note: This is distinct from the general Commutator data associated with rotor.

Pole width	Width of the commutating poles
Pole height	Height of the commutating poles.
Pole length	Length of the commutating poles
Shoe width	Shoe width of the commutating poles
Shoe height	Shoe height of the commutating poles.
Second air gap	Length of the second air gap between the commutating pole and the frame.
Pole stacking factor	Stacking factor for the commutating poles.
Pole material	Steel type of the commutating poles. Click the button to display the Select Definition window.
Pole insulation	Thickness of insulation on the pole body side.

Winding Data for Commutating

If you have inserted commutating for a General DC machine, an additional winding icon appears in the project tree for the associated winding.

Winding type	Specified as Round, Cylinder coil, or Edgewise coil, by clicking the button to display the Winding Type selection window.
Parallel branches	Number of parallel branches.

Conductors per pole	Number of conductors per pole. 0 for auto-design. Odd number of strands for the case where the input and output leads are on different sides.
Number of strands	Number of strands (number of wires per conductor). 0 for auto-design.
Wire wrap	Double side wire wrap thickness. 0 for auto-pickup in the wire library.
Wire size.	Click the button to display the Wire Size selection window.
Axial Clearance	Axial gap between field winding and pole body on the inner coil.
Limited cross width	Limited cross-section width for winding design or arrangement. 0 for available maximum area.
Limited cross height	Limited cross-section height for winding design or arrangement. 0 for available maximum area.
Winding fillet.	

Defining the Rotor Data for a General DC Machine

The rotor is equipped with slots containing copper conductors that are connected to the commutator. The commutator acts as a mechanical rectifier in the motor.

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine>Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general stator data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the stacking factor for the rotor core in the **Stacking Factor** field. This value relates to the effective magnetic length of the core, and ranges from 0 to 1. It is defined as the total length minus the total insulation from the laminations, divided by the total length. A value of 1 indicates that the rotor is not laminated.
3. Enter the number of slots in the rotor core in the **Number of Slots** field.
4. Select a **Slot Type**:
   a. Click the button.
      The **Select Slot Type** window appears.
   b. Click a button to select the desired slot type (1, 2, 3, 4, 5, or 6). Though slots **3** and **4** are visually similar, they differ in how the edges are constructed. Slot **3** has a tapered edge leading from the slot opening to the main slot body. Slot **4** has a rounded edge at the same location, where the quantity **Hr1** defines the radius of the corner slot. TIP: When

you run the mouse over each option, the diagram changes to show that pole type.

c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.

Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.

5. Enter the number of lamination sectors in the **Lamination Sectors** field.
6. Enter the outer diameter of the rotor core in the **Outer Diameter** field.
7. Enter the inner diameter of the rotor core in the **Inner Diameter** field.
8. Enter the length of the rotor core in the **Length** field.
9. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
10. Enter the thickness of the pole press boards in the **Press Board Thickness** field.
11. Enter the number of slots in the skew width in the **Skew Width** field.
12. Click **OK** to close the **Properties** window.

Rotor Data for General DC Machines

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Stacking Factor	The effective magnetic length of the rotor core.
Number of Slots	The number of slots the rotor core contains.
Slot Type	The type of slots in the rotor core. Click the button to open the **Select Slot Type** window.
Lamination Sectors	The number of lamination sectors.
Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Press Board Thickness	The thickness of the pole press boards.
Skew Width	The skew width measured in slot number.

Defining the Rotor Slots for a General DC Machine

To define the physical dimensions of the rotor slots:

1. To open the **Rotor Slot Data Properties** window, double-click the **Machine-Rotor-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box. Using this option causes the software to converge to a flux density value of 1.5 Tesla in the rotor teeth.
3. Enter the available slot dimensions. The following dimensions may be listed, depending on the **Slot Type** selected and depending on whether or not **Auto Design** is selected.:

Hs0	Always available.
Hs1	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Always available.

4. Click **OK** to close the **Properties** window.

Rotor Slot Data for General DC Machines

To access the rotor slot data, double-click the **Machine-Rotor-Slot** entry in the project tree.

The **Rotor Slot Data Properties** window contains the following fields:

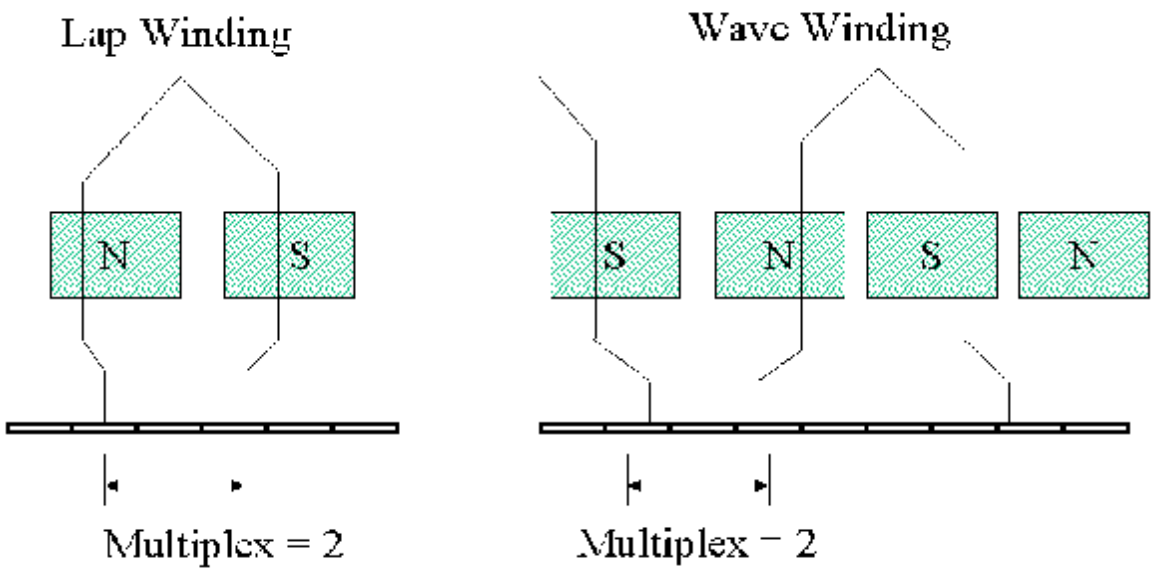
Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-**

	Rotor-Slot is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension (see the diagram shown in the modeling window when **Machine-Rotor-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected). Rs is added when the slot type is 3 or 4.

Defining the Rotor Windings and Conductors for a General DC Machine

To define the rotor windings, wires, and conductors:

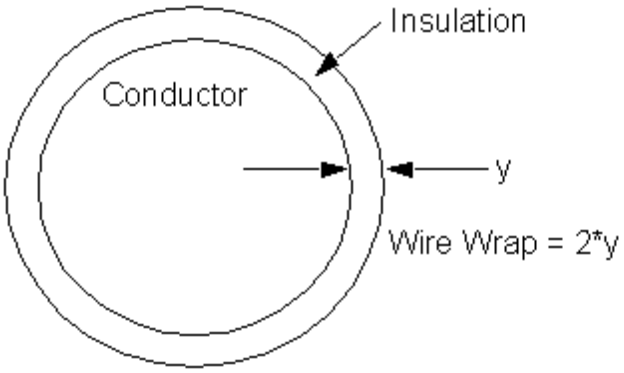
1. To open the **Rotor Slot Winding Properties** window, double-click the **Machine-Rotor-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
      The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Lap**
      - **Wave**
      - **Frog Leg**
4. Enter the number of windings in the **Multiplex Number** field (1 for a single winding, 2 for double windings, 3 for triple windings). For a lap winding, the multiplex number is the number of commutators between the start and end of one winding, and the number of parallel branches is equal to the number of poles multiplied by the multiplex number. For a wave winding, the number of parallel branches equals the multiplex number multiplied by two.



5. Enter the number of virtual slots per each real slot in the **Virtual Slots** field. The rotor is assumed to have two layers of conductors, an upper and a lower layer. Each layer of conductors can have a number of windings, which are referred to as virtual slots.

Note	For example, the upper and lower layer can have two windings each, which would yield a virtual slot number of two; for a 12 slot machine, this would yield 24 commutation segments.

6. Enter the total number of conductors in each rotor slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers. This value is the total number of conductors in one real full rotor slot.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
    The **Wire Size** window appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

    a. When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window.

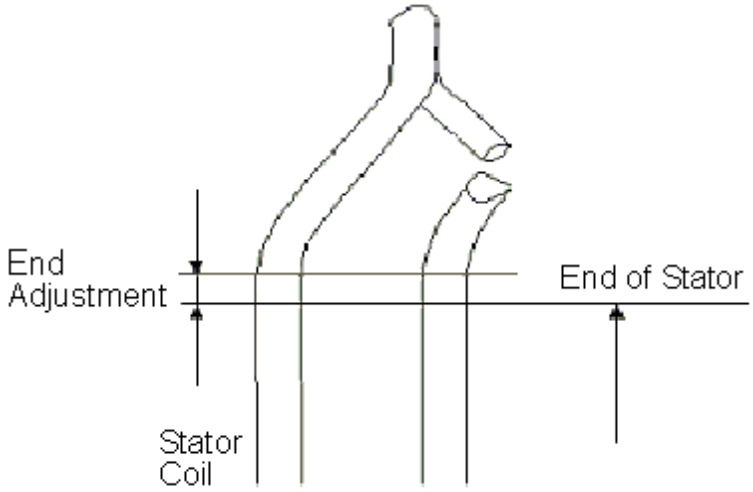
b. Click the **End/Insulation** tab.

c. Select or clear the **Input Half-turn Length** check box.

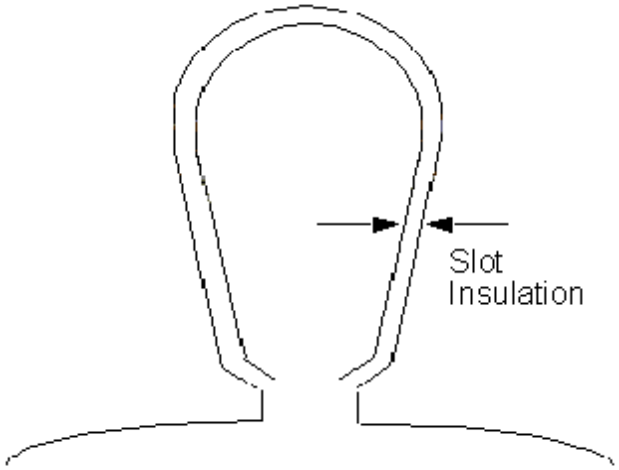
d. Do one of the following:

- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the

conductor extends vertically beyond the end of the stator.



5. Enter the inner radius of the base corner in the **Base Inner Radius** field.
6. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
7. Enter the distance between two rotor coils in the **End Clearance** field.
8. Enter the thickness of the slot liner insulation in the **Slot Liner** field.



9. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
10. Enter the thickness of the insulation layer in the **Layer Insulation** field.
11. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.

12. Select the type of equalizer connection from the **Equalizer Connection** pull-down menu. Select from **None**, **Half**, or **Full**.
13. Click **OK** to close the **Properties** window.

Defining Different Size Wires for a General DC Machine Rotor Winding

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Rotor Winding Data for General DC Machines

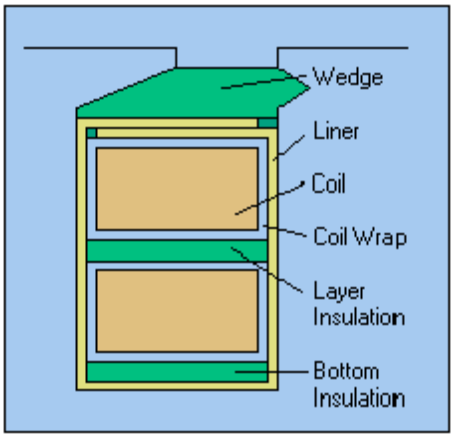
To access the rotor winding data, double-click the **Machine-Rotor-Winding** entry in the project tree.

The **Rotor Winding Data Properties** window contains the following fields:

Winding tab	**Winding Type**	The type of rotor winding. Click the button to open the **Winding Type** window and choose from **Lap**, **Wave**,

		and **Frog Leg**.
	Multiplex Number	Single, double, or triple windings (**1**, **2**, or **3**).
	Virtual Slots	The number of virtual slots per real slot.
	Conductors per Slot	The number of conductors per rotor slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the rotor coils.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio

		between the cross-sectional area of all conductors in one slot and the entire slot area.
	Equalizer Connection	The connection type of the equalizer. Select from **None**, **Half**, or **Full**.



Vent Data for General DC Machines

By option, you can insert or remove Vent data for general DC machines. If you have inserted a Vent, the icon appears under the rotor winding in the project tree.

To insert a vent:

1. Right-click on the rotor icon to display the pop-up menu.
2. Click **Insert Vent**.

To remove an existing vent:

1. Right click on the Stator icon to display the pop-up menu.
2. Click **Remove Vent**.

The **Vent Data Properties** window contains the following fields.

Vent Ducts	Number of radial vent ducts
Duct Width	Width of radial vent ducts
Magnetic Spacer Width	Width of magnetic spacer which hold vent ducts. 0 for non-magnetic spacer.
Duct Pitch	Vent ducts
Holes per Row	Number of axial vent holes per row
Inner Hole Diameter	Diameter of vent holes in inner row.

Outer Hole Diameter	Diameter of vent holes in outer row.
Inner Hole Location	Center-to-center diameter of inner row hole vents.
Outer Hole Location	Center-to-center diameter of outer row hole vents.
Banding Slots	Number of axial banding slots to tight the rotor winding.
Width of Banding Slots	Width of axial banding slots
Depth of Banding Slots	Depth of axial banding slots

Defining the Commutator and Brush for a General DC Machine

The commutator allows current transfer between DC terminals or brushes and the rotor coils, providing the current to the system as a function of rotation. Due to the action of the commutator, the corresponding magnetic field has a fixed distribution with respect to the stator.

To define the commutator and brush pairs:

1. To open the **Commutator Data Properties** window, double-click the **Machine>Commutator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Commutator** tab.
3. Select **Cylinder** or **Pancake Type** as the **Commutator Type**.

Note	When you place the mouse cursor over the commutator type, an outline of the commutator appears.

4. For **Cylinder** commutators, do the following:
   a. Enter the **Commutator Diameter**.
   b. Enter the **Commutator Length**.
5. For **Pancake** commutators, do the following:
   a. Enter the **Outer Diameter**.
   b. Enter the **Inner Diameter**.
6. Enter the thickness of the insulation between two consecutive commutator segments in the **Commutator Insulation** field.
7. Click the **Brush** tab.
8. Enter the **Brush Width**.
9. Enter the **Brush Length**.
10. Enter the number of brush pairs when using a wave armature winding in the **Brush Pairs** field.
11. Enter the angle of displacement from the neutral axis, in mechanical degrees, in the **Brush Displacement** field.

Note	The brush displacement is positive for the counter-clockwise direction. For

	example, if the rotor turns clockwise and the brush displacement is also clockwise, then the angle is negative; if the rotor turns clockwise but the brush displacement is counter-clockwise, then the angle is positive.

12. Enter the voltage drop across one brush pair in the **Brush Drop** field.
13. Enter the mechanical pressure of the brushes as they press against the commutator in the **Brush Press** field.
14. Enter the **Frictional Coefficient** of the brush.

Note	If the **Friction Loss** field is used in the **General** window, the **Brush Press** and **Frictional Coefficient** fields will be hidden in the **Commutator/Brush** window. These fields are shown only when the **Friction Loss** field in the **General** window is set to zero.

15. Click **OK** to close the **Properties** window.

Commutator and Brush Data for General DC Machines

To access the commutator and brush data, double-click the **Machine>Commutator** entry in the project tree.

The **Commutator Data Properties** window contains the following fields:

Commutator tab	**Commutator Type**	The type of commutator. Click the button to open the **Select Commutator Type** window and select from **Cylinder** or **Pancake**.
	Commutator Diameter	For a **Cylinder** commutator type, the diameter of the commutator.
	Commutator Length	For a **Cylinder** commutator type, the length of the commutator.
	Outer Diameter	For a **Pancake** commutator type, the outer diameter of the commutator.
	Inner Diameter	For a **Pancake** commutator type, the inner diameter of the commutator.
	Commutator Insulation	The thickness of the insulation between the two commutator bars.
Brush tab	**Brush Width**	The width of the brush.
	Brush Length	The length of the brush.
	Brush Pairs	The number of brush pairs.
	Brush Displacement	The displacement of the brush from the neutral position, in mechanical degrees (positive for anti-rotating direction).
	Brush Drop	The voltage drop across a one-pair brush.

	Brush Press	The brush press per unit area. (Available only when **Frictional Loss** is set to zero for the machine.)
	Frictional Coefficient	The frictional coefficient of the brush. (Available only when **Frictional Loss** is set to zero for the machine.)

Defining the Shaft Data for a General DC Machine

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Select or clear the **No Fan** check box to specify whether or not the machine contains a ventilation fan.
4. If you cleared the **No Fan** check box, then do the following:
   a. Enter the outer diameter of the ventilation fan in the **Fan Diameter** field.
   b. Enter the width of the fan blades in the **Blade Width** field.
5. Click **OK** to close the **Properties** window.

Setting Up Analysis Parameters for a General DC Machine

To define the solution data:

1. To open the **Solution Setup** window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **Motor** for this machine type.
3. Select the **Load Type** used in the motor from the following options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor.
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

4. Enter the output power in the **Rated Output Power** field.
5. Enter the applied or output rated DC voltage in the **Rated Voltage** field.

6. Enter the given rated speed in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **DC Machine** tab.
9. Select one of the following from the **Field Exciting Type** pull-down list:
   - **Separately Excited**
   - **Self Excited**
10. Enter the **Exciting Voltage,** and select the units.
11. Enter the **Series Resistance**, and select the units.
12. To automatically obtained the Exciting Voltage and Series Resistance via the **Rated Speed**, rather than entering their values, then select the **Determined by Rated Speed** check box.
13. Click **OK** to close the **Solution Setup** window.

Solution Data for General DC Machines

Solution Data for General DC Machines

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	***General** tab*. Select **Motor** or **Generator** from the pull-down list.
Load Type	*On the* **General** *tab.* For a motor, select from **Const Speed**, **Const Power**, **Const Torque**, **Linear Torque**, and **Fan Load**. The default is **Const Power**. For a generator, select from **Infinite Bus** and **Independent Generato**r.
Rated Output Power	***General** tab*. Type a value for the rated output voltage, and select the units.
Rated Voltage	***General** tab*. Type a value for the rated voltage, and select the units.
Rated Speed	***General** tab*. Type a value for the rated speed, and select the units.
Operating Temperature	***General** tab*. Type a value for the operating temperature, and select the units.
Field Exciting Type	***DC Machine** tab.* Select **Separately Excited** or **Self Excited** from the pull-down list.
Determined by Rated Speed	Select this check box to automatically calculate the **Exciting Voltage** and the **Series Resistance** from the **Rated Speed**, rather than entering the values.

Exciting Voltage	Enter a voltage value in the field, and select the units from the pull-down list.
Series Resistance	Enter a resistance value in the field, and select the units from the pull-down list.

Setting Up Analysis Parameters for a General DC Machine

Claw-Pole Alternators

After you have selected **Claw-Pole Alternators** as your model type, enter the motor data to define the following:

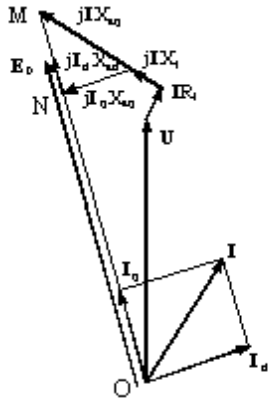
- General data, such as the output power, rated voltage, and speed.
- Stator data.
- Stator slot data.
- Stator winding data.
- Rotor data, such as the slot types and dimensions, rotor diameter, and lamination.
- Rotor pole data.
- Shaft data.
- Optional machine housing.
- Solution data.

Analysis Approach for Claw-Pole Alternators

Claw-pole alternators (or claw-pole synchronous generators) are widely used in auto industry. They receive mechanical energy at the shaft and transform it into electrical energy.

The stator of a claw-pole alternator is equipped with a polyphase winding. The rotor is comprised of claw poles with the same pole number as the stator winding. The claw poles of the rotor are magnetized by a cylinder winding and/or a cylinder permanent magnet. The spinning rotor creates a rotating magnetic field in the air gap, which produces induced voltage in the stator winding.

The performance of a claw-pole alternator is analyzed based on the frequency-domain phasor diagram, as shown in the figure below.



If a claw-pole alternator is equipped with a permanent magnet, the d-axis armature reactance X_{ad} and q-axis armature reactance X_{aq} are about constant. Otherwise, X_{ad} is a linearized nonlinear parameter, and X_{aq} is a linear parameter. The d-axis synchronous reactance X_d and q-axis synchronous reactance X_q are calculated directly from the following:

$$X_d = X_1 + X_{ad}$$

$$X_q = X_1 + X_{aq}$$

Rotor Equipped with an Excitation Winding

If the rotor is equipped with an excitation winding, the exciting current can be adjusted, and the d- and the q-axis currents are obtained based on the following process.

Take the input voltage *U* as the reference phasor, let the power factor angle be *f*, then the current phasor is

The phasor represented by **OM** can be expressed as

$$\mathbf{OM} = \mathbf{U} + \mathbf{I}(R_1 + jX_q)$$

The phasor represented by **OM** can be used to determine the direction of E_0.

θ

Let denote the power angle (the angle that *U* lags E_0), then the angle that *I* lags E_0 is

$$\Psi = \varphi + \theta$$

The d- and the q-axis currents are obtained as follows

$$I_d = I\sin\psi$$

$$I_q = I\cos\psi$$

In the phasor diagrams, the phasor length ON represents the d-axis back emf due to the d-axis resultant flux linkage and is used to determine the d-axis field saturation. From the no-load characteristic curve of the magnetic circuit, E_0, X_{ad} and the excitation current If can be determined based on the frozen method.

Rotor Equipped with a Permanent Magnet Only

If the rotor is equipped with a permanent magnet only, the field excitation can not be adjusted, and the d- and the q-axis currents are obtained based on the following process.

θ

For a given power angle (the angle that *U* lags E_0), we have

$$I_d X_d + I_q R_1 = -(U\cos\theta - E_0)$$

$$-I_d R_1 + I_q X_q = U\sin\theta$$

Solving for I_d and I_q yields.

$$I_d = -\frac{X_q(U\cos\theta - E_0) - R_1 U\sin\theta}{R^2_1 + X_d X_q}$$

$$I_q = \frac{R_1(U\cos\theta - E_0) + X_d U\sin\theta}{R^2_1 + X_d X_q}$$

ω

Let the angle that *I* lags E_0 be , we have

$$\Psi = \tanh\frac{I_d}{I_q}$$

The power factor angle f (the angle that *I* lags *U*) is

$$\varphi = \Psi - \theta$$

Power and Efficiency

The output electric power is

$$P_2 = 3UI\cos\varphi$$

The input mechanical power is

$$P_1 = P_2 + P_{fw} + P_{Cua} + P_{Fe} + P_{Cuf}$$

where P_{fw}, P_{Cua}, P_{Fe}, , and P_{Cuf} are the frictional and wind, the armature copper, the iron-core, the excitation winding copper (if an excitation winding is equipped) losses, respectively.

The input mechanical torque is

$$T_1 = \frac{P_1}{\omega}$$

where ω denotes the synchronous speed in rad/s.

The efficiency of the generator is:

$$\eta = \frac{P_2}{P_1} \times 100\ \%$$

Defining a Claw-Pole Alternator

The general procedure for defining a claw-pole alternator is as follows:

1. Create the alternator project.
2. Double-click the **Machine** entry in the project tree to define the general data.
3. Double-click the **Machine-Stator** entry in the project tree to define the stator geometry.
4. Double-click the **Machine-Stator-Slot** entry in the project tree to define the stator slot dimensions.
5. Double-click the **Machine-Stator-Winding** entry in the project tree to define the stator windings and conductors.
6. Double-click the **Machine-Rotor** entry in the project tree to define the rotor geometry.

7. Double-click the **Machine-Rotor-Pole** entry in the project tree to define the pole, embrace, offset, and air gap data for the rotor pole.
8. Double-click the **Machine-Shaft** entry in the project tree to define the magnetism of the shaft.
9. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
10. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
11. Choose **File>Save** to save the project.
12. Choose **RMxprt>Analyze** to analyze the design.

Note	When you place the cursor over an entry field in the data windows, a brief description of that field appears in the status bar at the bottom of the **RMxprt** window.

Once analyzed, the model can be viewed in the Maxwell 2D Modeler, or it can be used to create a new Maxwell 2D project, and new Maxwell 3D design.

Refer to the *Claw-Pole Alternator Problem* application note, on the technical support page of the Ansys web site, for a specific example of a permanent-magnet DC motor problem.

Defining the General Data for a Claw-Pole Alternator

Use the **General** window to define the basic parameters of the alternator, such as the power settings, speed, and rated voltage.

To define the general data:

1. To open the **General Data Properties** window, double-click the **Machine** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the number of poles for the machine in the **Number of Poles** field. This value is the total number of poles in the stator (or the number of pole pairs multiplied by two).
3. Enter or select the **Number of Phases** (2, 3, or 4).
4. Enter the energy loss due to friction at the given speed in the **Frictional Loss** field.
5. Enter the wind loss due to air resistance measured at the reference speed in the **Wind Loss** field.
6. Enter the given speed in the **Reference Speed** field.
7. Click **OK** to close the **Properties** window.

General Data for Claw-Pole Alternators

To access the general data, double-click the **Machine** entry in the project tree.

The **General Data Properties** window for a three-phase induction motor contains the following fields:

Machine Type	The machine type you selected when inserting a new RMxprt design (Claw-Pole Synchronous Machine).
Frictional Loss	The frictional energy loss (due to friction and air resistance) measured at the reference speed.
Number of Poles	The number of poles the machine contains.
Number of Phases	The number of phases.
Wind Loss	The wind loss measured at the reference speed.
Reference Speed	The given speed of reference.

Defining the Stator Data for a Claw-Pole Alternator

Use the **Stator Properties** windows to define the stator dimensions, slots, windings, and conductors.

The stator is the outer lamination stack where the polyphase voltage windings reside.

To define the general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.
5. Enter the stacking factor for the stator core in the **Stacking Factor** field. This value is a ratio of he effective magnetic length of the core, and ranges from 0 to 1. The stacking factor is defined as the total length minus the total insulation from the laminations, divided by the total length. A value of 1 indicates that the rotor is not laminated.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 4).

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.

c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.

9. Enter the skew width, measured in slot number, in the **Skew Width** field.
10. Click **OK** to close the **Properties** window.

Stator Data for Claw-Pole Alternators

To access the general stator data, double-click the **Machine>Stator** entry in the project tree.

The **Stator Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator core.
Inner Diameter	The inner diameter of the stator core.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Skew Width	The skew width measured in slot number.

Defining the Stator Slot Data for a Claw-Pole Alternator

To define the stator slots:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine-Stator-Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.
3. Optionally, to design dimensions of slots **Bs1** and **Bs2** based on the stator tooth width, select the **Parallel Tooth** check box, and enter a value in the **Tooth Width** field.

4. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	Available only when **Auto Design** and **Parallel Tooth** are both cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	Rs is added when the slot type is 3 or 4.

5. Click **OK** to close the **Properties** window.

Stator Slot Data for Claw-Pole Alternators

To access the stator slot data, double-click the **Machine-Stator-Slot** entry in the project tree.

The **Stator Slot Data Properties** window contains the following fields:

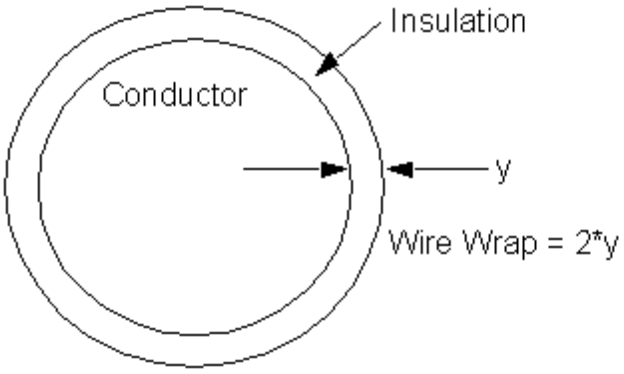
Auto Design	Select or clear this to enable or disable auto-design of slots **Hs2**, **Bs1**, and **Bs2**. When this check box is selected, only two other fields appear in the window: **Hs0** and **Bs0**.
Parallel Tooth	Select this to design **Bs1** and **Bs2** based on the tooth width. When this check box is selected, the **Bs1** and **Bs2** fields are removed, and the **Tooth Width** field is added.
Tooth Width	The tooth width for the parallel tooth, on which **Bs1** and **Bs2** are designed.
Hs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Hs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs0	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs1	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Bs2	A slot dimension (see the diagram shown in the modeling window when **Machine-Stator-Slot** is selected).
Rs	A slot dimension. (see the diagram shown in the modeling window when **Machine-**

	Stator-Slot is selected). Rs is added when the slot type is 3 or 4.

Defining the Stator Winding Data for a Claw-Pole Alternator

To define the stator windings and conductors:

1. To open the **Stator Slot Winding Properties** window, double-click the **Machine-Stator-Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Click the **Winding** tab.
3. Enter the number of layers in the stator winding in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
   The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**
5. Select or enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.
6. Enter the total number of conductors in each stator slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



10. Select the **Wire Size**:

a. Click the button for **Wire Size**.
   The **Wire Size** window appears.
b. Select a value from the **Wire Diameter** pull-down list.
c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

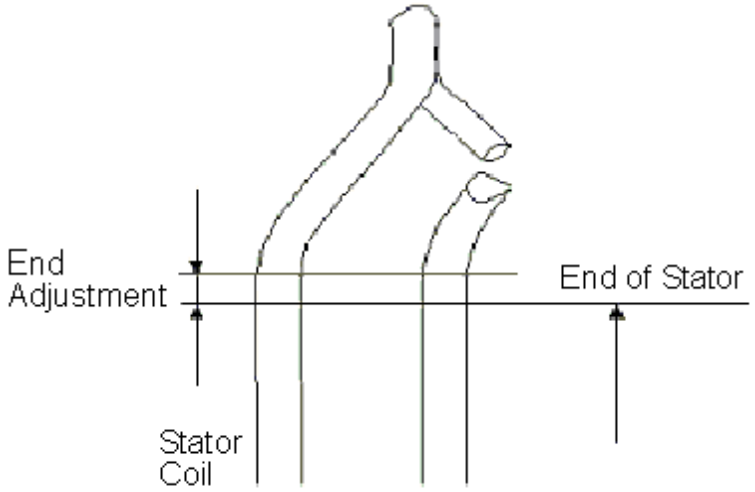
< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines**command.

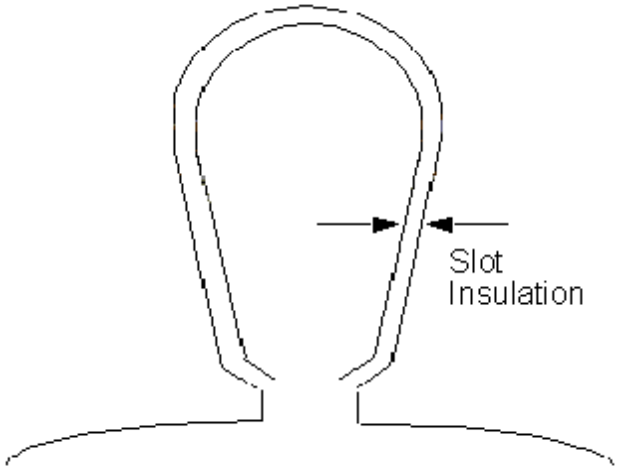
When you are done setting the wire size, click **OK** to close the **Wire Size** window and return to the **Properties** window. Click the **End/Insulation** tab. Select or clear the **Input Half-turn Length** check box. Do one of the following:

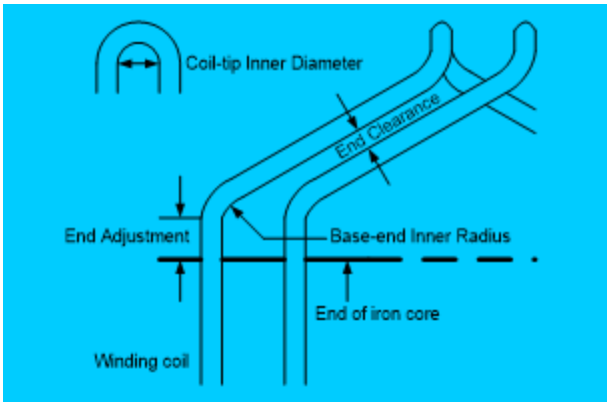
- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator coils in the **End Adjustment** field. The end adjustment is the distance one end of the

conductor extends vertically beyond the end of the stator.



11. Enter the inner radius of the base corner in the **Base Inner Radius** field.
12. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
13. Enter the distance between two stator coils in the **End Clearance** field.
14. Enter the thickness of the slot liner insulation in the **Slot Liner** field.





15. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.
16. Enter the thickness of the insulation layer in the **Layer Insulation** field.
17. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
18. Click **OK** to close the **Properties** window.

Winding Editor for a Claw-Pole Alternator

For a claw-pole alternator, you may want to specify a different number of conductors for each stator slot. The **Winding Editor** makes this possible by enabling you to specify the number of turns for each coil.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.
   The **Winding Editor** window appears.
2. In the table in the upper left, set which phase you want for each coil and which slot is the “in” and “out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by clicking the **Periodic Multiplier** check box and specifying a value.
4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** window.

Defining Different Size Wires for a Claw-Pole Alternator

Use the **Gauge** option in the Wire Size window if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Enter the **Width** of the wire in the table.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Click **Add** to add the new wire data.
5. Repeat steps 3 and 4 for each size wire you want to add.
6. When you are finished defining the wires, click **OK** to close the **Wire Size** window and return to the RMxprt **Properties** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

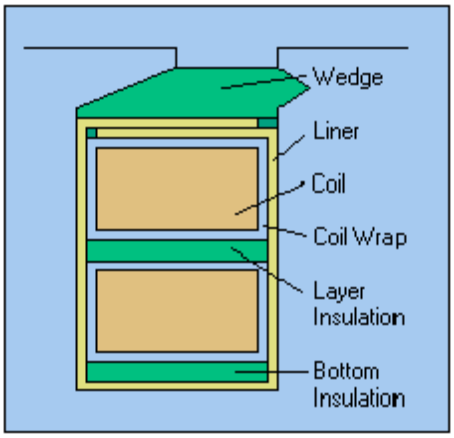
Stator Winding Data for Claw-Pole Alternators

To access the stator winding data, double-click the **Machine-Stator-Winding** entry in the project tree.

The **Stator Winding Data Properties** window contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole Coiled**, **Half Coiled**, and **Editor**.
	Parallel Branches	The number of parallel branches in the stator winding.
	Conductors per Slot	The number of conductors per stator slot (0 for auto-design).

	Coil Pitch	The coil pitch measured in number of slots.
	Number of Strands	The number of wires per conductor (0 for auto-design).
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** window where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Adjustment** field appears instead.
	Half Turn Length	The half-turn length of the armature winding.
	End Adjustment	The end length adjustment of the stator coils, which is the distance one end of the conductor extends vertically beyond the end of the stator.
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip.
	End Clearance	The end clearance between two adjacent coils.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.



Defining the Rotor Data for a Claw-Pole Alternator

The rotor is equipped with slots containing copper conductors that are connected to the commutator. The commutator acts as a mechanical rectifier in the motor.

The rotor consists of copper bars in which current is induced by the magnetic fields produced by the stator windings. In the project tree, double-click **Machine-Rotor** and **Machine-Rotor-Pole** to define the rotor and the pole.

To define general rotor data:

1. To open the **Rotor Data Properties** window, double-click the **Machine>Rotor** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the outer diameter of the rotor in the **Outer Diameter** field.
3. Enter the inner diameter of the rotor in the **Inner Diameter** field.
4. Enter the length of the rotor core in the **Length** field.
5. Select a **Steel Type** for the rotor core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
6. Enter the diameter of the rotor yoke in the **Yoke Diameter** field.
7. Click **OK** to close the **Properties** window.

Rotor Data for Claw-Pole Alternators

To access the general rotor data, double-click the **Machine>Rotor** entry in the project tree.

The **Rotor Data Properties** window contains the following fields:

Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Steel Type	The steel type of the rotor core. Click the button to open the **Select Definition** window.
Yoke Diameter	The diameter of the rotor yoke.

Defining the Rotor Pole for a Claw-Pole Alternator

The rotor pole drives the electromagnetic field which is coupled with the stator windings. Use the **Rotor Pole Data Properties** window to define the rotor pole.

Note	Some of the fields in the **Rotor Pole** window change, or are inactive, depending on the **Rotor Type** you select.

To define the rotor pole:

1. To open the **Rotor Pole Data Properties** window, double-click the **Machine-Rotor-Pole** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the pole embrace at the pole tip in the **Tip Embrace** field. This value must be between 0 and 1, exclusive.
3. Enter the pole embrace at the pole root in the **Root Embrace** field. This value must be between 0 and 2, exclusive.
4. Enter the pole thickness at the pole tip in the **Tip Thickness** field.
5. Enter the pole thickness at the pole root in the **Root Thickness** field.
6. Enter the **Pole Length**.
7. Enter the **Slot Depth**.
8. Enter the **Shoe Thickness**.
9. Select the type of magnet to use in the rotor pole from the **Magnet Type** pull-down menu.
10. If a magnet is being used, enter its length in the **Magnet Length** field.
11. Enter the width of the second air gap in the **Second Air Gap** field.
12. Click **OK** to close the **Properties** window.

Rotor Pole Data for Claw-Pole Alternators

To access the pole rotor data, double-click the **Machine-Rotor-Pole** entry in the project tree.

The **Rotor Pole Data Properties** window contains the following fields:

Tip	The pole embrace at the pole tip. Must be > 0 and < 1.

Embrace	
Root Embrace	The pole embrace at the pole root. Must be > 0 and < 2.
Tip Thickness	The pole thickness at the pole tip.
Root Thickness	The pole thickness at the pole root.
Pole Length	The length of the pole.
Slot Depth	The slot depth.
Shoe Thickness	The shoe thickness.
Magnet Type	The type of magnet. Click the button to open the **Select Definition** window. For all pole types.
Magnet Length	The length of the magnet (if a magnet is used).
Second Air Gap	The width of the second air gap.

Defining the Shaft Data for a Claw-Pole Alternator

To define the shaft:

1. To open the **Shaft Data Properties** window, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Click **OK** to close the **Properties** window.

Shaft Data for Claw-Pole Alternators

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material.

Setting Up Analysis Parameters for a Claw-Pole Alternator

To define the solution data:

1. To open the Solution Setup window, right-click **Analysis** in the project tree, and click **Add Solution Setup**.
2. Click the **General** tab. The **Operation Type** is automatically set to **General** for this machine type.
3. Select the **Load Type** used in the machine from the following options:

Infinite Bus	When the generator is connected to an infinite bus of the power system, the terminal voltages remain constant and the output power is determined by the output currents.
Independent Generator	The generator supplies electrical power to a load inductor. For an AC generator, the resistance and inductance of the load inductor are determined by the rated output power, the rated voltage, and the rated power factor. For a DC generator, the resistance of the load resistor is determined by the rated output power and the rated voltage.

4. Enter the output power developed at the shaft of the generator in the **Rated Output Power** field.
5. Enter the RMS line-to-line voltage in the **Rated Voltage** field.
6. Enter the desired output speed of the alternator at the load point in the **Rated Speed** field.
7. Enter the temperature at which the system functions in the **Operating Temperature** field.
8. Click the **Claw-Pole Synchronous Machine** tab.
9. Enter a value in the **Rated Power Factor** field.
10. To enter an **Input Exciting Current**, select the check box, enter a value, and select the units.
11. Click **OK** to close the **Solution Setup** window.

Solution Data for Claw-Pole Alternators

Solution Data for Claw-Pole Alternators

To access the solution data, right-click **Analysis** in the project tree, and click **Add Solution Setup**. For this machine type, there is only one tab, the **General** tab.

The **Solution Setup** window contains the following fields:

Operation Type	***General** tab*. Select **Motor** or **Generator** from the pull-down list. **Generator** is automatically selected for this machine type
Load Type	*On the* **General** *tab.* Select from **Infinite Bus** and **Independent Generato**r.
Rated Output Power	***General** tab*. Type a value for the rated output voltage, and select the units.
Rated Voltage	***General** tab*. Type a value for the rated voltage, and select the units.

Rated Speed	***General** tab*. Type a value for the rated speed, and select the units.
Operating Temperature	***General** tab*. Type a value for the operating temperature, and select the units.
Rated Power Factor	***Claw-Pole Synchronous Machine** tab.* Type a value in the field.
Input Exciting Current	Select this check box, enter a value, and select the units. If this check box is cleared, the value will be calculated automatically rather than entered.

Also see Analysis Approach for the Three-Phase Non-Salient Synchronous Machine

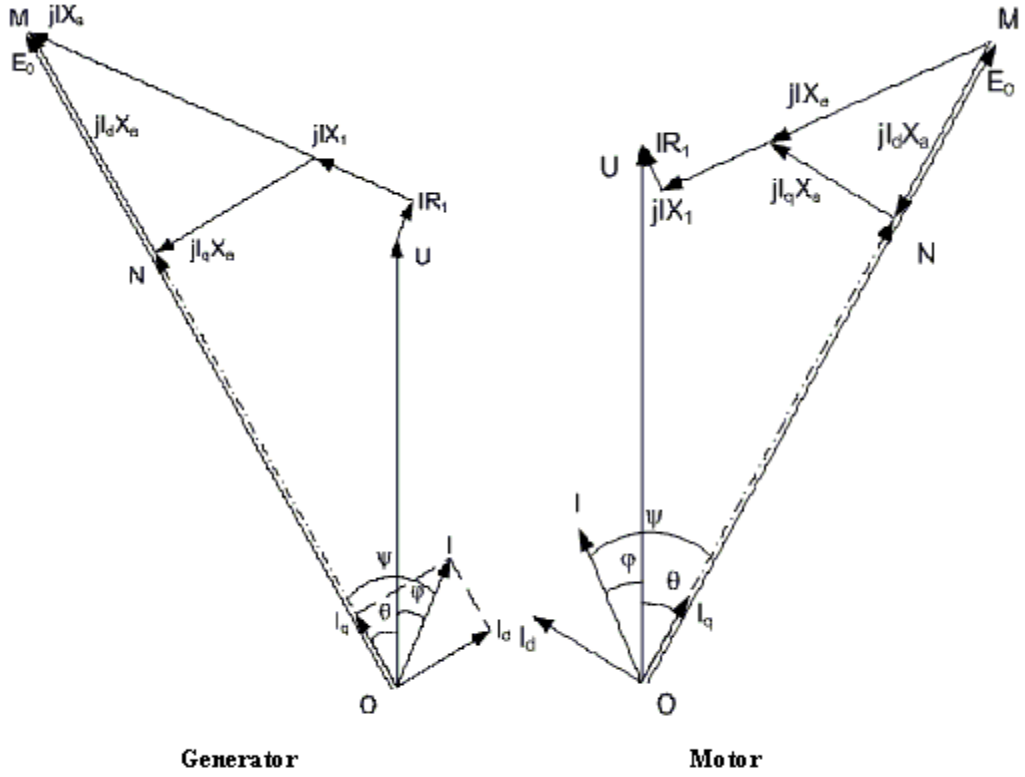
Analysis Approach for Three-Phase Non-Salient Synchronous Machines

The three-phase non-salient-pole synchronous electric machine has two types: the generator and the motor. Their basic structures are the same. The three-phase non-salient-pole synchronous generators are the main source of the electrical energy for industrial, commercial, and private use. They receive the mechanical energy at the shaft and transform it into the electrical energy. The rotor is equipped with a non-salient-pole winding excited by a DC source. The stator is equipped with a three-phase winding that has a sinusoidal spatial distribution. The spinning rotor produces a rotating magnetic field in the air gap of the machine. The frequency of the voltage induced in the stator is given by:

$$f = (pn)/60$$

where *p* is the number of pairs of poles, and n is the mechanical speed of the rotor in rpm, which is called the synchronous speed. The machine is capable of producing both the active and the reactive power as required by the load connected at the stator terminal.

Usually the frequency-domain phasor diagram is adopted to analyze the characteristics. The phasor diagrams for a generator and a motor are shown.



In the figure, R_1, X_1, and X_a are the armature resistance, the armature leakage reactance, and the armature reactance, respectively. In a non-salient-pole synchronous machine, $X_{ad} \cong X_{aq}$ and they are both expressed by X_a. Taking the input voltage **U** as the reference phasor, for a given current:

$$\mathbf{I} = \mathrm{I}\angle -\varphi$$

where φ is the angle **I** lags **U** , which is called the power factor angle.

The internal back EMF induced by the resultant air gap field considering the effects of armature reaction $\mathbf{E_i}$ can be derived from:

$$\boldsymbol{E_i} = \begin{cases} \boldsymbol{U} + (R_1 + \boldsymbol{j}X_1) \cdot \boldsymbol{I} & \textit{for Generator} \\ \boldsymbol{U} - (R_1 + \boldsymbol{j}X_1) \cdot \boldsymbol{I} & \textit{for motor} \end{cases}$$

Based on $\mathbf{E_i}$, the resultant air gap flux considering the effects of armature reaction can be computed, and therefore, the magnetic circuit can be solved. With solved magnetic saturation factor, saturated X_a is derived, and therefore, the no-load induced voltage $\mathbf{E_0}$ with the same magnetic saturation (frozen magnetic circuit) can be calculated from:

$$\boldsymbol{E_0} = \begin{cases} \boldsymbol{E_i} + (\boldsymbol{j}X_a) \cdot \boldsymbol{I} & \textit{for Generator} \\ \boldsymbol{E_i} - (\boldsymbol{j}X_a) \cdot \boldsymbol{I} & \textit{for motor} \end{cases}$$

Let the angle **U** legs $\mathbf{E_0}$ be θ, which is called the power angle for the generator or the torque angle for the motor, then the angle **I** lags $\mathbf{E_0}$ is

$$\psi = \varphi + \theta$$

The d- and the q-axis currents can be obtained respectively as follows:

$$\mathbf{I} = \begin{bmatrix} I_d \\ I_q \end{bmatrix} = I \begin{bmatrix} \sin\psi \\ \cos\psi \end{bmatrix}$$

Based on the magnetic circuit solution and $\mathbf{E_0}$, X_a and the excitation current I_f can be determined based on the frozen method.

1. For the generator:

The output power (electric power) is directly computed from the voltage and the current as:

$$P_2 = 3UI\cos\varphi$$

The input power (mechanical power) is defined as:

$$P_1 = P_2 + P_{fw} + P_{Cua} + P_{Fe} + P_{add} + P_{cuf} + P_{ex}$$

where P_{fw}, P_{Cua}, P_{Fe}, P_{add}, P_{cuf} and P_{ex} are the frictional and wind loss, the armature copper loss, the iron-core loss, the additional loss, the field winding copper loss, and the exciter loss, respectively.

The input mechanical shaft torque is:

$$T_1 = \frac{P_1}{\omega}$$

where ω denotes the synchronous speed in rad/s.

1. For the motor:

The input power (electric power) is directly computed from the voltage and the current as:

$$P_1 = 3UI\cos\varphi$$

The output power (mechanical power) is defined as:

$$P_2 = P_1 - (P_{fw} + P_{Cua} + P_{Fe} + P_{add} + P_{cuf} + P_{ex})$$

where P_{fw}, P_{Cua}, P_{Fe}, P_{add}, P_{cuf} and P_{ex} are the frictional and wind loss, the armature copper loss, the iron-core loss, the additional loss, the field winding copper loss, and the exciter loss, respectively.

The output mechanical shaft torque is:

$$T_2 = \frac{P_2}{\omega}$$

The efficiency is computed for both the generator and the motor by:

$$\eta = \frac{P_2}{P_1} \cdot 100\,\%$$

Defining Three-Phase Non-Salient Synchronous Machines

Defining Three-Phase Non-Salient Synchronous Machines

The general procedure for defining a three-phase non-salient synchronous machine is as follows:

1. Create the non-salient synchronous machine project.
2. After you have selected **Three-Phase Non-Salient Synchronous Machine** as your model type, you must define the following:

- General data, such as number of poles, losses, and reference speed.
- Stator data, such as dimensions, slot type, skew, and laminations.
- Define the Stator slot dimensions.
- Winding data, such as the parallel branches, conductors, and wire dimensions and insulation.
- Rotor data, such as the rotor dimensions, lamination and slot type.
- Define the Rotor slot data.
- Define the Shaft Data.
- Solution data, such as specifying motor or generator application, and rated output voltage and frequency.

You may also use the following options:

- Add a machine housing.
- Add a damper to or remove an existing damper from the rotor;
- Add vents to and remove existing vents from the stator.

Defining the General Data for a Three-Phase NSSM

To access the general data, double-click the **Machine** entry in the project tree.

The **Properties** window for a three-phase non-salient synchronous machine contains the following fields to be entered:

Machine Type	The machine type you selected when inserting a new RMxprt design (Three Phase Non-Salient Synchronous Machine).
Number of	The number of poles the machine contains. This value is the total number of

Poles	poles in the stator (or the number of pole pairs multiplied by two).
Frictional Loss	The frictional energy loss (due to friction) measured at the reference speed.
Windage Loss	The windage loss (due to air resistance) measured at the reference speed.
Reference Speed	The given speed of reference.

Related Topics

Defining the Stator for Three-Phase NSSM

Defining the Stator for Three-Phase NSSM

The stator is the outer lamination stack where the three-phase windings reside.

Double-click the icon **Machine>Stator** in the project tree to display the **Properties** dialog box.

The **Properties** window contains the following fields:

Outer Diameter	The outer diameter of the stator.
Inner Diameter	The inner diameter of the stator.
Length	The length of the stator core.
Stacking Factor	The stacking factor of the stator core.
Steel Type	The steel type of the stator core. Click the button to open the **Select Definition** window.
Number of Slots	The number of slots the stator core contains.
Slot Type	The type of slots in the stator core. Click the button to open the **Select Slot Type** window.
Lamination Sectors	The number of lamination sectors.
Pressboard Thickness	The magnetic press board thickness (enter 0 for a non-magnetic press board).
Skew Width	The skew width measured in slot number.

To define general stator data:

1. To open the **Stator Data Properties** window, double-click the **Machine>Stator** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the **Outer Diameter** of the stator.
3. Enter the **Inner Diameter** of the stator.
4. Enter the length of the stator core in the **Length** field.

5. Enter the stacking factor for the stator core in the **Stacking Factor** field.
6. Select a **Steel Type** for the stator core:
   a. Click the button for **Steel Type**.
      The **Select Definition** window appears.
   b. Select a steel type from the list, or define a new steel type.
   c. Click **OK** to close the **Select Definition** window and return to the **Properties** window.
7. Enter the **Number of Slots** in the stator.
8. Select the **Slot Type**:
   a. Click the button for the **Slot Type**.
      The **Select Slot Type** window appears.
   b. Select a slot type (available types include 1 through 6). Slot types **1** though **4** are filled with round wire. Slot types **5** and **6** are filled with rectangular wire. If **Auto Design** is enabled, the software designs an optimum slot geometry; in this case, you can input the tooth width dimension, and the software determines the slot width accordingly.

Note	When you place the mouse cursor over the slot type, a schematic of the selected type appears, displaying the slot dimension variables.

   Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.

   c. Click **OK** to close the **Select Slot Type** window and return to the **Properties** window.
9. Enter the number of sectors in the **Lamination Sectors** field.
10. Enter the thickness of the magnetic pressboard in the **Pressboard Thickness** field. Enter **0** for a non-magnetic pressboard.
11. Enter the skew width, measured in slot number, in the **Skew Width** field.
12. Click **OK** to close the **Properties** window.

Defining Stator Slots for a Three-Phase NSSM

Defining Stator Slots for a Three-Phase NSSM

To define the slot dimensions:

1. To open the **Stator Slot Data Properties** window, double-click the **Machine>Stator>Slot** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Optionally, to automatically design the dimensions of slots **Hs2**, **Bs1**, and **Bs2**, select the **Auto Design** check box.

3. Enter the available slot dimensions.

Hs0	Always available.
Hs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	Always available.
Bs1	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs2	Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.

4. Click **OK** to close the **Properties** window.

Defining Stator Windings and Insulation for a Three-Phase NSSM

Defining Stator Windings and Insulation for a Three-Phase NSSM

Double-click the icon **Machine>Stator>Winding** in the project tree to display the **Properties** dialog box, which has two tab sheets: **Winding** and **End/Insulation**.

Define Wires, Conductors and Windings of NSSM Stator

In the **Winding** tab, define the wire, conductor and winding of the stator.

Winding Layers	The number of layers in the stator winding. Select the winding layers from the pull-down list (available choices 1 and 2).
Winding Type	The type of the stator winding. Set the winding type to **Editor** to use the **Winding Editor** dialog to design the coil windings
Parallel Branches	The number of parallel branches in one phase of the stator winding.
Conductors per Slot	The total number of conductors in each stator slot. This value is the number of turns per coil multiplied by the number of layers. Enter 0 to have RMxprt auto-design this value.
Coil Pitch	The coil pitch measured in number of slots. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5.
Number of Strands	The number of wires per conductor. Enter 0 to have RMxprt auto-design this value.
Wire Wrap	The thickness of the double-sided wire wrap. Enter 0 to automatically obtain this value from the wire library.
Wire Size	Wire size (0 for auto-design). You can assign wire size of round wires or rectangle wires. When the slot type you selected is 1 to 4, round wires are used.

	When the slot type you selected is 5 or 6, rectangle wires are used.

Define End Windings and Insulation of NSSM Stator

Winding Editor

Define End Windings and Insulation of NSSM Stator

In the tab sheet **End/Insulation**, define the end winding and the insulation of the stator.

Input Half-turn Length	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the row **Half Turn Length** appears the next time you open the **Properties** dialog box. When this check box is cleared, the row **End Adjustment** appears instead.
Half-turn Length	The half-turn length of the armature winding. It is available when **Input Half-turn Length** is selected.
End Adjustment	The end length adjustment of the stator coils, which is the distance of one end of the conductor extending vertically beyond the end of the stator. It is available when **Input Half-turn Length** is cleared.
Base Inner Radius	The inner radius of the base corner.
Tip Inner Diameter	The inner diameter of the coil tip.
End Clearance	The end clearance between two adjacent stator coils.
Coil Wrap	Single-side coil wrap insulation thickness.
Slot Liner	The thickness of the slot liner insulation.
Wedge Thickness	The thickness of the wedge insulation.
Limited Fill Factor	The limited slot fill factor for the wire design.
Layer Insulation	The thickness of the insulation layer.
Bottom Insulation	Bottom insulation thickness.

Related Topics

Define Wires, Conductors, and Windings of NSSM Stator

Winding Editor

For a non-salient synchronous motor, you may want to specify a different number of conductors for each stator slot. The **Winding Editor** makes this possible by enabling you to specify the number of turns for each coil. To enable the **Winding Editor**, you must have set the **Winding Property** for the **Winding Type** to **Editor**.

Stator Vent Data for Three-Phase NSSM

To insert a vent on a stator for a three phase synchronous machine:

1. Right click on the stator icon in the project tree to display the shortcut menu.
2. Click **Insert Vent**.

   The vent icon appears in the project tree under the stator.

To remove an existing vent item,

1. Right-click on the stator icon in the project tree to display the shortcut menu.
2. Click **Remove Vent**.

   This removes the vent item from the project tree.

To access the Vent properties for a vent, double click on a vent item. The **Vent Properties** window contains the following fields.

Vent Ducts	The number of radial vent ducts.
Duct Width	The width of the radial vent ducts.
Magnetic spacer width	Width of magnetic spacer which holds vent ducts. O for non-magnetic spacer.
Duct pitch.	Center-to-Center distance between two adjacent Vent ducts

Define NSSM Rotor Data

Double-click the icon **Machine>Rotor** in the project tree to display the **Properties** dialog box, which has one tab sheet: **Rotor**. In the **Rotor** tab, define the rotor general data.

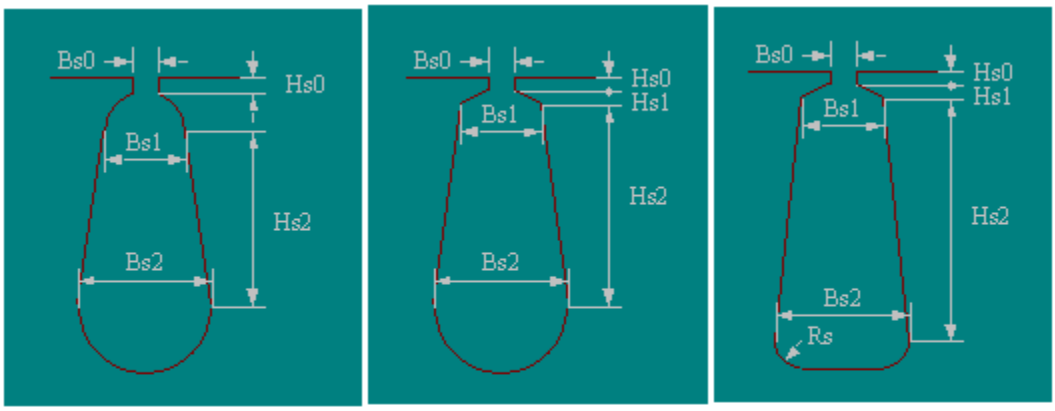
Outer Diameter	The outer diameter of the rotor core.
Inner Diameter	The inner diameter of the rotor core.
Length	The length of the rotor core.
Stacking Factor	Stacking factor of the rotor core.
Steel Type	Select a steel type for the rotor core material.
Press Board Thickness	Magnetic press board thickness, 0 for non-magnetic press board.
Indexing Slots	Number of indexing slots of the rotor core used to determine slot

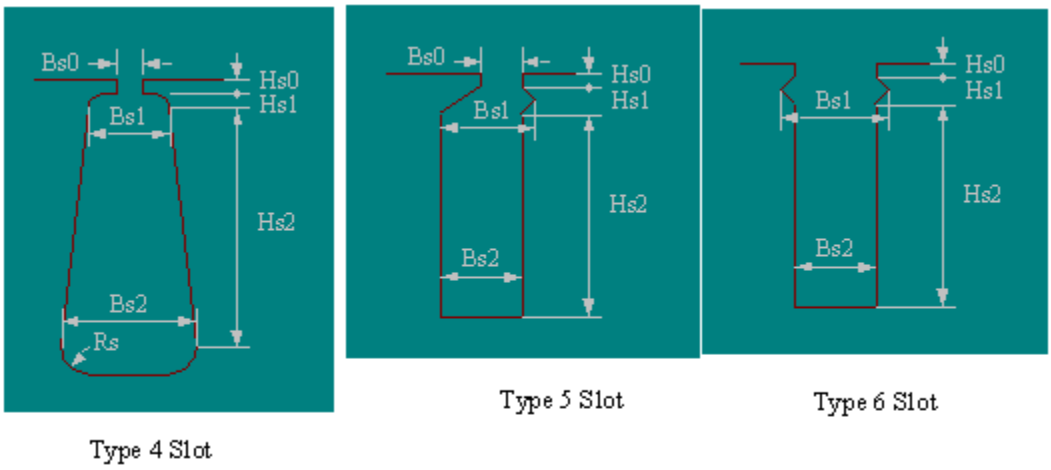
	pitch.
Real Slots	Number of Slots of the rotor core.
Slot Type	Slot type of the rotor core. There are six types of rotor slots.

Define NSSM Rotor Slot

Double-click the icon **Machine>Rotor>Slot** in the project tree to display the **Properties** dialog box.

In the **Slot** tab, define the available rotor slot dimensions as illustrated. There are in total six types of slots that are available:





Related Topics

Define NSSM Rotor Winding

Define NSSM Rotor Winding

The rotor winding is equipped on the rotor pole to provide the excitation for the magnetic field.

Double click the icon **Machine>Rotor>Winding** in the project tree to display the **Properties** dialog box, where you define the wires and physical dimensions of the rotor winding.

In the **Winding** tab, the following are defined:.

Parallel Branches	The number of parallel branches in the rotor winding.
Conductors per Slot	The number of conductors per slot (0 for auto-design).
Number of Strands	The number of wires per conductor (0 for auto-design).
Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
Wire Size	Wire size (0 for auto-design). You can assign wire size of round wires or rectangle wires. When you select Round Wire for Winding Type, round wires are used ((refer to section 8.4.1 Assign Round Wire Sizes). Otherwise, rectangle wires are used (refer to section 8.4.2 Assign Rectangular Wire Size).

In the **End/Insulation** tab the following are defined:

Input Half-turn Length	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the row **Half Turn Length** appears the next time you open the **Properties** dialog box. When this check box is cleared, the row **End Adjustment** appears instead.
Half-turn Length	The half-turn length of the armature winding. It is available when **Input Half-turn Length** is selected.
End Adjustment	One-side end extended length.
Inner Fillet Radius	Inner fillet radius at the span corner.
End Clearance	End clearance between two adjacent coils.
Coil Wrap	Insulation: single-side coil wrap thickness.
Slot Liner	Insulation: slot liner thickness.
Wedge Thickness	Insulation: wedge thickness.
Bottom Insulation	Insulation: bottom insulation thickness.
Limited Cross Height	The limited cross-section height for the winding design or arrangement, or Overall Height as shown in Figure 12.12 (0 for available maximum area).

Winding Fillet	The size of the winding fillet.

Related Topics

Define NSSM Shaft Data

Rotor Vent Data for NSSMs

By option, you can add vents to a rotor in a three-phase NSSM.

To add a vents to the rotor:

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Insert Vent**.
   The vent icon appears in the project tree under the rotor.

To remove a vent to stator in a three-phase induction motor.

1. Select the rotor icon in the project tree.
2. Right-click to display the pop-up menu and select **Remove Vent**.
   The vent icon disappears in the project tree under the stator.

The Vent data for the NSSM rotor includes the following fields.

Surface Ducts	Number of surface tangential vent ducts
Surface Duct Width	Width of surface tangential vent ducts
Surface Duct Depth	Depth of surface tangential vent ducts
Surface Duct Pitch	Pitch of surface tangential vent ducts
Axial Ducts	Number of axial vent ducts per pole
Axial Duct Width	Width of axial vent ducts in main teeth
Axial Duct Depth	Depth of axial vent ducts in main teeth

Define NSSM Shaft Data

To define the shaft:

1. Click the icon **Machine>Shaft** in the project tree to display the **Properties** dialog box.
2. In the tab sheet Shaft, select or clear the check box **Magnetic Shaft** to specify whether or not the shaft is to be made of the magnetic material.
3. Click **OK** to close the **Properties** dialog box.

Analysis Setup for Three-Phase Non-Salient Synchronous Machines

Add Solution Setup for NSSM

To set up the solution data:

1. Right click the icon Analysis in the project tree, then click Add Solution Setup from the shortcut menu to display the dialog box Properties. There are two tab sheets.
2. On the **General** tab, define the solution setup data.

Operation Type	Two options from the pull-down list: Generator and Motor.
Load Type	Select a load type for the motor or generator from the pull-down list (refer to section 7.8 Assign Load Types).
Rated Apparent Power	The output electric apparent power in kVA developed at the terminal for the generator, or **Rated Output Power**: The output mechanical power in kW developed at the shaft for the motor.
Rated Voltage	The RMS line-to-line voltage.
Rated Speed	The desired synchronous speed.
Operating Temperature	The temperature at which the system functions, and select the units. The Operating Temperature will affect all winding resistances and therefore affect all ohmic losses.

3. On the **NSSM** tab, define the connection data:

Rated Power Factor	The rated power factor. For generators, the rated output power is determined by the rated apparent power multiplying the rated power factor.
Winding Connection	Select Wye or Delta from the pull-down list.
Exciter Efficiency	The percentage efficiency of the exciter used to supply the rotor winding with the DC current if it is mechanically connected to the shaft of the generator. The efficiency value ranges between 0% and 100% and will only affect the total efficiency result.
Input Exciting Current	If the check box is selected, the companying edit box is enabled. You need to input the exciting current value and select the units if needed.
Exciting Current	Exciting current for rated operation.

4. Click OK to close the pop-up dialog box

Validate NSSM Solution Setup

1. Click **RMxprt>Validation Check** to display the information box Validation Check.
2. If any items do not pass validation, use the diagnostic information in the window to resolve any issues.
3. Click Close to close the information box Validation Check.
4. When the design has been validated, click RMxprt>Analyze All.
5. The analysis progress is shown in the Progress window and the analysis message is shown in the Message Manager.

Design Output for Non-Salient Synchronous Machines

When **RMxprt** has completed a solution, you can display and analyze the results in the following ways:

View Performance

To view the solutions:

Click **RMxprt>Results>Solution Data** to display the information box Solutions. It has three tab sheets.

In the tab sheet Performance, from the pull-down list Data, you have 13 different data tables for the line start permanent magnet motor, which can be used to define Output Variables for design optimization:

- FEA input Data
- Field Winding
- Full-load Magnetic Variables
- Important Factors
- Material Consumption
- No-load Magnetic Variables
- Rated Operation
- Stator Slot
- Stator Winding
- Steady State Parameters per Unit
- Transient Data
- Transient Data per Unit
- Unsaturated Steady State Parameters

View Design Sheet

In the tab sheet Design Sheet, you have 12 sets of information, as follows:

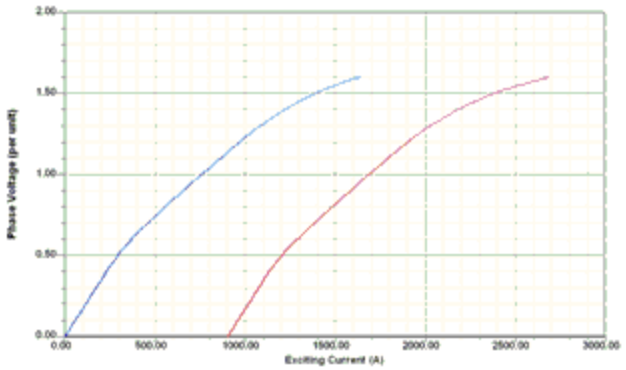
- General Data
- Stator Data
- Stator Winding Data
- Rotor Data
- Field Winding Data
- Some Factors and Material Consumption
- Unsaturated Steady State Parameters
- No Load Magnetic Data
- Full Load Magnetic Data
- Full Load Electric Data
- Transient Parameters and Time Constants
- Transient FEA Input Data

Note	To print the **Design Sheet**: Right click the **Design Sheet**, select **Print** from the shortcut menu, select the printer and other parameters from the dialog box **Print**, and click **OK** to print.

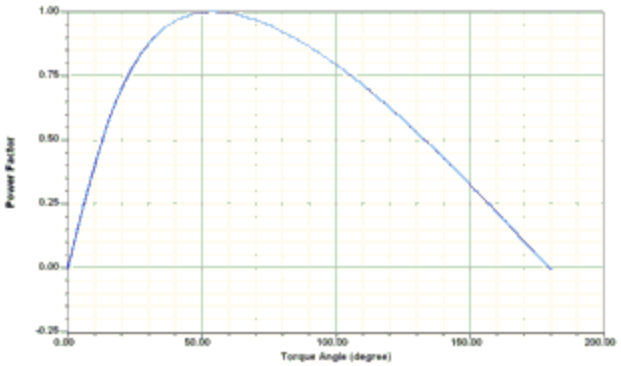
View Curves

In the tab sheet **Curves**, from the pull-down list Name, you have 10 curves as shown:

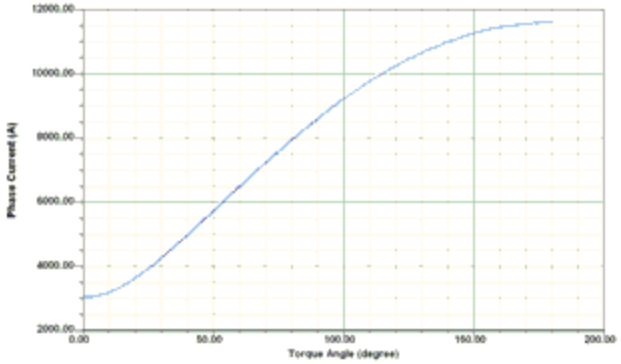
Phase Voltage vs Exciting Current



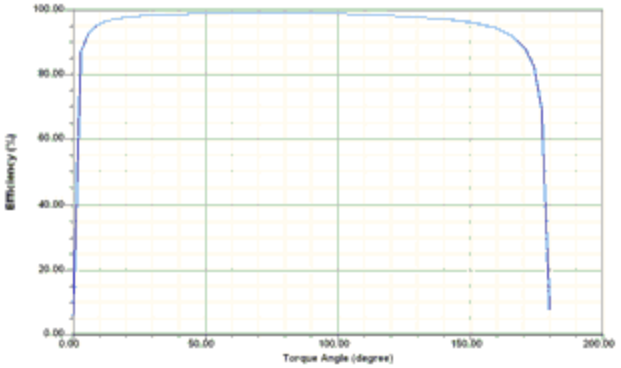
Power Factor vs Torque Angle



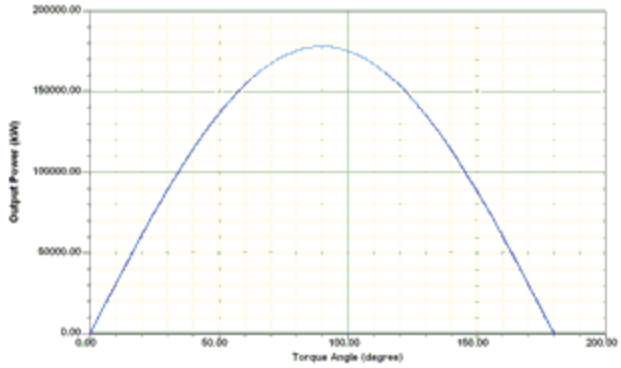
Armature Phase Current vs Torque Angle



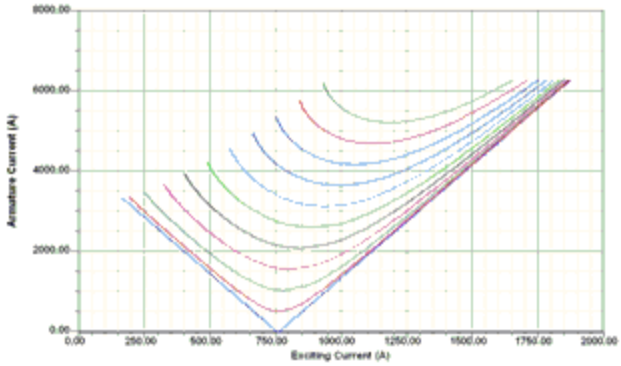
Efficiency vs Torque Angle



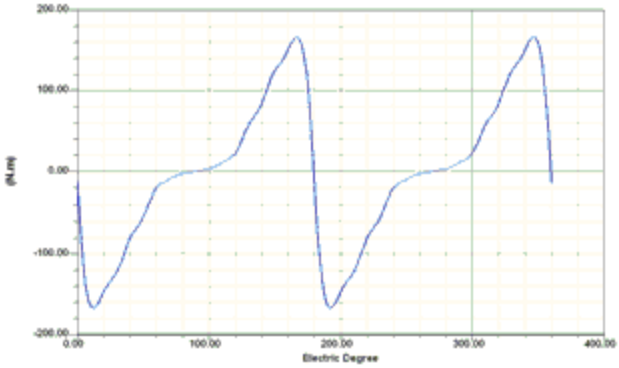
Output Power vs Torque Angle



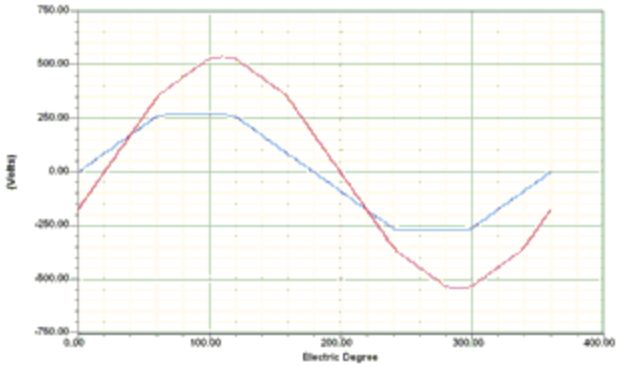
Armature Current vs Exciting Current



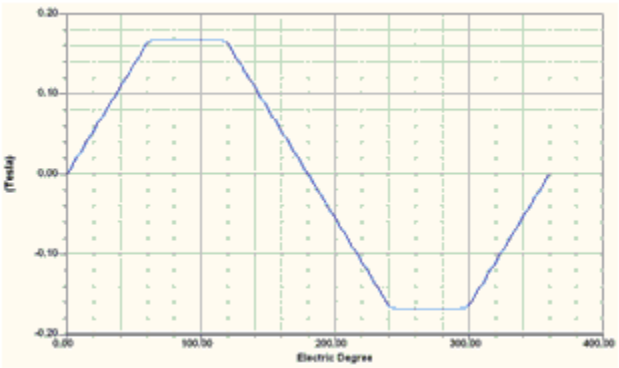
Cogging Torque in Two Teeth



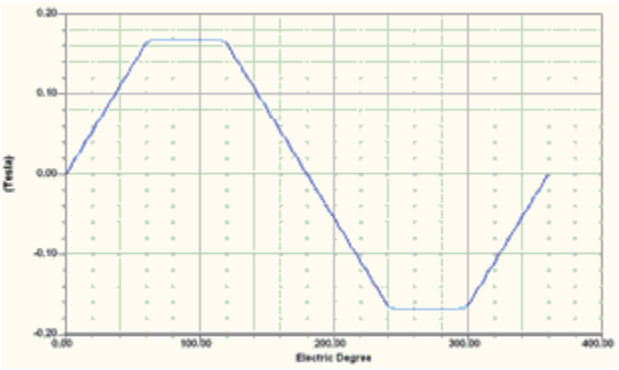
Induced Coil Voltages at No Load



Air-Gap Flux Density at No-Load



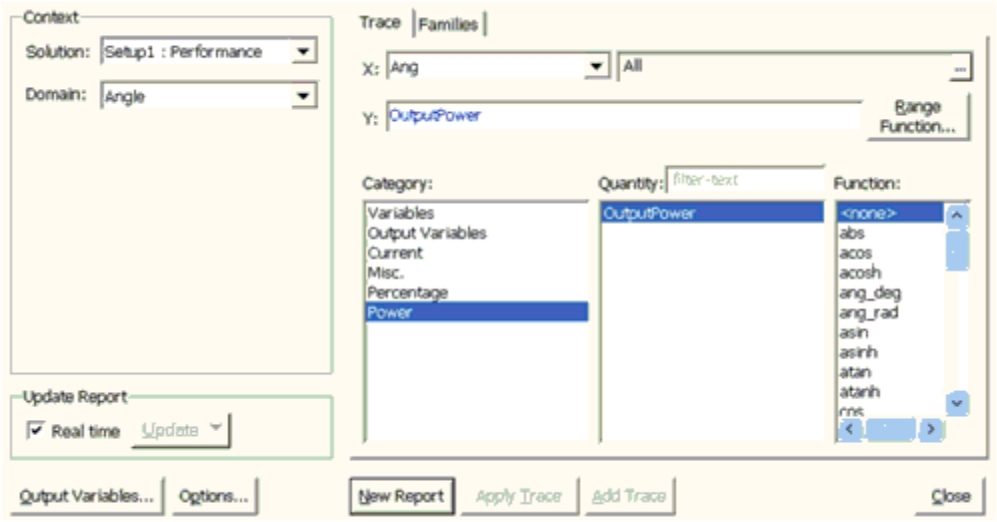
Induced Winding Voltages at No-Load



Note	To print the plots from the **Curve**: Right click on the plot, select **Print** from the shortcut menu, select the printer and other parameters from the dialog box **Print**, and click **OK** to print.

Create Reports

1. Click **RMxprt>Results>Create RMxprt Report>Rectangular Plot**.
   The dialog box **Report** appears as shown:



2. Under the tab sheet **Trace**, there are **Variables, Output Variables, Current, Misc, Percentage, and Power** under the **Category** column. Select one from the **Category** column, select the traces that belong to it from the **Quantity** column, and click the button **Add Trace** to add them one by one. Finally click the button **New report** to create the plot. You can always add additional curves to the same plot by repeating the process.
3. Double click the icon **Results>XY Plot1** to display the graph with multiple traces in a new window.

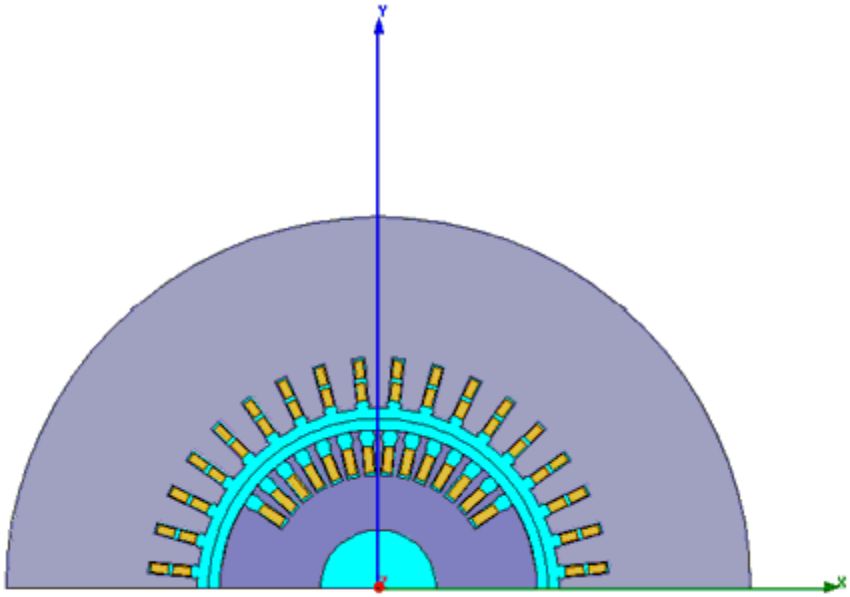
Note	To print the plots from the **Curves**: Right click on the plot, select **Print** from the shortcut menu, select the printer and other parameters from the dialog box **Print**, and click **OK** to print. To get a screen shot of from the **Curves**: Right click on the plot, select **Copy Image**, then paste to a destination file.

Transient FEA of the Non-Salient Synchronous Machines

If you expect to continue the transient or electromagnetic-field FEA with Maxwell2D, you can create a Maxwell2D design directly from RMxprt. For transient FEA, RMxprt can create a Maxwell2D design with all setups completed.

Create Maxwell 2D Design

Click the command **RMxprt>Analysis Setup>Create Maxwell Design…** in RMxprt to create a Maxwell2D design with Auto setup checked (refer to subsection 5.2.1 Create Maxwell 2D Design). A Maxwell2D design called Maxwell2DDesign1 is created with the displayed geometry as shown below. All setups are automatically completed by RMxprt.



Review Maxwell2D Design Setups

This section reviews all setups automatically completed by RMxprt. For detailed setup process, please refer to **APPENDIX Setup Maxwell 2D Designs**.

Solution Type Setup

Click **Maxwell 2D>Solution Type…** in Maxwell2D, you can review that the **Solution Type** is set as **Magnetic Transient**.

Model Setup

1. Model Depth

   Click **Maxwell 2D>Design Setting…** in Maxwell2D and click **Set Model Depth…** tab to review the Model Depth: 3590 mm.
2. Motion Type

   Double click on **Maxwell2DDesign1>Model>MotionSetup1** in the Project Manager window. In the **Type** tab you can review the **Motion Type** being set as **Rotation**, and the **Moving Vector** as **Positive Global: Z**.
3. Initial Position

In the **Data** tab of the **Motion Setup** panel you can review the **Initial Position** being set as **100** deg with **Rotate Limit** unchecked. The rotor initial position is set to such a position that the initial flux linkage of the phase-A winding is at its negative maximum value.

4. Mechanical Load

   In the **Mechanical** tab of the **Motion Setup** panel you can review the **Angular Velocity** being set as **3000** rpm with **Consider Mechanical Transient** unchecked.

5. Symmetry Multiplier

   Right click on **Maxwell2DDesign1>Model** in the Project Manager window, and select **Set Geometry Multiplier** in the pop-up panel, you can review that the **Symmetry Multiplier** is set as **2**.

Boundary Setup

1. Vector Potential Boundary

   Double click on **Maxwell2DDesign1>Boundaries>VectorPotential1** in the Project Manager window, you can review that the highlighted outer half circle in the geometry is set as the **Vector Potential Boundary**, and its value is set as **0**.

2. Independent Boundary

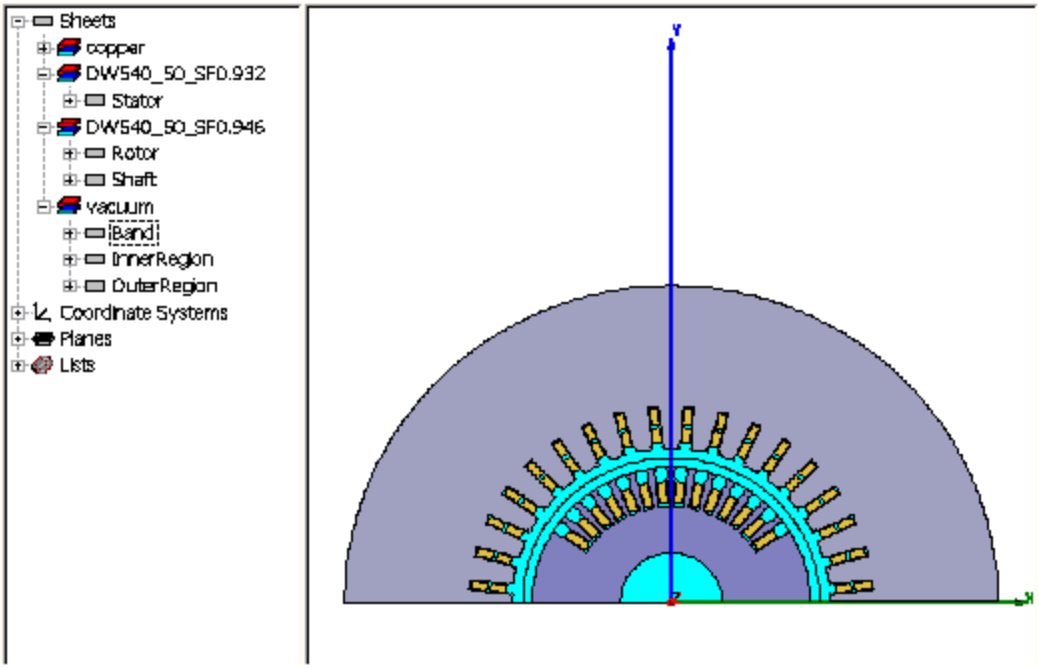
   Click on **Maxwell2DDesign1>Boundaries>Independent1** in the Project Manager window, you can review that the highlighted arrowhead line from left to right in the geometry is set as the **Independent Boundary**.

3. Dependent Boundary

   Double click on **Maxwell2DDesign1>Boundaries>Dependent1** in the Project Manager window, you can review that the highlighted arrowhead line from right to left in the geometry is set as the **Dependent Boundary**, and the relation of the dependent boundary to the independent boundary is set as
   Bs = -Bm. This is because the geometry includes only 1 magnetic pole of the machine.

Material Assignment

In the Maxwell2D modeler windows history tree, you can see that all stator and rotor coil terminals are assigned to material copper by default. **Band**, **InnerRegion** and **OuterRegion** are assigned as vacuum as shown:



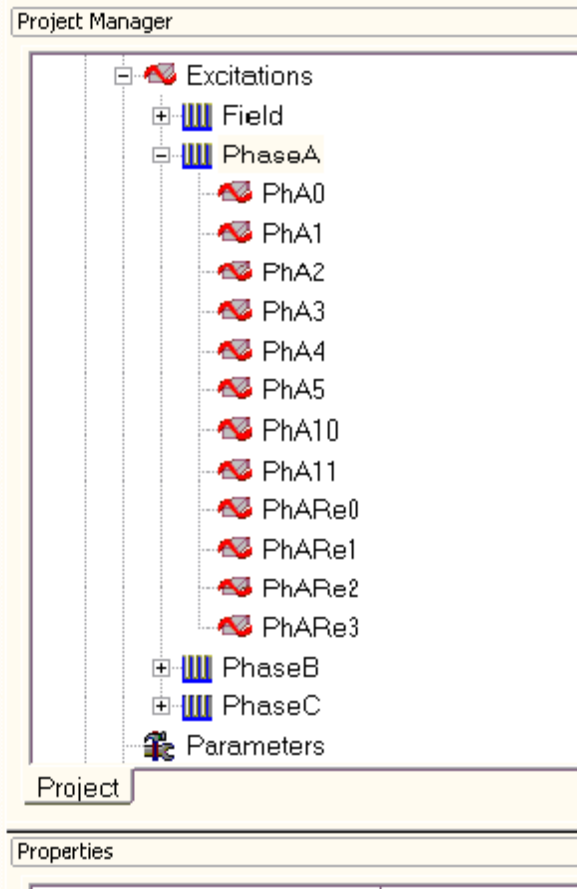
Two new materials called DW540_50_SF0.932, and DW540_50_SF0.946 are automatically created for **Stator** and **Rotor**, based on the original material of DW540_50 used in RMxprt and the equivalent stacking factors of 0.932 and 0.946. Shaft is also assigned as DW540_50_SF0.946, because the shaft is defined as magnetic in RMxprt.

Excitation Setup

1. Windings

   Click on **Maxwell2DDesign1>Excitations>PhaseA** in the Project Manager window, all objects assigned to this phase are highlighted in the modeler window. In the Properties window, you can review all winding properties: **Voltage** for **Winding Type**; **Stranded** for **IsSolid**; **0.00226117** ohms for **Resistance**; **8.87325e-005** H for **Inductance**; **1** for **Number of Parallel Branches**; 11267.7 * sin(2*pi*50*time-43.4944*pi/180) for **Voltage**, where **50** is the **frequency** in Hz, **11267.7** is the **phase peak voltage** in Volts, **pi** is a predefined constant, and **time** is a predefined variable for time. By using sin function instead of cos function, the applied voltage and back EMF are in phase. Therefore, a phase shift in the applied voltage source will be the power angle of the motor. 43.4944 degrees is the power angle at full load operation. The values for resistance, inductance and number of parallel branches are obtained from the TRANSIENT FEA INPUT DATA section in RMxprt design sheet.

   Clicking on **PhaseB**, **PhaseC**, or **Field**, you can review all objects assigned to this winding in the modeler window, and winding properties in the **Properties** window.

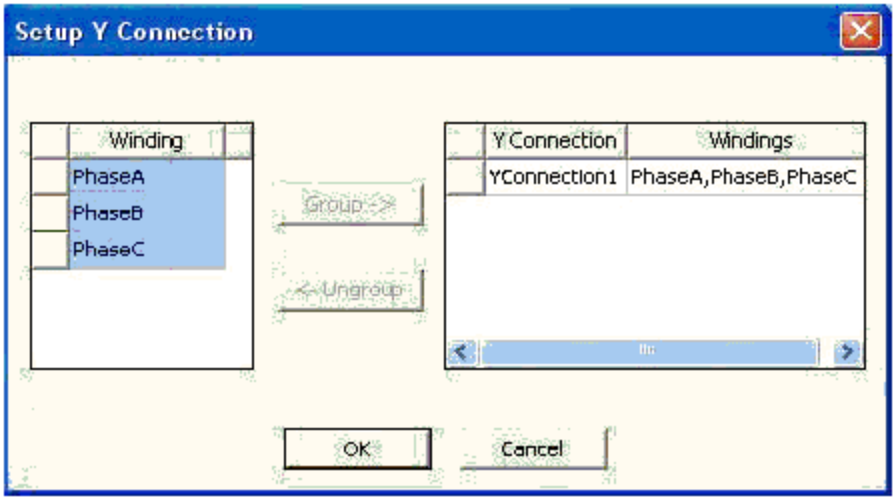


2. Coil Terminals

   A winding consists of several coil terminals, and two coil terminals represent a coil in a complete 2D model. Since we are working with only one-half of the motor structure, one coil terminal can represent one complete coil with independent/dependent boundary conditions provided. A coil terminal has properties of **Number of Conductors** and **Polarity Type**. **Number of Conductors** is the number of turns per coil, and it is equal to the **Number of Turns** given in RMxprt divided by number of coils per phase. **Polarity Type** defines the direction of the current in the coil; it can be either positive or negative. Expand a winding and click on a coil terminal, you can review the object corresponding to this coil terminal in the modeler window and all coil terminal properties in the **Properties** window. In this example, **Number of Conductors** of A, B, and C coil terminals is assigned as 1, and it is 12 for the Field windings. Click on **PhaseB**, **PhaseC**, or **Field**, you can review all objects assigned to this winding in the modeler window, and winding properties in the properties window.

3. Y Connection for Three-Phase Windings

   Right click on **Maxwell2DDesign1>Excitations** in the Project Manager Window, and click **Setup Y Connection…** in the pop-up panel, you can review the Y -connection setup.



Mesh Operation Setup

Maxwell2D mesh maker can create meshes according to predefined mesh operations. A mesh operation defines one or more conditions for some selected objects for mesh maker to create meshes that satisfy the conditions. RMxprt automatically sets up some mesh operations for different machine parts based on geometry sizes. For this example, mesh operations include Length_Coil (set maximum mesh length as 18 mm for all coils), Length_Field (set maximum mesh length as 19 mm for field winding coils), Length_Main (set the maximum mesh length as 135 mm for all other parts), SurfApprox_Main (set the limited Surface Deviation as 1.175 mm and the limited Normal Deviation as 30 deg for all parts with true-surface arcs).

Click on one of the mesh operations under **Maxwell2DDesign1>Mesh** in the Project Manager window, you can review its properties in the Properties window.

Solution Setup

Click on **Maxwell2DDesign1>Analysis>Setup1** in the Project Manager window, you can review its properties in the Properties window: 0.2s for Stop time, that is 10 periods; 0.0002s for Time step with 100 steps per period.

Analyze Maxwell 2D Design

Before analyzing the Maxwell2D design, you may want to Generate Mesh and Plot Mesh. You may also want to create several Quick Reports to display results.

To analyze the Maxwell2D design: right click on **Maxwell2DDesign1>Analysis>Setup1** in the project tree, and click **Analyze**. While the design is being analyzed, you can update one or all result reports and view the reports.

To update all reports: right click on **Maxwell2DDesign1>Results** in the project tree, and select **Update All Reports**.

To update one report: right click on the report under **Maxwell2DDesign1>Results** in the project tree, and select **Update Report**.

To view all traces of a report: when you double click on the report under **Maxwell2DDesign1>Results** in the project tree, the Modeler window changes to the Results window, and all traces (a curve in a report is a trace) of the selected reports are displayed in the Results window.

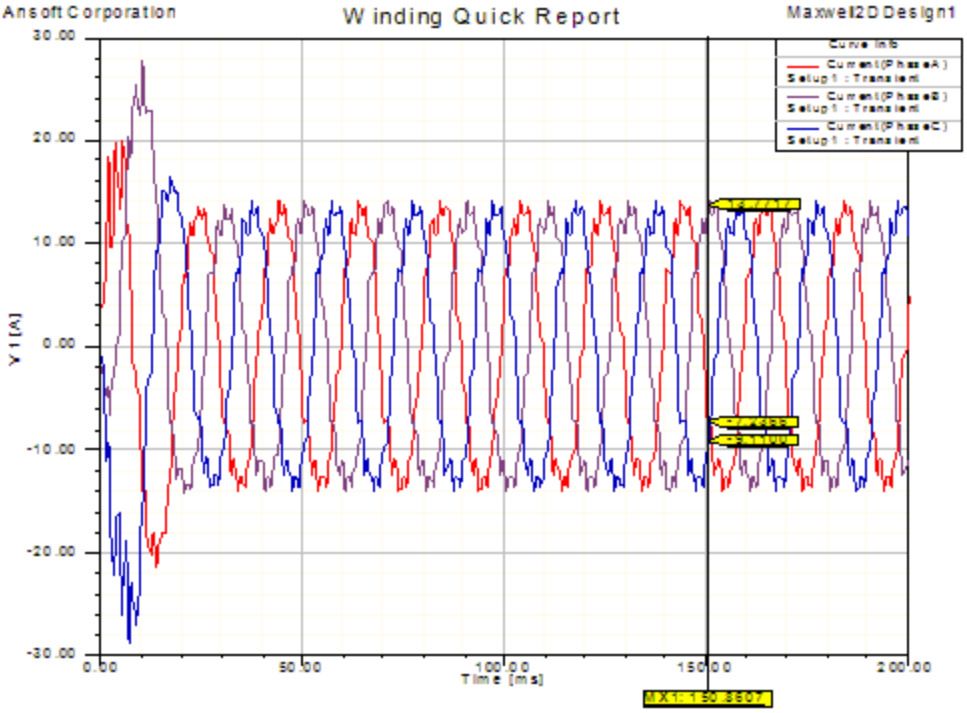
To view a trace of a report: when you click on a trace of a report under **Maxwell2DDesign1>Results** in the project tree, the selected trace is highlighted in the Results window.

To cancel the simulation: right click on the progress bar in the progress window, and pick up **Abort** in the pop-up panel.

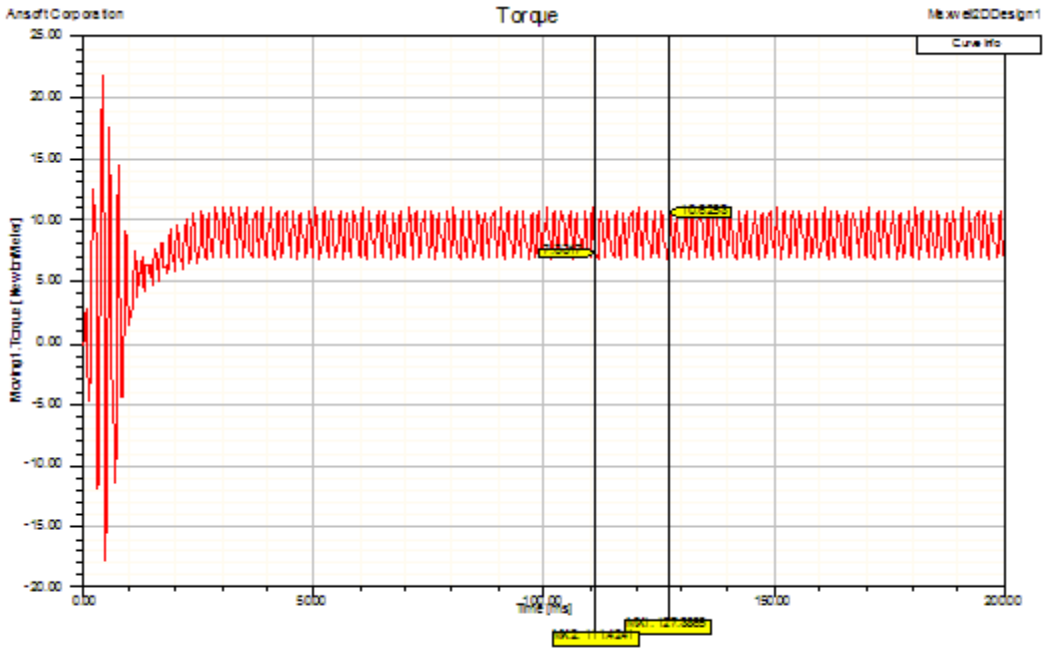
To stop the simulation so that you can continue the simulation later: right click on the progress bar in the progress window, and pick up **Clean Stop** in the pop-up panel.

For this example, the simulated three-phase currents and the electro-magnetic torque are shown in Figure 12.24 and 12.25, respectively.

Right click on the Winding Quick Report in the Results window, and pick up Marker>Add X Marker in the pop-up panel, yellow-shaded boxes are added in the report to indicate X and all Y values. Click on the X box (or the vertical line), and drag it to some place where you see the steady-state peak value of a phase current as shown:



Add X makers in Torque Quick Report to indicate the steady-state maximum and minimum values of torque as shown below. The average torque can be approximately obtained from the maximum and minimum values as Tav = (Tmax + Tmin) / 2 = (10.63 + 7.33) / 2 = 8.98 Nm.



Generic Rotating Machines

The Generic Rotating Machine (GRM) templates allow you to define any of several machine types using the core types listed below.

Core Type	Description
SLOT_AC	Slotted core with AC winding
SLOT_CAGE	Slotted core with squirrel-cage damper
SALNT_POLE	Salient-pole core with field winding
PM_INTERIOR	Interior permanent magnet core
SOLID	Solid core with/without copper/hysteresis sleeve
AXIAL_AC	Axial-flux slotted core with AC winding
AXIAL_CAGE	Axial-flux slotted core with squirrel-cage damper
AXIAL_PM	Axial-flux permanent magnet core
NONS_RELU	Non-salient reluctance core without winding

The machine templates that can be selected, with their associated core type combinations, source types, and position control usage, are listed in the following table.

Note	Refer to "Defining a Generic Rotating Machine" below for detailed information on selecting GRM templates and defining the corresponding machine types.

GRM Machine Type	Stator Type / Rotor Type	Source Type	Position Control
Inner-Rotor Induction Machine	SLOT_AC / SLOT_CAGE	AC	No
Outer-Rotor Induction Machine	SLOT_AC / SLOT_CAGE	AC	No
Solid-Rotor Induction Machine	SLOT_AC / SOLID	AC	No
Wound-Rotor Induction Machine	SLOT_AC / SLOT_AC	AC	No
Double-Fed Induction Generator	SLOT_AC / SLOT_AC	AC	No
Axial-Flux Induction Machine	AXIAL_AC / AXIAL_CAGE	AC	No
Hysteresis Machine	SLOT_AC / SOLID	AC	No
Rotating-Field Synchronous Machine	SLOT_AC / SALNT_POLE	AC	No
Rotating Armature Synchronous Machine	SLOT_AC / SALNT_POLE	AC	No
Reluctance Synchronous Machine	SLOT_AC / NONS_RELU	AC	No
IPM Synchronous Machine	SLOT_AC / PM_INTERIOR	AC	No

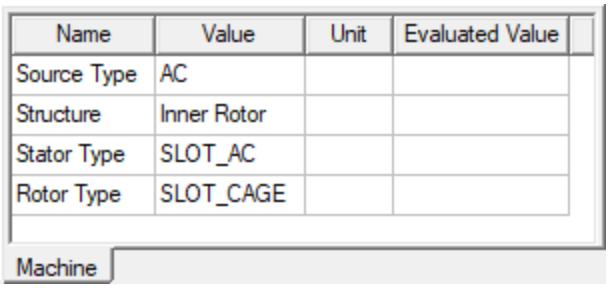
Defining an Inner-Rotor Induction Machine

Note	Refer to "Analysis Approach for Three-Phase Induction Motors" on page 26-510 for general information on this machine type.

The general procedure for defining an Inner-Rotor Induction Machine is as follows:

1. Insert an **Inner-Rotor Induction Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **Inner-Rotor Induction Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:



3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, winding, and optionally, vent for the SLOT_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core, damper and damper slot, and optionally, vent for the SLOT_CAGE core type.

5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
7. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
8. Choose **File>Save** to save the project.
9. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

Analysis Approach for Three-Phase Induction Motors

For a three-phase induction motor, the stator winding (with a sinusoidal spatial distribution and *p* pairs of poles) is connected to a three-phase symmetric voltage power supply. The resulting currents in the stator produce a rotating magnetic field. The rotor winding is often a squirrel cage type with the number of poles dictated by the number of poles in the stator. Currents are induced in the rotor bars and produce, in turn, a second rotating magnetic field. The two rotating fields produce a resultant rotating magnetic field in the air gap of the machine. The interaction of this field in the air gap with the rotor bar currents produces an electromagnetic torque, which acts on the rotor in the direction of the rotation of the field in the air gap. A torque of equal value acts upon the stator in the opposite direction.

The stator winding, which is connected to a phase of the supply system, has *p* coils, each with a symmetric spatial distribution and an opening of $\pi D/2p$, where *D* is the diameter of the winding. In this case, the magnetic field in the air gap has *p* periods, and the winding has *p* pairs of poles.

The performance of three-phase induction motors (IndM3) is analyzed based on the equivalent circuit of one phase in the frequency domain as shown in Figure 1.

In the figure, R1 is the stator resistance, X1 is stator leakage reactance, which consists of stator slot leakage reactance, end-winding leakage reactance, and differential leakage reactance. X2 and R2 are rotor leakage reactance and rotor resistance, respectively. X2 includes rotor slot leakage reactance, end-ring leakage reactance, differential leakage reactance, and skewing leakage reactance. Due to the saturation of the leakage field, X1 and X2 are nonlinear. The

parameters in the equivalent circuit are dependent on the stator and rotor currents. Due to the skin effects, X2 and R2 are the equivalent values from a distributed-parameter circuit, as shown in Figure 2.

They vary with the rotor slip s. All rotor parameters have been referred to the stator side.

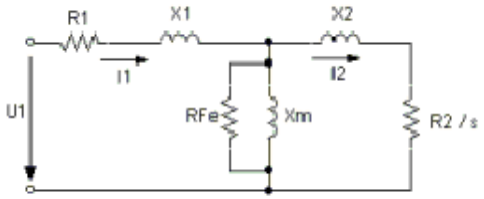

Figure 1

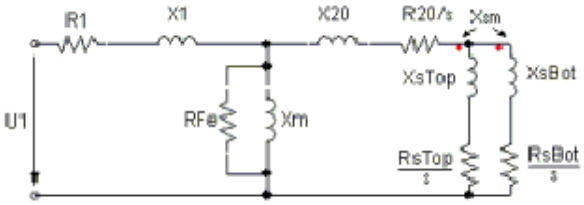

Figure 2

In the exciting branch, Xm is the magnetizing reactance, and RFe is the resistance corresponding to iron-core losses. Xm is a linearized nonlinear parameter that varies with the saturation of the main field.

After a phase voltage U1 is applied to the phase terminals, stator phase current I1 and rotor current I2, which has been referred to the stator, can be easily computed by the circuit analysis. The electromagnetic power Pm, or air-gap power, is computed by the following:

```
Pm = 3 * I2^2 * R2/s
```

The electromagnetic torque Tm is:

$$Tm = Pm / \omega$$

where w is the synchronous speed in rad/s.

The output mechanical shaft torque T2 is:

```
T2 = Tm - Tfw
```

where Tfw is the frictional and wind torque.

The output power is:

$$P2 = T2 * \omega_2$$

where $\omega_2 = \omega * (1 - s)$ and is rotor speed in rad/s.

The input power is:

```
P1 = P2 + Pfw + Pcu2 + PFe + Pcu1 + Ps
```

where Pfw, Pcu2, PFe, Pcu1, and Ps are frictional and wind loss, rotor copper loss, iron-core loss, stator copper loss, and stray loss, respectively.

The power factor is derived from:

```
PF = P1/(m * U1 * I1)
```

The efficiency is computed by:

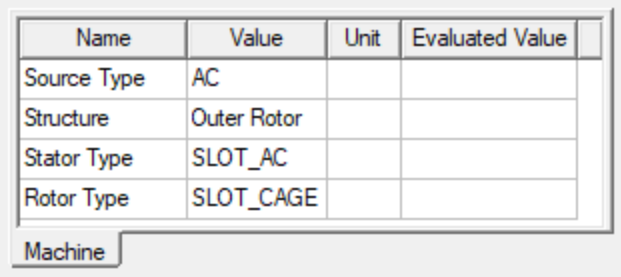
```
eff = P2/P1 * 100%
```

Defining an Outer-Rotor Induction Machine

Note	Refer to "Analysis Approach for Three-Phase Induction Motors" on the next page for general information on this machine type.

The general procedure for defining an Outer-Rotor Induction Machine is as follows:

1. Insert an **Outer-Rotor Induction Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **Outer-Rotor Induction Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:



Name	Value	Unit	Evaluated Value
Source Type	AC		
Structure	Outer Rotor		
Stator Type	SLOT_AC		
Rotor Type	SLOT_CAGE		

Machine

3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, winding, and optionally, vent for the SLOT_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core, damper and damper slot, and optionally, vent for the SLOT_CAGE core type.
5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
7. Choose **File>Save** to save the project.
8. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

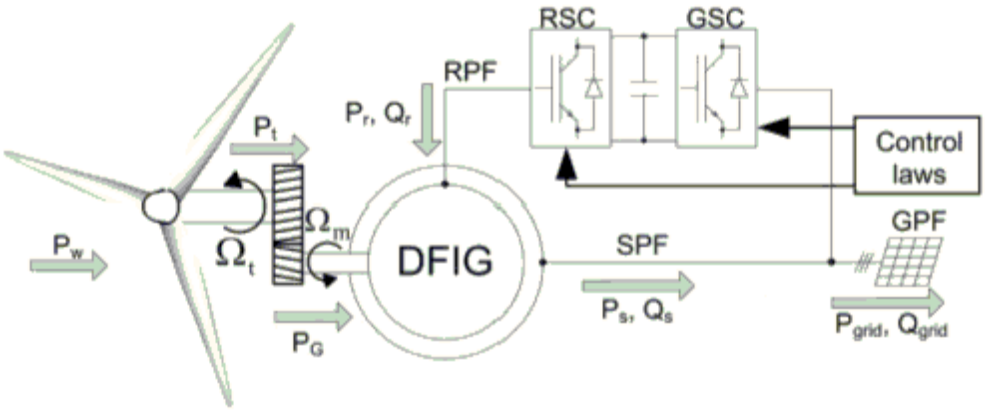
Analysis Approach **for a Doubly Fed Induction Generator**

A Doubly Fed Induction Generator (DFIG) can be configured to operate as any of the following types:

- Generator

DFIG Operating as a Generator

Doubly-fed induction generators (DFIGs) are widely used in wind power systems. A DFIG works as a component of a wind power system, as shown below, where the wind turbine transforms wind energy into mechanical energy, and the DFIG transforms mechanical energy into electrical energy.



For a DFIG, both the stator and the rotor are equipped with poly-phase AC windings. The stator and rotor windings may, or may not, have the same number of phases, but they must have the same number of poles *p*. In order to produce terminal voltages with desired frequency *f* in the stator winding, the rotor winding must be excited by balanced poly-phase currents with the slip frequency sf via an AC-DC-AC convert. Slip *s* is defined as:

$$s = 1 - n/n_0$$

where *n* is the rotor speed, and n_0 is the synchronous speed as given below:

$$n_0 = 60f/p$$

When the rotor speed is *lower* than the synchronous speed, the rotor currents have the same phase sequence as the stator currents, and the rotor winding gets power from the converter. However, when the rotor speed is *higher* than the synchronous speed, the phase sequence of the rotor currents is different from that of the stator currents, and the rotor winding outputs power to the converter.

For a given wind turbine, the power coefficient (the ratio of turbine power to the wind power), is a function of the tip speed ratio (the ratio of the blade tip speed to the wind speed). In order to track the maximum power point, the tip speed ratio must keep constant - at its optimal value. The input mechanical power with Maximum Power Point Tracking (MPPT) must satisfy:

$$P_{mech} = P_{m\_ref} \cdot (\omega_m / \omega_{ref})^3$$

where P_{m_ref} is the turbine power with MPPT at a reference speed of ω_{ref} based on the optimal tip speed ratio, and ω_m is the rotor speed in rad/s.

The rotor mechanical loss is:

$$P_f = P_{f\_ref} \cdot (\omega_m / \omega_{ref})^3$$

where P_{f_ref} is mechanical loss measured at a reference speed of ω_{ref}.

The electro-magnetic power in the air gap is:

$$P_{em} = (P_{mech} - P_f) / (1 - s)$$

Therefore, the stator output electrical power at rated operation is:

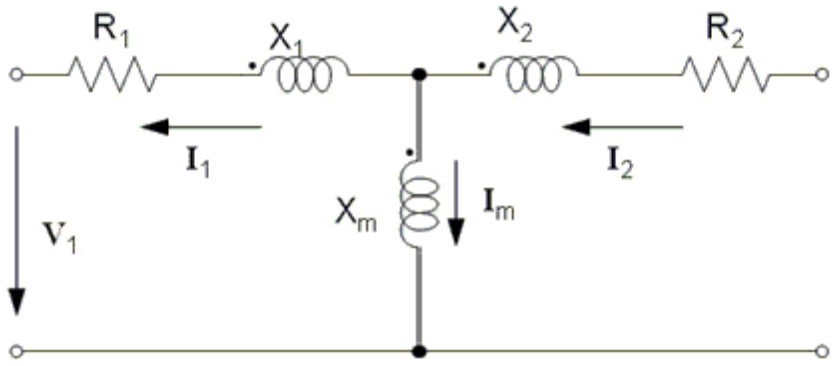
$$P_1 = P_{em} - m_1 I_1^2 R_1 = m_1 V_1 I_1 \cos\varphi$$

where m_1 is the number of phases of the stator winding, R_1 is the stator phase resistance, V_1 is the stator rated phase voltage, I_1 is the rated stator phase current to be determined, and $\cos\varphi$ is the rated power factor. Solving for I_1, one obtains:

$$I_1 = \frac{2P_{em} / m_1}{V_1 \cos\varphi + \sqrt{(V_1 \cos\varphi)^2 + 4R_1 P_{em} / m_1}}$$

Then, based on the equivalent circuit shown below, one obtains:

$$\mathbf{V}_1 = V_1 \angle 0$$
$$\mathbf{I}_1 = I_1 \angle -\varphi$$
$$\mathbf{E}_m = \mathbf{V}_1 + \mathbf{I}_1 (R_1 + jX_1)$$
$$\mathbf{I}_m = (\mathbf{E}_m / X_m(E_m))$$
$$\mathbf{I}_2 = I_2 \angle -\varphi_2 = \mathbf{I}_1 + \mathbf{I}_m$$



Now, rotor input electrical power can be computed as:

$$P_2 = sP_{em} + m_2 I_2^{\ 2} R_2$$

where m_2 is the number of phases of the rotor winding.
The electromagnetic torque T_{em} is:

$$T_{em} = \frac{P_{em}}{\omega}$$

where ω ? denotes the synchronous speed in rad/s.
The input mechanical torque on the shaft is:

$$T_{mech} = T_{em} + T_f$$

where T_f denotes the frictional torque.
The total electrical output power is:

$$P_{elec} = P_1 - P_2 - p_{Fe}$$

where p_{Fe} is the core loss.

The efficiency is defined as:

$$\eta = \frac{P_{elec}}{P_{mech}} \times 100\%$$

Defining an Axial-Flux Induction Machine

Note	Refer to "Analysis Approach for Three-Phase Induction Motors" on page 26-510 for general information on this machine type.

The general procedure for defining an Axial-Flux Induction Machine is as follows:

1. Insert an **Axial-Flux Induction Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **Axial-Flux Induction Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:

Name	Value	Unit	Evaluated Value
Source Type	AC		
Structure	Axial-Flux Rotor		
Stator Type	AXIAL_AC		
Rotor Type	AXIAL_CAGE		
Double-Sided	None		
Air Gap Length	0	mm	0mm

Machine

3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, and winding for the AXIAL_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core, damper and damper slot for the AXIAL_CAGE core type.
5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
7. Choose **File>Save** to save the project.
8. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

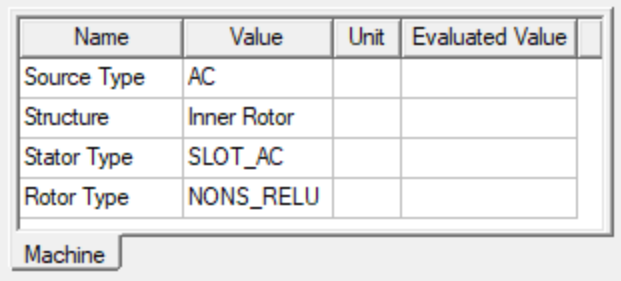
Defining a Reluctance Synchronous Machine

Note	Refer to "Analysis Approach for Three-Phase Synchronous Machines" on page 26-323 for general information on this machine type.

The general procedure for defining a Reluctance Synchronous Machine is as follows:

1. Insert a **Reluctance Synchronous Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **Reluctance Synchronous Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:



3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, winding, and optionally, vent for the SLOT_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core and pole for the NONS_RELU core type.
5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.

6. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
7. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
8. Choose **File>Save** to save the project.
9. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

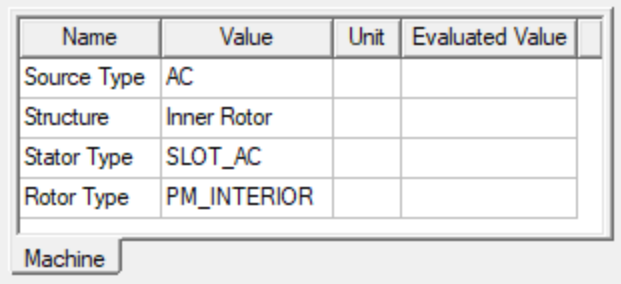
Defining an IPM Synchronous Machine

Note	Refer to "Analysis Approach for Three-Phase Synchronous Machines" on page 26-323 for general information on this machine type.

The general procedure for defining an IPM Synchronous Machine is as follows:

1. Insert an **IPM Synchronous Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **IPM Synchronous Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:



3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, winding, and optionally, vent for the SLOT_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core and pole for the PM_INTERIOR core type.

5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
7. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
8. Choose **File>Save** to save the project.
9. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

Defining an Axial-Flux PM Synchronous Machine

Note	Refer to "Analysis Approach for Three-Phase Synchronous Machines" on page 26-323 for general information on this machine type.

The general procedure for defining an Axial-Flux PM Synchronous Machine is as follows:

1. Insert an **Axial-Flux PM Synchronous Machine** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **Axial-Flux PM Synchronous Machine** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:

Name	Value	Unit	Evaluated Value
Source Type	AC		
Structure	Axial-Flux Rotor		
Stator Type	AXIAL_AC		
Rotor Type	AXIAL_PM		
Double-Sided	None		
Air Gap Length	0	mm	0mm

Machine

3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, and winding for the AXIAL_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core, damper and damper slot for the AXIAL_PM core type.
5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.
7. Choose **File>Save** to save the project.
8. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

Defining an IPM Brushless DC Motor

Note	Refer to "Analysis Approach for Brushless PMDC Motors" on page 26-351 for general information on this machine type.

The general procedure for defining an IPM Brushless DC Motor is as follows:

1. Insert an **IPM Brushless DC Motor** into a new or existing project by choosing **Generate RMxprt Solutions** for the **Design Flow**, **General** for the **Machine Type**, then select **IPM Brushless DC Motor** from the expandable list.
2. Click the **Machine** entry in the project tree to set the machine properties as shown:

Name	Value	Unit	Evaluated Value
Source Type	DC		
Structure	Inner Rotor		
Stator Type	SLOT_AC		
Rotor Type	PM_INTERIOR		

Machine

3. Click to expand the **Machine>Stator** entry in the project tree to define data for the stator and its associated core and core slot, winding, circuit, and optionally, vent for the SLOT_AC core type.
4. Click to expand the **Machine>Rotor** entry in the project tree to define data for the rotor and its associated core and pole for the PM_INTERIOR core type.
5. Click the **Machine>Shaft** entry in the project tree to define the magnetism, frictional and windage losses, and reference speed of the shaft.
6. Optionally, right-click the **Machine** entry in the project tree and click **Insert Housing** to add a machine housing.
7. Right-click **Analysis** in the project tree, and click **Add Solution Setup** to define the solution data.

8. Choose **File>Save** to save the project.
9. Choose **RMxprt>Analyze** to analyze the design.

Once analyzed, the model can be used to create a new Maxwell 2D or 3D design.

Generic Rotating Machine Core Types

The Generic Rotating Machine (GRM) templates allow you to define any of several machine types using the core types listed below.

Core Type	Description
SLOT_AC	Slotted core with AC winding
SLOT_CAGE	Slotted core with squirrel-cage damper
SALNT_POLE	Salient-pole core with field winding
PM_INTERIOR	Interior permanent magnet core
SOLID	Solid core with/without copper/hysteresis sleeve
AXIAL_AC	Axial-flux slotted core with AC winding
AXIAL_CAGE	Axial-flux slotted core with squirrel-cage damper
AXIAL_PM	Axial-flux permanent magnet core
NONS_RELU	Non-salient reluctance core without winding

Note	Refer to "Defining a Generic Rotating Machine" on page 26-504 for detailed information on selecting GRM templates and defining the corresponding machine types that use these core types.

"Defining a Generic Rotating Machine" on page 26-504

Defining Data for the SLOT_AC Core Type

The general procedure for defining a SLOT_AC core type is as follows:

1. Double-click the **Machine>Stator** (or **Machine>Rotor**, if applicable) entry in the project tree to define data for the stator (or rotor). The **Stator** (or **Rotor**) **Properties**dialog box contains the following fields:

Number of Poles	The number of poles on which the winding is wound. Default is 2.
Number of Slots	The number of slots of the iron core. Default is 18.
Circuit Type	The drive circuit type. Select from the following six types (default is Y3): • Y3: Y-Type, 3-Phase • L3: Loop-Type, 3-Phase • S3: Star-Type, 3-Phase • C2: Cross-Type, 2-Phase • L4: Loop-Type, 4-Phase • S4: Star-Type, 4-Phase **Note** When you place the mouse cursor over the circuit type, a circuit diagram of the selected type appears in the dialog,
Slot Type	The slot type of the iron core. Click the **Slot Type** button to open the **Select Slot Type** dialog box. Select the desired type. Default is Type 1. **Note** When you place the mouse cursor over the slot type, a diagram of the selected type appears in the dialog box, displaying the slot dimension variables. Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.
Position Control	Determines if the drive circuit is controlled by position signals from a position sensor. (Checked for **IPM Brushless DC Motor** core type. Unchecked for all other types.)

2. Double-click the **Core** entry in the project tree to define data for the stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Check the box if the press board is made of magnetic material.
Skew Width	The skew width measured in degrees.
Lamination Sectors	The number of lamination sectors.

3. Double-click the **Slot** entry in the project tree to define the stator slot dimensions. Enter the available slot dimensions.

   An image of the selected slot type showing the dimension labels is displayed on the Diagram tab. The dimensions properties that appear depend on the **Slot Type** (selected above) and on whether or not **Auto Design** or **Parallel Tooth** is selected:

Auto Design	Check the box to have RMxprt auto design the Hs2, Bs1, and Bs2 dimensions.
Parallel Tooth	Check the box to have RMxprt design Bs1 and Bs2 based on **Tooth Width**. – Available only when **Auto Design** is cleared.
Tooth Width	The tooth width for parallel tooth. – Available only when **Parallel Tooth** is selected.
Hs0	– Always available.
Hs1	– Available only when the slot type is 2, 3, 4, 5, or 6.
Hs2	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	– Available only when the slot type is 1, 2, 3, 4, or 5.
Bs1	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.

Bs2	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	– Available only when the slot type is 3 or 4.

4. Double-click the **Winding** entry in the project tree to define the conductors, windings, and insulation data for the winding
5. For an IPM Brushless DC Motor stator only, double-click the **Circuit** entry in the project tree to define the properties for the position control circuit.
6. Optionally, you can right-click on Core in the project tree to insert or remove Vent data.

Defining Data for the SLOT_CAGE Core Type

The general procedure for defining a SLOT_CAGE core type is as follows:

1. Double-click the **Machine>Rotor** entry in the project tree to define data for the rotor. In the **Rotor Properties**dialog box, enter the number of slots in the **Number of Slots** field. There are no additional settings.
2. Double-click the **Core** entry in the project tree to define data for the rotor core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Check the box if the press board is made of magnetic material.
Skew Width	The skew width measured in degrees.
Half Slot	Check the box to set the rotor damper slots to half slots.
Double Cage	Check the box to add a bottom damper.

3. Double-click the **Machine>Rotor>Core>Damper** (or **Bottom Damper**) entry in the project tree to open the **Properties** dialog box. (You can also enter values for the following properties in the **Properties** window of the desktop without opening a separate dialog box.)

Slot Type	The slot type of the damper. Click the **Slot Type** button

	to open the **Select Slot Type** dialog box. Select the desired type. Default is Type 1. **Note** When you place the mouse cursor over the slot type, a diagram of the selected type appears in the dialog box, displaying the slot dimension variables.
Cast Cage	Check the box if the cage is cast. – Not available for **Bottom Damper**.
Bar Fitting Gap	The gap between the slot edge and bar edge.
Bar End Extension	The single-side end extended bar length. – Not available for **Bottom Damper**.
End Ring Width	The axial length of the end ring. – Not available for **Bottom Damper**.
End Ring Height	The radial height of the end ring. – Not available for **Bottom Damper**.
Bar Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material.
End Ring Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material. – Not available for **Bottom Damper**.

4. Double-click the **Damper>Slot** (and **Bottom Damper>Slot**, if used) entry in the project tree to define the slot dimensions. Enter the slot dimensions.

   An image of the selected slot type showing the dimension labels is displayed on the Diagram tab. Below are the slot dimensions properties that appear:

Hs0	Slot dimension Hs0.
Hs01	Slot dimension Hs01.
Hs2	Slot dimension Hs2.
Bs0	Slot dimension Bs0.
Bs1	Slot dimension Bs1.
Bs2	Slot dimension Bs2.

5. Optionally, you can right-click on Core in the project tree to insert or remove Vent data.

Defining Data for the SOLID Core Type

The general procedure for defining a SOLID core type is as follows:

1. Double-click the **Machine>Rotor>Core**) entry in the project tree to define data for the core. The **Core Properties**dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.

Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Sleeve Type	Select the Sleeve type: • **No Sleeve** No Sleeve is selected by default if the machine type is **Solid-Rotor Induction**. • **Hysteresis** Hysteresis will be selected by default if the machine type is **Hysteresis Machine**. • **Conductor**
Sleeve Thickness	The sleeve thickness. Available only when the **Sleeve Type** is either **Hysteresis** or **Conductor**.
Sleeve Material	The sleeve material type of the core. Click the button to open the **Select Definition** window and select the desired material. If the **Sleeve Type** is **Hysteresis**, the message manager informs you if your choice is not a hysteresis type material. Similarly, If the **Sleeve Type** is **Conductor**, the message manager informs you if your choice is not a conductor type material. (Available only when the **Sleeve Type** is either **Hysteresis** or **Conductor**.)

Defining Data for the AXIAL_AC Core Type

The general procedure for defining an AXIAL_AC core type is as follows:

1. Double-click the **Machine>Stator** entry in the project tree to define data for the stator. The **Stator Properties**dialog box contains the following fields:

Number of Poles	The number of poles on which the winding is wound. Default is 2.
Number of Slots	The number of slots of the iron core. Default is 18.
Circuit Type	The drive circuit type. Select from the following six types (default is Y3):

	• Y3: Y-Type, 3-Phase • L3: Loop-Type, 3-Phase • S3: Star-Type, 3-Phase • C2: Cross-Type, 2-Phase • L4: Loop-Type, 4-Phase • S4: Star-Type, 4-Phase **Note** When you place the mouse cursor over the circuit type, a circuit diagram of the selected type appears in the dialog,
Slot Type	The slot type of the iron core. Click the **Slot Type** button to open the **Select Slot Type** dialog box. Select the desired type. Default is Type 1. **Note** When you place the mouse cursor over the slot type, a diagram of the selected type appears in the dialog box, displaying the slot dimension variables. Optionally, check **User Defined Slot** if you wish to define the slot dimensions using the **Slot Editor**.
Position Control	Determines if the drive circuit is controlled by position signals from a position sensor. (Checked for **Axial-Flux Brushless DC Motor** core type. Unchecked for all other types.)

2. Double-click the **Core** entry in the project tree to define data for the stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.

3. Double-click the **Slot** entry in the project tree to define the stator slot dimensions. Enter the available slot dimensions.

   An image of the selected slot type showing the dimension labels is displayed on the Diagram tab. The dimensions properties that appear depend on the **Slot Type** (selected above) and on whether or not **Auto Design** or **Parallel Tooth** is selected:

Auto Design	Check the box to have RMxprt auto design the Hs2, Bs1, and Bs2 dimensions.

Parallel Tooth	Check the box to have RMxprt design Bs1 and Bs2 based on **Tooth Width**. – Available only when **Auto Design** is cleared.
Tooth Width	The tooth width for parallel tooth. – Available when **Parallel Tooth** is selected.
Hs0	– Always available.
Hs1	– Available only when the slot type is 2, 3, 4, 5, or 6.
Hs2	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically.
Bs0	– Available only when the slot type is 1, 2, 3, 4, or 5.
Bs1	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Bs2	– Available only when **Auto Design** is cleared. When **Auto Design** is selected, this slot dimension is determined automatically. When **Parallel Tooth** is selected, this slot dimension is determined based on the value entered in the **Tooth Width** field.
Rs	– Available only when the slot type is 3 or 4.

4. Double-click the **Winding** entry in the project tree to define the conductors, windings, and insulation data for the winding
5. For an Axial-Flux Brushless DC Motor stator only, double-click the **Circuit** entry in the project tree to define the properties for the position control circuit.

Defining Data for the AXIAL_CAGE Core Type

The general procedure for defining a AXIAL_CAGE core type is as follows:

1. Double-click the **Machine>Rotor** entry in the project tree to define data for the rotor. In the **Rotor Properties**dialog box, enter the number of slots in the **Number of Slots** field. There are no additional settings.
2. Double-click the **Core** entry in the project tree to define data for the rotor core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.

Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Check the box if the press board is made of magnetic material.
Skew Width	The skew width measured in degrees.
Half Slot	Check the box to set the rotor damper slots to half slots.
Double Cage	Check the box to add a bottom damper.

3. Double-click the **Machine>Rotor>Core>Damper** (or **Bottom Damper**) entry in the project tree to open the **Properties** dialog box. (You can also enter values for the following properties in the **Properties** window of the desktop without opening a separate dialog box.)

Slot Type	The slot type of the damper. Click the **Slot Type** button to open the **Select Slot Type** dialog box. Select the desired type. Default is Type 1. **Note** When you place the mouse cursor over the slot type, a diagram of the selected type appears in the dialog box, displaying the slot dimension variables.
Cast Cage	Check the box if the cage is cast. – Not available for **Bottom Damper**.
Bar Fitting Gap	The gap between the slot edge and bar edge.
Bar End Extension	The single-side end extended bar length. – Not available for **Bottom Damper**.
End Ring Width	The axial length of the end ring. – Not available for **Bottom Damper**.
End Ring Height	The radial height of the end ring. – Not available for **Bottom Damper**.
Bar Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material.
End Ring Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material. – Not available for **Bottom Damper**.

4. Double-click the **Damper>Slot** (and **Bottom Damper>Slot**, if used) entry in the project tree to define the slot dimensions. Enter the slot dimensions.

   An image of the selected slot type showing the dimension labels is displayed on the Diagram tab. Below are the slot dimensions properties that appear:

Hs0	Slot dimension Hs0.
Hs01	Slot dimension Hs01.
Hs2	Slot dimension Hs2.
Bs0	Slot dimension Bs0.
Bs1	Slot dimension Bs1.
Bs2	Slot dimension Bs2.

Defining Data for the SALNT_POLE Core Type

The general procedure for defining a SALNT_POLE core type is as follows:

1. Double-click the **Machine>Rotor** (or **Machine>Stator**, if applicable) entry in the project tree to define data for the rotor (or stator). In the **Rotor** (or **Stator**) **Properties**dialog box, enter the number of poles in the **Number of Poles** field (default is 2). There are no additional settings.
2. Double-click the **Core** entry in the project tree to define data for the rotor or stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Check the box if the press board is made of magnetic material.
Skew Width	The skew width measured in degrees.
Pole Type	Click the **Pole Type** button to open the **Select Pole Type** dialog box. The SALNT_POLE rotor core type supports one pole type: Type 1; while the SALNT_POLE stator supports two pole types. A diagram displaying the pole dimension variables appears on the Diagram tab. **Note** When you place the mouse cursor over the pole type, a diagram of the selected type appears in the dialog box, displaying the pole dimension variables.

3. Double-click the **Machine>Rotor>Core>Pole** or **Machine>Stator>Core>Pole**entry in the project tree to open its **Properties** dialog.

Second Air Gap	The second air gap between the pole body and the yoke.
Pole Body Width	Pole body width dimension.
Pole Body Height	Pole body height dimension.
Pole Shoe Width	Pole shoe width dimension.
Pole Shoe Height	Pole shoe height dimension.
Pole Arc Offset	The pole-arc center offset from the rotor center.
Second Pole Arc	Check if you want the pole surface to include a second arc or line in a half-pole range. When checked, enables Off2_x and Off2_y.
Off2_x	Offset of the second arc perpendicular to the pole-center line. – Available when **Second Pole Arc** is checked.
Off2_y	Offset of the second arc in parallel with the pole-center line. – Available when **Second Pole Arc** is checked.
Stacking Factor	The effective magnetic length of the rotor pole.
Steel Type	Steel material type. Click the button to open the **Select Definition** window and select the steel material type from the list. Use the **Material Filter** tab settings to filter for **Steel** materials.
Bp1	Pole dimension Bp1. – Available only for stator core **Pole Type** 1.
Bp2	Pole dimension Bp2. – Available only for stator core **Pole Type** 1.
Rp1	Pole dimension Rp1. – Available only for stator core **Pole Type** 2.
Rp2	Pole dimension Rp2. – Available only for stator core **Pole Type** 2.

4. Optionally, you can add a damper by right-clicking **Core** in the project tree and selecting **Insert Damper**. You can then double-click the **Machine>Rotor>Core>Damper** entry in the project tree to open the **Properties** dialog box. (You can also enter values for the following properties in the **Properties** window of the desktop without opening a separate dialog box.)

Damper Slots Per Pole	The number of damper slots per pole.

Slot Type	The slot type of the damper. Click the **Slot Type** button to open the **Select Slot Type** dialog box. Select the desired type. Default is Type 1. **Note** When you place the mouse cursor over the slot type, a diagram of the selected type appears in the dialog box, displaying the slot dimension variables.
Cast Rotor	Check the box if the cage is cast.
Bar Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material.
End Length	The single-side end bar length. – Available only when the **End Ring Type** is 2 or 3.
End Ring Width	The axial length of the end ring. – Available only when the **End Ring Type** is 2 or 3.
End Ring Height	The radial height of the end ring. – Available only when the **End Ring Type** is 2 or 3.
End Ring Conductor Type	Click the button to open the **Select Definition** window and select the desired conductor material. – Not available for **Bottom Damper**.
End Ring Type	Click the button to open the **Select Definition** window and select the desired end ring type. **Note** When you place the mouse cursor over the end ring type, an explanation appears in the dialog box, describing the end ring.
Slot Pitch	The slot pitch for the damper slots.
Center Slot Pitch	The center slot pitch for the damper slots.
Bar Fitting Gap	The gap between the slot edge and bar edge.

5. If a damper is present, double-click the **Damper>Slot** entry in the project tree to define the slot dimensions. Enter the slot dimensions.

   An image of the selected slot type showing the dimension labels is displayed on the Diagram tab. Below are the slot dimensions properties that appear:

Hs0	Slot dimension Hs0.
Hs01	Slot dimension Hs01.
Hs2	Slot dimension Hs2.
Bs0	Slot dimension Bs0.
Bs1	Slot dimension Bs1.
Bs2	Slot dimension Bs2.

6. Double-click the **Machine>Rotor>Field** or **Machine>Stator>Field** entry in the project tree to open its **Properties** dialog and define the Field Data.
7. Double-click the **Machine>Rotor>Field>Winding** or **Machine>Stator>Field>Winding** entry in the project tree to open its **Properties** dialog and define the Field Winding Data.
8. Optionally for machine rotors only, you can right-click on **Machine>Rotor** in the project tree and select **Insert Brush** to define brush data. Double-click **Brush** in the project tree to open its **Properties** dialog box contains the following fields:

Diameter	Brush surface diameter.
Brush Width	Brush width.
Brush Length	Brush length.
Brush Drop	Voltage drop of a brush.
Contact Resistance	Contact resistance of a brush.
Brush Press	Brush pressure per unit area.
Frictional Coefficient	Frictional coefficient of a brush.

Defining SALNT_POLE Stator and Rotor Field Data for a Generic Rotating Machine.

To define the stator and rotor windings and insulation data:

1. To open the Stator or Rotor Field **Properties** window, double-click the **Machine-Stator-Field** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Enter the thickness of the insulation under the pole shoe in the **Shoe Insulation** field.
3. Enter the thickness of the insulation at the pole body side in the **Pole Insulation** field.
4. Enter the minimum gap in the **Winding Clearance** field. The winding clearance is one of the following: the minimum gap between two field windings, or the minimum gap between a field winding and a commutating winding.
5. Enter the exciter efficiency value in the **Exciter Efficiency** field.
6. Enter the exciting current value in the **Exciting Current** field.
7. Click **OK** to close the **Properties** window.

Defining SALNT_POLE Stator and Rotor Field Winding Data for a Generic Rotating Machine.

Note	Not applicable for SALNT_STEP stators.

1. To open the rotor or stator field winding **Properties** dialog box, double-click the **Machine>Stator>Field>Winding** or **Machine>Rotor>Field>Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate dialog box.)

2. Select a **Winding Type**:
   a. Click the button for **Winding Type** to open the **Winding Type** window.
   b. Select **Round**, **Cylinder**, or **EdgeWise** winding.

   When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the three types of windings:

Type	Description
Round	A Round winding: Cylinder	A Cylinder winding: EdgeWise	An EdgeWise winding: 
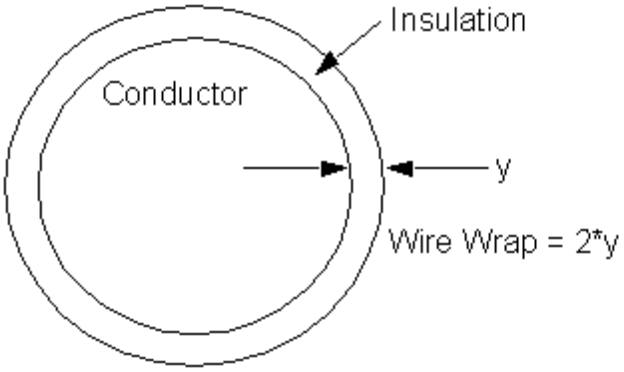
3. Once you have selected a winding, click **OK** to close the **Winding Type** dialog box and return to the **Properties** window.
4. Enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.

5. Enter the total number of conductors for each pole in the **Conductors per Pole** field. Odd numbers for input and output leads on different sides. Enter 0 to have RMxprt auto-design this value.
6. For Round and Cylinder winding types, enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.

Note	The **Number of Strands** field is invisible (not used) when the EdgeWise winding type has been selected.

7. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



8. For an **EdgeWise** winding type, enter the thickness of the inter-turn insulation in the **Inter-turn Insulation** field.

Note	The **Inter-turn Insulation** field is invisible (not used) when either the Round or Cylinder winding type has been selected.

9. Select the **Wire Size**:
   a. Click the button for **Wire Size** to open the **Wire Size** dialog box.
   b. Select a value from the **Wire Diameter** pull-down list.
   c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

<*number*>	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.

MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>General Options>Machines** command.

d. When you are done setting the wire size, click **OK** to close the **Wire Size** dialog box and return to the **Properties** dialog box.

10. When you are done setting the wire size, click **OK** to close the **Wire Size** dialog box and return to the **Properties** dialog box.
11. Click the **Conductor Type** button to open the **Select Definition** window **Materials** tab and selecting the desired conductor material type. Use the **Material Filter** tab settings to filter for **Conductor** materials. Click **OK** to close the window.
12. Enter the axial gap between the field winding and pole body in the **Axial Clearance** field.
13. Enter the inner radius at winding fillet in the **Winding Fillet** field.
14. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
15. Enter the limited cross-section width for winding design or arrangement in the **Limited Cross Width** field. Enter 0 for maximum available area.
16. Enter the limited cross-section height for winding design or arrangement in the **Limited Cross Height** field. Enter 0 for maximum available area.
17. Click **OK** to close the **Properties** dialog box.

Defining Data for the NONS_RELU Core Type

The general procedure for defining a NONS_RELU core type is as follows:

1. Double-click the **Machine>Rotor** entry in the project tree to define data for the rotor. In the **Rotor Properties**dialog box, enter the number of poles in the **Number of Poles** field (default is 2). There are no additional settings.
2. Double-click the **Core** entry in the project tree to define data for the rotor or stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.

Press Board Thickness	The thickness of the pole press boards.
Magnetic Press Board	Check the box if the press board is made of magnetic material.
Skew Width	The skew width measured in degrees.
Pole Type	Click the **Pole Type** button to open the **Select Pole Type** dialog box. The NONS_RELU rotor core type supports four pole types: • 1 – Laminated • 2 – Concentric-polyline • 3 – Hyperbolic-curve • 4 – Hyperbolic-polyline Default type is 4 – Hyperbolic-polyline. **Note** When you place the mouse cursor over the pole type, a diagram of the selected type appears in the dialog.

3. Double-click the **Machine>Rotor>Core>Pole** entry in the project tree to open its **Properties** dialog box, which contains the following fields:

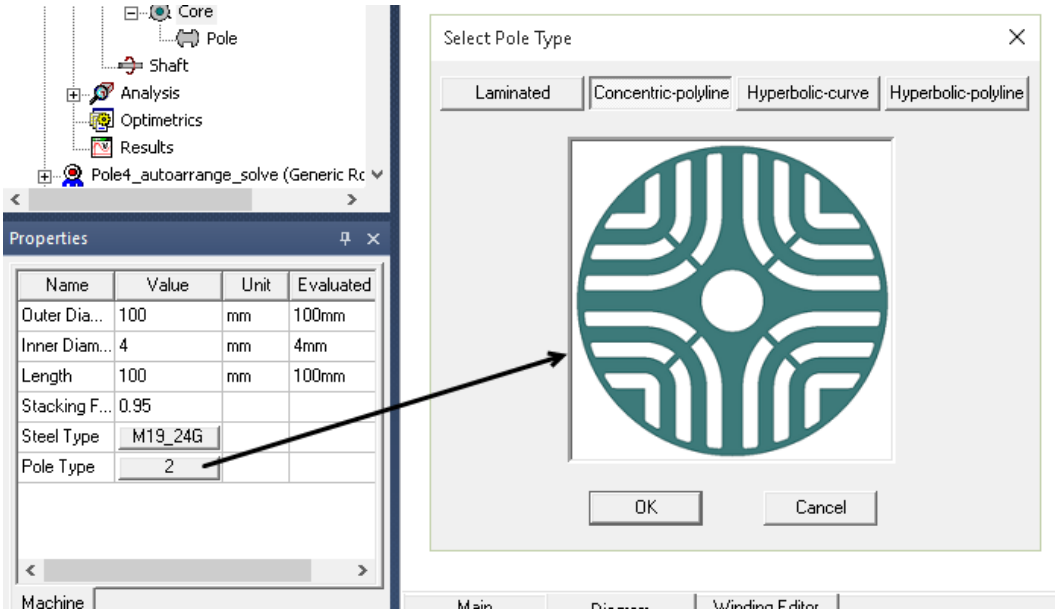
Note	The currently selected pole type diagram displays on the machine editor window Diagram tab.

Barriers per Pole	Number of barriers in one pole. Invisible when pole type is 1 (Laminated).
H	Bridge thickness. Invisible when pole type is 1 (Laminated).
W	Rib width at the barrier center. Invisible when pole type is 1 (Laminated).
R	Barrier fillet radius. Invisible when pole type is 1 (Laminated).
R0	Radius of the bottom barrier arch for Pole Type 2 (Concentric-polyline); or line connecting arch radius for Pole Type 4 (Hyperbolic-polyline). Visible only when Pole Type is 2 or 4.
Rb	In-circle radius of the bottom barriers.
B0	The first (from inner to outer) barrier width at the barrier center. Invisible when pole type is 1 (Laminated).
Y0	The first yoke width (between the first and the

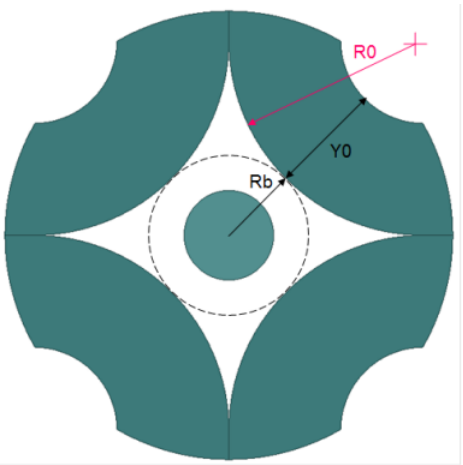
	second barriers) at the barrier center.
Barrier Auto Arrangement	Check the box to let barriers be auto-arranged. Invisible when pole type is 1 (Laminated).
Extra Barriers	For pole types 2, 3, or 4, if the number of **Barriers per Pole** is greater than 1, and **Barrier Auto Arrangement** has not been enabled, the **Extra BarriersSetup** button opens the **Barriers Setup** dialog in which you can specify the **Bi** (bottom widths of the additional barriers) and **Yi** (bottom widths of the additional yokes) dimensions. Invisible if the number of **Barriers per Pole** is 1, or if **Barrier Auto Arrangement** has been enabled.

NONS_RELU Rotor Core Pole Types

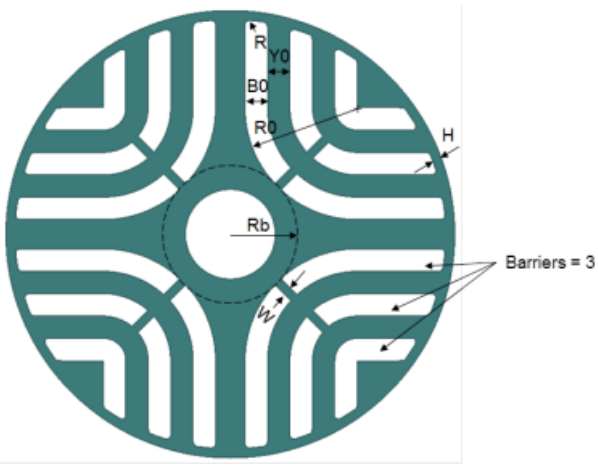
The NONS_RELU rotor core type supports four pole types. You can choose the pole type by selecting the **Machine>Rotor>Core** entry in the project tree, then clicking the **Pole Type** button in its Properties window to open the **Select Pole Type** window.



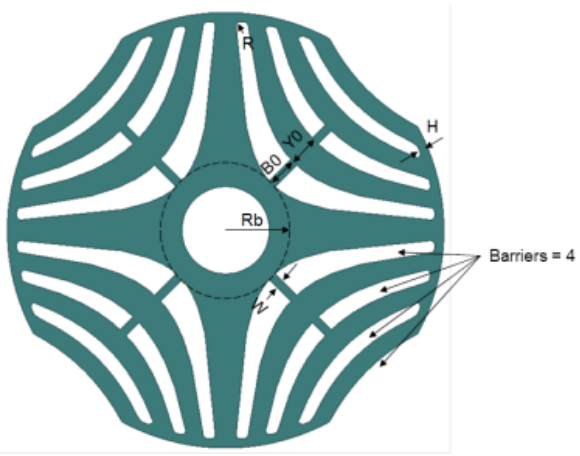
The four available pole types are shown below. Refer to *Defining Data for the NONS_RELU Core Type* for details on defining the various pole properties.



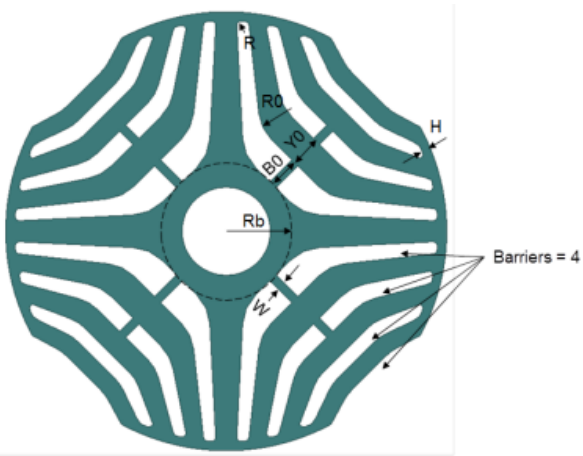
Laminated (Type 1)



Concentric-polyline (Type 2)



Hyperbolic-curve (Type 3)



Hyperbolic-polyline (Type 4)

Defining Data for the PM_INTERIOR Core Type

The general procedure for defining a PM_INTERIOR core type is as follows:

1. Double-click the **Machine>Rotor** entry in the project tree to define data for the rotor. In the **Rotor Properties**dialog box, enter the number of poles in the **Number of Poles** field (default is 4). There are no additional settings.
2. Double-click the **Core** entry in the project tree to define data for the rotor or stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Pole Type	Click the **Pole Type** button to open the **Select Pole Type** dialog box. The PM_INTERIOR rotor core type supports six pole types: Default type is 3. **Note** When you place the mouse cursor over the pole type, a diagram of the selected type appears in the dialog.

3. Double-click the **Machine>Rotor>Core>Pole** entry in the project tree to open its **Properties** dialog box, which contains the following fields:

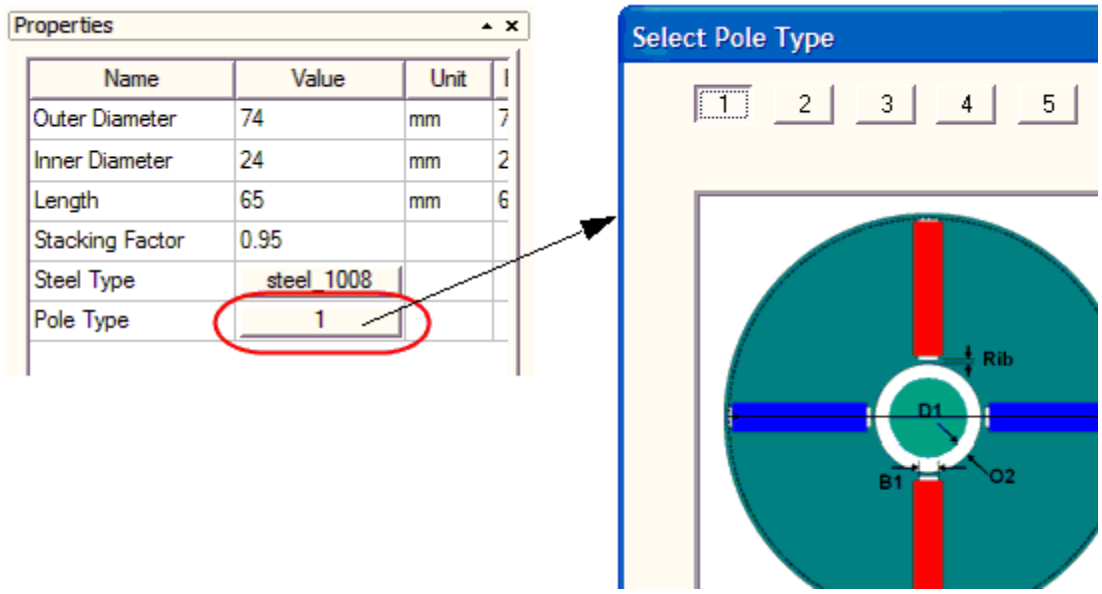
Note	The currently selected pole type diagram displays on the machine editor window Diagram tab.

D1	Limited diameter for magnet ducts.
O1	Magnet duct dimension. Invisible when pole type is 1 or 2.
O2	Magnet duct dimension.
B1	Magnet duct dimension.
Rib	Magnet duct dimension.
HRib	Magnet duct dimension. Invisible when pole type is 1,2, or 6.
Layers	Number of duct layers.
Layer Pitch	Pitch between two duct layers.
Magnet Thickness	Magnet thickness, or duct thickness.
Magnet Width	Total width of all magnets per pole.
Magnet Type	Magnet material type. Click the button to open the **Select Definition** window and select the magnet material type from the list. Use the **Material Filter** tab settings to

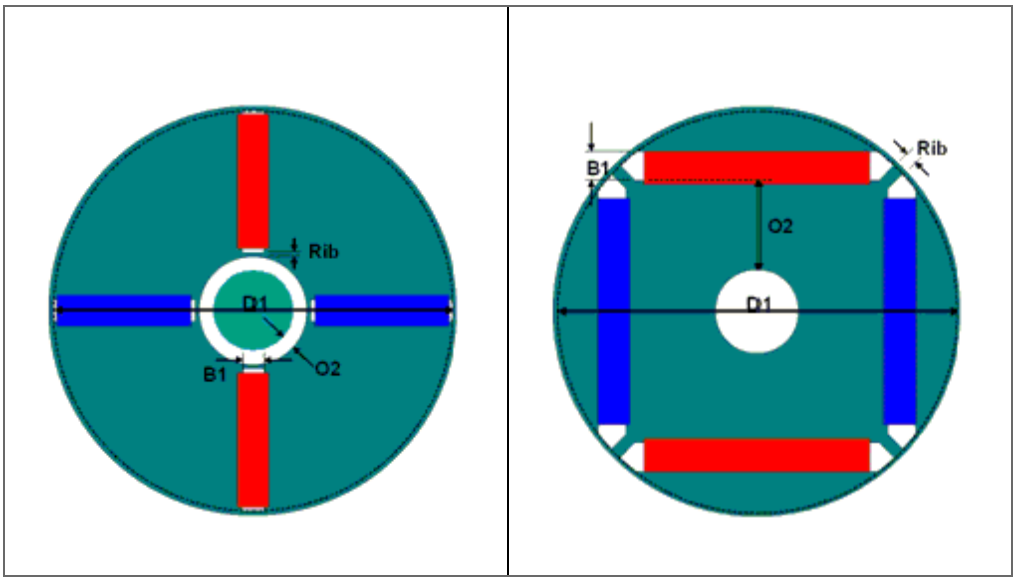
	filter for **Magnet** materials.

PM_INTERIOR Rotor Core Pole Types

The PM_INTERIOR rotor core type supports six pole types. You can choose the pole type by selecting the **Machine>Rotor>Core** entry in the project tree, then clicking the **Pole Type** button in its Properties window to open the **Select Pole Type** window.



The six available pole types are shown below. Refer to *Defining Data for the PM_INTERIOR Core Type* for details on defining the various pole properties.



Pole Type 1	Pole Type 2
	Pole Type 3	**Pole Type 4**
	Pole Type 5	**Pole Type 6**

Defining Data for the AXIAL_PM Core Type

The general procedure for defining a AXIAL_PM core type is as follows:

1. Double-click the **Machine>Rotor** entry in the project tree to define data for the rotor. In the **Rotor Properties**dialog box, enter the number of poles in the **Number of Poles** field (default is 2). There are no additional settings.

2. Double-click the **Core** entry in the project tree to define data for the rotor or stator core. The core data **Properties** dialog box contains the following fields:

Outer Diameter	The outer diameter of the core.
Inner Diameter	The inner diameter of the core.
Length	The length of the core.
Stacking Factor	The effective magnetic length of the core. Default is 0.95.
Steel Type	The steel type of the core. Click the button to open the **Select Definition** window and select the desired material.
Skew Width	The skew width measured in degrees.

3. Double-click the **Machine>Rotor>Core>Pole** entry in the project tree to open its **Properties** dialog box, which contains the following fields:

Embrace	Pole embrace value.
Magnet Type	Magnet material type. Click the button to open the **Select Definition** window and select the magnet material type from the list. Use the **Material Filter** tab settings to filter for **Magnet** materials.
Magnet Length	The radial length of the magnet.
Magnet Thickness	Axial thickness of the magnet, per side.

Defining the Stator and Rotor Windings for a Generic Rotating Machine

Note	This section is not applicable to: • AXIAL_PM type stators or rotors. • PM_INTERIOR, AXIAL_CAGE, and SOLID type rotors. • SALNT_POLE type stators and rotors. Refer to *Defining SALNT_POLE Stator and Rotor Field Winding Data for a Generic Rotating Machine* for winding information for SALNT_POLE stators and rotors. • SALNT_STEP type stators.

To define the wires, conductors, insulation, and windings of a stator or rotor:

1. To open the rotor or stator slot winding **Properties** dialog box, double-click the **Machine>Stator>Winding** or **Machine>Rotor>Winding** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate dialog box.)
2. Click the **Winding** tab.

3. Choose the desired number of layers in the winding from the drop-down list in the **Winding Layers** field.
4. Select a **Winding Type**:
   a. Click the button for **Winding Type**.
      The **Winding Type** window appears.
   b. Select from one of the following three types of winding:
      - **Whole Coiled**
      - **Half Coiled**
      - **Editor**

When you place the mouse cursor over a winding button, an outline of the selected winding appears. The following table describes the six types of windings that are possible (three for one-layer and three for two-layer):

Type	Description
Winding Editor (one-layer)	A user-defined one-layer winding arrangement. You need to set up the winding arrangement for each slot in the Winding Editor.
Whole-Coiled (one-layer)	A one-layer whole-coiled winding: Half-Coiled (one-layer)	A one-layer concentric half-coiled winding:

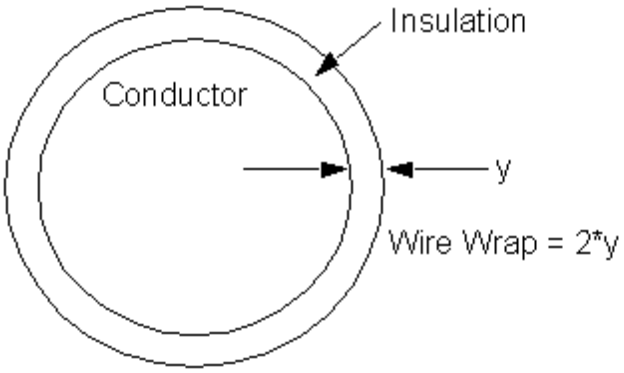
	Winding Editor (two-layer)	A user-defined two-layer winding arrangement. When you select for winding layers you can specify a different winding arrangement for each slot in the Winding Editor.
Whole-Coiled (two-layer)	A two-layer whole-coiled winding:  The phase belt for this winding configuration is equal to 360/2*m*, where *m* is the phase number.
Half-Coiled (two-layer)	A two-layer half-coiled winding:

	 There is only one coil per phase per pair of poles.

Note	For a two-layer winding, if you check Constant Pitch in the Winding Editor, only the top layer needs to be defined; the bottom layer is determined according to the coil pitch.

Once you have clicked a button to select a winding, click **OK** to close the **Winding Type** dialog box and return to the **Properties** window.

5. Enter the number of parallel branches in one phase of the winding in the **Parallel Branches** field.
6. Enter the total number of conductors in each slot in the **Conductors per Slot** field. This value is the number of turns per coil multiplied by the number of layers. Enter 0 to have RMxprt auto-design this value.
7. Enter the coil pitch, measured in number of slots, in the **Coil Pitch** field. The coil pitch is the number of slots separating one winding. For example, if a coil starts in slot 1 and ends in slot 6, it has a coil pitch of 5. This field is not displayed when the number of **Winding Layers** is 1.
8. Enter the number of wires per conductor in the **Number of Strands** field. Enter 0 to have RMxprt auto-design this value.
9. Enter the thickness of the double-sided wire wrap in the **Wire Wrap** field. Enter 0 to automatically obtain this value from the wire library.



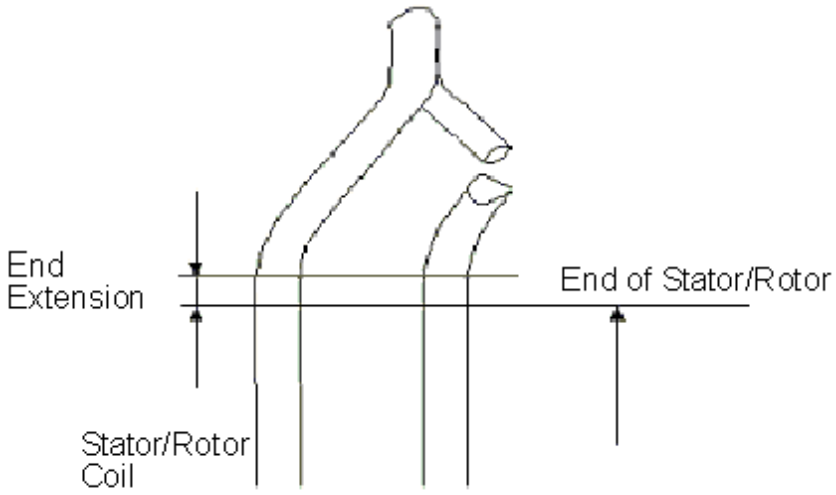
10. Select the **Wire Size**:
    a. Click the button for **Wire Size**.
       The **Wire Size** dialog box appears.
    b. Select a value from the **Wire Diameter** pull-down list.
    c. Select a wire gauge from the **Gauge** pull-down menu. You can select from the following options:

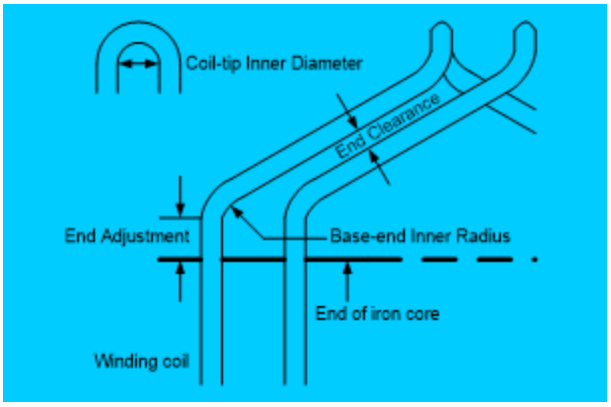
< ***number*** **>**	You can select a specific gauge number. When you select a gauge number, the **Wire Diameter** field is automatically updated.
USER	This option allows you to manually enter the **Wire Diameter**. This is useful when you want to enter a diameter that does not correspond to a particular wire gauge.
AUTO	This option sets the **Wire Diameter** to zero, and RMxprt automatically calculates the optimal value. The diameter information is then written to the output file when you analyze the design.
MIXED	This option allows you to define a conductor that is made of different size wires. For example, a single conductor may consist of 5 wires, 3 wires with a diameter of 0.21mm and 2 with a diameter of 0.13mm.

       The gauge number is based on AWG settings. You can create your own wire table using **Machine>Wire**, and then you can select this wire table using the **Tools>Options>Machine Options** command.

    When you are done setting the wire size, click **OK** to close the **Wire Size** dialog box and return to the **Properties** dialog box.
11. Click the button for **Conductor Type**. This opens the **Select Definition** dialog box in which you select the material type to be used for the winding.
12. Click the **End/Insulation** tab. Select or clear the **Input Half-turn Length** check box. Do one of the following:

- If you selected **Input Half-turn Length**, then enter the half-turn length of the armature winding in the Half Turn Length field.
- If you cleared **Input Half-turn Length**, then enter the end length adjustment of the stator/rotor coils in the **End Extension** field. The end extension is the distance one end of the conductor extends vertically beyond the end of the stator or rotor.





13. Enter the span length correction factor to scale the end span length in the **Correction Factor** field.
14. Enter the inner radius of the base corner in the **Base Inner Radius** field.
15. Enter the inner diameter of the coil tip in the **Tip Inner Diameter** field.
16. Enter the distance between two adjacent coils in the **End Clearance** field.
17. Enter the thickness of the single-side coil wrap insulation in the **Coil Wrap** field.
    This field is applicable and displayed only for slot types 5 and 6.
18. Enter the thickness of the slot liner insulation in the **Slot Liner** field.
19. Enter the thickness of the wedge insulation in the **Wedge Thickness** field.

20. Enter the thickness of the insulation layer in the **Layer Insulation** field.
    This field is applicable and displayed only when the **Winding Layers** value is 2.
21. Enter the bottom insulation thickness in the **Bottom Insulation** field.
    This field is applicable and displayed only for slot types 5 and 6.
22. Enter the limited slot fill factor for the wire design in the **Limited Fill Factor** field. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.
    This field is applicable and displayed only for slot types 1, 2, 3, and 4.
23. Enter the top spare slot space for a dual-winding machine in the **Top Spare Space** field.
24. Enter the bottom spare slot space for a dual-winding machine in the **Bottom Spare Space** field.
25. Click **OK** to close the **Properties** dialog box.

Stator and Rotor Winding Data for Generic Rotating Machines

Note	This section is not applicable to: • AXIAL_PM type stators or rotors. • PM_INTERIOR, AXIAL_CAGE, and SOLID type rotors. • SALNT_POLE type stators and rotors. Refer to *Defining SALNT_POLE Stator and Rotor Field Winding Data for a Generic Rotating Machine* for winding information for SALNT_POLE stators and rotors.

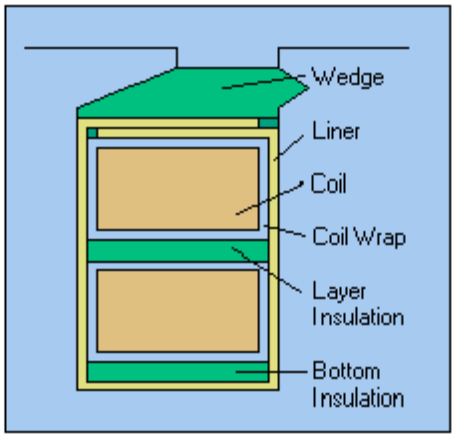
To access the core slot data, double-click either the **Machine>Rotor>Core>Slot** or the **Machine>Rotor>Core>Slot** entry in the project tree.

The winding data **Properties** dialog box contains the following fields:

Winding tab	**Winding Layers**	The number of winding layers. (The bottom layer is for another side slot if the core is double-sided.) Select 1 or 2 in the pull-down list. Default value is 2. **Winding Layers** is always 2 if the core is double-sided.
	Winding Type	The type of stator winding. Click the button to open the **Winding Type** window and choose from **Whole-Coiled**, **Half-Coiled**, and **Editor**. Default value is **Whole-Coiled**.
	Parallel Branches	The number of parallel branches in the winding. Default value is 1.
	Conductors per Slot	The number of conductors per slot (0 for auto-design).
	Coil Pitch	The coil pitch measured in number of slots. This field is displayed only when the number of **Winding Layers** is 2. **Coil Pitch** is always 0 if the core is double-sided.

	Number of Strands	The number of wires per conductor (0 for auto-design). Default value is 1.
	Wire Wrap	The thickness of the double-sided wire wrap (0 to automatically obtain this value from the wire library).
	Wire Size	The diameter of the wire (0 for auto-design). Click the button to open the **Wire Size** dialog box where you can specify units, wire type, diameter, and gauge.
End/Insulation tab	**Input Half-turn Length**	Select or clear this check box to specify whether or not you want to enter the half-turn length. When this check box is selected, the **Half Turn Length** field appears the next time you open the **Properties** window. When this check box is selected, the **End Extension** field appears instead. Default value is unchecked.
	Half Turn Length	The average half-turn length of the armature winding. Visible only when **Input Half Turn Length** is checked.
	End Extension	The end length adjustment of the coils, which is the distance one end of the conductor extends vertically beyond the end of the stator or rotor. Invisible when **Input Half Turn Length** is checked.
	Correction Factor	End span length correction factor to scale the end span length. Must be > 0. Default value is 1.0. Invisible when **Input Half Turn Length** is checked
	Base Inner Radius	The inner radius of the base corner.
	Tip Inner Diameter	The inner diameter of the coil tip. Invisible if the core is double-sided.
	End Clearance	The end clearance between two adjacent coils.
	Coil Wrap	The thickness of the single-side coil wrap. This field is displayed only when the **Slot Type** is 5 or 6.
	Slot Liner	The thickness of the slot liner insulation.
	Wedge Thickness	The thickness of the wedge insulation.
	Layer Insulation	The thickness of the insulation layer. Invisible when number of winding layers is 1 or the core is double-sided.
	Bottom Insulation	Thickness of the bottom insulation. This field is displayed only when the **Slot Type** is 5 or 6.
	Limited Fill Factor	The limited slot fill factor for the wire design. The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area. This field is displayed only for Slot Types 1, 2, 3, or 4.

	Top Spare Space	The top spare slot space for a dual-winding machine. The value must be greater-than or equal-to 0 and less-than 1.
	Bottom Spare Space	The bottom spare slot space for a dual-winding machine. The value must be greater-than or equal-to 0. Also, the sum of the **Top Spare Space** and **Bottom Spare Space** values must less-than 1.
	Conductor Type	Conductor material type of the Stator/Rotor Winding.



Winding Editor for a Generic Rotating Machine

For a generic rotating machine, you may want to specify a different number of conductors for each stator or rotor slot. The **Winding Editor** enables you to specify the number of turns for each coil. To enable the **Winding Editor**, you must have set the **Winding Property** for the **Winding Type** to **Editor**.

To specify the number of turns for each coil:

1. Click **Machine>Winding>Edit Layout**.

   The **Winding Editor** dialog box appears.

2. In the table in the upper left, set which **Phase** you want for each coil and which slot is the “In” and “Out” slot for the current in each coil.
3. If you are working on a quarter or half model, you may want to specify a multiplier by selecting a value from the **Periodic Multiplier** drop-down menu.

4. Select or deselect the **Constant Turns** or **Constant Pitch** check boxes, depending on whether you want to be able to change these setting in the table above. When these options are selected, you cannot change the turns or pitch.
5. When you are satisfied with the coil settings, click **OK** to close the **Winding Editor** dialog box.

Defining Different Size Wires for a Generic Rotating Machine

Use the **Gauge** option if you have a conductor that is made up different size wires.

To define different size wires:

1. In the **Wire Size** window, select **MIXED** from the **Gauge** pull-down menu.
2. Select either **Round** or **Rectangular** as the **Wire Type**.
3. Enter the appropriate wire data in the table:
   - For a round wire:
     - Click **Add** to add the new wire data.
     - Enter the **Diameter** in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this diameter.
   - For a rectangular wire:
     - Click **Add** to add the new wire data.
     - Enter the **Width** of the wire in the table. The width should be greater than the thickness.
     - Enter the **Thickness** of the wire in the table.
     - Enter the **Fillet** value in the table.
     - Enter a **Number** in the table to specify how many of the conductor's wires have this data.
4. Repeat step 3 for each size wire you want to add.
5. When you are finished defining the wires, click **OK** to close the **Wire Size** window.

Note	For example, if one conductor is made up of 5 wires, and 3 of those wires have a diameter of 0.21mm, and the other 2 have a diameter of 0.13mm, then the mixed wire size table will have two lines. The first line will list Diameter = 0.21 and Number = 3. The second line will list Diameter = 0.13 and Number = 2. An equivalent wire diameter is displayed as Wire Size value in the Winding tab in the Properties window.

Defining the Stator and Rotor Circuits for a Generic Rotating Machine

You can define stator and rotor Circuit parameters for generic rotating machines whose Source Type is DC.

Note	This procedure is not applicable to: • AXIAL_PM type stators or rotors. • SALNT_POLE type stators or rotors.

	• AXIAL_AC, AXIAL_CAGE, SLOT_CAGE, and SOLID type rotors. • PM_INTERIOR type rotors.

To define the circuit parameters of a stator or rotor:

1. To define the circuit parameters click either the stator or rotor Circuit icon in the project tree. You can then edit the brush parameters directly in the Properties window. (You can also open the rotor or stator circuit **Properties** dialog box by double-clicking the **Machine>Stator>Circuit** or **Machine>Rotor>Circuit** entry in the project tree on the desktop.)
2. Select the **Control Type** from the drop down menu. Choices are: DC, CCC, PWM, and HCC.
3. If the stator or rotor **Position Control** has been enabled, set the **Lead Angle of Trigger** value.
4. If the **Control Type** chosen is either DC or CCC, set the **Trigger Pulse Width**. The default value is 120.
5. Set the **Transistor Drop** (voltage drop of one transistor).
6. Set the **Diode Drop**.
7. If the **Control Type** is CCC, set the **Maximum Current** and **Minimum Current** values.
8. If the **Control Type** is PWM, set the **Modulation Index** and **Carrier Frequency Times**.
9. If the **Control Type** is HCC, set the **Reference Amplitude** and **Hysteresis Band**.

Stator and Rotor Circuit Data for Generic Rotating Machines

To access the stator or rotor circuit data, double-click either the **Machine>Stator>Circuit** or the **Machine>Rotor>Circuit** entry in the project tree.

Note	This section is not applicable to PM_INTERIOR and SALNT_STEP rotors .

The circuit data **Properties** dialog box contains the following fields:

Control Type	Control Type: DC, CCC (chopping current control), PWM, HCC (hysteresis current control). Default is DC. **Note** For SALNT_STEP Stators, only DC and CCC control types are available.
Lead Angle of Trigger	Lead angle of trigger in electrical degrees. Visible only when the machine stator or rotor **Position Control** is enabled.
Trigger Pulse Width	Trigger pulse width in electrical degrees. Visible only when **Control Type** is DC or CCC. Default value is 120.
Transistor Drop	Voltage drop of one transistor.

Diode Drop	Voltage drop of one diode, or the total voltage for star-type circuits in the discharge loop.
Maximum Current	Maximum current for chopping current control. Visible only when **Control Type** is CCC.
Minimum Current	Minimum current for chopping current control. Visible only when **Control Type** is CCC.
Modulation Index	Modulation index (the ratio of the sine-wave amplitude to the triangular amplitude). Visible only when **Control Type** is PWM.
Carrier Frequency Times	Carrier frequency times (the ratio of the triangular frequency to the sine-wave frequency). Visible only when **Control Type** is PWM.
Reference Amplitude	The amplitude of the sine-wave reference current. Visible only when **Control Type** is HCC.
Hysteresis Band	The difference between the upper and lower hysteresis limits. Visible only when **Control Type** is HCC.

Defining the Axial AC Rotor Brush for a Generic Rotating Machine

Optionally, you can insert or remove brush data for generic rotating machines that have an Axial AC Rotor Structure. If you have inserted a brush, the icon appears under the core slot in the project tree.

To insert a brush:

1. Right-click on the rotor core icon to display the pop-up menu.
2. Click **Insert Brush**.
3. To edit the brush data, double-click the brush icon to open the brush properties dialog.

   The brush data **Properties** dialog box contains the following fields:

Diameter	Brush surface diameter.
Brush Width	Brush width.
Brush Length	Brush length.
Brush Drop	Voltage drop of a brush.
Contact Resistance	Contact resistance of a brush.
Brush Press	Brush pressure per unit area.
Frictional Coefficient	Frictional coefficient of a brush.

To remove an existing brush:

1. Right click on the rotor icon to display the pop-up menu.
2. Click **Remove Brush**.

Vent Data for Generic Rotating Machines

Optionally, you can insert or remove Vent data for generic rotating machines that have either an Inner Rotor or Outer Rotor Structure. If you have inserted a Vent, the icon appears under the core slot in the project tree.

Note	• This section does not apply to the SALNT_POLE, NONS_RELU, or SOLID rotor types.

To insert a vent:

1. Right-click on the stator or rotor core icon to display the pop-up menu.
2. Click **Insert Vent**.

To remove an existing vent:

1. Right click on the stator or rotor icon to display the pop-up menu.
2. Click **Remove Vent**.

The vent data **Properties** dialog box contains the following fields.

Vent Ducts	Number of radial vent ducts. Default is 0.
Duct Width	Width of radial vent ducts.
Magnetic Spacer Width	Width of magnetic spacer which hold vent ducts. 0 for non-magnetic spacer.
Duct Pitch	Vent ducts
Holes per Row	Number of axial vent holes per row Not available for SLOT_CAGE rotor type.
Inner Hole Diameter	Diameter of vent holes in inner row. Not available for SLOT_CAGE rotor type.
Outer Hole Diameter	Diameter of vent holes in outer row. Not available for SLOT_CAGE rotor type.
Inner Hole Location	Center-to-center diameter of inner row hole vents. Not available for SLOT_CAGE rotor type.
Outer Hole Location	Center-to-center diameter of outer row hole vents. Not available for SLOT_CAGE rotor type.

Defining the Shaft Data for a Generic Rotating Machine

To define the shaft:

1. To open the shaft data **Properties** dialog box, double-click the **Machine>Shaft** entry in the project tree on the desktop. (You can also enter values in the **Properties** section of the desktop without opening a separate window.)
2. Select or clear the **Magnetic Shaft** check box to specify whether or not the shaft is to be made of magnetic material.
3. Enter the frictional loss in the **Frictional Loss** field.
4. Enter the windage loss (or power for wind power generators) measured at the **Reference Speed** in the **Windage Loss or Power** field.
5. Enter the reference speed at which frictional and windage losses are measured in the **Reference Speed** field.
6. Click **OK** to close the **Properties** window.

Shaft Data for General DC Machines

To access the shaft data, double-click the **Machine>Shaft** entry in the project tree.

The **Shaft Data Properties** window contains the following fields:

Magnetic Shaft	Select or clear this check box to indicate whether or not the shaft is made of magnetic material. When selected, the shaft is magnetic. Default is unchecked for PM_INTERIOR rotor type.
Frictional Loss	The frictional loss measured at the **Reference Speed**.
Windage Loss or Power	The **Windage Loss** (or **Power** for wind power generators) measured at the **Reference Speed**.
Reference Speed	The speed at which the friction and windage losses are measured. Default is 3600 rpm for PM_INTERIOR and AXIAL_CAGE rotor types.

Setting Up Analysis Parameters for a Generic Rotating Machine

To define solution parameters for a generic rotating machine:

1. Right-click **Analysis** in the project tree, and click **Add Solution Setup**.

   The **Solution Setup** dialog box appears.
2. Click the **General** tab.
   a. If you wish to change the automatically assigned setup name, enter a name for the setup in the **Setup Name** field.
   b. The solution setup is enabled by default. Uncheck the **Enabled** box to disable the setup, if desired.
   c. Select an operation type (**Motor**, **Generator**, or **Wind Generator**) from the **Operation Type** pull-down list. The **Operation Type** is set to **Motor** by default.
   d. Select the **Load Type** used in the machine.

- If the **Operation Type** is **Motor**, select one of the following **Load Type** options:

Const Speed	The speed remains constant in the motor.
Const Power	The output power remains constant in the motor. (Default type.)
Const Torque	The torque remains constant regardless of the speed. In this case, $T_{load} = T_{rated}$, given by the output power divided by the given rated speed.
Linear Torque	The torque increases linearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})$ where T_{rated} is given by the output power divided by the given rated speed.
Fan Load	The load varies nonlinearly with speed. In this case, $T_{load} = T_{rated} * (n/n_{rated})^2$ where T_{rated} is given by the output power divided by the given rated speed.

- If the **Operation Type** is either **Generator** or **Wind Generator**, select one of the following **Load Type** options:

Infinite Bus	When the generator is connected to an infinite bus of the power system, the terminal voltages remain constant and the output power is determined by the output currents.
Independent Generator	The generator supplies electrical power to a load inductor. For an AC generator, the resistance and inductance of the load inductor are determined by the rated output power, the rated voltage, and the rated power factor. For a DC generator, the resistance of the load resistor is determined by the rated output power and the rated voltage.

e. Enter the rated mechanical or electrical output (apparent) power in the **Rated Output Power** field.

When the **Operation Type** is **Generator** and **Source Type** is **AC**, the property name changes to **Rated Apparent Power (kVA)**, and the unit column is blank.

f. Enter the applied or output rated voltage in the **Rated Voltage** field. (RMS value for AC source.) Default value is 208 V.

g. Enter the temperature at which the system functions in the **Operating Temperature** field. Default is 75 cel.

3. Click the **Generic Rotating Machine (GRM)** tab.

a. For AC source type machines, enter the rated power factor in the **Rated Power Factor** field. The default value is 0.8. This field is invisible when the **Source Type** is **DC**.

b. For AC source type machines, if you wish to determine load impedance when the phase current leads the phase voltage, enable the **Capacitive Power Factor** check box. This field is invisible when the **Source Type** is **DC**.

c. Enter the source frequency in the **Frequency** field and select the appropriate unit of measure. The default value is 60 Hz. This field is invisible when the **Source Type** is **DC**.

d. Optionally, you can click the **Use Defaults** button to restore the tab settings to default values.

4. Optionally, click the **Defaults** tab. This tab contains two buttons:
   - Click the **Save Defaults** button to save the currently-defined settings as defaults for future setups.
   - Click the **Revert to Standard Defaults** button to clear existing user-defined defaults and revert to the standard settings.
5. Click **OK** to close the **Solution Setup** window.

Solution Data for Generic Rotating Machines

Solution Data for Generic Rotating Machines

To access the solution data, double-click the solution setup located under **Analysis** in the project tree to open the solution **Properties** dialog box. Solution data is also accessible in the desktop **Properties** window for the selected setup.

The solution setup Properties contains the following fields:

General tab:

Name	The name of the setup. Not editable.
Enabled	Check box that enables/disables the solution setup. Default is checked (enabled)
Operation Type	Set the type of operation for the machine analysis. Pull-down list selections are: Motor, Generator, Wind Generator. Default is Motor.
Load Type	Select the mechanical or electrical load type from the pull-down list. For Motor **Operation Type** the selections are: Const Speed, Const Power, Const Torque, Linear Torque, Fan Load. Default is Const Power. For Generator and Wind Generator **Operation Type** the selections are: Infinite Bus and Independent Generator. Default is Infinite Bus.
Rated Output Power	Enter the rated mechanical or electrical output (apparent) power, and select the unit.
Rated Voltage	Enter a value for the rated voltage and select the unit.
Rated Speed	Type a value for the rated speed, and select the unit.
Operating Temperature	Type a value for the operating temperature, and select the unit.

GRM tab:

Rated Power Factor	Enter the rated power factor for AC Source Type. This field is displayed only for AC Source Type. Default value is 0.8.
Capacitive Power Factor	Check box that enables/disables use of a capacitive power factor. Used together with the **Rated Power Factor** when the phase current leads the phase voltage, to determine load impedance. Default is unchecked.
Frequency	Enter a value for the frequency, and select the unit.

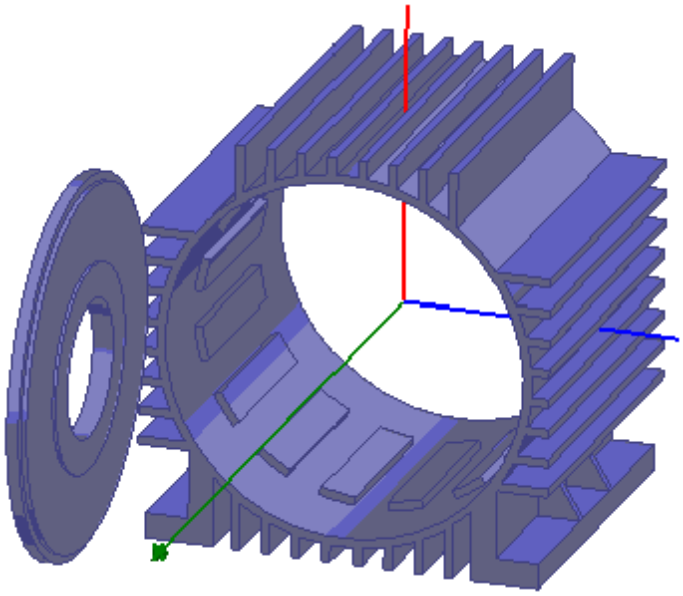
Adding Machine Housings

You can add machine housing parts to all machine types. Please note that machine housings for Generic Rotating Machines and Single-Phase Induction Motors are available only for Inner Rotor type machines. RMxprt designs that include machine housings can be exported to **Motor-CAD™** for advanced thermal analysis.



1. To include a Housing in the design, right-click the Machine icon in the Project Manager tree and select **Insert Housing**. A new Housing icon is added to the machine design containing Front Cap and Rear Cap housing elements.
2. Right-click on Housing in the Project Manager tree to include and specify parameter data for the following housing elements:

- Duct
- Fin
- Flange
- Foot

3. Specify properties for the Housing and related elements by selecting them and setting parameter data values either in the Properties window or Properties dialog.
4. You can remove the Housing and all related elements by right-clicking Machine and selecting **Remove Housing**. Individual housing elements can be removed by right-clicking Housing and selecting the desired **Remove** *<objectname>* menu item.

Note	The Front Cap and Rear Cap elements are always included with the Housing and cannot be removed individually.

Placing Components in the Maxwell Circuit Editor Schematic

Assigning Component Properties in Maxwell Circuit Editor

Schematic Editor

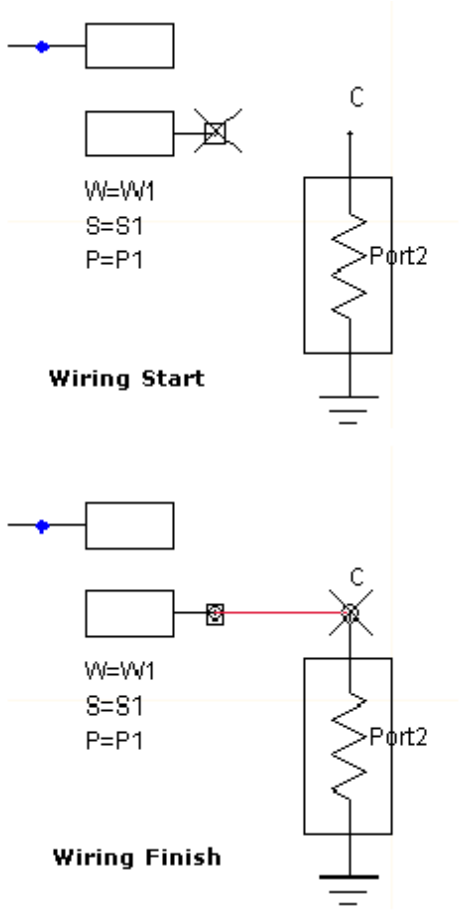
The Schematic editor is the tool for creating circuit schematics, or designs for a transient solution type. A design graphically represents and captures the electrical structure and characteristics of a circuit. You create such a design by starting the schematic editor and placing components, ports, connectors, and wires into a default empty schematic.

The Schematic Editor Window

The **Schematic Editor** window allows you to place components and wire them together. You can move components by simply selecting and dragging them. **Copy** and **Paste** can be used on

components and their wires within the schematic editor. You can also copy and paste to other schematics.

As you place the cursor near a pin of a component, it changes from an arrow to an **X**. This indicates that the schematic editor is in the wiring mode. In the wiring mode, click to start drawing a wire. Click again to end the wire.



Commonly used items such as ports, grounds, and page connectors can be placed in the schematic by selecting them from the **Draw** menu.

Controls to **Zoom In**, **Zoom Out**, and **Fit Drawing** to the editor window are available on the **View** menu, the **View** ribbon tab, and on the shortcut menu that opens when you right-click in a schematic.

If your mouse has a wheel, you can zoom while moving the mouse wheel up (zoom in) or down (zoom out). You can scroll vertically by holding down the **Shift** key while moving the mouse wheel or scroll horizontally by holding down the **Ctrl** key while moving the mouse wheel. This behavior can be changed using the **Zoom with mouse wheel** setting located in the Options dialog box, Schematic Editor/General section. If **Zoom with mouse wheel** is set to false (unchecked), you can scroll vertically with the mouse wheel, and zoom with the mouse wheel by pressing the **Shift** key.

The **arrow keys** scroll the view up, down, left, or right in small increments. The page up and page down keys scroll the view up or down in larger increments. If your mouse has a scroll wheel, move the wheel up to scroll up and down to scroll down. If you scroll so far that no objects are in the view, select **Fit Drawing** from the **View** drop-down on the schematic editor top menu bar (or press **Ctrl+D**) to re-center the entire design, resized to fill the window.

Setting Schematic Editor Options

These options are set under **Schematic Editor** in the **Options** dialog box.

To set **Schematic Editor** options:

1. Click **Tools>Options>General Options**.
2. Click **Schematic Editor**.
3. Make your changes on the appropriate panels:
   - General
   - Fonts
   - Colors
   - Wiring
   - Multiple Placement
   - Symbol Editor
4. Click **OK**.

Schematic Editor Options: General

These options are set in the **General** panel under **Schematic Editor** in the **Options** dialog.

- **Symbol Graphics** – specifies the graphic symbol style (**IEEE** or **Traditional**) to be used on schematics. Each style contains two or more active levels for the graphic objects that comprise a symbol.
- **SubCircuit Pin Spacing** – specifies the pin spacing in grid units for pins on a subcircuit component symbol. The default value is 1 grid unit.
- **Show Pin Labels** – specifies that pin labels are to be displayed in the **Schematic Editor**.
- **Property Display Angle Follows Symbol Angle** – specifies that displayed text properties rotate when the associated component is rotated. Disabled by default.
- **Update Property Display on Definition Update** – specifies that when component symbol definitions are updated, the displayed properties of instances of the updated component on the schematic are automatically updated. Enabled by default. If not enabled, only the symbol graphics are updated.
- **Auto Scroll when close to edges** – specifies that the **Schematic Editor** display will scroll automatically when the cursor is placed close to the edge of the editor window.
- **Show advanced property data** – turns on the display of less often used property tabs, such as Symbol and General for components.
- **Zoom with mouse wheel** – controls the behavior of the mouse wheel on mice so equipped. When enabled, you can zoom while moving the mouse wheel up (zoom in) or

down (zoom out); and scroll vertically by holding down the **Shift** key while moving the mouse wheel or scroll horizontally by holding down the **Ctrl** key while moving the mouse wheel. When disabled, you can scroll vertically with the mouse wheel, and zoom with the mouse wheel by pressing the **Shift** key

- **Net name display** – sets the net name property display distance from the net.
- **Symbol Scaling Factor** – Third-party vendors often follow a different symbol dimensioning system than that used in Maxwell. Symbol sizes that look appropriate in a third-party application may not be appropriate for Maxwell. To mitigate such issues, the Symbol Scaling factor can be used during import to scale the incoming symbol graphics for symbol formats such as SVG by the specified amount. Similarly, when exporting, the symbol can be rescaled to the original dimensions.
- **Selection Colors** – sets the colors of the first and subsequent objects as they are selected on a schematic.

Schematic Editor Options: Fonts

These options are set in the **Fonts** panel under **Schematic Editor** in the **Options** dialog.

Set the **Font Name** (from a drop-down selection list) and **Size** for text used on schematics on the **Fonts** tab of the **Schematic Editor Options** dialog box. A **Sample Text** display window shows the appearance of the specified font and size. **Apply this font to all property displays in the active schematic** specifies that all displays in the schematic editor are to use the font style and size you selected.

Schematic Editor Options: Colors

These options are set in the **Color** panel under **Schematic Editor** in the **Options** dialog.

The **Schematic Objects** panel allows you to set the color for each **Object Type**.

- **Object Type** – a drop-down menu used to select the object type whose colors you want to modify. Types are: **Components**, **Interface Ports**, **Page Ports**, **Global Ports**, **Grounds**, **Graphic Items**, **Wires**, **Buses, Title Blocks, Page Borders,** and **Page Border Text**.
- **Set Color** – implements the color you have selected for the object type.
- **Clear Color** – resets the color of the selected object type to its default value.

The **Individual Definitions** panel lets you set the color for specified **Components** and **Wire Domains**.

- **Component Name** – is used to identify the component whose colors you want to modify. (Visible only when the **Components Object Type** is selected.)
- **Add** – allows you to add a component whose colors you want to define. (Visible only when the **Components Object Type** is selected.)
- **Wire Domain** – a drop-down menu used to select the wire domain whose color you want to modify. Each Wire Domain is assigned a unique color by default. For Maxwell, the Domain is: **Conservative - Electrical**.

  - **Set Color**– implements the color you have selected for the specified component. All future instances of the component added to the active schematic window display will possess the selected color.
  - **Clear Color**– resets the color of the component to its default value.
- **Apply these color settings to the current schematic** – applies the color settings for the selected **Object Type** to objects of that type in the active schematic window.

Schematic Editor Options: Wiring Tab

The following options are set on the **Wiring** panel under **Schematic Editor** in the **Options** dialog box.

Connectivity Options:

- **Show Merge Wire dialog before combining wires** – displays the **Merge Wire** dialog box before combining wires to allow for changes to the merge configuration.
- **Show Split Wire dialog before separating wires** – displays the **Split Wire** dialog box before separating wires to allow for changes to the split configuration
- **When renaming a physically separate piece of wire** – offers two choices:
  – **Split into a different net**
  – **Keep connected (name all pieces the same)**
- **Show GlobalPort Disconnect dialog before separating** – displays the **GlobalPort Disconnect** dialog before separating wires to allow for changes to the global port configuration.

Schematic Editor Options: Multiple Placement

Multiple placement allows you to place several objects of the same type in the schematic using repeated mouse clicks. These options are set in the **Multiple Placement**panel under **Schematic Editor** in the **Options** dialog.

Check the desired objects in the **Items for multiple placement** list.

- **Components**
- **Interface Ports**
- **Grounds**
- **Page Connectors**
- **Global Ports**

Schematic Editor Options: Symbol Editor

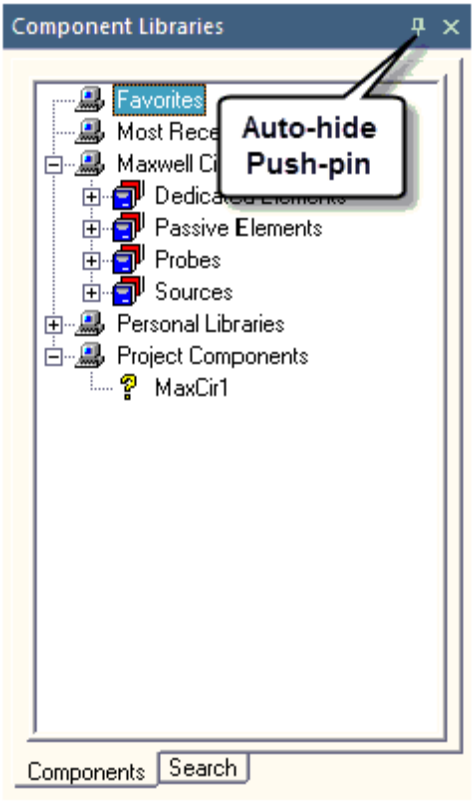
These options are set in the **Symbol Editor** panel under **Schematic Editor** in the **Options** dialog.

- **Adjust Pin Orientation on Drag** – enables symbol pin orientation to be adjusted automatically as pins are dragged to the desired side of a symbol in the symbol editor.

The Component Libraries Window

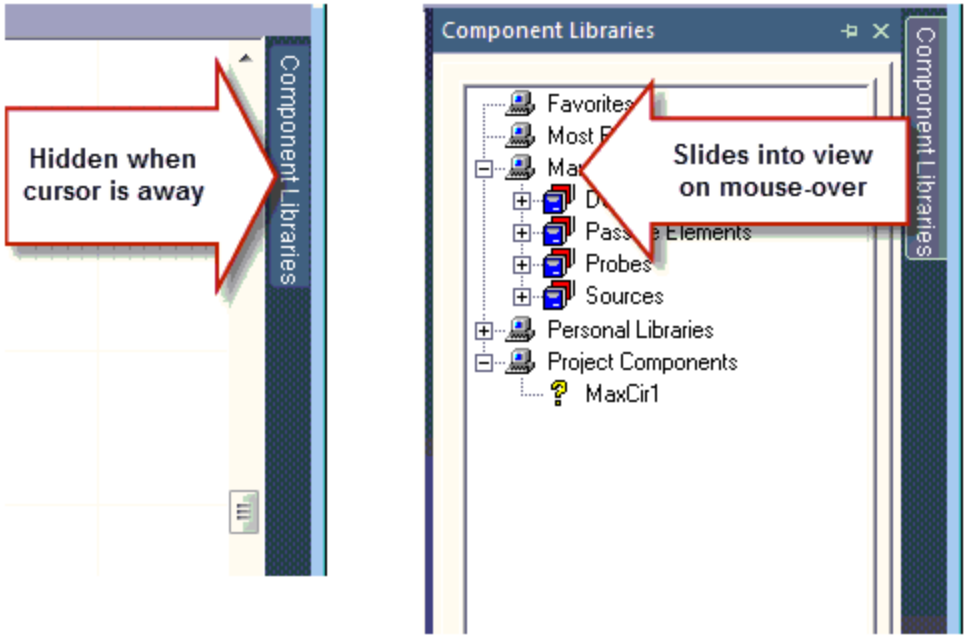
The Component Libraries window is a dockable window that allows you to select and search for schematic components that are available in the installed libraries. The Component Libraries window contains a Components tab and a Search tab.

A typical Component Libraries window is shown below. Your actual window contents will vary with the libraries installed and with use.



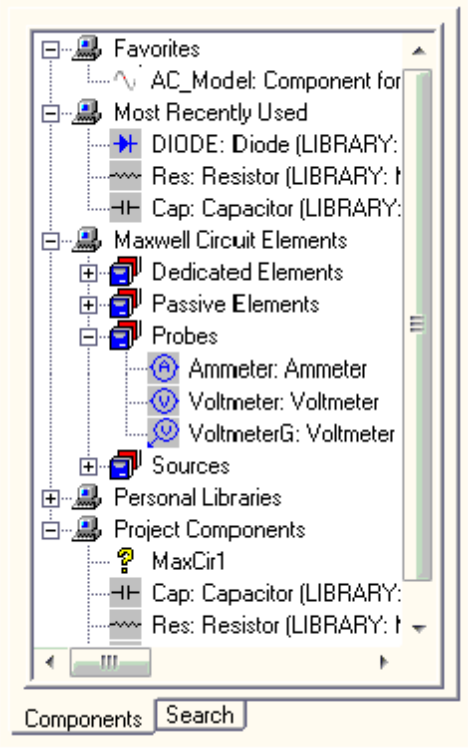
Auto-Hide Feature

Clicking the auto-hide push-pin in the upper right corner of the Component Libraries window toggles the auto-hide feature “on” and “off.” When auto-hide is enabled, the Component Libraries window slides out of sight and a Component Libraries “mouse-over button” appears on the edge of the main window. The Component Libraries window remains hidden until you move the mouse cursor over the mouse-over button. The Component Libraries window then slides into view for use; then hides again when the cursor moves out of the Component Libraries window.



The Components Tab

The **Components** tab in the **Component Libraries** window allows you to browse and select schematic components from the available elements libraries. The installed libraries are listed alphabetically in hierarchical folders grouped by component function. For example, the **Dedicated Elements** library expands as shown.



Individual elements are designated by icons next to the element abbreviation and name.

Right-clicking a component opens a shortcut menu where you can choose to:

- add the component to the Favorites folder
- place the component on a schematic
- view component help

The **Component** tab includes a **Favorites** folder and a **Most Recently Used** folder. These folders help provide quick access to components. Elements used in the current project are listed under **Project Components**.

Using the Favorites and Most Recently Used Folders

To add a library element as a favorite:

1. Select the desired element and right-click to display the shortcut menu.
2. Select **Add to Favorites** to place the component in the **Favorites** folder. When a component is in the **Favorites** folder, you can select, place, edit, view the component help, and load its example project (if one exists) from there.

To remove an element from the **Favorites** folder:

1. Select an element and right click to display the short cut menu.
2. Click **Remove from Favorites**.

The **Most Recently Used** folder contains a list of the most recently used elements. For convenience, these elements can be selected and placed from this folder. The number of elements in the folder is controlled by the **Tools>Options>General Options** dialog under the **Component Libraries Options** tab. The default number of elements is 10.

Help for Components

To launch help for a component from the **Components** tab of the **Component Libraries** window:

1. Right-click its icon.
2. Click **View Component Help**.

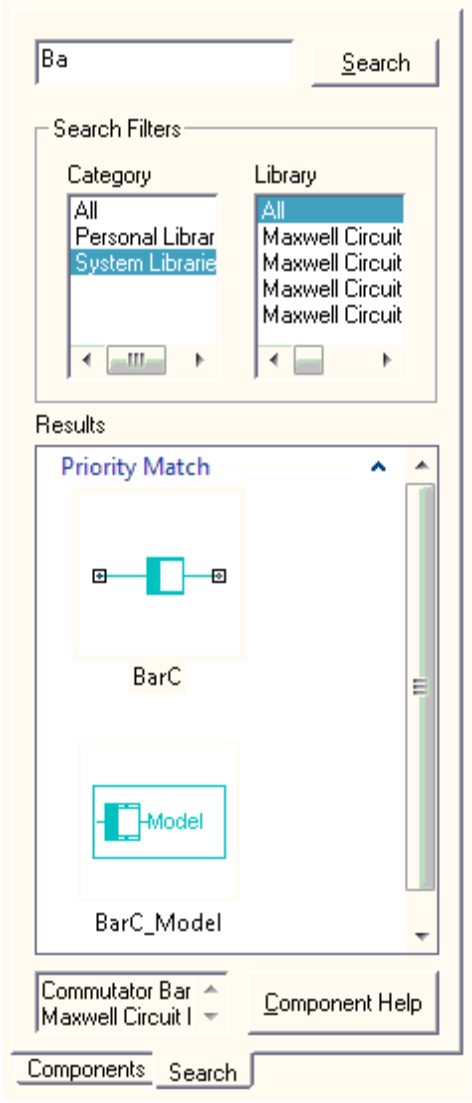
Placing Components on a Schematic

To place a component, do one of the following:

- Double-click its icon.
- Select, drag, and drop a component in the schematic editor.
- Right-click its icon, and then select **Place Component**.

The Search Tab

The **Search** tab allows you to enter full or partial words (case-insensitive) present in the names or descriptions of components in the search field. The search is done dynamically as you type. You can also restrict the search by select the categories and libraries you want to include in the search. Use the **Ctrl** key to select multiple categories or libraries.



For users running Microsoft® Windows Vista® or later, results appear in the **Results** panel as symbols representing the components matched by the search, and arranged in groups, depending on how well a search string matches the component. Generally, components which match the search string exactly appear in the **Best Match** group. The Match groupings do not appear in Windows® versions older than Vista®. Instead the results are simply presented sorted by priority.

When you select a particular component you can see its description and library path in the text box at the bottom of the tab. You can either drag and drop the desired component from the **Results** panel onto the schematic, or double-click to attach it to the mouse. Use the **Component Help** button to view help information for components.

Copying and Pasting Properties

You can copy and paste properties for primitive drawing elements (graphical objects) and components.

Primitive drawing elements (graphical objects)

You can copy and paste the common properties of the following primitive drawing elements (graphical objects):

- Arcs
- Circles
- Lines
- Rectangles
- Polygons
- Text
- Images

Components

Properties are copied only when property names match.

Parameters, and property displays are copied along with properties and their attributes.

Note	Property displays are copied to the same location as the source if they are on the left, bottom, right, top or center. Custom location property displays are copied to the default bottom location.

To Copy and Paste Selected Properties for Components

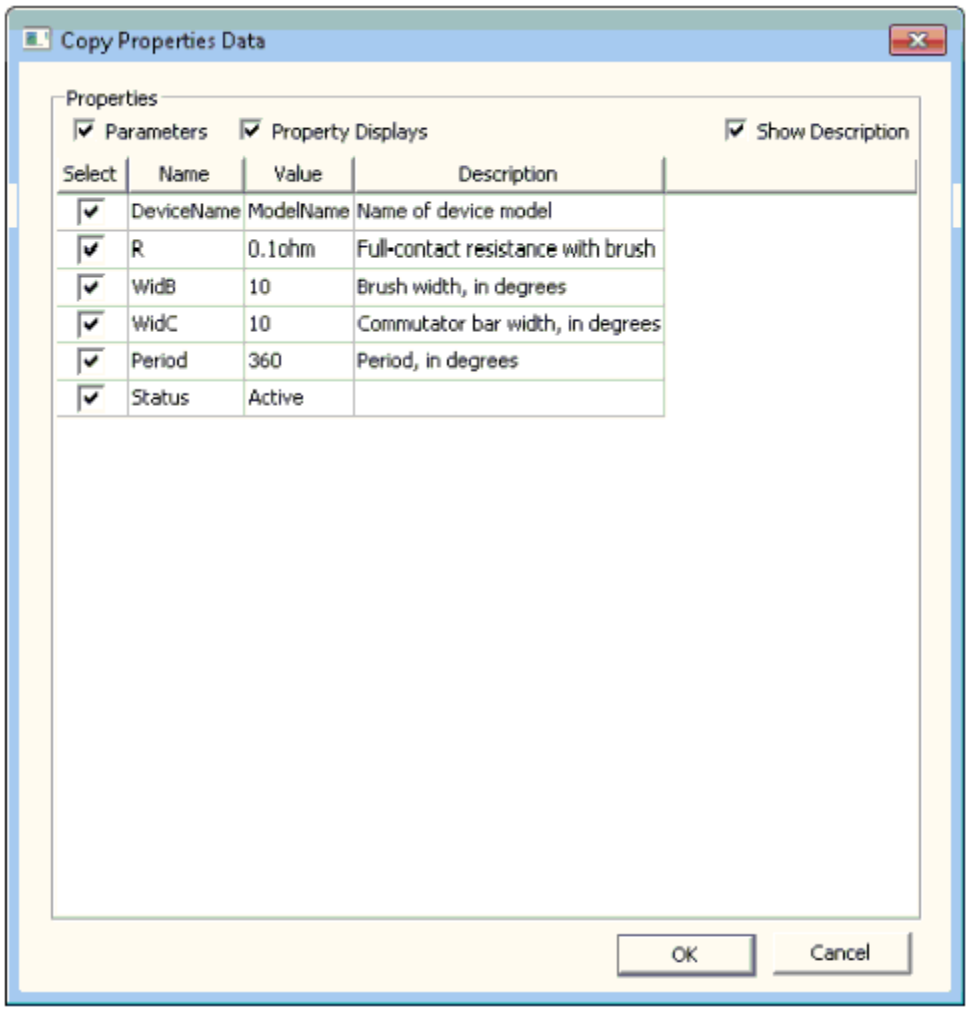
To copy and paste selected properties from one component to one or more components:

1. Select the component you want to copy from.
2. Use one of the following methods to access Copy Data:
   - Click **Edit** > **Copy Data**.
   - Right-click the object and select **Copy Data**.
   - Press **Ctrl+Shift+C**.
3. Select the components you want to paste to.
4. Paste the properties by using one of the following methods:
   - Select **Edit** > **Paste Data**.
   - Right-click the component and select **Paste Data.**
   - Press **Ctrl+Shift+V**.

   The **Copy Properties Data** window is displayed.



5. Do one of the following to select the properties to copy.
   - Select one or more of the following check boxes: Parameters, or Property Displays.
   - Click **Select** in the first column to toggle between selecting all and clearing all.
   - Click the **Select** check box for the property. If you do not want to include the property, clear the **Select** check box.

   Click the **Show Description** check box to display the descriptions for each property.
6. Click **OK**. The properties are pasted into the component.

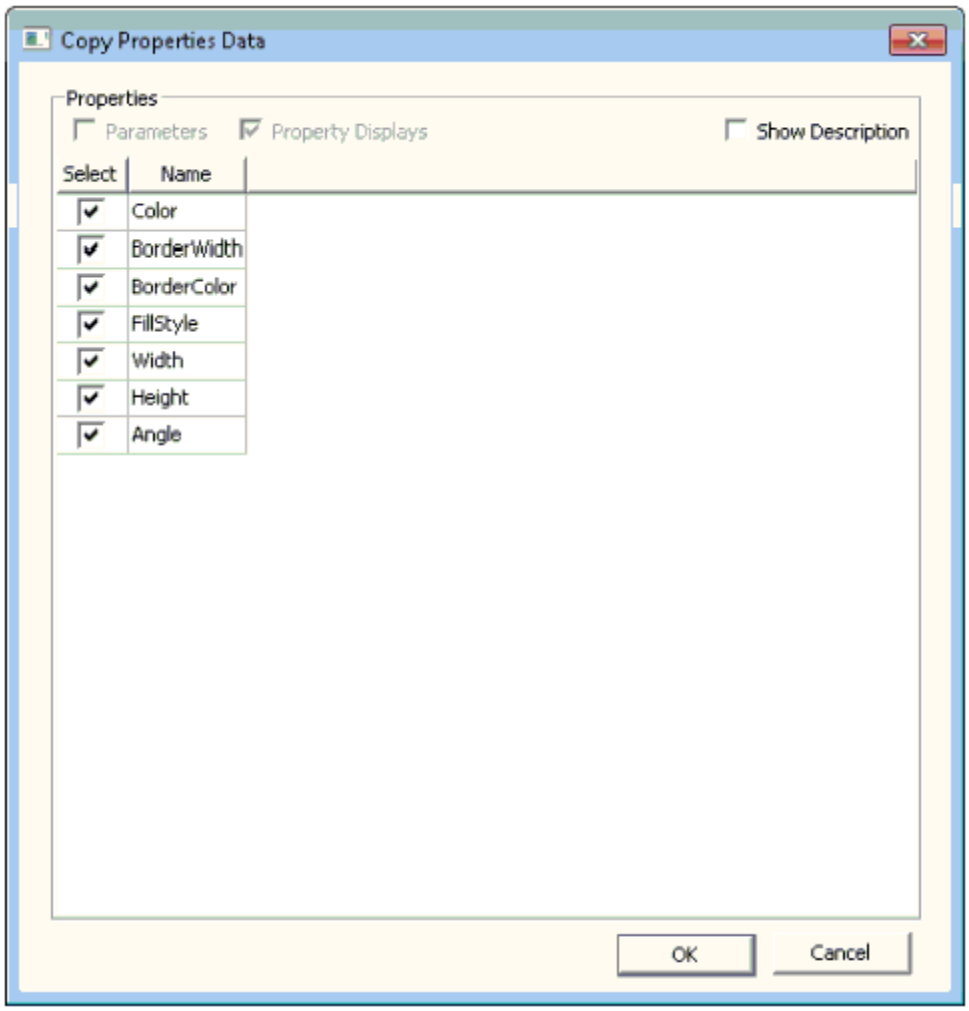
1. Select the object you want to copy from.
2. Use one of the following methods to access Copy Data:
   - Click **Edit** > **Copy Data**.
   - Right-click the object and select **Copy Data**.
   - Press **Ctrl+Shift+C**.
3. Select the object you want to paste to.
4. Paste the properties by using one of the following methods:
   - Select **Edit** > **Paste Data**.
   - Right-click the component and select **Paste Data.**
   - Press **Ctrl+Shift+V**.

   The **Copy Properties Data** window is displayed.



5. In the **Properties** pane, keep the default selections or clear the check boxes for the properties you do not want to copy.

   Click the **Show Description** check box to display the description for each property.
6. Click **OK**. The properties are pasted into the object.

Components

A number of components are available in the Circuit simulator.

To view and select components, click the **Components** tab in the **Component Libraries Window**. To expand a component subgroup, double-click its book icon. To read about a specific component, right-click its icon in the tree and select **View Component Help**.

The following types of elements are available in Maxwell Circuit Editor:

- Dedicated Elements
- Passive Elements
- Probes
- Sources

Once components are placed in the schematic for a project, they appear in the project tree beneath the **Project Components** branch. The most recently placed components also appear under the **Most Recently Used** branch in the project tree. You can also set **Favorites** that can be accessed from the project tree.

Assigning Component Properties in Maxwell Circuit Editor

Dedicated Elements

The following dedicated elements are available in the Maxwell Circuit Editor project tree:

- AC_Model: Component for identifying windings with AC currents
- BarC: Commutator Bar
- BarC_Model: Model Data for Commutator Bar
- ECE3_Model: ECE 3-Phase Model
- ECE6_MODEL: ECE 6-Phase Model
- ECEF_MODEL: ECE Frequency Model
- ECEIM_MODEL: ECE Induction Motor Model
- ECEL_Model: ECE Linear Motion Model
- ECER_Model: ECE Rotation Model
- ECESRM_Model: ECE Switched Reluctance Motor Model
- ECET_Model: ECE Transformer Model
- ECEW_Model: ECE Winding Model
- Winding: Winding

The text before the colon (**:**) represents the component name and can be changed in the **Properties** window once the component is placed in the schematic.

Assigning Component Properties in Maxwell Circuit Editor

AC_Model

The AC_model element is used to decrease the number of electric periods required to reach steady state when feeding windings of inductive loads with voltage sources in the external circuit

editor. It assumes that the average current over one electric period in all windings defined in the AC_model is zero.

After each electric period, the initial current value of the windings is automatically manipulated to compensate for the offset current of the previous electric period. This allows you to modify currents for AC windings at the beginning of each period without interrupting the transient process. If the offset current of the last period is below a defined tolerance, no manipulation of the phase currents is triggered.

To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Param Values tab selected).

The AC_Model contains the following parameters:

- DeviceName, which identifies the name of device model.
- Windings, which is the AC winding list separated by commas. For example, PhA, PhB, PhC. Setting this parameter to “All” will include all windings.
- Frequency, which shows the frequency of the AC currents in Hz.
- Tolerance, which is the ratio of the DC component to the AC amplitude that defines the threshold value triggering a manipulation of the initial current for the subsequent electric period.

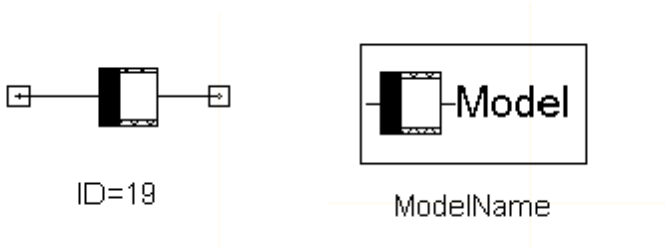
> **Note:** For Maxwell 2D/3D designs of AC machines, RMxprt automatically enables an alternating flux (AF) model in the voltage definition for each winding to reduce transient solution time to reach steady state when the Maxwell 2D or 3D model is created. Also refer to *Using the AF (alternating flux) model* for information on using the AF model to fast reach steady state for transient simulations whose excitation is the Sinusoidal Voltage Source component.

Commutator Bar and Commutator Bar Model

The commutator bar element is intended to be used for the motor model with a commutator. This element models the variable (periodic) contact resistance between the brush and the commutator bars, as well as the switching (commutation of the current) that occurs when the brush makes contact with the two adjacent commutator bars.

The element itself must always be used together with the corresponding commutator bar model. The commutator bar model can be dropped on the sheet anywhere and needs no connections.

Only the commutator bar element itself should be connected as required by the application. The commutator bar elements need to reference the applicable commutator model.



Once the commutator bar element has been dropped on the sheet, you can double-click it to access the properties (make sure the **Parameter Values** tab is selected). Specify the applicable commutator bar model name in the MOD line and also the Lag parameter in degrees. Lag identifies the angle the commutator bar has to rotate from TIME = 0 in the chosen sense of rotation until it is perfectly aligned with the brush. By defa1ult, the element ID and lagging angle in degrees are displayed next to the element.

The commutator bar model needs to be dropped on the circuit sheet. It is unique for every commutator bar element. The commutator bar model contains the following parameters:

- Model name that has to be referenced by all the commutator bar elements;
- R, the full contact resistance between brush and commutator bar, regardless of which of the two is wider;
- WidB is the brush width in mechanical degrees;
- WidC is the commutator bar width in mechanical degrees (does not include the insulation between two adjacent bars);
- Period is the angular periodicity of the positive (or negative) brushes; use 360 for a two pole machine, 180 for a four pole machine with lap winding, etc.

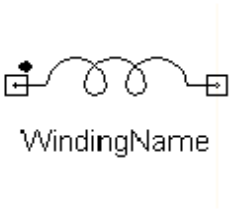
An Application of the Commutating Bar Element.

Winding

The winding element is used in the Maxwell Circuit Editor to create the necessary connection between the finite element model (the type of solution that supports the concept of winding, such as the transient type of analysis, with or without motion) and the driving circuits. It is necessary that the name(s) assigned for the winding(s) in the finite element model are matched exactly in the driving circuit created in Maxwell Circuit Editor. Windings can be placed on the design sheet at any moment while you are creating the circuitry to be used to drive the finite element windings.

To change the name of the winding placed on the sheet, click the winding symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Param Values tab selected).

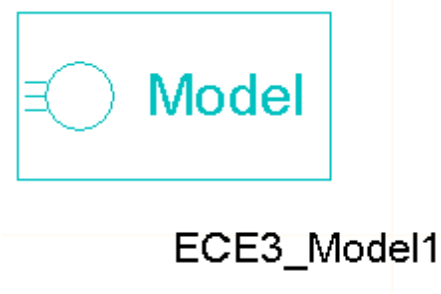


Note	The dot next to the winding symbol is used as the positive reference for the initial current (positive current is oriented from the "dotted" terminal toward to "un-dotted" terminal of the winding, through the winding).

ECE3_Model

The ECE3 model enables you to create an ECE model from Maxwell Transient solutions. Compared with the procedure for creating ECE model from Maxwell Magnetostatic solutions, creating an ECE model directly from Maxwell Transient solutions takes advantage of winding and motion setups in Maxwell Transient.

The ECE3 model is used to set up the sweeping of currents in three-phase windings. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).



The ECE3_Model contains the following parameters:

- DeviceName – the name of the device model with default name ECE3_Model1.
- Windings – specifies the comma-separated name list of three-phase windings whose currents are to be swept.
- CurrentSweeps – specifies the current amplitude sweep list. The format is: "v1, v2, (dv1, n1), v3, …", where v1, v2, v3 specify individual sweeping values, and (dv1, n1) specify a sweep range with dv1 being the increment, and n1 the number of increments. For example, a list of "(0.5A, 5)" is equivalent to "0, 0.5A, 1A, 1.5A, 2A, 2.5A".
- PhAngIntervals – specifies the sweep types, or the number of phase-angle sweep intervals. For three-phase windings, only two independent variables are swept to derive

three-phase currents, instead of directly sweeping three-phase currents. The two independent variables could be DQ currents (I_d, I_q), two-phase currents (I_α, I_β), or current amplitude and phase angle (I_m,β).

PhAngIntervals = 0, 1, or 2, is defined for the DQ current sweep type, and 3 for the two-phase current sweep type.

- When PhAngIntervals = 0, both I_d and I_q are swept based on the original setup of CurrentSweeps, and the look-up table is extended according to odd-symmetric conditions in a post-processing step.
- When PhAngIntervals = 1, the I_d sweep is extended symmetrically to sample negative and positive current values. In contrast, the I_q sweep is based on the original setup of CurrentSweeps and extended in the look-up table according to odd-symmetric conditions in a post-processing step.
- When PhAngIntervals = 2, both I_d and I_q sweeps are extended symmetrically from negative to positive, sampling positive and negative values for both, I_d and I_q. Accordingly, the computed look-up table does not need to be extended in post-processing.
- When PhAngIntervals = 3, both I_α and I_β sweeps are extended symmetrically from negative to positive, and the computed look-up table is not extended in post-processing.
- When PhAngIntervals ≥ 12, the current amplitude and phase angle sweep type are defined. The current amplitude I_m is swept based on the setup of CurrentSweeps, and the phase angle is swept from 0 to 360 electrical degrees with the increment $\Delta\beta = 360°/(\text{PhAngIntervals})$.

- Res – phase winding resistance (available when Show Hidden is checked. Default value is 1mΩ).
- IndE – phase end-leakage inductance (available when Show Hidden is checked. Default value is 1μH).

An ECE3_Model can be used individually to create the ECE model of a three-phase inductor, or combined with the ECER_Model for three-phase PM machines. It can also be combined with the ECER_Model and ECEW_Model for winding excited three-phase synchronous machines. An ECE3_Model with DQ current sweep type must always be used with an ECER_Model.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the lists of current sweeps until all sweeps are finished. An ECE model is then created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

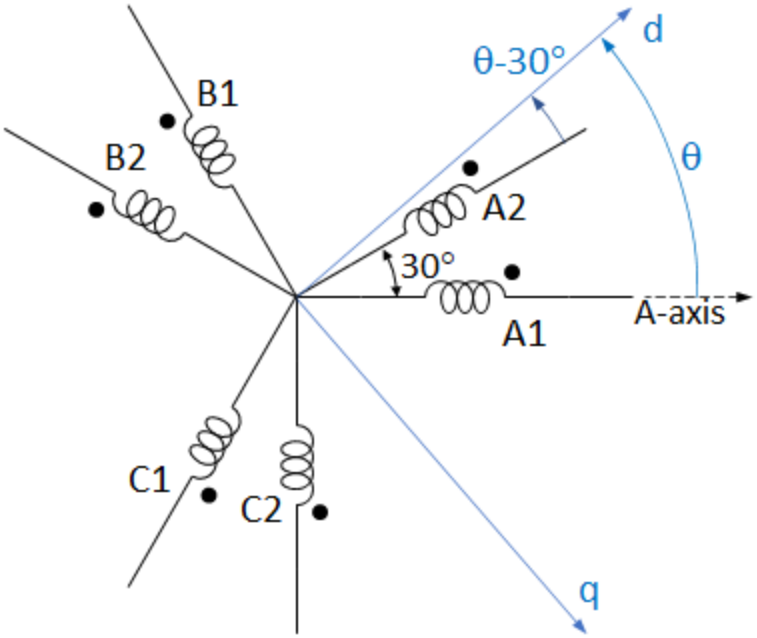
Note	You can add an ECE3_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Coupling Maxwell to a Twin Builder Component* topic in the Maxwell Help

ECE6_Model

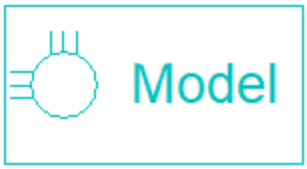
The ECE6 model enables you to create an ECE model from Maxwell Transient solutions. Compared with the procedure for creating ECE model from Maxwell Magnetostatic solutions, creating an ECE model directly from Maxwell Transient solutions takes advantage of winding and motion setups in Maxwell Transient.

The ECE6 model is used to set up the sweeping of currents in a six-phase winding, which is described as dual three-phase windings. These two three-phase windings are shifted by 30 electrical degrees. The figure below shows the set-2 three-phase windings lagging behind the set-1 three-phase windings by 30 electrical degrees, and dq axes in rotor with the q-axis lagging behind the d-axis by 90 electrical degrees.



We define the rotor initial position with θ = 0 as the position where the rotor d-axis aligns with the axis of the phase A1 winding. That is, the phase A1 gets maximum flux linkage when θ = 0.

To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).



ECE6_Model1

The ECE6_Model contains the following parameters:

- DeviceName – the name of the device model with default name ECE6_Model1.
- Windings – specify winding names in the order of arrangement. Windings are separated by commas within each three-phase set, and by semicolon between the two three-phase sets. Please notice that the winding list always starts with the leading set and ends with the lagging set. For the phase windings as shown in the figure above, the winding list is specified as:

  A1 B1, C1; A2, B2, C2
- CurrentSweeps – to specify sweeping values for d- and q-axis currents, Id and Iq, respectively, you only need to list 0 and all positive sweeping currents. All negative currents will be swept, or extended, symmetrically from the specified positive sweeping values. For example: 0, 1, 10
- PhAngIntervals – specify the type to extend the sweeping list and look-up table. Valid values are: 0, 1, or 2 only. Value 0 specifies the type that both Id and Iq are post-extended; Value 1 specifies the type that Id is pre-extended, and Iq is post-extended; Value 2 specifies the type that both Id and Iq are pre-extended. Here, “pre-extended” means the sweeping list for a current is symmetrically extended from the sweeping values specified in CurrentSweeps, and “post-extended” means the look-up table for a current, which is derived from the sweeping values specified in CurrentSweeps, is extended based on even or odd symmetric conditions. In a post extension, the symmetric conditions are applicable only for fundamental fields. Therefore, it is not necessary to consider all harmonics in the look-up table for post-extended variables. In such a case, all harmonic components will be filtered by using the average values over various rotor positions for all dq0 flux linkages and torque to reduce the length of the look-up table.
- Res – phase winding resistance (available when Show Hidden is checked).
- IndE – phase end-leakage inductance (available when Show Hidden is checked).

Transformation between the six-phase and dq0 systems

The current transformation from dq0 system to set-1 ABC system is:

$$\begin{bmatrix} I_{A1} \\ I_{B1} \\ I_{C1} \end{bmatrix} = \mathbf{C}(\theta) \cdot \begin{bmatrix} I_{d1} \\ I_{q1} \\ I_{01} \end{bmatrix}$$

where

$$\mathbf{C}(\theta) = \begin{bmatrix} \cos(\theta) & \sin(\theta) & 1 \\ \cos\left(\theta - \frac{2\pi}{3}\right) & \sin\left(\theta - \frac{2\pi}{3}\right) & 1 \\ \cos\left(\theta - \frac{4\pi}{3}\right) & \sin\left(\theta - \frac{4\pi}{3}\right) & 1 \end{bmatrix}$$

Since the set-2 winding lags behind the set-1 winding by 30 electrical degrees, the current transformation from dq0 system to set-2 ABC system is:

$$\begin{bmatrix} I_{A2} \\ I_{B2} \\ I_{C2} \end{bmatrix} = \mathbf{C}\left(\theta - \frac{\pi}{6}\right) \cdot \begin{bmatrix} I_{d2} \\ I_{q2} \\ I_{02} \end{bmatrix}$$

The contribution of 0-axis currents (I_{01}, I_{02}) to winding flux linkages can be considered by zero-inductance L_0, which is usually assumed to be constant. Therefore, it is not necessary to sweep 0-axis currents. In general, to cover all possible operation cases, the remaining four independent currents (I_{d1}, I_{q1}, I_{d2}, I_{q2}) need to be swept. However, in most applications, to get the benefits of 6-phase windings, these dual three-phase windings are operated with balanced currents, that is, in the winding set lagging behind by 30 electrical degrees in space, the currents lag behind by 30 degrees in time. In such cases, the dq currents on both winding sets are the same. Therefore, to save FEA simulation time, we sweep only two independent currents (I_d, I_q) during FEA simulation, and assign

$$\begin{cases} I_{d1} = I_{d2} = I_d \\ I_{q1} = I_{q2} = I_q \end{cases}$$

During circuit simulation, we measure dual three-phase currents (I_{A1}, I_{B1}, I_{C1}) and (I_{A2}, I_{B2}, I_{C2}), and transform them to dq currents by

$$\begin{bmatrix} I_{d1} \\ I_{q1} \\ I_{01} \end{bmatrix} = \mathbf{C}^{-1}(\theta) \cdot \begin{bmatrix} I_{A1} \\ I_{B1} \\ I_{C1} \end{bmatrix}$$

and

$$\begin{bmatrix} I_{d2} \\ I_{q2} \\ I_{02} \end{bmatrix} = \mathbf{C}^{-1}\left(\theta - \frac{\pi}{6}\right) \cdot \begin{bmatrix} I_{A2} \\ I_{B2} \\ I_{C2} \end{bmatrix}$$

where

$$\mathbf{C}^{-1}(\theta) = \frac{2}{3} \begin{bmatrix} \cos(\theta) & \cos\left(\theta - \frac{2\pi}{3}\right) & \cos\left(\theta - \frac{4\pi}{3}\right) \\ \sin(\theta) & \sin\left(\theta - \frac{2\pi}{3}\right) & \sin\left(\theta - \frac{4\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix}$$

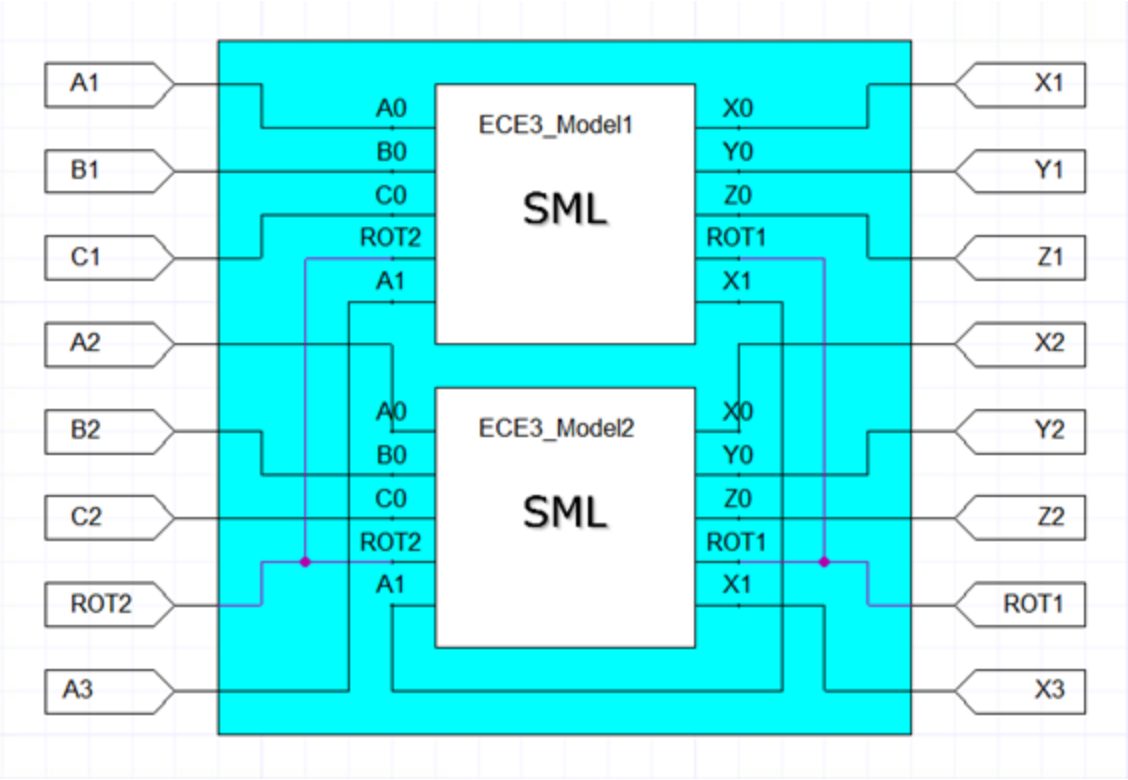
The dq currents used in the look-up table are:

$$\begin{cases} I_d = (I_{d1} + I_{d2})/2 \\ I_q = (I_{q1} + I_{q2})/2 \end{cases}$$

Since the two sets of three-phase windings have the same turns, the fundamental field produced by the average dq currents will be the same as that produced by the real dq currents. Therefore, for unbalanced operations, replacing the real dq currents (I_{d1}, I_{q1}) and (I_{d2}, I_{q2}) in the two winding sets by the average dq currents (I_d, I_q) will not cause noticeable errors.

Circuit Model and Look-up Table

The circuit model for 6-phase machines consists of two sub-circuits of 3-phase machines with the dq currents of the other sub-circuit being the input arguments, as shown below, where the initial position, an input argument of the sub-circuit model, of ECE3_Model2 is set 30 electrical degrees lagging behind ECE3_Model1. The mechanical ports represented by (ROT1, ROT2) of the two sub-circuit are connected in parallel, and the torque values in the look-up table are a half of the FEA solutions for each sweep. The field winding, if it exists, represented by (A3, X3) in the circuit model, is obtained by series connection of the field windings, represented by (A1, X1), of the two sub-circuits.



The flux linkage values in the look-up table of the field winding in the sub-circuit are a half of the FEA solutions. The input dq currents of the other sub-circuit are used to get the average dq currents as the input of the look-up table. The following is an example of the data structure of the look-up table of a 6-phase machine with wound field.

The sub-circuit data include basic data, specified resistances and leakage inductances of all windings, value list for all controlling variables, and value list for all controlled variables of al sweeps.

The basic data are listed between “B_BasicData” and “E_BasicData”, which include the version number, the number of poles, and d- and q-axis leakage inductance between the 2-set 3-phase windings.

The data between “B_PhaseImp” and “E_PhaseImp” list the winding resistances and end leakage inductances, which are not included in 2D FEA results, for each winding. The winding resistances and end leakage inductances are obtained from specified parameters Res and IndE of the ECE6_Model, as well as ECEW_Model if it is included.

The data between “B_Sweeping” and “E_Sweeping” provide all sweeping variables, and their sweeping data lists. Each sweeping variable, corresponding to one ECE sweeping model, starts with a keyword and follows one or two sweeping data list. The sweeping data list is in the format of (n: v0 v1 …) representing the number of sweeps and sweeping values. Keyword “Id_Iq” means the dq current sweep, “Iw” represents wound field current sweep, and “Rotate” indicates the rotor position sweep.

The data between “B_OutputMaxtrix” and “E_OutputMatrix” lists solutions of all sweeps. The first column is the sweeping index from 0 to n-1, here n is the total number of sweeps. The total number of sweeps is 7x7x5x49 = 12005. The 2nd to 4th columns list the dq0 flux linkages of all sweeps for the present sub-circuit. If the field winding exists, the 5th column lists its flux linkage. The last column list torque values of all sweeps.

From FEA solutions, we get results of flux linkages of all windings. The dq0 flux linkages can be obtained from

$$\begin{bmatrix} \lambda_{d1} \\ \lambda_{q1} \\ \lambda_{01} \end{bmatrix} = \mathbf{C}^{-1}(\theta) \cdot \begin{bmatrix} \lambda_{A1} \\ \lambda_{B1} \\ \lambda_{C1} \end{bmatrix}$$

and

$$\begin{bmatrix} \lambda_{d2} \\ \lambda_{q2} \\ \lambda_{02} \end{bmatrix} = \mathbf{C}^{-1}\left(\theta - \frac{\pi}{6}\right) \cdot \begin{bmatrix} \lambda_{A2} \\ \lambda_{B2} \\ \lambda_{C2} \end{bmatrix}$$

Since set-2 windings lag behind set-1 windings by 30 electrical degrees, the ABC flux linkages of the set-2 windings will lag behind those of the set-1 windings by 30 degrees. As the result, the dq0 flux linkages satisfy

$$\begin{cases} \lambda_{d1}\left(\theta + 30^{\circ}\right) = \lambda_{d2}\left(\theta\right) \\ \lambda_{q1}\left(\theta + 30^{\circ}\right) = \lambda_{q2}\left(\theta\right) \\ \lambda_{01}\left(\theta + 30^{\circ}\right) = -\lambda_{02}\left(\theta\right) \end{cases}$$

The repeatable period for the d- and q-axis flux linkages is 60 electrical degrees, but that for the 0-axis flux linkage is 120 electrical degrees. Therefore, all dq0 flux linkages must be extended to 120 electrical degrees by

$$\begin{cases} \lambda_{d1}\left(\theta + 60^{\circ}\right) = \lambda_{d1}\left(\theta\right) \\ \lambda_{q1}\left(\theta + 60^{\circ}\right) = \lambda_{q1}\left(\theta\right) \\ \lambda_{01}\left(\theta + 60^{\circ}\right) = -\lambda_{01}\left(\theta\right) \end{cases}$$

The extended dq0 flux linkages in the final look-up table are based on the same dq currents in two winding sets. During the circuit simulation, if the dq currents in the two windings are not the same, the dq flux linkages obtained from the look-up table must be modified as described below. The modified d-axis flux linkage is

$$\lambda_{d1}{}' = \lambda_{Fd} + L_{d1} I_{d1} + M_{d12} I_{d2}$$

$$= \lambda_{d1} + L_{1d}\left(I_{d1} - I_{d2}\right)/2$$

where λ_{Fd} is the flux linkage produced by wound field winding current, or PM, and

$$L_{1d} = L_{d1} - M_{d12}$$

$$\lambda_{d1} = \lambda_{Fd} + L_{d1} I_d + M_{d12} I_d$$

which can be directly obtained from the look-up table. Similarly, the q-axis flux linkage is modified by

$$\lambda_{q1}{}' = \lambda_{q1} + L_{1q}\left(I_{q1} - I_{q2}\right)/2$$

where $L_{1q} = L_{1d}$, and λ_{q1} can be directly obtained from the look-up table. To filter the slot effects, the d- or q-axis leakage inductance L_{1d} can be computed from

$$L_{1d} = \frac{1}{n}\sum_{i=1}^{n} 0.5\left[\left(L_{d1} - M_{d12}\right)_i + \left(L_{q1} - M_{q12}\right)_i\right]$$

where *i* represents the sweeping index.

The d- and q-axis self-inductance and mutual inductance between 2 winding sets are derived from

$$\begin{bmatrix} L_{d1} & 0 & 0 \\ 0 & L_{q1} & 0 \\ 0 & 0 & L_{01} \end{bmatrix} = \mathbf{C}^{-1}(\theta) \cdot \begin{bmatrix} L_{A1} & M_{A1B1} & M_{A1C1} \\ M_{B1A1} & L_{B1} & M_{B1C1} \\ M_{C1A1} & M_{C1B1} & L_{C1} \end{bmatrix} \cdot \mathbf{C}(\theta)$$

and

$$\begin{bmatrix} M_{d12} & 0 & 0 \\ 0 & M_{q12} & 0 \\ 0 & 0 & M_{012} \end{bmatrix} = \mathbf{C}^{-1}(\theta) \cdot \begin{bmatrix} M_{A1A2} & M_{A1B2} & M_{A1C2} \\ M_{B1A2} & M_{B1B2} & M_{B1C2} \\ M_{C1A2} & M_{C1B2} & M_{C1C2} \end{bmatrix} \cdot \mathbf{C}\left(\theta - \frac{\pi}{6}\right)$$

An ECE6_Model should be used with an ECER_Model.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the lists of current sweeps until all sweeps are finished. An ECE model is then created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

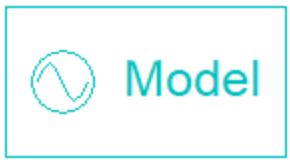
Note	You can add an ECE6_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Coupling Maxwell to a Twin Builder Component* topic in the Maxwell Help

ECEF_Model

The ECEF model enables you to create an ECE model from Maxwell Eddy Current solutions.

The ECEF model is used to set up a frequency sweep. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).



ECEF_Model1

The ECEF_Model contains the following parameters:

- DeviceName –the name of the device model with default name ECEF_Model1.
- FreqSweeps – specifies the frequency sweep list. The format is: "v1, v2, (dv1, n1), v3, …", where v1, v2, v3 specify individual sweeping values, and (dv1, n1) specify a sweep range with dv1 being the increment, and n1 the number of increments. For example, a list of "50Hz, (10Hz, 5)" is equivalent to "50Hz, 60Hz, 70Hz, 80Hz, 90Hz, 100Hz".

An ECEF_Model cannot be used individually. It should be used combined with an ECEIM_Model for induction motors.

At Maxwell run time, the circuit simulator assigns current, slip, as well as frequency if ECEF_ Model is added, to Maxwell Eddy Current solver until all sweeps are finished. An ECE model is created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

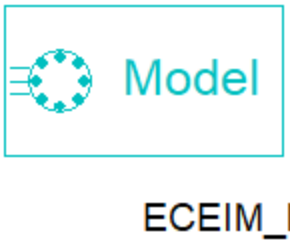
Note	You can add an ECEF_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Coupling Maxwell to a Twin Builder Component* topic in the Maxwell Help

ECEIM_Model

The ECEIM model enables you to create an ECE model of a three-phase induction motor from Maxwell Eddy Current solutions.

To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).



The ECEIM_Model contains the following parameters:

- DeviceName – the name of the device model with default name ECEIM_Model1.
- Windings – specifies the comma-separated name list of three-phase windings whose currents are to be swept.
- CurrentSweeps – specifies lists of sweep currents. The format is: “v1, v2, (dv1, n1), v3, …”, where v1, v2, v3 specify individual sweep values, and (dv1, n1) specify a sweeping range with dv1 being the increment, and n1 the number of increments. For example, a list of “-2.5A, (0.5A, 10)” is equivalent to "-2.5A, -2A, -1.5A, -1A, -0.5A, 0, 0.5A, 1A, 1.5A, 2A, 2.5A", and a list of "(0.5A, 5)" is equivalent to “0, 0.5A, 1A, 1.5A, 2A, 2.5A”.
- SkewAng – specifies the skew angle (in mechanical degrees) of the stator or rotor core for 2D only (available when Show Hidden is checked).
- Res – phase winding resistance (available when Show Hidden is checked).
- IndE – phase end-leakage inductance (available when Show Hidden is checked).

The ECEIM model is used to set up the sweeping of currents in three-phase windings. A slip sweep is added together with the current sweep. The slip sweep is fixed (not user-configurable) with a list of the following 13 values: 0.01, 0.02, 0.04, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0. To simulate the real operation of induction motors at a specified slip with Eddy Current solvers, the rotating rotor is treated as a locked rotor with equivalent rotor resistances and inductances.

An ECEIM_Model can be used individually to create the ECE model of a three-phase induction machine, or combined with the ECEF_Model for sweeping frequency.

At Maxwell run time, the circuit simulator assigns current, slip, as well as frequency if ECEF_ Model is added, to Maxwell Eddy Current solver until all sweeps are finished. An ECE model is then created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

Note	You can add an ECEIM_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Coupling Maxwell to a Twin Builder Component* topic in the Maxwell Help.

Circuit and Parameters

Due to saturation and skin effects, the stator leakage inductance might be nonlinear, and the rotor leakage inductance will be nonlinear and slip dependent. The rotor leakage inductance can be decoupled into two parts, non-linear only and slip dependent only, as explained below.

The stator and rotor non-linear can be expressed as

$$\begin{cases} L_1\left(I_1\right) = L_{10} + L_{1m}/k_{s1}\left(I_1\right) \\ L_2\left(I_1\right) = L_{20} + L_{2m}/k_{s2}\left(I_1\right) \end{cases}$$

where

$$\begin{cases} k_{s1}\left(I_1\right) = \left(I_1/I_{T1}\right)/\left(1 - e^{-I_1/I_{T1}}\right) \\ k_{s2}\left(I_1\right) = \left(I_1/I_{T2}\right)/\left(1 - e^{-I_1/I_{T2}}\right) \end{cases}$$

The slip-dependent rotor resistance and leakage inductance are

$$\begin{cases} R_{2s} = k_r R_{2s0} \\ L_{2s} = k_x L_{2s0} \end{cases}$$

where

$$\begin{cases} k_r\left(\xi\right) = \xi\frac{\sinh(2\xi)+\sin(2\xi)}{\cosh(2\xi)-\cos(2\xi)} \\ k_x\left(\xi\right) = \frac{3}{2\xi}\frac{\sinh(2\xi)-\sin(2\xi)}{\cosh(2\xi)-\cos(2\xi)} \end{cases}$$

with

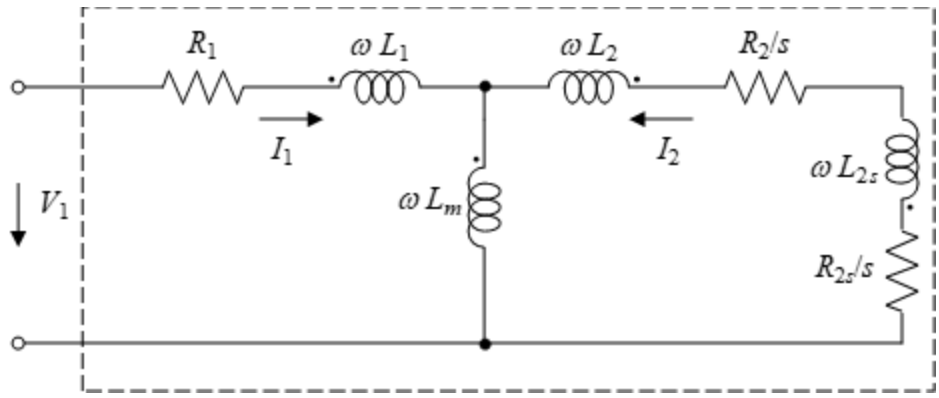
$$\xi = \xi_0\sqrt{s}$$

In the above equations, I_1 is the stator phase current and s is the rotor slip, L_{10}, L_{1m}, L_{20}, L_{2m}, I_{T1}, I_{T2}, R_{2s0}, L_{2s0} and ξ_0, as well as R_2 in the circuit, are 10 constant parameters identified from the eddy-current FEA solutions at different stator currents and rotor slips. If the stator or rotor leakage inductance is constant, L_{1m} or L_{2m} is zero, and I_{1T} or L_{T2} is not used in such a case.

The non-linear main inductance in the circuit is expressed as

$$L_m = L_{m0}/k_{sm}$$

where, L_{m0} is a constant parameter, and k_{sm} is the saturation factor of main field which is expressed as a look-up table. Both L_{m0} and k_{sm} are identified from the eddy current FEA solutions with different stator currents at no-load operation (with rotor slip being near zero).



Since R_{2s0} and L_{2s0} are slip dependent, the above circuit can be implemented in the frequency domain only. If the rotor bar is divided into two sections with top section ratio of k_1, and the bottom section ratio of $k_2 = 1 - k_1$, the resistance and self-inductance of the top section will be:

$$\begin{cases} R_{2t} = R_{2s0}/k_1 \\ L_{2t} = k_1 L_{2s0} \end{cases}$$

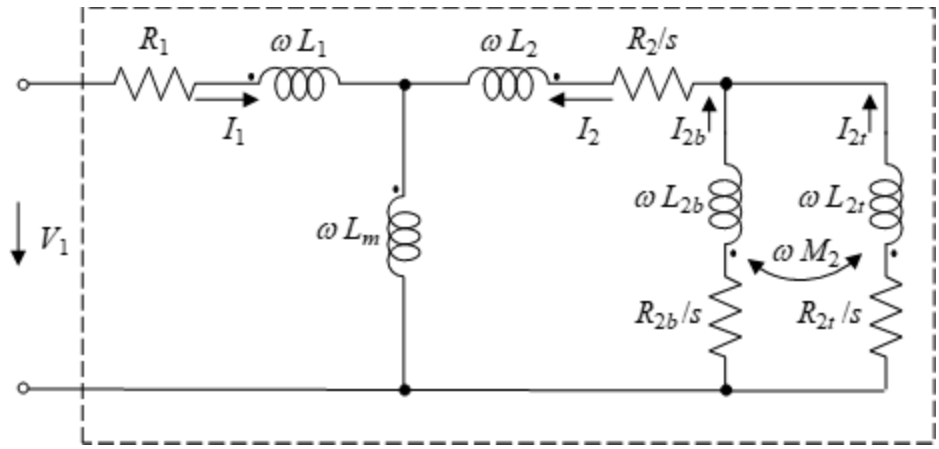
and the resistance and self-inductance of the bottom section are:

$$\begin{cases} R_{2b} = R_{2s0}/k_2 \\ L_{2b} = k_2 L_{2s0} + 3k_1 L_{2s0} \end{cases}$$

The mutual inductance between the top and bottom sections is:

$$M_2 = \frac{3}{2} k_1 L_{2s0}$$

The circuit with distributed rotor sections is shown in the following figure:



After all parameters in the first circuit are identified, the top section ratio k_1 is identified by minimizing the error of the impedance between the two circuits. All identified parameters are saved in file **ece_table.txt**, as shown in the figure below.

In above figure, r_1, $l1_e$, and *skew* are directly obtained from ECEIM_Model inputs Res, IndE, and SkewAng, respectively, 10 parameters, l10, l1m, it1, r20, l20, l2m, it2, r2s0, l2s0, kxi0 (ξ0), and lm0, as well as the look-up table between B_SatFactorForXm0_im_ksm and E_ SatFactorForXm0_im_ksm, are identified based on the first circuit, and k1 is identified based on the second circuit. Parameter l00 is the zero-sequence inductance. The err value represents the relative error of impedances between the FEA solutions and the parameter-derived results. If the value of use_tanh is 1, the saturation factors for the stator and rotor leakage inductances will be expressed as:

$$\begin{cases} k_{s1}\left(I_1\right) = \left(I_1/I_{T1}\right)/tanh(I_1/I_{T1}) \\ k_{s2}\left(I_1\right) = \left(I_1/I_{T2}\right)/tanh(I_1/I_{T1}) \end{cases}$$

to achieve smaller identification error, where tanh() is a hyperbolic tangent function.

Core Loss Parameters

Core losses can be computed for each sweep in eddy-current solver. To include core loss computation, users must check the **Core Loss** setting in the **Excitations/Set Core Loss** panel. Since core losses are computed in a post-process, including core loss computation will not affect the parameter identification of the induction machine circuit.

The stator and/or rotor core losses can be obtained from lamination steel or power ferrite material. For lamination steel material, the stator core loss can be computed from the phase circuit variables and expressed as:

$$P_{fe1} = k_{hs} {E_m}^2 / f + k_{cs} {E_m}^2 + k_{es} {E_m}^{1.5}$$

where k_{hs}, k_{cs}, and k_{es} are to-be-determined parameters, E_m is the phase induced voltage magnitude, and f is the frequency. For power ferrite material, core loss is expressed as:

$$P_{fe1} = C_m {E_m}^A f^B$$

where C_m, A, and B are to-be-determined parameters. The three parameters for either material can be identified at different induced voltage magnitudes and different frequencies by minimizing the error of core losses between the FEA solutions and the results obtained from the above equations. One of the above two equations will be automatically selected according to their identified errors. If the identified error based on the first equation is smaller than that based on the second equation, the first equation for lamination steel material will be selected. Otherwise, the second equation for power ferrite material will be selected. The core loss resistance is derived from core loss, and for lamination steel material, it is given by:

$$R_{fe1} = \frac{{E_m}^2/2}{P_{fe1}/3} = \frac{1.5}{k_{hs}/f + k_{cs} + k_{es}/{E_m}^{0.5}}$$

For power ferrite material, core loss resistance is given by:

$$R_{fe1} = \frac{{E_m}^2/2}{P_{fe1}/3} = \frac{1.5}{C_m {E_m}^{A-2} f^B}$$

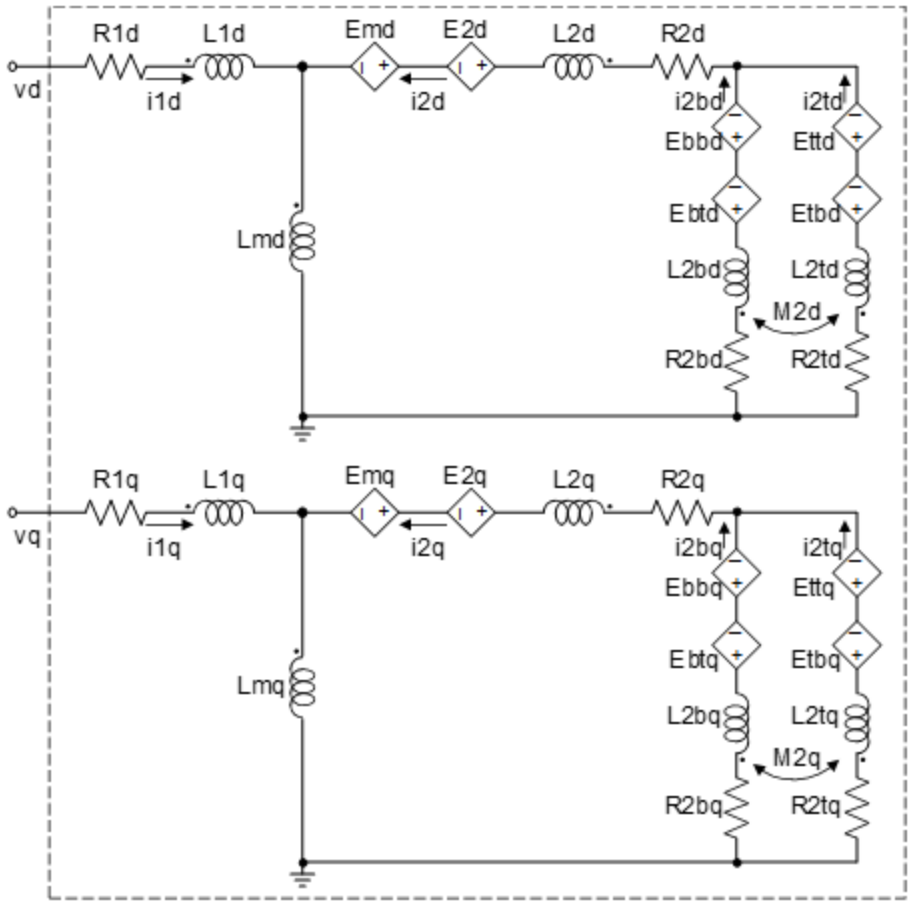
Replacing E_m by sE_m and f by sf, where s is the rotor slip, we can calculate rotor core loss in the same way as the stator core loss. Then the rotor core loss resistance for lamination steel material is:

$$R_{fe2} = \frac{{E_m}^2/2}{P_{fe2}/3} = \frac{1.5}{s k_{hs}/f + s^2 k_{cs} + s^{1.5} k_{es}/{E_m}^{0.5}}$$

and the rotor core loss resistance for power ferrite material is:

$$R_{fe2} = \frac{{E_m}^2/2}{P_{fe2}/3} = \frac{1.5}{C_m {E_m}^{A-2} f^B s^{A+B}}$$

Core loss resistance is frequency-dependent. In a time-domain circuit, as shown in the following figure, what we can measure are time-instant values. In order to use frequency-dependent resistance in a time-domain circuit, we need to calculate the frequency based on measurable time-instant values.



By measuring the induced voltages across Lmd and Lmq at time t, noted as Vmd and Vmq, respectively, we can compute the magnitude of induced voltage as:

$$V_m = \sqrt{V_{md}{}^2 + V_{md}{}^2}$$

Similarly, by measuring the flus linkages of Lmd and Lmq at time t, noted as λmd and λmq, respectively, we can compute the magnitude of flux linkage as:

$$\lambda_m = \sqrt{\lambda_{md}{}^2 + \lambda_{mq}{}^2}$$

The frequency then can be obtained from:

$$f = \frac{V_m}{2\pi\lambda_m}$$

and the induced voltage magnitude in three-phase side E_m for core loss resistance computation can be obtained by V_m with a factor of two-phase to three-phase transformation. The slip *s* for the computation of rotor core loss resistance can be obtained from the number of poles, rotor speed, and frequency.

The identified core loss parameters are listed between B_CorelossParam and E_CorelossParam in **ece_table.txt** file, as shown below.

```
B_CorelossParam
 typeS  3
 khs    0.00372061
 kcs    1.32565e-05
 kes    0.000768336
 errS   0.140547
 typeR  1
 khr    0.000180694
 kcr    5.1108e-06
 ker    -5.19829e-05
 errR   0.00768287
E_CorelossParam
```

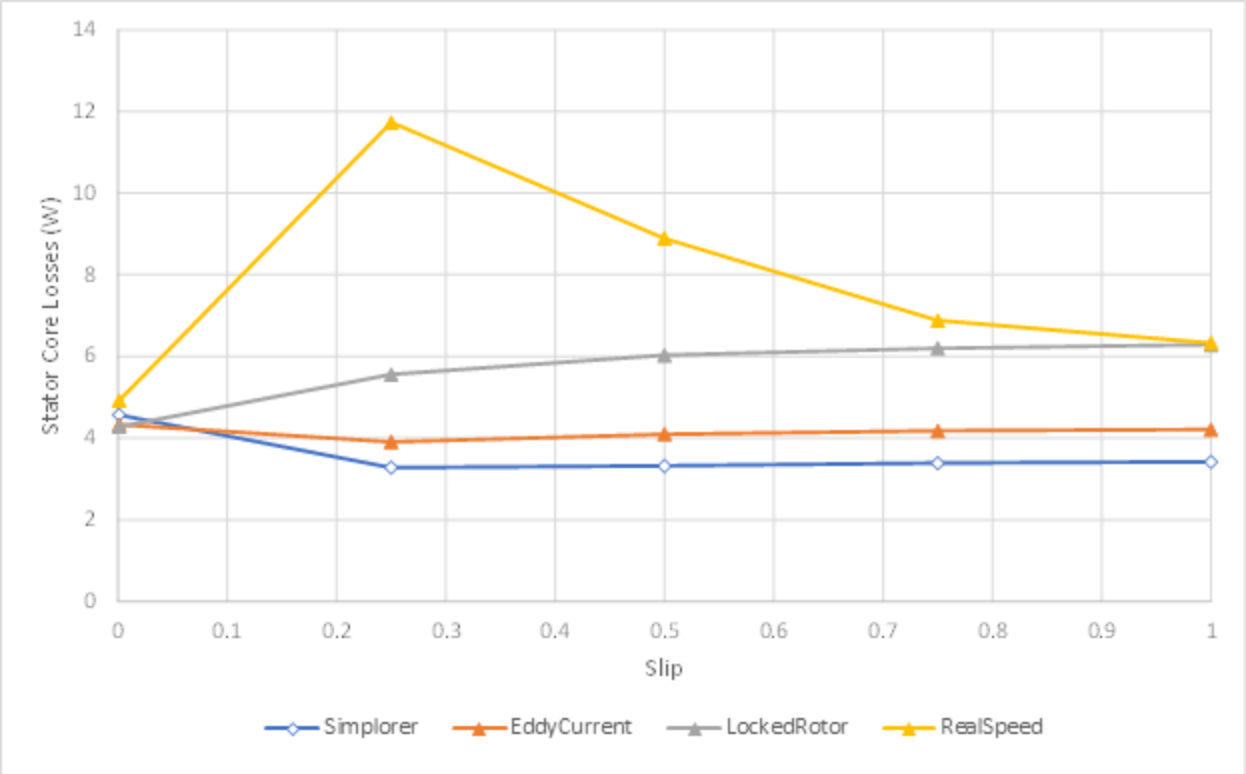
In the above figure, parameters typeS, khs, kcs, kes, and errS are for stator core loss. When typeS is 0, the circuit model will not include the stator core loss. When typeS is 1 or 3, the parameters are lamination-steel-based, and when it is 2 or 4, the parameters khs, kcs, and kes represent Cm, A, and B, respectively, for power ferrite material. When typeS is 1 or 2, two stator core loss resistances are connected in parallel with Lmd and Lmq, otherwise, when it is 3 or 4, two core loss resistances are connected from the input nodes of L1d and L1q to the ground. The errS value is the regression error for the stator core loss. Similarly, parameters typeR, khr, kcr, ker, and errR are for rotor core loss with the same definition as the parameters for stator core loss.

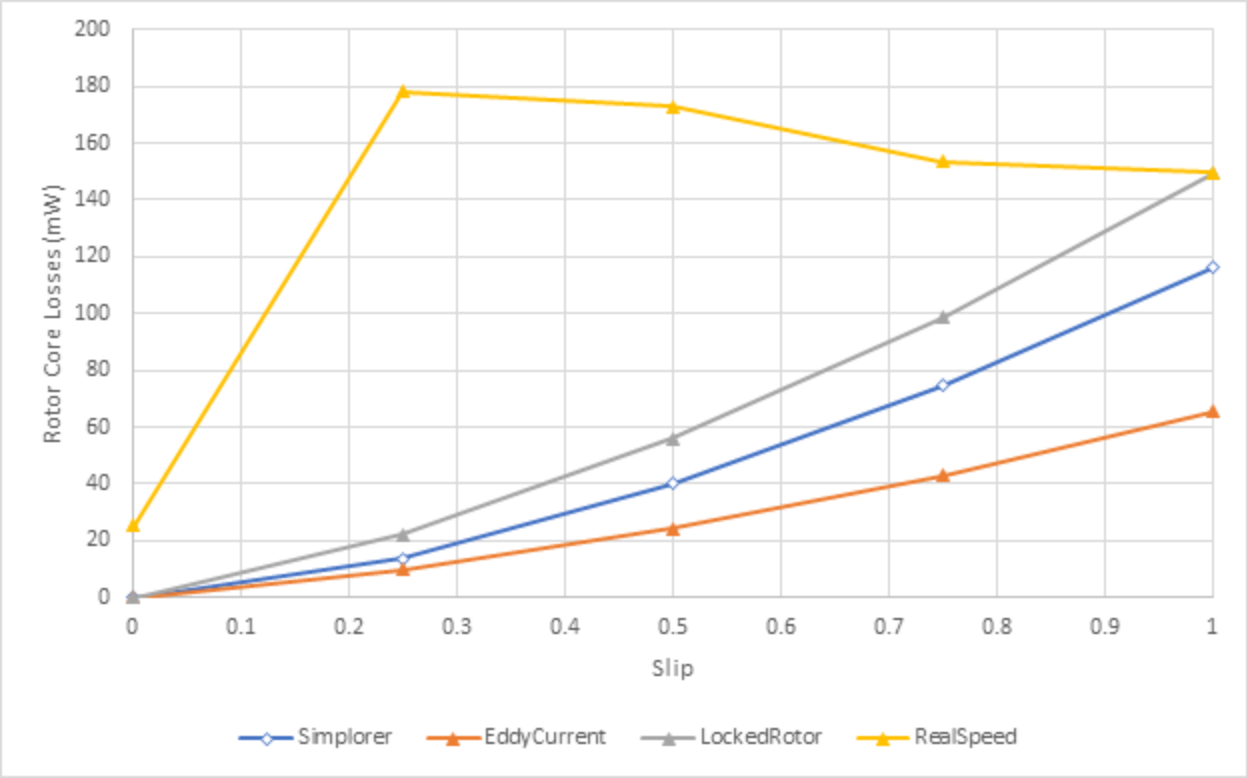
Since core loss parameters are identified from Maxwell eddy-current solutions at no-load operation based on the method referring the rotor frequency from the real operation condition to a locked-rotor operation (called locked-rotor method), the predicted core loss from the identified parameters will be under-estimated due to the following approximation errors:

1. The error caused by field difference between no-load and load operations. At no-load operation, the field in an induction machine is mainly the main flux which links both the stator and rotor windings, while at load operation, the main fluxes created by the stator and rotor currents will mostly offset each other, remaining large leakage fluxes which will go through the stator and rotor tooth tips. In the stator, the leakage flux will add to the main flux, causing the stator core loss increasing. In the rotor, the leakage flux will partially cancel the main flux, causing the rotor core loss decreasing a little.
2. The error caused by difference between sinusoidal (eddy-current solver) and non-sinusoidal (transient solver) waveforms. In eddy-current solver, core loss is computed based on pure sinusoidal waveforms, but in transient solver, core loss is computed based on real non-sinusoidal waveforms due to non-linearity. The harmonic field components will cause additional core losses in both stator and rotor cores in transient analysis.
3. The error caused by difference between locked-rotor and rotating operations. When rotor is rotating, the slot effects will cause additional core losses at the surfaces of the stator and rotor cores known as surface losses, as well as additional core loss at teeth of the stator and rotor cores known as pulsation losses.

The above three loss errors can be illustrated by the following two figures for stator and rotor core losses, respectively. In the figures, curves labeled with “Simplorer” are obtained from the system

simulation based on the extracted core loss parameters, curves labeled with “EddyCurrent” are obtained from the eddy-current simulation based on the locked-rotor method, curves labeled with “LockedRotor” are obtained from the transient simulation based on the locked-rotor method, and curves labeled with “RealSpeed” are obtained from the transient simulation with real rotor speed. The loss difference between curves “EddyCurrent” and “Simplorer” represents the error described in (1), the loss difference between curves “LockedRotor” and “EddyCurrent” indicates the error described in (2), and the loss difference between curves “RealSpeed” and “LockedRotor” is the error described in (3), which will increase as the stator currents increase, and will decrease as the rotor speed decreases.





Therefore, compare to Maxwell transient analysis, the core loss obtained from the circuit simulation will be under-estimated, especially at load operation. To adjust the simulated core loss, we introduce an argument KPfe in SIMPLORER (Twin Builder) circuit model to scale core losses for both stator and rotor. The default value of KPfe is 1.0. The reasonable value of KPfe at full-load operation may range from 1.5 to 2.5.

Since the stator and rotor core loss resistances are non-linear and frequency dependent, we allow users to consider or not consider core loss effects on circuit variables to avoid possible divergence during circuit simulation. When we input a positive value for KPfe, we will consider core loss effects by connecting the core loss resistances with derived values. When the input value for KPfe is negative, the core loss resistances are disconnected.

No matter core loss effects are considered or not, the stator and/or rotor core losses are output via circuit arguments Pfe1 and/or Pfe2 in the SIMPLORER (Twin Builder) circuit model.

ECEL_Model

The ECEL model is used to set up the sweeping of mover position of a translational motion. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).

ECEL_Model1

The ECEL_Model contains the following parameters:

- DeviceName − the name of the device model with the default name as ECEL_Model1;
- MotionMax − the maximum motion range for sweeping;
- MotionIntervals − the number of uniform sweeping intervals for motion range;
- MotionType − the motion type: 0 for limited motion; 1: for periodic motion with full sweeping; 2 or more: for periodic motion with half or less sweeping.
- MotionDir − the motion direction in (x, y, z);

The initial position set in Maxwell designs is always referred to as 0 position in ECE model. When MotionType >= 1 (for periodic motions), the number of sweepings is equal to MotionIntervals. In such a case, the last point at MotionMax is not swept and is automatically extended from the first sweeping point at zero position based on the periodic conditions. When MotionType = 0 (for limited motion), the number of sweepings is equal to MotionIntervals + 1. In such a case, the motion limit is always ranged from 0 to MotionMax in the ECE model.

An ECEL_Model cannot be used individually. It should be used combined with an ECEW_Model and/or an ECE3_Model for rotational electrical machines.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the lists of current and position sweeps until all sweeps are finished. An ECE model is created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircui>/Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

Note	You can add an ECEL_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to "Coupling Maxwell to a Twin Builder Component " on page 17-84 .

ECER_Model

The ECER model enables you to create an ECE model from Maxwell Transient solutions. Compared with the procedure for creating ECE model from Maxwell Magnetostatic solutions, creating an ECE model directly from Maxwell Transient solutions takes advantage of winding and motion setups in Maxwell Transient.

The ECER model is used to set up the sweeping of rotor position. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).

The ECER_Model contains the following parameters:

- DeviceName –the name of the device model with default name ECER_Model1.
- RotAngMax – specifies the maximum rotating angle (in mechanical degrees) for sweeping.
- InElecDeg – check to define RotAngMax in elec. degrees, uncheck in mech. degrees
- RotAngIntervals – specifies the number of uniform sweep intervals for rotating angle.
- SkewAng – specifies the skew angle (in mechanical degrees) of the stator or rotor core for 2D only.
- Poles – specifies the number of poles of the machine.
- Slots – specifies the number of stator slots to determine cogging torque period (available when Show Hidden is checked).
- Output – specifies how the look-up table outputs the winding flux linkages. 0 for flux linkages in ABC; 1 for flux linkages in DQ0; 2 for inductances in DQ and field flux linkage (available when Show Hidden is checked).

An ECER_Model cannot be used individually. It should be used combined with an ECEW_Model and/or an ECE3_Model for rotational electrical machines. When DQFluxOutput is checked, it must be combined with an ECE3_Model.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the lists of current sweeps until all sweeps are finished. An ECE model is created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

Note	You can add an ECER_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

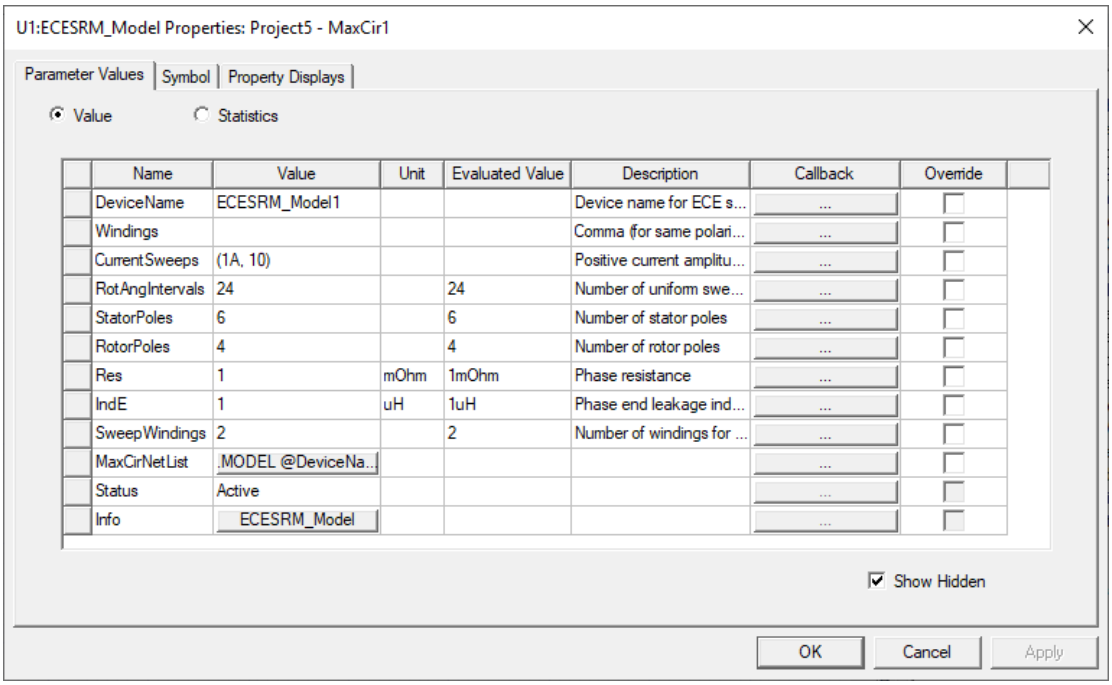
For more information on coupling Maxwell designs to Twin Builder components, refer to "Coupling Maxwell to a Twin Builder Component " on page 17-84 .

ECESRM_Model

The ECESRM model enables you to create an ECE model of a switched reluctance motor from Maxwell 2D and 3D Transient solutions.

To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).

ECESRM_Model1



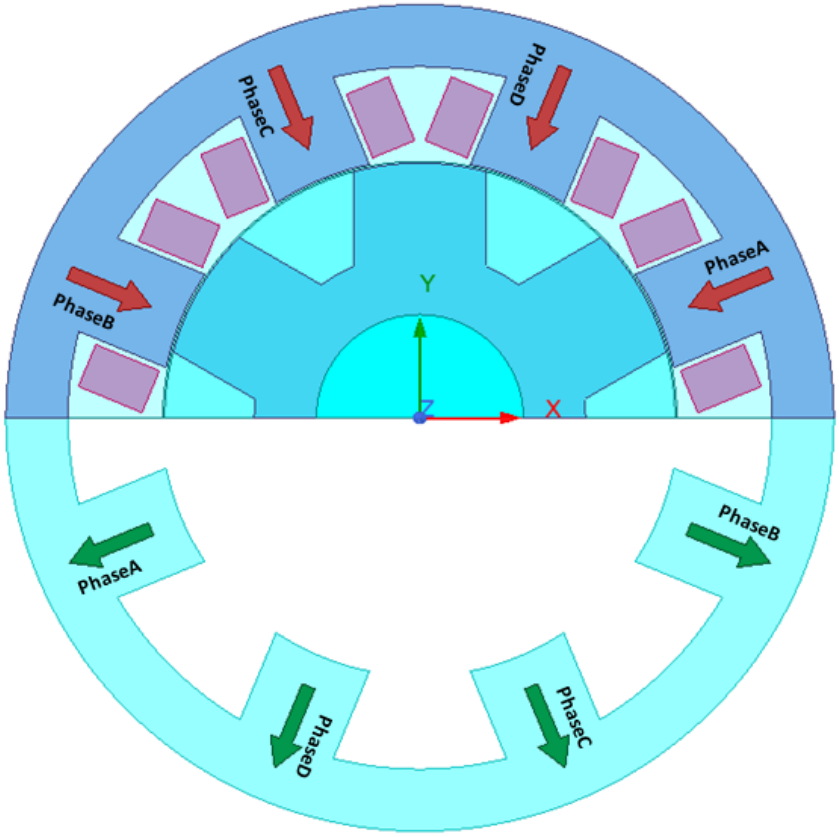
The ECESRM_Model contains the following parameters:

- DeviceName – the name of the device model with default name ECESRM_Model1.
- Windings – specifies winding names in the order of arrangement. Windings are separated by commas or semicolons. If two adjacent windings are defined with the same polarity, they will be separated by a comma “,”, otherwise by a semicolon “;”. For

example, for an 8/6 pole SRM, as shown below, windings for phase A, B, C and D are arranged in clockwise direction. The adjacent two windings of phase A and phase B have different polarities, and all other two adjacent windings have the same polarities. Therefore, windings can be specified in ECESRM_Model as:

“PhaseA; PhaseB, PhaseC, PhaseD”

where the separator between PhaseA and PhaseB is “;”, indicating different polarities between them. The last separator between PhaseD and PhaseA is not required because the total number of semicolons should be an odd number, and the last separator can be automatically determined.



- CurrentSweeps – specifies current sweeps in a winding. The first winding in the winding list is always excited with sweeping current. You just need to list 0 and all positive sweeping currents. All negative currents will be swept, or extended, symmetrically from the positive sweeping currents.
- RotAngIntervals – specifies the number of uniform sweeping intervals for rotor position in one rotor-pole region. For a 6-pole rotor, one rotor-pole region will be 60 mechanical degrees. If RotAngIntervals = 24, the sweeping step for rotor position will be 2.5 mechanical degrees.
- StatorPoles and RotorPoles – specifies the numbers of stator and rotor poles.
- Res and IndE – specifies winding resistance and end-leakage inductance for 2D.
- SweepWindings – specifies the number of windings to be excited. The value of SweepWindings could be 0, 1, or 2. Value 0 is for the case that only one winding current

is swept, and all mutual effects of other winding currents are ignored; value 1 is for the case that only one winding current is swept, and the mutual effects on winding flux linkage are considered, but the mutual effects of other windings currents on field saturation and torque are ignored; value 2 is for the case that two winding currents are swept, and all mutual effects are considered.

Look-up Table Processing

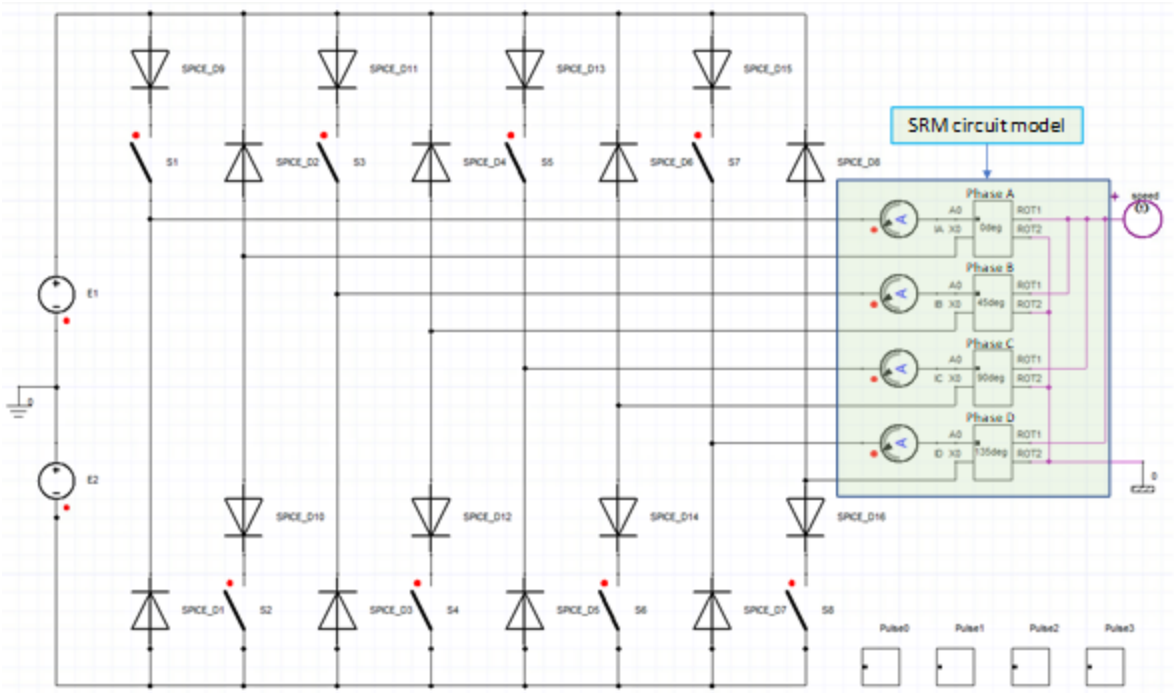
For an SRM, if a winding is triggered after the previously triggered winding has finished the free-wheeling process, there will be no mutual effects between the currently triggered winding and the previously triggered winding. In such a case, only one winding is excited with current at any time. In many cases, in order to increase power capacity, a winding could be triggered when the previous triggered winding is still working. In this situation, two windings could be excited with currents in some time periods. Therefore, we will provide different sweep types for different applications, which is specified by parameter SweepWindings, as described below.

- SweepWindings = 0

  SweepWindings = 0 means only one winding is excited, and all mutual effects between windings are ignored. The first listed winding PhaseA is excited with sweeping currents in the range of [0, Im], and the look-up table for the negative currents is automatically extended based on symmetry conditions. The final circuit model derived from this setting is equivalent to the circuit which is manually created by:

  i. Obtaining a single-phase circuit sub-model using ECEW_Model and ECER_Model.

  ii. connecting single-phase circuit sub-models for all phases with suitable IniPos settings, as shown in the circuit inside the shaded rectangle below.



This sweep type has the smallest look-up table, which includes controlling variables of one winding current and rotor position, and controlled variables of flux linkage and torque. For this sweep type, it is not necessary to solve the field for negative sweeping currents. The look-up table for the negative currents can be automatically extended based on symmetry conditions, as given below:

$$\begin{cases} F_{this}\left(-I_{this},\theta\right) = -F_{this}\left(I_{this},\theta\right) \\ T\left(-I_{this},\theta\right) = T\left(I_{this},\theta\right) \end{cases}$$

where $F_{this}(I_{this}, \theta)$ and $T(I_{this}, \theta)$, as outputs of look-up table, are the flux linkage of the excited winding and rotor torque, respectively, and the controlling variables I_{this} and θ are the winding current and rotor position, respectively.

- SweepWindings = 1

  SweepWindings = 1 means only one winding is excited, and the mutual effects on winding flux linkage are considered, but the mutual effects on field saturation and torque are ignored. In order to easily illustrate windings for look-up table creation, we call the excited winding, PhaseA, as *this* winding, PhaseB as *next* winding, and PhaseD as *pre*vious winding. In this way, in the first single-phase sub-model as shown in the figure above, *this*/*next*/*pre*vious windings represent phase A/B/D windings. In the second single-phase sub-model, they represent phase B/C/A windings, and so on. Only *this* winding has a circuit inside a single-phase sub-model. The mutual effects of the *next*/*pre*vious currents on this-winding flux linkage are considered by:

$$F = F_{this}\left(I_{this},\theta\right) \pm I_{next}\cdot M_{next}\left(I_{this},\theta\right) \pm I_{pre}\cdot M_{pre}\left(I_{this},\theta\right)$$

  where $F_{this}(I_{this}, \theta)$, $M_{next}(I_{this}, \theta)$, $M_{pre}(I_{this}, \theta)$, as outputs of look-up table, are flux linkage, mutual inductance between *this* and *next* windings, and mutual inductance between *this* and *pre*vious windings, respectively. Controlling variables I_{this} and θ represent *this*-winding current and rotor position, respectively. The *next* and *pre*vious winding currents, $I_{next}$and I_{pre}, respectively, are delivered via parameters of single-phase sub-models. The signs before the *next* and *pre*vious winding currents will be automatically determined in the final SRM model based on the separators for *pre*vious, *this* and *next* windings. Like the case of SweepWindings = 0, the look-up table for the negative currents can be automatically extended based on symmetry conditions, as given below:

$$\begin{cases} F_{this}\left(-I_{this},\theta\right) = -F_{this}\left(I_{this},\theta\right) \\ M_{next}\left(-I_{this},\theta\right) = M_{next}\left(I_{this},\theta\right) \\ M_{pre}\left(-I_{this},\theta\right) = M_{pre}\left(I_{this},\theta\right) \\ T\left(-I_{this},\theta\right) = T\left(I_{this},\theta\right) \end{cases}$$

  Comparing this with the sweep type of SweepWindings = 0, this sweep type has the same controlling variables with the same sweeping points, but it has a larger-size look-up table because it has more controlled variables.

- SweepWindings = 2

  SweepWindings = 2 means two windings, *this* and *next* windings, are excited, therefore all mutual effects on winding flux linkage, field saturation and torque are considered. If

CurrentSweep in the ECESRM_Model is specified in the range of [0, Im], the *this*-winding current will be swept in the range of [-Im, Im], and the *next*-winding current will be swept in the range of [0, Im]. After field simulations for all sweeps are completed, we obtain a clean look-up table. This look-up table has two controlled variables (*this*-winding flux linkage F_{this} and torque T); and three controlling variables (*this*-winding current I_{this}, *next*-winding current I_{next}, and rotor position θ). In this clean look-up table, T is the torque produced by *this*-winding current but considered the mutual effects of *next*-winding current. In field analysis, a torque can be derived based on field solutions and be expressed, by numerical integration over all related mesh elements, as:

$$T_m = \sum_{i=1}^{n} k_{Ti} \left(\mathbf{B}_i \cdot \mathbf{B}_i \right)$$

where $\mathbf{B_i}$ is the flux-density vector created by all winding currents, and k_{Ti} is a coefficient, in mesh element *i*. If we freeze the permeabilities of all non-linear materials, the field becomes linear. Then, the flux density vector in any mesh elements can be expressed as:

$$\mathbf{B}_i = \mathbf{B}_{1i} + \mathbf{B}_{2i}$$

where $\mathbf{B_{1i}}$ and $\mathbf{B_{2i}}$ are the flux-density vectors created by this and next winding currents, respectively. Hence, the torque will be:

$$T_m = \sum_{i=1}^{n} k_{Ti} \left(\mathbf{B}_{1i} + \mathbf{B}_{2i} \right) \cdot \left(\mathbf{B}_{1i} + \mathbf{B}_{2i} \right) = T_{11} + 2T_{12} + T_{22}$$

with

$$\begin{cases} T_{11} = \sum_{i=1}^{n} k_{Ti} \left(\mathbf{B}_{1i} \cdot \mathbf{B}_{1i} \right) \\ T_{12} = \sum_{i=1}^{n} k_{Ti} \left(\mathbf{B}_{1i} \cdot \mathbf{B}_{2i} \right) \\ T_{22} = \sum_{i=1}^{n} k_{Ti} \left(\mathbf{B}_{2i} \cdot \mathbf{B}_{2i} \right) \end{cases}$$

In field analysis, we can get T_{11} by injecting current in this winding only, and we get T_{22} by infecting current in next winding only. Then we get:

$$T_{12} = (T_m - T_{11} - T_{22})/2$$

Finally, we get torque in the clean look-up table as:

$$T = T_{11} + T_{12}$$

The clean look-up table can be extended to a full look-up table based on even and odd symmetry conditions, as given below:

$$\begin{cases} F_{this} \left(I_{this}, -I_{next}, \theta \right) = -F_{this} \left(-I_{this}, I_{next}, \theta \right) \\ T \left(I_{this}, -I_{next}, \theta \right) = T \left(-I_{this}, I_{next}, \theta \right) \end{cases}$$

The flux linkage and torque in the look-up table are derived based on this-winding current with considering the mutual effects of next-winding current. In real operation with two excited windings, we need to get the flux linkage and torque produced by each winding

current. For example, in the circuit diagram above, if phases A and B are excited simultaneously, the flux linkage and torque, produced by phase-A current with mutual effects of phase-B current, can be directly obtained from the look-up table because phase-A current is *this*-winding current and phase-B current is *next*-winding current, as given below:

$$\begin{cases} F_1 = F_{this}\left(I_{this}, \pm I_{next}, \theta\right) \\ T_1 = T\left(I_{this}, \pm I_{next}, \theta\right) \end{cases}$$

where the sign before I_{next} is positive if the separator between *this* and *next* windings is the same as that between the first and second windings listed in the Windings field in the properties dialog box above, or negative otherwise. Since the look-up table includes the mutual-effect information, it is important to transfer the *next*-winding current to make sure the polarity relationship between *this* and *next* windings in a single-phase sub-model is the same as that for look-up table creation. For example, for the phase-A sub-model in the circuit diagram above, this sign is positive because the separator between *this* and *next* windings, or between PhaseA and PhaseB, is ";", which is the same as that between PhaseA and PhaseB for look-up table creation. However, for the phase-B sub-model, the sign is negative because the separator between *this* and *next* windings, or between PhaseB and PhaseC, is ",", which is different from the separator ";" between PhaseA and PhaseB for look-up table creation.

When we consider the flux linkage and torque produced by phase-B current with mutual effects of phase-A current, we cannot obtain them directly from the look-up table because in this situation phase-B current is *this*-wingding current and phase-A current is *pre*-winding current, but we can still obtain them from the look-up table based on symmetry conditions. In the winding polarities diagram above, if we mirror the geometry about the center line of the phase-B pole, then phase-A winding aligns with phase-C winding, and rotor position becomes negative. Based on this symmetry condition, we have:

$$\begin{cases} F_2 = F_{this}\left(I_{this}, \pm I_{pre}, -\theta\right) \\ T_2 = -T\left(I_{this}, \pm I_{pre}, -\theta\right) \end{cases}$$

where the sign before I_{pre} is positive if the separator between *this* and previous windings is the same as that between the first and second windings listed in the Windings field in the properties dialog box above, or negative otherwise.

In the final SRM model, the signs before *Inext* and Ipre for all single-phase sub-models will be automatically determined based on all separators listed in the Windings field, which, together with *Inext* and *Ipre*, are forwarded to sub-models via input parameters.

You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

Note	You can add an ECESRM_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the

	model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to the *Coupling Maxwell to a Twin Builder Component* topic in the Maxwell Help

ECET_Model

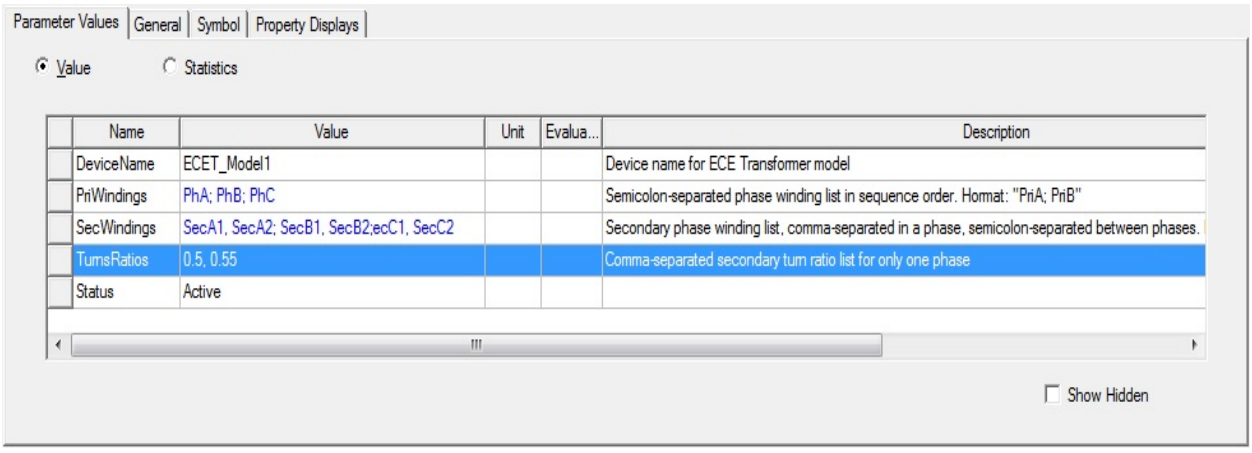
The ECET model is used to set up the sweeping of the magnetizing current for each phase of a single- or poly-phase transformer. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).

ECET_Model1

The ECET_Model contains the following parameters:

- DeviceName − the name of the device model with the default name as ECET_Model1;
- PriWindings − the name list of all primary windings with semicolons for separators between phase;
- SecWindings − the name list of all secondary windings with semicolons for separators between phases;
- TurnsRatios − the ratio of the secondary turns to the primary turns for only one phase.

If a transformer has two or more secondary windings for one phase, the secondary winding name list is separated by commas between winding names for the same phase, and TurnsRatios is a value list, instead of a single value, which is separated by commas between values for one phase. For example, for a three-phase transformer with two secondary windings for each phase, the parameters for ECET_Model are set as:



An ECET_Model cannot be used individually. It should be used combined with an ECEW_Model and/or an ECE3_Model.

In an ECE model look-up table, only the magnetizing inductance for each phase is assumed to be non-linear, and all leakage inductances for all primary and secondary windings are assumed to be constant. Therefore, only the magnetizing current of the primary winding for each phase is required to be swept, which reduces the number of sweeping points significantly.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the list of current sweeps until all sweeps are finished. An ECE model is created automatically.

You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. When the ECET_model is created and then imported into Twin Builder the following additional parameters are made available for use in Twin Builder:

- **r1*_[WindingName]*** is winding resistance (default = 0)
- **l1*_[WindingName]*** is end leakage inductance (default = 1mOhm, for 3D always = 0)
- **i0*_[WindingName]*** is initial current (default = 0)

For more information on coupling Maxwell equivalent circuit designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

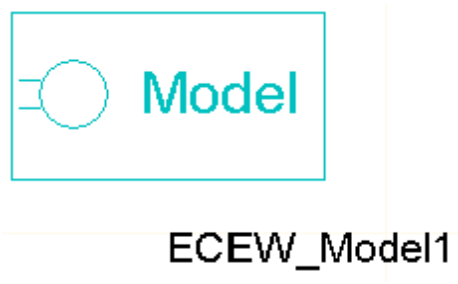
Note	You can add an ECET_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to "Coupling Maxwell to a Twin Builder Component " on page 17-84 .

ECEW_Model

The ECEW model enables you to create an ECE model from Maxwell Transient solutions. Compared with the procedure for creating ECE model from Maxwell Magnetostatic solutions, creating an ECE model directly from Maxwell Transient solutions takes advantage of winding and motion setups in Maxwell Transient.

The ECEW model is used to set up the sweeping of one winding current. To change the name of the model placed on the sheet, click the symbol on the sheet, and change the name of the component in the property window (Value field in the DeviceName line, with the Parameter Values tab selected).



The ECEW_Model contains the following parameters:

- DeviceName – the name of the device model with default name ECEW_Model1.
- WindingName – specifies the name of winding whose current is to be swept.
- CurrentSweeps – specifies lists of all sweep currents. The format is: “v1, v2, (dv1, n1), v3, …”, where v1, v2, v3 specify individual sweep values, and (dv1, n1) specify a sweeping range with dv1 being the increment, and n1 the number of increments. For example, a list of “-2.5A, (0.5A, 10)” is equivalent to "-2.5A, -2A, -1.5A, -1A, -0.5A, 0, 0.5A, 1A, 1.5A, 2A, 2.5A", and a list of "(0.5A, 5)" is equivalent to “0, 0.5A, 1A, 1.5A, 2A, 2.5A”.
- Res – phase winding resistance (available when Show Hidden is checked).
- IndE – phase end-leakage inductance (available when Show Hidden is checked).

An ECEW_Model can be used individually to create the ECE model of a single-phase inductor, or combined with other ECEW_Models to setup two or more windings for poly-phase inductors. It can also be combined with an ECER_Model, as well as an ECE3_Model, for rotational electrical machines.

For ECE model creation, the setup of Stop Time and Time step are ignored. At Maxwell run time, the circuit simulator assigns currents for all windings step-by-step based on the lists of current sweeps until all sweeps are finished. Then an ECE model is created automatically. You can import this ECE model in Twin Builder via the **Twin Builder>SubCircuit>Maxwell Component>Add Equivalent Circuit** menu command. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Equivalent Circuit Component* topic in the Twin Builder Help.

Note	You can add an ECEW_Model to an existing external circuit without deleting the original circuit. In such cases, the original circuit is ignored and can be kept for future use. If you want to recover the original circuit for a transient simulation, instead of ECE model creation, you just need to deactivate each ECE related model by right-clicking the model and selecting Deactivate in the short-cut menu.

For more information on coupling Maxwell designs to Twin Builder components, refer to "Coupling Maxwell to a Twin Builder Component " on page 17-84 .

Passive Elements

The following passive elements are available in the Maxwell Circuit Elements component library:

- Cap: Capacitor
- DIODE: Diode
- DIODE_Model: Diode Model Data
- Ind: Inductor
- IndM: Mutual Inductance
- Res: Resistor
- SW_I: Current Controlled Switch
- SW_I4: Current Controlled Switch with Controlling Port
- SW_IModel: Model Data for Current Controlled Switches
- SW_V: Voltage Controlled Switch
- SW_V4: Voltage Controlled Switch with Controlling Port
- SW_VModel: Model Data for Voltage Controlled Switches
- Transformer: Ideal Transformer

The text before the colon (**:**) represents the component name and can be changed in the **Properties** window once the component is placed in the schematic.

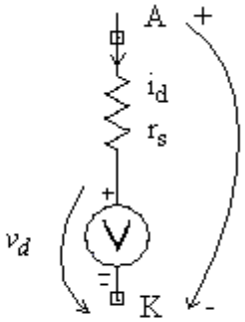
Assigning Component Properties in Maxwell Circuit Editor

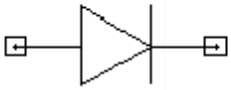
Diode & Diode Model

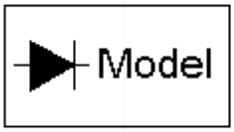
Diode element must always be used together with a diode model. One diode model element can be used as reference for multiple diodes, as needed. Thus, once a diode is placed on the design sheet, a corresponding model must also be present on the sheet. Once both needed elements (diode and diode model) have been placed on the sheet, right mouse click the diode model and specify the parameters as required by the application. Then, right mouse click the diode and create the reference to the corresponding model by entering the name of the model in the MOD line (Parameter Values tab should be selected). If you select the **Show Hidden** check box, the AREA diode parameter (used below in the model definition) becomes visible. The default value of the AREA parameter is 1.

The diode model used by Maxwell Circuit Editor is a static model as described by the following equation:

$$i_d = i_s \cdot \left(e^{v_d / v_t} - 1 \right) - \left(i_{bv} \cdot e^{-(v_d + BV)v_t} \right)$$







$$v_t = N \cdot (kT)/q$$

$$q = 1.6022 \cdot 10^{-19}\, C$$

$$k = 1.3807 \cdot 10^{-23}\, (J/K)$$

T is temperature in K, fixed at 300 K

$$i_s = IS \cdot AREA \cdot e^{\left(\frac{T/T_0 - 1}{kT - 1}\right) \cdot (EG)/v_t} \cdot \left(\frac{T}{T_0}\right)^{\frac{XTI}{N}}$$

$$i_{bv} = IBV \cdot AREA$$

$$r_s = \frac{RS}{AREA}$$

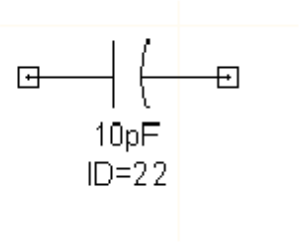
The model parameters are as follows:

- *IS* is the saturation current in Amps.
- *RS* is contact resistance in Ohms.
- *N* is the emission coefficient.

- *EG* is the barrier height at 0 K, in volts.
- *XTI* is the diode saturation current temperature coefficient.
- *BV* is the magnitude of the reverse breakdown voltage in volts.
- *IBV* is the magnitude of the reverse breakdown current in amps.
- *TNOM* is the reference temperature in Celsius.

Capacitor (CAP)

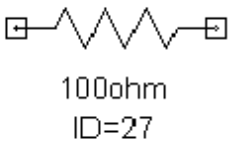
A capacitor is assumed to be ideal (without losses or inductance) and is defined by the value of its capacitance (in the unit chosen by the user) and the corresponding initial condition (initial voltage). The straight bar of the capacitor symbol is used as the positive reference, and the curved bar of the capacitor symbol is used as a negative reference for the initial voltage (expressed in volts). The default value of the initial voltage for all capacitors is zero. By default, the capacitance and element ID are displayed next to the component.



Resistor (Res)

Resistor is assumed to be ideal (without inductive or capacitive effects) and is defined by the value of its resistance (in the unit chosen by the user, Ohm by default.

By default the resistance and element ID are displayed next to the component.

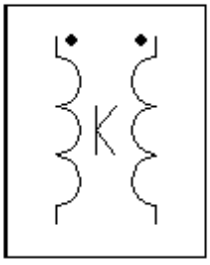


Inductor (IND)

Inductor is assumed to be ideal (without resistive or capacitive effects) and is defined by the value of its inductance (in the unit chosen by the user) and the corresponding initial condition (initial current). Note that the dot next to the inductor symbol is used as the positive reference for the initial current (positive current is oriented from the "dotted" terminal toward to "un-dotted" terminal of the inductor, through the inductor). The dot is also used to specify the mutual inductance between two or more inductors and thus determines the "polarized" terminals of the inductors. The default value of the initial current for all inductors is zero. By default the inductance and element ID are displayed next to the component.

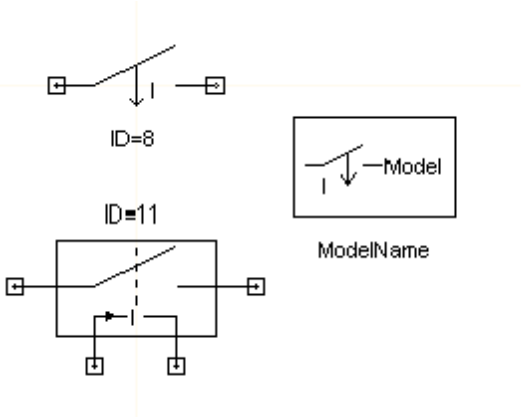
Mutual Inductance (IndM)

Mutual inductance is used to specify the inductive coupling between inductors. It is defined by specifying the IDs of the coupled inductors (always in pairs) and the coupling coefficient, a number between -1 and 1. The default value of the coupling coefficient is 0.95.



Current Controlled Switch (SW_I)

The current controlled switch comes in two flavors: with controlling port and without a controlling port. In either case a model data for the current controlled switch needs to be specified, similarly to the case of the diode.



Right-click the current controlled switch model and select Properties. With the Parameter Values tab selected, specify the switch model name (in the MOD line) as well as the ID of the controlling element: either an ammeter or a voltage source. In the later case the controlling quantity is the current through the voltage source. (Note that an ammeter is a voltage source with zero voltage, i.e. a short circuit).

The current controlled switch with controlling port allows for the controlling quantity to be wired directly using connections with wires. In this case a reference arrow in the controlling port is displayed and is internally used as current reference (positive current flow as indicated by the arrow).

In the model for the current controlled switch the following parameters are used:

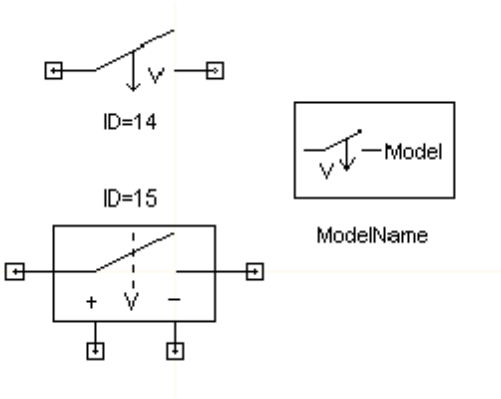
- *Ron* is the resistance of the switch in the **on** state (0.001 ohms default value).
- *Roff* is the resistance of the switch in the **off** state (1,000,000 ohms default value).
- *Ion* is the "**on**" value of the controlling current in amps. **If I>Ion, then R=Ron.**
- *Ioff* is the "**off**" value of the controlling current in amps. **If I<Ioff, then R=Roff.**

Note	Setting $\mathbf{R_{OFF} = 0}$ in the voltage or current controlled switch model data changes the behavior of the device into a **controlled conductance**, according to the following equation:

	$$G(P) = \frac{1}{R_{ON}} \cdot f_{control}(P)$$ where: $f_{control}(P)$ is a function describing the controlling signal -- a time, position, or speed dependent current source or voltage source. Function ***G(P)*** clearly shows that the magnitude of the conductance is dictated by both the value of R_{ON} and the magnitude of the control signal, while the time / position / speed dependency is dictated by the control signal itself.
Note	Setting $R_{ON} = 0$ in the voltage or current controlled switch model data changes the behavior of the device into a **controlled resistance**, according to the following equation: $R(P) = R_{OFF} \cdot f_{control}(P)$ where: $f_{control}(P)$ is a function describing the controlling signal -- a time, position, or speed dependent current source or voltage source. Function ***R(P)*** clearly shows that the magnitude of the conductance is dictated by both the value of R_{OFF} and the magnitude of the control signal, while the time / position / speed dependency is dictated by the control signal itself.

Voltage Controlled Switch (SW_V)

The voltage controlled switch comes in two flavors: with controlling port and without a controlling port. In either case a model data for the voltage controlled switch needs to be specified, similarly to the case of the diode and current controlled switches.



Right-click the voltage controlled switch model and select Properties. With the Parameter Values tab selected, specify the switch model name (in the MOD line) as well as the ID of the controlling element: either a voltmeter or a current source. In the later case the controlling quantity is the voltage across the current source. (Note that a voltmeter is a current source with zero current, i.e. an open circuit).

The voltage controlled switch with controlling port allows for the controlling quantity to be wired directly using connections with wires. In this case the reference for the voltage across the controlling port is displayed by "+" and "-" symbols and the two symbols are internally used as voltage reference.

In the model for the voltage controlled switch the following parameters are used:

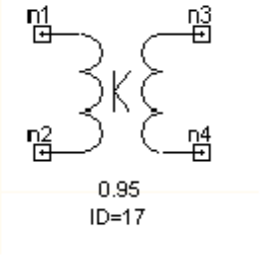
- Ron is the resistance of the switch in the **on** state (0.001 ohms default value).
- Roff is the resistance of the switch in the **off** state (1,000,000 ohms default value).
- Von is the "**on**" value of the controlling voltage in volts. **If V>Von, then R=Ron.**
- Voff is the "**off**" value of the controlling voltage in volts. **If V<Voff, then R=Roff.**

Note	Setting $\mathbf{R_{OFF} = 0}$ in the voltage or current controlled switch model data changes the behavior of the device into a **controlled conductance**, according to the following equation: $$G(P) = \frac{1}{R_{ON}} \cdot f_{control}(P)$$ where: $f_{control}(P)$ is a function describing the controlling signal -- a time, position, or speed dependent current source or voltage source. Function ***G(P)*** clearly shows that

	the magnitude of the conductance is dictated by both the value of R_{ON} and the magnitude of the control signal, while the time / position / speed dependency is dictated by the control signal itself.
Note	Setting $R_{ON} = 0$ in the voltage or current controlled switch model data changes the behavior of the device into a **controlled resistance**, according to the following equation: $R(P) = R_{OFF} \cdot f_{control}(P)$ where**:** $f_{control}(P)$ is a function describing the controlling signal -- a time, position, or speed dependent current source or voltage source. Function ***R(P)*** clearly shows that the magnitude of the conductance is dictated by both the value of R_{OFF} and the magnitude of the control signal, while the time / position / speed dependency is dictated by the control signal itself.

Transformer

The transformer is an ideal element of infinite power without resistive or capacitive effects and linear. It is defined the values of the primary and secondary inductances and the coupling coefficient between the two windings.



Probes

Three types of probes are available in the Maxwell Circuit Elements component library:

- Ammeter: Ammeter
- Voltmeter: Voltmeter
- VoltmeterG: Voltmeter with One Pin Grounded

The text before the colon (**:**) represents the component name and can be changed in the **Properties** window once the component is placed in the schematic.

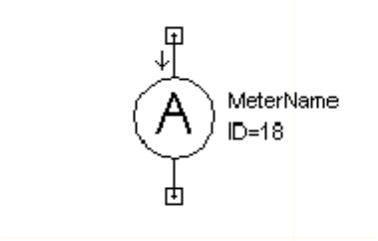
Related Topics

Assigning Component Properties in Maxwell Circuit Editor

Ammeter

The ammeter is an ideal element (equivalent with an ideal voltage source with zero voltage). An arrow is attached to the symbol so that a positive current measured by the ammeter flows as indicated by the arrow.

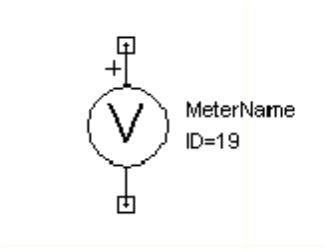
No numerical value is needed, just the element ID and name may by altered by the user.



Voltmeter

The voltmeter is an ideal element with two pins (equivalent with an ideal current source with zero current). A plus sign is attached to the voltmeter symbol so that a reference for the voltage measured by the voltmeter is possible.

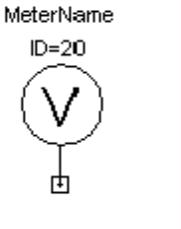
No numerical value is needed, just the element ID and name may by altered by the user.



Voltmeter with One Pin Grounded (VoltmeterG)

The voltmeter with one pin grounded is an ideal element with one pin, equivalent with an ideal current source with zero current. A plus sign is not necessary since it is assumed that the grounded pin (not available for connection in the circuit) is the negative one while the pin available for connection is the positive one. Thus, the reference for the voltage measured by the voltmeter is possible.

No numerical value is needed, just the element ID and name may by altered by the user.



Current and Voltage Sources

Sources available in the Maxwell Circuit Editor can be defined such that in general the dependency of the current or voltage can be made function of time, position, or speed. The type of dependency is part of the properties of the respective source and is always user-selectable. Thus, in the equation defining the behavior of the source (when specified), the variable "t" can mean TIME or POSITION or SPEED as selected by the user for each application.

The default dependency type is TIME.

The following types of sources are available in the Maxwell Circuit Elements component library:

- IDC: DC Current Source
- IExp: Exponential Current Source
- IPulse: Pulse Current Source
- IPWL: Piecewise Linear Current Source
- IPWM: PWM Current Source
- ISffm: Frequency Modulated Sinusoidal Current Source
- ISin: Sinusoidal Current Source
- VDC: DC Voltage Source
- VExp: Exponential Voltage Source
- VPulse: Pulse Voltage Source
- VPWL: Piecewise Linear Voltage Source
- VPWM: PWM Voltage Source
- VSffm: Frequency Modulated Sinusoidal Voltage Source
- VSin: Sinusoidal Voltage Source

The text before the colon (**:**) represents the component name and can be changed in the **Properties** window once the component is placed in the schematic.

Related Topics

Assigning Component Properties in Maxwell Circuit Editor

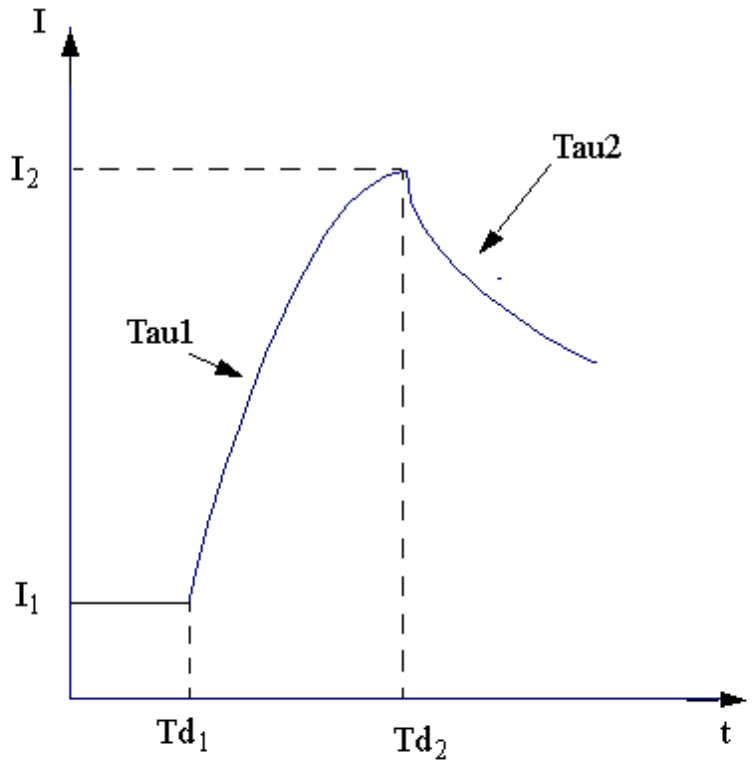
DC Current Source

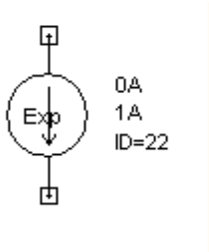
This type of source specifies the DC current flowing in a conductor. You can set either the total current or the current density flowing in the object.

- If total current is specified, the current density is assumed to be uniformly distributed throughout the object.
- If current density is specified, you may define a uniform current density or one that varies as a function of position.

Exponential Current Source

This is an independent current source with an exponential waveform of the current as function of time as shown in the following figure. The arrow symbol shows the direction of the positive current flow through the current source.



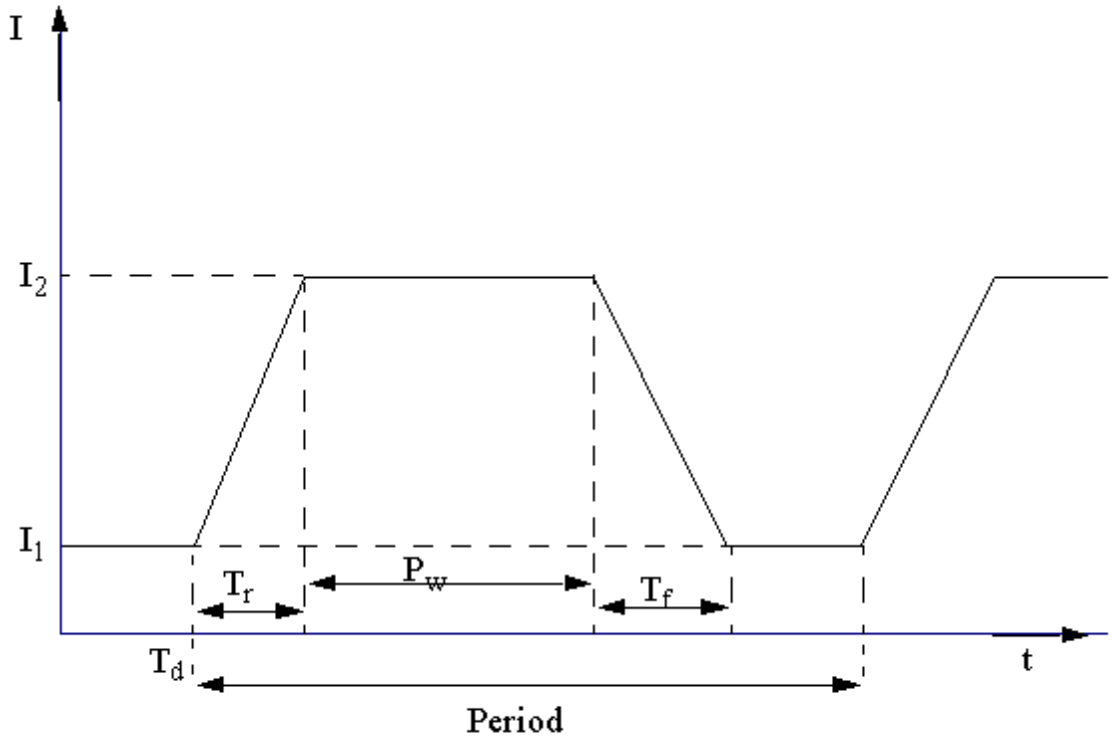


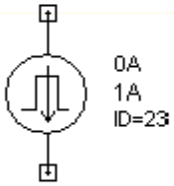
Thus, the parameters of this exponential source are:

- Initial current in Amps, I1;
- Peak current in Amps, I2;
- Rise time delay, Td1:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Rise time constant, Tau1:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time delay, Td2:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time constant, Tau2:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;

Pulse Current Source

This is an independent current source with a trapezoidal waveform of the current as a function of time. The arrow symbol shows the direction of the positive current flow through the current source.





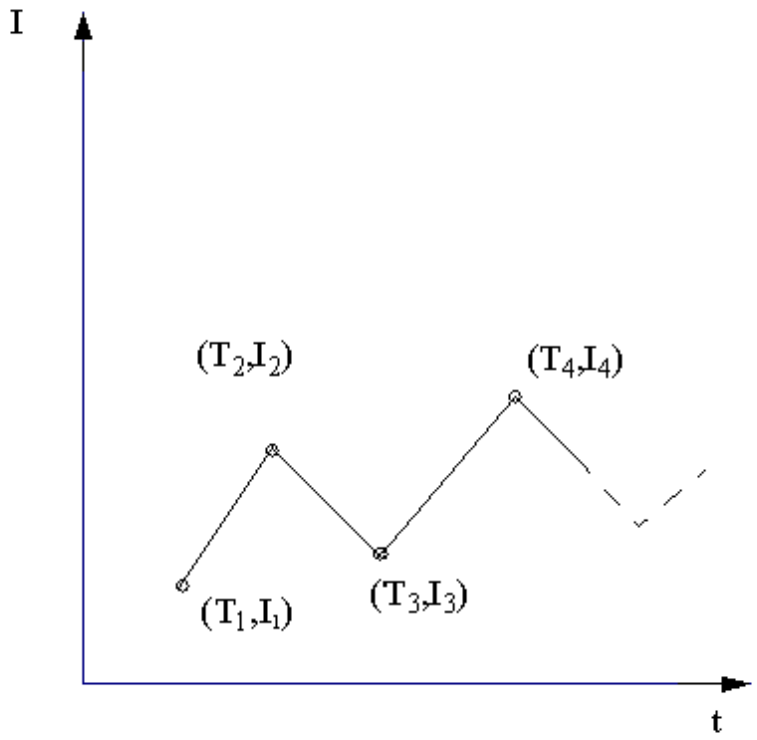
The parameters of a pulse current source are the following:

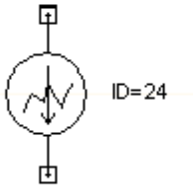
- Initial current in Amps, I1;
- Peak current in Amps, I2;
- Initial delay time, Td:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Rise time, Tr:
  - In seconds if type is TIME

    - In degrees if type is POSITION and type of motion is rotational;
    - In geometry units if type is POSITION and type of motion is translational;
    - In rpm if type is SPEED and type of motion is rotational;
    - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time Tf:
    - In seconds if type is TIME
    - In degrees if type is POSITION and type of motion is rotational;
    - In geometry units if type is POSITION and type of motion is translational;
    - In rpm if type is SPEED and type of motion is rotational;
    - In geometry units per second if type is SPEED and type of motion is translational;
- Pulse width, Pw:
    - In seconds if type is TIME
    - In degrees if type is POSITION and type of motion is rotational;
    - In geometry units if type is POSITION and type of motion is translational;
    - In rpm if type is SPEED and type of motion is rotational;
    - In geometry units per second if type is SPEED and type of motion is translational;
- Pulse period, Period:
    - In seconds if type is TIME
    - In degrees if type is POSITION and type of motion is rotational;
    - In geometry units if type is POSITION and type of motion is translational;
    - In rpm if type is SPEED and type of motion is rotational;
    - In geometry units per second if type is SPEED and type of motion is translational;

Piecewise Linear Current Source

This is an independent current source with a piecewise linear waveform of the current as a function of time. The arrow symbol shows the direction of the positive current flow through the current source.





A piecewise linear current source is described by up to 20 pairs (Ti, Ii), where every pair of values specifies the value Ii in Amps of the current at time Ti in the following units:

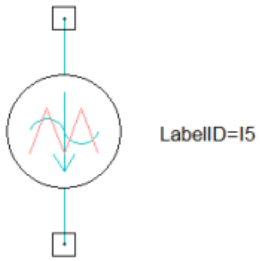
- In seconds if type is TIME.
- In degrees if type is POSITION and type of motion is rotational.
- In geometry units if type is POSITION and type of motion is translational.
- In rpm if type is SPEED and type of motion is rotational.
- In geometry units per second if type is SPEED and type of motion is translational.

PWM Current Source

The PWM current source component shown below provides PWM control signals used to support TDM parallel computation. (Refer to *Time Decomposition Method for Maxwell Transient Designs* in the Maxwell help.) The arrow symbol shows the direction of positive current flow through the current source.

Since all time steps in one subdivision along the time axis are solved together when TDM is used, all controlling signals in a control circuit cannot depend on solutions such as currents/voltages of the previous time step. Therefore, all diodes and switches which are controlled by independent voltages and currents are not supported.

In PWM control, the controlling signals are purely time and/or position dependent, therefore, PWM control is supported in TDM. In a PWM control circuit, since the upper and lower switches belong to the same phase are turned on and off at exactly same time, the free-wheeling diodes are not necessary. In order for users to directly use existing PWM control circuit, PWM current and voltage source components have been introduced to replace original controlling sub-circuit which includes a triangle current/voltage source connected in series with a sinusoidal current/voltage source. The circuit solver will detect all switches which are controlled by PWM current/voltage sources and automatically filter all related diodes, which means during the simulation, diodes are automatically excluded in PWM control circuit.

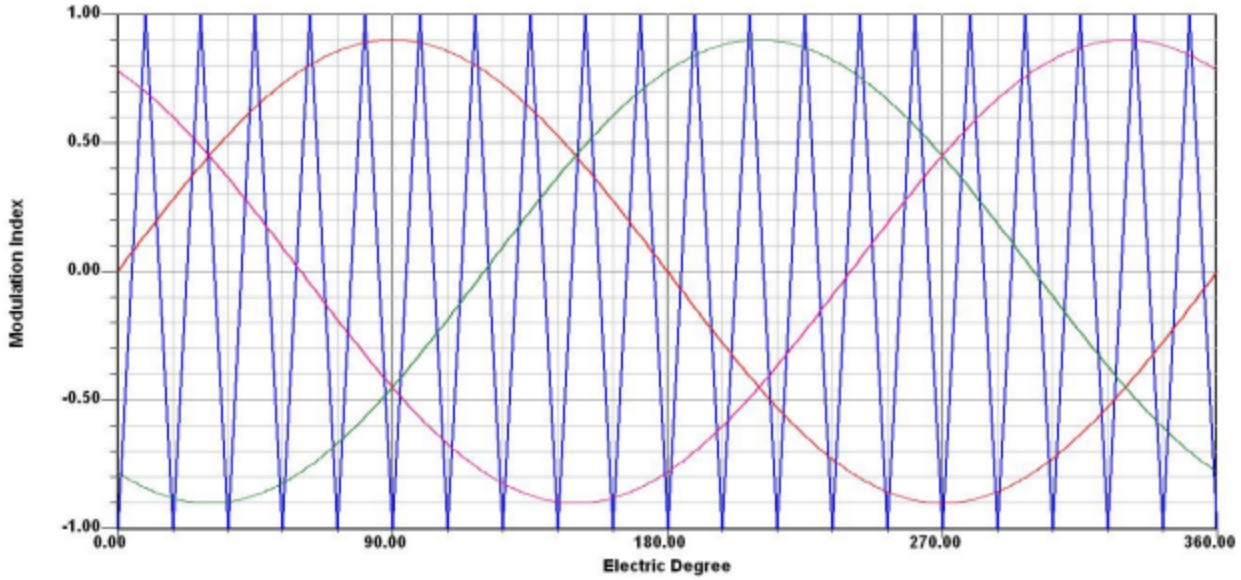


Note	Prior to the introduction of the PWM current source (IPWM) component, PWM control signals used to support TDM parallel computation were obtained from the difference of two current sources: a carrier signal with triangular waveform (IPulse), and a control signal with sinusoidal waveform (ISin)

An **IPWM** current source is defined by the following parameters:

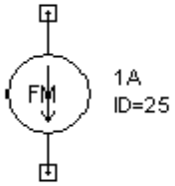
- **ModuIndex** is the modulation index, the ratio of control-signal amplitude to carrier-signal amplitude.
- **FreqTime** is the ratio of carrier-signal frequency to control-signal frequency.
- **IFreq** is the frequency of the control signal, if **Type** is **TIME**.
- **Phase** is the phase delay of the control signal, in electrical degrees.
- **Type** can be chosen as either **TIME** or **POS**, defining the output signal as a function of time or position.

The following figure shows typical three-phase PWM control signals.



Frequency-Modulated Sinusoidal Current Source

This is an independent current source with a single frequency modulated sinusoidal waveform of the current as a function of time. The arrow symbol shows the direction of the positive current flow through the current source.



The equation describing the waveform is:

$$I(t) = I_0 + I_a \cdot \sin[(2\pi \cdot F_C \cdot t) + M_{di} \cdot \sin(2\pi \cdot F_S \cdot t)]$$

where:

- Io is Offset current in Amps.
- Ia is the peak amplitude in Amps.
- FC is the carrier frequency if type is TIME.

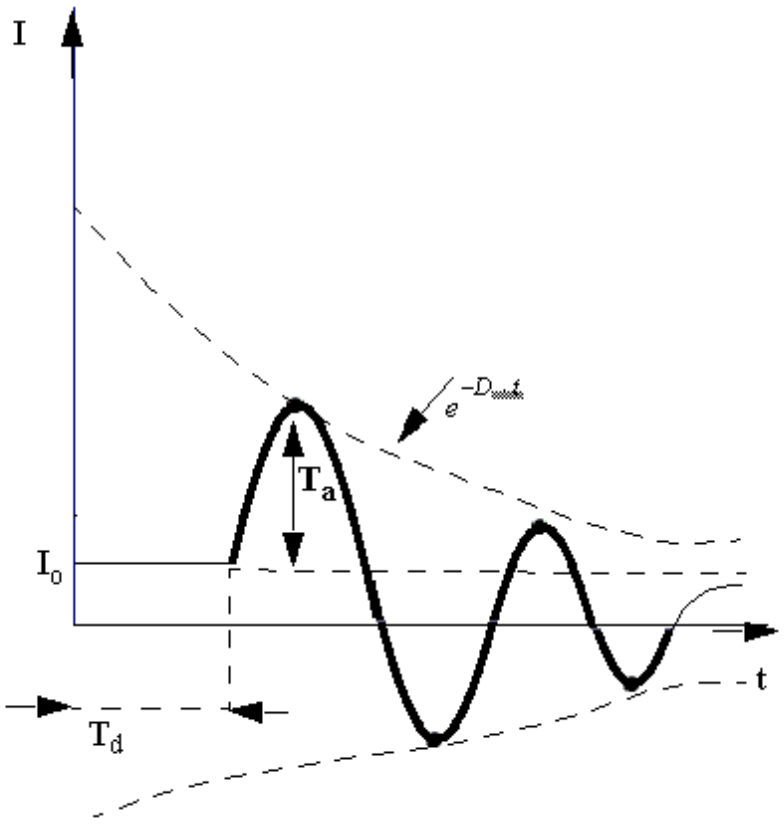
- Mdi is the modulation index.
- FS is the signal frequency if type is TIME.

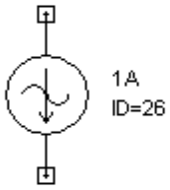
If the type is POSITION, the frequency should be calculated based on the respective spatial periodicity, taking into account the fact that "t" in the above equation is measured in degrees for rotational type of motion and in the user-defined geometry units for translational type of motion.

If the type is SPEED, the frequency should be calculated based on the respective speed periodicity, taking into account the fact that "t" in the above equation is measured in rpm for rotational type of motion and in the user-defined geometry units per second for translational type of motion.

Sinusoidal Current Source

This is an independent current source with an exponentially damped sinusoidal waveform of the current as a function of time. The arrow symbol shows the direction of the positive current flow through the current source.





The equation describing the waveform is:

$$I(t) = I_0 + I_a \cdot e^{-Df(t-T_d)} \cdot \sin[2 \cdot \pi \cdot IFreq \cdot (t-T_d) - Phase]$$

where:

- Io is Offset current in Amps.
- Ia is the peak amplitude in Amps.
- IFreq is the signal frequency if type is TIME.
- Td is the delay time in seconds if type is TIME.
- Phase is the signal phase delay if type is TIME.
- Df is the damping factor in 1/seconds if type is TIME.

If the type is POSITION, the frequency should be calculated based on the respective spatial periodicity, taking into account the fact that "t" in the above equation is measured in degrees for rotational type of motion and in the user-defined geometry units for translational type of motion. The delay and damping factor should also be interpreted accordingly.

If the type is SPEED, the frequency should be calculated based on the respective speed periodicity, taking into account the fact that "t" in the above equation is measured in rpm for rotational type of motion and in the user-defined geometry units per second for translational type of motion. The delay and damping factor should also be interpreted accordingly.

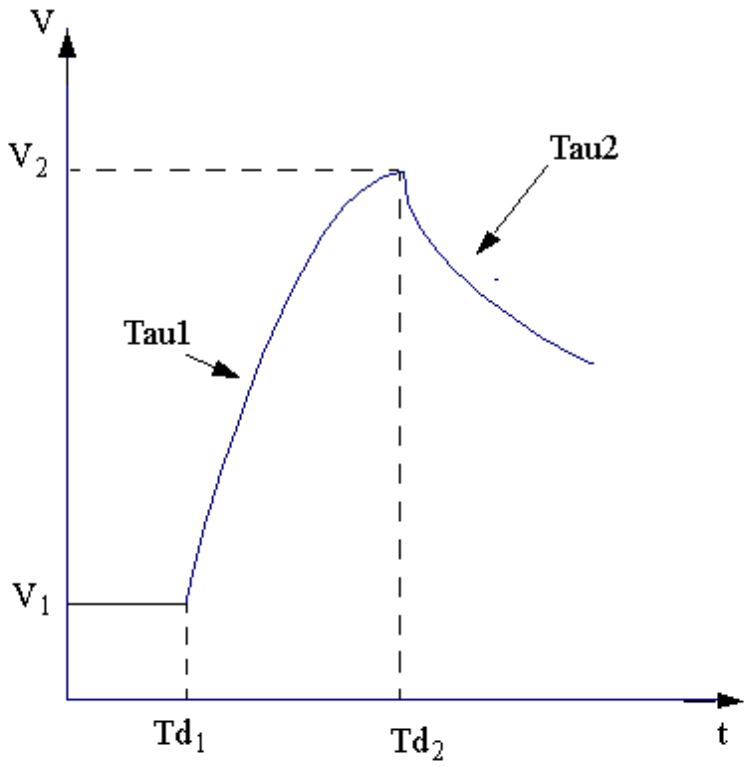
DC Voltage Source

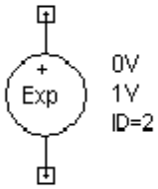
This type of source specifies the total DC voltage (electric potential) on a conductor. Voltages can be defined as constants or as math functions; however, the potential on a conductor is constant over the entire conductor. Note that conductors that touch should be set to the same voltage or defined as a single voltage source, since their potentials are identical.

DC voltage may also be specified on an edge or edges. Voltages can be defined as constant or as functions of position (for instance, to model a specific distribution of potential on the surface of a dielectric).

Exponential Voltage Source

This is an independent voltage source with an exponential waveform of the voltage as a function of time. The "+" and "-" symbols are used to mark the polarity of the source.





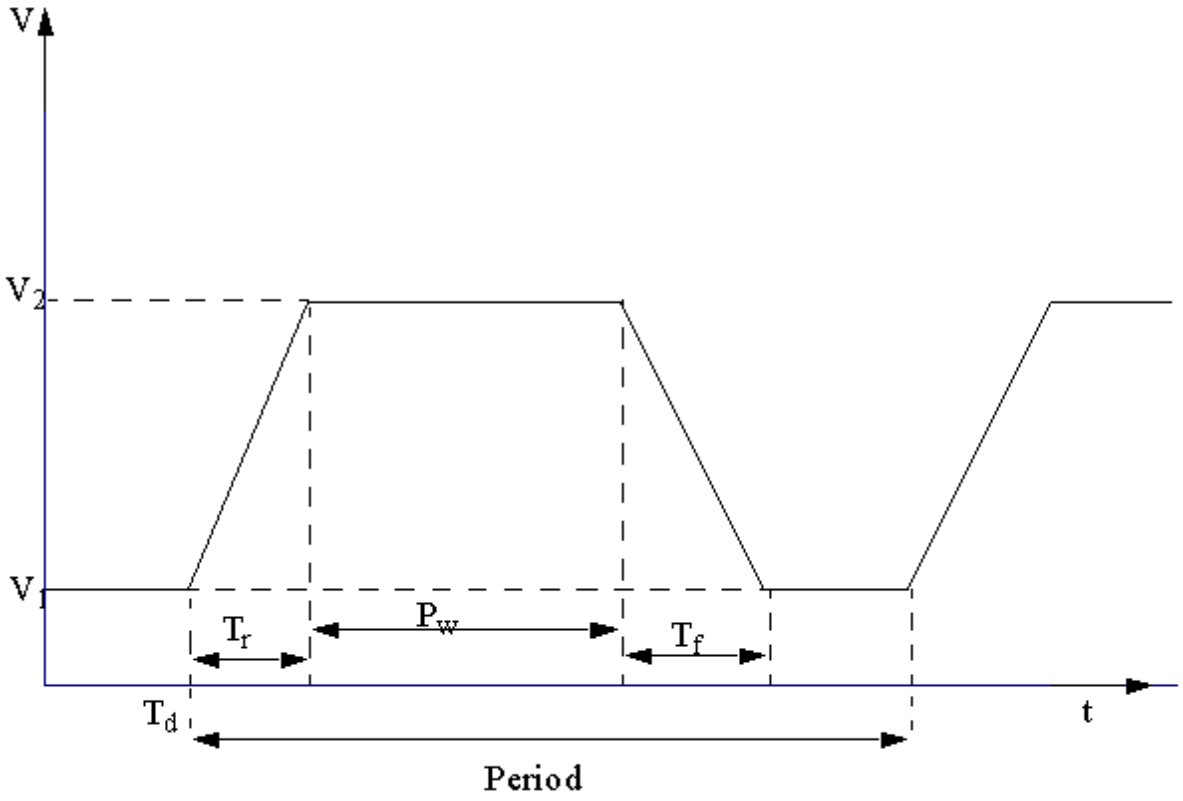
The parameters of an exponential voltage source are the following:

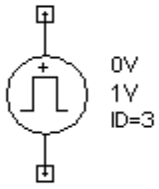
- Initial voltage in Volts, V1.
- Peak voltage in Volts, V2.
- Rise time delay, Td1:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;

  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Rise time constant, Tau1:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time delay, Td2:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time constant, Tau2:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;

Pulse Voltage Source

This is an independent voltage source with a trapezoidal waveform of the voltage as a function of time. The "+" and "-" symbols are used to mark the polarity of the source.





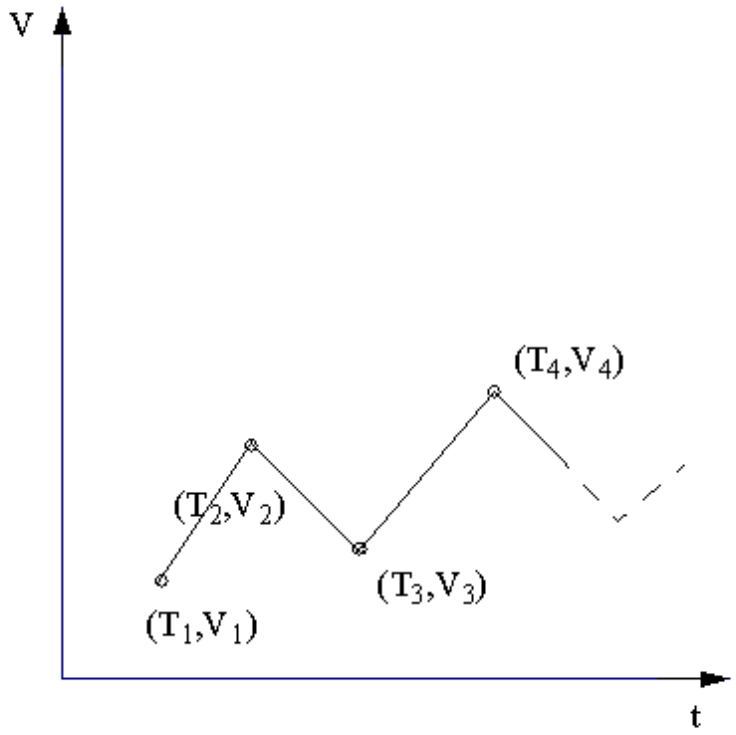
The parameters of a voltage pulse source are the following:

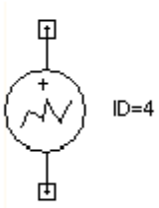
- Initial voltage in Volts, V1.
- Peak voltage in Volts, V2.
- Initial delay time, Td:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;

- Rise time, Tr:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Fall time Tf:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Pulse width, Pw:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;
- Pulse period, Period:
  - In seconds if type is TIME
  - In degrees if type is POSITION and type of motion is rotational;
  - In geometry units if type is POSITION and type of motion is translational;
  - In rpm if type is SPEED and type of motion is rotational;
  - In geometry units per second if type is SPEED and type of motion is translational;

Piecewise Linear Voltage Source

This is an independent voltage source with a piecewise linear waveform of the voltage as a function of time. The "+" and "-" symbols are used to mark the polarity of the source.





A piecewise linear voltage source is described by up to 20 pairs (Ti, Vi), where every pair of values specifies the value Vi in Volts of the voltage at time Ti in the following units:

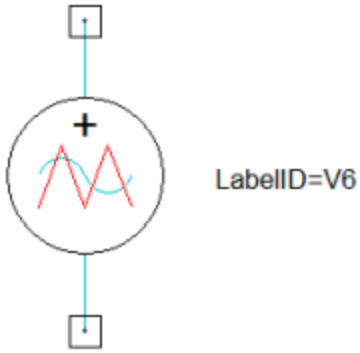
- In seconds if type is TIME.
- In degrees if type is POSITION and type of motion is rotational.
- In geometry units if type is POSITION and type of motion is translational.
- In rpm if type is SPEED and type of motion is rotational.
- In geometry units per second if type is SPEED and type of motion is translational.

PWM Voltage Source

The PWM voltage source component shown below provides PWM control signals used to support TDM parallel computation. (Refer to *Time Decomposition Method for Maxwell Transient Designs* in the Maxwell help.) The "+" symbol is used to mark the polarity of the source.

Since all time steps in one subdivision along the time axis are solved together when TDM is used, all controlling signals in a control circuit cannot depend on solutions such as currents/voltages of the previous time step. Therefore, all diodes and switches which are controlled by independent voltages and currents are not supported.

In PWM control, the controlling signals are purely time and/or position dependent, therefore, PWM control is supported in TDM. In a PWM control circuit, since the upper and lower switches belong to the same phase are turned on and off at exactly same time, the free-wheeling diodes are not necessary. In order for users to directly use existing PWM control circuit, PWM current and voltage source components have been introduced to replace original controlling sub-circuit which includes a triangle current/voltage source connected in series with a sinusoidal current/voltage source. The circuit solver will detect all switches which are controlled by PWM current/voltage sources and automatically filter all related diodes, which means during the simulation, diodes are automatically excluded in PWM control circuit.

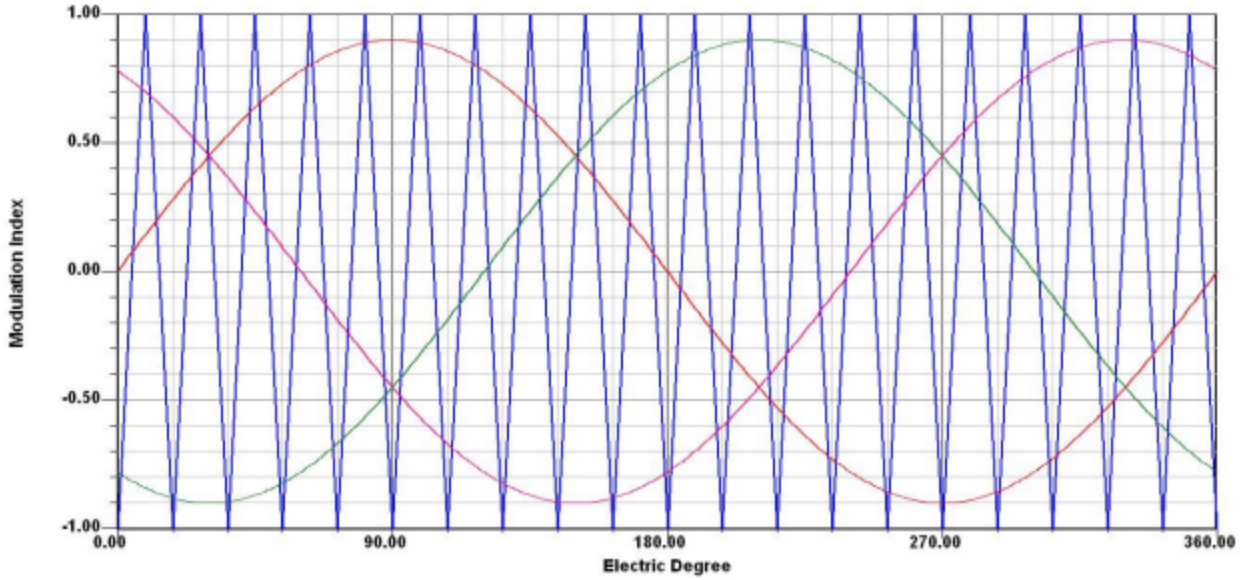


Note	Prior to the introduction of the PWM voltage source (VPWM) component, PWM control signals used to support TDM parallel computation were obtained from the difference of two voltage sources: a carrier signal with triangular waveform (VPulse), and a control signal with sinusoidal waveform (VSin)

A **VPWM** source is defined by the following parameters:

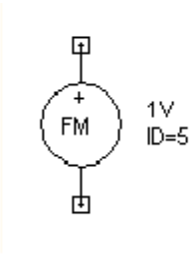
- **ModuIndex** is the modulation index, the ratio of control-signal amplitude to carrier-signal amplitude.
- **FreqTime** is the ratio of carrier-signal frequency to control-signal frequency.
- **VFreq** is the frequency of the control signal, if **Type** is **TIME**.
- **Phase** is the phase delay of the control signal, in electrical degrees.
- **Type** can be chosen as either **TIME** or **POS**, defining the output signal as a function of time or position.

The following figure shows typical three-phase PWM control signals.



Frequency-Modulated Sinusoidal Voltage Source

This is an independent voltage source with a single frequency modulated sinusoidal waveform of the voltage as a function of time. The "+" and "-" symbols are used to mark the polarity of the source.



The equation describing the waveform is:

$$V(t) = V_0 + V_a \cdot \sin[(2\pi \cdot F_C \cdot t) + M_{di} \cdot \sin(2\pi \cdot F_S \cdot t)]$$

where:

- Vo is Offset voltage in Volts.
- Va is the peak amplitude in Volts.
- FC is the carrier frequency if type is TIME.

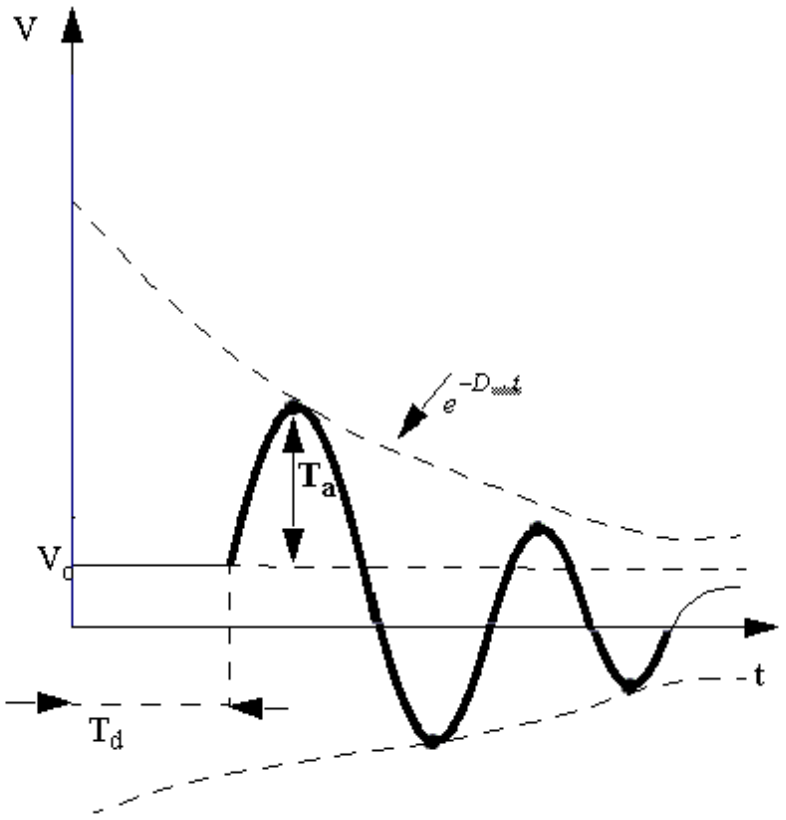
- Mdi is the modulation index.
- FS is the signal frequency if type is TIME.

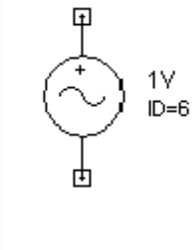
If the type is POSITION, the frequency should be calculated based on the respective spatial periodicity. taking into account the fact that "t" in the above equation is measured in degrees for rotational type of motion and in the user-defined geometry units for translational type of motion.

If the type is SPEED, the frequency should be calculated based on the respective speed periodicity, taking into account the fact that "t" in the above equation is measured in rpm for rotational type of motion and in the user-defined geometry units per second for translational type of motion.

Sinusoidal Voltage Source

This is an independent voltage source with an exponentially damped sinusoidal waveform of the voltage as a function of time. The "+" and "-" symbols are used to mark the polarity of the source.





The equation describing the waveform is:

$$V(t) = V_0 + V_a \cdot e^{-Df(t-T_d)} \cdot \sin[2 \cdot \pi \cdot VFreq \cdot (t-T_d) - Phase]$$

where:

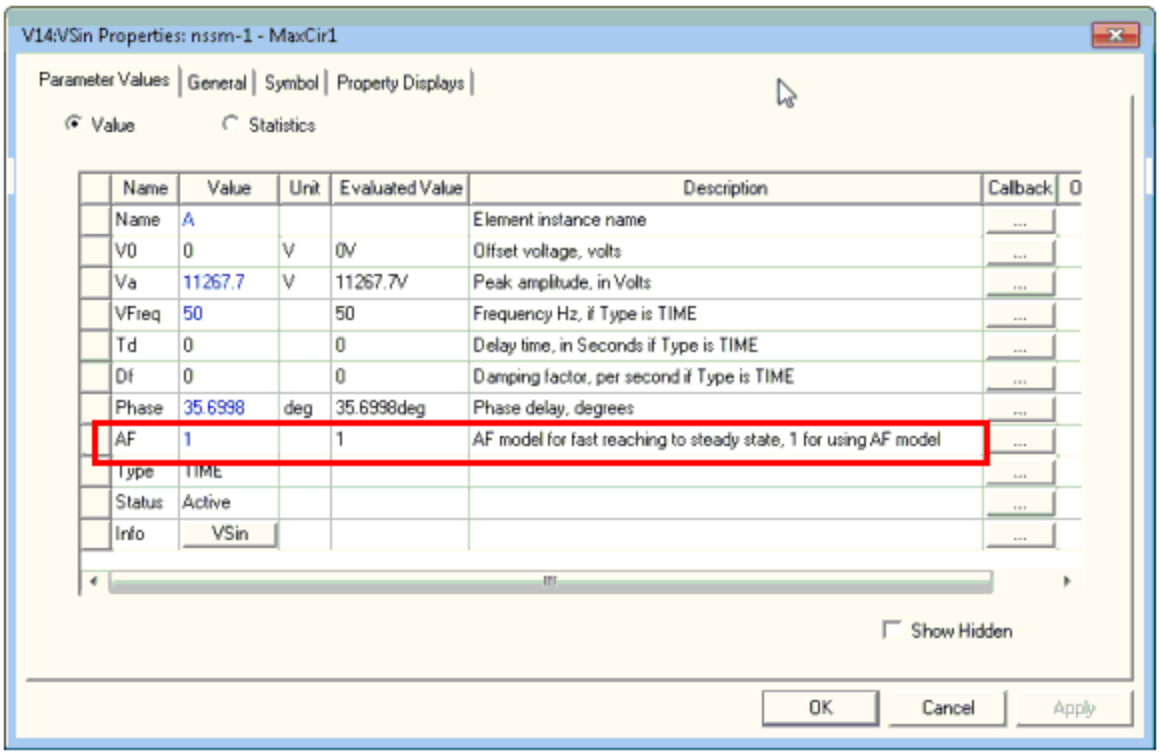
- Vo is Offset voltage in Volts.
- Va is the peak amplitude in Volts.
- VFreq is the signal frequency if type is TIME.
- Td is the delay time in seconds if type is TIME.
- Phase is the signal phase delay if type is TIME.
- Df is the damping factor in 1/seconds if type is TIME.

If the type is POSITION, the frequency should be calculated based on the respective spatial periodicity, taking into account the fact that "t" in the above equation is measured in degrees for rotational type of motion and in the user-defined geometry units for translational type of motion. The delay and damping factor should also be interpreted accordingly.

If the type is SPEED, the frequency should be calculated based on the respective speed periodicity, taking into account the fact that "t" in the above equation is measured in rpm for rotational type of motion and in the user-defined geometry units per second for translational type of motion. The delay and damping factor should also be interpreted accordingly.

Using the AF (alternating flux) model

For transient simulations whose excitation is the sinusoidal voltage source, the DC flux linkage component may take a very long time to decay, especially for a device with a large time constant. Setting AF=1 enables the AF model to be used by the Maxwell transient solver.



The AF model algorithm adds an additional voltage component to the original voltage definition during the first half-cycle to quickly eliminate the DC flux linkage, thus speeding up simulation solutions.

Note	• RMxprt automatically enables the AF model in the voltage definition for each winding when the Maxwell 2D or 3D model and associated Maxwell circuit are created. • This speedup capability is only applicable to voltage sources whose integration of voltage quantity over one period is zero. This means the DC component of all voltage sources must also be zero.

Placing Components in the Maxwell Circuit Editor Schematic

To place a circuit component:

1. Click the **Components** tab in the **Component Libraries Window**.
2. In the tree, expand the **Maxwell Circuit Elements** branch.
3. Expand the branch containing the component you want to place. The choices are **Dedicated Elements**, **Passive Elements**, **Probes**, and **Sources**.
4. Click to select the name of the component you want to place.
5. Drag the component to the Schematic window.
   A diagram of the component appears connected to the mouse pointer.

6. Release the mouse button to place the component in the location you prefer.
7. To place a second component of the same type, move the mouse pointer to another location, and release it again.
8. To exit from placement mode, do one of the following
   - To place the component a final time before exiting, press **ENTER**.
   - To exit without placing the component again, press **SPACE**.

Hint	To access these commands, you can also right-click and select one of the following from the shortcut menu: • Place and Finish • Finish

Assigning Component Properties in Maxwell Circuit Editor

Assigning Component Properties in Maxwell Circuit Editor

Once a component has been placed in the Schematic window, do the following to edit its properties:

1. Double-click the component.
   The **Properties** window opens.
2. Make the desired edits on the following four tabs:
   - Parameter Values
   - General
   - Symbol
   - Property Displays

Note	Variables may be assigned to parameter values in the circuit by entering a variable name in the parameter value field and assigning a value in the **Add Variable** dialog box. Variables assigned in **Maxwell Circuit Editor** will be exported with the circuit and are available for modifying when the circuit is imported into another Ansys application.

3. Optionally, you can select or clear the **Show Hidden** check box on any of the **Properties** window tabs.
4. Click **OK**.

The specific properties differ per component, as seen in the help topics describing each circuit component.

Each tab of the **Properties** window contains a list of parameters (each individual row) and properties you need to set for each parameter (each column is a property).

Callback Scripting Using PropHost Object

Callback Scripting Using PropHost Object

Callback scripts are scripts that can be set in the Property Dialog for individual properties by clicking the button in the Callback column and choosing a script that is saved with the project. Callback scripts can contain any legal script commands including general Ansys script function calls (e.g. GetApplication(), …). In addition, they can call functions on a special object named PropHost. The PropHost represents the PropServer (owner of properties) that contains the Property that is calling the Callback script. Therefore, the Callback script can use the PropHost's functions to query or set other properties in the same PropServer. Refer to the Property Level scripting commands for more information.

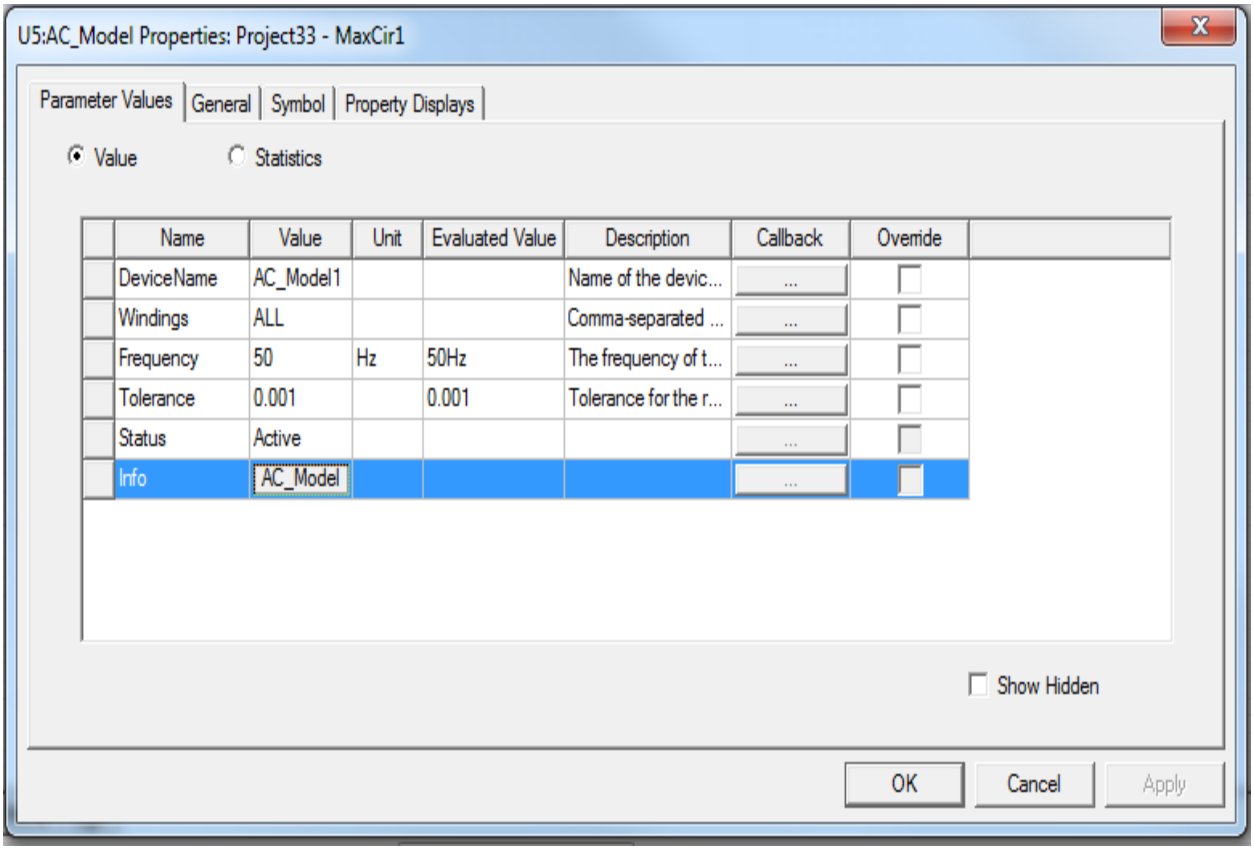
Opening the Help for Circuit Components

To start the help for any component from the schematic editor:

1. In the Schematic editor, double-click the component for which you want to view help.
   The **Properties** dialog box opens.
2. Click the **Parameter Values** tab.
3. Select the **Value** radio button.
4. In the **Info** row, click the button in the **Value** column, as shown below for **AC_Model**:



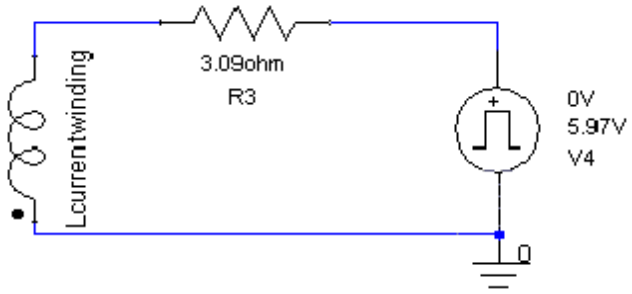
The help viewer opens to display the component's specifications.

Setting Up an External Circuit Using the Maxwell Circuit Editor

Note	One use for an external circuit can be to supply an excitation to a coil terminal, rather than using a voltage type of excitation.

Note	External circuits intended for use with the Time Decomposition Method (TDM) can only support basic circuit elements that are solution-independent. This is because, for TDM, all time steps (or all time steps in a subdivision) are solved simultaneously - and thus the circuit topology and its parameters must be known before solving. Therefore some circuit elements, such as solution-dependent switches, diodes, capacitors, and inductors which are not directly connected to windings in series, are not supported.

The driving circuit for the winding in this design consists of a voltage source in series with a resistor and with the winding. When complete, the circuit should look similar to the following figure.



To set up the external circuit, follow this general procedure:

1. Add the circuit elements.
2. Connect the circuit elements in series.
3. Export the netlist.
4. Save the Maxwell Circuit Editor project.
5. Assign the external circuit.

Add the Circuit Elements

To add the circuit elements in Maxwell Circuit Editor:

1. Click **Project>Insert Maxwell Circuit Design**.
   The circuit sheet appears.
2. Place the winding circuit element on the sheet:
   a. In the **Component Libraries**, under **Maxwell Circuit Elements>Dedicated Elements**, select the **Winding** element.
   b. Drag it onto the sheet.
   c. Right-click, and select **Finish** to place the component.
   d. To view the properties, double-click the component in the Schematic window.
   The **Properties** window appears.
   e. Change the **Name** to **currentwinding**, the same name you used when defining the winding in the Maxwell design.
   f. Click **OK**.
   g. Click **Draw>Rotate**, and position the winding vertically.
3. Place a resistor on the sheet:
   a. In the project tree, under **Passive Elements**, select **Resistor**.
   b. Drag the resistor onto the sheet.
   c. Right-click, and select **Finish** to place it where desired.
   d. Double-click the symbol of the resistor, change the value of the resistor, **R**, to **3.09**, keep the **Unit** value set to **ohm**, and click **OK**. The default is 100 Ohms.
4. Place a voltage pulse on the sheet:

a. In the project tree, under **Sources** select a **VPulse** element (Pulse Voltage Source).
b. Drag it to the sheet, and then right-click and select **Finish** to place it onto the sheet.
c. Double-click the source element symbol on the sheet, and then specify the following source characteristics:

Parameter	Value	Description
V1	0	Initial voltage
V2	5.97	Peak voltage
Tr	0.001	Rise time
Tf	0.001	Fall time
Pw	1	Pulse width
Period	2	

d. Leave the other fields set to the default values, and click **OK**.

Connect the Circuit Elements in Series

To connect the circuit elements in series:

1. From within the Maxwell Circuit Editor, click **Draw>Wire**.
2. Click each terminal.
3. When done, place the Ground symbol: Click **Draw>Ground**, place the **Ground** symbol on the sheet, right-click, and select **Finish** to place the symbol.
4. Connect the ground to the circuit: Click **Draw>Wire**, and draw the final wire.

Export the Netlist

To export the netlist:

1. From within the Maxwell Circuit Editor, click **Maxwell Circuit>Export Netlist**.
   The **Netlist Export** dialog box appears.

Note	To view the netlist before exporting it, click **Maxwell Circuit>Browse Netlist**.

2. Select the folder where you want to save the external circuit file.
3. Type a name for the circuit in the **File name** box.
4. Click **Save**.
   The **Netlist Export** dialog box closes and the Maxwell Circuit Editor reappears.

Save the Maxwell Circuit Editor Project

To save the project and exit Maxwell Circuit Editor:

1. Click **File>Save**, type a name for the project, and click **Save** to save the Maxwell Circuit Editor project.
2. Click **File>Exit** to close the Maxwell Circuit Editor program.

Assign the External Circuit

To assign the circuit in the Maxwell design:

1. Click **Maxwell2D** (or **3D**)**>Excitations>External Circuit>Edit External Circuit**.
   The **Edit External Circuit** dialog box appears.
2. Click **Import Circuit Netlist**.
   The **Select File** dialog box appears.
3. Select **Designer Net List Files (*.sph)** from the **Files of type** pull-down list.
4. Browse to the location where you saved the circuit, select it, and click **Open** to import it.
5. Click **OK** to close the **Edit External Circuit** dialog box.

Renaming a Source in Maxwell Circuit Editor

To rename a source that is drawn in the Schematic:

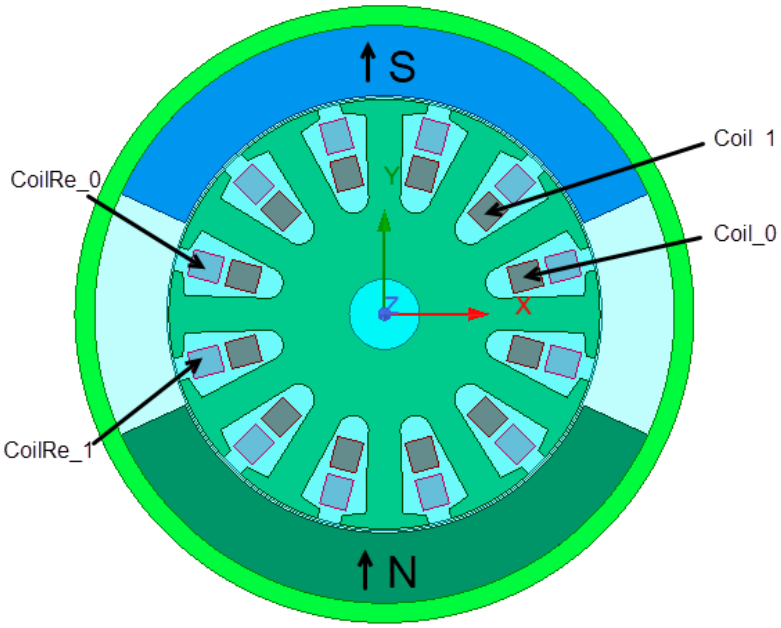
1. Double-click the source.
   The **Properties** dialog box appears.
2. Click the **Parameter Values** tab (which should be the default tab visible).
3. Change the text value in the **Name** row.
4. Click **OK**.
   The new name appears for the source label in the Schematic.

Applying the Commutating Bar Element

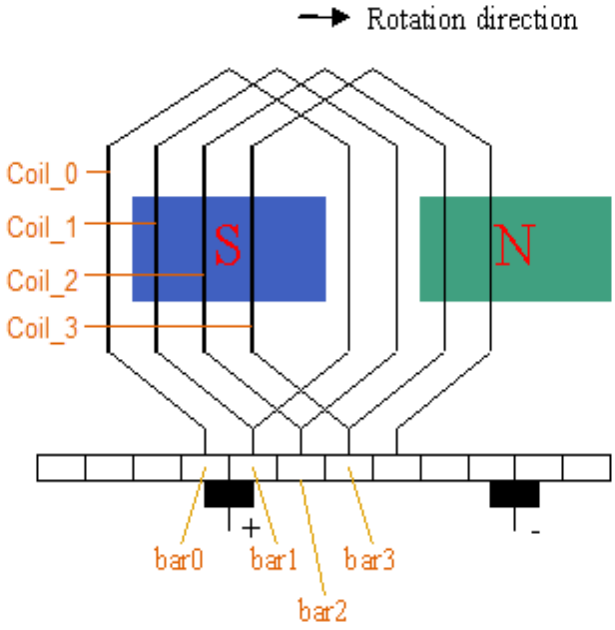
This paragraph describes how to apply the commutating bar element to simulate the commutating process of brush-type DC machines. A two-pole 12-slot PMDC motor (shown below) is used as an example.

Note	The example used here is based on the **stndj-1.aedt** project found in the *<install_dir>*/Examples/RMxprt/pmdc folder.

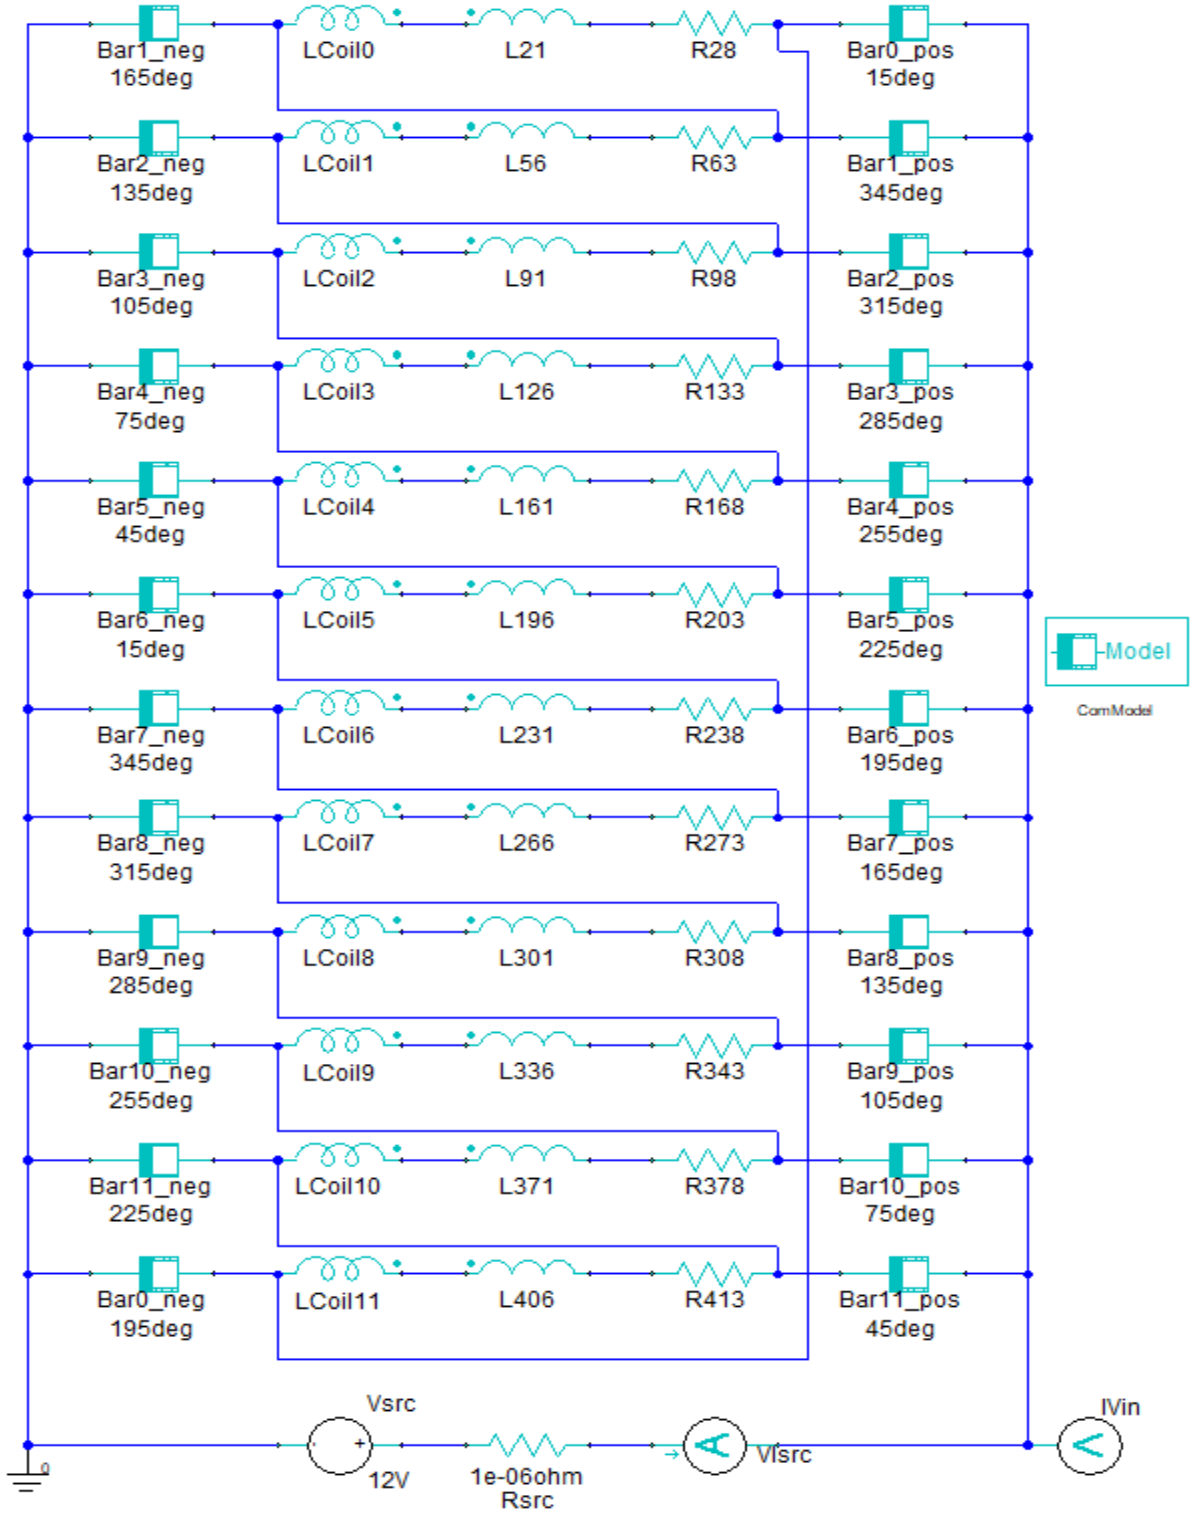
The flux direction inside the S pole permanent magnet is from the air gap to stator yoke, and that of the N pole is from the stator yoke to the air gap.



The DC winding is of lap type with coil pitch of 5 slots. The flat-out extensional drawing of the motor indicating the relationship of permanent magnets, coils, commutating bars, and brushes at the initial position is shown below. With the rotation direction shown, the brush aligned with the S pole is positive, and the brush aligned with the N pole is negative. The "go" terminal of Coil_0 connects to bar0, and its return terminal connects to bar1; the "go" terminal of Coil_1 connects to bar1, and its return terminal connects to bar2; and so on.

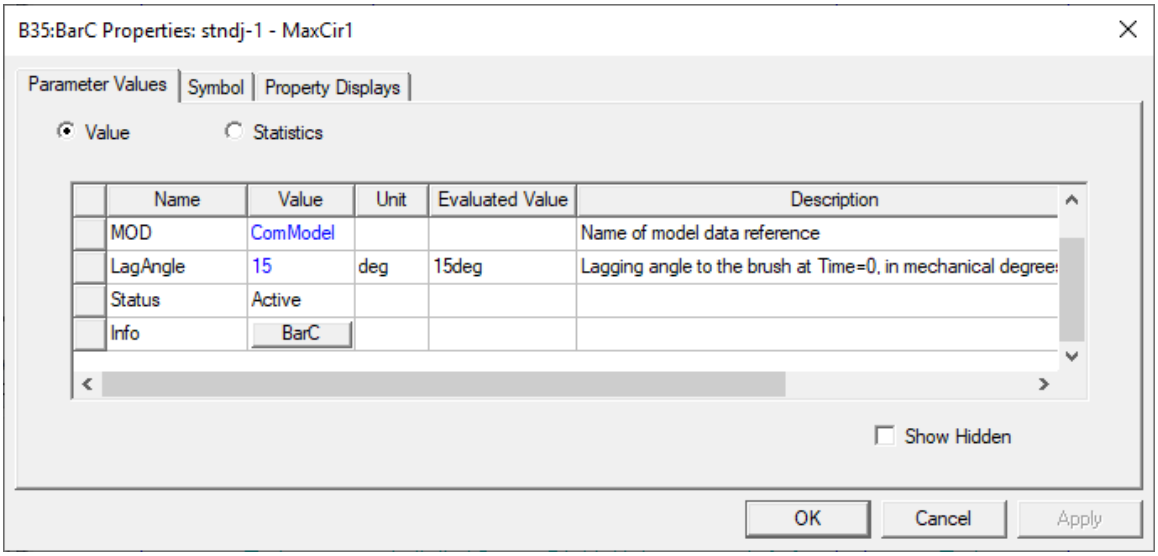


At the initial time, bar0 lags the positive brush by 15 mechanical degrees (a half commutating bar pitch), and it lags the negative brush by 195 mechanical degrees; bar1 lags the positive brush by -15 mechanical degrees, or 345 degrees, and it lags the negative brush by 165 mechanical degrees; and so on. The functional connection of each commutating bar with the positive brush or negative brush is modeled by BarC (commutating bar) elements, as shown below.

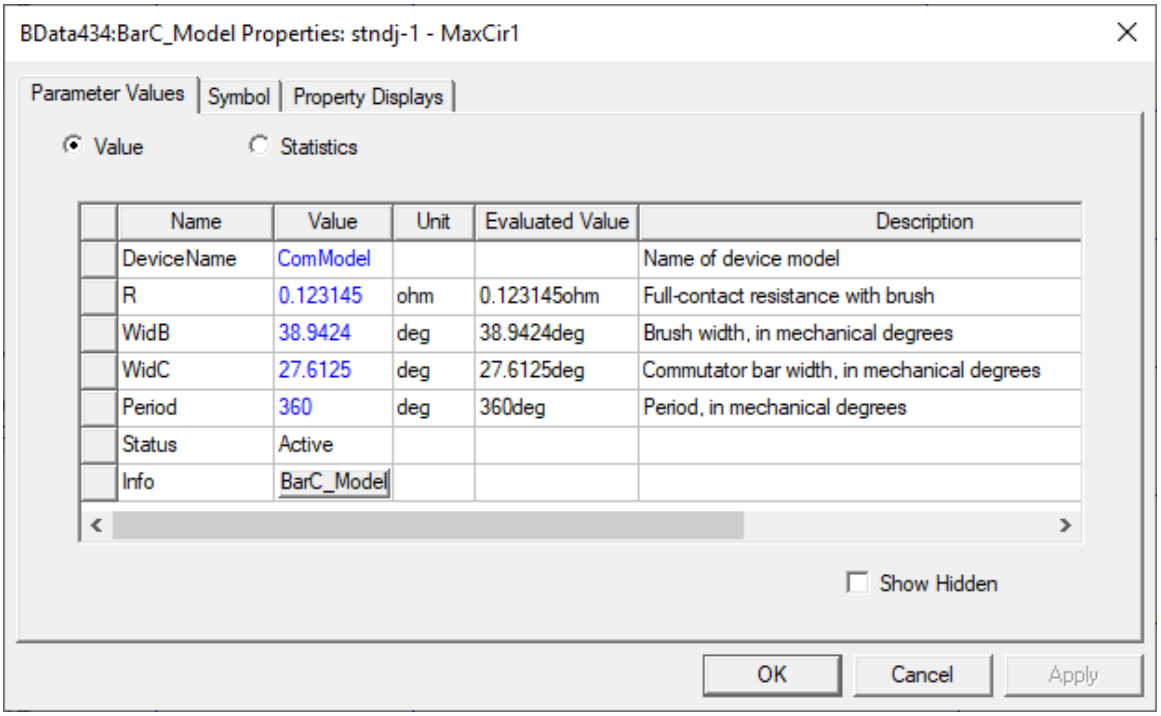


Elements Bar0_pos through Bar11_pos represent the functional connections of bar0 to bar11 with the positive brush, respectively. Elements Bar0_neg through Bar11_neg give the functional

connections of bar1 to bar11, and bar0 with the negative brush, respectively. The additional inductor in series with each coil inductance represents the end turn effect that is desirable to consider in a 2D model and possibly also in a 3D model that does not include the end turn geometry. The additional series resistor in series with each coil represents the global resistance of the coil and needs to be included in both 2D and 3D simulations. The values below the BarC element symbols are the respective lagging angles in mechanical degrees. The element parameters can be edited by double-clicking on the element, as shown below.



The input value "ComModel" for MOD is the model name that defines the parameters of commutating bars and brushes. The parameters of ComModel can be edited by double-clicking the BarC_Model element.



Note	As a rule, each BarC element references a unique BarC_Model element.

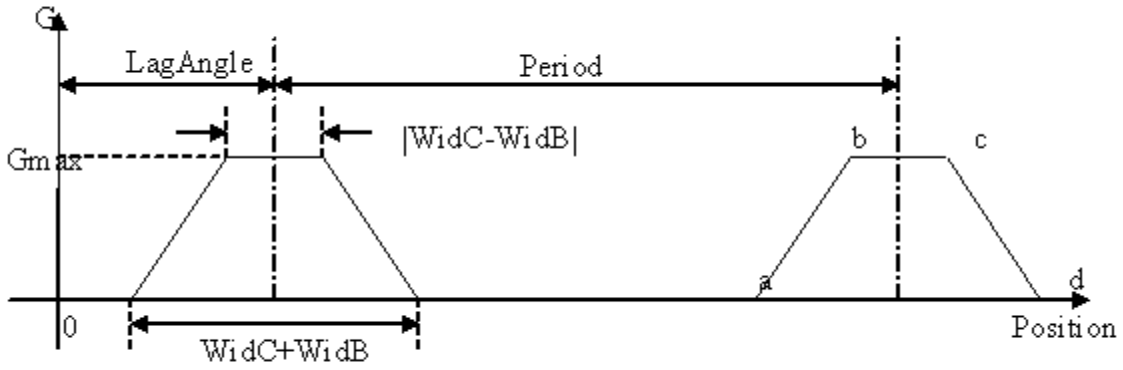
In this design, the commutator diameter is 24mm, and the brush width is 8mm. Therefore, the brush width in mechanical degrees is the following:

*WidB = 2 * arcsin(8/24) = 38.9 (deg)*

The number of commutator bars is 12 (the same as the number of slots), and the commutator insulation thickness is 0.5mm. Therefore, the commutator bar width in mechanical degrees is the following:

*WidC = 360/12 - 2 * arcsin(0.5/24) = 27.6 (deg)*

The electric conductance between a commutating bar and a brush varies with the rotor position and can be derived from the model parameters as shown below, where *Gmax = 1 / R*.



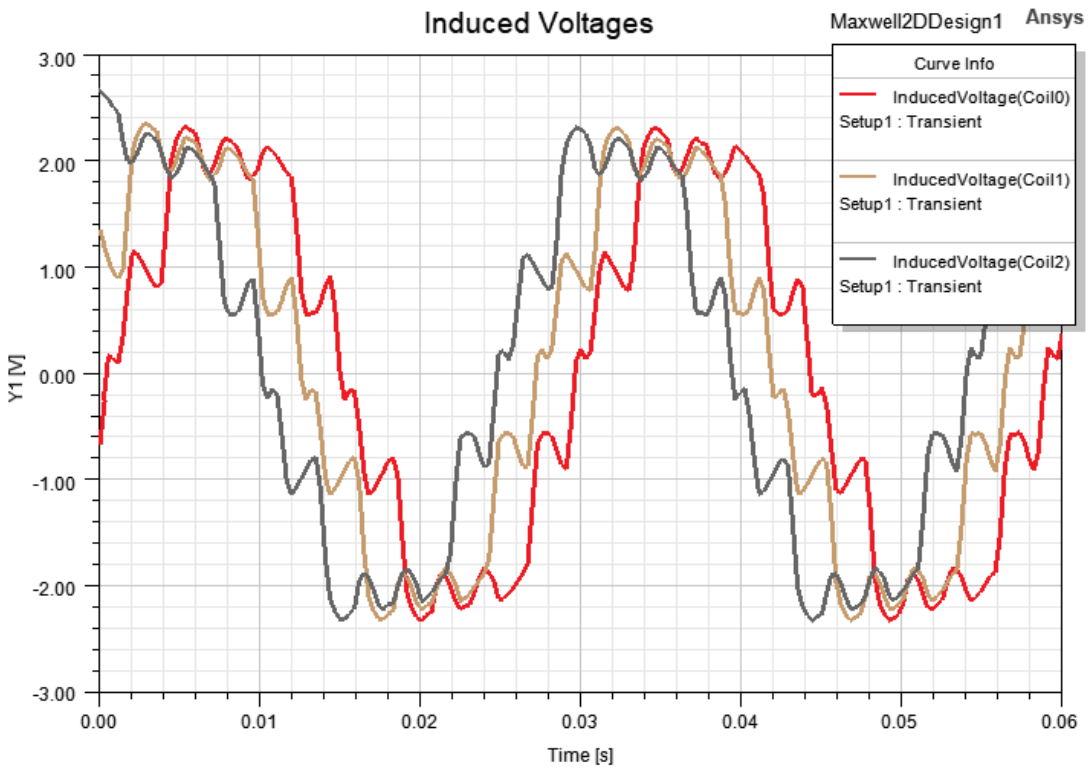
Electric conductance as a function of rotor position

LagAngle is treated as a BarC element parameter because it is different for different commutating bars. All other values (Gmax, WidB, WidC, and Period) can be obtained from BarC_Model parameters. Positions a, b, c, and d correspond to the positions when one side of a commutating bar (solid color) aligns to one side of a brush, as shown below.

Different conducting position when WidB > WidC

Different conducting position when WidB < WidC

The computed no-load induced voltages for three of the coils, taking into account the commutating process, are shown below.



28 - Maxwell 2D Technical Notes

Maxwell® 2D is an interactive software package that uses the finite element method (FEM) analysis to simulate and solve two-dimensional electromagnetic field problems. Maxwell integrates with other Ansys software to perform complex tasks while remaining easy to use.

Maxwell 2D is used for analyzing electric and magnetic fields in structures with uniform cross-sections or full rotational symmetry — where the field patterns in the entire device can be analyzed by modeling the field patterns in its cross-section.

In general, 2D modeling of electromagnetic fields solves for the fields in a 2D cross-section of a device which is considered to be placed far away from the extremities of the devices, thus ignoring end effects. While it can provide excellent accuracy for all applicable modeling tasks, 2D solution sequences cannot be always used to accurately model electromagnetic devices. Devices where end effects are significant or that may not exhibit complete rotational symmetry must be modeled in 3D for greatest accuracy.

Optimization Overview

Solvers

Maxwell 2D consists of the following solver modules:

Electrostatic Field Solver	Computes the static electric field that exists in a structure given a distribution of DC voltages and static charges. A capacitance matrix, force, torque, and flux linkage may also be computed from the electric field.

Magnetostatic Field Solver	Computes the static magnetic field that exists in a structure given a distribution of DC currents and permanent magnets. The magnetic field may be computed in structures with both nonlinear and linear materials. An inductance matrix, force, torque, and flux linkage may also be computed from the energy stored in the magnetic field.
AC Conduction Field Solver	Computes the AC voltages and current density distribution in a material having both conductive and dielectric properties given a distribution of AC voltages. An admittance matrix and current flow may also be computed from the calculated fields.
DC Conduction Field Solver	Computes the DC currents that flow in a lossy dielectric given a distribution of DC voltages. A conductance matrix and current flow may also be computed from the computed electric field solution.
Eddy Current Field Solver	Computes the oscillating magnetic field that exists in a structure given a distribution of AC currents. Also computes current densities, taking into account all eddy current effects (including skin effects). An impedance matrix, force, torque, core loss, and current flow may also be computed from the computed field solution.
Transient Magnetic Solver	Computes transient (Time Domain) magnetic fields caused by permanent magnets, conductors, and windings supplied by voltage and/or current sources with arbitrary variation as functions of time, position and speed. It can also be coupled with external circuits. Rotational or translational motion effects can be included in the simulation.

Electrostatic Field Simulation

The electrostatic field simulator computes static electric fields arising from potential differences and charge distributions.

Electrostatic Theory

The electrostatic field simulator solves for the electric potential, $\phi(x,y)$, in this field equation:

$$\nabla\bullet(\varepsilon_r\varepsilon_0\nabla\phi(x,y)) = -\rho$$

where:

- $\phi(x,y)$ is the electric potential.
- ε_r is the relative permittivity. It can be different for each material.
- ε_o is the permittivity of free space, 8.854×10^{-12} F/m.
- $\rho(x,y)$ is the charge density.

This equation is derived from Gauss's Law and from Faraday's law of induction. Gauss's Law indicates that the net electric flux passing through any closed surface is equal to the net positive charge enclosed by that surface. In differential form, Gauss's Law is:

$$\nabla \bullet \boldsymbol{D} = \rho$$

where **D**(x,y) is the electric flux density. Since $D=\varepsilon_r\varepsilon_o E$, then:

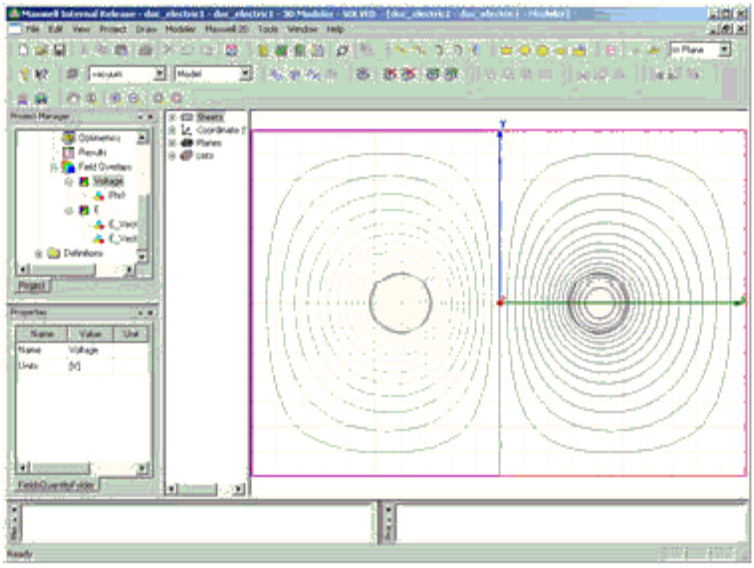
$$\nabla \bullet (\varepsilon_r \varepsilon_0 \boldsymbol{E}(x,y)) = \rho$$

In a static field, as a consequence of Faraday's law, $E = -\nabla\phi$. Therefore,

$$\nabla \bullet (\varepsilon_r \varepsilon_0 \nabla\phi(x,y)) = -\rho$$

which is the equation that the electrostatic field simulator solves using the finite element method. After the solution for the potential is generated, the system automatically computes the E-field and D-field using the relations $E = -\nabla\phi$ and $D=\varepsilon_r\varepsilon_o E$.

An contour plot of electric potential generated by the electrostatic field simulator is shown below:



Capacitance

At the simplest level, capacitance relates to the amount of energy stored in the electric field in and surrounding a structure. In a single circuit, the capacitance represents the amount of energy stored in the electric field that arises due to a voltage differential across a dielectric.

$$W_e = \frac{1}{2} C v^2$$

where W_e is the energy stored in the electric field, C is the capacitance, and v is the voltage across the dielectric.

Maxwell computes the capacitance between two conductors by simulating the electric field that arises when a voltage differential is applied. By computing the energy stored in the field, the corresponding capacitance can be computed.

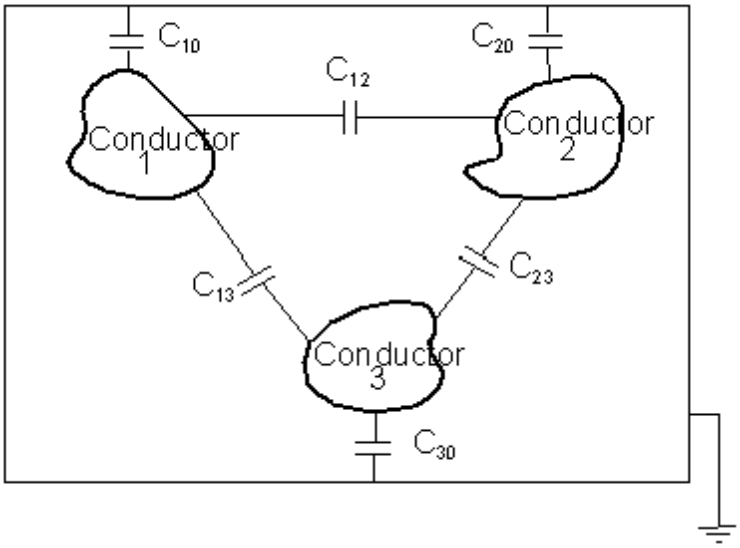
$$C = \frac{2W_e}{v^2}$$

To compute capacitances using this method, the E-field and D-field associated with a given distribution of voltages must first be computed. The electrostatic field simulator, which computes the electric potential at all points in the problem region, does this.

Capacitance in Terms of Charges and Voltages

A capacitance matrix represents the charge coupling within a group of conductors — that is, the relationship between charges and voltages for the conductors. Given the three conductors shown below, with the outside boundary taken as a reference, the net charge on each object will be:

$$Q_1 = C_{10} V_1 + C_{12}(V_1 - V_2) + C_{13}(V_1 - V_3)$$
$$Q_2 = C_{20} V_2 + C_{12}(V_2 - V_1) + C_{23}(V_2 - V_3)$$
$$Q_3 = C_{30} V_3 + C_{13}(V_3 - V_1) + C_{23}(V_3 - V_2)$$



This can be expressed in matrix form as:

$$\begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} & -C_{12} & -C_{13} \\ -C_{12} & C_{20}+C_{12}+C_{23} & -C_{23} \\ -C_{13} & -C_{23} & C_{30}+C_{13}+C_{23} \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \\ V_3 \end{bmatrix}$$

The capacitance matrix above gives the relationship between Q and V for the three conductors and ground. In a device with *n* conductors, this relationship would be expressed by an *n* x *n* capacitance matrix. Capacitance matrix values are specified in farads (coulombs/volt).

If one volt is applied to Conductor 1 and zero volts is applied to the other two conductors, the capacitance matrix becomes:

$$\begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix} = [C] \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} \\ -C_{12} \\ -C_{13} \end{bmatrix}$$

The diagonal elements in the matrix (such as $C_{(1,1)}$) are the sum of all capacitances from one conductor to all other conductors. These terms represent the self-capacitance of the conductors. Each is numerically equal to the charge on a conductor when one volt is applied to that conductor and the other conductors (including ground) are set to zero volts. For instance,

$C_{(1,1)} = C_{10} + C_{12} + C_{13}$

The off-diagonal terms in each column (such as $C_{(1,2)}$, $C_{(1,3)}$) are numerically equal to the charges induced on other conductors in the system when one volt is applied to that conductor. For instance, in column one of the example capacitance matrix, $C_{(1,2)}$ is equal to $-C_{12}$. This is equal to the charge induced on Conductor 2 when one volt is applied to Conductor 1 and zero volts are applied to Conductor 2.

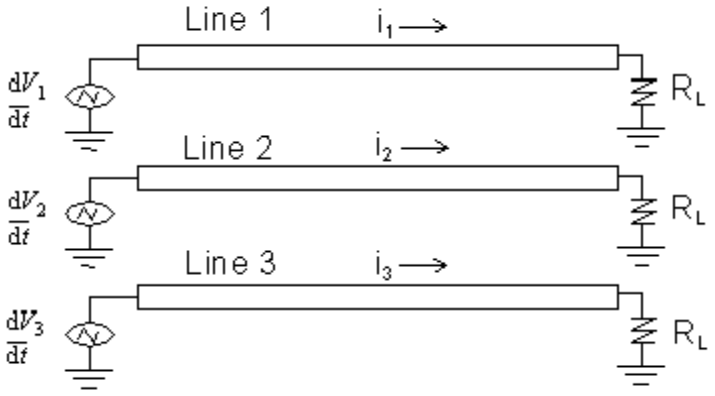
The off-diagonal terms are simply the negative values of the capacitances between the corresponding conductors (the mutual capacitances). In column one of the example capacitance matrix, the off-diagonal terms represent the capacitances between Conductor 1 and the other two conductors; in column two, the terms represent the capacitance between Conductor 2 and the other conductors; and so forth.

Note that the capacitance matrix is symmetric about the diagonal. This indicates that the mutual effects between any two objects are identical. For instance, $C_{(1,3)}$, the capacitance between Conductor 1 and Conductor 3 ($-C_{13}$), is equal to $C_{(3,1)}$, the capacitance between Conductor 3 and Conductor 1.

Capacitance in Terms of Currents and Time Varying Voltages

A capacitance matrix can also represent the relationship between currents and time varying voltages in a system of conductors.

Given the three transmission lines shown here,



the currents caused by the time varying voltage source on each line are given by the following relationship:

$$\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} & -C_{12} & -C_{13} \\ -C_{12} & C_{20}+C_{12}+C_{23} & -C_{23} \\ -C_{13} & -C_{23} & C_{30}+C_{13}+C_{23} \end{bmatrix} \begin{bmatrix} dV_1/(dt) \\ dV_2/(dt) \\ dV_3/(dt) \end{bmatrix}$$

If dV_2/dt and dV_3/dt are set to zero, this relationship becomes:

$$\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} = [C] \begin{bmatrix} dV_1/(dt) \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} \\ -C_{12} \\ -C_{13} \end{bmatrix} (dV_1/(dt))$$

This gives the currents that are induced on Line 2 and Line 3 when a time varying voltage source is applied to Line 1 — that is, the capacitive coupling between the three lines, or the short circuit capacitance.

Computing Capacitance

To compute a capacitance matrix for a structure, the Maxwell performs a sequence of electrostatic field simulations. In each field simulation, one volt is applied to a single conductor and zero volts is applied to all other conductors. Therefore, for an *n*-conductor system, *n* field simulations are automatically performed.

The energy stored in the electric field associated with the capacitance between two conductors is given by the following relation:

$$W_{ij} = \frac{1}{2}\int_{\Omega} \boldsymbol{D}_i \bullet \boldsymbol{E}_j d\Omega$$

where:

- *Wij* is the energy in the electric field associated with flux lines that connect charges on conductor *i* to those on conductor *j*.
- *Di* is the electric flux density associated with the case in which one volt is placed on conductor *i*.
- *Ej* is the electric field associated with the case in which one volt is placed on conductor *j*.

The capacitance between conductors *i* and *j* is therefore:

$$C = \frac{2W_{ij}}{v^2} = \int_{\Omega} \boldsymbol{D}_i \bullet \boldsymbol{E}_j d\Omega$$

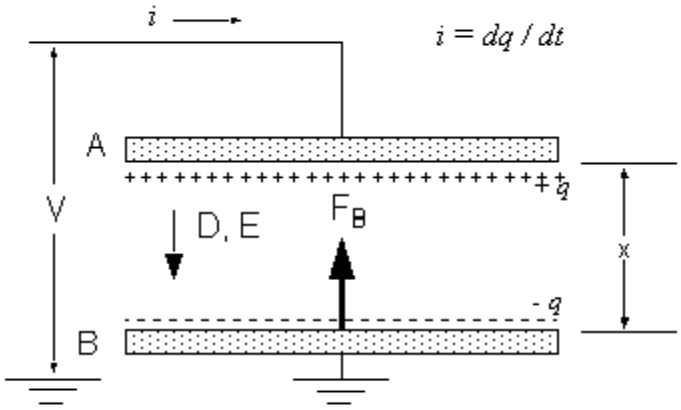
Virtual Forces (Electrostatic)

To compute the virtual force on an object, the electrostatic field simulator uses the principle of virtual work. In the structure shown below, the force on the bottom plate (plate B) in the direction of the displacement, x, is given by the following relationship:

$$F_B = \left.\frac{dW(v,x)}{dx}\right|_{V = Constant}$$

where W is the stored energy of the system,

$$W(v,x) = \frac{1}{2}\int_{Vol} \boldsymbol{E} \bullet \boldsymbol{D}\, dVol$$



Unlike the classical virtual work method, the plate is not actually moved during the numerical process of the force computation. Instead, only the triangles that lie along the outside surface of the object are virtually distorted. W and its derivative, dW/dx, are calculated from a single field solution using finite element interpolation functions.

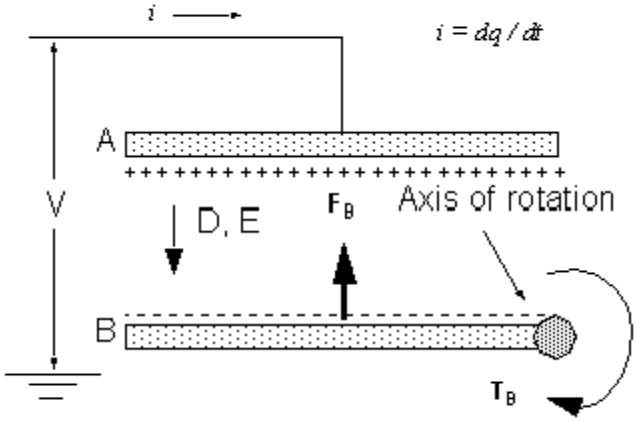
Virtual Torques (Electrostatic)

Similar to the virtual force calculation, the system uses virtual work principles to compute the torque on an object. In the structure shown below, the virtual torque on the bottom plate (plate B) about the axis of rotation is given by the following relationship:

$$T_B = \left.\frac{dW(v,\theta)}{d\theta}\right|_{V = Constant}$$

where W is the stored energy of the system,

$$W(v,\theta) = \frac{1}{2}\int_{Vol} \boldsymbol{E} \bullet \boldsymbol{D}\, dVol$$



Unlike the classical virtual work method, the plate is not actually rotated during the numerical process of the torque computation. Instead, only the triangles that lie along the outside surface of the object are virtually distorted. W and its derivative, dW/dθ, are calculated from a single field solution using finite element interpolation functions.

Flux Linkage (Electrostatic)

To compute the electric flux linkage, the electrostatic field solver uses the following relationship:

$$\Psi = \int \boldsymbol{E} \bullet d\boldsymbol{A}$$

where *E* is the electric field and *A* is the area over which flux density is computed.

- In cartesian (XY) models, the area is found by sweeping the flux line you've drawn in the xy-plane into the z direction — forming a 3D surface. The electric flux value computed is the

flux per meter depth in the z direction.

- In axisymmetric (RZ) models, the area is found by rotating the flux line you've drawn in the rz-plane 360 degrees about the z axis. The electric flux computed is the total flux that passes through this surface.

A separate flux linkage value is computed for each line you draw.

Magnetostatic Field Simulation

The magnetostatic field simulator lets you compute static magnetic fields arising from DC currents and other sources like permanent magnets and external magnetic fields. Magnetic fields in both linear and nonlinear materials can be simulated.

Magnetostatic Theory

The magnetostatic field simulator solves for the magnetic vector potential, $\mathbf{A}_Z(x,y)$ in this field equation:

$$\boldsymbol{J}_z(x,y) = \nabla\times\left(\frac{1}{\mu_r\mu_0}(\nabla\times\boldsymbol{A}_z(x,y))\right)$$

where:

- *Az(x,y)* is the z component of the magnetic vector potential.
- *Jz(x,y)* is the DC current density field flowing in the direction of transmission.
- μ_r is the relative permeability of each material.
- μ_0 is the permeability of free space.

Given *Jz(x,y)* as an excitation, the magnetostatic field simulator computes the magnetic vector potential at all points in space.

Note	In general, both **J** and **A** are vectors. However, **J** is assumed to only have a z-component. A consequence of this is that **A** only has a z-component as well. Both quantities can therefore be treated as scalars.

The equation that the magnetostatic field solver computes is derived from Ampere's law, which is:

$$\nabla\times\boldsymbol{H} = \boldsymbol{J}$$

$$\nabla\cdot\boldsymbol{B} = 0 \qquad H = \frac{B}{\mu_r\mu_0}$$

and from Maxwell's equation, . Since , then:

$$\nabla \times \left(\frac{\boldsymbol{B}}{\mu_r \mu_0} \right) = \boldsymbol{J}$$

$\boldsymbol{B} = \nabla \times \boldsymbol{A}$ $\nabla \cdot \boldsymbol{B} = 0$

Since , due to , then:

$$\nabla \times \left(\frac{1}{\mu_r \mu_0} \nabla \times \boldsymbol{A} \right) = \boldsymbol{J}$$

The magnetostatic field simulator solves this equation using the finite element method.

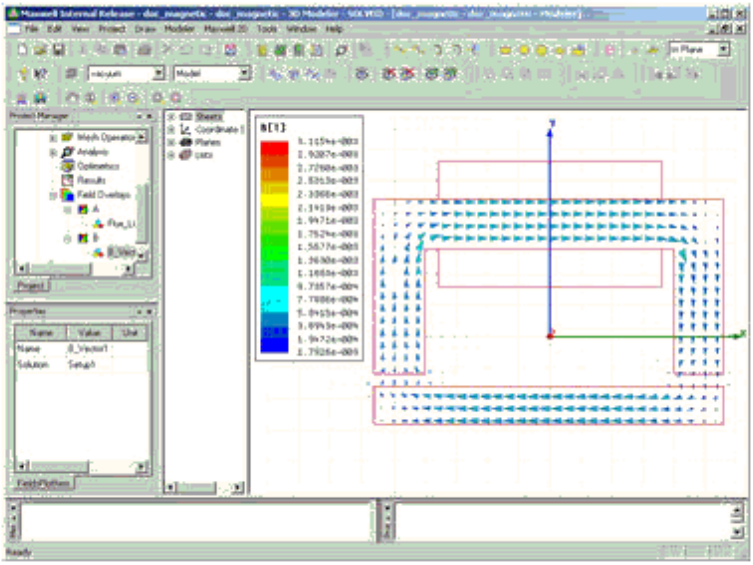
After $\mathbf{A}_Z(x,y)$ is computed, the magnetic flux density, **B**, and the magnetic field, **H**, can then be computed using the relationships:

$$\boldsymbol{B} = \nabla \times \boldsymbol{A}$$

$$\boldsymbol{H} = \frac{\boldsymbol{B}}{\mu_r \mu_0}$$

and **H**, for linear materials, is:

Both **B** and **H** lie in the xy cross-section being analyzed. An arrow plot of a B-field generated by the magnetostatic field simulator is shown below:



Inductance

At the simplest level, inductance relates to how much energy is stored in the magnetic field when current flows.

$$W_m = \frac{1}{2} L i^2$$

where:

- *Wm* is the energy stored in the magnetic field
- *L* is the inductance
- *i* is the current flowing in the circuit

The Maxwell computes inductances associated with a structure by simulating the magnetic field that arises when various voltages and currents are applied. Then, by computing the energy stored in those fields, it can then compute the necessary inductances:

$$L = \frac{2 W_m}{i^2}$$

To compute inductances using this method, the B-field and H-field associated with a distribution of currents must first be computed. The magnetostatic field simulator, which computes the magnetic vector potential at all points in the problem region, performs this task.

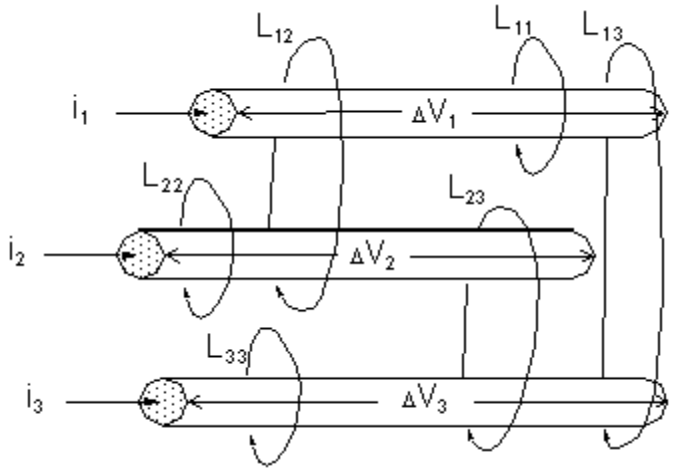
Inductance in Terms of Flux Linkage and Currents

An inductance matrix represents the magnetic flux linkage between the current loops in a system. Given the three current loops below, the relationship between induced flux and currents is as follows:

$\lambda_1 = L_{11}\, i_1 + L_{12}\, i_2 + L_{13}\, i_3$

$\lambda_2 = L_{12}\, i_1 + L_{22}\, i_2 + L_{23}\, i_3$

$\lambda_3 = L_{13}\, i_1 + L_{23}\, i_2 + L_{33}\, i_3$



This can be expressed in matrix form as:

$$\begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix} = \begin{bmatrix} L_{11} & L_{12} & L_{13} \\ L_{12} & L_{22} & L_{23} \\ L_{13} & L_{23} & L_{33} \end{bmatrix} \begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix}$$

The inductance matrix above gives the relationship between λ and *i* for the three independent current loops. In a device with *n* current loops, this relationship would be expressed by an $n \times n$ inductance matrix. Inductance matrix values are specified in henries.

If one ampere is applied to Current Loop 1 and zero amperes are applied to the other two loops, the inductance matrix becomes:

$$\begin{bmatrix}\lambda_1\\ \lambda_2\\ \lambda_3\end{bmatrix} = \begin{bmatrix}L\end{bmatrix}\begin{bmatrix}1\\ 0\\ 0\end{bmatrix} = \begin{bmatrix}L_{11}\\ L_{12}\\ L_{13}\end{bmatrix}$$

The diagonal terms in the matrix (such as L_{11}) represent the self-inductance of each current loop. Self-inductance is numerically equal to the flux linkage in a current loop when one ampere is flowing in it, and no current is flowing in the other loops. For example, L_{11} is equal to the flux in Current Loop 1 when one ampere is flowing in that current loop, and no current is flowing in the other loops.

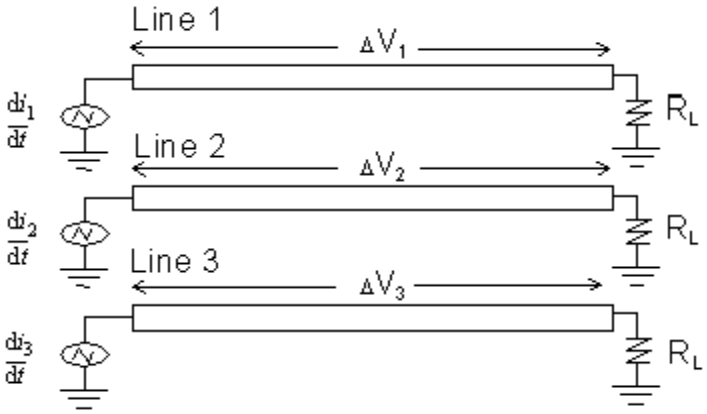
The off-diagonal terms (such as L_{12}, L_{13}) represent the mutual inductances between the current loops. Mutual inductance is numerically equal to the flux linkage in a current loop when one ampere is flowing through another loop, and no current is flowing anywhere else. For example, L_{12} is equal to the flux linkage in Loop1 when one ampere is applied to Loop 2 and no current is flowing in the other loops.

Note that the inductance matrix is symmetric about the diagonal. This indicates that the mutual effects between any two loops are identical. For instance, L_{13}, the inductance between Current Loop 1 and Current Loop 3, is equal to the inductance between Current Loop 3 and Current Loop 1.

Inductance in Terms of Voltages and Time Varying Currents

An inductance matrix can also represent the relationship between voltage and current fluctuations in a system. Given the three transmission lines shown below, the voltage changes caused by the time varying current source on each line are given by:

$$\begin{bmatrix}\Delta V_1\\ \Delta V_2\\ \Delta V_3\end{bmatrix} = \begin{bmatrix}L_{11} & L_{12} & L_{13}\\ L_{12} & L_{22} & L_{23}\\ L_{13} & L_{23} & L_{33}\end{bmatrix}\begin{bmatrix}(di_1)/(dt)\\ (di_2)/(dt)\\ (di_3)/(dt)\end{bmatrix}$$



The inductance matrix above gives the relationship between ΔV and *di/dt* for the three independent transmission lines.

If di_2/dt and di_3/dt are set to zero, this relationship becomes

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \\ \Delta V_3 \end{bmatrix} = [L] \begin{bmatrix} (di_1)/(dt) \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} L_{11} \\ L_{12} \\ L_{13} \end{bmatrix} (di_1)/(dt)$$

This gives the voltage changes that are induced on Lines 2 and 3 when a time-varying current source is applied to Line 1 — that is, the inductive coupling between all the loops.

Computing an Inductance Matrix

To compute an inductance matrix, the software performs a sequence of magnetostatic field simulations. In each field simulation, one ampere is allowed to flow in a single conductor. The current returns as defined under **Maxwell2D>Parameters>Assign>Matrix** — either in the conductor you identified as the return path, or along outside balloon, value (Dirichlet) or odd symmetry boundaries. No current flows in any other conductor.

For an n-conductor system, *n* field simulations are automatically performed. The energy stored in the magnetic field that couples two conductors is:

$$W_{ij} = \frac{1}{2} L I^2 = \frac{1}{2} \int_{\Omega} B_i \bullet H_j d\Omega$$

where:

- *Wij* is the energy stored in the magnetic field linking conductor *i* with conductor *j*.
- *I* is the current in conductor *i*.
- *Bi* is the magnetic flux density where one ampere is allowed to flow through conductor *i*.
- *Hj* is the magnetic field where one ampere is allowed to flow through conductor *j*.

The inductance coupling conductors *i* and *j* is therefore:

$$L_{ij} = \frac{2 W_{ij}}{I^2} = \int_{\Omega} B_i \bullet H_j d\Omega$$

For multiturn conductors, the net value of inductance is the value given by:

$$L_{net} = N^2 L_{matrix}$$

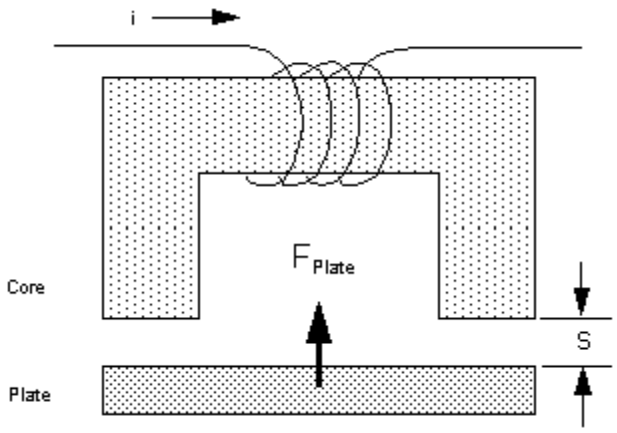
where *N* is the number of turns in the coil.

Virtual Forces (Magnetostatic)

To compute the force on an object, the system uses the principle of virtual work. In the structure shown below, the force on the plate in the direction of the displacement, *s*, is given by the following relationship:

$$\boldsymbol{F}_{plate} = \left. \frac{dW(s,i)}{ds} \right|_{i = const} = \frac{\partial}{\partial s} \left[\int_V \left(\int_0^H \boldsymbol{B} \bullet d\boldsymbol{H} \right) dV \right]$$

where W(s,i) is the magnetic coenergy of the system. The current, i, is held constant.



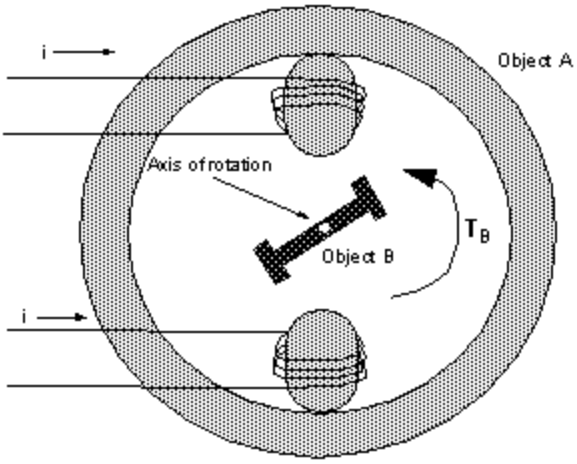
Unlike the classical virtual work method, the plate is not actually moved during the force computation. Instead, only the triangles that lie along the outside surface of the object are virtually distorted. Thus, the force computation only requires one field solution.

Virtual Torques (Magnetostatic)

Similar to the virtual force calculation, the system uses virtual work principles to compute the torque on an object. In the structure shown below, the torque on Object B about the axis of rotation is given by the following relationship:

$$T_B = \left.\frac{dW(\theta, i)}{d\theta}\right|_{i = const} = \frac{\partial}{\partial\theta}\left[\int_V \left(\int_0^H \boldsymbol{B} \bullet d\boldsymbol{H}\right) dV\right]$$

where W(θ, i) is the magnetic coenergy of the system. The current, i, is held constant.



Unlike the classical virtual work method, Object B is not actually rotated during the torque computation. Instead, only the triangles that lie along the outside surface of the object are virtually distorted. Thus, the change in the system's coenergy (and therefore the virtual torque) is given by the change in the coenergy of these triangles.

Flux Linkage (Magnetostatic)

To compute the magnetic flux linkage, the magnetostatic field solver uses the following relationship:

$$\Psi_i = L_{ii} I_i + \left(\sum_{j=1}^{n} L_{ij} I_j \right) + \Psi_m$$

where:

$L_{ii} I_i$ defines the flux linkage due to self-inductance in a coil,

$\sum_{j=1}^{n} L_{ij} I_j$ is the flux linkage due to mutual inductance between coils (i ≠ j), and

Ψ_m is the permanent magnetic flux linkage .

The energy method is used to calculate the inductance of a winding, which is then multiplied by the current flowing in the winding to get the flux linkage.

To obtain a correct flux vector, all current-carrying coils must be made part of the L-matrix computation. If you leave out L-entries that belong to current-carrying coils, the fluxes will be incorrect. (Refer to *Inductance in Terms of Flux Linkage and Currents* for additional information.)

Note	Maxwell no longer uses the following computation algorithm:

	$\psi = \int \boldsymbol{B} \bullet d\boldsymbol{A}$

Eddy Current Theory

Time-varying currents flowing in a conductor produce a time-varying magnetic field in planes perpendicular to the conductor. In turn, this magnetic field induces eddy currents in the source conductor and in any other conductor parallel to it. The eddy current field solver calculates the eddy currents by solving for **A** and ϕ in the field equation:

$$\nabla \times \frac{1}{\mu}(\nabla \times \boldsymbol{A}) = (\sigma + j\omega\varepsilon)(-j\omega\boldsymbol{A} - \nabla\phi)$$

where:

- *A* is the magnetic vector potential.
- ϕ is the electric scalar potential.
- μ is the absolute magnetic permeability.
- ω is the angular frequency at which all quantities are oscillating.

- σ is the conductivity.
- ε is the absolute permittivity.

Note	The eddy current equation is derived from Maxwell's equations. Phasor notation is used to represent complex quantities.

A plot of flux lines produced by eddy currents that were computed in a structure by the eddy current solver is shown below:

Components of Current Density

Notice that the right side of the equation:

$$\nabla \times \frac{1}{\mu}(\nabla \times \boldsymbol{A}) = (\sigma + j\omega\varepsilon)(-j\omega\boldsymbol{A} - \nabla\phi)$$

$(-j\omega \boldsymbol{A} - \nabla\phi)$

consists of a complex conductivity multiplied by the complex value of **E** . It is therefore equal to the complex current density, **J**, which has three components:

- $-\sigma\nabla\phi$
  $\mathbf{J_s}$, the source current density due to differences in electric potential, .
- $\mathbf{J}_e$, the induced eddy current density due to time-varying magnetic fields, - $j\omega\sigma\mathbf{A}$.
- $j\omega\varepsilon(-j\omega \boldsymbol{A} - \nabla\phi)$
  $\mathbf{J}_d$, the displacement current density (time-varying electric fields), .

The total current density is the sum of these three components. The $j\omega$ term in the eddy and displacement components indicate that they are a function of frequency and become increasingly significant as the frequency increases.

Integrating the Current Density

When setting up a problem, you specify the total current flowing in any conductor that is connected to an external source. Therefore, the eddy current module is able to make use of a second equation:

$$I_T = \int_\Omega (\sigma + j\omega\varepsilon)(-j\omega \boldsymbol{A} - \nabla\phi) d\Omega$$

which simply reflects the fact the total current in a conductor equals the integral of the current density over the cross-section of the conductor, Ω.

Eddy Current Assumptions

The eddy current field solver makes the following assumptions about the field quantities for which it solves:

- Time-varying electromagnetic quantities are assumed to have the periodic waveform:

$$\boldsymbol{F}(t) = F_m \cos(\omega t + \theta)$$

- All quantities must have the same frequency (angular frequency), but can have different phase angles (θ). If a current is not a pure sinusoid, decompose it into sinusoidal harmonics, and solve separately at each frequency, but only for linear problems.
- All currents (source, eddy, and displacement) are assumed to flow perpendicular to the plane being studied (that is, in the z-direction for XY applications). Therefore, the magnetic

fields associated with these currents lie within the xy-plane. As a result, **A**, the magnetic vector potential, has a z-component only.

- Because no currents flow in the xy-plane, the electric field, **E**, has a z-component only. It follows that ϕ is constant over the cross-section of each conductor in the problem.

Deriving the Eddy Current Equation

The eddy current field solver uses the finite element method to compute **A** and ϕ using these two relationships:

$$\nabla \times \frac{1}{\mu}(\nabla \times \boldsymbol{A}) = (\sigma + j\omega\varepsilon)(-j\omega\boldsymbol{A} - \nabla\phi)$$

$$I_T = \int_{\Omega} (\sigma + j\omega\varepsilon)(-j\omega\boldsymbol{A} - \nabla\phi)d\Omega$$

where:

- A is the magnetic vector potential.
- ϕ is the electric scalar potential.
- μ is the magnetic permeability.
- ω is the angular frequency at which all quantities are oscillating.
- σ is the conductivity.
- ε is the permittivity.
- I_T is the total current flowing in conductors.

The following section shows how these equations are derived from Maxwell's equations.

Maxwell's Equations

The eddy current field simulator solves for time harmonic electromagnetic fields governed by Maxwell's equations:

$$\nabla \times \boldsymbol{H} = \boldsymbol{J} + \frac{\partial \boldsymbol{D}}{\partial t}$$

$$\nabla \times \boldsymbol{E} = -\frac{\partial \boldsymbol{B}}{\partial t}$$

$$\nabla \bullet \boldsymbol{D} = \rho$$

$$\nabla \bullet \boldsymbol{B} = 0$$

where:

- $\boldsymbol{E}$ is the electric field.
- $\boldsymbol{D}$ is the electric displacement, $\varepsilon \boldsymbol{E}$.
- $\boldsymbol{B}$ is the magnetic flux density.
- $\boldsymbol{H}$ is the magnetic field intensity, $\mathbf{B}/\mu$.
- $\boldsymbol{J}$ is the conduction current density, $\sigma \boldsymbol{E}$.
- ρ is the charge density.

The eddy current solver assumes that all time-varying electromagnetic quantities in the problem have the form:

$$\boldsymbol{F}(t) = F_m \cos(\omega t + \theta)$$

Using Euler's formula:

$$e^{j\alpha} = \cos\alpha + j\sin\alpha$$

If $\alpha = \omega t + \theta$, $\mathbf{F}(t)$ equals the real portion of $e^{j(\omega t+\theta)}$:

$$\boldsymbol{F}(t) = \Re\left[F_m e^{j(\omega t+\theta)}\right] = \Re[F_m(\cos(\omega t+\theta) + j\sin(\omega t+\theta))] = F_m \cos(\omega t+\theta)$$

Now, because each time-varying quantity has the form $F_m e^{j\theta} e^{j\omega t}$, $\frac{\partial \boldsymbol{D}}{\partial t}$ and $\frac{\partial \boldsymbol{B}}{\partial t}$ are equal to $j\omega\mathbf{D}$ and $j\omega\mathbf{B}$.

Therefore, with this simplification and the relations $\mathbf{H}=\mu\mathbf{B}$, $\mathbf{D}=\varepsilon\mathbf{E}$, and $\mathbf{J}=\sigma\mathbf{E}$, Maxwell's equations reduce to:

$$\nabla\times\frac{1}{\mu}\boldsymbol{B} = (\sigma\boldsymbol{E} + j\omega\varepsilon\boldsymbol{E})$$

$$\nabla\times\boldsymbol{E} = -j\omega\boldsymbol{B}$$

$$\nabla\bullet\varepsilon\boldsymbol{E} = \rho$$

$$\nabla\bullet\boldsymbol{B} = 0$$

Relationship of Magnetic and Electric Field

The quantity that the eddy current field simulator actually solves for is **A**, the magnetic vector potential. It is given by:

$$\nabla\times\boldsymbol{A} = \boldsymbol{B}$$

Substituting this into the first of Maxwell's equations, the result is:

$$\nabla\times\frac{1}{\mu}(\nabla\times\boldsymbol{A}) = (\sigma\boldsymbol{E} + j\omega\varepsilon\boldsymbol{E})$$

A solution for **E** in terms of **A** is given by:

$$\boldsymbol{E} = -j\omega\boldsymbol{A} - \nabla\phi$$

where ϕ is the electric potential. Substituting the right side of this relationship for **E** into the previous equation results in:

$$\nabla\times\frac{1}{\mu}(\nabla\times\boldsymbol{A}) = (-j\omega\boldsymbol{A} - \nabla\phi)(\sigma + j\omega\varepsilon)$$

This equation is one of the two used by the eddy current solver to compute **A** and ϕ.

Relationship of Current and Current Density

Notice that the previous equation is in the form of a complex conductivity, $(\sigma+j\omega\varepsilon)$, times the complex value of **E**. The result is the complex current density, **J**. Therefore, the integral of this expression over the cross-section of a conductor is constrained to equal the total current that is specified as flowing in that conductor:

$$I_t = \int_\Omega \boldsymbol{J}d\Omega = \int_\omega \frac{1}{\mu}(\sigma + j\omega\varepsilon)(-j\omega\boldsymbol{A} - \nabla\phi)d\omega$$

This is the second equation that the eddy current solver uses in computing **A** and ϕ.

The total current, *It*, in this equation is the quantity you specify when setting up a problem. It is the total current flowing in a conductor, and includes:

- $-\int_\Omega \sigma\nabla\phi d\Omega$

  I_s, the current from an external source, .

- $-\int_\Omega j\omega\sigma\boldsymbol{A}d\Omega$

  I_e, the induced eddy current, .

- $\int_\Omega j\omega\varepsilon(-j\omega\boldsymbol{A} - \nabla\phi)d\Omega$

  I_d, the displacement current, .

For problems solved by the eddy current solver, **B** is assumed to lie in the xy plane. Therefore, **A** can only have a component in the z-direction. The simulator does not have to solve for the x and y components of **A**. Since **E** only has a z-component, ϕ is a constant for each cross-section of a conductor. Therefore, Maxwell does not have to solve for ϕ at every node.

For a more detailed discussion of eddy current and skin effect problems in multiconductor systems, see:

J. Weiss, Z. Cendes. "A One-Step Finite Element Method for Multiconductor Skin Effect Problems", *IEEE Transactions on Power Apparatus and Systems*, Vol. PAS-101, No. 10 October 1982.

Eddy Currents and Skin Depth

Induced currents allow magnetic fields to penetrate conductors only to a certain depth, which is approximated by the formula:

$$\delta = \sqrt{\frac{2}{\omega \sigma \mu_0 \mu_r}} \quad \text{(in meters)}$$

where:

- ω is the angular frequency, which is equal to $2\pi f$. (f is the frequency at which source currents and voltages oscillate during the solution.)
- σ is the conductor's conductivity, in siemens/meter.
- μ_r is the conductor's relative permeability, in amperes/meter.
- μ_0 is the permeability of free space, which is equal to $4\pi \times 10^{-7}$ A/m.

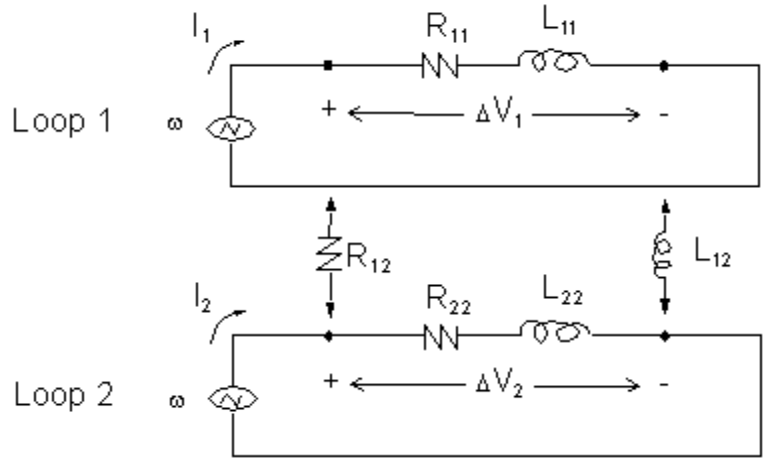
Currents will be concentrated near the surface of the conductor, decaying rapidly past the skin depth. As the formula above indicates, the skin depth gets smaller as the frequency increases.

Impedance Matrix

An impedance matrix summarizes the relationship between AC voltages and AC currents in multi-conductor systems. Given the two current loops below, the relationships between voltages and currents in each loop is as follows:

$$(\Delta V_1 = I_1 R_{11} + I_2 R_{12} + I_1 j\omega L_{11} + I_2 j\omega L_{12}) Size$$

$$\Delta V_2 = I_2 R_{22} + I_1 R_{12} + I_2 j\omega L_{22} + I_1 j\omega L_{12}$$



This can be expressed in matrix form as:

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \end{bmatrix} = \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{12} & Z_{22} \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \end{bmatrix}$$

where:

- *Vi* and *Ii* are phasors.
- *Z11* = $R_{11} + j\omega L_{11}$ (the self-impedance of Loop 1).
- *Z12* = $R_{12} + j\omega L_{12}$ (the mutual impedance between Loops 1 and 2).
- *Z22* = $R_{22} + j\omega L_{22}$ (the self-impedance of Loop 2).

The impedance matrix above gives the relationship between V and I for the two current loops. In a device with *n* current loops, this relationship would be expressed by an *n* x *n* impedance matrix. The matrix values displayed by the software are resistance and inductance (not resistance and reactance) and therefore do not include jω.

Note	All impedances are complex numbers in the form: $$Z = R + j\omega L$$ where:

	• ω is equal to $2\pi f$, where f is the frequency of the AC current source. • R is the AC resistance, given in ohms/meter (XY) or ohms (RZ). • L is the AC inductance, given in henries/meter (XY) or henries (RZ).

Computing an Impedance Matrix

Maxwell breaks down the impedance matrix computation into two parts. First, it solves for the inductance matrix (L-matrix) associated with the model. It then solves for the resistance matrix (R-matrix). When it finishes solving for these matrices, the simulator combines them to form the impedance matrix, using the relationship $Z=R+j\omega L$.

To compute the inductance and resistance matrices for the impedance solution, the simulator generates an eddy-current field solution for each conductor in the matrix.

In the first solution, the current in the first conductor is set to one ampere; currents in the other conductors that are included in the impedance matrix are set to zero. This is done by imposing current sources on the conductors.

In the second solution, the current in the second conductor is set to one ampere, and all other conductors that are included in the impedance matrix are set to zero amperes, and so forth. Conductors that are not included in the impedance matrix are not affected.

"Matrix Inductance " below
"Matrix Resistance " on page 28-31
"Inductance and Resistance in Impedance Computations " on page 28-31

Matrix Inductance

To compute the inductance of the current loop, the simulator calculates the average energy, W_{AV}, of the system after a field solution is computed:

$$W_{AV} = \frac{1}{4}\int_V \boldsymbol{B} \bullet \boldsymbol{H}^* dV$$

Since the instantaneous energy of the system is equal to:

$$W_{Inst} = \frac{1}{2} L i^2$$

where the instantaneous value of the current is related to the peak value of the current by $i = I_{Peak}\cos(\omega t+\theta)$. The average value for the energy can then be found by integrating the instantaneous energy:

$$W_{AV} = \frac{1}{2\pi}\int_0^{2\pi} W_{Inst} d\omega t = \left(\frac{L}{2}\right)\left(\frac{1}{2\pi}\right)\int_0^{2\pi} I_{Peak}^2 [\cos(\omega t + \theta)]^2 d\omega t$$

From this, the average energy of the system is equal to:

$$W_{AV} = \left(\frac{L}{2}\right) I_{RMS}^2 = \left(\frac{L}{2}\right)\left(\frac{I_{Peak}}{\sqrt{2}}\right)^2 = \left(\frac{L}{4}\right) I_{Peak}^2$$

The inductance, therefore is:

$$L = \frac{4W_{AV}}{I_{Peak}^2}$$

The software assumes that the object for which impedance is being computed has a peak current of one ampere per coil turn flowing through it. Thus, the inductance is simply $4W_{AV}$.

The eddy current simulator includes the eddy effect in conductors when it computes inductance during an impedance solution.

Matrix Resistance

To compute the resistance, the simulator calculates the ohmic loss, P, after a field solution has been computed:

$$P = \frac{1}{2\sigma}\int_V \boldsymbol{J} \bullet \boldsymbol{J}^* dV$$

The ohmic loss is related to the resistance by:

$$P = RI_{RMS}^2$$

The resistance is therefore:

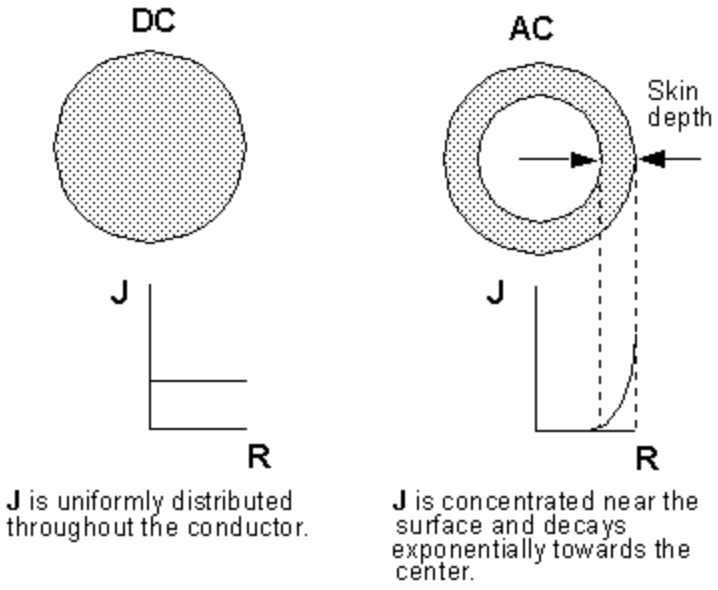
$$R = \frac{P}{I_{RMS}^2} = \frac{2P}{I_{Peak}^2}$$

The system assumes that the object for which impedance is being computed has a peak current of one ampere per coil turn flowing through it. Therefore, the resistance is simply 2P.

Note that the resistance for an eddy current problem will be higher than the equivalent DC resistance, due to the skin concentration of currents.

Inductance and Resistance in Impedance Computations

The inductances and resistances computed during an impedance matrix solution are different from those computed for the equivalent DC case. This figure shows how they differ:



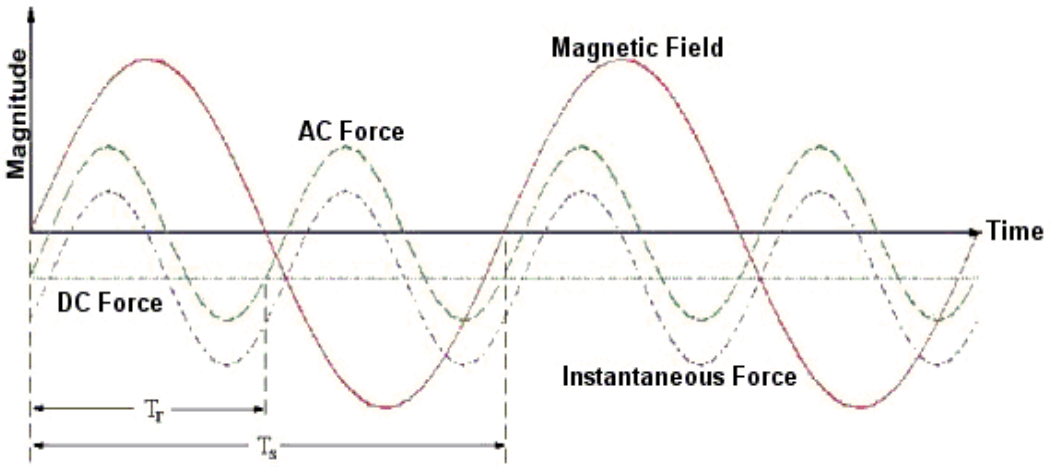
The current density, **J**, in the DC case (the conductor on the left) is evenly distributed throughout the cross-section of the conductor. The current density in the AC case (the conductor on the right) is distributed non-uniformly on the surface due to skin effect. Since the area through which current can flow is smaller, it follows that the resistance to the current flow is higher in the impedance matrix than in a resistance matrix computed for the equivalent DC case.

In the DC example, no eddy currents occur. The magnetic field created by the current flowing through the conductor is static. In the AC example, the oscillating magnetic field induces currents in conductors in the model. These induced currents affect the computation of inductance for the impedance matrix, causing it to be different from the equivalent DC computation of inductance.

Virtual Forces (Eddy Current)

Virtual force in an eddy current problem is computed the same way as virtual force in a magnetostatic problem. The only difference is that the average value of force over time is computed — not the instantaneous force at a given time.

The difference between the time-averaged (or DC) force, AC force, and instantaneous force is shown below:



Force oscillates at twice the frequency of the source current and magnetic field:

$$f_F = \frac{1}{T_F} = 2f_S$$

where:

- f_F is the frequency of the force.
- f_S is the frequency of the source current and magnetic field.
- T_F is the period of the force.

The time-averaged (or DC) force, AC force, and instantaneous force can be determined by:

$$F_{DC} = \frac{1}{2}\int Re\left|\bar{J} \times \bar{B}^{*}\right| dV$$

$$F_{AC} = \frac{1}{2}\int Re\left|\bar{J} \times \bar{B}\right| dV$$

$$F_{INST} = F_{DC} + F_{AC}$$

The AC force, F_{AC} must be evaluated at a particular phase (=ωt) in order to determine its magnitude at an instant in time. However, the peak value of the AC force is reported as the “AC Magnitude” in the force and torque solution panel for Maxwell 2D.

Virtual Torques (Eddy Current)

Virtual torque in an eddy current problem is computed the same way as virtual torque in a magnetostatic problem. The only difference is that the average value of the torque over time is computed, not the net torque at a given time.

Current Flow (Eddy Current)

To compute the current flow, the eddy current field solver uses the following relationship:

$$I = \int \boldsymbol{J} \bullet d\boldsymbol{A}$$

where:

- *I* is the current.
- ***J*** is the current density, given by:

$$\boldsymbol{J} = (\sigma + j\omega\varepsilon_r)(-j\omega\boldsymbol{A} - \nabla\phi)$$

- *A* is the area over which the current flow is computed.
  - In cartesian (XY) models, the area is found by sweeping the current flow line you’ve drawn in the xy-plane into the z direction — forming a 3D surface. The current flow computed is the current per meter depth in the z-direction.
  - In axisymmetric (RZ) models, the area is found by revolving the flux line you’ve drawn in the rz-plane 360 degrees around the z-axis, forming a 3D surface. The current flow computed is the total current that passes through this surface.

A separate current flow value is computed for each line you draw.

Nonlinear Eddy Current Field Simulation

Note	Applicable to both Maxwell 2D and 3D Eddy current solvers.

The Maxwell 2D and 3D Eddy current solvers, for designs with nonlinear materials, allow you to analyze the fundamental components of B and H at a specified frequency.

Related Topics

"Nonlinear Eddy Current Theory " below

"Sinusoidal B " below

Nonlinear Eddy Current Theory

Note	Applicable to both Maxwell 2D and 3D Eddy current solvers.

Unlike linear problems in which the field solution is assumed to be based on the sinusoidal complex peak field values in a steady state, nonlinear problems are usually based on all harmonic components of the fields.

That is to say for nonlinear problems, though the current is sinusoidal at its input, the resulting fields are “harmonically rich.” Although the B- and H-fields are not sinusoidal at output, the Maxwell 2D and 3D non-linear Eddy current solvers use equivalent fundamental components of B and H to approximate non-linear field behavior associated with the assigned non-linear BH characteristic.

Related Topics

"Sinusoidal B " below

Sinusoidal B

Note	Applicable to both Maxwell 2D and 3D Eddy current solvers.

Assuming both that **B** is sinusoidal with time, **t**, and that the value of **H** is derived from the original BH-curve, introduce a new value $\mathbf{H_e}$ to represent the effective magnetic field.

The derivation of the effective H_e is based on the equivalence of averaged energy between using original, non-sinusoidal H field and the effective sinusoidal field $H_e\sin(\omega t)$. That is:

$$\frac{4}{T}\int_0^{\frac{T}{4}} H_e \sin(\omega t) B_m \sin(\omega t) dt = \frac{4}{T}\int_0^{\frac{T}{4}} (H \cdot B) dt$$

with:

$$T = \frac{2\pi}{\omega}$$

the above expression becomes:

$$\int_0^{\frac{\pi}{2}} H_e B_m \sin^2(\omega t)\ d\omega t = \int_0^{\frac{\pi}{2}} (H \cdot B) d\omega$$

Allowing $\alpha=\omega t$ and extracting $\mathbf{H_e}$, simplifying yields:

$$H_e B_m \int_0^{\frac{\pi}{2}} \left(\frac{1 - \cos 2\alpha}{2}\right) d\alpha = \int_0^{\frac{\pi}{2}} (H \cdot B) d\alpha$$

or:

$$H_e = \frac{4}{\pi} \int_0^{\frac{\pi}{2}} \frac{(H \cdot B)}{B_m} d\alpha$$

where:

- *Bm* corresponds to the last point on the original BH characteristic (in the saturation portion) and which is made equal with $\pi/2$.

The above equation is used to derive an effective (B_m, H_e) characteristic for the frequency domain simulation. This process is required to be performed only once for a particular BH curve. During the simulation, H_e is determined for a specific B_m such that an equivalent permeability can be computed as the ratio B_m / H_e and used in the calculations.

DC Conduction Field Simulation

The DC conduction field simulator allows you to analyze conduction currents due to static electric fields in conductors and lossy dielectrics.

DC Conduction Theory

When a material with a non-zero conductivity is subject to a potential difference, conduction current flows in the material. At all points in the problem space, the current density (**J**) will be proportional to the electric field (**E**) that is established due to the potential difference.

$$\boldsymbol{J}(x,y) = \sigma \boldsymbol{E}(x,y) = -\sigma \nabla \phi(x,y)$$

where:

- *J(x,y)* is the current density.
- *E(x,y)* is the electric field.
- σ is the conductivity of the material in MKS units (S/m).
- ϕ*(x,y)* is the electric potential.

The equation that the DC conduction field simulator solves is based on the fact that, under steady state conditions, the amount of charge, ρ, leaving any infinitesimally small region must equal the charge flowing into that region.

$$\nabla \bullet \boldsymbol{J} = -\frac{\partial \rho}{\partial t} = 0$$

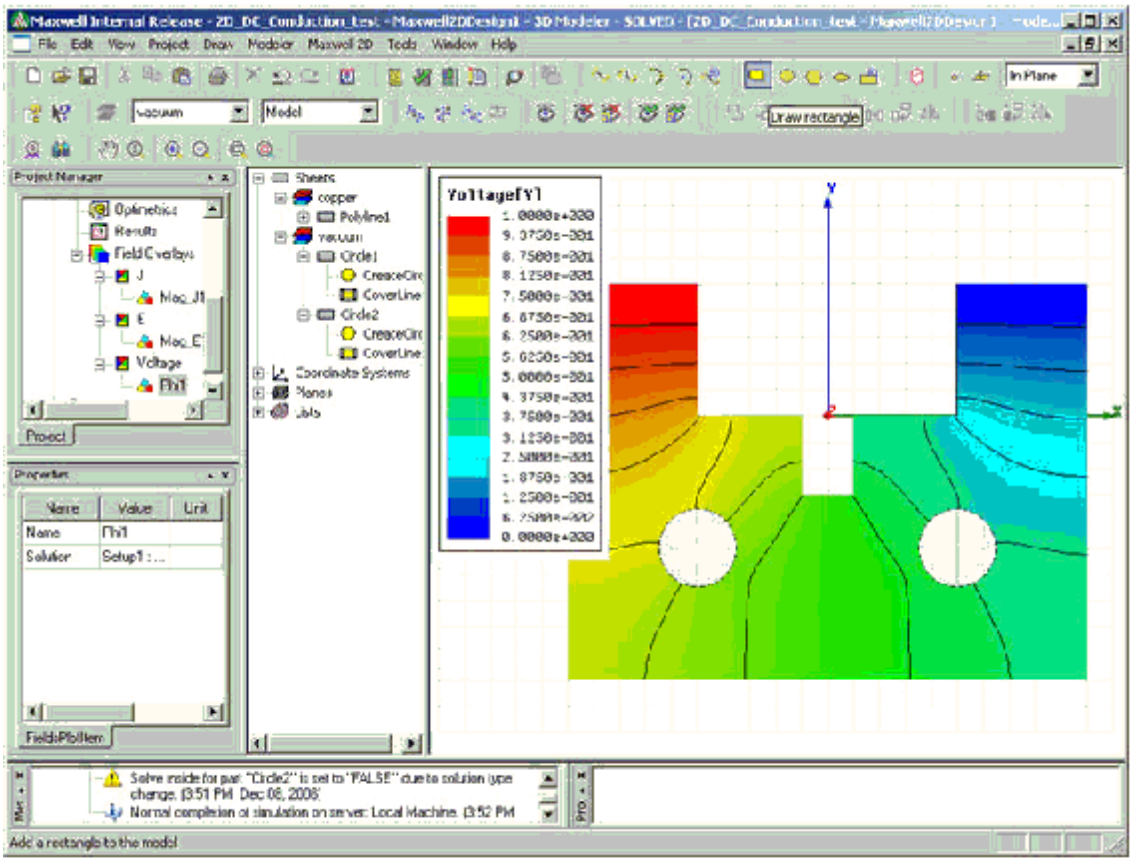
The field quantity that DC conduction actually solves for is the electric potential, ϕ, in the following equation:

$$\nabla \bullet (\sigma \nabla \phi) = 0$$

$$-\sigma \nabla \phi = \boldsymbol{J}$$

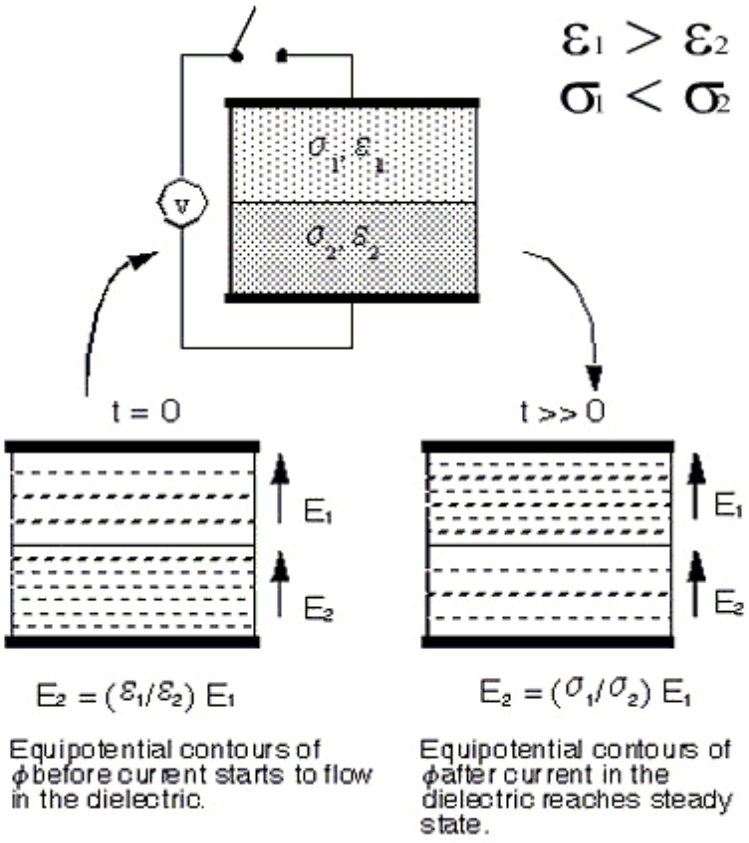
Note that .

A plot of electric potential that was computed by the DC conduction solver is shown below:



Steady-state Conditions

The DC conduction solver assumes that current flow in the conducting material has already reached steady state conditions. The implication of this assumption becomes clear when you compare the initial and steady state conditions of a simple problem such as that shown here:



First, consider the interval before steady state is reached. Assume that the switch establishing the potential across the parallel plates in the figure above closes at t=0. Also assume that the current required to deposit charges on the parallel plates (so that the voltage difference can be supported) occurs instantaneously.

However, it will take a while for current to start flowing in the dielectric. The time it takes for current to flow is determined by the time constant of the material. Therefore, at t=0, there will be an electric field in the dielectric, but no current and no free charges. Consequently, the relationship that must be satisfied at the interface of the two dielectrics is:

$$\nabla \bullet \boldsymbol{D} = \rho$$

or, equivalently:

$$\nabla \bullet \varepsilon \boldsymbol{E} = \rho$$

At the interface between the two dielectrics, this relationship implies that:

$$\varepsilon_1 \boldsymbol{E}_{n1} = \varepsilon_2 \boldsymbol{E}_{n2} \Rightarrow \boldsymbol{E}_{n1} = \frac{\varepsilon_2}{\varepsilon_1} \boldsymbol{E}_{n2}$$

where $\mathbf{E}_n$ is the normal component of **E**. Therefore, at t=0, before current starts to flow in the two dielectrics, $\phi(x,y)$ is determined entirely by the permittivity of the dielectrics. Use the electrostatic field solver to solve for $\phi(x,y)$ in such a case.

After current starts to flow in the dielectric and steady state is reached, free charges are able to accumulate at the boundaries of the two dielectrics. The free charge, ρ, is no longer zero.

$$\nabla \bullet \boldsymbol{J} = -\frac{\partial \rho}{\partial t} = 0$$

The relationship that must be satisfied now is:

$$\nabla \bullet \sigma \boldsymbol{E} = 0$$

or, equivalently,

This relationship implies that:

$$\sigma_1 \boldsymbol{E}_{n1} = \sigma_2 \boldsymbol{E}_{n2} \Rightarrow \boldsymbol{E}_{n1} = \frac{\sigma_2}{\sigma_1} \boldsymbol{E}_{n2}$$

In this case, the solution depends on the conductivity (σ) of the materials rather than on their dielectric constant (ε). The DC conduction solver analyzes the steady state condition. Therefore, use the DC conduction field solver when steady state conditions have been reached.

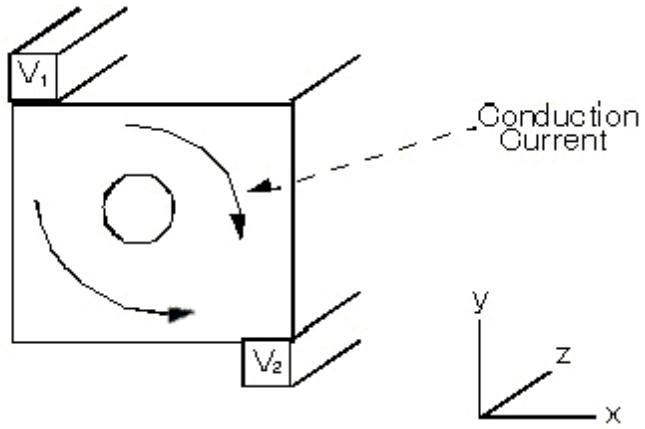
Relevant Time Constant

The time constant that determines how long it will take the current flowing in the conductive material to reach steady state is given by $\tau=\varepsilon/\sigma$. In a good conductor such as steel ($\varepsilon=9\text{x}10^{-12}$, $\sigma=1\text{x}10^{7}$), $\tau = 9\text{x}10^{-19}$ seconds. Steady state conditions are reached almost instantaneously and in such cases you should use the DC conduction solver to analyze the potential field.

On the other hand, for a good dielectric such as fused quartz ($\sigma=1\text{x}10^{-17}$), the time constant is on the order of 10^5 seconds. There will be a significant period before steady state currents start to flow and you should use the electrostatic solver to analyze the electric field. For many materials in between, a complete analysis may require an electric transient field solution.

Conductance

A conductance matrix gives the relationship between currents and voltage drops. In the following figure, two conductors at voltages V_1 and V_2 are touching a bar with a conductance, G.



Because the bar is not a perfect insulator, current will flow between the two conductors. Given the conductors shown on the previous page, the relationship between the conduction current and the voltage drop, V, in each conductor is:

$$I = GV$$

where:

- *I* is the conduction current.
- *G* is the conductance, measured in Siemens.
- *V* is the voltage drop given by V_1-V_2.

Conductance, as evident from the equation, is the inverse of resistance. Therefore, if a material has a large conductance, it will be a better conductor, and if it has a low conductance, it will be a better resistor.

Current Flow (DC Conduction)

To compute current flow, the DC conduction field solver uses the following relationship:

$$I = \int_A \boldsymbol{J} \bullet d\boldsymbol{A}$$

where:

- *I* is the current.
- *J* is the current density, given by:

$$\boldsymbol{J} = \sigma \boldsymbol{E} = -\sigma \nabla \phi$$

- *A* is the area over which the current flow is computed.
  - In cartesian (XY) models, the area is found by sweeping the current flow line you've drawn in the xy-plane into the z direction — forming a 3D surface. The current flow computed is the current per meter depth in the z direction.
  - In axisymmetric (RZ) models, the area is found by revolving the flux line you've drawn in the rz-plane 360 degrees around the z-axis, forming a 3D surface. The current flow computed is the total current that passes through this surface.

A separate current flow value can be computed for each line you draw.

AC Conduction Field Simulation

The AC conduction field solver allows you to analyze conduction currents caused by time-varying electric fields in conductors and lossy dielectrics.

AC Conduction Theory

The AC conduction field simulator solves for ϕ in the following equation:

$$\nabla \bullet [\sigma \boldsymbol{E} + j\omega\varepsilon \nabla \phi(x, y)] = 0$$

where:

- $\phi(x,y)$ is the magnitude and phase of the electric potential at each value of x and y.
- ω is the angular frequency at which the potential is oscillating.
- σ is the conductivity.
- ε is the permittivity.

The above equation is derived from:

$$\nabla \bullet (\boldsymbol{J} + j\omega \boldsymbol{D}) = 0$$

where:

- *J* is the current density, σ**E**.
- *D* is the electric flux density, ε**E**.
- *E* is the electric field, -∇ϕ.

Complex quantities are represented using phasor notation.

AC Conduction Assumptions

The AC conduction field solver assumes the following conditions about field quantities:

- All time-varying electromagnetic quantities have the periodic waveform:

$$\boldsymbol{F}(t) = F_m \cos(\omega t + \theta)$$

  where all quantities must have the same value of ω, but can have different phase angles (θ).
- If a current is not a pure sinusoid, it is decomposed into sinusoidal harmonics, and solved separately at each frequency.
- The component of **E** due to time-varying magnetic fields caused by conduction currents can be neglected.

Admittance

Admittance can best be explained as the inverse of impedance, and is expressed by:

$$Y = G + j\omega C$$

where:

- ω is equal to $2\pi f$, where *f* is the frequency of the AC voltage source.
- *Y* is the admittance in Siemens/meter.
- *G* is the conductance in Siemens/meter.
- ωC is the susceptance in Siemens/meter.

Note	The matrix values displayed by the software are conductance in ohms/meter and capacitance in farads/meter (not conductance and susceptance) and therefore do not include jω.

Current Flow

To compute current flow, the AC conduction field solver uses the following relationship:

$$I = \int_A \boldsymbol{J} \bullet d\boldsymbol{A}$$

where:

- *I* is the current.
- *J* is the current density, given by **J** = σ**E**.
- *A* is the area over which the current flow is computed. It is found by sweeping the current flow line you've drawn in the xy-plane into the z direction, forming a surface. The current flow computed is the current per meter depth in the z direction.

A separate current flow value can be computed for each line you draw.

Axisymmetric Field Simulation

If you selected **Cylindrical About Z** as the geometry mode when setting the solution type, a special version of the selected field solver is used. It assumes that the 2D geometry being studied sweeps 360° around the z-axis of a cylindrical coordinate system, enabling you to model devices like solenoids and insulators that have an axis of rotational symmetry. All electric or magnetic fields in the problem must also be rotationally symmetric so that the solution in any RZ-plane is the same as any other.

Note	All cylindrical about Z models must be drawn in the XZ plane with X >= 0

Axisymmetric field simulation is available for the following solvers:

- Electrostatic
- Magnetostatic
- Eddy Current
- DC Conduction
- AC Conduction
- Transient with and without motion

Any field solution involving a long plank-shaped object is different from a solution involving an annular object — even though the same equation is solved for both types of geometries. Mathematically, the difference between cartesian and axisymmetric field solutions arises from the difference in how gradients, curls and divergences are expressed in the two coordinate systems.

- In a cartesian (xyz) coordinate system, these operators are defined as follows (where F is a scalar quantity and **F** is a vector quantity):

$$\nabla F(x,y,z) = \frac{\partial F}{\partial x}\hat{x} + \frac{\partial F}{\partial y}\hat{y} + \frac{\partial F}{\partial z}\hat{z}$$

$$\nabla \bullet \boldsymbol{F}(x,y,z) = \frac{\partial F_x}{\partial x} + \frac{\partial F_y}{\partial y} + \frac{\partial F_z}{\partial z}$$

$$\nabla \times \boldsymbol{F} = \begin{bmatrix} \hat{\boldsymbol{x}} & \hat{\boldsymbol{y}} & \hat{\boldsymbol{z}} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ F_x & F_y & F_z \end{bmatrix}$$

If **F** has a z-component only, the curl is defined as:

$$\nabla \times \boldsymbol{F} = \frac{\partial F_z}{\partial y}\hat{x} - \frac{\partial F_z}{\partial x}\hat{y}$$

- In a cylindrical (r, ϕ, z) coordinate system, these operators are defined as:

$$\nabla F(r,\phi,z) = \frac{\partial F}{\partial r}\hat{r} + \left(\frac{1}{r}\right)\frac{\partial F}{\partial \phi}\hat{\phi} + \frac{\partial F}{\partial z}\hat{z}$$

$$\nabla \bullet \boldsymbol{F}(r,\phi,z) = \left(\frac{1}{r}\right)\frac{\partial (r F_r)}{\partial r} + \left(\frac{1}{r}\right)\frac{\partial F}{\partial \phi}\phi + \frac{\partial F}{\partial z}z$$

$$\nabla \times \boldsymbol{F} = \begin{bmatrix} \hat{\boldsymbol{r}} & r\hat{\boldsymbol{\phi}} & \hat{\boldsymbol{z}} \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial \phi} & \frac{\partial}{\partial z} \\ F_r & rF_\phi & F_z \end{bmatrix}$$

If **F** has a ϕ-component only, the curl is defined as:

$$\nabla \times \boldsymbol{F} = \left(\frac{1}{r}\right)\left[-\frac{\partial(rF_\phi)}{\partial z}\hat{\boldsymbol{r}} + \frac{\partial(rF_\phi)}{\partial r}\hat{\boldsymbol{z}}\right]$$

In the cylindrical case, an extra *r* shows up in places where there is no analogous *x* in the cartesian case, resulting in a different field solution. The calculations involving the differences in mathematics between axisymmetric and cartesian models are implicitly handled by the Maxwell and are transparent to you.

Transient Simulation

Transient Solver only.

The transient solver allows you to analyze the magnetic fields, energy, force/torque, power loss, core loss, speed, and flux of a model at various time steps of a solution over a specified period of time. This solver allows for non-sinusoidal current or voltage excitation, as well as rotational or translational motion.

Transient Simulation Assumptions

The transient solver assumes the following conditions about the problem:

- If motion occurs in the model, no motion occurs outside the band object.
- Rotational motion can be cylindrical or non-cylindrical.
- More than one object can be assigned identical motion within the band object.

Time-Dependent Magnetic Field Simulation

For a 2D XY problem, the vectors have only one component in the z-direction. The time-dependent magnetic equation is expressed as:

$$\nabla \times \upsilon \nabla \times A = J_s - \sigma \frac{\partial A}{\partial t} - \sigma \nabla V + \nabla \times H_c + \sigma V \times \nabla \times A$$

where:

- H_c is the coercivity of the permanent magnet.
- v is the velocity of the moving parts.
- A is the magnetic vector potential.
- V is the electric potential.

υ

- is the reluctivity.
- J_s is the source current density.

The transient solver applies a reference frame that is fixed with respect to the components in the model by setting the velocity, v, equal to zero. This is possible by considering the equation for the magnetic vector potential both in moving part and stationary part in their own reference frame in which velocity is always zero. Because the moving components have now been fixed to their own coordinate system, the partial time derivative becomes the total time derivative of A. Thus, the motion equation becomes:

$$\nabla \times \upsilon \nabla \times A = J_s - \sigma \frac{\mathbf{d}A}{\mathbf{d}t} - \sigma \nabla V + \nabla \times H_c$$

which is obtainable at each time step at every node in the finite element model. In above equation the motion is contained implicitly in the total derivative of A.

Stranded Conductors

Stranded conductors lack eddy current behavior and are considered to be filaments too thin to model in a practical finite element grid. Because of this, the transient solver assumes that their contribution to the current density is averaged over the area of problem region.

These filaments can be connected in parallel or series, and carry the same current based on:

$$\nabla \times \upsilon \nabla \times A = J_s$$

where $\mathbf{j_s}$, the uniformly distributed current density is given by:

$$j_s = d_f \frac{N_f i_f}{S_f \cdot a \cdot p}$$

and:

- i_f is the total terminal current flowing into a filament coil group (or winding).
- N_f is the total conductor number of the filaments in the winding.
- A is the magnetic vector potential.
- a is the number of parallel branches in the winding.
- d_f is the polarity (+1 or -1) to represent forward or return paths.
- S_f is the total area of the cross-section of the region occupied by the winding.
- p is the ratio of the original full model to the field domain to be solved.

Note that the filaments in the winding may reside at several different locations as long as they are connected in series or parallel.

The voltage seen from the terminal of the winding is the sum of the voltage across all the wires as well as any possible external impedance based on:

$$d_f \frac{N_f}{S_f \cdot a} \iint \frac{\mathbf{d}A}{\mathbf{d}t} \cdot d\Omega + R' \cdot i_f + L' \cdot \frac{\mathbf{d}i_f}{\mathbf{d}t} = u_s$$

and:

$$R' = r_{dc} + r_{end} + r_{ext}$$

$$L' = l_{end} + l_{ext}$$

where:

- r_{dc} is the total DC resistance.
- r_{end} is the end-turn resistance of the winding.
- r_{ext} is the external resistance connected to the winding.
- l_{end} *is the end turn inductance of the winding*.
- l_{ext} is the external inductance connected to the winding.
- *l* is the thickness of the model.

Note	Please note that the main component of inductance is calculated by Maxwell; end effects -when they can be evaluated- can however be included in the model to increase the overall accuracy of the simulation.

Solid Conductors

Solid conductors are large enough to model with finite elements, where skin effects depend not only on the frequency of the system, but on the location of nearby conductors.

Based on Ampere's Law, the total current density, $\mathbf{j_t}$, in the system is given by:

$$j_t = -\sigma\frac{dA}{dt} - \sigma\nabla V$$

which reduces to:

$$j_t = -\sigma\frac{dA}{dt} + \frac{\sigma}{l}V_b$$

or:

$$j_t = j_e + j_s$$

where:

- *Vb* is the voltage difference across the conductors end points.
- *Je* is the eddy current density.
- *Js* is the source current density.

Solid Conductors with Current Sources

For solid conductors with a current source, the total current is known, while the source component is unknown. The transient solver computes the current source based on the following circuit

equation for the n^{th} conductor:

$$\int_{\Omega_c}\int\left(-\sigma\frac{\mathbf{d}A}{\mathbf{d}t}+j_{\boldsymbol{s}}\right)d\Omega = \int_{\Omega_C}\int j_{\boldsymbol{t}}d\Omega = I_t$$

where:

- $\Omega_{\mathbf{c}}$ is the width cross-section of the *n*th conductor.
- I_t is the known total current.
- J_s is the source component to be solved for.
- J_t is the total current density.

Solid Conductors with Voltage Sources

For solid conductors with a voltage source, the total voltage is known, while the total current density is unknown. The transient solver computes the unknown quantities based on the following circuit equation which is derived from the solid conductor equations. The resulting equation yields:

$$\int_{\Omega_c}\int\left(\sigma\frac{\mathbf{d}A}{\mathbf{d}t}+j_{\boldsymbol{t}}\right)d\Omega = \int_{\Omega_C}\int\frac{\sigma}{l}V_b\,d\Omega$$

where:

- $\Omega_{\mathbf{c}}$ is the width cross-section of the *n*th conductor.
- V_b is the known voltage source between the two conductors.
- J_t is the total current density to be solved for.
- σ is the conductivity.
- l is the thickness of the model.
- A is the magnetic vector potential.

Translational Motion

The transient motion simulator generates translational motion solutions based on the following motion equation:

$$ma + \lambda v = F_{em} + F_{load}$$

where:

- m is the mass of the object, in kg.
- a is the acceleration of the object, in m/s^2.
- v is the velocity, in m/s.
- F_{em} is the computed electromagnetic force, in N.
- F_{load} is the external load force, in N.
- λ is the damping, in N·s/m.

Rotational Motion

The transient motion simulator generates rotational motion solutions based on the following motion equation:

$$J\beta + \lambda\omega = T_{em} + T_{load}$$

where:

- J is the moment of inertia, in kg·m^2.
- Tem is the computed electromagnetic torque, in N·m.
- T_{load} is the external load torque, in N·m.
- ω is the angular speed, in rad/s.
- β is the angular acceleration, in rad/s^2.
- λ is the damping factor, in N·m·s.

Core Loss for Transient Solvers

Core loss allows the solver to find the total core loss on an object, or group of objects due to the distribution of the electric or magnetic field in the design.

For frequency domain applications:

At a given frequency, the core loss for electrical steel is based on the following expression:

$$p = K_h B_{\max}^2 f + K_c (B_{\max} f)^2 + K_e (B_{\max} f)^{1.5}$$

where:

- K_h is the hysteresis coefficient.
- K_c is the classical eddy coefficient.
- K_e is the excess or anomalous eddy current coefficient due to magnetic domians.
- B_{max} is the maximum amplitude of the flux density.
- f is the frequency.

Similarly, the power ferrite core loss is based on the following expression:

$$p = C_m f^x B_{\max}^y$$

where:

- C_m is a constant value determined by experiment.
- f is the frequency.
- B_{max} is the maximum amplitude of the flux density.

For transient (time domain) applications, the above expressions need to be modified in the following ways:

In the frequency domain, the core loss for power ferrites is given by the above formula, where C_m, x, and y are measured based on sinusoidal $B(t)$ waveform. If $x=1$, $y=2$, and $C_m=K_h$, the formula for power ferrite is that for hysteresis loss. If $x=y=2$, and $C_m=K_c$, it corresponds to classic eddy loss. If $x=y=1.5$, and $C_m=K_e$, it becomes excess loss. Therefore, the formula of power loss for ferrite can be used to describe all individual components for core loss for both electric steel and power ferrite.

Based on the formula for ferrite core loss in the frequency domain, the following expression can be derived to compute core loss in the *time* domain:

$$P_f = C_t |H_{irr}|^{y-x} \left| \frac{dB}{dt} \right|^x$$

where H_{irr} is the irreversible component of the magnetic field strength $H_{irr}=H-H_{rev}$, with H_{rev} being the reversible component of H, which can be obtained from the BH curve based on B. To obtain H_{irr}, an equivalent ellipse is used with the property that the area of the ellipse equals the are of the original hysteresis curve. This explains why, in the process of obtaining the hysteresis loss, the $B(H)$ curve and K_h coefficient are used.

The equation of the equivalent ellipse is given by:

$$\left(\frac{H_{irr}}{H_m}\right)^2 + \left(\frac{B}{B_m}\right)^2 = 1$$

where

$$H_m = \frac{K_h \cdot B_m}{x}$$

and B_m is the amplitude of a minor BH loop which is obtained based on continuously updated history information of the magnetic flux density, which allows the algorithm to account for the contribution of minor loops to the core loss.

With H_{irr} and dB/dt, the loss can be easily evaluated. For the other components of the core loss (i.e., different combinations of x and y), unknown coefficients can be derived using the property that the formula for core loss in the time domain gives the same result as the formula for core loss applied for the frequency used in the experiment.

Phasor Notation

Time varying quantities that have the form:

$$\boldsymbol{F}(t) = F_m \cos(\omega t + \theta)$$

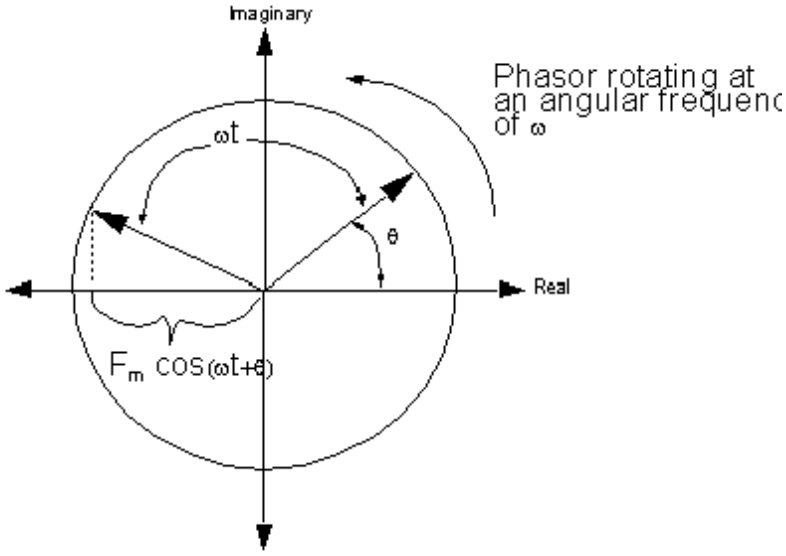
can be represented as rotating phasors in the complex plane. Using Euler's formula:

$$e^{j\alpha} = \cos\alpha + j\sin\alpha$$

If $\alpha = \omega t + \theta$, **F**(t) equals the real portion of $e^{j(\omega t+\theta)}$:

$$\boldsymbol{F}(t) = \Re\left[F_m e^{j(\omega t+\theta)}\right] = \Re[F_m(\cos(\omega t+\theta) + j\sin(\omega t+\theta))] = F_m\cos(\omega t+\theta)$$

Each time-varying quantity has the form $F_m e^{j\theta} e^{j\omega t}$. The $F_m e^{j\theta}$ component is merely a complex constant that can be represented by a stationary phasor in the complex plane. The $F_m e^{j\omega t}$ component is a complex number that depends on *t*, and can be represented as a rotating phasor in the complex plane, as shown here.



The phasor's projection on the real axis oscillates sinusoidally. It reaches a peak when parallel with the real axis, and crosses zero when parallel with the imaginary axis. Thus, a phasor with $\theta=90°$ represents a quantity that peaks 90 degrees after a phasor with $\theta=0°$.

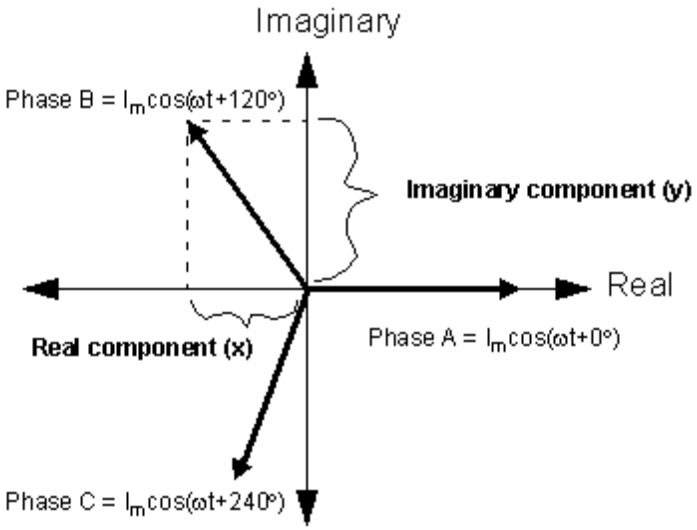
Real and Imaginary Components

Maxwell expects you to enter magnitudes and phase angles when you specify voltages, currents, and other boundary or source quantities in models where time-varying fields are to be computed (that is, eddy current, AC conduction, and eddy axial models). But when the magnitude and phase angle of a quantity are functions of position, it is easier to specify the functions in terms of real and imaginary components "x+jy" rather than in terms of magnitude and amplitude. Therefore, when you specify currents and boundary conditions as functions, the system expects you to describe the functions in terms of real and imaginary components.

The "x+jy" description of a phasor indicates that the phasor is the sum of two components — a sinusoid that peaks at $\omega t=0°$ and a sinusoid that peaks at $\omega t=90°$.

- The "x" component of the phasor is called the real component and can be represented by a phasor that lies on the real axis of the complex plane.
- The "y" component is called the imaginary component and is represented by a phasor that lies on the j-axis of the complex plane.

The real and imaginary components of a three-phase system are shown below:



The real and imaginary components are related to the magnitude and phase of a sinusoid in this way:

$$I_m = \sqrt{x^2 + y^2}$$

$$\theta = \operatorname{atan}\frac{y}{x}$$

Boundary Conditions

Boundary conditions define the behavior of the electric or magnetic field at object interfaces or edges of the problem region. They are always necessary in order to insure the uniqueness of the electromagnetic field calculation. They can also be used to:

1. Simulate structures that are magnetically isolated, electrically insulated, or electrically isolated.
2. Set the electric or magnetic potential at a surface to a constant value or a function of position, in order to define the behavior of the electric or magnetic field on that surface
3. Simulate the field patterns that would exist in a structure while modeling only part of it. To do this, you can define planes of symmetry where electric or magnetic fields are either tangential to or normal to the surface. Additionally, you can define planes of symmetry

where the field on one surface matches the magnitude and direction (or opposite direction) of the field on another surface.

4. Simulate the field patterns produced by thin resistive layers on conductors (DC conduction solver) or eddy currents with very tiny skin depths in conductors (eddy current solver), without having to explicitly draw, assign materials to, or solve for fields inside the objects in question.

Available boundary types in Maxwell 2D are listed in the following table. Select from the table to see more information about a specific boundary type or for information on how to apply it in a specific problem type.

Boundary Condition	Applying in Problem Type
Vector Potential	Magnetostatic Eddy Current Transient
Symmetry	Magnetostatic Electrostatic AC Conduction DC Conduction Eddy Current Transient
Balloon	Magnetostatic Electrostatic AC Conduction DC Conduction Eddy Current Transient
Impedance	Eddy Current
Resistance	DC Conduction
Independent/Dependent	Magnetostatic Electrostatic AC Conduction DC Conduction Eddy Current Transient

Vector Potential

The Vector Potential boundary is available for use in Magnetostatic, Eddy Current, and Transient solver type designs. Use Vector Potential boundaries to set the magnetic vector potential, $\mathbf{A}_Z$, to a

constant value on a boundary.

The potential can also be defined as a function of position using math functions. Normally, this type of boundary condition is used to specify the potential of outer boundaries. It can also be used to set the interface between two objects to a potential, modeling the presence of a very thin conductor between the objects. They are sometimes called Dirichlet boundaries.

The behavior of the magnetic field on a Vector Potential boundary depends on whether you define a constant or functional potential on the boundary. Remember that the magnetic vector potential, **A**, is defined to be a field that satisfies the equation:

$$\nabla \times \boldsymbol{A} = \boldsymbol{B}$$

Since the magnetostatic field solver assumes that **A** has a z-component only and **B** lies in the xy-plane, the relationship of **B** to **A** is given by the following:

$$\boldsymbol{B} = \frac{\partial \boldsymbol{A}_Z}{\partial y}\hat{\boldsymbol{x}} - \frac{\partial \boldsymbol{A}_Z}{\partial x}\hat{\boldsymbol{y}}$$

If $\mathbf{A}_Z$ is constant along a horizontal boundary, the partial derivatives of $\mathbf{A}_Z$ with respect to x will be zero — forcing **B** to have an x-component only, and be tangential to the boundary. Likewise, if $\mathbf{A}_Z$ is constant along a vertical boundary, the partial of $\mathbf{A}_Z$ with respect to y will be zero — forcing **B** to have a y-component only and again indicating that the field will be tangential.

In general, the magnetic field will be tangential to any boundary on which $\mathbf{A}_Z$ has been set to a constant.

If the potential is a function of position, the partial derivatives of $\mathbf{A}_Z$ with respect to x and y will not necessarily be zero. It all depends on what type of math function was used to specify the potential. Thus, **B** may not be tangential to the boundary and some flux will cross it.

In eddy current problems, the magnetic vector potential is a time-varying quantity in the form:

$$\boldsymbol{A}_Z(t) = A_m \cos(\omega t + \theta)$$

where A_m is the magnitude of the potential and θ is its phase angle — its offset from a pure cosine wave. Therefore, when specifying $\mathbf{A}_Z$ on a boundary, you must enter both its magnitude and phase. The magnitude and phase of the potential can also be defined as a function of position using math functions.

Vector Potential Boundaries in Axisymmetric Models

In axisymmetric models, **A** is assumed to have only a ϕ-component and **B** is assumed to lie only in the rz-plane. The relationship between $\mathbf{A}_\phi$ and **B** is given by:

$$\boldsymbol{B} = \frac{1}{r}\left[-\frac{\partial}{\partial z}(rA_\phi)\hat{\boldsymbol{r}} + \frac{\partial}{\partial r}(rA_\phi)\hat{\boldsymbol{z}}\right]$$

Because equipotential lines of $r\mathbf{A}_\phi$ in axisymmetric models coincide with the lines of magnetic flux, you must specify values or functions of $r\mathbf{A}$ (not **A**) when setting value boundaries.

Symmetry

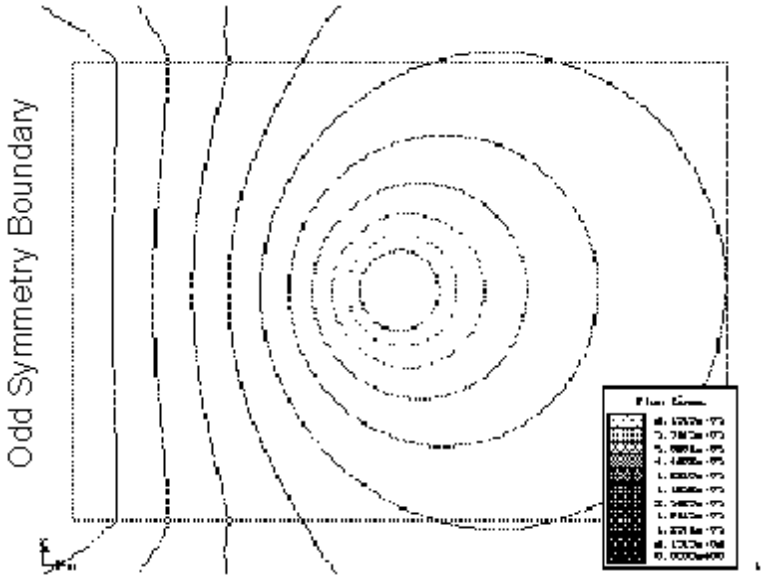
The symmetry boundary is available for use in Magnetostatic, Eddy Current, Transient, Electrostatic, AC Conduction, and DC Conduction solver type designs. A symmetry boundary models a plane of symmetry in a structure. Use this type of boundary condition to take advantage of geometric symmetry and electrical symmetry in a structure. Doing so enables you to reduce the size of your model — allowing you to conserve computing resources. Two types of symmetry boundaries — **Odd** and **Even** — are available for use.

Odd Symmetry

An odd symmetry boundary models a structure in which the signs (positive or negative) of all currents, voltages, or charges on one side of a symmetry plane are the opposite of those on the other side. In magnetic field problems, the magnetic field is tangential to this type of boundary; while in electric field problems, the field is perpendicular to the boundary and equipotential lines are tangential to the boundary.

To define an odd symmetry boundary for magnetic field problems, the simulator sets the selected edge to a vector potential boundary with a magnetic vector potential of zero — acting as a magnetic mirror to the model. For electric field problems, the simulator sets the selected edge to a voltage of zero.

For instance, the plane of symmetry shown below is modeled by an odd symmetry boundary, since the direction of the current flow in the conductor on the left side of the symmetry plane is the opposite of the current flow in the conductor on the right side of the plane (the side that is modeled):

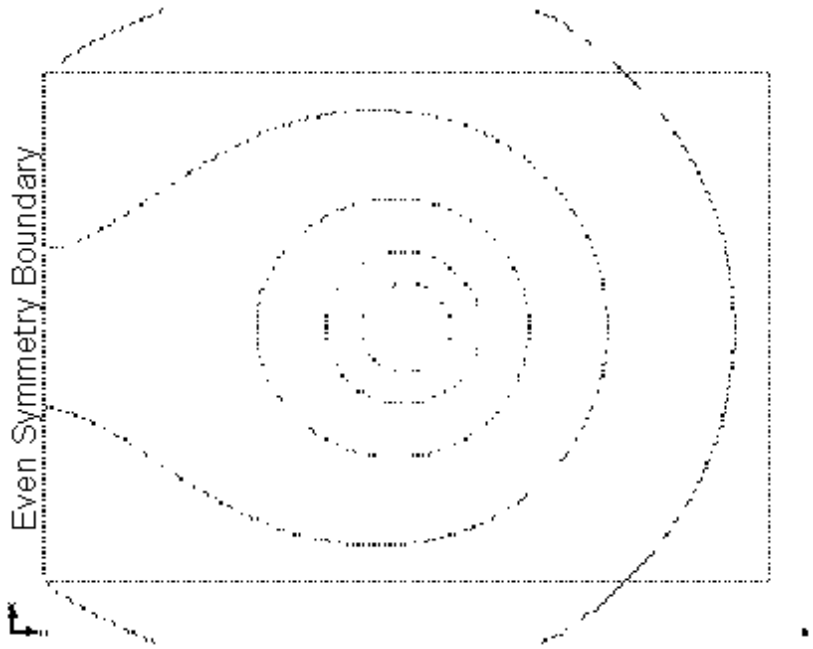


Even Symmetry

An even symmetry boundary models a structure in which the signs (positive or negative) of the currents, voltages, or charges on one side of a symmetry plane are the same as those on the other side. The magnetic field is perpendicular to this type of boundary; while the electric field is tangential to this type of boundary, and contours of equal potential are perpendicular to it.

To define an even symmetry boundary, the simulator sets the selected edge to a Neumann boundary.

For instance, the plane of symmetry shown below could be modeled by an even symmetry boundary, since the direction of the current flow in the conductor on the left side of the symmetry plane is the same as that of the current flow in the conductor on the right side of the plane (the side that is modeled):



Balloon

The balloon boundary is available for use in Magnetostatic, Eddy Current, Transient, Electrostatic, AC Conduction, and DC Conduction solver type designs. Balloon boundaries model the region outside the drawing space as being nearly “infinitely” large — effectively isolating the model from other sources of current or magnetic fields. Visualize the **background** object as extending to infinity along the edges identified as balloon boundaries.

For magnetic solution types, the magnetic vector potential, $\mathbf{A}_Z$ or $\mathbf{A}_\phi$, goes to zero at infinity. The lines of magnetic flux are neither tangential to nor normal to a balloon boundary.

For electric field solution types, two types of balloon boundaries are available:

Charge	Models the case where the charge at infinity matches the charge in the solution region, forcing the net charge to be zero. Physically, this represents an electrically insulated system. This is the default for Electrostatic solutions.
Voltage	Models the case where the voltage at infinity is zero. Physically, this represents an electrically grounded system. In most cases, the results will be very similar to those produced with the **Charge** option; however, the charge at infinity may not exactly match the charge in the drawing region.

The E-field is neither tangential to nor normal to a balloon boundary.

Impedance

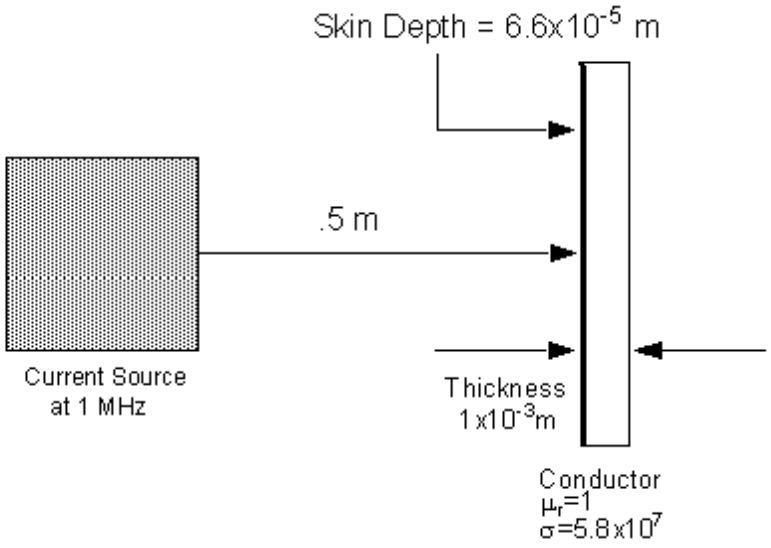
The impedance boundary is available for use in Eddy Current solutions. Impedance boundaries allow you to simulate the effect of induced currents in a conductor without explicitly computing them. The ohmic loss due to induced currents is computed from the tangential components of the H-field along the impedance boundary — the surface of the object that you are interested in.

Use this boundary condition for models where the following conditions occur:

- The skin depth in the conductor of interest is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the Maxwell 2D's meshmaker may not be able to create a fine enough mesh in the conductor to compute eddy currents.
- The magnetic field decays much more rapidly inside the conductor in the direction that is normal to the surface than it does in directions that are tangential to the surface.
- The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

The object itself must be excluded from the solution region by making the object a perfect conductor. When drawing the geometry, make the surface along which eddy currents are to be computed an outer surface of the problem region. Then, when defining boundaries, assign an impedance boundary to this surface. By entering the conductivity, σ, and the relative permeability, μ_r, of the object, you specify the skin depth of induced eddy currents. The simulator uses this skin depth when computing the electromagnetic field solution. It assumes that the H-field falls off exponentially inside the conductor.

For instance, suppose you want to compute eddy current losses in the conductor next to the current source shown below.



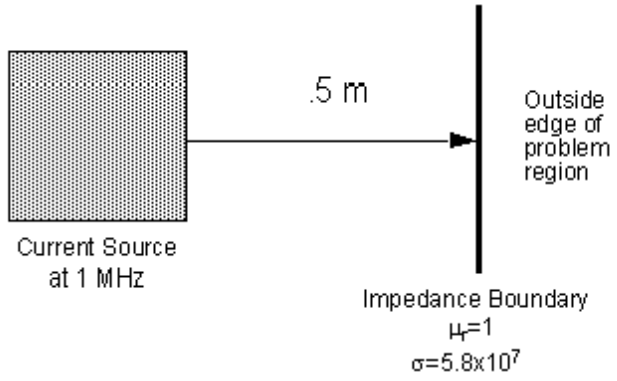
If AC current is passing through the current source at a frequency of 1 MHz, the skin depth in the conductor is given by the following relationship:

$$\delta = \sqrt{\frac{2}{\omega \sigma \mu_r \mu_0}}$$

where:

- $\omega = 2\pi f = 2\pi \times 10^6 = 6.28 \times 10^6$ radians/second
- $\sigma = 5.8 \times 10^7$ siemens/meter
- $\mu_r = 1$
- $\mu_0 = 4\pi \times 10^{-7}$ henries/meter

Substituting these values into this equation, the skin depth is found to be 6.6×10^{-5} meters. Since this is much smaller than the thickness of the conductor and the surface where currents are induced is relatively far away from the current source, an impedance boundary can be used to model the induced currents in the conductor, as shown below. The conductor itself is not included in the model; instead, the outside boundary of the model is moved to the inside surface of the conductor. This outside surface is defined as an impedance boundary, using the conductivity and permeability specified previously.



After generating a solution, you can compute the ohmic loss for the surface using the plane calculator and plot the loss density on the boundary.

For impedance boundaries, ohmic loss is given by:

$$P = \sqrt{\frac{\omega \mu_0 \mu_r}{8\sigma}} \int_{Sur} \boldsymbol{H}_t \bullet \boldsymbol{H}_t^* \, ds \quad \text{(Watts)}$$

where:

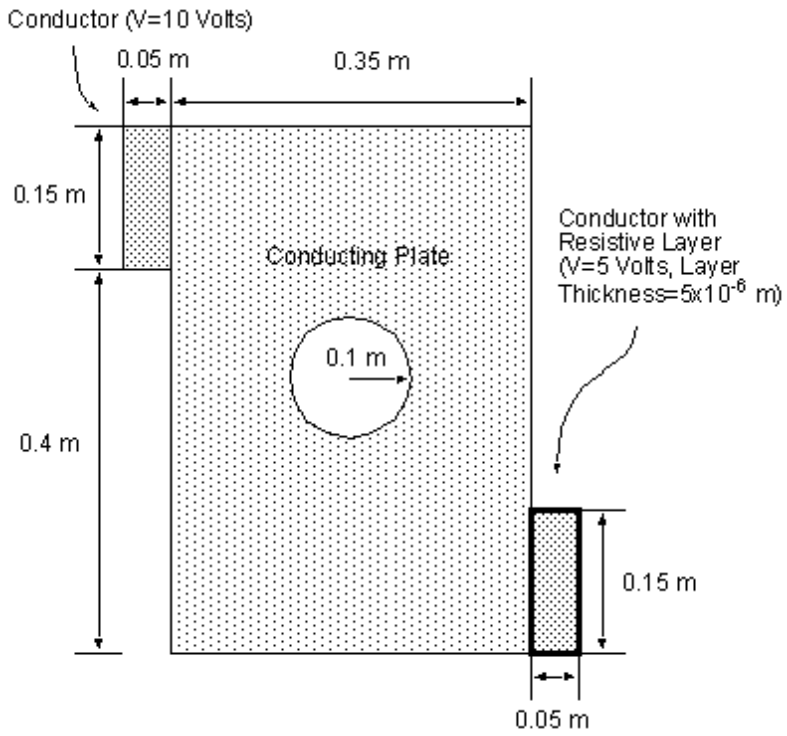
- ω is the angular frequency, which is equal to $2\pi f$.
- σ is the conductor's conductivity in siemens/meter.
- μ_r is the conductor's relative permeability.
- μ_0 is the permeability of free space, which is equal to $4\pi \times 10^{-7}$ H/m.
- $\boldsymbol{H_t}$ is the tangential component of **H** on the impedance boundary.
- $\boldsymbol{H_t^*}$ is the complex conjugate tangential component of **H** on the impedance boundary.

Note	Keep in mind that an impedance boundary approximates the effect of eddy currents acting at a shallow skin depth; it does not directly compute them. In general, the fields modeled using an impedance boundary will closely match the field patterns that would actually occur in the structure. However, the field patterns may be different at discontinuities in the surface such as corners.

Resistance

The resistance boundary is available for use in DC Conduction solutions. A resistance boundary models a very thin layer of resistive material (such as that caused by deposits or oxidation on a metallic surface) on a conductor at a known potential. Use this boundary condition when the resistive layer's thickness is much smaller than the other dimensions of the model.

For instance, in the following example, the resistive layer on the conductor is 5×10^{-6} meters thick. Since this is four orders of magnitude smaller than the dimensions of the model, use a resistance boundary on the conductor to avoid having to create a very thin object modeling the layer — which could cause problems when the Maxwell generates a mesh for the model and solves for its conduction currents.

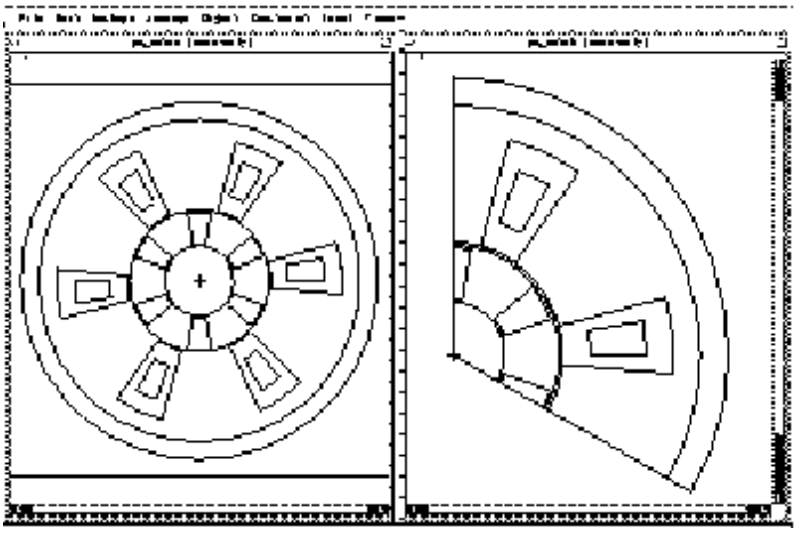


Specify the thickness and conductivity of the resistive material, and the potential of the conductor. Apply resistance boundaries only to the outside edge of the problem space. The external region touching a resistance boundary is assumed to be a PEC (perfect conductor) with a known potential value that is specified in the resistance boundary setup. For the example above, if the PEC region is included in the design model, solve inside should not be selected to exclude it from the FEM (finite element method) problem domain.

Independent/Dependent

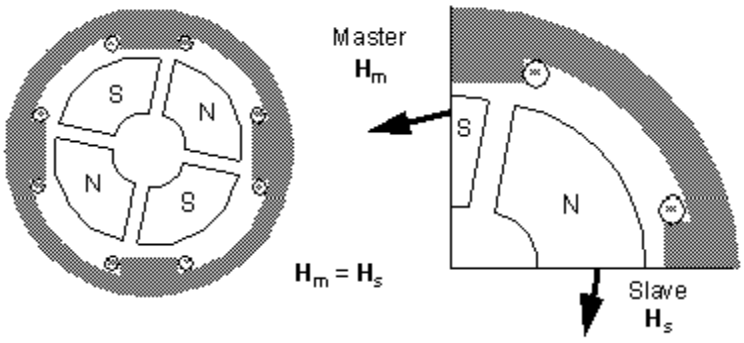
Independent/Dependent boundaries are available for use in Magnetostatic, Eddy Current, Transient, Electrostatic, AC Conduction, and DC Conduction solver type designs. Matching boundaries allow you to take advantage of periodicity in a structure. For example, the following figure shows the cross-section of a DC motor. The field in such a motor repeats itself every 120 degrees; that is, the field pattern in one third of the motor matches the magnitude and direction (or the opposite of the direction) of the field pattern in the other two thirds.

Matching boundaries force the magnetic field at each point on one boundary (the “dependent” boundary) to match the magnetic field at each corresponding point on the other surface (the “independent” boundary). Modeling one third of the structure allows you to make efficient use of the available computing resources:



To define matching boundaries, you must define both an independent matching boundary and a dependent matching boundary.

The condition that needs to be enforced, as illustrated in the following figure, is that the magnitude of the magnetic field at each point on the dependent boundary surface must match the magnetic field at each corresponding point on the independent boundary surface. The field on the dependent boundary must point in either the same direction or in the exact opposite direction as the field on the independent boundary:



One-quarter of a periodic structure (DC motor) modeled using matching boundaries.

Note that a Vector Potential (Dirichlet), Neumann or symmetry boundary cannot be used to simulate periodicity because the magnetic field is not necessarily either perpendicular or tangential to periodic surfaces. For example, in the quarter model shown above, the magnetic field is exactly perpendicular to the bounding surfaces only when the gap separating the permanent magnets is perfectly horizontal or vertical. For all other positions of the rotor, matching boundaries are required to take advantage of symmetry.

2D Sources/Excitations

To compute fields for a structure, you must define a source of charge, voltage, current, or electric or magnetic fields for your model. Assign at least one object or edge as either a source (such as a current, charge, or voltage) or a value boundary.

Permanently polarized or magnetized materials also act as sources of charge or magnetic field (respectively). If you do not identify some type of source, the Maxwell 2D will not be able to generate a solution.

The field quantities computed by each solver — and the required electromagnetic sources — are given in the following table:

Field Solver	Sources	Field Computed	Derived Field Quantities
Electrostatic	Voltages charges charge density floating	ϕ	**E**, **D**
Magnetostatic	DC current current density	$\mathbf{A}_Z$ (XY models), $\mathbf{A}_\phi$ (RZ models)	**H**, **B**
Eddy Current	AC currents current density	$\mathbf{A}_Z(\omega t)$ (XY models), $\mathbf{A}_\phi(\omega t)$ (RZ models)	$\mathbf{J}_Z(\omega t)$ (XY models), $\mathbf{J}_\phi(\omega t)$ (RZ models), **H** (ωt), **B**(ωt),
DC Conduction	DC voltages	ϕ	**E**, **D**, **J**
AC Conduction	AC voltages	$\phi(\omega t)$	**E**(ωt), **J**(ωt)
Transient	Transient voltages and currents through External Circuit connection. Current; current density; coil; end connection	$\mathbf{A}_Z$ (XY and RZ models)	**H**, **B**

where:

- **A** is the magnetic vector potential.
- **H** is the magnetic field.
- **B** is the magnetic flux density.
- ϕ is the electric potential.
- **E** is the electric field.

- **D** is the electric flux density.
- **J** is the current density.

These quantities are phasors in AC simulations.

2D Voltage Sources

Voltage sources are available for the Electrostatic, DC Conduction, AC Conduction and Transient solver types. Voltage sources specify the total DC voltage (electric potential), or the magnitude and phase of the AC voltage on a conductor. Voltages can be defined as constants or as functions; however, the voltage is assumed to be uniform over the source.

Voltage sources may also be specified on a selected edge or edges.

Related Topics

AC Voltage Source
DC Voltage Source

DC Voltage Source

This type of source specifies the total DC voltage (electric potential) on a conductor. Voltages can be defined as constants or as math functions; however, the potential on a conductor is constant over the entire conductor. Note that conductors that touch should be set to the same voltage or defined as a single voltage source, since their potentials are identical.

DC voltage may also be specified on an edge or edges. Voltages can be defined as constant or as functions of position (for instance, to model a specific distribution of potential on the surface of a dielectric).

AC Voltage Source

AC voltage sources are used in AC conduction, and Transient models. All voltages in AC models are time-varying quantities in the form:

$$V(t) = V_m \cos(\omega t + \theta)$$

where V_m is the magnitude of the voltage and θ is its phase angle — the offset of the current from a pure cosine wave. Therefore, when specifying a voltage, you must enter both its magnitude and phase.

2D Current/Current Density

Current sources are available in the Magnetostatic, Eddy Current, and Transient solver types. This type of source specifies the total DC current, or the magnitude and phase of the AC current on a conductor. Currents can be defined as total current, current density, or as functions.

Current sources may also be specified on a selected edge or edges. Edge currents can be defined as total surface current or a surface current density. In the case of edge currents, Eddy current effects are not modeled, since all currents are surface currents.

Generally:

- If the total surface current is specified, the current density is assumed to be uniform.
- If the current density is specified, you may define a uniform current density or one that varies as a function of position to model specific distributions of current on the surface.

Related Topics

AC Current Source

DC Current Source

DC Current Source

This type of source specifies the DC current flowing in a conductor. You can set either the total current or the current density flowing in the object.

- If total current is specified, the current density is assumed to be uniformly distributed throughout the object.
- If current density is specified, you may define a uniform current density or one that varies as a function of position.

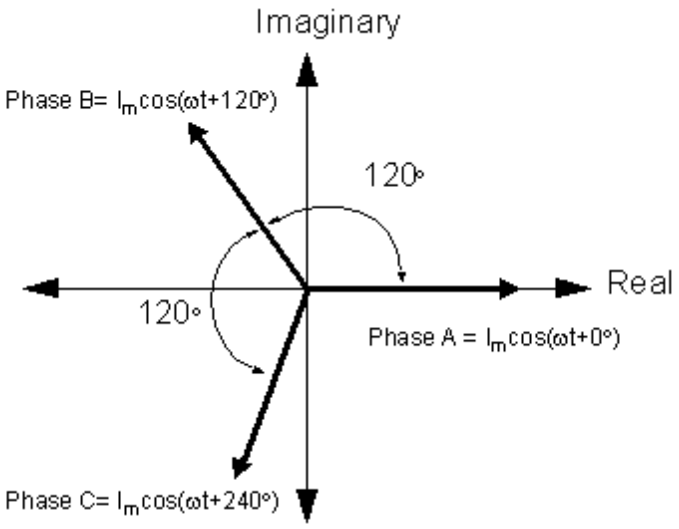
AC Current Source

Remember, all AC currents are time-varying quantities in the form:

$$I = I_m \cos(\omega t + \theta)$$

where I_m is the magnitude of the current and θ is its phase angle — the offset of the current from a pure cosine wave. Therefore, when specifying a current or current density, you must enter both its magnitude and phase.

- In a single-phase system, time t=0 is usually chosen so that the phase angle, θ, is zero — that is, the current peaks at t=0.
- In multi-phase systems involving currents that are out of phase with each other, time t=0 is usually chosen so that one current has a phase angle equal to zero. For example, phase angles in a three-phase system could be assigned as shown here:

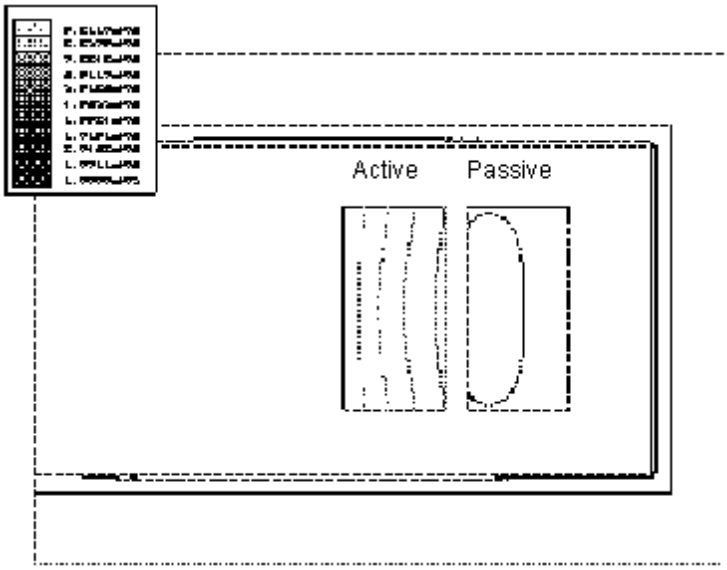


Active vs Passive Conductors

In addition, the conductors in an eddy current model can be divided into two groups:

- “Active” conductors. These conductors are connected to an external current source. Their total current is constrained to the value you specify.
- “Passive” conductors. These conductors are not connected to an external source, but current may be induced in them. Treat any conductor in which the current is constrained to zero (an open circuit) as being connected to a zero-amp current source.

Active and passive conductors are shown in the figure below. In this simple transformer model, the coil on the left is an active conductor carrying 1500 amps of current. The coil on the right is a passive conductor in which current is induced by the oscillating magnetic field. The total current is plotted.



Passive Conductors

Passive conductors can have eddy and displacement currents flowing through them, but have no component of source current. Two types of passive conductors may be defined:

- To define a passive conductor modeling a short circuit, simply assign a conducting material to the desired object. Do not assign source current to it. There are no constraints on the eddy and displacement currents flowing in this type of passive conductor. For cartesian models, visualize this type of conductor as being infinitely long and eventually looping back on itself. For axisymmetric models, visualize this type of conductor as a conducting ring that carries no source current.
- To define a passive conductor modeling an open circuit, assign a solid current source with a magnitude and phase of zero to it. Current may be induced in it, but the net current is constrained to zero amps. In cartesian models, visualize this type of conductor as an infinitely long conducting rod with no return path for current. In axisymmetric models, visualize this type of conductor as a conducting ring with a gap in it.

Current Sources for Touching Conductors

Conductors whose surfaces touch are assigned sources as follows:

- If they are not assigned the same material, these conductors must be defined as a parallel source. Otherwise, they will behave as if they are separated by a thin layer of insulating material.
- If they are assigned the same material, these conductors may be defined either as a parallel source or as grouped conductors assigned a solid source.

This distributes current appropriately across the surfaces of the conductors.

Current Sources for Perfect Conductors

This describes the case in which all current in a perfect conductor flows only on the surface of the conductor. Magnetic fields cannot penetrate this type of conductor. You can only specify the total DC current when defining a perfect conductor as a current source.

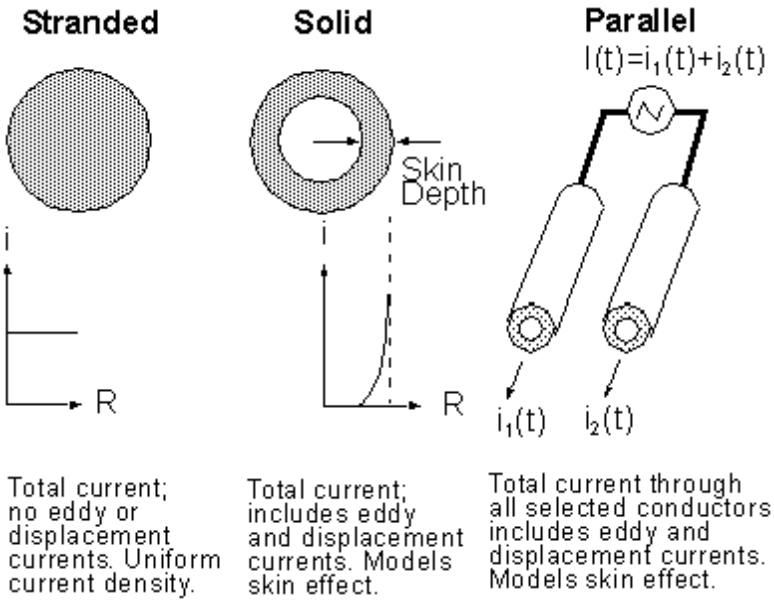
A perfect current source specifies the magnitude and phase of the AC current flowing through a perfect conductor. All currents in perfect conductors are surface currents, simulating the conductor's behavior at very high frequencies. You can only specify the magnitude and phase of the total current.

Solid, Stranded, and Parallel Current Sources

These types of sources specify the magnitude and phase of the AC current flowing through a conductor. Solid current sources model eddy and displacement currents in a solid conductor. The amount of eddy current and displacement current — as well as the amount of source current — are included in the total current you specify.

- Stranded current sources model current as being carried on strands within a conductor. They can be used to model conductors made up of many individual insulated turns, all small enough so that eddy currents can be neglected. Eddy currents and displacement currents are not computed inside the conductor. Either the total current or the current density may be specified. A uniform current density is assumed throughout the conductor, unless a functional current density is defined.
- Parallel current sources connect two or more conductors in parallel to an outside source. The total current flowing through *all* selected conductors (including eddy and displacement currents) is specified. However, the current flowing through individual conductors in the parallel group is unconstrained and its value is computed during the solution.

The differences between each type of AC current source are shown below:



For solid and parallel current sources, the current you specify is the total current in the conductor:

$$I_{Total} = I_{Source} + I_{Eddy} + I_{Displacement}$$

where:

- I_{Total} is the total current flowing through the source. It satisfies Ohm's law with the potential seen by the source.
- I_{Source} is the current due to the potential difference generated by the external source. It is the current that the source would supply if you reduced the potential difference by the back EMF produced by the eddy and displacement currents in the conductor.
- I_{Eddy} is the eddy current induced in the conductor due to time-varying magnetic fields penetrating the conductor.
- $I_{Displacement}$ is the displacement current due to time-varying electric fields in the conductor. It becomes significant only at very high frequencies.

For stranded current sources, the current you specify is the total source current (or source current density), $I_{total} = I_{source}$. Eddy current and displacement current effects are neglected.

2D Charge/Charge Density

This type of source specifies the total charge or charge density on a non-conducting object.

- If the total charge is specified, charge is assumed to be uniformly distributed throughout the interior of the object.

- If a constant value for the charge density is specified, charge is assumed to be uniformly distributed throughout the object. The charge density can also be specified as a function of position to model a distribution of charge that varies inside the object.

This type of source may also specify the charge on a selected edge or edges. It is used primarily to assign surface charges to non-conductors. The “surfaces” being referred to are those created by extending the edge in the z direction (cartesian models) or revolving it around the z-axis (axisymmetric models). Specify either the total charge or the charge density.

If the total charge is specified, charge is assumed to be evenly distributed on the selected surface.

If the charge density is specified, you can define either a uniform charge density or one that varies as a function of position — to model specific distributions of charge on the surface.

The electrostatic field simulator computes the electric potential on the edge during the solution.

2D Floating

This type of source specifies the total charge on a conductor, identifying it as a floating conductor. Charge is assumed to be evenly distributed on the object’s surface. Its value can be defined as a constant or as a function of position; however, charge is distributed over a conductor so that the electric potential is constant throughout the conductor. Because of this, the E-field is equal to zero in this region and no solution is computed inside the conductor.

External Circuit Connections

You may define transient current sources and transient voltage sources using the **Maxwell Circuit Editor**. This allows you to define an external circuit netlist which can be connected to the 2D model to act as a source in the time domain.

To define an external connection, the general procedure should be followed:

1. Create sheets objects to be used as terminals.
2. Assign the **Coil Terminal** excitation to the sheet objects.
3. Create a **Winding**, provide a unique name for the winding, and specify **External Circuit** as the winding type. Select either **Solid** or **Strand** as the type of conductor for the external connection.

Note	You cannot mix solid and stranded sources in the external circuit.

4. Choose **Winding**, and add the **Coil Terminals** to the winding using the **Add Terminals** dialog box.
5. Launch the **Maxwell Circuit Editor** from the Windows Start menu.
6. Add a **Winding** element to the circuit with the same name as given to the winding in the Maxwell design.
7. Add additional circuit element to the schematic to create the external source circuitry for the winding.

Note	The transient solver accepts only the following subset of elements available in Schematic Capture: resistors, inductors, capacitors, diodes, switch on voltages, switch on currents, current sources, voltage sources, current meters, and voltage meters.

8. **Export** the circuit to a netlist, and **Save** and **Exit** the **Maxwell Circuit Editor**.
9. In the Maxwell design, use the **Edit External Circuits** command to **Import** the netlist.

The external circuit is now ready for use in the Maxwell design.

References for Electric or Magnetic Potential

You must specify a reference for electric scalar potential or magnetic vector potential that Maxwell 2D can use when computing fields. To do so, assign one of the following boundary or source types to at least one surface in your model:

- Value boundary
- Voltage source
- Odd symmetry boundary
- Balloon boundary

If you do not set a reference for electric or magnetic potential, the model is not uniquely defined and an error message appears when you try to generate a field solution. This problem usually occurs when you set up:

- Electrostatic problems that contain only charge sources. The electrostatic field solver requires that a reference voltage be defined in order to compute the electric potential (and from it, the electric field) in the problem region.
- Magnetostatic and eddy current problems that contain only current sources. These solvers require that a reference value of $\mathbf{A}_Z$ or $r\mathbf{A}_\phi$ reference value be set in order to compute the magnetic vector potential (A_Z) and from it, the magnetic field in the problem region.

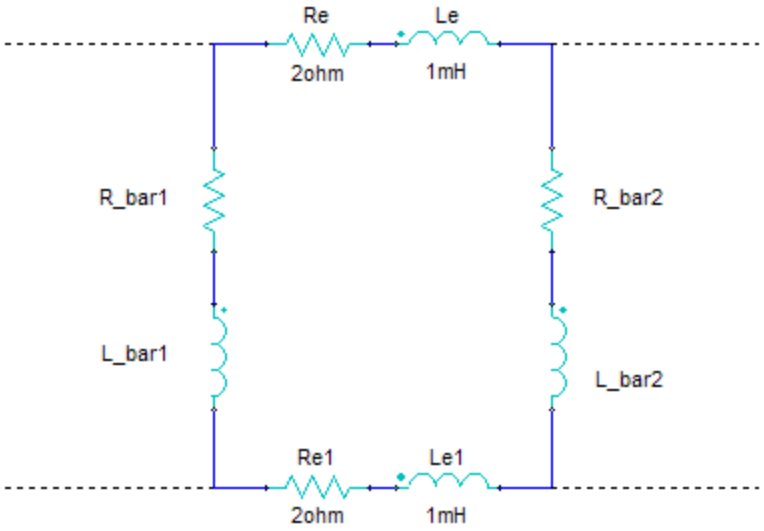
End Connections in 2D Transient and Eddy Current

Choose this command to assign an end connection to a group of solid objects. This causes all objects in the group to be connected electrically in parallel using a finite resistance and inductance between adjacent objects.

End connections are primarily used in passive conductors (with no source current assigned) when modeling cylindrical squirrel cage induction motors.

For evenly distributed conductors, the End Resistance, R_e, and the End Inductance, L_e, are assigned between the ends of each conductor pair.

Note	• Re and Le are the values on one end of the squirrel cage as shown in the schematic below. Therefore in Maxwell 2D, you would enter 2ohm and 1mH for this squirrel cage. • The current reported as EndConnection1 is the current in the first bar located counter clock-wise from the X axis. • All objects included in End Connection automatically have Eddy Effects enabled.



For unevenly distributed conductors, the user supplied resistance and inductance values are scaled such that the supplied values are used directly for the conductor pair with the smallest angle between them. All other conductor pairs are assigned values that are scaled up according to the following equations:

$$r_{eij} = r_e(\theta_{ij}/\theta_{smallest})$$
$$L_{eij} = L_e(\theta_{ij}/\theta_{smallest})$$

Where θ_{ij} is the angle between the conductor *i* and conductor *j*.

Functional Boundaries and Sources

Functional boundaries and sources have defined by math functions, and are used:

- To model distributions of charge, current or voltage that vary as a function of position.
- To model external fields that vary as functions of position.
- To define voltage, current, charge or boundary values as variables to be used in a parametric sweep.

29 - Maxwell 3D Technical Notes

Maxwell® 3D is an interactive software package that uses the finite element method (FEM) analysis to simulate and solve three-dimensional electromagnetic field problems. Maxwell integrates with other Ansys software to perform complex tasks while remaining easy to use.

Introduction to Maxwell

Maxwell 3D® supports the following five types of solutions:

- **Electric** 3D fields, which can fall in one of three categories:
  - Electrostatic 3D fields in dielectrics caused by a user-specified distribution of voltages and charges. Additional computed quantities you can specify include torque, force, and capacitances.
  - Electric 3D fields in conductors, characterized by a spatial distribution of voltage, electric field, and DC current density. The main additional quantity in this case is power loss.
  - A combination of the first two with conduction solutions being used as boundary conditions for an electrostatic problem.
- **Magnetostatic** linear and nonlinear 3D fields caused by a user-specified distribution of DC current density, voltage, permanent magnets, or externally applied magnetic fields. Additional computed quantities you can specify include torque, force, and inductances (self and mutual).
- **Harmonic (Eddy current)** (sinusoidal variation in time) steady state 3D magnetic fields with pulsation-induced eddy currents in massive (solid) conductors caused by one of the following: by a user-specified distribution of AC currents (all with the same frequency but with possibly different initial phase angles), or by externally applied magnetic fields.

  The electric field solution is correct *inside* a conductor due to Ohm's law and self-consistent current densities (including current-bunching in solid conductors). *Outside* a conductor, Maxwell 3D's electric field permits some wave effects, such as propagation to a radiation boundary, but is limited in application and will ignore capacitance effect along source conductors (no charge-bunching). In general, there is no change in the electrical phase angle of the applied current source along the length of a conductor.
- **Transient Magnetic** (time domain) 3D magnetic fields caused by permanent magnets and windings supplied by voltage and/or current sources with arbitrary variation as functions of time; electrical circuits will be connected with the windings. Rotational or translational motion effects can also be included in the simulation.
- **Transient Magnetic with A-Phi Formulation** (time domain) 3D magnetic fields caused by permanent magnets, voltages, currents, and windings supplied by voltage and/or current sources with arbitrary variation as functions of time; electrical circuits can be coupled with the field solution via the windings. Displacement current (capacitive) effect can also be included in the simulation.
- **Transient Electric** (time domain) 3D electric fields caused by time-varying voltages, charge distributions, or current excitations in inhomogeneous materials. The transient electric field simulator computes time-varying electric fields. Electric potential is the solution quantity.

The complex functionality built into the Maxwell 3D solvers is accessed through the main user interface (called the desktop). With the version 11 interface and later, you can model the problem in a fairly arbitrary order (rather than following the steps in a precise order as was required in previous versions of Maxwell).

This flexibility allows experienced users to develop a modeling style that suits their preferences. Once the model is created, the automated Maxwell solution sequence takes over and fully controls the solution process without any interaction from the user. When the solution becomes available, the user can perform a variety of post-processing tasks as required by the design application.

For users new to electromagnetic field simulation, Ansys recommends the following sequence of modeling steps:

1. Based on your application, choose the type of electromagnetic analysis to be performed.
2. Draw the geometry of the model using the drawing space provided by the Modeler menu and Draw menu commands available through the Maxwell desktop interface.
3. Assign the material properties to all solid objects in the model, and define new material properties if materials in the default library do not provide the needed material.

Note	**Caution**: Always make sure the material properties assigned to an object correspond to the real properties of the materials in the electromagnetic device that is being simulated. Material properties supplied in the default library are generic properties and may not always be substituted for actual properties.

4. Specify the field sources (excitations) and boundary conditions for your unique solution.
5. Define additional global parameters that you want to calculate (such as force, torque, inductance/capacitance, etc.).
6. Define mesh operations for special applications (such as seeding in areas/objects of interest).
7. Specify solution options.
8. Start the solution process.
9. When the solution becomes available, perform post processing, such as plotting field quantities and calculating expressions.

The basic modeling entity is the design (model). The next level up is the project. A project is a collection of one or more designs (models) that is saved in a single *.aedt file. A new project is automatically created when Ansys Electronics Desktop is launched. As many Maxwell designs as needed can be added to a single project.

When setting up a Maxwell design, specific commands are available via the menu bar or ribbons using the mouse. You can also work directly in the project tree (the Project Manager area) of the desktop.

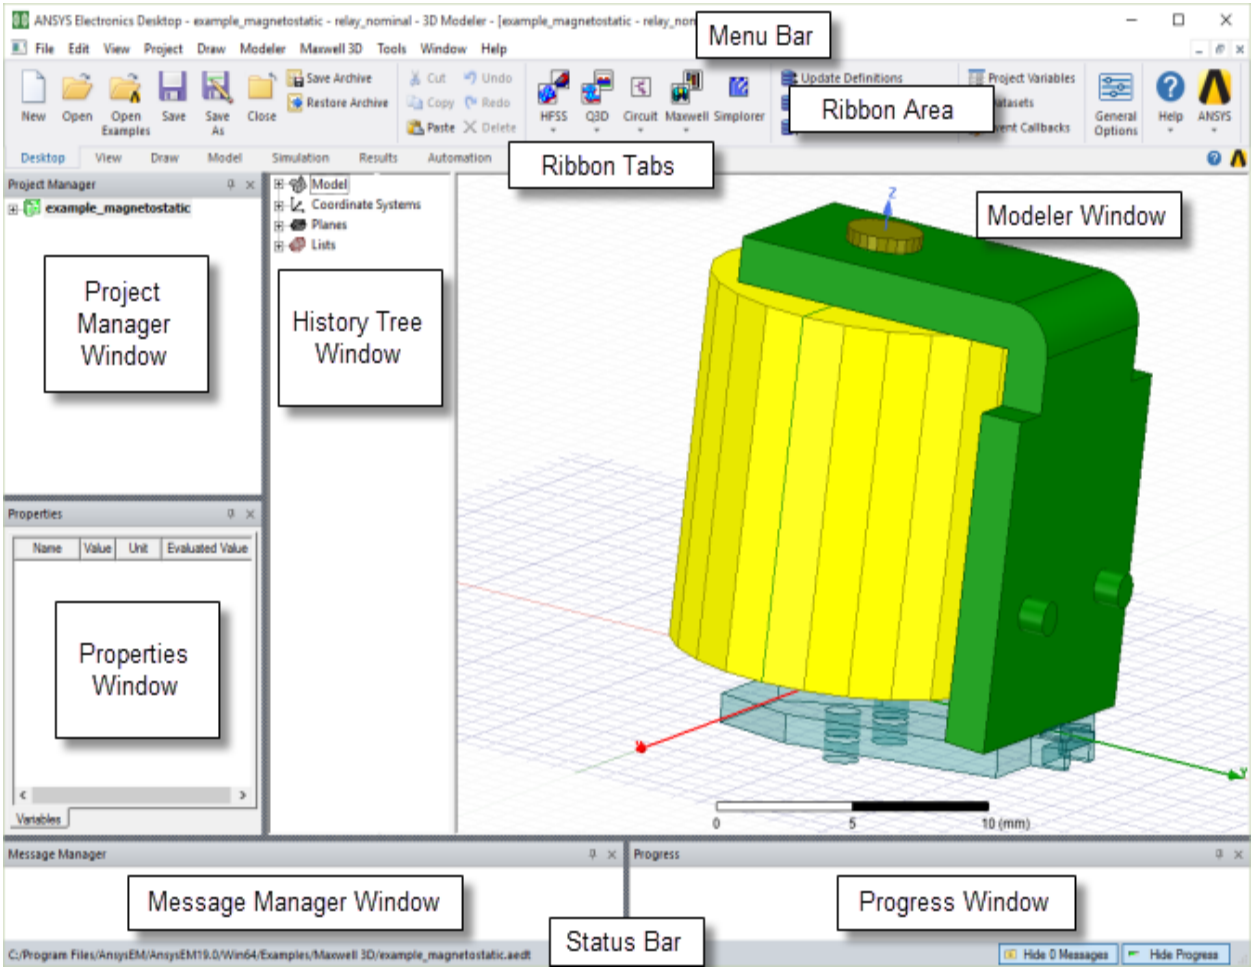
Mouse Button Usage

In general the left mouse button is used to select items (menu commands, objects, properties, etc.). Double-clicking the left mouse button on an item opens a properties window and allows you

to visualize settings and edit properties. Right-clicking is context-dependent and, in general, allows you to perform context-specific operations (such as assigning boundary conditions or excitations or performing field plots on previously selected geometry entities, exiting the zoom mode or draw mode, etc.).

Maxwell Desktop

A brief description of the desktop workspace is provided below in a graphical format. The desktop commands are located on the menu bar. The ribbons contains graphical symbols for the widely used commands. The results of the modeling operations (as far as the geometry is concerned) are reflected in the 3D modeler window and in the history tree window. The property window displays the attributes of selected objects (when the attribute tab is selected) or command characteristics (parameters) if the command tab is selected. The main modeling phases are accessible through the project manager. The message window displays messages (info, warnings, and errors) while the progress window shows the progress of the current solution process. The status bar is context dependent and typically contains info guiding the user in the modeling process (displays current status or expected input from user in the process of executing a command).

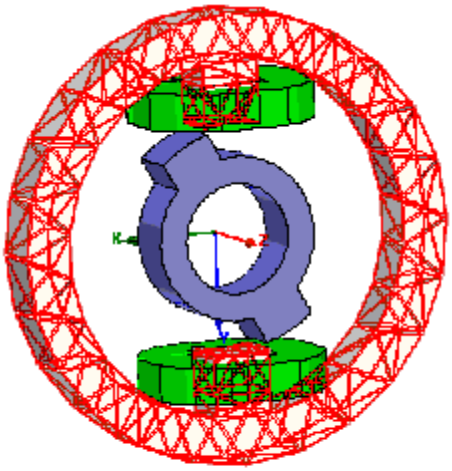


Finite Element Analysis

Finite element analysis (FEA) is a very sophisticated tool widely used by engineers, scientists, and researchers to solve engineering problems arising from various physical fields such as electromagnetic, thermal, structural, fluid flow, acoustic, and others. Currently the finite element method is clearly the dominant numerical analysis method for the simulation of physical field distributions, with success not paralleled by any other numerical technique. In essence, the finite element method finds the solution to any engineering problem that can be described by a finite set of spatial partial derivative equations with appropriate boundary and initial conditions. It is used to solve problems for an extremely wide variety of static, steady state, and transient engineering applications from diverse markets such as automotive, aerospace, nuclear, biomedical, etc.

The finite element method has a solid theoretical foundation. It is based on mathematical theorems that guarantee an asymptotic increase of the accuracy of the field calculation toward the exact solution as the size of the finite elements used in the solution process decreases. For time domain solutions the spatial discretization of the problem must be refined in a manner coordinated with the time steps of the calculation according to estimated time constants of the solution (such as magnetic diffusion time constant).

Maxwell solves the electromagnetic field problems by solving Maxwell's equations in a finite region of space with appropriate boundary conditions and — when necessary — with user-specified initial conditions in order to obtain a solution with guaranteed uniqueness. In order to obtain the set of algebraic equations to be solved, the geometry of the problem is discretized automatically into tetrahedral elements. All the model solids are meshed automatically by the mesher. The assembly of all tetrahedra is referred to as the finite element mesh of the model or simply the mesh. Inside each tetrahedron, the unknowns characteristic for the field being calculated are represented as polynomials of second order. Thus, in regions with rapid spatial field variation, the mesh density needs to be increased for good solution accuracy (see also adaptive mesh refinement).



Mesh shown on the outer armature of a rotational actuator

Types of Solutions and Degrees of Freedom (DOFs)

Solving an electromagnetic field problem is always based on solving Maxwell's equations. However the process of obtaining the solution is typically based on solving a second order consequence of Maxwell's equations with the consideration of applicable constitutive equations. At the same time -- as a rule -- a subset of complete Maxwell's equations is considered according to characteristic aspects of the application. Thus for reasons of efficiency of the solution, applications are classified as electrostatic, magnetostatic, frequency domain or time domain and as a consequence a specific type of solver is used in each case. This allows the users to obtain the solution with the desired accuracy but always within the limits of the fundamental assumptions made when the application was classified along the lines of the above mentioned criteria. The guide lines that can be used to correctly identify the type of solution to use are mentioned in the following paragraphs. The unknowns for each type of solution can be different, depending on the formulation.

Size of Mesh Vs. Accuracy

There is a trade-off among the size of the mesh, the desired level of accuracy, and the amount of available computing resources.

The accuracy of the solution depends on the size of each of the individual elements (tetrahedra). Generally speaking, solutions based on meshes using thousands of elements are more accurate than solutions based on coarse meshes using relatively few elements. To generate a precise description of a field quantity, each element must occupy a region that is small enough for the field to be adequately interpolated from the nodal values.

However, generating a field solution involves inverting a matrix with approximately as many elements as there are tetrahedra nodes. For meshes with a large number of elements, such an inversion requires a significant amount of computing power and memory. Therefore, it is desirable to use a mesh fine enough to obtain an accurate field solution but not so fine that it overwhelms the available computer memory and processing power.

To produce the optimal mesh, Maxwell uses an iterative process, called an adaptive analysis, in which the mesh is automatically refined in critical regions. First, it generates a solution based on a coarse initial mesh. Then, it refines the mesh in areas of high error density and generates a new solution. When selected parameters converge to within a desired limit, Maxwell breaks out of the loop.

The Mesh Generation Process

Following is the general mesh generation process:

1. Maxwell generates an initial mesh, which includes surface approximation settings. If necessary, the mesher will automatically perform any repairs needed to recover an accurate mesh representation of a model. The solution profile will indicate when mesh repairs have been made, and the results of these repairs will be displayed per object in the mesh statistics panel.
2. Any mesh operations that were defined are used to refine the mesh.
3. Using the resulting mesh, Maxwell computes the electromagnetic fields that exist inside the structure based on the assigned excitations.
4. If you are performing an adaptive analysis, Maxwell uses the current finite element solution to estimate the regions of the problem domain where the exact solution has strong error. Tetrahedra in these regions are refined.
5. Maxwell generates another solution using the refined mesh.
6. Maxwell recomputes the error, and the iterative process (solve — error analysis — adaptive refinement) repeats until the convergence criteria are satisfied or the maximum number of adaptive passes is completed.
7. If a frequency sweep is being performed, then Maxwell solves the problem at the other frequency points without further refining the mesh. An adaptive solution is performed only at the specified solution frequency.

Note	Maxwell does not generate an initial mesh each time it starts the solution process. The initial mesh is generated only if a current mesh is unavailable.

Seeding the Mesh

In Maxwell, mesh operations are optional mesh refinement settings that enable you to provide Maxwell with engineering guidance based on your knowledge of the parts of the model geometry that are critical to the structure's electromagnetic performance. Providing such guidance to Maxwell prior to beginning the adaptive analysis process can reduce (sometimes extensively) the number of passes necessary to converge upon a field solution as well as the final number of tetrahedra in the mesh for that solution. Although adaptive analysis convergence targets areas where field behavior is found, refining the mesh using more than the standard criteria, such as material characteristics, can result in finding areas of critical field behavior as soon as the first few passes are solved.

The technique of guiding Maxwell's mesh construction is referred to as "seeding" the mesh. Seeding is performed using the **Mesh** commands on the Maxwell menu.

You can instruct Maxwell to refine the length of tetrahedral elements on a surface or within a volume until they are below a certain value (length-based mesh refinement) or you can instruct Maxwell to refine the surface triangle length of all tetrahedral elements on a surface or volume to within a specified value (skin depth-based mesh refinement.) These types of mesh operations can be defined at any time. If you apply them before the adaptive solution process, they are used to refine the initial mesh after it has been generated. You can also choose to apply mesh operations without generating a solution, in which case the mesh operations are applied to the current mesh.

In a few circumstances, you may also want to define a mesh operation that modifies Maxwell's surface approximation settings for one or more faces. Surface approximation settings are only applied to the initial mesh.

Defining Mesh Operations

Technical Notes: The Mesh Generation Process

Guidelines for Seeding the Mesh

While seeding the mesh is not required, it is useful in the following conditions:

- Seeding the mesh inside a volume in the model geometry where regions of strong electric or magnetic fields (with strong capacitive or inductive loading) are expected. Examples include a capacitively loaded gap in a resonant structure, sharp waveguide angles or corners, or gaps between multi-coupled lines in filter structures.
- Seeding the mesh on every face of higher aspect ratio boundaries, such as long PCB traces or on the surfaces of long wires. Spacing the mesh points roughly equal to the

trace width of the wire diameter enables you to more accurately capture the behavior of the high-aspect structure from the first adaptive pass.

Defining Mesh Operations

Length-Based Mesh Refinement

When you request length-based mesh refinement, you instruct Maxwell to refine the length of tetrahedral elements until they are below a specified value. The length of a tetrahedron is defined as the length of its longest edge.

You can specify the maximum length of tetrahedra on faces or inside of objects. You can also specify the maximum number of elements that are added during the refinement. When the initial mesh has been generated, the refinement criteria you specified will be used to refine the initial mesh.

Assigning Length-Based Mesh Refinement on Object Faces

Assigning Length-Based Mesh Refinement Inside Objects

Skin Depth-Based Mesh Refinement

When you request skin depth-based mesh refinement, you instruct Maxwell to refine the surface triangle length of all tetrahedral elements on a face to within a specified value. A layered mesh is created based on the surface mesh. The layers are graded based on the skin depth and number of layers you specify.

During skin depth-based mesh refinement, Maxwell creates a series of layers that are planes parallel to the object face, and that are spaced within the specified skin depth. For each point on the surface of the face, a series of points (P0, P1, P2, ..., Pn) are added to the mesh, where n is the number of layers. P0 is the point on the surface and the distance from P0 to Pn is the skin depth. The points are spaced in a non-uniform manner, with the distance between them decreasing in a geometric progression, as you move from Pn to P0.

For example, if

Skin Depth:	12 mm
Number of Layers of Elements:	4

then

Distance [P0,P1]:	0.8 mm.
Distance [P1,P2]:	1.6 mm.
Distance [P2,P3]:	3.2 mm.
Distance [P3,P4]:	6.4 mm.
Distance [P0,P4]:	0.8 + 1.6 + 3.2 + 6.4 = 12 mm

The skin depth-based refinement first satisfies the surface triangle edge length criterion, then introduces the series of points to each additional layer. If a limit has been placed on mesh growth, one of the following happens:

- The limit is set high enough to complete the skin depth refinement.
- The limit is set high enough to satisfy the surface triangle edge length criterion, but not high enough to complete the depth seeding.
- The limit is not set high enough to satisfy even the surface triangle edge length criterion.

Because refining by skin depth can add many seeding points, you should first refine the surface of the object using length-based mesh refinement to obtain an accurate count of the number of points Maxwell will add when refining by skin depth. This allows you to reach the surface edge length criterion and approximate the number of elements in the mesh and the number of points on the surfaces before proceeding to skin depth seeding.

The refinement criteria you specified are used to refine the current mesh.

Surface Approximation Settings

Object surfaces in Maxwell may be planar, cylindrical or conical, toroidal, spherical, or splines. The original model surfaces are called *true surfaces*. To create a finite element mesh, Maxwell first divides all true surfaces into triangles. These triangulated surfaces are called faceted surfaces because a series of straight line segments represents each curved or planar surface.

For planar surfaces, the triangles lie exactly on the model faces; there is no difference in the location or the normal of the true surface and the meshed surface. When an object's surface is non-planar, the faceted triangle faces lie a small distance from the object's true surface. This distance is called the *surface deviation*, and it is measured in the model's units. The surface deviation is greater near the triangle centers and less near the triangle vertices.

The normal of a curved surface is different depending on its location, but it is constant for each triangle. (In this context, "normal" is defined as a line perpendicular to the surface.) The angular difference between the normal of the curved surface and the corresponding mesh surface is called the *normal deviation* and is measured in degrees.

The *aspect ratio* of triangles used in planar surfaces is based on the ratio of circumscribed radius to the in-radius of the triangle. It is unity for an equilateral triangle and approaches infinity as the triangle becomes thinner.

You can modify the surface deviation, the maximum permitted normal deviation, and the maximum aspect ratio of triangles settings on one or more faces at a time in the **Surface Approximation** dialog box. (Click **Maxwell3D>Mesh>Assign Mesh Operation>Surface Approximation**.)

The surface approximation settings are applied to the initial mesh.

Note	For the initial mesh, all the vertices of the triangles lie on the true surfaces. During mesh refinement, all the points are first added to the faceted surface for all products, not to the true surfaces. Then, for all Maxwell projects, and for curvilinear meshing enabled HFSS and HFIE projects, the points on the faceted surfaces will be moved to the curved surface locations when such movement does not degrade the quality of the mesh.

Modifying Surface Approximation Settings

Technical Notes: Guidelines for Modifying Surface Approximation Settings

Technical Notes: The Mesh Generation Process

Guidelines for Modifying Surface Approximation Settings

If you intend to modify the surface approximation settings for an object face or faces, keep the following guidelines in mind:

- When necessary, override the default surface approximation settings to represent curved surfaces more accurately. More accurate representation will increase the mesh size and consume more CPU time and memory. The default settings are adequate for most circumstances.
- If you want to obtain a faster solution by using a cruder representation of curved surfaces, set the coarser setting for the whole object, not just a single face.
- It is difficult for Maxwell to satisfy aspect ratio demands if the aspect ratio value is set close to 1 because an arbitrary shape cannot be filled with only equilateral triangles. Therefore, setting the aspect ratio to 1 can lead to unreasonably large meshes. Maxwell limits the aspect ratio to 4 for planar objects and 1.2 for curved objects.

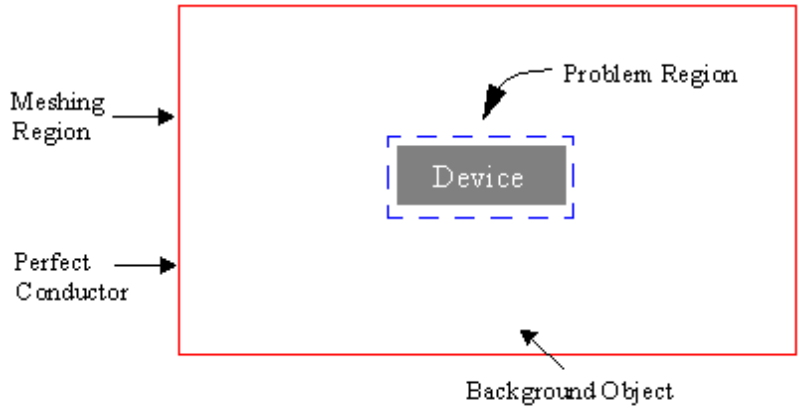
Meshing Region Vs. Problem Region

Maxwell distinguishes between the problem region and the meshing region. The *problem region* is the region in which the solution is generated and the mesh is refined. The *meshing region*, which includes the problem region, is the area in which an initial mesh is generated. After an initial mesh is generated, the mesh is refined only in the problem region.

The problem region encompasses an area that is just large enough to include the entire design, but no larger. Maxwell automatically defines the problem region during the solution process. If you are interested in effects outside of the structure, such as radiated effects, then you can create a virtual object to expand the size of the problem region to include these areas.

The meshing region, like the problem region, is a box that completely encloses the structure. However the meshing region must be at least 10 times larger than the model. The part of the meshing region not occupied by objects is considered to be the *background* object. The background extends to the boundaries of the meshing region and fills in any voids not occupied by objects. Since the background object is defined as a perfect conductor, no solution is generated inside the background even though an initial mesh is generated for it. Maxwell automatically defines the meshing region during the solution process.

The problem region and the meshing region are illustrated below.



Model Resolution

Model Resolution is a setting that determines the smallest details of a model that the mesher should capture and represent in the mesh.

Many times the analysis starts with the geometry already drawn in a different tool for different purpose. Some tools are designed for manufacturing and the resulting models contain lots of extra details not needed for electromagnetic analysis. If the user removes such details in the original tool the results will be better. But if the user does not have access to the original drawing tool or redrawing the model without these details is not possible, **Model Resolution** is another way to remove the details from analysis.

When the user sets the model resolution length to be L, the mesher will start with a surface representation of the model accurate to the modeler's tolerance limit. Then it will progressively remove edges, move points, merge points etc., within the allowable model resolution limit and simplify the surface mesh. During this process, tiny fillets, rounds, and chamfer protrusions are removed.

Other common model translation anomalies are also handled using **Model Resolution**. For example, some geometry engines will blindly export all of the surfaces as splines. When a user imports such a model for analysis, it would result in very large number of triangles. If the surface can be represented by a smaller set of triangles using Model Resolution, this procedure would reduce the number of triangles in the surface mesh.

The user can start with a model resolution length around 0.1*wavelength. If the model resolution length chosen by the user is too large, the mesher will detect it and report it as an error. The model resolution length is specified in the user units of the modeler. It can be set on selected bodies only. The default value is 100* the tolerance limit of the modeler.

Modifying Model Resolution

Electric Field Calculation

The Electric field solver uses the electric scalar potential values as DOFs. There are two basic types of static electric field solutions, as well as the combination of these two:

- For the electrostatic solution, it is assumed that all objects are stationary (velocity is zero everywhere in the space where the electrostatic field is calculated), there is no time

  $$\frac{\partial}{\partial t} = 0$$

  variation of any of the electromagnetic quantities ( ) and there is no current flow in conductors (conductors are in electrostatic equilibrium) and thus Joule losses are zero everywhere. All conductors are considered to be perfect and equipotential such that there is no electric field inside conductors. The unknowns (DOFs) are electric scalar potentials at all the nodes of the tetrahedra of the mesh. The distribution of conductivity in the space of the problem is irrelevant, only the distribution of permittivity is relevant for the solution process.

Note	For the electrostatic solution, if two or more conductors touch each other, they should be united into one object by using the Modeler Boolean operation "Unite" before analysis.

- For the DC current flow solution, only the conductors (with electric conductivity σ > Insulator/Conductor Threshold) are considered in the solution process. The DOFs are also the electric scalar potentials at the nodes of the mesh. Here the distribution of electric conductivity is relevant for the solution process while the permittivity is irrelevant. There is DC current flow in conductors (conductors are not equipotential) and there is non-zero Joule loss (ohmic power loss) in the conductors (which are part of an excited current path).

The conductors are considered to be immobile (velocity is zero everywhere). The magnetic field associated with the DC current flow is not calculated and is totally de-coupled from the calculated electric field distribution in conductors.

- The combination of the DC current flow and electrostatic solution is based on the division of the arrangement into conductors and insulators. Conductors are those objects whose electric conductivity σ is greater then or equal to the Insulator/Conductor threshold, and insulators are those whose conductivity σ is less then the Insulator/Conductor threshold. The solution of such problems is performed in two steps: first the DC conduction problem in the conductors is computed, then the electrostatic solution in insulators is calculated using the electric scalar potential of the conductors as a voltage boundary condition.

For the electric field solution, there are ten nodal DOFs (electric scalar potential unknowns) associated with each tetrahedron at each of the four vertices and at each of the six mid-edge nodes. Therefore, a quadratic approximation of the electric scalar potential inside each tetrahedron can be obtained.

The **electrostatic field solver** solves a Poisson type partial differential equation for the electric potential unknown, Φ, with appropriate boundary conditions:

$$\nabla \cdot (\varepsilon_r \cdot \varepsilon_0 \nabla \Phi) = -\rho_v$$

where:

$\Phi(x, y, z)$

- is the electric potential scalar function of position.

$\varepsilon_r(x, y, z)$

- is the relative permittivity, which is a function of position and can be isotropic or orthotropic.

$\varepsilon_0 = 8.854 \times 10^{-12}$

- F/m is the permittivity of a vacuum.

$\rho_v(x, y, z)$

- is the volume density of the electric charge.

Once the electric potential is obtained by solving the above second order differential equation in the domain of the problem, Maxwell's equations and the applicable constitutive equation are then used to obtain the electric field strength, $\vec{E}$, and electric flux density, $\vec{D}$, vectors, as follows:

$$\vec{E} = -\nabla\Phi$$

$$\vec{D} = \varepsilon_r \cdot \varepsilon_0 \cdot \vec{E}$$

Typical sources for electrostatic problems are net **charges** (assumed to have a uniform distribution) applied to perfect insulator model objects or on surfaces that cannot touch conductors and **voltages** (electric potential applied to perfect conductor model objects or on surfaces, also called a Dirichlet boundary condition). Additionally, a **floating** boundary condition can be applied to perfect conductors (surrounded by insulators) or to surfaces surrounded by perfect insulators.

Volume charge density is another allowed excitation, which can have a spatial distribution specified by the user and can be applied to insulating objects only that do not touch conductors.

At the interface between two dielectrics, the normal component of the electric flux density vector has no jump if the charge density at the respective interface is zero:

$$\varepsilon_1 \cdot E_{n1} = \varepsilon_2 \cdot E_{n2}$$

where the permittivity and normal electric field values are considered in the two dielectrics and are designated by the subscripts 1 and 2. Alternatively, when crossing a surface with non-zero charge density, the normal component of the electric flux density has a jump equal to the respective local superficial charge density. It follows that in dielectrics (such as air, for example) in the immediate vicinity of conductive objects (perfect conductors), the (normal) component of the electric flux density is equal to the neighboring local charge density on the metallic surface (since in metallic objects the field value is zero).

Note	When voltages are applied to conductors, the charge transferred from the DC source (s) to the conductors almost instantly receives a superficial distribution. For real (good) conductors, the time constant for the diffusion of the charge is of the order of 10^{-19}s. Therefore, for all practical instances, we consider the charge relaxation process to occur instantly. Once the charge on conductors reaches the steady state (almost instantaneously), the electric field in the neighboring dielectrics has a distribution that is

	governed by the laws of electrostatics, and the field in conductors is null while the field distribution in dielectrics is dictated - as far as material properties are concerned - by the respective permittivities and is independent of the conductivity of the electric conductors. This is why, in electrostatics, we can consider the real conductors to be perfect conductors.

Electrostatic regime of the electromagnetic field is rarely achieved in practice rigorously speaking. However very good approximations are many times possible to use for practical situations within the limits specified above.

The DC current flow solver solves the following equation:

$$\nabla \cdot (\sigma \nabla \Phi) = 0$$

where:

$\Phi(x,y,z)$

- is the electric potential scalar function of position.

  $\sigma(x,y,z)$

- is the electric conductivity (in SI it is measured in S/m), which is a function of position and can be isotropic or orthotropic.

Once the electric potential is obtained by solving the above second order differential equation in the domain of the problem, Maxwell's equations and the applicable constitutive equation (Ohm's law in a local formulation) are then used to obtain the electric field strength and the electric current density $\vec{J}$ vectors:

$$\vec{E} = -\nabla \Phi$$

$$\vec{J} = \sigma \cdot \vec{E}$$

Typical sources for DC current flow problems are **currents** applied on surfaces of conductors and **voltages** (electric potential applied to surfaces of conductors). The direction of the applied current is either "in" or "out", always normal to the respective surfaces.

Note	Multiple conduction paths are allowed. Each conduction path that has a current excitation must also have either a voltage applied or a **sink** to ensure a unique solution.

The sink is a particular excitation (without a numerical value assigned to it) that is used to ensure the divergence-free character of the calculated DC current density vector in each conduction path.

At the interface between two different conductors, the normal component of the current density vector is continuous:

$$\sigma_1 \cdot E_{n1} = \sigma_2 \cdot E_{n2}$$

For DC current flow problems, the solution is dictated everywhere inside the conductors by the distribution of electric conductivity, as far as material properties are concerned.

Charge, voltage, floating, current, and sink type excitations are called "terminal" type excitations since they can be referenced in a matrix extraction setup.

In perfect conductors, no computation occurs, and the electric scalar potential (the unknown in the problem) has a uniform value. However, in the post-processing phase, the (constant) distribution of the electric scalar potential (voltage) is correctly rendered. No solution is available in solids explicitly excluded from the solution.

The solution of any field problem is only possible if appropriate boundary conditions have been set. The boundary conditions have three purposes:

- Boundary conditions are always necessary from a mathematical perspective in order to ensure the uniqueness of the solution calculated by Maxwell.
- Boundary conditions occasionally represent a convenient way of modeling different ideal situations. For example, in order to model the field in a dielectric sandwiched between two very thin conducting objects (the thickness is at least two orders of magnitude less than the other relevant dimensions of the respective conducting objects), only the two respective surfaces need to be modeled on either side of the dielectric object. In the setup, those top and bottom surfaces carry appropriate boundary conditions, and the field in the dielectric is correctly simulated without having to draw the respective conductors.
- Boundary conditions also occasionally provide a convenient way of taking advantage of symmetry situations. In such cases, the models must have the same geometric and material properties, as well as electric symmetry.

Typical boundary conditions include voltage, floating, and insulation boundary conditions. In the case of an **insulating boundary condition**, a conductor must exist at least on one of the sides of the respective surface.

The default boundary condition applied to all faces of the boundary of the electric field (static or stationary) problem is a Neumann homogeneous condition. This condition enforces an electric field tangent behavior of the solution in the immediate vicinity of the boundaries. There is no need to apply any particular boundary condition at the interface between objects with different material

properties, as the solution automatically ensures -in average - the continuity of the tangential component of the electric field strength ($\vec{E}$) and the continuity of the normal component of the electric flux density vector ($\vec{D}$) across surfaces with zero superficial electric charge density (for electrostatic problems).

Symmetry for an Electric Field Solution

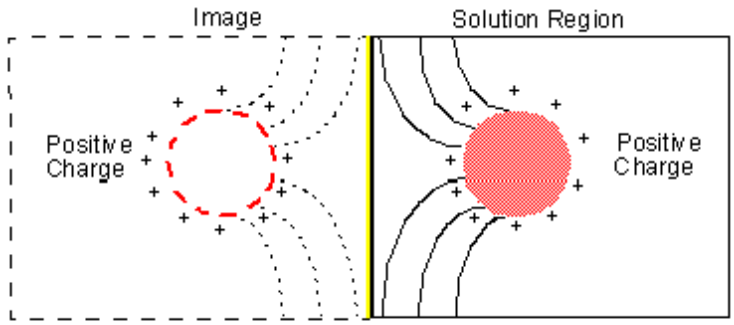
A symmetry boundary models a plane of symmetry in a structure. Use this type of boundary condition to take advantage of both geometric symmetry and electric symmetry. Doing so enables you to reduce the size of your model - allowing you to conserve computing resources. Two types of symmetry boundaries are available:

- Even Symmetry (Flux Tangential)
- Odd Symmetry (Flux Normal)

These boundaries can only be assigned to the outside edges of the solution region.

Even Symmetry (Flux Tangential) for an Electric Field Solution

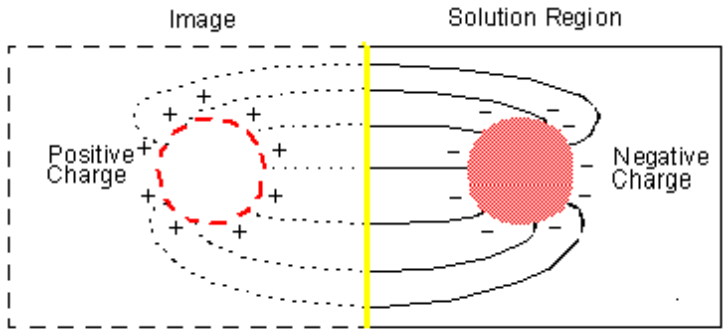
Use an even symmetry boundary to define a plane of symmetry where the signs (positive or negative) of the voltages and charges on one side of the plane are the same as those on the other side. Electric flux is tangential to the boundary and thus does not cross it. To define an even symmetry boundary, the simulator sets the selected edge to a Neumann boundary - acting as an electrical mirror to the model.



The E-field is tangential to an even symmetry boundary.

Odd Symmetry (Flux Normal) for an Electric Field Solution

Use an odd symmetry boundary to define a plane of symmetry where the signs (positive or negative) of all charges and voltages on one side of the plane are the opposite of those on the other side. Electric flux is normal to the boundary. To define an odd symmetry boundary, the simulator sets the selected edge to a voltage boundary with a potential of zero volts.



The E-field is perpendicular to an odd symmetry boundary.

Matching Boundary for an Electric Field Solution

Matching boundaries allow you to model planes of periodicity where the E-field on one surface matches the E-field on another. They are very useful for modeling devices such as motors, in which the electric field repeats every 180^o, 120^o, 90^o, or less. They enable you to model the smallest possible periodic segment of the device - reducing the amount of computing resources needed during the solution.

To set up matching boundaries, you must create an independent boundary and a dependent boundary. Unlike symmetry boundaries, **E** does not have to be tangential or normal to these boundaries. The only condition is that the fields on the two boundaries must have the same magnitude and direction (or the same magnitude and opposite directions).

Independent Boundary for an Electric Field Solution

The simulator computes the electric field on an independent boundary using the charges and voltages that you specified for the model as input. No other special conditions are imposed.

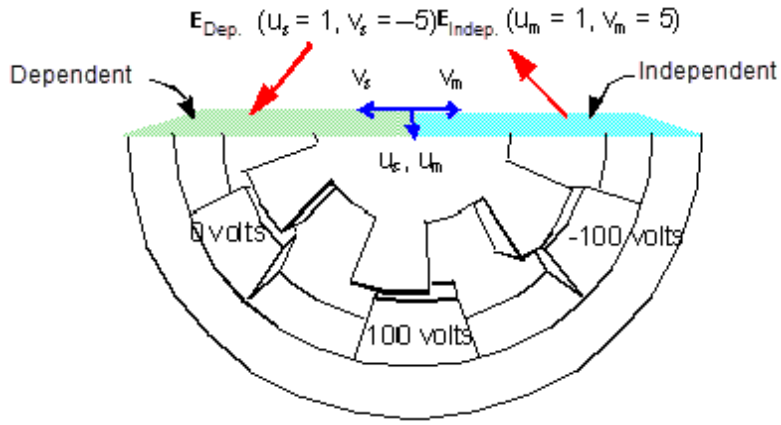
Dependent Boundary for an Electric Field Solution

The electric field on the dependent boundary is forced to match the field on the independent boundary. The magnitude of the electric field on both boundaries is the same. The fields on the two boundaries can either point in the same direction, or in opposite directions.

When to Use Matching Boundaries for an Electric Field Solution

Consider a simple electrostatic micromotor in which the rotor is held at zero volts and the six stator poles are switched between zero volts, 100 volts, and -100 volts. The E-field pattern at any point in time repeats itself every 180^{o} — causing the field in one half of the motor to match the field in the other half.

If you use matching boundaries, you only need to model half of the motor, as shown below. The E-field on the dependent boundary (the left side of the motor) is forced to match the magnitude and point in the opposite direction from the E-field on the independent boundary (the right side of the motor) - simulating the field pattern that would occur if the entire motor was modeled.



A symmetry boundary cannot be used in place of matching boundaries in this example. The electric field is not necessarily either perpendicular or tangential to the motor's periodic surfaces. In the example above, the electric field would be exactly tangential to the periodic surface only when the poles of the rotor are aligned with the poles of the stator. In the other positions of the rotor, the field is not tangential and matching boundaries are required.

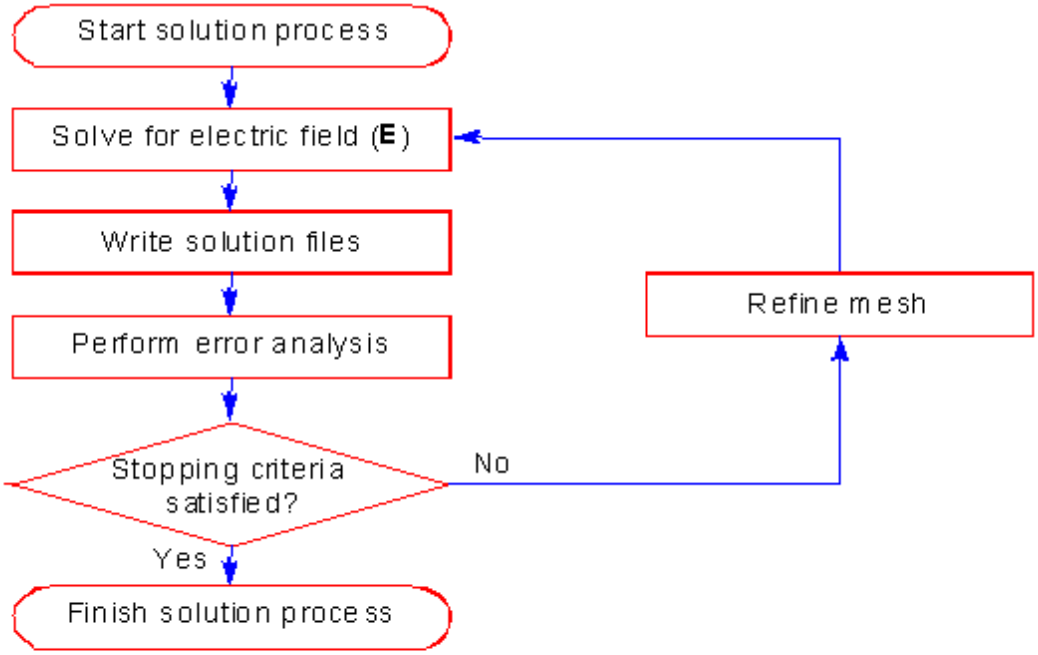
A **combined DC current flow + Electrostatic solution type** is also possible. In this case, the voltage distribution on conductors from the DC current flow solution is used as a Dirichlet (applied voltage) boundary condition in the electrostatic phase of the solution process. This type of sequence allows a certain class of problem involving electrostatic fields surrounding conductors with DC current flow to achieve a comprehensive solution. In this case, the solution provides the electric field in conductors and dielectrics.

Solution Process for an Electric Field Solution

Maxwell's electrostatic solver computes and stores the value of the electric potential at the vertices and midpoints of the edges of each tetrahedron in the finite element mesh. It solves for the electric field using the following relationship:

$$\vec{E} = -\nabla\Phi$$

After E is calculated, Maxwell writes out solution files and performs an error analysis. In an adaptive analysis, it refines the tetrahedra with the highest error, and continues solving until the stopping criterion is met. In a non-adaptive solution, the process stops.



Electric Field Energy for an Electric Field Solution

The energy, U, that is stored in a static electric field is given by the following equation:

$$U = \frac{1}{2}\int_{Vol} \vec{\mathbf{E}} \bullet \vec{\mathbf{D}} dVol$$

where:

- **E** is the electric field.
- **D** is the electric flux density.

Capacitance Matrix for an Electric Field Solution

Capacitance matrices can be expressed in terms of charge and voltage, or current and time-varying voltage. The unit of capacitance is F.

Note	For a capacitance matrix, the elements are defined based on excitations, not solids.

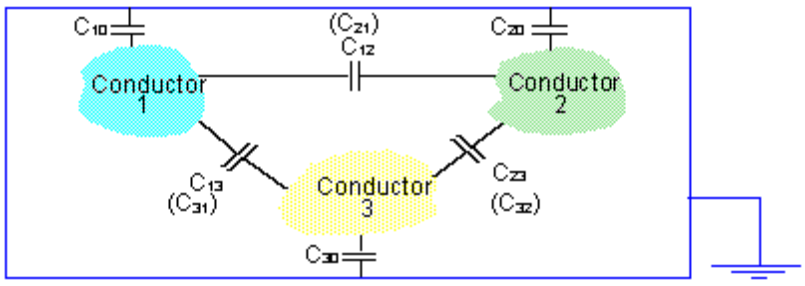
Capacitance in Terms of Charge and Voltage

A capacitance matrix represents the charge coupling within a group of conductors - that is, the relationship between their charges and voltages. Given a ground reference for the three conductors below, the net charge on each object is:

$$Q_1 = C_{10}V_1 + C_{12}(V_1 - V_2) + C_{13}(V_1 - V_3)$$

$$Q_2 = C_{20}V_2 + C_{21}(V_2 - V_1) + C_{23}(V_2 - V_3)$$

$$Q_3 = C_{30}V_3 + C_{31}(V_3 - V_1) + C_{32}(V_3 - V_2)$$



This can be expressed in matrix form as the following:

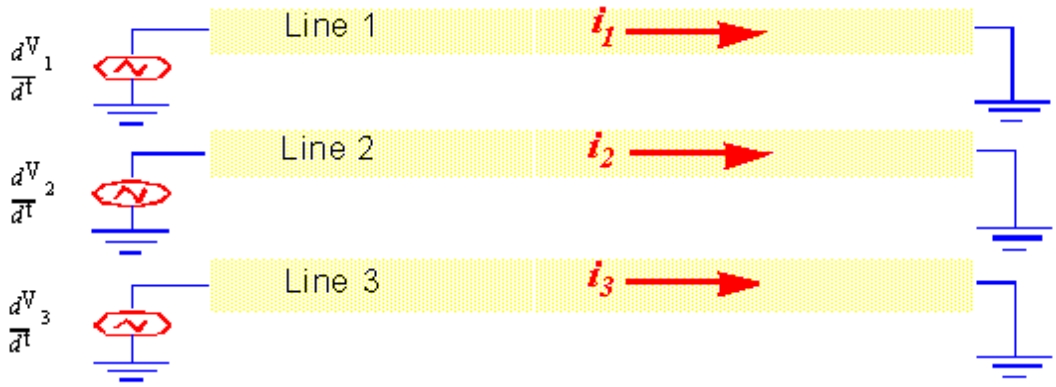
$$\begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} & -C_{12} & -C_{13} \\ -C_{12} & C_{20}+C_{12}+C_{23} & -C_{23} \\ -C_{13} & -C_{23} & C_{30}+C_{13}+C_{23} \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \\ V_3 \end{bmatrix}$$

The capacitance matrix above gives the relationship between Q and V for the three conductors and ground. An n-conductor device would have an n x n capacitance matrix.

Capacitance in Terms of Current and Time Varying Voltage

A capacitance matrix can also represent the relationship between currents and time varying voltages in a system of conductors. Given the three transmission lines shown below, the currents caused by the time varying voltage source on each line are given by the following equation:

$$\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} = \begin{bmatrix} C_{10}+C_{12}+C_{13} & -C_{12} & -C_{13} \\ -C_{12} & C_{20}+C_{12}+C_{23} & -C_{23} \\ -C_{13} & -C_{23} & C_{30}+C_{13}+C_{23} \end{bmatrix} \begin{bmatrix} \frac{dV_1}{dt} \\ \frac{dV_2}{dt} \\ \frac{dV_3}{dt} \end{bmatrix}$$



If dV_2/dt and dV_3/dt are set to zero, this relationship becomes the following:

$$\begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix} = [C] \begin{bmatrix} \frac{dV_1}{dt} \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} C_{10} + C_{12} + C_{13} \\ -C_{12} \\ -C_{13} \end{bmatrix} \frac{dV_1}{dt}$$

This gives the currents that are induced on Line 2 and Line 3 when a time varying voltage source is applied to Line 1 - that is, the capacitive coupling between the three lines, or the short circuit capacitance.

The capacitance matrix can be exported to a circuit/system simulator, such as Twin Builder, where it can be used in a transient simulation.

Matrix Elements for an Electric Field Solution

If one volt is applied to Conductor 1 and zero volts are applied to the other two conductors, the capacitance matrix becomes the following:

$$\begin{bmatrix} Q_1 \\ Q_2 \\ Q_3 \end{bmatrix} = [C] \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} C_{10} + C_{12} + C_{13} \\ -C_{12} \\ -C_{13} \end{bmatrix}$$

Diagonal Elements for an Electric Field Solution

These terms (such as C_{11}) are the sum of all capacitances from one conductor to all other conductors. These terms represent the self-capacitance of the conductors. Each is numerically equal to the charge on a conductor when one volt is applied to that conductor and the other conductors (including ground) are set to zero volts. For instance, $C_{11} = C_{10} + C_{12} + C_{13}$. This term is equal to the charge on Conductor 1 when it is set to one volt and the other conductors are set to zero volts.

Off-Diagonal Elements for a Capacitance Matrix

The terms in each column (such as C_{12} , C_{13}) are numerically equal to the charges induced on other conductors in the system when one volt is applied to a single conductor. For instance, in column one of the capacitance matrix shown above, C_{12} is equal to - C_{12}. This is equal to the charge induced on Conductor 2 when one volt is applied to Conductor 1 and zero volts are applied to Conductor 2.

The off-diagonal terms are simply the negative values of the capacitances between the corresponding conductors (the mutual capacitances). In column one of the example capacitance matrix, the off-diagonal terms represent the capacitances between Conductor 1 and the other two conductors; in column two, the terms represent the capacitance between Conductor 2 and the other conductors; and so forth.

Symmetry for a Capacitance Matrix

The capacitance matrix is symmetric about the diagonal. This indicates that the mutual effects between any two objects are identical. For instance, C_{13}, the capacitance between Conductor 1 and Conductor 3 (C_{13}), is equal to C_{31}, the capacitance between Conductor 3 and Conductor 1.

Solution Process for a Capacitance Matrix

To solve for the capacitance matrix, the electrostatic solver generates a single field solution. The system computes each entry of the capacitance matrix using the following relationship:

$$C = \int E \bullet D d\Omega$$

where the contributions of each conductor to the capacitance matrix are modeled using numerical matrix manipulation techniques.

$$D = \varepsilon E$$

Only conductors with voltage excitations can be included in a capacitance matrix calculation.

Lumped Capacitance

Lumped capacitance is essentially the result of a 1x1 capacitance matrix. It is used to calculate the electric field energy, U, from the E-field and D-field. Since the energy can also be expressed as:

$$U = \frac{1}{2} C V^2$$

the capacitance is:

$$C = \frac{2U}{V^2}$$

Maxwell assumes that the problem is set up so that the following is true:

- One conductor (or group of conductors) is set to +1 volt.
- Another conductor (or group of conductors) is set to zero volts.
- All other conductors are floating.

Therefore, the lumped capacitance between all conductors set to one volt and all those set to zero volts is simply 2U.

Warning	The lumped capacitance computation, as described above, is invalid if you assigned voltages other than +1V or 0V to the conductors in your model.

Note	For cases where a matrix extraction is desired in Maxwell, the respective extraction needs to be compatible with the hypothesis made regarding the equipotentiality of the respective surfaces, lack of radiation, etc., characteristic to a low frequency circuit

	approximation. In the circuit representation, the respective lumped elements are interconnected with other circuit elements at the nodes that physically represent the "terminals" in the electromagnetic field problem. Thus, it is possible (within the limits of the lumped circuit elements and applicable theory) to have circuit elements with field effects, such as capacitors and inductors, capable of storing energy. You can access these elements through the provided terminals/nodes, which can then be viewed as energy ports since most of the extracted elements have the capability to store energy. The volume charge density excitation is not a "terminal" type of excitation since the objects to which it is applied cannot, as a rule, be considered equipotential.

Conductance Matrix for a 3D DC Conduction Solution

The Maxwell 3D conductance matrix relates the currents and the voltages as:

$$\begin{bmatrix} I_1 \\ I_2 \\ \cdots \\ I_n \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} & \cdots & G_{1n} \\ G_{21} & G_{22} & ... & G_{2n} \\ ... & ... & ... & ... \\ G_{n1} & G_{n2} & ... & G_{nn} \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \\ \cdots \\ V_n \end{bmatrix}$$

Or in more concise form:

$$I = GV$$

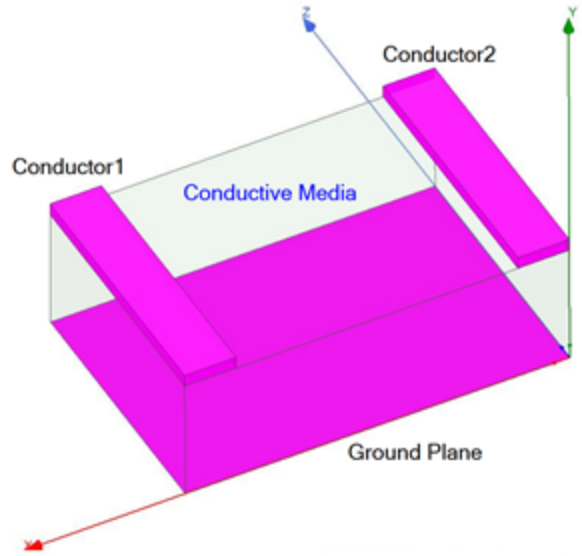
where:

- I is conduction current
- G is conductance
- V is voltage

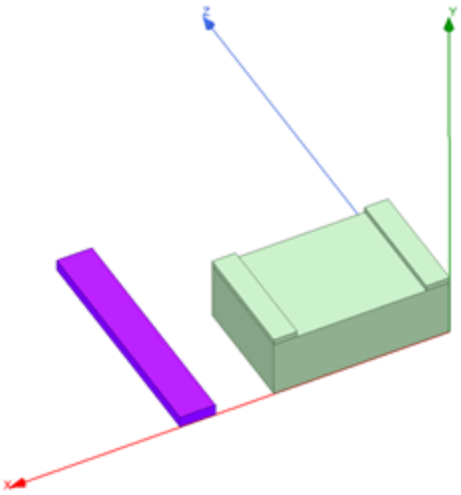
For a simple two conductor system with a ground plane (V=0), where there are conductive media in the middle. Referring to the figure below, the current flowing through **Conductor1** and **Conductor2**, I1 and I2, are related to their voltages V1 and V2 as:

$I_1=G_{11}*V_1+G_{12}*V_2$

$I_2=G_{21}*V_1+G_{22}*V_2$



Maxwell 3D can also handle designs that have disconnected conducting regions (multiple singly-connected regions).



The relationship between the Maxwell conductance matrix G^M and the Spice conductance matrix G^S is:

a. $G^M_{i,i} = G^S_{i,1} + G^S_{i,2} + G^S_{i,3} + \ldots + G^S_{i,n}$ (i=1,2,…,n)

b. $G^M_{i,j} = - G^S_{i,j}$ (for i not equal to j)

A ground reference is needed for extracting this matrix. For the Maxwell 3D DC conduction solver, the “sink” excitation, which can be assigned only to surfaces, will be treated as ground. If there is no sink excitation, you must explicitly choose at least one "ground" from the list of voltage excitations in the parameter matrix dialog box.

In the conductance matrix extraction, if there are n “signals” (which can be associated with 3D volume body or 2D sheet body), each one of the n signal ports will be excited with 1 volt while leaving the other signal ports at 0 volt (the ground will be kept at 0voltage). After calculating the solutions for the excitation settings, losses are computed using the entries of the Maxwell conductance matrix G^M.

Lorentz Force for an Electrostatic Calculation

The component of the Lorentz force due to current in an electric field is:

$$\boldsymbol{F} = \int_{Vol} q\boldsymbol{E}\, dVol$$

where:

- q is the charge.
- $\boldsymbol{E}$ is the electric field.

Warning	The Lorentz force does not compute the correct force on objects that are assigned materials with a relative permittivity greater than one. To find the force on these objects, use virtual force.

Lorentz Torque for an Electrostatic Calculation

The system uses Lorentz forces to compute the torque around the x, y, and z axes. The Lorentz torque is given by the following equation:

$$\bar{\boldsymbol{T}} = \int_{Vol} q(\bar{r} \times \bar{\boldsymbol{E}})dVol$$

where:

- $\boldsymbol{r}$ is the displacement vector from the axis of rotation.
- q is the charge.
- $\boldsymbol{E}$ is the electric field.

This integral is computed for the x-, y-, and z-axes, giving the net torque on the object(s) about each axis of rotation.

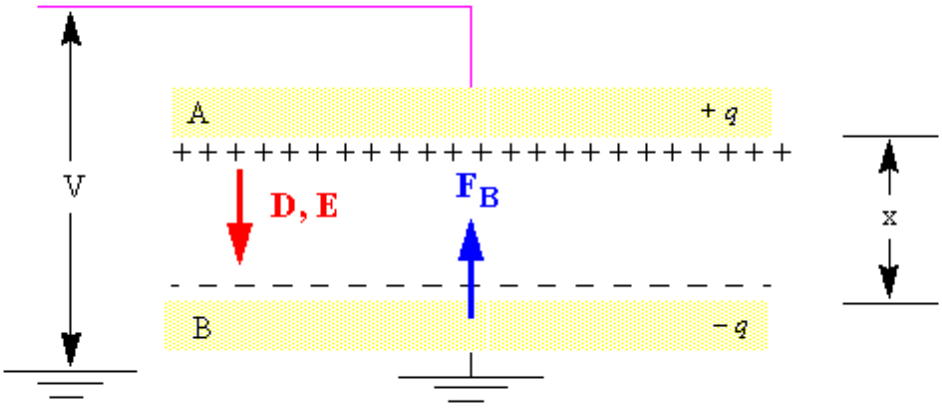
Warning	The Lorentz torque does not compute the correct torque on objects that are assigned materials with a relative permeability greater than one. To find the torque on these objects, use virtual torque.

Virtual Force for an Electrostatic Calculation

To compute the virtual force on an object, the electrostatic field simulator uses the principle of virtual work. In the structure shown below, the force on the bottom plate (plate B) in the direction of the displacement, x, is given by the following relationship:

$$\boldsymbol{F}_B = \left.\frac{dU(v,x)}{dx}\right|_{V = ConstantPotential}$$

where U is the electric field energy.



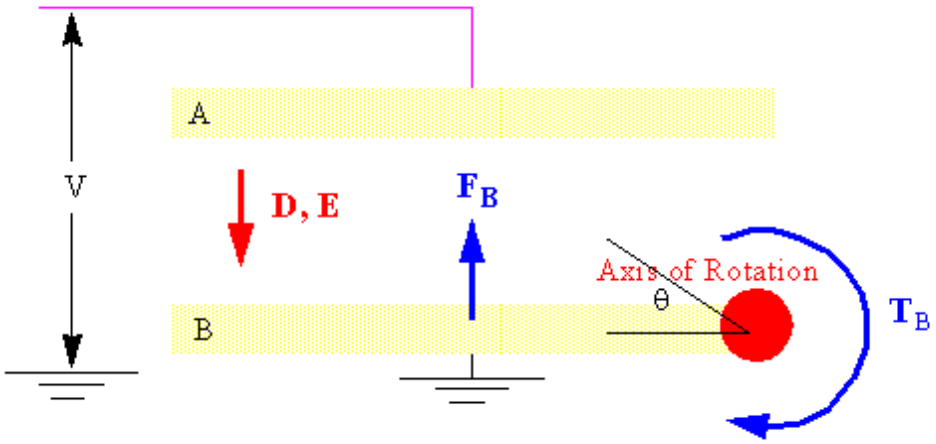
Unlike the classical virtual work method, the plate is not actually moved during the numerical process of the force computation. Instead, only the tetrahedra that lie along the outside surface of the object are virtually distorted. U and its derivative, *dU/dx*, are calculated from a single field solution using finite element interpolation functions.

Virtual Torque for an Electrostatic Calculation

Similar to the virtual force calculation, the system uses virtual work principles to compute the torque on an object. In the structure shown below, the virtual torque on the bottom plate (plate B) about the axis of rotation is given by the following relationship:

$$\boldsymbol{T}_B = \left.\frac{dU(v,\theta)}{d\theta}\right|_{V = ConstantPotential}$$

where U is the electric field energy.



Unlike the classical virtual work method, the plate is not actually rotated during the numerical process of the torque computation. Instead, only the tetrahedra that lie along the outside surface of the object are virtually distorted. U and its derivative, *dU/dθ*, are calculated from a single field solution using finite element interpolation functions.

Ohmic Loss for DC Conduction

The Ohmic loss, *P*, that is generated in conductors when solving DC current flow problems, is given by the following equation:

$$P = \int_{Vol} (\vec{E} \cdot \vec{J}) dVol$$

where

$\vec{E}$

- is the electric field.

$\vec{J}$

- is the electric current density.

For the sake of brevity, the ohmic loss density in the post processor should be labeled as **Ohmic Loss**. The total ohmic loss of an object or the whole arrangement can be calculated by integrating over a proper volume in the Field Calculator.

Surface Charge Density

The Surface Charge Density, ρ_s, that is generated on a surface between two materials when solving electric field problems, is given by the following equation:

$$n \cdot (D_2 - D_1) = \rho_s$$

$$n \cdot (\varepsilon_2 E_2 - \varepsilon_1 E_1) = \rho_s$$

where

- E_1 is the electric field and ε_1 the permittivity in the material on one side of the boundary.
- E_2 is the electric field and ε_2 the permittivity in the material on the opposite side of the boundary.
- n in the normal vector of the surface.

To calculate the surface charge, you must first select a surface in the modeling window.

Surface Current Density

For impedance boundary, the Surface Current Density, *Jsurf*, is computed as the cross product of the surface normal of the impedance boundary and the difference between H fields on the top and bottom of the boundary., and is given by the following equation:

$$Jsurf = n \times (H_{top} - H_{bottom})$$

where

- n is the surface normal vector.
- $(H_{top} - H_{bottom})$ is the difference between H fields on the top and bottom of the impedance boundary.

In order to calculate the surface current density, you must first select a surface in the modeling window.

Magnetostatic Field Calculation

In a **magnetostatic solution**, the magnetic field is produced by DC currents flowing in conductors/coils and by permanent magnets. The electric field is restricted to the objects modeled as real (non-ideal) conductors. The electric field existing inside the conductors as a consequence of the DC current flow is totally decoupled from the magnetic field. Thus, as far as magnetic material properties are concerned, the distribution of the magnetic field is influenced by the spatial distribution of the permeability. There are no time variation effects included in a magnetostatic solution, and objects are considered to be stationary. The energy transformation occurring in connection with a magnetostatic solution is only due to the ohmic losses associated with the currents flowing in real conductors.

The magnetostatic field solution verifies the following two Maxwell's equations:

$$\nabla \times \vec{H} = \vec{J}$$

$$\nabla \cdot \vec{B} = 0$$

with the following constitutive (material) relationship being also applicable:

$$\vec{B} = \mu_0(\vec{H} + \vec{M}) = \mu_0 \cdot \mu_r \cdot \vec{H} + \mu_0 \cdot \vec{M}_p$$

where:

$\vec{H}(x,y,z)$

- is the magnetic field strength.

$\vec{B}(x,y,z)$

- is the magnetic flux density.

$\vec{J}(x,y,z)$

- is the conduction current density.

$\vec{M}_p(x,y,z)$

- is the permanent magnetization.

$\mu_0 = 4 \cdot \pi \cdot 10^{-7}\ H/m$

- is the permeability of vacuum.

μ_r

- is the relative permeability.

For nonlinear materials, the dependency between the H and B fields is nonlinear and can be isotropic or orthotropic (in the case of anisotropic material behavior, μ_r is a tensor). Similarly, for permanent magnets, nonlinearity can occur in practical cases and is allowed. Additionally, if a demagnetized condition is to be taken into account for (nonlinear) permanent magnets operating below the knee, Maxwell provides an advanced setup option allowing a solution based on a previously computed demagnetization operating point. If nonlinearity occurs in soft materials (with negligible hysteresis) simultaneously with orthotropic behavior, Maxwell requires that the BH curves for the principal directions in the respective material(s) be provided. From these curves, the energy dependency on H is extracted for each of the respective principal directions and is used in the process of obtaining the nonlinear permeability tensor used in the Newton-Raphson iterative solution process:

$$\vec{B} = \vec{B}_0 + [\tilde{\mu}] \cdot (\vec{H} - \vec{H}_0)$$

$$[\tilde{\mu}] = \frac{\partial \vec{B}}{\partial \vec{H}} = [\Delta\tilde{\mu}] + [\mu]$$

where $\vec{B}_0$ and $\vec{H}_0$ are the previous field solution, $[\Delta\tilde{\mu}]$ is a general full tensor, and $[\mu]$ is given by the following:

$$[\mu] = \begin{bmatrix} \mu_x & & \\ & \mu_y & \\ & & \mu_z \end{bmatrix}$$

μ_x, μ_y, μ_z with taking into account the anisotropic effects of any laminations present in the model.

The 3D magnetostatic solver considers the magnetic field H with the following components:

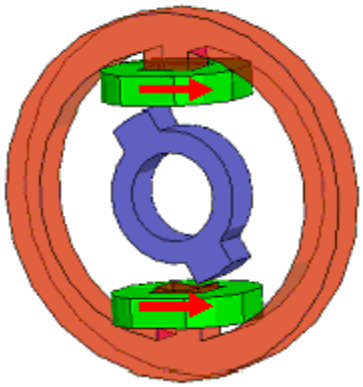
$$\vec{H} = \vec{H}_p + \nabla\varphi + \vec{H}_c$$

where φ is the magnetic scalar potential, $\vec{H}_p$ is a particular solution constructed by assigning values to all the edges in the mesh in such a way that Ampere's law holds on all contours of all tetrahedra faces in the mesh, and $\vec{H}_c$ accounts for the permanent magnets if any. Thus, the DOFs are the nodal values of the magnetic scalar potential with ten values per tetrahedron at each of the four vertices and all six mid edge nodes, ensuring a quadratic approximation inside each finite element.

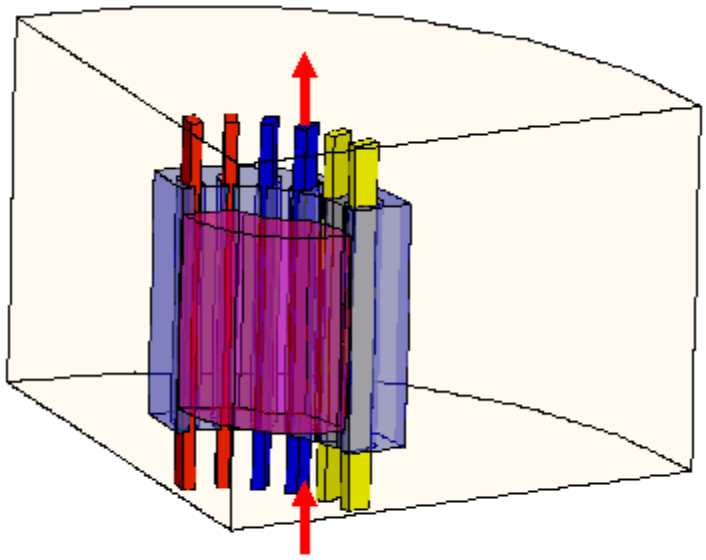
There are major advantages of this formulation over other existing ones, including using considerably fewer computational resources (due to the scalar nature of the DOFs), not requiring a gauge due to excellent numerical stability, significantly reducing cancellation errors, and capably of automatically multiplying connected iron regions. The magnetostatic solver handles both 3D linear and nonlinear problems. In the case of nonlinear applications, a classic Newton-Raphson iterative algorithm with user-controlled accuracy is used.

The magnetostatic solver calculates the magnetic field distribution produced by a combination of known DC current density vector distribution and a spatial distribution of objects with permanents magnetization. It is also possible to apply boundary conditions to a model such that the simulation of the immersion of a device into an external magnetic field is also possible. In this latter case, the boundary conditions should be applied in such a way that Maxwell's equations are not violated inside the domain of the solution or at the boundaries.

Typical sources for magnetostatic field problems include voltage, current, permanent magnetization, and current density. When applying the sources for the magnetic field problems, the applied current distribution must be divergence free in the entire space of the solution as it is physical for quasi-stationary conduction current density distributions. Thus, the conduction paths (s) for the applied current distributions must be closed when totally contained within the solution space for the problem, or must begin and end at the boundaries.



Conduction paths in the two coils are closed (one current excitation applied on terminals in each coil)



Current excitations are applied at the boundaries at both ends of conductors (no "terminals" need to be defined)

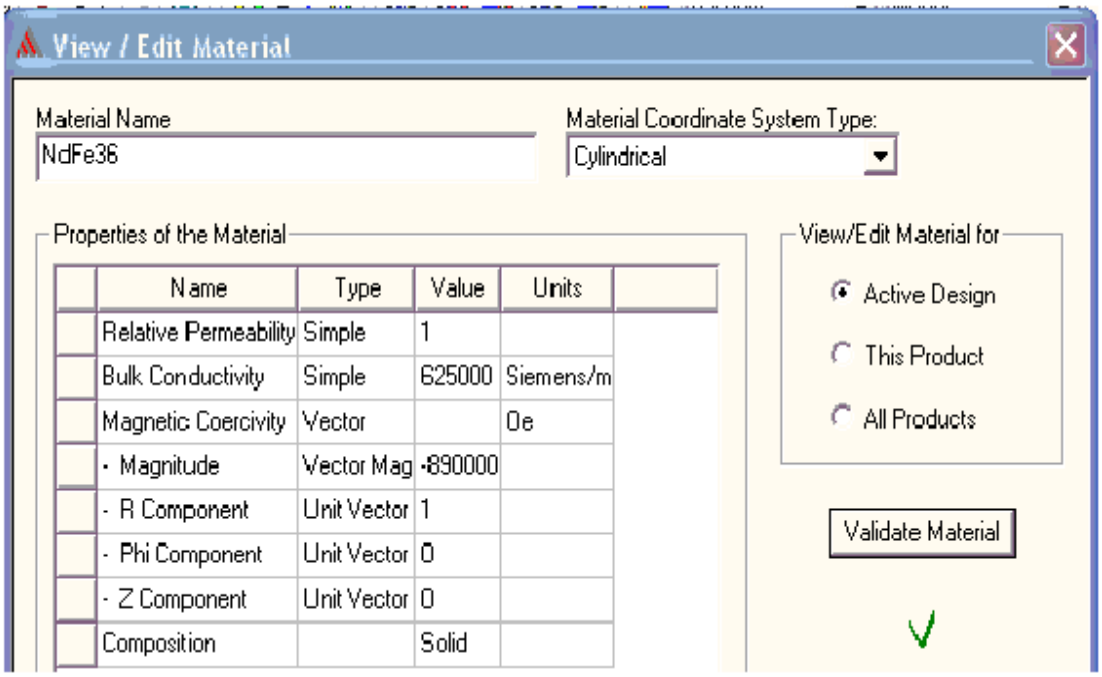
The total current applied to conductors that touch the boundaries does not require the existence of terminals at the ends where the current is applied because the respective planar surfaces of the conductors in the plane of the region (background) can be used to apply the excitations. In the case of a closed conduction path, a terminal (sheet object) must be created, matching the cross-section of the conductor at the desired location such that the excitation (current/voltage) can be applied.

Note	Current and voltage excitations cannot be mixed on any conduction path.

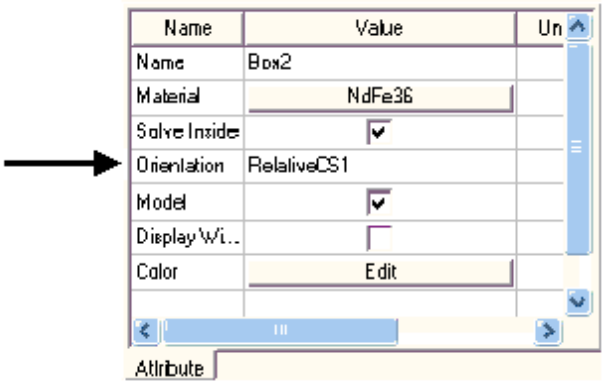
Voltage excitations (at least two) must be specified such that the current can flow in the respective conductors to form an uninterrupted conduction path. **Voltage drop** excitation should by used in the case of closed conduction paths (possibly containing objects with different electric conductivities), primarily in situations where the total current is unknown. One voltage drop excitation per conduction path should be applied. The total current for any conduction path should add up to zero.

The magnetostatic solver does not compute the electric field distribution associated with a voltage distribution outside conductors. However, the electric field inside conductors is indirectly available for post processing via the conduction current density distribution, which is available. Thus it is possible to calculate the ohmic loss in conductors with applied current or voltage excitations.

Permanent magnetization in Maxwell® is treated as a material property, but we mention it here because of its source characteristics.



Permanent magnetization can be specified in Cartesian, cylindrical, or spherical material coordinate systems, as shown in the above window where the R, Phi, and Z components (in a cylindrical system, considered here as example) can be specified in any meaningful combination. The actual direction of the vector property is decided when the property is assigned to the object and when the desired coordinate system is chosen (the global coordinate system always exists, while additional ones can be defined). If necessary, additional relative coordinate systems can be defined and used to specify the orientation of the vector property.



While the type of material coordinate system is embedded into the material definition, the actual orientation is not, such that a material property defined, for instance, in a cylindrical system can be applied to multiple objects with different orientations if multiple relative local coordinate systems were defined and used in the process of assigning the respective material property.

A **typical boundary conditions** used in magnetostatic problems is the **magnetic field tangent** (the default, natural boundary condition that is automatically applied on all surfaces of the problem space -the surfaces of the geometry entity containing the model inside it). This default boundary condition can be overwritten if other boundary conditions are applied on exterior surfaces of the solution space. The default boundary condition confines the magnetic field to the solution space; therefore, this boundary must be placed at some distance from the sources to avoid over-constraining the fields by placing the boundaries to close to the model objects. While it is difficult to provide "recipes" with general validity on the placement of the boundaries of problems, a good rule of thumb asserts that if a model can be imagined as being contained in a sphere of radius R, then the boundaries can be placed at a 4-5 radii R from the imaginary center of the model.

The **Zero Tangential H Field** allows the user to prescribe a normal (in average) field orientation on an arbitrary surface. This boundary condition does not require any further user input, meaning that no value and coordinate system specification are necessary.

In the case of **Tangential H Field** boundary condition, the values of two tangential components and a surface coordinate system must be defined and subsequently used in the assignment process of this boundary condition. This boundary condition is restricted to two kinds of surfaces: planar or cylindrical. The CS in the planar case would be a rectangular coordinate system with X and Y components of H in the plane. The coordinate system in the cylindrical case would be a coordinate system with a Z axis coinciding with the axis of the cylinder, and the two components to input would be the PHI and Z axis components of H.

In the case of the tangential H field, caution is advised: This boundary condition should be specified such that Ampere's theorem is not violated inside the field domain or at the boundaries.

Symmetry boundary conditions are used to solve problems with symmetry and, thus, allow the users to take advantage of the significantly reduced problem size for a given accuracy.

Symmetry boundary conditions can be one of two kinds:

- Odd (flux tangent)
- Even (Flux normal)

Although the use of this symmetry boundary condition overlaps with previous conditions to some extent, the symmetry boundary conditions should only be used in clear symmetry cases.

Symmetry for a Magnetostatic Field Solution

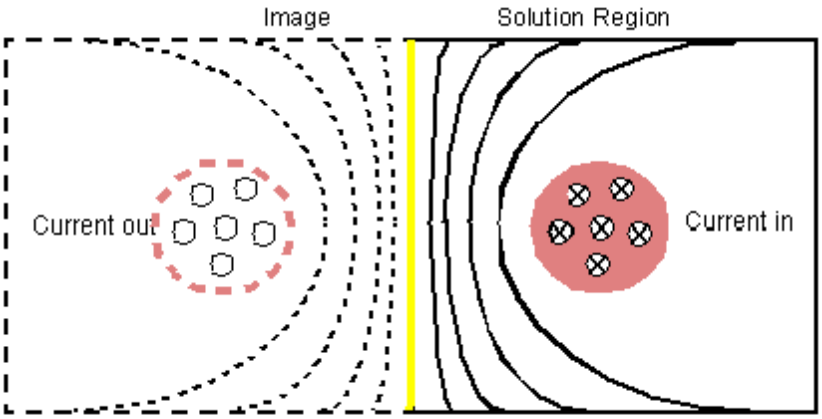
A Symmetry boundary models a plane of symmetry in a structure. Use this type of boundary condition to take advantage of geometric and magnetic symmetry in a structure. Doing so enables you to reduce the size of your model, which helps to conserve computing resources. Two types of symmetry are available:

- Odd Symmetry (Flux Tangential)
- Even Symmetry (Flux Normal)

These boundaries can only be assigned to the outside edges of the solution region.

Odd Symmetry (Flux Tangential) for a Magnetostatic Field Solution

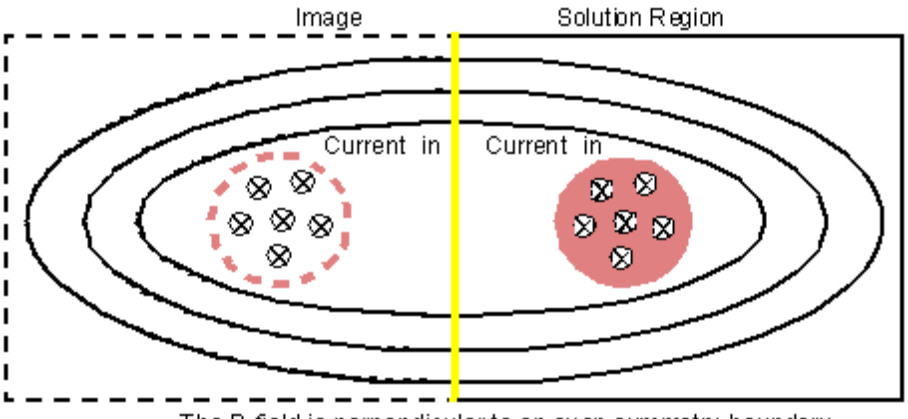
Use an odd symmetry boundary to model a plane of symmetry in which current on one side of a plane flows in the opposite direction to current on the other side of the plane. Magnetic flux is tangential to this type of boundary. To define an odd symmetry boundary, the simulator sets the selected edge to a Neumann boundary.



The B-field is tangential to an odd symmetry boundary.

Even Symmetry (Flux Normal) for a Magnetostatic Field Solution

Use an even symmetry boundary to define a plane of symmetry where the direction of current flow is the same on both sides of the plane. Magnetic flux is normal to this type of boundary. To define an even symmetry boundary, the simulator sets the selected edge to a Magnetic Field boundary with a field value of zero - acting as a magnetic mirror to the model.



The B-field is perpendicular to an even symmetry boundary.

Warning	When using even symmetry boundaries, be careful that you do not violate Ampere's

	law.

Matching Boundary for a Magnetostatic Field Solution

Matching boundaries allow you to model planes of periodicity where the H-field on one surface exactly matches the H-field on another. They force the magnetic field at each point on one surface (the "independent" boundary) to match the magnetic field at each corresponding point on the other surface (the "independent" boundary). They are very useful for modeling devices such as motors, in which the magnetic field repeats every 180^o, 120^o, 90^o, or less. Basically, they enable you to model the smallest possible periodic segment of the device - reducing the amount of computing resources needed during the solution.

To set up matching boundaries, you must create both an independent boundary and a dependent boundary. Unlike Symmetry boundaries, **H** does not have to be tangential or normal to these boundaries. The only condition is that the fields on the two boundaries must have the same magnitude and direction (or the same magnitude and opposite directions).

Independent Boundary for a Magnetostatic Field Solution

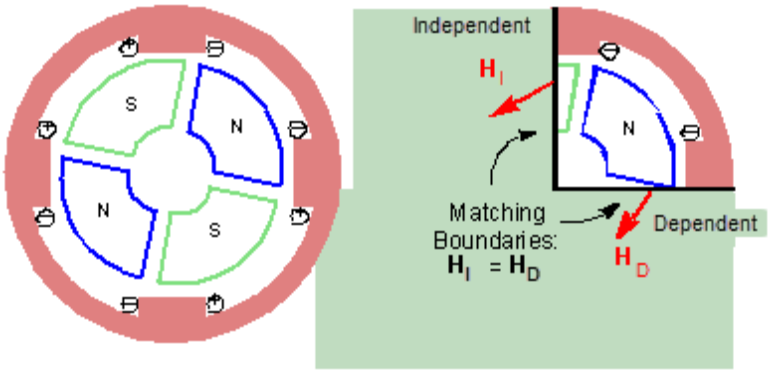
The simulator computes the magnetic field on an independent boundary using currents, permanent magnets, and magnetic fields as input. The field is then mapped to the dependent boundary.

Dependent Boundary for a Magnetostatic Field Solution

The magnetic field on the dependent boundary is forced to match the field on the independent boundary. The magnitude of the magnetic field on both boundaries is the same. However, the fields on the two boundaries can either point in the same direction, or in opposite directions, as specified by the user during setup.

When to Use Matching Boundaries for a Magnetostatic Field Solution

Matching boundaries enable you to take advantage of periodicity in a structure. For example, below is a diagram of the cross-section of a simple brushless DC motor. The field in such a motor repeats itself every 90 degrees; that is, the field pattern in one quarter of the motor matches the magnitude and direction (or the opposite of the direction) of the field pattern in the other three quarters. With matching boundaries, all you have to model is one quarter of the structure.

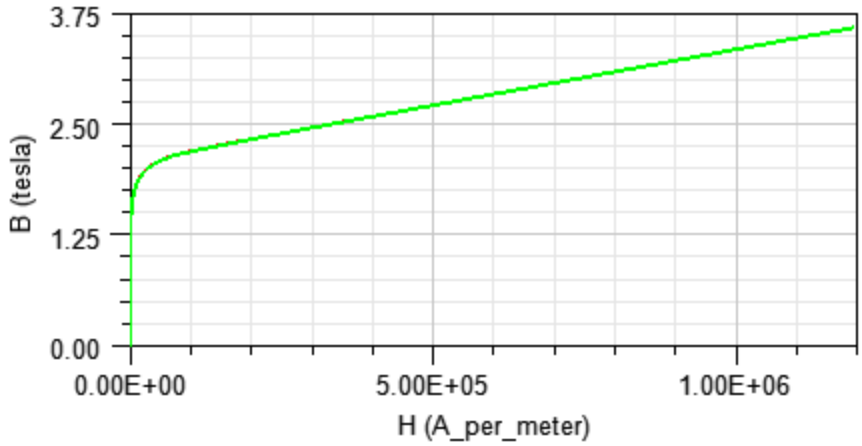


A Symmetry boundary cannot be used to simulate periodicity because the magnetic field is not necessarily either perpendicular or tangential to periodic surfaces. For example, in the quarter model shown on the right, the magnetic field is exactly perpendicular to the bounding surfaces only when the gap separating the permanent magnets is perfectly horizontal or vertical. For all other positions of the rotor, matching boundaries are required.

Nonlinear Materials

Magnetostatic

If a material has a permeability that varies with the flux density, a **B** vs. **H** curve (B-H curve) such as the one below is needed to describe the material's nonlinear behavior.



In nonlinear materials, the B-field (magnetic flux density) is a function of itself:

$$\boldsymbol{B} = \mu_r(B)\mu_o H$$

where $\mu_r(B)$, the relative permeability, depends on the magnitude of the B-field at each point in the material. Therefore, to model the magnetic behavior of the material, a curve relating the B-field directly to the H-field is used to describe the nonlinear relationship.

See also Advanced Nonlinear Options for Magnetostatic Solutions or Magnetization for Transient Solutions for more information about permeability and magnetization settings.

Solution Process for a Magnetostatic Field Solution

In general, the solution process involves a phase in which the distribution of current density (if not already known) is obtained, followed by the calculation of the distribution of magnetic field that corresponds to the distribution of the sources. In the case of solid conductors with an applied current source, an automatic process is initiated such that following an iterative process involving adaptive mesh refinement, the current density vector distribution is obtained and subsequently the corresponding magnetic field distribution is computed. In the case of stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments, or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

Magnetic Field Energy for a Magnetostatic Field Solution

The magnetic energy of a system is given by the following expressions. The expressions represent total values of energy for the volumes taken into account. Note that the integrals have simpler expressions if the material property of the object considered is a linear one. In case of linear material properties magnetic energy and co-energy values are identical (W = Wc).

- In linear materials, the energy is:

$$W = \frac{1}{2} \int_{Vol} \boldsymbol{B} \bullet \boldsymbol{H} \, dVol$$

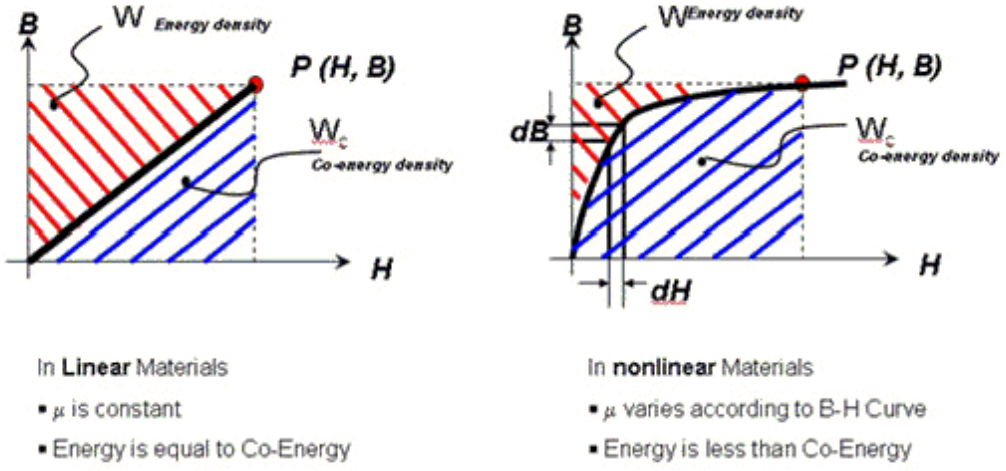
- In nonlinear materials, the energy is:

$$W = \int_{Vol} w \bullet dVol = \int_{Vol} \left(\int_{0}^{B} (\boldsymbol{H} \bullet d\boldsymbol{B}) \right) dVol$$

where:

- **H** is the magnetic field.
- **B** is the magnetic flux density.

The following figure represents graphically the definitions of both energy and co-energy densities. Note that both are local quantities (i.e. are function of X, Y, Z coordinates of the location in the model) and also depend on the operating point on the applicable B-H curve. Energy is equal to the area above the BH-curve, and coenergy is equal to the shaded blue area below the BH-curve.



For the sake of brevity, the magnetic flux density in the post processor should be labeled as **Magnetic Flux**. The total magnetic flux of an object or the whole arrangement can be calculated by integrating over a proper volume in the Field Calculator.

Magnetic Coenergy for a Magnetostatic Field Solution

The magnetic coenergy of a system is given by the following expressions. The expressions represent total values of co-energy for the volumes taken into account. Note that the integrals have simpler expressions if the material property of the object considered is a linear one. In case of linear material properties magnetic energy and co-energy values are identical (W = Wc).

- In linear materials, the coenergy is:

$$W_c = \frac{1}{2}\int_{Vol} \boldsymbol{B} \bullet \boldsymbol{H}\, dVol$$

- In nonlinear materials, the coenergy is:

$$W_c = \int_{Vol} w_c \bullet dVol = \int_{Vol}\left(\int_0^H (\boldsymbol{B} \bullet d\boldsymbol{H})\right) dVol$$

where:

- **H** is the magnetic field.
- **B** is the magnetic flux density.

The coenergy is related to the magnetic field energy.

Note	In case permanent magnets are part of the model, as a rule, the magnetic energy reported by the solver and the post processor may be different. This occurs because the adaptive meshing part of the solution sequence runs a special computation so that it can avoid situations with a total zero energy of the field (problems with permanent magnets and no other excitation). To avoid such situations, the solver uses (and reports) the total energy, which includes the absolute value of the energy inside the permanent magnets. Because of this, the energy reported by the solver in these cases is greater than the energy reported by the post processor.

Magnetic Apparent Energy for a Magnetostatic Field Solution

The magnetic apparent energy of a system is given by the following expression:

$$W_A = \frac{1}{2} H_0 B_0$$

where:

- $\mathbf{H_0}$ is the magnetic field final operating point.
- $\mathbf{B_0}$ is the magnetic flux density final operating point .

Apparent energy is equal to the shaded area below.

Inductance Matrix for a Magnetostatic Field Solution

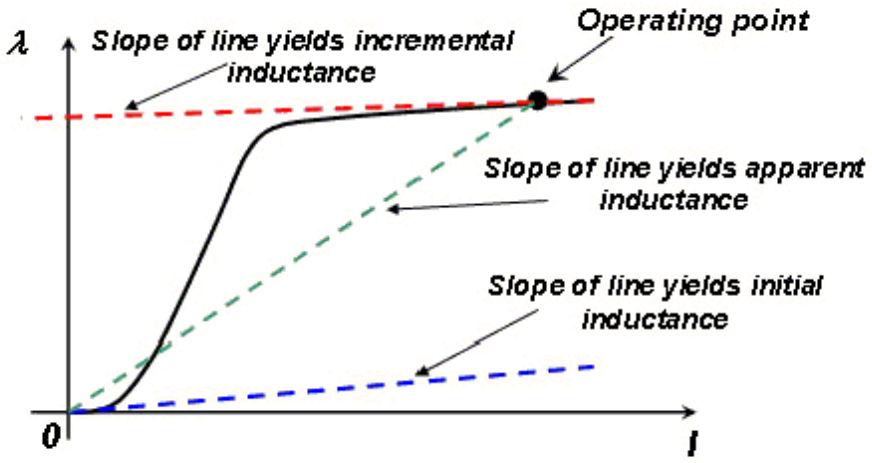
Inductance matrices can be expressed in terms of flux linkage and current, or in terms of voltage and time-varying current. Inductance values are given in henries.

Types of Inductance

For nonlinear materials, the definition of inductance requires additional detail compared to the linear case. Three commonly used inductance values are illustrated in the figure above - each inductance has useful applications. Maxwell uses apparent inductance to calculate flux linkage as a function of the independent variables, since it changes with current as the material properties change. To obtain apparent inductances for nonlinear materials in Maxwell, a two-step procedure is followed:

1. A nonlinear magnetostatic solution is generated with all sources at user specified values. This establishes a value of permeability that varies with each mesh element, since the degree of saturation varies throughout the device.
2. These self-consistent values are used in a linear solution for the inductance matrix, with each coil current set to one ampere. The resulting values are apparent inductances, which vary with each specified coil current operating point because the material properties change.

The inductance calculation is now linearized on the self-consistent values. If the coil currents had been increased to the specified values in the first step, in the linearized model, the resulting magnetic field would be identical to the nonlinear solution. Therefore, the inductances from the second step are the ratios of respective flux linkages to coil current, at the nonlinear operating point originally determined.



Nonlinear Inductance — Current vs. Flux Linkage

The slope of any line drawn on the figure above has units of inductance (henries) and any area enclosed on this plot represents units of energy in joules if magnetic flux is expressed in Webers and current is expressed in Amperes. The three inductances are defined as:

Incremental (differential)	The slope of a line tangent to the curve at the operating point. Incremental inductance is the usual textbook definition. For small signal AC analysis in

inductance $L_{inc} = \frac{d\lambda}{dI}$	Maxwell SPICE or Saber, incremental inductance is evaluated using an operating point determined from a DC solution. Incremental inductance can also be used in time domain system simulations by using the compensation theorem, but it has no useful relationship to stored energy.
Apparent inductance $L_{app} = \frac{\lambda}{I}$	The slope of a line from the origin to the operating point. Apparent inductance gives the total flux linkage as a function of current, so it is well-suited for the state equation or basis function approach to time domain simulations. For small-signal AC analysis, apparent inductance cannot be used directly, but can be used to supply the proper derivatives to Maxwell SPICE. Energy can be calculated with apparent inductance, but the result is not really the stored energy because it ignores the path taken along the nonlinear curve. Apparent inductance does not provide the actual stored energy at the specified operating point. However, during time domain simulations, apparent inductance varies with current, and tracks the nonlinear curve shown in the figure.
Initial inductance L_{init}	The slope of a line tangent to the curve at the origin. Initial inductance applies to many magnetic materials that have a "toe" in the magnetization curve. Laboratory measurements at 0 A DC measure initial inductance, not the "linear" value that may be somewhat higher. Note: Initial inductance is a particular case of the incremental inductance where the slope of the respective line passes through the origin of the (flux - current) plane.

For linear materials, all three inductance values are equal. For nonlinear materials, the three values are generally different. Except for initial inductance, each value varies with the operating point. Ignoring the "toe" of the curve, the relation Lapp > Linc holds. Energy taken from or supplied to the external circuit, as determined from the terminal voltage and current, will be correct.

The apparent inductance calculated by Maxwell at the actual operating point due to all sources in the model (currents in the coils but also permanent magnets) is the base of all inductance calculations. Incremental (differential) inductance information can be easily derived from the flux vs current characteristic.

It should be noted that the apparent value relates to the local frozen, current dependent absolute permeability as described above in the two step process. Incremental inductance relates to another physical quantity which is the differential (incremental) permeability defined as dB/dH.

Solver calculated magnetostatic energy (reported as part of the solution convergence data) is the apparent energy, always equal to the global, model-wise average between energy and co-energy. For the linear material case in the entire model there is only one value of the inductance L = L*init* = L*incr* = L*app*.

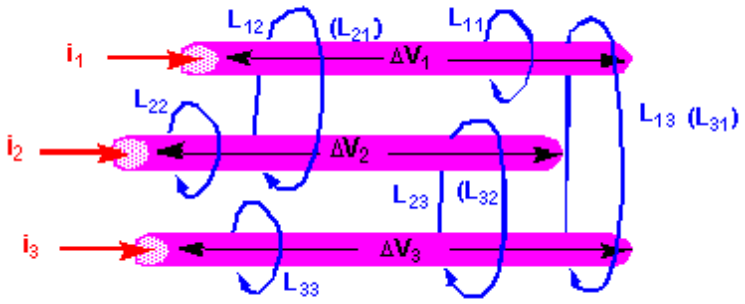
Inductance in Terms of Flux Linkage and Current

An inductance matrix represents the magnetic flux linkage between current loops. Given the three current loops below, the relationship between induced flux and currents is:

$$\lambda_1 = L_{11} i_1 + L_{12} i_2 + L_{13} i_3$$

$$\lambda_2 = L_{21} i_1 + L_{22} i_2 + L_{23} i_3$$

$$\lambda_3 = L_{31} i_1 + L_{32} i_2 + L_{33} i_3$$



This can be expressed in matrix form as:

$$\begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix} = \begin{bmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{bmatrix} \begin{bmatrix} i_1 \\ i_2 \\ i_3 \end{bmatrix}$$

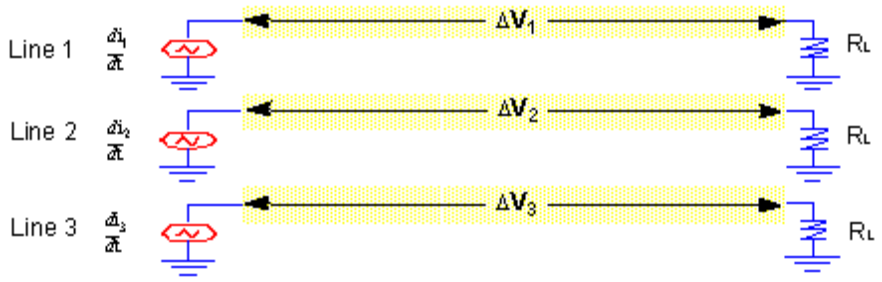
λ

The inductance matrix above gives the relationship between and i for the three independent current loops. A device with n current loops would have an n n inductance matrix.

Inductance in Terms of Voltage and Time-Varying Current

An inductance matrix can also represent the relationship between voltage and current fluctuations in a system. Given the three independent transmission lines shown below, the voltage changes caused by the time varying current source on each line are given by:

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \\ \Delta V_3 \end{bmatrix} = \begin{bmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{bmatrix} \begin{bmatrix} \frac{di_1}{dt} \\ \frac{di_2}{dt} \\ \frac{di_3}{dt} \end{bmatrix}$$



Δ

The inductance matrix above gives the relationship between V and dI/dt for the three transmission lines. If di_2/dt and di_3/dt are set to zero, this relationship becomes:

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \\ \Delta V_3 \end{bmatrix} = [L] \begin{bmatrix} \frac{di_1}{dt} \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} L_{11} \\ L_{12} \\ L_{13} \end{bmatrix} \frac{di_1}{dt}$$

This gives the voltage changes that are induced on Lines 2 and 3 when a time-varying current source is applied to Line 1 - that is, the inductive coupling between the three loops.

The inductance matrix can be exported to a circuit/system simulator, such as Twin Builder, where it can be used in a transient simulation.

Matrix Elements for an Inductance Matrix

If one amp is applied to Current Loop 1 and zero amps is applied to the other two loops, the inductance matrix becomes the following:

$$\begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \lambda_3 \end{bmatrix} = [L] \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} L_{11} \\ L_{12} \\ L_{13} \end{bmatrix}$$

Diagonal Elements for an Inductance Matrix

Terms such as L_{11} represent the self-inductance of each current loop. Self-inductance is numerically equal to the flux linkage in a current loop when one amp is flowing in it, and no current is flowing in the other loops. For example, L_{11} is equal to the flux in Current Loop 1 when one amp is flowing in that current loop, and no current is flowing in the other loops.

Off-Diagonal Elements for an Inductance Matrix

Terms such as L_{12} and L_{13} represent the mutual inductances between the current loops. Mutual inductance is numerically equal to the flux linkage in a current loop when one amp is flowing through another loop, and no current is flowing anywhere else. For example, L_{12} is equal to the flux linkage in Loop 1 when one amp is applied to Loop 2 and no current is flowing in the other loops.

Symmetry for an Inductance Matrix

The inductance matrix is symmetric about the diagonal. This indicates that the mutual effects between any two loops are identical. For instance, L_{13}, the inductance between Current Loop 1 and Current Loop 3, is equal to the inductance between Current Loop 3 and Current Loop 1.

Solution Process for an Inductance Matrix

To solve for the inductance matrix, the magnetostatic solver generates a single field solution. The system computes each entry of the inductance matrix using the following relationships:

$$U = \frac{1}{2}LI^2 = \frac{1}{2}\int H \bullet B d\Omega$$

But, assuming that the current, i, is one ampere:

$$L = \int H \bullet B d\Omega$$

where:

$$B = \mu H$$

Each conductor in the matrix is assumed to be part of an independent current loop. The contributions of each loop to the inductance matrix are modeled using numerical matrix manipulation techniques.

Warning	Inductance is valid for different current levels in linear and nonlinear models: • In models containing only linear materials, the system assumes that one amp of current flows through each loop. The inductance matrix that is computed for these models is valid for all current levels. • In models containing nonlinear materials, the system uses the currents you specified when setting up boundaries and sources. The inductance matrix that is computed for these models is valid only for these current levels.

Grouping Inductance Matrix Elements

The results of the inductance matrix calculation may be post processed into series/parallel windings using the grouping function. The operations of the grouping function can be one of two cases:

- Grouping all coils in series connection by grouping into 1 branch
- Grouping in a mixed series/parallel combination by setting the number of branches to a value of 2 or more.

Series Grouping

The inductances of the coils can be calculated as follows:

$$Lcoil_i = L_i \cdot n_i^2$$

Where $\mathbf{L_i}$ is the per-turn inductance of the source calculated by the field solver and $\mathbf{n_i}$ is the number of turns specified in the grouping dialog box. Combining inductors in series, which is the case when the number of branches is set to 1, is done according to:

$$L_{seriesgroup} = \sum_{i=1}^{m} Lcoil_i + \sum_{\substack{i,j=1 \\ i \neq j}}^{m} M_{ij} \cdot n_i \cdot n_j + \sum_{\substack{i,j=1 \\ i \neq j}}^{m} M_{ji} \cdot n_i \cdot n_j$$

where:

- *m* is the number of source entries being grouped.
- $Lcoil_i$ represents the self inductance term for each coil entry to be grouped according to the equation above.
- *Mij* and *Mji* are the mutual inductance terms between the sources being grouped. *Mij* and *Mji* must generally be considered separately as the matrix may be unsymmetric.
- n_i are the number of turns for each coil in the group.

Parallel Branches

If the number branches in the group is set to a value other than 1, the coils are first grouped in series as described above, and then divided into by the number if branches specified.

The grouped inductance is then calculated as follows:

$$L_{branch} = \frac{L_{seriesgroup}}{k^2}$$

Where *k* is the number of branches set for the group.

The calculation above only relies on the inductance matrix calculated during the field solution and can therefore be manipulated as a post processing calculation.

Lorentz Force

The component of the Lorentz force due to current in a magnetic field is:

$$\boldsymbol{F} = \int_{Vol} \boldsymbol{J} \times \boldsymbol{B}\, dVol$$

where:

- ***J*** is the current density.
- ***B*** is the magnetic flux density.

Note	The Lorentz force does not compute the correct force on objects that are assigned materials with a relative permeability greater than one (that is, materials where $\mu \neq \mu_0$). To find the force on these objects, use virtual force.

Note: For PCB applications, the parameter force calculated by using virtual force is not accurate if the mesh in air gaps between two layers is not fine enough. It is strongly recommended to compute parameter forces on conducting objects by using the Lorentz force option.

Lorentz Torque

The system uses Lorentz forces to compute the torque around the x-, y-, and z-axes. The Lorentz torque is given by the following equation:

$$\boldsymbol{T} = \int_{Vol} \boldsymbol{r} \times (\boldsymbol{J} \times \boldsymbol{B}) dVol$$

where:

- $\boldsymbol{r}$ is the displacement vector from the axis of rotation.
- $\boldsymbol{J}$ is the current density.
- $\boldsymbol{B}$ is the magnetic flux density.

This integral is computed for the x-, y-, and z-axes, giving the net torque on the object(s) about each axis of rotation.

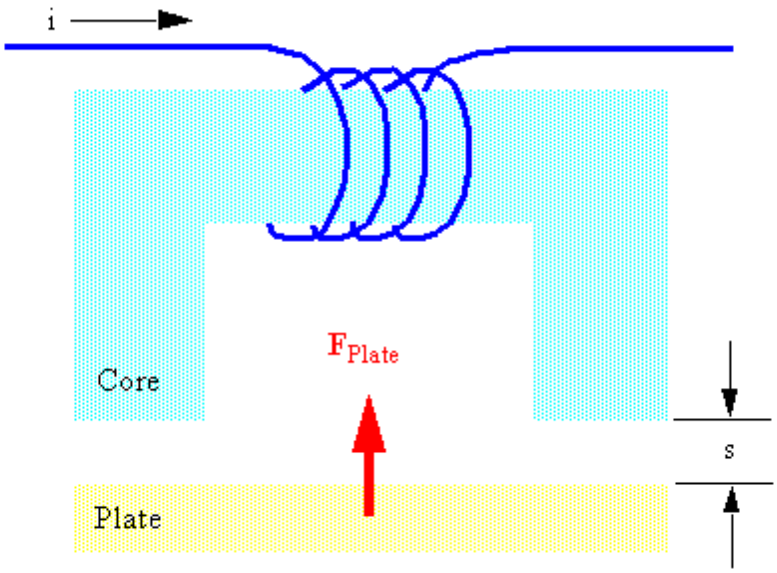
Note	The Lorentz torque does not compute the correct torque on objects that are assigned materials with a relative permeability greater than one (that is, materials where $\mu \neq \mu_0$). To find the torque on these objects, use virtual torque.

Virtual Force

To compute the virtual force on an object, the system uses the principle of virtual work. In the structure shown below, the force on the plate in the direction of the displacement, s, is given by the following relationship:

$$\boldsymbol{F}_{plate} = \left. \frac{dW(s,i)}{ds} \right|_{i = Constant}$$

where W(s,i) is the magnetic coenergy of the system. The current, i, is held constant.



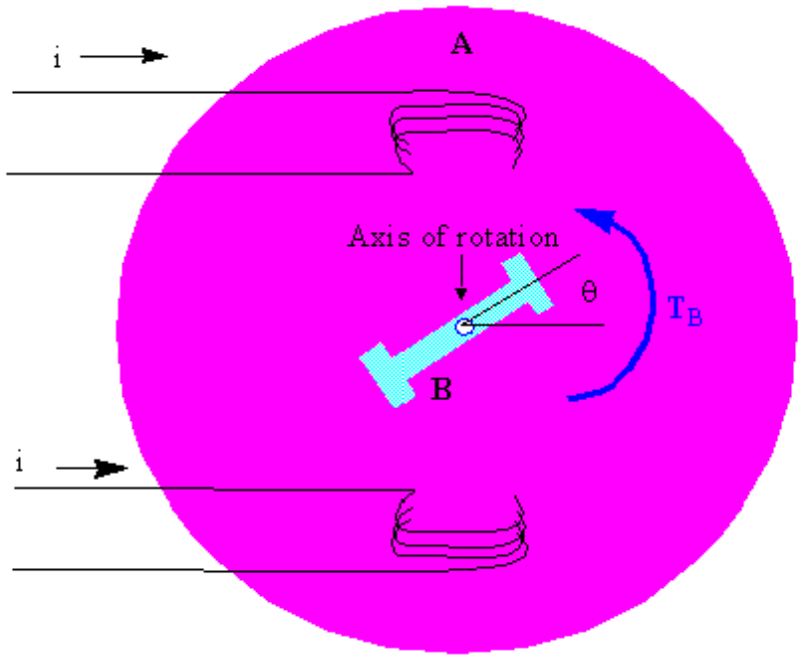
Unlike the classical virtual work method, the plate is not actually moved during the force computation. Instead, only the tetrahedra that lie along the outside surface of the object are virtually distorted. Thus, the force computation only requires one field solution.

Virtual Torque

Similar to the virtual force calculation, the system uses virtual work principles to compute the torque on an object. In the structure shown below, the torque on Object B about the axis of rotation is given by the following relationship:

$$T_B = \left. \frac{dW(\theta, i)}{d\theta} \right|_{i = Constant}$$

where W(θ, i) is the magnetic coenergy of the system. The current, i, is held constant.



Unlike the classical virtual work method, Object B is not actually rotated during the force computation. Instead, only the tetrahedra that lie along the outside surface of the object are virtually distorted. Thus, the change in the system's coenergy (and therefore the virtual torque) is given by the change in the coenergy of these tetrahedra.

Frequency Domain (Eddy Current) Solver

$\vec{T}-\Omega$

The **3D eddy current solver (frequency domain or harmonic solver)** uses the formulation. It is based on the assumption that all electromagnetic fields pulsate with the same frequency (specified by the user) and have magnitudes and initial phase angles calculated by Maxwell. There are no moving objects (velocity is zero everywhere). Permanent magnets cannot be part of the model, and all materials are assumed to be linear theoretically. For designs with nonlinear materials, analysis is based on the fundamental components of B and H at a specified frequency as a proximation. See Nonlinear eddy field simulation for more information.

Electromagnetic radiation can also be simulated.

In the non-conducting regions the magnetic field strength is given by the following equation:

$$\vec{H} = \vec{H}_p + \nabla\Omega$$

using node element with the same quadratic approximation as for the case of the magnetostatic solver.

In regions with non-zero conductivity where eddy current calculation has been set up, the following equation is true:

$$\vec{H} = \vec{H}_p + \nabla\Omega + \vec{T}$$

where

$\vec{T}$

is the electric vector potential calculated using edge elements. At the interface between conductors and non-conductors the tangential component of the electric vector potential is constrained to zero.

The quantity calculated by Maxwell is in this case the magnetic field H(x,y,z).

For eddy current problems, typical sources associated with non-winding excitation are Current and Current Density; typical sources associated with winding excitation are Current and Voltage. In applying the sources for the magnetic field problems, keep in mind that the applied current distribution must be divergence free in the entire space of the solution as it is physical for (quasi) stationary conduction current density distributions. Thus, the conduction paths(s) for the applied current distributions must be closed when totally contained within the solution space for the problem or must begin and end at the boundaries. The total current applied to conductors that touch the boundaries doesn't require the existence of terminals at the ends where the current is applied, the respective planar surfaces of the conductors in the plane of the region (background) can be used to apply the excitations.

Typical boundary conditions used in eddy current problems include **magnetic field tangent** (the default, natural boundary condition which is automatically applied on all surfaces of the problem space -the surfaces of the geometry entity containing the model inside it). This default boundary condition can be overwritten if other boundary conditions are applied on exterior surfaces of the solution space. The default boundary condition confines the magnetic field to the solution space and thus this boundary must be placed at some distance from the sources of the problem to avoid over-constraining the fields by placing the boundaries to close to the model objects. While it is difficult to provide "recipes" with general validity on the placement of the boundaries of problems, a good rule of thumb says that if a model can be imagined as being contained in a sphere of radius R, the boundaries can be placed at a 4-5 radii R from the imaginary center of the model.

The **Zero Tangential H Field** allows you to prescribe a normal (in average) magnetic field orientation on an arbitrary surface. This boundary condition does not require any further user input, that is, no value and coordinate system specification are necessary.

In the case of **Tangential H Field** boundary condition the values of two tangential complex components (real and imaginary) and a surface coordinate system have to be defined and subsequently used in the assignment process of this boundary condition. This boundary condition

is restricted to two kinds of surfaces: planar or cylindrical. The CS in the planar case would be a rectangular coordinate system with X and Y components of H in the plane. The coordinate system in the cylindrical case would be a coordinate system with a Z axis coinciding with the axis of the cylinder and the two components to input would be the PHI and Z axis components of H.

In the case of the tangential H field caution is advised: this boundary condition should be specified such that Ampere's theorem is not violated inside the field domain or at the boundaries. This boundary condition is very useful to simulate the behavior of devices "immersed" in an electromagnetic filed of desired magnitude and orientation.

Symmetry boundary conditions are used to solve problems with symmetry and thus allows the users to take advantage of the significant reduction of the problem size for a given accuracy. Symmetry boundary conditions are of two kinds, **Odd (flux tangent)** or **Even (Flux normal)**. Although the use of this symmetry boundary condition overlaps with previous conditions to some extent, the symmetry boundary conditions should only be used in clear symmetry cases.

The **Insulating** boundary condition is of particular use for applications where very thin insulating layers are impractical to model due for example to high aspect ratio geometries that would be generated and associated meshing difficulties. Thus insulating boundary condition can be assigned to surfaces of separation between conductors. Another remarkable situation where such a boundary condition proves to be extremely useful is in modeling faults in conductors (cracks for example). Thus, modeling 2D (sheet) objects at the location of the respective cracks and applying the insulation boundary condition proves to be a very effective way of modeling the flaws without having to generate 3D cracks that would be difficult and impractical to mesh.

Phasor Notation for an Eddy Current Solution

Time varying quantities that have the form:

$$\boldsymbol{F}(t) = F_m \cos(\omega t + \theta)$$

can be represented as rotating phasors in the complex plane. Using Euler's formula:

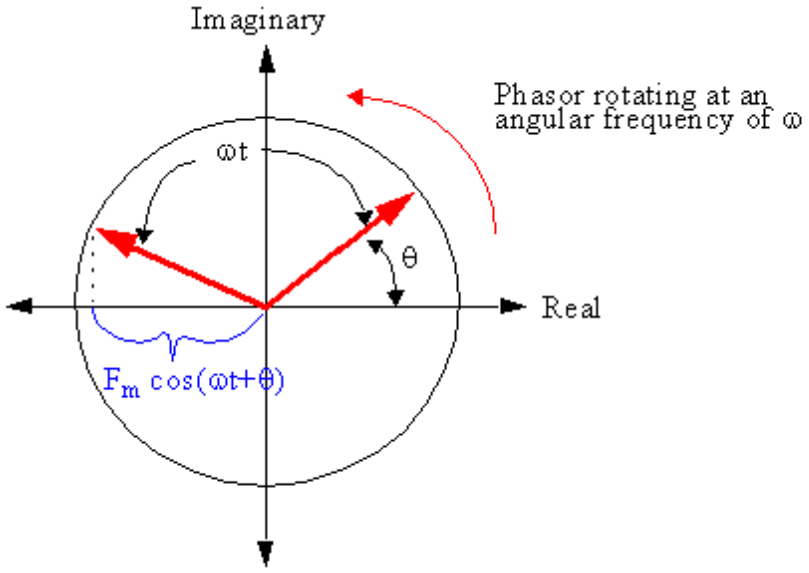
$$e^{j\alpha} = \cos\alpha + j\sin\alpha$$

$$e^{j(\omega t + \theta)}$$

If a = w*t*+q, **F**(t) equals the real portion of :

$$F(t) = \Re\left[F_m e^{j(\omega t+\theta)}\right] = \Re[F_m(\cos(\omega t+\theta)+j\sin(\omega t+\theta))] = F_m\cos(\omega t+\theta)$$

Each time-varying quantity has the form $F_m e^{j\theta} e^{j\omega t}$. The component $F_m e^{j\theta}$ is a complex constant that can be represented by a stationary phasor in the complex plane. The component $e^{j\omega t}$ is a complex number that depends on *t* and can be represented as a rotating phasor in the complex plane. The phasor's projection on the real axis oscillates sinusoidally. It reaches a peak when parallel with the real axis, and crosses zero when parallel with the imaginary axis. Therefore, a phasor with $\theta=90^o$ represents a quantity that peaks 90 degrees after a phasor with $\theta=0^o$.

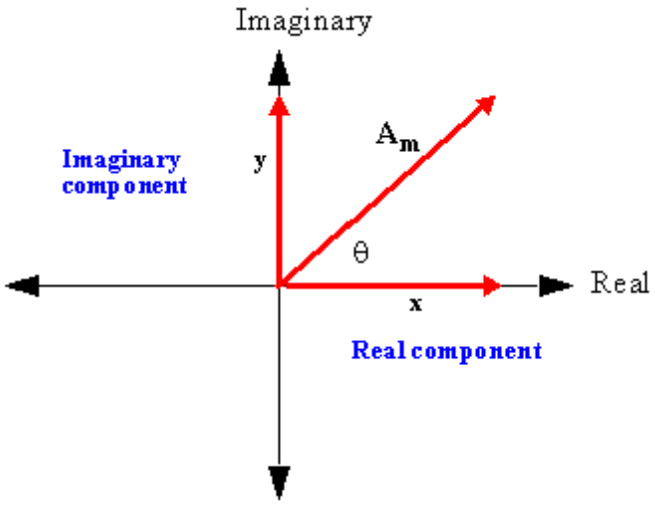


Real and Imaginary Components for an Eddy Current Solution

In general, you must enter a magnitude and phase for all AC voltages, currents, and other boundary or source quantities. But if the magnitude and phase angle of a quantity are functions of position, specify the functions in terms of real and imaginary components (x+jy). The "x+jy" description of a phasor indicates that the phasor is the sum of two components - a sinusoid that peaks at $\omega t=0°$and a sinusoid that peaks at $\omega t=90°$.

- The "x" component of the phasor is the real component and is represented by a phasor that lies on the real axis of the complex plane.
- The "y" component is the imaginary component and is represented by a phasor that lies on the j-axis of the complex plane.

The real and imaginary components of a three phase system are shown below:



They are related to the magnitude and phase of a sinusoid in this way:

$$A_m e^{j\theta} = x + jy = A_m(\cos\theta + j\sin\theta)$$

$$A_m = \sqrt{x^2 + y^2}$$

$$\theta = \text{atan}\left[\frac{y}{x}\right]$$

where the real and imaginary components are:

$$Re = A_m \cos\theta$$

$$Im = A_m \sin\theta$$

For a symmetric three-phase system, θ = 0, 120, 240 degrees, respectively.

For a frequency domain simulation (eddy current), all sources (currents, fields) must have the same frequency. Therefore, the simulation frequency is specified as a global input parameter.

In simulations where the electromagnetic radiation is included the displacement, currents are included in the calculation. In such a situation, the dependency between H and J is given by the following equation:

$$\nabla \times \vec{H} = J + \frac{\partial}{\partial t}(\varepsilon \vec{E})$$

Solution Process for an Eddy Current Solution

To solve for the magnetic field, **H**, the solver computes the values as follows:

$$\nabla \times \left(\frac{1}{\sigma + j \cdot \omega \cdot \epsilon} \nabla \times H\right) = -j \cdot \omega \cdot \mu \cdot H$$

In conductors where eddy currents occur, **H** is computed directly from source currents and applied magnetic fields.

In non-conducting regions, H is computed from the magnetic scalar potential:

$$\nabla \bullet (\mu \nabla \phi) = 0$$

Directly solving for **H** requires more computing resources than using the magnetic potential, so this is done only in regions where the magnetic potential cannot be used.

The solver combines the solutions and solves for the magnetic field. **H** is forced to be continuous on the boundaries, producing a continuous field solution throughout the model. It then saves the completed solution to a file and performs an error analysis. In an adaptive analysis, it refines the tetrahedra with the highest error and continues solving until the stopping criterion is met.

Note	Always use the peak value in the applied excitations in an eddy current solution!

Skin Depth for an Eddy Current Solution

Induced currents allow magnetic fields to penetrate conductors only to a certain depth, of about 4-5 skin depths. The skin depth is approximated by the following formula:

$$\delta = \sqrt{\frac{2}{\omega \sigma \mu_0 \mu_r}}$$

where:

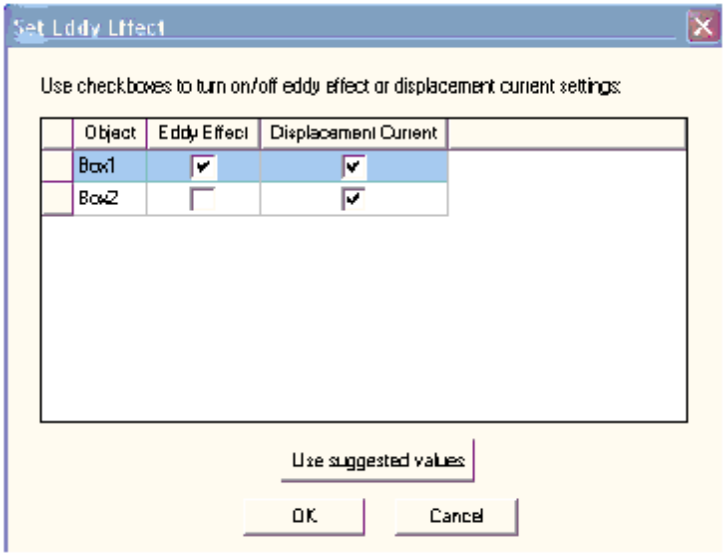
- ω is the angular frequency, which is equal to $2\pi f$ (f is the frequency at which source currents and voltages oscillate during the solution).
- σ is the conductor's conductivity in siemens/meter.
- μ_r is the conductor's relative permeability.
- μ_0 is the permeability of free space, which is equal to 4 x 10-7 H/m.

Currents are concentrated near the surface of the conductor, decaying rapidly past the skin depth. As the formula above indicates, the skin depth gets smaller as the frequency increases.

Note	Due to the skin concentration of current, AC inductances and resistances are not equal

	to their DC equivalents. This affects the inductance and resistance values computed during impedance computations.

Both the skin depth / proximity effects and the displacement effects must be specifically requested. Under the excitation setup, the respective effects can be specified for objects in the model as shown below:



Eddy (skin/proximity) effect can only be specified for objects with non-zero conductivity.

By default, eddy/displacement current effects are turned off. Including these in the calculation has a potentially significant impact on the solution time since the electric vector potential calculation is activated, causing the size of the solved matrix to increase significantly if the regions with the electric vector potential to be calculated have a large number of finite elements.

Displacement current calculation is normally activated in dielectrics (including vacuum) and allows electromagnetic waves to propagate. In such cases, a radiation boundary condition should also be used in the problem setup.

Magnetic Field Energy for an Eddy Current Solution

The energy density in the general case includes the magnetic and electric energy densities. The AC magnetic field energy is given by the following:

$$U = \frac{1}{4} Re(\boldsymbol{B} \bullet \boldsymbol{H}^* + (\boldsymbol{E} \bullet \boldsymbol{D}^*))$$

where:

- $\boldsymbol{B}$ is the magnetic flux density.
- $\boldsymbol{H}$ is the magnetic field.

- ***E*** is the electric field.
- ***D*** is the electric displacement.
- *Re* is the real part operation.
- The superscript * denotes complex conjugate.
- The symbol · is the dot product.

For the sake of brevity, the energy density in the post processor is labeled as **Energy**. The total energy (U) of an object or the whole arrangement can be calculated by integrating the energy density over a proper volume in the Field Calculator, as follows:

$$U = \frac{1}{4}\iiint_{Vol} Re(\boldsymbol{B} \bullet \boldsymbol{H}^* + (\boldsymbol{E} \bullet \boldsymbol{D}^*))dVol$$

This represents the average energy over time, not the instantaneous energy at a specific point in the cycle. (The 1/4 factor is explained by the use of peak values for excitations.)

Hysteresis Loss for an Eddy Current Solution

The hysteresis loss is given by: the following

$$U = -\int_{Vol} \omega Im\left[\frac{1}{2}(\boldsymbol{B} \bullet \boldsymbol{H}^*)\right]dVol$$

where:

- ***B*** is the magnetic flux density.
- ***H**** is the complex conjugate of the magnetic field, ***H***.
- ω is the angular frequency, equal to $2\pi f$ (where *f* is the solution frequency).

The magnetic hysteresis loss density (p_h) is given by the following:

$$p_h = \frac{1}{2}\omega Im(B \cdot \boldsymbol{H}^*)$$

where:

- *Im* is the imaginary part.
- ω is the angular frequency.

For the sake of brevity, the hysteresis loss density in the post processor is labeled as **Hysteresis Loss**. The total magnetic hysteresis loss (p_h) of an object or the whole arrangement can be

calculated by integrating the hysteresis loss density over a proper volume in the Field Calculator, as follows:

$$p_h = -\frac{1}{2}\omega \iiint_{Vol} Im(B \cdot \boldsymbol{H}^*) dVol$$

Hysteresis loss applies if the structure includes materials with a non-zero value for the tangent of the magnetic loss angle (equivalent to a non-zero imaginary permeability). Otherwise, it is equal to zero.

Ohmic Loss for an Eddy Current Solution

Ohmic loss is given by:

$$P = \int_{Vol} \frac{\boldsymbol{J} \bullet \boldsymbol{J}^*}{2\sigma} dVol \qquad \text{(Watts)}$$

where:

- ***J*** is the current density.
- ***J**** is the complex conjugate of the current density.
- σ is the conductivity in siemens/meter.

Ohmic loss is used to compute the power loss in a structure ($P=I^2R$).

For impedance boundaries, ohmic loss is given by:

$$P = \sqrt{\frac{\omega \mu_0 \mu_r}{8\sigma}} \int_{Sur} \boldsymbol{H}_t \bullet \boldsymbol{H}_t^* \, ds \text{ (Watts)}$$

where:

- *w* is the angular frequency, which is equal to 2πf. (f is the frequency at which source currents and voltages oscillate during the solution.
- *s* is the conductor's conductivity in siemens/meter.
- μ_r is the conductor's relative permeability.
- μ_0 is the permeability of free space, which is equal to 4π x 10–7 H/m.

- H_t is the tangential component of H on the impedance boundary.
- H_t^* is the complex conjugate tangential component of H on the impedance boundary.

The ohmic loss density (p_o) is given by the following:

$$p_o = \frac{1}{2} Re(\mathbf{E} \cdot \mathbf{J_c}^*)$$

This loss is calculated from the conduction component of the current density:

$$\mathbf{J}_c = [\sigma]\mathbf{E}$$

For the sake of brevity, the ohmic loss density in the post processor is labeled as **Ohmic Loss**. The total ohmic loss (p_o) of an object or the whole arrangement can be calculated by integrating the ohmic loss density over a proper volume in the Field Calculator, as follows:

$$p_o = \frac{1}{2} \iiint_{Vol} Re(\mathbf{E} \cdot \mathbf{J_c}^*) d\,Vol$$

Dielectric Loss for an Eddy Current Solution

The dielectric loss density (p_d) is as follows:

$$p_d = \frac{1}{2} Re[\mathbf{E} \cdot (\mathbf{J} - \mathbf{J_c})^*]$$

The current density and the conduction current density are defined by the following two equations:

$$\mathbf{J} = \nabla \times \mathbf{H}$$

$$\mathbf{J}_c = [\sigma]\mathbf{E}$$

For the sake of brevity, the dielectric loss density in the dielectric loss density in the post processor should be labeled as **Dielectric Loss**. The total dielectric loss (p_d) of an object or the whole arrangement can be calculated by integrating over a proper volume in the Field Calculator, as follows:

$$p_d = \frac{1}{2}\iiint_{Vol} Re[\mathbf{E} \cdot (\mathbf{J} - \mathbf{J_c})^*]\, dVol$$

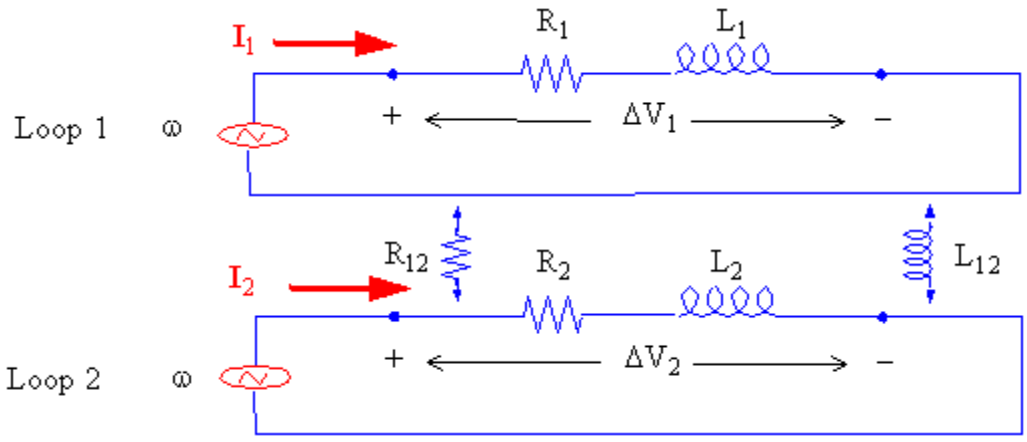
The dielectric loss can also be called *electric hysteresis loss*.

Impedance Matrix for an Eddy Current Solution

An impedance matrix gives the relationship between AC voltages and AC currents for multiple conductors. In the current loops below, the voltage and current in each loop is:

$$\Delta V_1 = I_1 R_1 + I_1 j\omega L_{11} + I_2 j\omega L_{12}$$

$$\Delta V_2 = I_2 R_2 + I_2 j\omega L_{22} + I_1 j\omega L_{12}$$



This can be expressed in matrix form as:

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \end{bmatrix} = \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{12} & Z_{22} \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \end{bmatrix}$$

where:

- ΔV_i and I_i are phasors.
- $Z_{11} = R_1 + j\omega L_{11}$ (the self-impedance of Loop 1).
- $Z_{12} = R_{12} + j\omega L_{12}$ (the mutual impedance between Loops 1 and 2).
- $Z_{22} = R_2 + j\omega L_{22}$ (the self-impedance of Loop 2).

A device with n current loops would have an $n \times n$ impedance matrix.

Matrix Elements for an Impedance Matrix

All impedances are complex numbers in the form:

$$Z = R + j\omega L$$

where:

- ω is the angular frequency of the AC voltages and currents, which is equal to $2\pi f$ (where f is the solution frequency).

- *R* is the resistance, given in ohms.
- *L* is the inductance, given in henries.

If one amp flows in Loop 1 and zero amps in Loop 2, the impedance matrix becomes:

$$\begin{bmatrix} \Delta V_1 \\ \Delta V_2 \end{bmatrix} = \begin{bmatrix} Z \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} Z_{11} \\ Z_{12} \end{bmatrix}$$

Diagonal Elements for an Impedance Matrix

The self-impedance of Loop 1 is given by $Z_{11} = R_1 + j\omega L_{11}$.

- R_1 represents the internal resistance of the current loop.
- L_{11} represents the self-inductance of the loop. The $j\omega L_{11}$ term represents the inductive reactance of the loop — the apparent AC inductance due to the loop's self inductance.

Off-Diagonal Elements for an Impedance Matrix

The mutual impedance between Loops 1 and 2 is given by $Z_{12} = R_{12} + j\omega L_{12}$.

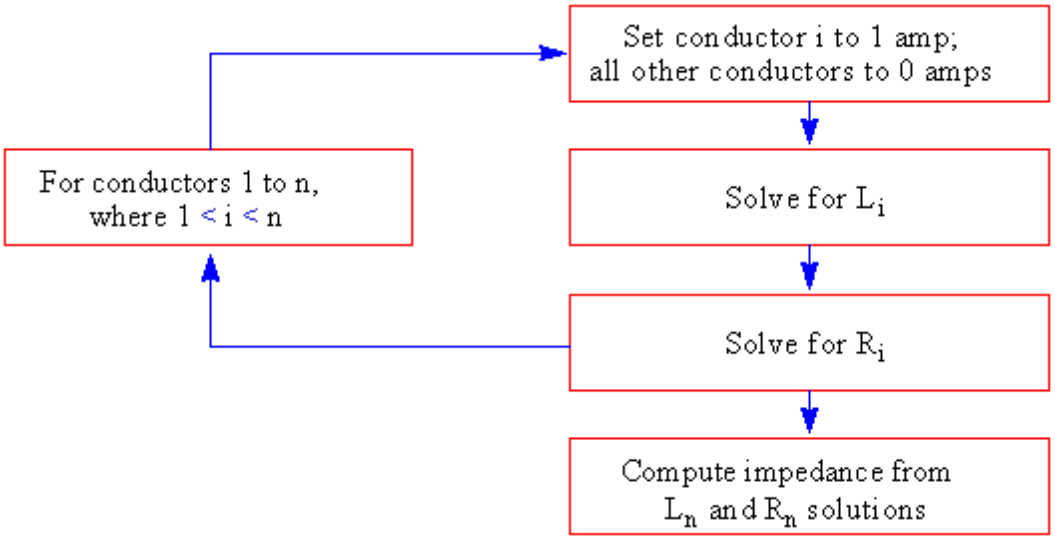
- R_{12} represents the mutual resistance of a neighboring conductor as seen from the source conductor.
- L_{12} represents the mutual inductance between the loops. The $j\omega L_{12}$ term represents the inductive reactance between the loops — the apparent AC inductance due to the mutual inductance.

Symmetry for an Impedance Matrix

The impedance matrix is symmetric about the diagonal. This indicates that the mutual effects between any two loops are identical.

Solution Process for an Impedance Matrix

The simulator divides the impedance matrix computation into two parts, as shown below.



The solver generates a field solution for each conductor in the matrix. Each conductor is assumed to be part of an independent current loop. In the first solution, the current in the first conductor is set to one amp; currents in the other conductors are set to zero. This is done by imposing current sources on the conductors. In the second solution, the current in the second conductor is set to one amp and all other conductors are set to zero amps, and so forth. Objects that are not included in the impedance matrix are not affected.

Using the field solution as input, the simulator performs inductance and resistance computations. When it finishes solving for the inductance and resistance, the simulator combines them to form the impedance matrix, using the relationship:

$$Z_i = R_i + j\omega L_i$$

Inductance for an Impedance Matrix

The inductance solution for an impedance computation is similar to a magnetostatic inductance solution. The system computes the following for each matrix entry:

$$L_{ij} = \int \boldsymbol{B}_i \bullet \boldsymbol{H}_j^* d\Omega$$

where:

- ***B*** is the magnetic flux density.
- ***H**** is the complex conjugate of the magnetic field.

Resistance for an Impedance Matrix

To find the resistance, the system computes the ohmic loss, P, for each loop:

$$P = \frac{1}{2\sigma}\int \boldsymbol{J} \bullet \boldsymbol{J}^* \, d\Omega$$

where **J** is the current density. Ohmic loss can also be expressed in terms of resistance and total current, $P=RI_{RMS}^2$, where:

$$I_{RMS} = \frac{I_{Peak}}{\sqrt{2}}$$

The resistance, therefore, is:

$$R = \frac{P}{I_{RMS}^2} = \frac{\frac{1}{2\sigma}\int \boldsymbol{J} \bullet \boldsymbol{J}^* \, d\Omega}{I_{RMS}^2} = \frac{\int \boldsymbol{J} \bullet \boldsymbol{J}^* \, d\Omega}{\sigma I_{Peak}^2}$$

To solve this, the system computes the conduction current, **J**, for each conductor. Each subsolution, $\mathbf{J}_i$, represents the contribution of a current loop toward the matrix. After it solves for **J** for all conductors, the system computes the resistance matrix.

Note	Since all current loops are assumed to be independent, an impedance matrix only contains terms for their internal resistance (or self-resistance). It does not include terms for the mutual resistances between loops.

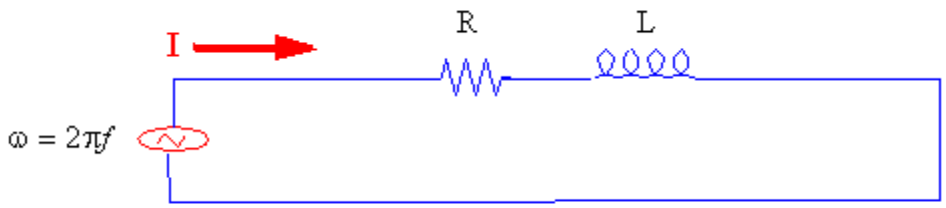
Line Impedance

Line impedance is represented by a 1x1 impedance matrix. That is to say, the line impedance is the impedance of a single current loop given by:

$$Z = R + j\omega L$$

where:

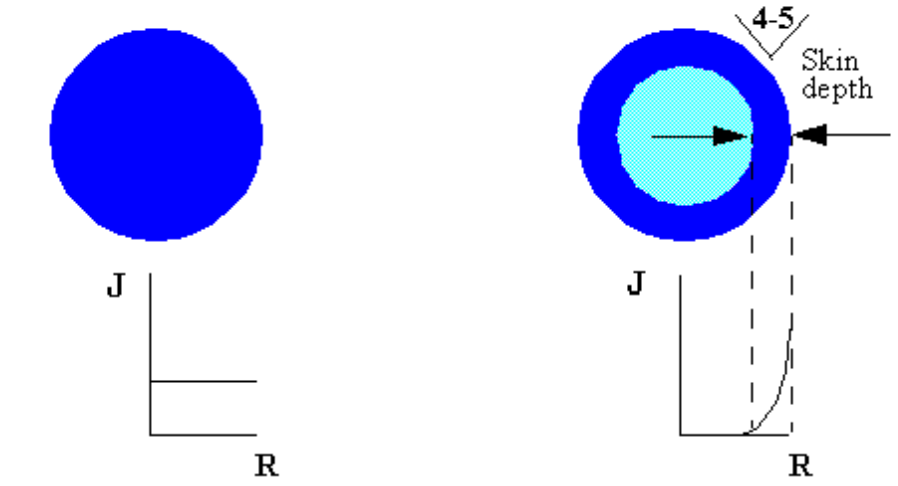
- ω is the angular frequency of the AC voltages and currents, which is equal to $2\pi f$ (where f is the solution frequency).
- R is the self-resistance of the loop.
- L is the self-inductance of the loop.



The inductance and resistance components of line impedance are computed separately.

AC Inductance and Resistance for an Impedance Matrix

The inductances and resistances computed during an impedance solution are different from those computed for the equivalent DC case, as shown below. The darker blue area represents the cross-section of the current flowing in the conductors.



DC: **J** is uniformly distributed throughout the conductor.

AC: **J** is concentrated near the surface and decays exponentially toward the conductor's center.

The current density, **J**, in the DC case (the conductor on the left) is evenly distributed throughout the cross-section of the conductor. The current density in the AC case (the conductor on the right) is distributed close to the surface due to skin concentration of currents. Since the area through

which current can flow is smaller, it follows that the resistance to the current flow is higher in the impedance matrix than in the equivalent DC case.

In the DC example, no eddy currents occur. The magnetic field created by the current flowing through the conductor is static. In the AC example, the oscillating magnetic field induces currents in other conductors in the model. These induced currents affect the computation of inductance for the impedance matrix, causing it to be different from the equivalent DC inductance.

Lorentz Force in an Eddy Current Solution

The Lorentz force represents the average force on an object (or group of objects) due to currents in a time-varying magnetic field. Lorentz force is given by:

$$\boldsymbol{F}(t) = \int_{Vol} \boldsymbol{J}(t) \times \boldsymbol{B}(t)\, dVol$$

where:

- ***J(t)*** is the current density.
- ***B(t)*** is the magnetic flux density.

The average force is found by integrating the instantaneous force:

$$\boldsymbol{F}_{AV} = \frac{1}{2\pi}\int_{0}^{2\pi} \boldsymbol{F}_{Inst}\, d\omega t = \frac{1}{2\pi}\int_{0}^{2\pi}\left(\int_{Vol} \boldsymbol{J}(t) \times \boldsymbol{B}(t)\, dVol\right) d\omega t$$

Warning	The Lorentz force does not compute the correct average force on objects that are assigned materials with a relative permeability greater than one. To find the force on these objects, use virtual force.

Lorentz Torque in an Eddy Current Solution

The Lorentz torque represents the average torque on an object or group of objects due to currents in a time-varying magnetic field. The Lorentz torque is given by:

$$\boldsymbol{T}(t) = \int_{Vol} \boldsymbol{r} \times [\boldsymbol{J}(t) \times \boldsymbol{B}(t)]\, dVol$$

where:

- ***r*** is the displacement vector from the axis of rotation.
- ***J(t)*** is the current density.
- ***B(t)*** is the magnetic flux density.

The average torque is found by integrating the instantaneous torque:

$$\boldsymbol{T}_{AV} = \frac{1}{2\pi}\int_0^{2\pi} \boldsymbol{T}_{Inst}\, d\omega t = \frac{1}{2\pi}\int_0^{2\pi}\left(\int_{Vol} \boldsymbol{r} \times [\boldsymbol{J}(t) \times \boldsymbol{B}(t)]\, dVol\right) d\omega t$$

This integral is computed for the x-, y- and z-axes, giving the average torque on the object(s) about each axis of rotation.

Warning	The Lorentz torque does not compute the correct average torque on objects that are assigned materials with a relative permeability greater than one. To find the torque on these objects, use virtual torque.

Virtual Force in an Eddy Current Solution

Virtual force in an eddy current problem is computed the same way as the magnetostatic virtual force. The only difference is that the average force over time is computed — not the net (instantaneous) force at a given time. The average virtual force is found by integrating the instantaneous force:

$$\boldsymbol{F}_{AV} = \frac{1}{2\pi}\int_0^{2\pi} \boldsymbol{F}_{Inst}\, d\omega t = \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{dW(s,i)}{ds}\right) d\omega t$$

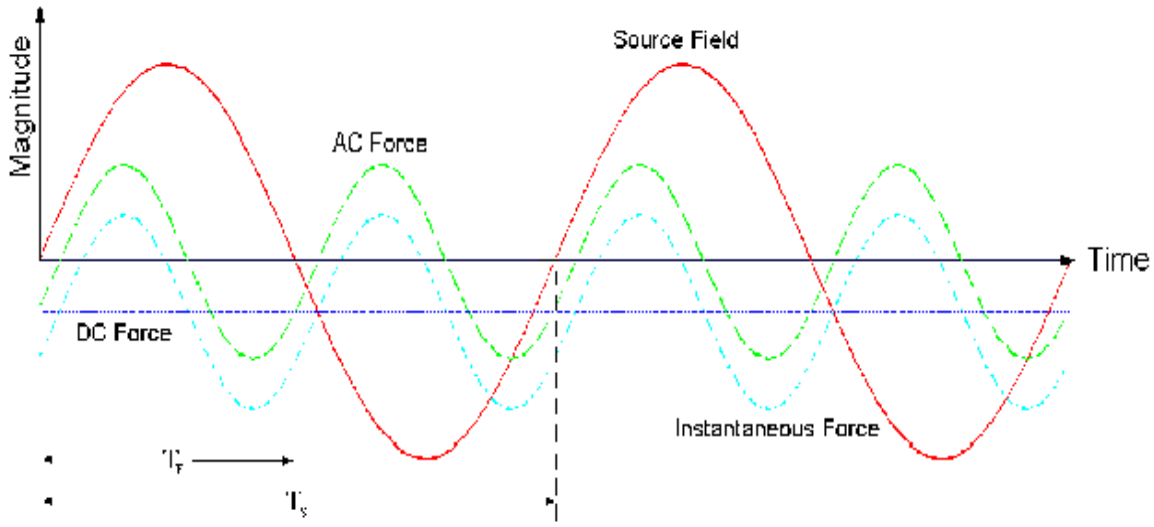
Virtual Torque in an Eddy Current Solution

Virtual torque in an eddy current problem is computed the same way as the magnetostatic virtual torque. The only difference is that the average torque over time is computed — not the net torque at a given time. The average torque is found by integrating the instantaneous torque:

$$\boldsymbol{T}_{AV} = \frac{1}{2\pi}\int_0^{2\pi} \boldsymbol{T}_{Inst}\, d\omega t = \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{dW(\theta,i)}{d\theta}\right) d\omega t$$

Average Force in an Eddy Current Solution

The Lorentz force and virtual force computed for an eddy current model represent the average force, not the instantaneous force at a specific point in the AC magnetic field's cycle. Similarly, the Lorentz torque and virtual torque represent the average torque over time, since these torque computations make use of the time-averaged force. The difference between the time-averaged (or DC) force, AC force, and instantaneous force is shown below:



Force oscillates at twice the frequency of the source current and magnetic field:

$$f_F = \frac{1}{T_F} = 2f_S$$

where:

- f_F is the frequency of the force.
- f_S is the frequency of the source current and magnetic field.
- T_F is the period of the force.

The time-averaged (or DC) force, AC force, and instantaneous force can be determined by:

$$F_{DC} = \frac{1}{2}\int Re\left|\bar{J} \times \bar{B}^{*}\right| dV$$

$$F_{AC} = \frac{1}{2}\int Re\left|\bar{J} \times \bar{B}\right| dV$$

$$F_{INST} = F_{DC} + F_{AC}$$

The AC force, F_{AC} must be evaluated at a particular phase (=ωt) in order to determine its magnitude at an instant in time.

3D AC Conduction Solver

AC conduction analysis is the study of:

- electric field
- losses arising in conductors and imperfect (lossy) dielectrics from the application of an alternating (AC) voltage or external current to the electrodes.
- C and G parameters extraction

In this harmonic formulation, the magnetic fields are considered negligible, and the electromagnetic field can be treated as electro-quasistatic. The electric field is derived from the electric scalar potential φ.

One can use this analysis to determine the voltage, electric field, electric flux density, and electric current density distributions, capacitive effects, extract the C and G parameters in electric devices as a function of frequency in response to time-harmonic loading.

Complex arithmetic is used to represent harmonic time-dependency as outlined below.

Governing equations

Given the Ampere's Law in frequency domain,

$$\nabla \times \boldsymbol{H} = \boldsymbol{J_c} + j\omega \boldsymbol{D}$$

it is possible to obtain the continuity equation solved by the 3D AC conduction solver,

$$\nabla \cdot \left(\mathbf{J_c} + j\omega \mathbf{D}\right) = 0$$

where:

H is the magnetic field

$\mathbf{J_c}$ is the conduction current density

ω is the angular frequency at which the potential is oscillating

D is the displacement flux density

Constitutive relations

The constitutive relations are given by:

$$\mathbf{J}_c = \sigma_s \, (E) \; \mathbf{E}$$

and

$$\mathbf{D} = \dot{\varepsilon} \;\; (E) \; \mathbf{E}$$

where:

σ_s is the static field electrical conductivity

$\dot{\varepsilon}$ is the complex dielectric permittivity: $\dot{\varepsilon} = \varepsilon' - j\varepsilon''$

Continuity equation including lossy domains

Applying the above constitutive relations in the continuity equation, one obtains:

$$\nabla \cdot (\sigma_s \; \mathbf{E} + j\omega\dot{\varepsilon} \; \mathbf{E}) = 0$$

$$\nabla \cdot [(\sigma_s + \omega\varepsilon'') \; \mathbf{E} + j\omega\varepsilon' \; \mathbf{E}] = 0$$

$\sigma_s + \omega\varepsilon''$ represents the equivalent conductivity (σ_e) composed by a static (σ_s) and an alternating (σ_a) part, which is caused by dipole rotation when the material is submitted to an alternating electrical field.

$$\sigma_e = \sigma_s + \omega\varepsilon'' = \sigma_s + \sigma_a$$

Finally, the continuity equation can be written as:

$$\nabla \cdot [\nabla\varphi \, (\sigma_s + \omega\varepsilon'' + j\omega\varepsilon' \,)] = 0$$

It is of importance to mention that normally the dielectric lossy materials are defined in terms of the dielectric loss tangent *(tan δ)*. In this case, the alternating *tan δ* is considered:

$$\tan\delta_a = \frac{\varepsilon''}{\varepsilon'}$$

Consequently:

$$\varepsilon'' = \tan\delta_a \varepsilon'$$

Time-Harmonic Field Assumptions

The AC conduction field solver assumes the following conditions about field quantities:

- All time-varying electromagnetic quantities have the periodic waveform:

$$F(t) = F_m \cos(\omega t + \theta)$$

where all quantities must have the same value of ω, but can have different phase angles (θ).

- If a current is not a pure sinusoid, it is decomposed into sinusoidal harmonics, and solved separately at each frequency.
- The component of **E** due to time-varying magnetic fields caused by conduction currents can be neglected.

Non-linear Solution - 3D AC Conduction Solver

Unlike linear problems in which the field solution is assumed to be based on the sinusoidal complex peak field values in a steady state, nonlinear problems are usually based on all harmonic components of the fields.

The 3D AC Conduction solver supports the J-E and D-E non-linear properties, as stated in the constitutive relations:

$$\mathbf{J}_c = \sigma_s\,(E)\ \mathbf{E}$$

$$\mathbf{D} = \dot{\varepsilon}\ \ (E)\ \mathbf{E}$$

Thus for nonlinear problems, though the electric field is sinusoidal due to sinusoidal excitations, the resulting D and/or J fields can be “harmonically rich” due to the material non-linearity.

Although the D and J fields are not sinusoidal at output, the Maxwell 3D AC Conduction solver uses an effective property based on the sinusoidal E to approximate non-linear field behavior associated with the assigned non-linear JE and DE characteristic. Using the JE curve as an example, the effective conductivity is expressed by:

$$\sigma_{eff} = \frac{\frac{1}{T}\int_0^T J(|E|,t)dt}{\frac{2}{\pi}\widehat{E}}$$

The above equation is used to obtain the effective material property for each electric field value in the original curve, allowing to generate a new curve based on the effective properties. During the simulation process, the effective curve is used to calculate the conductivity and permittivity.

> **Note:** Though the complex permittivity *($\acute{\varepsilon}=\varepsilon'-j\varepsilon''$)* is considered in the constitutive relation, the D-E curve describes only its real part ε'.

Field Definitions for the 3D AC Conduction Solver

The fields can have different definitions in harmonic problems, mainly when dealing with lossy materials. In this section the fields available in the 3D AC conduction solver are presented.

Field Name	Type Definition
Voltage: electric potential φ	scalar and complex
Electric field (E)	vector and complex $\boldsymbol{E} = -\nabla\varphi$

Field Name	Type Definition
Electric flux density (D)	vector and complex $\mathbf{D} = \dot{\varepsilon}\ (E)\ \mathbf{E}$ where: $\dot{\varepsilon} = \varepsilon' - j\varepsilon''$
Total current density (J)	vector and complex $J = (\sigma_s(E) + \omega\varepsilon'' + j\omega\varepsilon'(E))E$
DC current density (Jc)	vector and complex $\mathbf{J}_c = \sigma_s\ (E)\ \mathbf{E}$
Ohmic loss	scalar and real $P_{ohmic} = \frac{1}{2} Re\left\{J_c \cdot E^*\right\}$ or $P_{ohmic} = \frac{1}{2} Re\left\{\sigma_s\ (E \cdot E^*)\right\}$
Dielectric loss	scalar and real $P_{dielectric} = \frac{1}{2} Re\left\{(J - J_c) \cdot E\right\}$ or $P_{dielectric} = \frac{1}{2} Re\left\{\omega\varepsilon''\ (E \cdot E^*)\right\}$
Energy	scalar and real $Energy = \frac{1}{4} Re\left\{\mathbf{D} \cdot \mathbf{E}^*\right\}$
Surface charge density (Qsurf)	scalar and complex $n \cdot (D_2 - D_1) = \rho_s$ or $n \cdot (\varepsilon_2 E_2 - \varepsilon_1 E_1) = \rho_s$ where • E_1 is the electric field and ε_1 the permittivity in the material on one side of the boundary. • E_2 is the electric field and ε_2 the permittivity in the material on opposite side of the boundary. • n is the normal vector of the surface.

Losses Calculation - 3D AC Conduction Solver

The average apparent power along the domain Ω is given by:

$$S = \frac{1}{2}\int_{\Omega} J^* \cdot E d\Omega$$

Consequently, the active (including Ohmic and dielectric) and reactive powers can be expressed by its real and imaginary parts, as follows:

$$P_{active} = \frac{1}{2} Re\left\{\int_{\Omega} J^* \cdot E d\Omega\right\}$$

$$P_{reactive} = \frac{1}{2} Im\left\{\int_{\Omega} J^* \cdot E d\Omega\right\}$$

Admittance - 3D AC Conduction Solver

Admittance can best be explained as the inverse of impedance, and is expressed by:

$$Y = G + j\omega C$$

where:

- ω is equal to $2\pi f$, where f is the frequency of the AC voltage source.
- Y is the admittance in Siemens.
- G is the conductance in Siemens.
- ωC is the susceptance in Siemens.

Note	The matrix values displayed by the software are conductance in ohms and capacitance in farads (not conductance and susceptance) and therefore do not include jω.

Admittance Matrix - 3D AC Conduction Solver

The electric parameters are obtained by the equivalence between the dissipated power in terms of discrete and continuous model.

In the discrete circuit, neglecting the inductive term, the average apparent power in the complex formalism is given by:

$$S = \frac{1}{2} U I^* = \frac{1}{2} V^2 Y = \frac{1}{2} V^2 \left(G + j\omega C\right)$$

In the continuous model,

$$\mathrm{S} = \frac{1}{2}\int_{\Omega} \boldsymbol{J}^* \cdot \boldsymbol{E}\, \mathrm{d}\Omega$$

Consequently, one can write:

$$S = \frac{1}{2}V^2 (G + j\omega C) = \frac{1}{2}\int_{\Omega} J^* \cdot E \, d\Omega$$

As the extraction of parameters is performed by applying a source of 1V at each port, the admittance can be obtained by integrating the power along the domain.

$$Y = G + j\omega C = \int_{\Omega} J^* \cdot E \, d\Omega$$

This process is repeated N (number of excitations) times and the parameters are obtained as follows:

$$G = Re\left\{\int_{\Omega} J^* \cdot E \, d\Omega\right\}$$

$$C = \frac{1}{\omega} Im\left\{\int_{\Omega} J^* \cdot E \, d\Omega\right\}$$

Iterative Matrix Solver Technical Details

Two iterative solvers (PCG and QMR) are supported in Maxwell. The PCG is supported in the magnetostatic and electrostatic solvers and QMR is supported in the eddy current solver.

For large simulations, the iterative solvers save significant memory - easily a factor two or more, and may be also faster than the direct solver.

Consider the matrix equation:

$Ax = b$	(1)

where A is a matrix, b a right hand side and x the solution.

When A^{-1} is computationally expensive or the exact solution x is impossible, an alternative is to seek an approximation $\tilde{x}$ to x, with an error $e = x - \tilde{x}$. The exact solution can therefore be rewritten as:

$e = x - \tilde{x}$	(2)

Substituting (2) into (1) results in the so-called residual equation:

$Ae = r$	(3)

where r is called the residual defined by:

$r = b - a\tilde{x}$	(4)

As mentioned above, the exact solution for e in (3) is impossible since it requires A^{-1}. However, if an approximation $M \approx A$ is available, the error e can be approximated in (3) by:

$\tilde{e} = M^{-1}r$	(5)

Finally, the approximation $\tilde{x}$ is updated by:

$$\tilde{x} \leftarrow \tilde{x} + \tilde{e} \quad (6)$$

It is (4)-(6) that form the foundation of the iterative solution method. A matrix solver using the iterative solution method is called an *iterative matrix solver*. The method starts with an initial guess $\tilde{x} = x_0$ and repeats (4)-(6) until the approximation $\tilde{x}$ to x is within tolerance, or the number of iterations exceeds a given number. In the former case, it is said the solution converges; while in the latter, it doesn't.

The residual r is used for measuring the closeness of $\tilde{x}$ to x. Since A and b in (1) can be scaled by the same factor without altering x, so does the residual r in (4). It typically makes more sense to replace $\|r\|$ as the stopping criterion with the relative residual:

$$res = \frac{\|r\|}{\|b\|} \quad (7)$$

where $\| \|$ stands for vector norm.

M

A
in (5) is called a preconditioner of . A good preconditioner greatly reduces the number of

M M A
iterations. The following makes a good preconditioner: is a good approximation to in

M^{-1}
some sense and is computationally cheap.

Some of the classic iterative matrix methods include:

- M A
  The Jacobi method where is the diagonal of .
- M A
  The Gauss-Seidel method where is the lower triangular or upper triangular matrix of .
- M
  The successive over-relaxation method (SOR) where is a weighted combination of the
  A
  lower triangular and upper triangular matrix of .

Refer to the following reference for the details of iterative solvers:

Henk A. van der Vorst, *"Iterative Krylov Methods for Large Linear System"* Cambridge University Press, 2003.

3D Transient Excitations (Sources)

$\vec{T}-\Omega$
In the **3D transient (time domain)**, the solver uses the formulation. Motion (translational or cylindrical/non-cylindrical rotation) is allowed, excitations - currents and/or voltages- can assume arbitrary shapes as functions of time, nonlinear BH material dependencies are also allowed. The support of voltage excitations for the windings has as consequence the fact that the winding currents are unknown and thus the formulation has to be modified slightly to allow Maxwell to account for source fields due to unknown currents in voltage - driven solid conductors (where eddy effects are evaluated) and in voltage-driven stranded conductors -where the eddy effects (such as skin and proximity effects) are ignored. Also for a simpler formulation of problems where motion is involved, Maxwell uses a particular convention and uses the fixed coordinate system for the Maxwell's equations in the moving and the stationary part of the model. Thus the motion term is completely eliminated for the translational type of motion while for the rotational type of motion a simpler formulation is obtained by using a cylindrical coordinate system with the z axis aligned with the actual rotation axis.

The formulation used by the Maxwell transient module supports Independent-Dependent boundary conditions and motion induced eddy currents everywhere in the model, in the stationary as well as in the moving parts of the model. Mechanical equations attached to the rigid-body moving parts allows a complex formulation with the electric circuits being strongly coupled with the finite element part and also coupled with the mechanical elements whenever transient mechanical effects are included by users in the solution. In this case the electromagnetic force / torque is calculated using the virtual work approach. For problems involving rotational type of motion a "sliding band" type of approach is followed and thus no re-meshing is done during the simulation. For translational type of motion the mesh in the band object (surrounding the part in motion) needs to be re-created at each time step with a degree of refinement which is dependent upon the mesh size in the moving object. In this later case the mesh in both stationary and moving objects remains unchanged as initially created by the user. For transient type of electromagnetic field analysis (with or without motion) the user is responsible for creating the mesh that is capable to "catch" the respective physics such as skin and proximity effects -if any- are to be present in the resulting fields.

The following three Maxwell's equations are relevant for transient (low frequency) applications:

$$\nabla \times H = \sigma(E)$$

$$\nabla \times \boldsymbol{E} = -\frac{\partial \boldsymbol{B}}{\partial t}$$

$$\nabla \cdot B = 0$$

The following two equations directly result from the above equations:

$$\nabla \times \frac{1}{\sigma} \nabla \times H + \frac{\partial B}{\partial t} = 0$$

$$\nabla \cdot B = 0$$

The final result is a formulation where vector fields are represented by first order edge elements and scalar fields are represented by second order nodal unknowns.

Field equations are coupled with circuit equations for both solid and stranded conductors because, in the case of applied voltage supplies, the currents are unknown. For the case of voltage driven solid conductors, the following equation is used to account for the ohmic drop across the i-th conductor loop:

$$V_{Ri} = \int_{R_C(i)} \iint J_{0i}(E + v \times B)dR$$

where J_{0i} represents the current density.

The current density J0i corresponds to 1A of net current in loop i and vanishes outside loop i.

The induced voltage can be derived from the following equation:

$$e_i = -\iiint_{R_C(i)} H_i \bullet B dR$$

where the integration is performed over the whole conductor region.

Stranded conductors are considered to be without induced eddy currents and, thus, are placed in the non-conducting region. This means that, for the purpose of calculating the ohmic voltage drop, we cannot use the same procedure we use for solid conductors. Instead, we use a lumped parameter to represent the DC resistance of the winding. We obtain the induced voltage due to the total flux linkage in a similar way as for solid conductors. In both cases, it is also possible to add an external inductance and capacitance.

For the time discretization, a backward time stepping scheme is used:

$$\left\{\frac{\mathbf{dx}}{\mathbf{dt}}\right\}^{t+\Delta t} = \frac{\left\{x^{t+\Delta t}\right\} - \{x\}^t}{\Delta t}$$

For the nonlinearities allowed in 3D transient applications, the classical Newton-Raphson algorithm is used.

The transient solver in Maxwell supports the **coil terminals** and **winding** definitions. Thus it is possible to specify the number of turns of coils in models which is necessary for the calculation of global quantities with high engineering value such as flux linkage and back emf of coils. Thus for the 3D transient solver a number of quantities are automatically calculated and displayed as 2D plots (functions of time): voltage (current), flux linkage, back emf. Other global quantities can be

also calculated by the 3D transient solver and displayed as 2D plots such as power loss, core loss, stranded loss, electromechanical quantities such as force/torque, speed and displacement.

A few types of sources can be used in 3D transient applications. The *Coil Terminal* type is discussed here.

A-Phi Formulation in Maxwell 3D (Transient)

Coil Terminals

A coil terminal excitation is the preferred excitation for Maxwell transient applications. This type of excitation can be specified as functional (arbitrary functions of time) and is very flexible; 6 different combinations can be used: current, voltage, and external circuit, with either solid or stranded conductor options.

The **current, stranded conductor** option should be used when setting coils of constant cross-section made of strands of wire (with no eddy current effects to be taken into account in the coil). The current can be functional and the specific variation as a function of time can be specified by the user.

When defining the function, already defined primitives such as sin( ), cos( ), exp( ), etc. can be used. For arbitrary variations, a piecewise linear capability can also be used by defining the corresponding dataset. You should also specify the number of winding turns.

Note	When using the stranded option, coils and, more generally, each individual current path must have a constant cross-section. However, coils and conductors that may have different individual cross-sections can be connected in windings.

The **current, solid conductor** option does not carry the restriction of constant a cross-section. The current path can have varying cross-section, and can also split as long as in the end all parallel branches merge into a unique current path. You can also define a functional excitation and apply it to the winding.

The **voltage, strand** option is similar to the corresponding current setting, with the obvious difference being that now the voltage is known, while the current remains unknown. In many situations when the voltage setup is used, other terminal characteristics that influence the current calculation are also specified: for instance, series resistance, inductance, and capacitance. No eddy current effects are taken into account, so a series resistance (DC resistance) must be specified. For this type of source, the cross-section of each conductor needs to be constant, but the cross-section can differ from one coil to another, and it is possible to construct windings using coils with different cross-sections. After the solver calculates the total current, the current is uniformly distributed on the cross-section, as it always is with a stranded option.

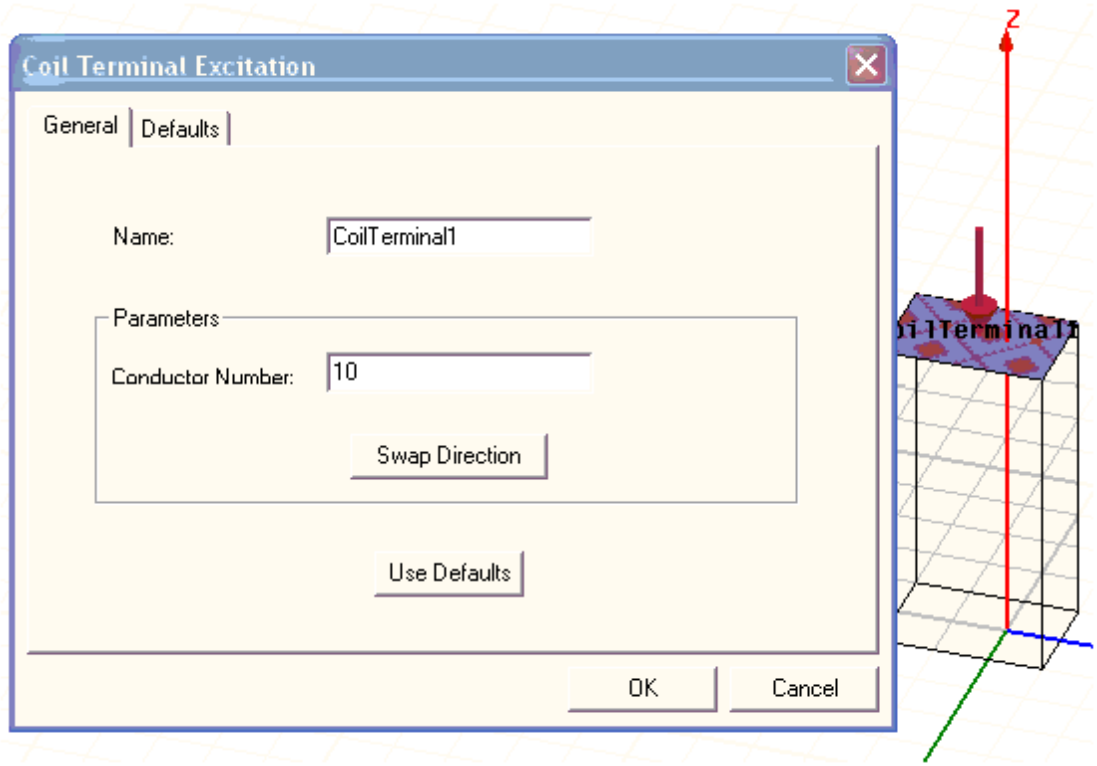
The **voltage, solid** option is chosen when solid conductors with eddy effects are part of the winding. In this situation, eddy current effects are taken into account. If required by the application,

you should also include other characteristics of the source, such as series resistance, inductance, and capacitance.

The **external strand** and **external solid** settings are used when the circuits attached to the windings have an increased degree of complexity. In the case of **external sources**, solid or stranded options are used, depending on whether or not eddy effects are to be taken into account.

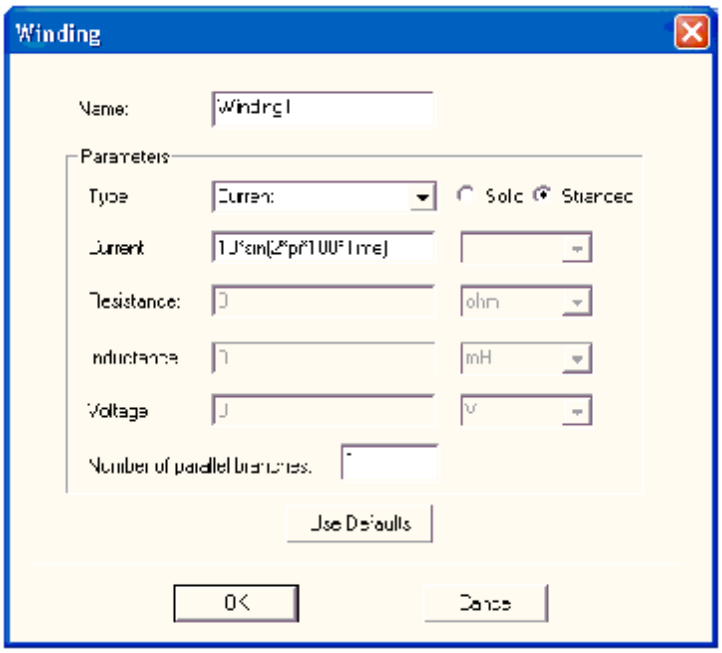
There are normally two phases in the process of defining windings.

1. First, define the terminal(s) by selecting the planar surface(s) as appropriate for the model, and then assign the coil terminal excitation by specifying the orientation of the current with respect to the terminal (current in or current out, graphically represented by an arrow). Specify the *actual* number of conductors (turns) intersecting *the chosen* planar surface (coil terminal), regardless of the symmetry (if any) of the problem.

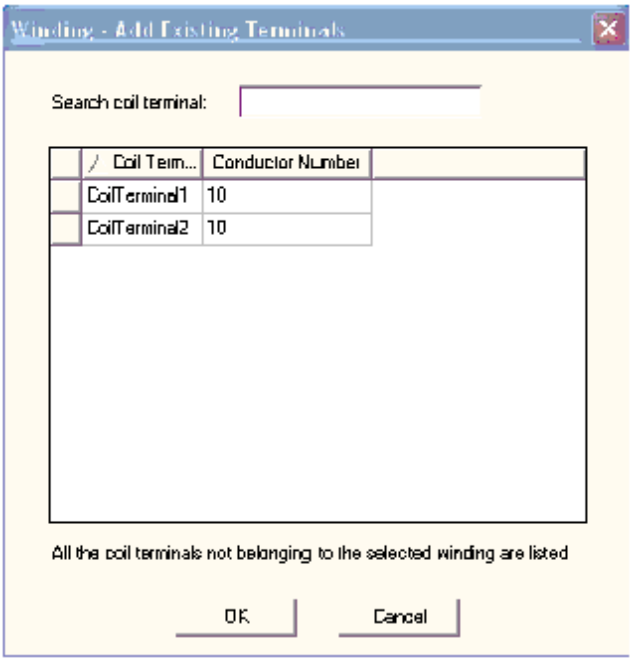


2. Right-click in the 3D Modeler window, add a new winding from the excitation menu (no need to select any geometry), and specify the remaining details of the setup (the screen shot below shows a sinusoidal current with 10 A amplitude and 100 Hz frequency being used in the setup.

Note	If external circuits are used in the excitation setup, they need to be created using the Maxwell Circuit Editor before they can be assigned to windings.



1. Right-click the winding in the property window, and specify the coil terminal(s) that belong to the winding (unassigned coil terminals are listed and can be selected from the respective window).



Solution Process for a Transient Solution

The solution process for 3D transient applications poses several challenges not apparent for other solver types. For instance, the behavior of fields is more complex than it is for static or steady-state applications, and a special finite element mesh structure is required in order for the software to accurately represent the physics.

Inductance Computation for 2D and 3D Transient Solutions

Because both 2D and 3D transient solutions are nonlinear, for inductance computation, Maxwell provides two options: *apparent inductance* and *incremental inductance*. After the FEA normal solution is completed at each time step, the permeability associated with *apparent inductance*, or the differential permeability associated with *incremental inductance*, of each element, is frozen – which is equivalent to freezing the coefficient matrix (the left side of the equation to be solved). In order to obtain winding self-inductance and mutual inductance, the solver sets an excitation current of 1A in the first winding, while setting all other winding currents to zero (permanent magnet effects are excluded). This excitation assignment corresponds to one source vector on the right-hand side of the equation to be solved. As a result, the calculated flux linkage provides the self-inductance for the first winding with 1A excitation current, and the calculated flux linkages represent mutual inductance for all other windings with zero current. Next, the solver excites the second winding with a current of 1A, while setting all other winding currents to zero (permanent magnet effects are excluded). This excitation assignment corresponds to another source vector on the right-hand side of the equation to be solved. The solver continues this process until all windings have been assigned 1A current in turn.

Flux Linkage in Maxwell 3D (Transient)

The 3D transient solver using the ***T***-Ω formulation, the turn density vector is defined as:

$$\boldsymbol{J}_k = \frac{N_k}{S_k}\boldsymbol{t}$$

where:

N_k is the number of turns;

S_k is the cross-sectional area of winding k; and

$\boldsymbol{t}$ is a unit vector tangent to the direction of winding wires.

In practice, this turn density vector is derived from the introduced basis function of the source field, $\boldsymbol{H}_k$, as:

$$\boldsymbol{J}_k = \nabla \times \boldsymbol{H}_k$$

where $\boldsymbol{H}_k$ is the field corresponding to a 1 ampere current in winding *k* and is obtained by solving a conduction problem:

$$\nabla \times \boldsymbol{H}_k = \boldsymbol{J} \qquad \nabla \times \boldsymbol{E} = 0 \qquad \boldsymbol{J} = \sigma \boldsymbol{E}$$

The turn density vector $\boldsymbol{J}_k$ corresponds to 1 ampere of net current in the winding *k*, and vanishes outside winding *k*. Thus, the induced voltage due to the total time derivative of flux linkage in winding *k* can be obtained by projecting the induced electric field *-dA/dt* onto the turn density vector $\boldsymbol{J}_k$ and integrating over the region of winding *k*:

$$e_k = -\iiint_{R_k} \boldsymbol{J}_k \bullet \frac{d\boldsymbol{A}}{dt} dR = -\iiint_{R_k} \nabla \times \boldsymbol{H}_k \bullet \frac{d\boldsymbol{A}}{dt} dR$$
$$= -\frac{d}{dt} \iiint_{R_k} \boldsymbol{H}_k \bullet \nabla \times \boldsymbol{A}\, dR - \oiint_{\Gamma} \boldsymbol{H}_k \times \boldsymbol{A} \bullet \boldsymbol{n}\, d\Gamma$$

where Γ is the boundary of a simply connected region, which is composed of the winding region R_k and the cutting region R_Σ that is introduced to fill the holes of the winding to avoid multi-valued problem of scalar potential. In such a case, since $\boldsymbol{H}_k$ has zero tangential component on boundary Γ, we have:

$$\oiint_{\Gamma} \boldsymbol{H}_k \times \boldsymbol{A} \bullet \boldsymbol{n}\, d\Gamma = 0$$

Then the induced voltage in winding *k* can be derived in terms of the $\boldsymbol{H}$ field as:

$$e_k = -\frac{d}{dt} \iiint_{R_k} \boldsymbol{H}_k \bullet \boldsymbol{B}\, dR$$

and therefore, the flux linkage in winding *k* be derived by:

$$\lambda_k = \iiint_{R_k} \boldsymbol{H}_k \bullet \boldsymbol{B}\, dR$$

A-Phi Formulation in Maxwell 3D (Transient)

For the Maxwell 3D A-Phi transient solver, solid and stranded conductors, and flux linkage, are defined as described below.

- **Solid Conductors**

  Maxwell 3D A-Phi transient solver is formulated using the magnetic vector potential *A* and electric scalar potential φ . The relations between the potentials and the magnetic field *B* and electric field *E* are:

$$\mathrm{B} = \nabla \times \mathrm{A}$$
$$\mathrm{E} = -\frac{\mathrm{dA}}{\mathrm{dt}} - \nabla \varphi$$

  Using Generalized Ampere's law, the current continuity equation, and the constitutive relations:

$$\nabla \times \mathrm{H} = J$$
$$\nabla \cdot J = 0$$
$$J = \sigma E + \frac{\mathrm{dD}}{\mathrm{dt}}$$
$$\mathrm{B} = \mu H$$
$$\mathrm{D} = \varepsilon E,$$

  the time dependent magnetic equation is expressed as:

$$\nabla \times v \nabla \times \mathrm{A} = -\sigma \frac{\mathrm{dA}}{\mathrm{dt}} - \sigma \nabla \varphi - \frac{\mathrm{d}}{\mathrm{dt}}(\varepsilon \frac{\mathrm{dA}}{\mathrm{dt}}) - \frac{\mathrm{d}}{\mathrm{dt}}(\varepsilon \nabla \varphi) + \nabla \times H_c$$
$$\nabla \cdot (-\sigma \frac{\mathrm{dA}}{\mathrm{dt}} - \sigma \nabla \varphi - \frac{\mathrm{d}}{\mathrm{dt}}(\varepsilon \frac{\mathrm{dA}}{\mathrm{dt}}) - \frac{\mathrm{d}}{\mathrm{dt}}(\varepsilon \nabla \varphi)) = 0,$$

  where:

  H is the magnetic field intensity

  J is the total current density including source, eddy, and displacement current contributions

  σ is the conductivity

μ is the permeability

ε is the permittivity

H_c is the coercivity of the permanent magnet

$v = \mu^{-1}$ is the reluctivity.

Since Maxwell 3D is used mostly for low frequency simulations, the radiation term

$$\frac{d}{dt}\left(\varepsilon \frac{dA}{dt}\right)$$

in the above equations is ignored in the A-Phi Solver. The first order edge elements for the magnetic vector potential and the second order nodal elements for the electric potential are used. The *tree-cotree* method is used to ensure the uniqueness of the magnetic vector potential A. The Degrees of Freedom (DOFs) of edge elements on the spanning tree of the finite element mesh are set to zero. The formulation above is used in the entire problem domain except in the stranded conductors.

- **Stranded Conductors**

  For stranded conductors, the current density is assumed to be constant over the conductor domain, where the eddy and displacement effects are ignored. Therefore, only Ampere's law is considered in stranded conductors,

$$\nabla \times v \nabla \times A = J$$

  The solver approximates the constant current density distribution over each conductor for a unit current before the transient solution starts. The approximated unit current density is:

$$\hat{J} \approx \hat{t} \frac{N}{S}$$

  where:

  $\hat{t}$ is the current (winding) direction

  I is the total terminal current

  S is the area of the coil terminal into which current is entering

  N is the number of turns

  J is then written as:

$$J = \hat{J} I$$

  For winding voltage excitation, the formulation is:

$$\nabla \times v \nabla \times \mathrm{A} - \hat{\mathrm{J}}\,\mathrm{I} = 0$$
$$\iiint_{\Omega_k} \hat{\mathrm{J}} \cdot \frac{\mathrm{dA}}{\mathrm{dt}} d\Omega + (R + \mathrm{R}_{ext})I + \mathrm{L}_{ext}\frac{\mathrm{dI}}{\mathrm{dt}} = V$$

where R is the DC resistance of the winding, and R_{ext} and L_{ext} are, respectively, the external resistance and inductance.

- **Flux Linkage**

  Flux linkage calculation for windings is relatively easy compared to T-Omega formulation. It is calculated using the equation:

$$\lambda_k = \iiint_{\Omega_k} J_k \cdot A \, d\Omega$$

  where J_k is the current density in the winding under 1A excitation, A is the total magnetic vector potential in the conductor, and Ω_k is the volume of the winding.

3D Transient Excitations (Sources)

Complex Field Behavior for a Transient Solution

For 3D transient applications, the behavior of the fields is more complex than it is for static or steady-state applications. A diffusion of the magnetic field into the materials occurs in 3D transient situations. The distribution of the magnetic field inside objects typically has a number of spatial harmonics, which usually means the time step used in the analysis should be less (sometimes much less) than the magnetic diffusion time constant. These time constants depend upon the geometry of objects and also upon their respective material properties. For example, for a cylinder, the magnetic diffusion time constant of the fundamental spatial harmonic is given by the following equation:

$$\tau = \frac{\mu\sigma a^2}{2.4048^2}$$

where μ is the permeability of the cylinder, σ is the conductivity, and a is the radius.

Special Mesh Structure for a Transient Solution

Since eddy currents are usually considered in conductive objects, a special finite element mesh structure is required in order to accurately capture the physics. In general, a careful planning of the (manual) meshing process is required in order to achieve an accurate solution with the available hardware resources.

Overcoming Challenges for a Transient Solution

There are a number of applications where the combined effects of magnetic diffusion and strong eddy effects represent a significant challenge. Add the effect of nonlinearities that may also be present, and you have the full picture of a difficult to solve application.

The following suggestions can help you overcome these challenges presented by some 3D transient applications:

- Use symmetry whenever the problem allows it.
- Set the eddy effects only on objects where it really counts.
- In general, all unnecessary details, such as details of a geometric nature, should be eliminated, particularly in cases where a large problem is the expected task.

Boundary Conditions for a Transient Solution

The behavior of the **H**-field at the edges of the problem space is controlled through boundary conditions. The following boundary conditions can be assigned for a 3D transient model:

- Natural boundaries are assigned to the surface between objects.
- Neumann boundary conditions (homogeneous) are assigned to the outside faces of the problem region.
- Odd Symmetry (Magnetic Flux Tangential)
- Even Symmetry (Magnetic Flux Normal)
- Matching
- Insulating

Default Boundary Conditions for a Transient Solution

By default, the Boundary/Source Manager automatically assigns the following boundary conditions for a 3D transient model:

Natural boundaries are assigned to the surface between objects.

Neumann boundary conditions (homogeneous) are assigned to the outside faces of the problem region.

Natural Boundary Conditions for a Transient Solution

Natural boundary conditions behave the same way as for magnetostatic or eddy (AC) problems: The normal component of B and the tangential component of H (surfaces without superficial current distribution) are continuous.

Neumann Boundary Conditions for a Transient Solution

Boundaries with Neumann conditions force the magnetic field (H) to be tangential, and the magnetic field (and the associated energy of the field is assumed to be confined to the region with overall Neumann boundaries. Typically, Neumann boundaries are placed at sufficient distance from the sources of the field to avoid an over-constraint of the solution.

By default, the Boundary/Source Manager automatically applies the Neumann boundary to all faces of the problem region — that is, surfaces exposed to the non-meshed space.

Symmetry for a Transient Solution

Symmetry boundary conditions take advantage of the symmetry of a problem. When deciding upon the symmetry, you must consider the geometry, as well as material properties and source distribution in space. Using symmetry boundary conditions when possible is very useful, particularly in 3D transient applications, which typically require large computing resources. Two types of symmetry are available:

- Odd Symmetry (Magnetic Flux Tangential)
- Even Symmetry (Magnetic Flux Normal)

These boundary conditions can be assigned to the faces of the problem region.

Odd Symmetry (Magnetic Flux Tangential) for a Transient Solution

Use an odd symmetry boundary to model a plane of symmetry in a symmetric problem in which current on one side of the plane flows in the opposite direction than current on the other side of the plane.

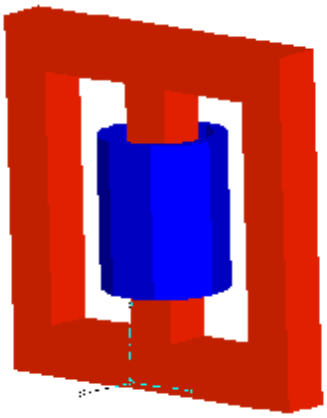
Note	If the odd symmetry plane cuts through an object with eddy currents that tend to flow normal to the magnetic flux tangent boundary, then the odd symmetry condition must be explicitly applied to the model. In this situation, you cannot rely on the default boundary condition.

Even Symmetry (Magnetic Flux Normal) for a Transient Solution

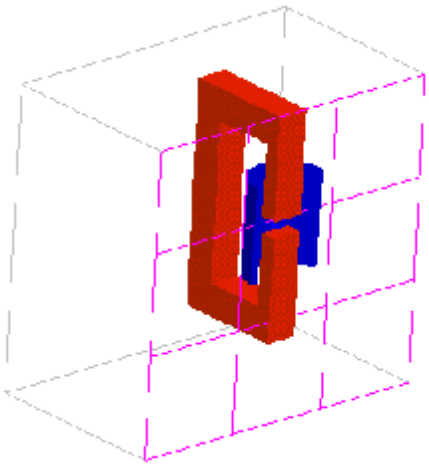
Use an even boundary to model a plane of symmetry in a symmetric problem in which the direction of current flow on both sides of the plane is the same. The currents on both sides of the plane are also assumed to have the same variation in time.

Examples of symmetry are shown in the following four pictures, where the inductor model presented has three-fold symmetry:

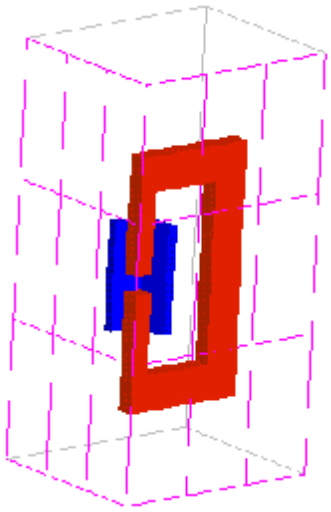
Full Model



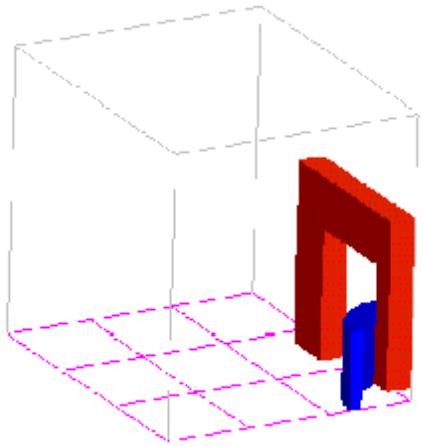
Half Model, Magnetic flux tangent Boundary condition on the symmetry plane



Quarter Model, 2 magnetic flux tangent boundary conditions



1/8 Model, 2 magnetic flux tangent boundary conditions (as in 1/4 model), one magnetic flux normal boundary condition (bottom plane)



Matching Boundary for a Transient Solution

Matching boundaries allow you to model planes of periodicity where the **H** field on one surface exactly matches the **H** field on another by forcing the magnetic field at each location on one surface (the "dependent" boundary) to match the magnetic field at the corresponding location on the other surface (the "independent" boundary). Matching boundaries are used in periodic structures and decrease the resources used in the computational process.

For matching boundaries, you need to set up both an independent and a dependent boundary. Unlike symmetry boundaries on independent and dependent boundaries, the **H** field does not need to be either tangential or normal to these boundaries. However, the **H** field on the two boundaries must have the same magnitude and direction (or the same magnitude and opposite direction) at each time step. The variation in time of the fields at corresponding locations is the same on matching (independent and dependent) boundaries.

Insulating Boundary for a Transient Solution

An insulating boundary prevents current from flowing across a surface - for instance, the interface between two adjacent conductors. Use an insulating boundary to model very thin layers of insulating material between conductors. Modeling thin insulating sheets saves you from the complications associated with the geometry of the insulation and also speeds up the solution process.

Meshing and Band Setting Recommendations for 3D Transient Applications With Motion

Maxwell supports three types of 3D transient problems with motion:

- Translational motion (motion along a user specified, linear direction).
- Rotational motion (non-cylindrical such as the pivoting rotation around an axis encountered in the armature of a relay).
- Rotational motion (cylindrical, such as the type of rotation encountered in an electric machine type of application).

Regardless of the particular type of motion involved, all types of motion applications require a band object that must contain the moving part(s). If there are multiple moving objects, all of the moving parts must be included in one all-inclusive object — this is because they all must be moving as one rigid body, with a single force acting on the assembly. Also, regardless of the type of motion, the user must create a mesh density capable of capturing the physical effects characteristic for the specific application, such as field gradients, skin and proximity effects, etc.

In terms of meshing, the main characteristic of the first two types of motion is that, during the analysis, a new mesh is created at each time step as the motion occurs. This re-meshed region is always inside the band object between the moving part(s) and the stationary part(s). The mesh corresponding to the moving part(s) and the stationary part(s) is kept fixed during the analysis. The mesh density inside the band object is always controlled during the solution process: the edges of any element created inside the band object during re-meshing will never be larger than the average element edge on the entire surface of the band object where it is in contact with both the moving and stationary parts. Thus, both the mesh density created for the moving part (in the area where it touches the band) and the mesh density in the stationary part (in the area where it touches the band) are used to actively control the mesh density in the re-meshed part throughout the entire solution process. This ensures good solution quality for any aspects conditioned by the quality of the mesh.

In maximizing the quality of the solution for 3D transient applications with motion, a number of observations and recommendations are available regarding the band object.

For applications with translational and non-cylindrical rotation types of motion:

- The band object can touch the symmetry plane if any exists.
- The moving object cannot touch a stationary object during motion (the gap between the moving object and the band can never become zero during analysis). The only exception to this rule is for the particular case when both the band and moving object surfaces touch a symmetry plane (if any exists in the respective setup) and the moving object slides along

the symmetry plane (in this case the symmetry plane, respective band, and moving object surfaces coincide);

- The band cannot have true surface faces; all faces must be segmented (for example created with the regular polyhedron primitive).
- The band object cannot separate the stationary part into unconnected sub-regions.

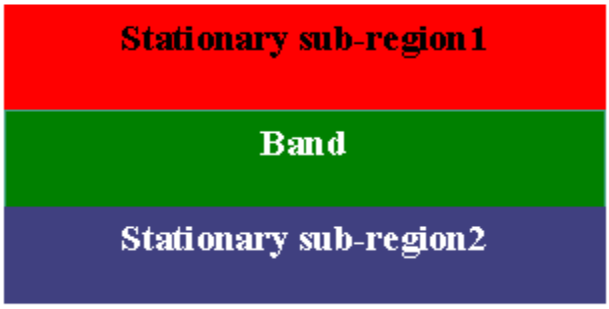


Fig.1 Band cannot separate the stationary part into unconnected regions

- Hollow objects cannot be used for band objects.
- Subtractions cannot be performed within the band object.

For the cylindrical type of rotational motion applications:

For this type of applications the band object must by somewhat larger than the rotating part(s) in ALL directions with only one exception, at the boundaries, which can just be touched. Thus the band object must effectively enclose the moving part, not just by touching it, in the radial and axial directions; so users have to leave some "room" between band and surrounding objects. The only exceptions allowed to the requirement mentioned above are: symmetry plane (if any exists), M-S or other boundaries as applicable for the application, can be touched i.e. at those planes it is allowed for the band surface(s) to coincide with the respective planes.

Additionally, the following observations are also applicable:

- For the band object, always use a facetted (regular polyhedron) type of cylindrical object or a wedge object if symmetry is used. The angular aperture of each facet depends on the problem; however, an opening of 2-3 degrees per facet is usually sufficient.
- Hollow cylinders cannot be used for band objects.
- Subtractions cannot be performed within the band object.
- The band object can separate the stationary part into unconnected sub-regions (a rotor sandwiched between two stators is allowed).

- Non-cylindrical band objects are allowed.

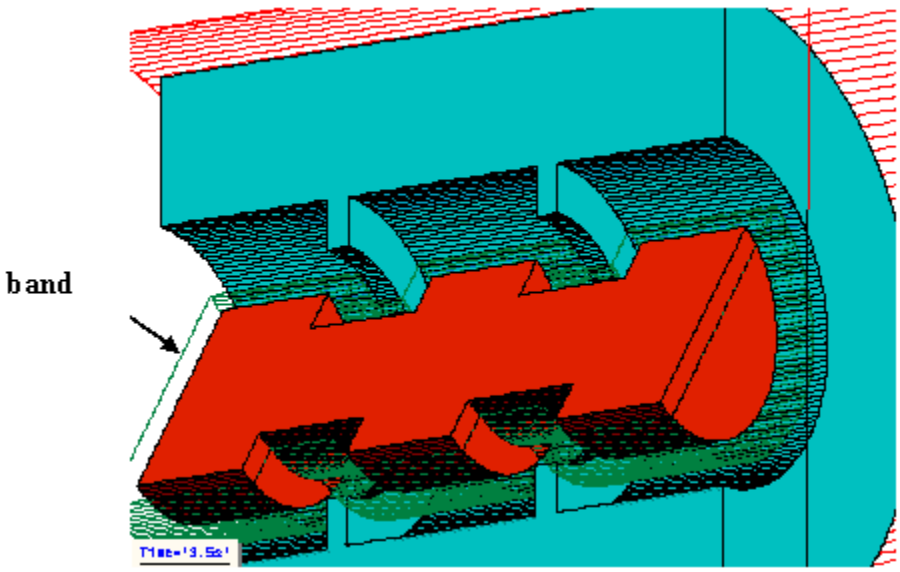

Fig. 2 Rotor and stator assembly with band object in between

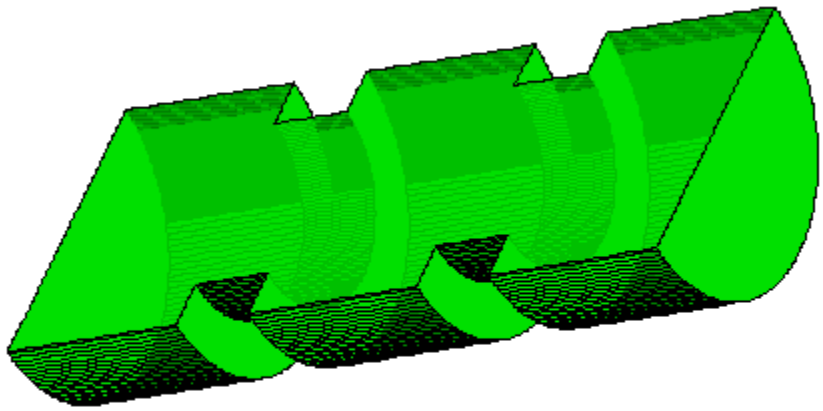

Fig. 3 Band object

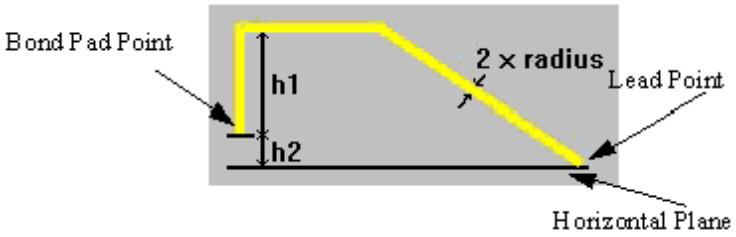
Geometric Objects — Bondwires

A bondwire is a thin metal wire that connects a metal signal trace with a chip. You can choose to draw a standard JEDEC 4-point bondwire, as shown below:



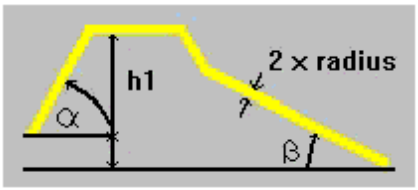
where

h1 = the height between the bond pad point and the top of the loop.

h2 = the height between the lead point and the bond pad point.

radius = half the diameter, or thickness of the wire.

You can draw a standard JEDEC 5-point bondwire, as shown below:



where

α = the angle between the horizontal plane and the wire at the bond pad point.

β = the angle between the horizontal plane and the wire at the lead point.

When drawing the bondwire, first select the bond pad point, a point in 3D space that defines the bond pad position in a horizontal plane. Then select the lead point, which indicates the distance the wire covers in the horizontal plane. Maxwell uses the distance between the bond pad and lead points to calculate the height between the bond pad and the lead point, or *h2*, a value that you can modify in the **Bondwires** dialog box.

Drawing Bondwires

Partial Simulation for Full Rotational Machine Models

A rotational machine can be simulated by using either a 360 deg full model, or a partial model with matching boundary. Full model simulation has higher memory and time cost than partial model simulation; while partial model would require manual operations to cut the model and assign a matching boundary. The manual cut on the geometry could introduce geometry issues which lead to poor mesh quality near matching boundaries.

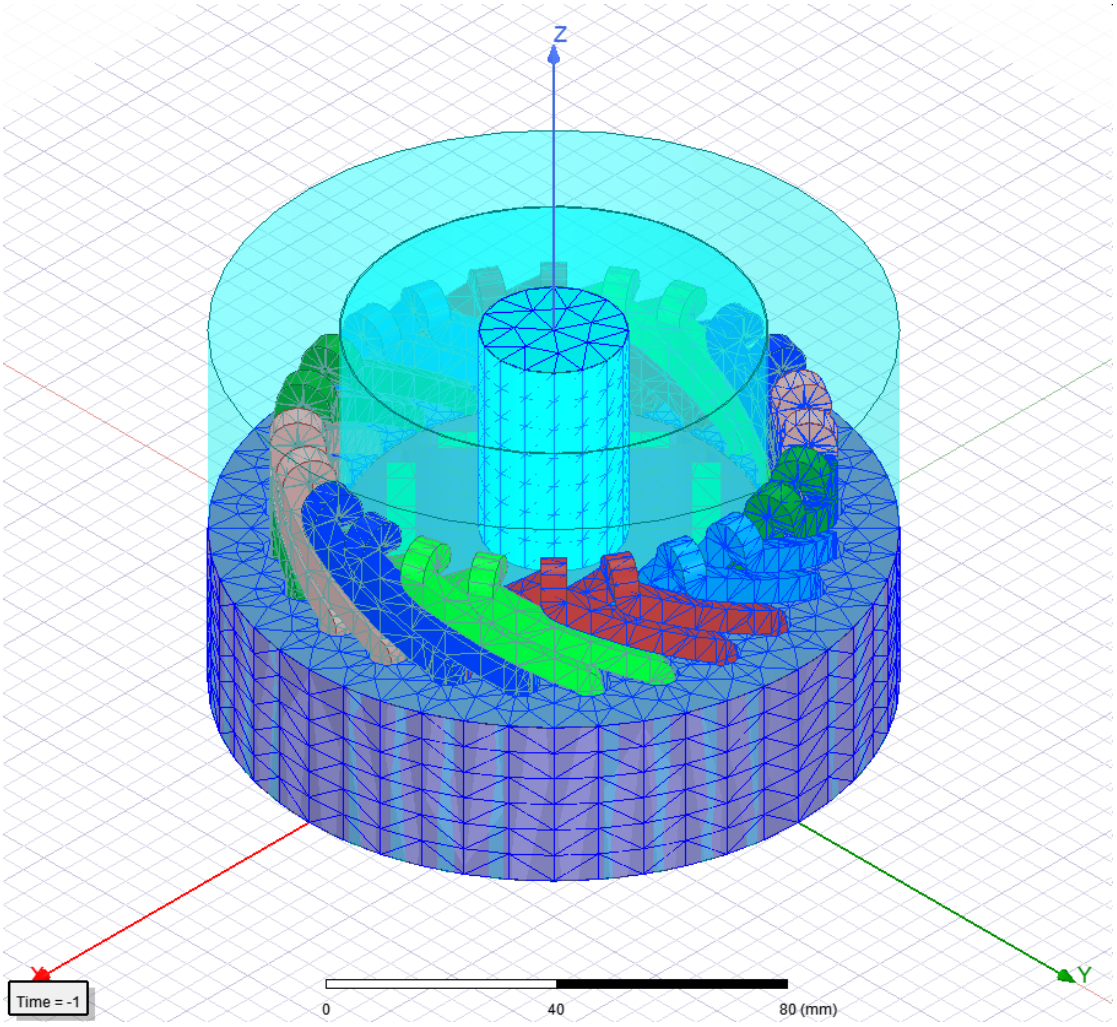
Partial simulation for full rotational machine models is designed to combine the benefits of full model simulation and partial model simulations. Without any manual cutting of the geometry, Maxwell can perform partial simulation for full rotational machines.

Background Information

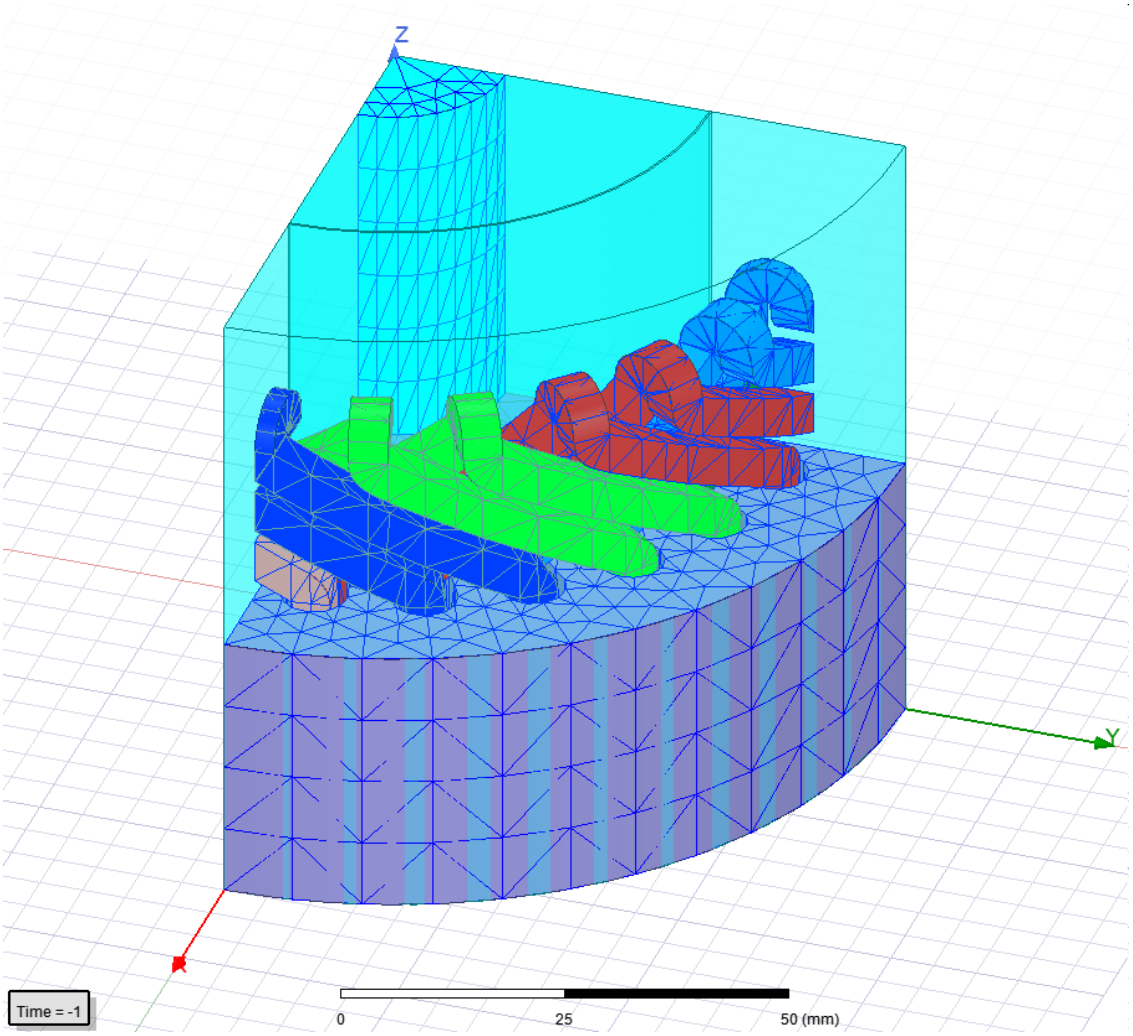
Partial simulation for a full rotational machine model generates and solves a partial mesh on the full model. Instead of a manual cutting of the geometry, this feature allows the mesher to decide where to make the cut. The mesher will also automatically create virtual matching boundaries for the partial mesh.

The following example uses the **ipm_2.aedt** model in the *[install_dir]***Examples\RMxprt\ipm** folder to generate a Maxwell 3D model with **Total circumferential fractions in created 360 deg geometry** on the **Symmetry Multiplier** tab set to 4.

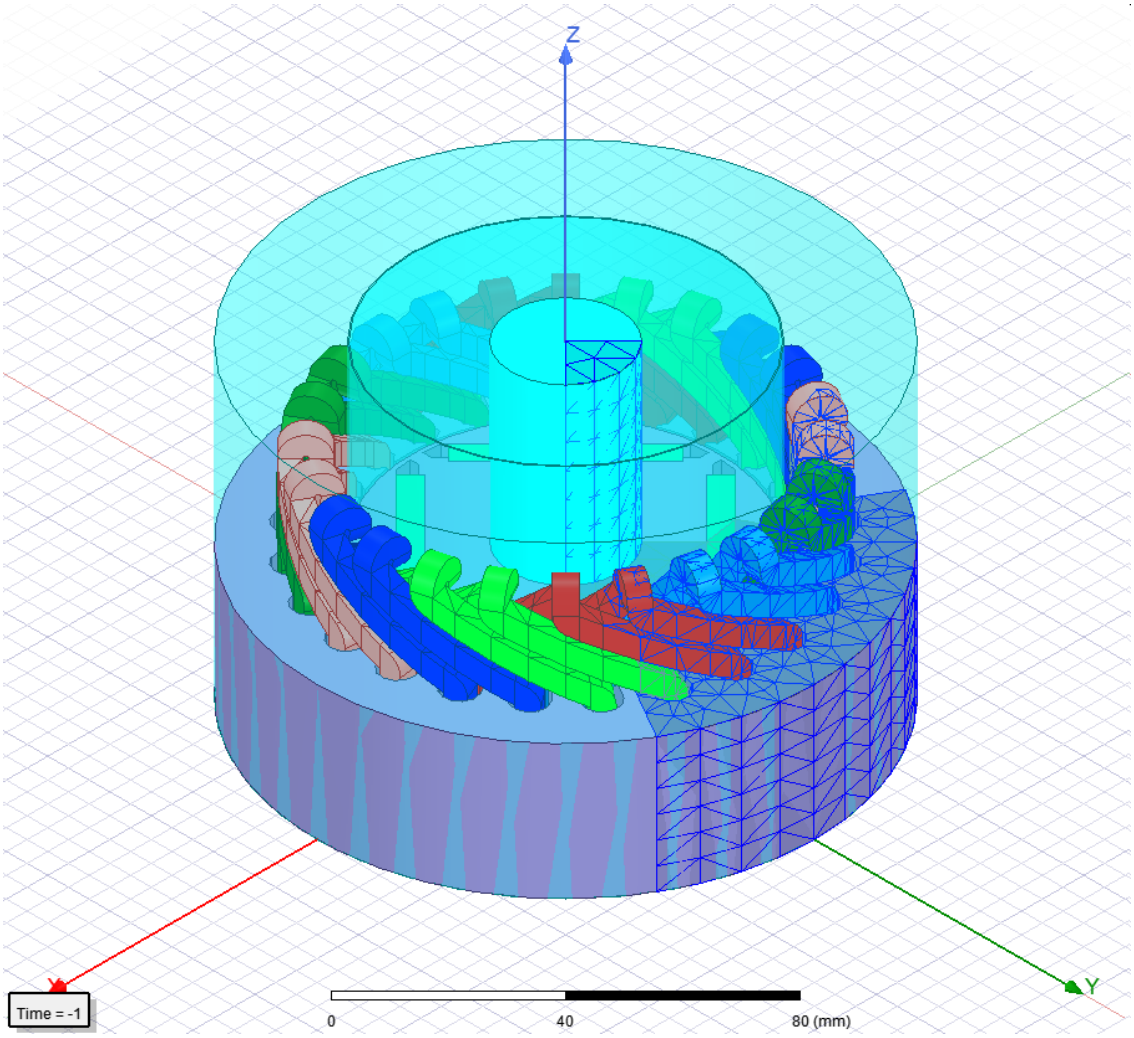
The figure below shows a full mesh on the full ipm_2 model with an element count of 95759.



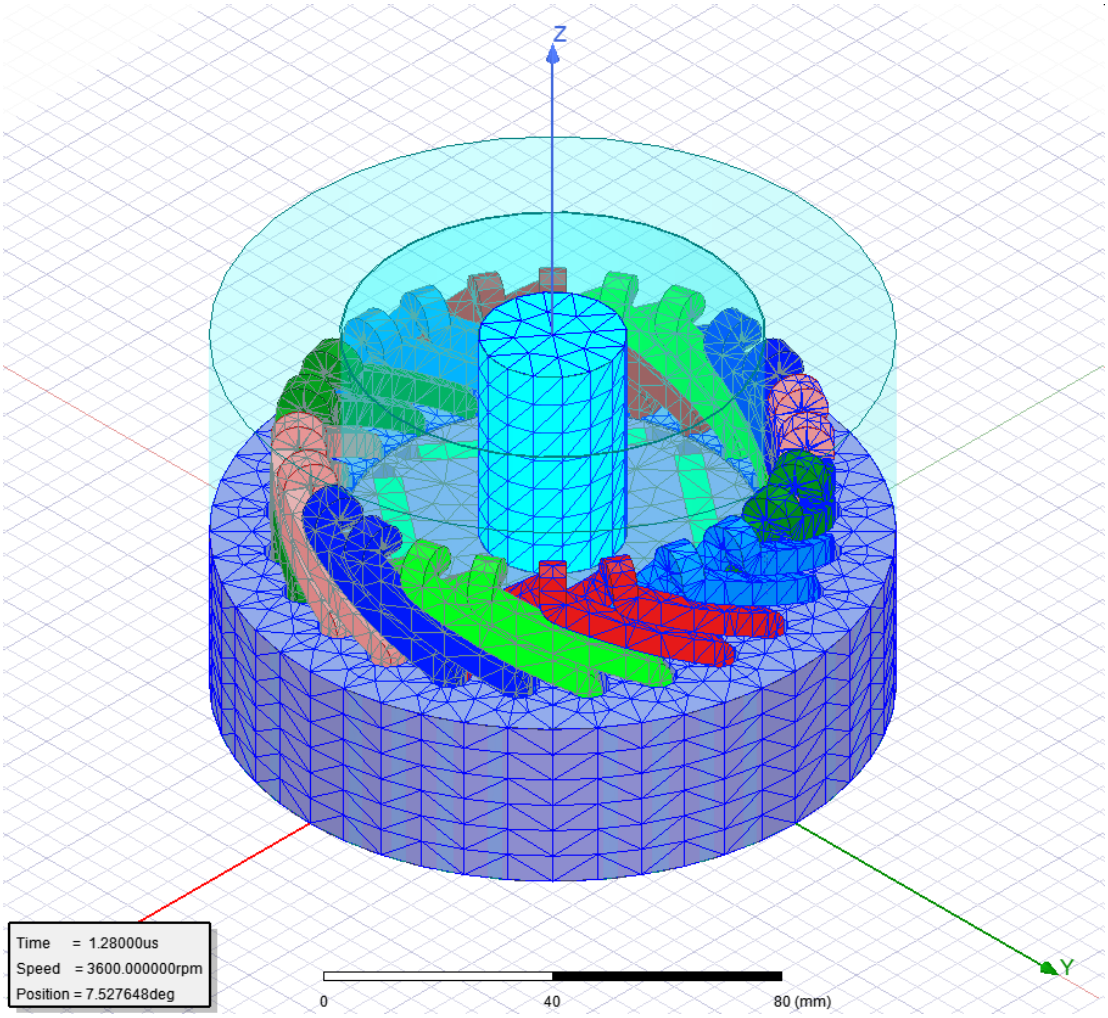
The following figure shows a partial mesh on a manually cut partial model for which the element count is 22194



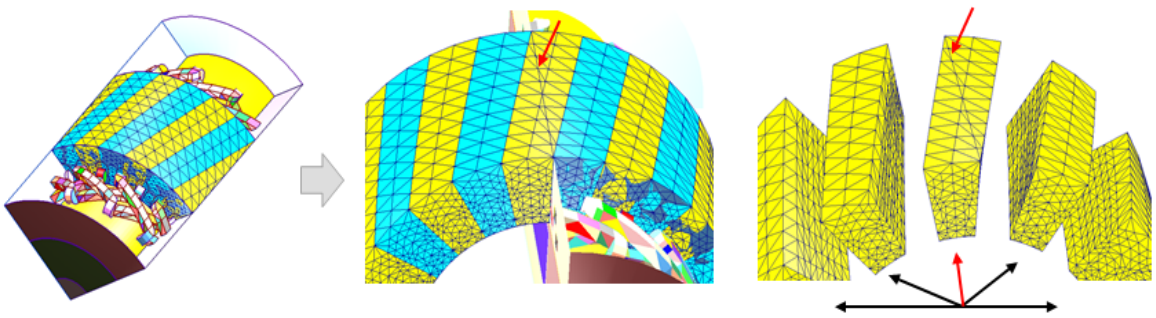
The following figure shows a behind-the-scene partial mesh on a full model for which the element count is 20298. Note that the element count for the partial mesh on a full model is comparable to partial mesh on a partial model, for which neither a manual model cut, nor matching boundary assignment is required.



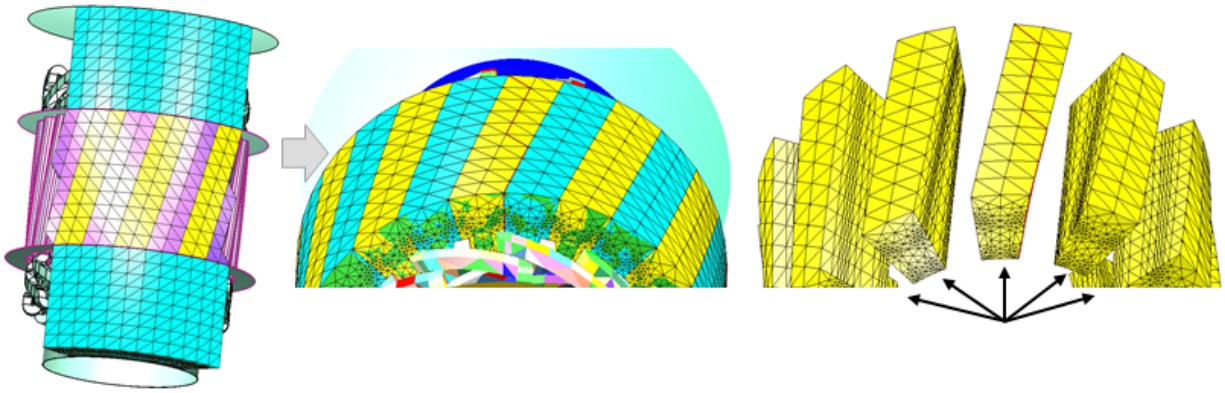
Note that when plotting the partial mesh on the full model, although behind-the-scene mesh only covers part of the model, the mesh plot will be copied and cover the full 360 degree model. Thus, the following model will actually be displayed.



A model with a skewed stator gets even more benefits with partial clone mesh. As shown below, because of the manual cut on the geometry, the skewed model cannot get a perfectly repeatable clone mesh near the matching boundary with partial mesh for a partial model.



On the other hand, with non-planar virtual matching boundary in partial mesh for the full model, identical mesh can be generated for all repeatable geometry patterns.



Workflow for Partial Simulation for a Full Rotational Machine Model

1. After solving the RMxprt machine design, create a full rotational Maxwell 3D machine design with 360 deg geometry.
2. Select **Solve one circumferential fraction** in Symmetry Multiplier settings.
    a. Enter an integer value for the **Total circumferential fractions in created 360 deg geometry**. For example, if a full model can be cut into a 1/4 partial model and matching boundary can be assign at 0 deg and 90 deg of the model, the integer value entered should be 4.
    b. Select either **Full** or **Half** for **Create geometry in axial direction** depending on whether the created model is the half model or the full model in axial direction.
    c. For a rotating machine, the simulation solution is periodic in the circumferential direction. Thus, select either Periodic or Half-periodic for **Field in one fraction** depending on whether the simulation solution in one fraction is of one period or half period physically.
    d. Click **OK** to close the dialog
3. Run simulation on the model.

Healing Models

> **Note:** Ansys Electronics Desktop (AEDT) uses a third-party modeling kernel to represent 3D geometry and to implement geometric operations in the 3D Modeler. In 2023 R1, AEDT has moved from the ACIS modeling kernel to Parasolid. This is part of an Ansys corporate migration of modeling technologies, based on the strength of the Parasolid kernel, its use by many CAD and CAE applications, and its active maintenance and enhancement by parent company Siemens.

The underlying solid modeling technology used by Ansys Electromagnetics products is provided by the Parasolid kernel geometric modeler. Users can create directly models using primitives and operations on primitives. In addition, users can import models saved in a variety of formats (Step, IGES, etc.) All the models are stored internally in Parasolid native format. When users import models into Ansys Electromagnetics products, translators are invoked that convert the models to this format. Parasolid regularly upgrades their solid modeling system. Third party vendors also create files in Parasolid format but the data in the files is in some cases not robust.

All of the above contribute to errors when a model is read. When translating from (for example) IGES, some accuracy is lost. Not all third party vendors write files to the supported formats with a high level of accuracy. Third party vendors sometimes create invalid files – the files are either targeted at earlier versions of the kernel, or incorporate invalid elements in the file. Sometimes there are errors in reading a file generated by an earlier version with the current version.

The modeling kernel is a highly specialized software component underlying the 3D Modeler in AEDT. The kernel represents the fundamental geometry and implements the operations that create and modify it. Simple geometry and operations are likely to be identical in different kernels and will migrate cleanly. More complex models may have discrepancies due to differences in geometry representation, tolerances, algorithms, or other implementation details. These differences may be subtle, but they can lead to challenges in the migration process.

After migrating to Parasolid, some objects may have invalid geometry or topology, leading to validation or meshing failures. In this case, customers are encouraged to take advantage of the 3D Modeler's built-in healing commands. The Parasolid kernel has very strong healing algorithms and it is often possible to automatically repair such geometry. In the worst-case scenario where healing is not successful, it may be necessary to redraw the object natively in 2023 R1.

Validating Projects

Error Types

When models are imported there are two types of errors – geometry errors and topology errors. Geometry errors are errors in definition of the underlying geometry while topology errors are errors in how the underlying components like faces, edges and vertices are connected. These have to be fixed before mesh analysis can be performed.

When models pass the initial validity checks, mesh generation could still fail. If bodies in the model overlap, mesh will not be invoked. If bodies are very close to each other, mesh might fail. Small features (small edges, small edges, sliver edges) might be present in the bodies which might cause mesh to fail.

The following are common errors present in models:-

1. api_check_entity() errors. These are errors detected by the kernel and are geometry and topology errors.
2. non-manifold topology. These are non-manifold edges and vertices that are present in the model.

Note	One of the requirements for valid mesh generation is that the surface mesh must be ***manifold***, that is, a plot of all the surface triangles of a 3D solid object should not have any “holes.” Such a mesh is often referred to as a ***watertight*** mesh. If there is a hole and you were to fill the object with water, the water would leak out of that hole – the mesh would not be ***watertight***. Zero-area holes (often called cracks) will also “leak.” Having multiple triangles cover the same patch also results in a mesh that is not manifold. Refer to *Detecting Errors* below for information on detecting and correcting such errors.

3. Body pair intersection. This detects if pairs of bodies intersect.
4. Small feature detection – small edge length, small face area and sliver face detection.
5. Mis-aligned entities detection – detects pairs of faces from bodies that can be aligned to remove interbody intersections. This improves the odds of mesh success.
6. Mesh failure error display. This is available for single body, body pairs and last simulation run (all bodies in model). Errors reported by the meshing module are reported to the user.

Errors of type 1, 2, and 3 must be resolved before the mesh can be applied to the model.

Detecting Errors

Errors in the model can be detected by the following methods:

1. Perform a validation check (**Maxwell3D >Validation check**). This returns the following types of errors — api_check_entity() errors, non-manifold errors, and intersection errors — and works on all the bodies present in the model.

2. Run an object analysis (**Modeler >Model Analysis >Analyze Objects**) on a subset of bodies in the model. This returns api_check_entity() errors and non-manifold edge/vertex errors, and, optionally small edge, small face and sliver face detection errors.
3. Run an interobject misalignment analysis (**Modeler >Model Analysis >Analyze Interobject Misalignment**). This yields face pairs from different bodies that are slightly misaligned with respect to each other. This misalignment causes the faces to intersect each other or to create small volumetric portion between the bodies that might cause mesh to fail. If these faces are aligned — that is, the faces are made to share the same surface definition — then the gap between the faces is eliminated and there is a higher likelihood that the mesh will succeed.
4. Run a surface mesh analysis (**Modeler >Model Analysis >Analyze Surface Mesh**). For the selected bodies, a mesh is invoked on each individual body and, optionally, on body pairs. Errors from running the mesh analysis are displayed, helping you focus on bodies/body pairs that fail meshing. If these are fixed, there is a higher probability that the mesh will succeed.
5. Mesh errors from the last simulation run are displayed.

Errors for 2, 3, 4 and 5 are displayed in the **Model Analysis** dialog box. Using the menu items for 2, 3 and 4 displays the dialog box. This dialog box can also be opened by clicking **Modeler >Model Analysis >Show Analysis Dialog**.

Healing and Meshing

Potential problems with 3D Models

This section lists problems that can prevent a 3D model from being meshed successfully. Subsequent sections will describe how these problems can be detected and addressed.

Kernel errors

The underlying solid modeling technology used by Ansys Electromagnetics 3D products Maxwell, HFSS and Q3D is provided by the Parasolid kernel. You can create models directly in the drawing environment of these Ansys Electromagnetics products using primitives, such as boxes, cylinders, etc. and operations on primitives, such as Boolean operations. In addition, you can import models produced by other CAD tools in a variety of formats such as STEP, IGES, etc. In Ansys Electromagnetics 3D products, all models are stored internally in the kernel's native format. When you import models into Ansys Electromagnetics products, translators are invoked that convert the models to this format. Often, models that were created in other CAD tools were created initially for other purposes than electromagnetic analysis, such as,. for mechanical design or just for display purposes. They may have imperfections that make them illegal to the kernel. Further, there can be compatibility issues between different versions and even flavors of modeling tools. All this can lead to errors in imported 3D models.

If you use Ansys Electromagnetics products to create geometry models, and thereby avoid model import and translation, you are unlikely to encounter such problems.

Mixed dimensionality

Even if a model is imported and translated without errors, there is a restriction to be aware of. The kernel cannot handle mixed-dimensionality models. One of the goals of Ansys Electromagnetics use of the kernel modeling system is to create a valid volumetric mesh for simulation. Mixed-dimensionality models will not yield a valid volumetric mesh. Therefore, the Ansys Electromagnetics tools will not mesh objects with mixed dimensionality, so-called non-manifold objects. For instance, imagine a 3D object representing a curved metal plate with a small but finite thickness. If it reaches zero thickness somewhere while having non-zero thickness elsewhere, it has mixed dimensionality, 2D as well as 3D. You will get an error message saying that the object is non manifold. Of course, 2D and 3D objects can co-exist in a model, but any one object cannot be both 2D and 3D.

Intersecting objects

Another restriction is that Ansys Electromagnetics 3D tools do not allow partial intersections (also known as partial overlaps) between 3D objects. Each element of the mesh has to belong unambiguously to one object. There is no problem if one object is enclosed completely inside a bigger object, but partial intersections lead to ambiguities. As long as there are partial object intersections, the mesh generator will not attempt to create a mesh. Instead, you will get an error message notifying you which objects are intersecting. You must remove the intersections before you can proceed. You can do this by changing the shapes of objects slightly, or by subtracting one object from the other.

Caveat: If, as a result of a subtraction, the model has pairs of true surfaces that are coincident (that is, smooth curved surfaces that fit exactly one inside the other), you make it harder for the mesh generator to create a mesh. This is because the kernel creates segmentations on each of these surfaces, and these segmentations are not guaranteed to fit. Setting a small value for Surface Deviation under ***Mesh>Assign Mesh Operation>Surface Approximation*** *increases your chance of success in such a case, but it is better to avoid such situations if you can.*

Small features and misalignment

When there are no kernel errors in the model, no non-manifold objects and no partial object intersections, the mesh generator can be invoked to create a valid mesh for the electromagnetic analysis. Even if the geometry is valid, mesh generation can still fail. Possible causes are the presence of very short edges, very small faces, long and thin sliver faces, and slight misalignments between faces that are supposed to be coincident.

Detecting and Addressing Model Problems to Improve Meshing

The following sections describe a systematic procedure to detect and address model problems that can interfere with the meshing process.

Technical Notes: *Healing During Geometry Import*

Technical Notes: *Healing After Geometry Import*

Technical Notes: *Removing Object Intersections*

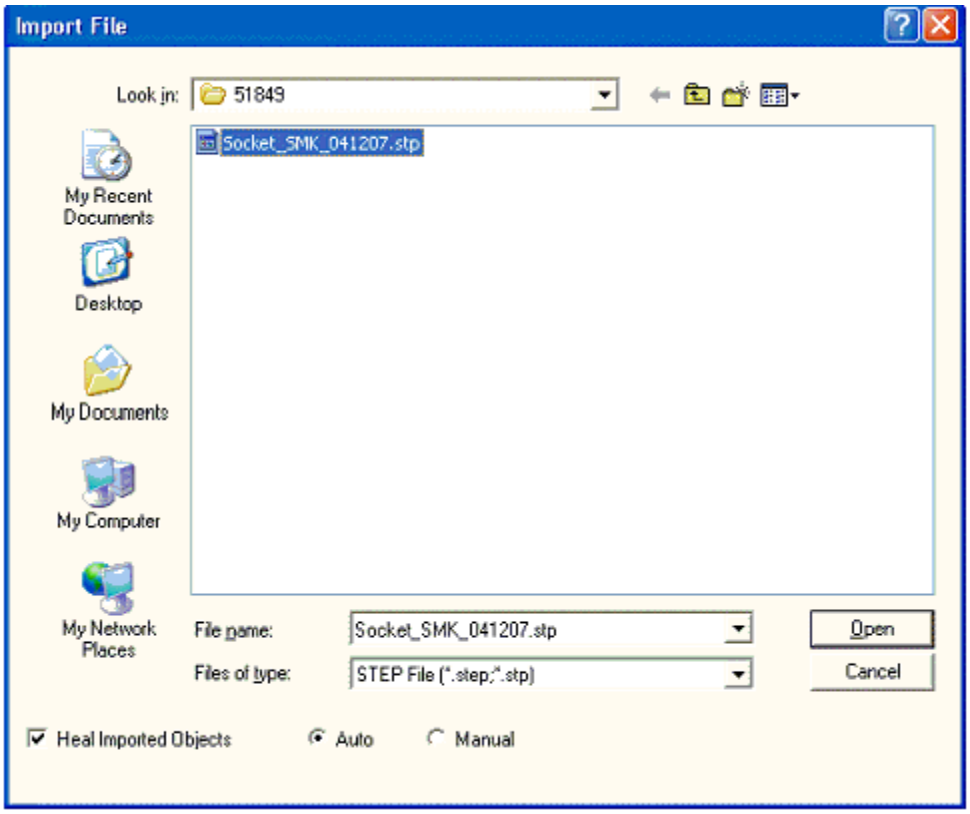
Technical Notes: *Removing Small Features*

Technical Notes: *Aligning Objects*

Technical Notes: *Troubleshooting if Meshing Still Fails*

Stage One: Healing during geometry import

In case you do not draw your entire geometry in the Ansys Electromagnetics environment but wish to import (part of) it, in the **Import File** window you select which geometry file to import. At the bottom of this window is a check box "**Heal Imported Objects**". Two modes exist, "auto" and "manual". Auto Healing will try to address geometry kernel errors and non-manifold errors, the first two classes of potential problems listed earlier. It will also fix surface normals in the body and updating orientation of body, to avoid having a body with negative volume.



Manual healing adds small-feature removal to this. You can remove small features at this stage if you wish. However, the usual approach is to apply auto-healing at this stage and leave small-feature removal until later.

Stage Two: Healing after geometry import

Healing can only be performed on objects that have no drawing history other than "import". If necessary, object history can be deleted through **Modeler >Purge History**. If that causes a warning that another object will be deleted, you may need to purge the history of that other object first, or purge the histories of several objects simultaneously.

At any time after import, you can perform a Validation Check: **Maxwell3D >Validation Check**. This will enable you to focus on bodies and body pairs that need attention before a mesh can be created.

1. Select the objects that have geometry kernel errors, such as failing api_check_entity(), and the objects that have non-manifold features, i.e. mixed dimensionality.
2. Invoke **Modeler >Model Analysis >Analyze Objects**.

   This will bring up an **Options** dialog to set thresholds for small feature detection and on completion, the **Model Analysis** dialog is displayed. All bodies in the model are shown in the objects grid along with their status. Bodies can have the following status:

1. Good
2. Null Body
3. Analysis not performed
4. Invalid entities found
5. Small-entity errors

Invalid-entity errors are geometry kernel errors and non-manifold errors. Small-entity errors are small faces, sliver faces and small edges that are optionally detected based on user-defined parameters.

Note	Invalid-entity errors must be fixed before a mesh can be generated.

To fix invalid entity errors:

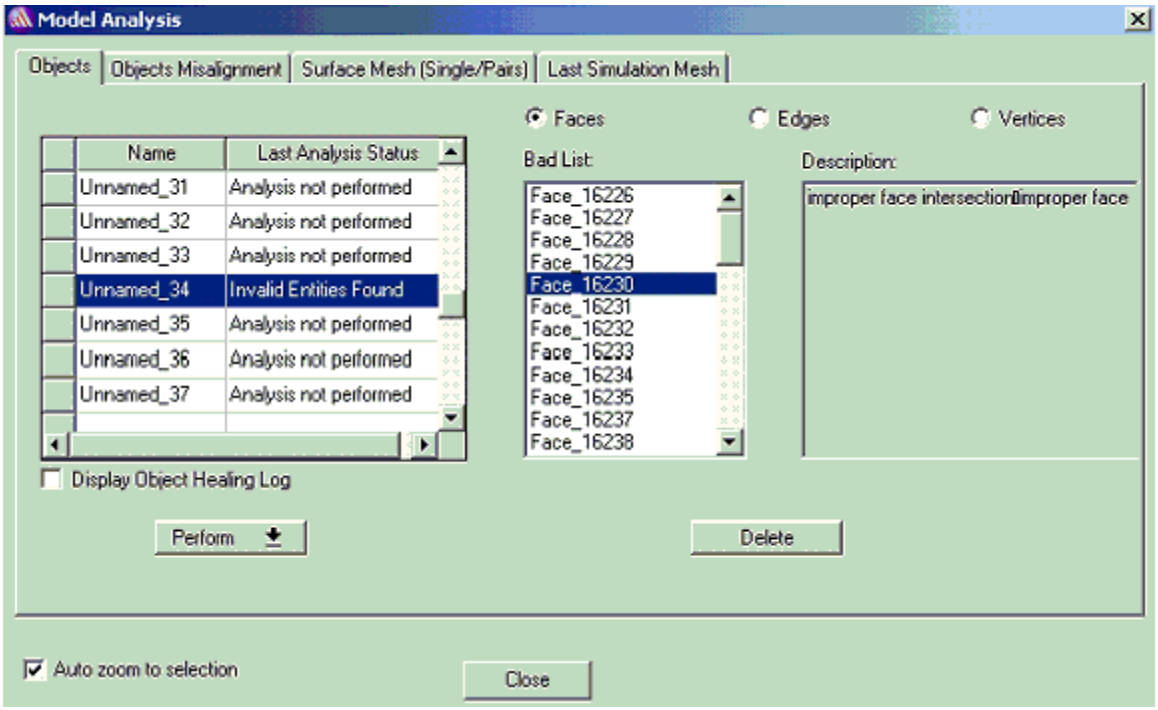
1. Choose the bodies that have "Invalid Entities Found."
2. In the same window, choose **Perform->Heal Objects**, with or without an optional setting for small-feature removal.

   In most cases, the bodies will be healed and the errors fixed.
3. If errors still persist, choose "offending" faces and edges and click on **Delete**.

   This will replace the selected face/edge entity by a tolerant edge/vertex respectively.

In order to avoid unintended changes, it is good practice to do the following:

1. At the bottom of the **Model Analysis** window, check the box "Auto Zoom to Selection."
2. Select one face or edge at a time
3. Decide for each face and edge whether you want to delete it.



Note	Healing causes changes to the geometry and topology of the body being healed. Validation check has to be re-run after healing is done to identify body pairs that intersect. It is possible that after healing, bodies that were disjoint before now overlap.

In some cases the replacement of the face/edge by tolerant edge/vertex will fail. If the object remains invalid, you know at this point what parts of the object are invalid. You will need to change that part of the object manually, either in Ansys Electromagnetics drawing environment or in the original CAD tool, to make it pass. Often, the invalid entities are in small details that can be changed without noticeably affecting the results of the electromagnetic analysis. For example, it may be possible to create a small object, well placed in the "offending" region, and to unite it with or subtract it from the problematic object, such that the "offending" details no longer exist.

Stage Three: Removing Object Intersections

If there are any intersecting objects, a Validation Check will list them. You must eliminate object intersections before a mesh can be created.

In complicated models, before making changes, it is good practice to inspect the overlap visually. A way to do this is to:

1. Duplicate both objects and place the copies outside the model.
2. Perform Boolean Intersect on the copies.

   This will show you what causes the intersection and will help you decide how to remove it.
3. Then, delete the copies.

The easiest way to eliminate object overlap is to subtract one object from the other, in the order that leaves the desired material in the region of overlap. If the overlap is very small and you can choose the order of subtraction, choose one that does not create coincident true surfaces, if possible.

Caveat: if as a result of a subtraction the model has pairs of true surfaces that are coincident, that is, smooth curved surfaces that fit exactly one inside the other, you will make it harder for the mesh generator to create a mesh. This is because the geometry kernel will create segmentations on each of these surfaces, and these segmentations are not guaranteed to fit. Setting a small value for **Surface Deviation** under **Mesh>Assign Mesh Operation>Surface Approximation** increases your chance of success in such a case, but it's better to avoid such situations if you can.

A way to eliminate object intersections without subtraction is to split one object in parts, in such a way that some parts are completely enclosed in the other object, and some parts are completely outside the other object. Even for complicated objects, this is possible through a sequence of Boolean operations on the objects and copies of the objects.

At this point, the geometry has no geometry kernel errors, no non-manifold objects and no partial object intersections. A mesh can be created for the electromagnetic analysis.

Stage Four: Removing Small Features

Even though, in principle, the geometry may be ready for a mesh to be created, it is possible that small features in the geometry lead to a mesh that is unnecessarily large and contains long and thin tetrahedra that make the simulation converge slower. Small features may even cause the mesh generation to fail. By small, we mean details on an object that are thousands of times smaller than the main features of the object, and that, in most cases, are unintended consequences of the drawing history in another CAD tool. Therefore, it is advantageous to remove small features.

To do this, you may need to purge the history of objects, since healing and related operations can only be performed on objects without history beyond import. You may have noticed that you could have invoked small-feature removal at several earlier stages. There is no objection to doing it earlier. The reason why it is presented here as stage four is that the previous stages were necessary while this one is optional.

To start the small-feature removal:

1. Select objects and invoke object analysis through **Modeler >Model Analysis >Analyze Objects**.

   Alternatively, without objects selected, use **Modeler >Model Analysis >Show Analysis Dialog >Objects** and select objects from the list. In the **Model Analysis window**, invoke **Perform >Analyze Objects**.

   The software will report the smallest edge length and the smallest face area, and enable you to set thresholds for the detection of short edges, small faces and sliver faces.
2. Upon clicking OK, the analysis is performed.

   As a result of the analysis, the software presents a list of all faces and edges that do not meet the thresholds set by you.

3. Check the box "Auto-Zoom to Selection" at the bottom of the Model Analysis window and click on small faces and short edges in the list.

   Inspect them visually and decide whether they can be deleted. It is good practice to delete them one by one rather than deleting many at once in order to prevent unintended changes.

   Sometimes, an edge or face cannot be deleted, and you get a message notifying you. In that case, either ignore it, or revisit it after deleting some other details first, or revisit it later manually in the 3D drawing environment.

   At this point, the geometry has no errors, no non-manifold objects and no partial object intersections. Furthermore, there are fewer small features that were unintended or unimportant for the electromagnetic analysis, so the quality of the model has improved.

Stage Five: Aligning Objects

Objects that touch each other in imported geometries do not always have well-aligned faces. Often, this is a consequence of the limited level of precision in the imported file. Misaligned faces can cause tiny object intersections or tiny gaps between objects, which in turn can lead to an inefficient mesh or even a failure to create the mesh.

To repair such occurrences in an automated way, you can select groups of objects and invoke **Modeler >Model Analysis >Analyze Interobject Misalignment**. This will yield face pairs from different bodies that are slightly misaligned with respect to each other.

In the window that shows this list, check the box "**Auto-Zoom to Selection**" and select face pairs from the list. When you decide that faces should be aligned, click Align Faces. In some cases, face alignment will fail if the topology of the body would change by a large amount after alignment. In that case, you can decide to ignore it, as it may not be a problem, or revisit it later manually in the 3D Modeler environment.

Note	In complicated models, the **Interobject Misalignment** analysis can take a long time if you select all objects before launching the analysis. If you do not know which pairs of objects to analyze, just let the mesh generator try to make a mesh. If the mesh fails, a list is presented to you of misalignments that the mesh generator finds suspicious but did not want to adjust without permission. Not every misalignment in the list is always a problem: this is a list of features that might need your attention.

Note	As face misalignments between touching objects can cause small object intersections, this alignment capability can already serve a useful role in stage three.

Stage Six: Troubleshooting if meshing still fails

If mesh generation fails, information about the reasons for the failure is presented under **Modeler >Model Analysis >Show Analysis Dialog >View Mesh Feedback**.

Again, check the box "Auto Zoom to Selection" and click on the errors in the list. This can give you hints about which parts of the model are causing difficulties.

For instance, there may be self-intersecting bodies or faces. Such errors can have a variety of causes, such as a face that is supposed to be planar, but of which the vertices do not quite lie in the same plane. When you zoom and search you are likely to see what causes the problem.

Also, there may be face misalignments. Once you know they exist, you can inspect them and decide whether to align them under the Objects Misalignment tab.

One of the tabs of the **Model Analysis** window is the **Surface Mesh** tab. Under that tab, you can try to create surface meshes for objects and pairs of objects. Since a surface mesh on selected objects is easier to create than a volume mesh for the whole model, this can help you to identify quickly which objects are causing difficulties and why.

Also, in order to determine which objects are causing difficulties, you can exclude objects temporarily from the model. If the mesh succeeds without them, this helps to identify the reason for failure. To exclude an object temporarily, select it and uncheck "Model" in its properties window. Then try to create the mesh again.

Once you know which objects make the mesh fail, you can try to make small changes to them that do not affect the electrical properties noticeably but help the mesh maker succeed. For example:

- Zoom in on details and consider removing details;
- Find coincident true surfaces and move one of the faces over a very short distance so the pair of faces is not coincident anymore;
- Split very complicated objects into multiple less-complicated objects;
- Delete a complicated 3D ground object and create a 2D ground through a boundary condition on the appropriate faces of a dielectric;
- Replace imported objects by objects drawn in Ansys Electromagnetics 3D modeling environment. For instance, some CAD tools produce cylinders that consist of two half cylinders that have a seam where they join. The fit is not always perfect.

Finally, for coincident true surfaces, set a very small value for **Surface Deviation** under **Mesh> Assign Mesh Operation> Surface Approximation**. Parasolid will give them more segments, but you can compensate for that with **Model Resolution**. In a parametric sweep, you can experiment with settings for **Surface Deviation** and **Model Resolution**.

Handling Complicated Models

Complicated models, often imported from a CAD tool or layout tool, may slow down the interface, use a lot of RAM during file I/O and other operations, contain imperfections and object overlaps.

After analysis, post processing of such models may be time consuming. Maxwell has several options and features that address these problems.

- Interface Options for Complicated Models
- Geometry Imperfections and Complicated Models
- Object Overlap Settings for Complicated Models
- Post Processing Settings for Complicated Models

Interface Options for Complicated Models

To improve the speed of the interface when dealing with complicated geometries, do the following:

Under **Tools>Options>Modeler Options**, on the **Display** tab...

- Set "Default View Render" to "Wire Frame". Wire-frame rendering is faster than shaded rendering.
- Turn off "Display UV Isolines". For models with curved faces, this will simplify the wire-frame display, so the rendering will be faster.
- Turn off "Visualize History of Objects". This will remove visualization of objects that are part of the model history. For large models, this is faster and uses less memory.

Under **View>Visualization Settings**

- Use larger deviations to view curved objects in less detail.

Under **Modeler>Import**

- Uncheck "Check Model" and "Heal Imported Objects." This helps for complicated models: Validation and healing take considerable time for such models. Use this option to defer checking to a later stage (especially in cases where you know that you want to mesh the model as is).

Under **Tools>Options>General Options**, on the **Project Options** tab…

- Turn off "Do Autosave" or set the autosave interval to a larger value, for example, 50. Auto-save can be time consuming.

Geometry Imperfections and Complicated Models

Modeler>Import

Many formats can be handled. It is recommended to import a version of the geometry that is as close as possible to its source, rather than geometries that have been translated before from one format to another, or that have been imported into another computational tool and later exported from it.

Modeler>Validation Settings

Geometry imperfections are listed as kernel errors when executing **Maxwell>Validation Check** and when starting an analysis. It is recommended to attempt to heal objects with such errors. However, Maxwell enables you to bypass the errors (not the check itself) by choosing a setting under **Modeler>Validation Settings**. "Warning Only" enables you to ignore all errors. "Basic" enables you to bypass all but the most severe errors. The Maxwell mesh generator has been enhanced to handle many geometry errors.

Object Overlap Settings for Complicated Models

In the **Set Material Override Tab** in the **Maxwell3D>Design Settings** menu...

Complicated geometries often have small object overlaps. This setting will allow overlaps between dielectrics and metals. In the overlap region, the metal will locally take priority over the dielectric, as if this part of the dielectric has been subtracted. Overlaps between two dielectrics and overlaps between two metals are still not allowed.

Post Processing for Complicated Models

Under **Tools>Options>General Options**, on the **Miscellaneous Options** tab...

- Turn off "Dynamically update postprocessing data during edits". This will disable expensive updating of existing reports and plots.
- Turn off "Update reports on file open". This will disable expensive updating of reports and plots when opening a project.

Materials

This section of the *Technical Notes* includes information on the following material properties:

Simple Materials

- Relative Permeability
- Relative Permittivity
- Bulk Conductivity
- Dielectric Loss Tangent
- Magnetic Loss Tangent

Frequency Dependent

- Frequency-dependent material properties.

Anisotropic materials

- Anisotropic materials
- Anisotropic relative permeability tensors
- Anisotropic relative permittivity tensors
- Anisotropic conductivity tensors
- Anisotropic dielectric loss tangent tensors
- Anisotropic magnetic loss tangent tensors
- Anisotropic materials and ports

Ferrite materials

- Magnetic Saturation
- Lande G Factor
- Delta H

Magnetostrictive materials

- Magnetostriction Modeling of Nonlinear Magnetic Material

Relative Complex Permeability

The permeability of dielectrics is assumed to be complex, as follows:

$$\mu = \mu' - j\mu''$$

The relative permeability is a dimensionless quantity, defined as follows:

$$\mu' = \mu_r \mu_0$$

where μ_0 is the permeability of free space.
The permeability can also be expressed as

$$\mu = \mu'\left(1 - j\frac{\mu''}{\mu'}\right)$$

where μ' is the real portion of μ and μ''/μ' is the magnetic loss tangent.

Relative Complex Permittivity

The permittivity of dielectrics is assumed to be complex, as follows:

$$\varepsilon = \varepsilon' - j\varepsilon''$$

which can also be expressed as

$$\varepsilon = \varepsilon'\left(1 - j\frac{\varepsilon''}{\varepsilon'}\right)$$

where ε' is the real portion of ε and from which the relative permittivity is defined as:

$$\varepsilon' = \varepsilon_r \varepsilon_0$$

where ε_0 is the permittivity of free space.

$\varepsilon''/\varepsilon'$ is the dielectric loss tangent.

If a material's losses due to bulk conductivity will be significant, such as in semiconductor dielectric materials, an additional bulk conductivity value, σ, must be added. From the time harmonic form of Maxwell's equations, the complex permittivity, ε_c is defined as

$$\nabla \times H = (\sigma + j\omega\varepsilon)E = j\omega\varepsilon_c E$$

where

$$\varepsilon_c = \varepsilon(1 - j\tan\delta - j\frac{\sigma}{\omega\varepsilon})$$

Bulk Conductivity

Maxwell is capable of including conductivity in the model either as a bulk material loss factor, similar to dielectric loss tangent, or as an impedance boundary condition applied to the outer surfaces of the object. The choice of bulk material loss instead of the boundary condition is made by selecting **Solve Inside** in the **Properties** window and by adding an Impedance Boundary on the surface of the object.

The choice between bulk material loss and the surface impedance boundary condition is problem dependent. The boundary condition can be applied whenever the conductor is much thicker than the skin depth at the solution frequency. In this case, the unknowns within the conductor are not included in the unknown vector, resulting in a smaller matrix and a faster analysis. However, if the conductor is not thick relative to the skin depth, the bulk material conductivity must be used to arrive at an accurate solution. With this assumption, the wave equation reduces to

$$\nabla\times\left(\frac{-1}{j\omega\mu}\nabla\times\boldsymbol{E}\right) = (j\omega\varepsilon + \sigma)\boldsymbol{E}$$

Related Topics

Impedance Boundary

Dielectric Loss Tangent

To represent a dielectric that dissipates the power of a high-frequency electric field, enter a dielectric loss tangent, $\varepsilon''/\varepsilon'$, property value for the material. The smaller the loss tangent, the less

lossy the material.

The dielectric loss tangent may vary with frequency. To simulate the variances, define a function for the dielectric loss tangent.

Magnetic Loss Tangent

To represent a magnetic material such as ferrite that dissipates the power of a high-frequency magnetic field, enter a magnetic loss tangent, μ''/μ', property value for the material. The smaller the loss tangent, the less lossy the material.

Note	If you plan to do a fast frequency sweep for a design that includes dielectrics, make sure that the dielectric or magnetic loss tangent does not vary significantly over the requested frequency range. If they do, the results may not be what you expect. In cases where the loss tangent does vary significantly over the frequency range in which you are interested, copy and solve the design several times, adjusting the loss tangent and associated frequency range for the copied design so that the loss tangent is relatively stable over the design's requested frequency range.

Note	When magnetic loss tangent is used, the resulting hysteresis core loss will be reflected in the resistance term for both the impedance matrix and the Simplorer Dynamic Eddy Current ROM.

Imaginary Permeability

Eddy Current

Some materials exhibit a permeability that includes both a real and imaginary component. The imaginary component is used to model magnetic losses in a time-varying field using the relationship:

$$B = (\mu_r' - j(\mu_r''))\mu_0 H$$

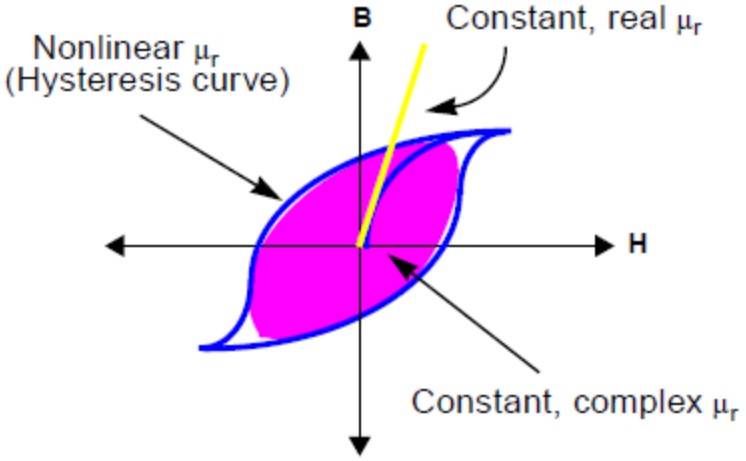
where:

μ_r' is the real component of the relative permeability.

μ_r'' is the imaginary component of the relative permeability.

μ_0 is the permeability of free space.

As shown below, a complex relative permeability causes the B field to lag behind the H field – similar to the behavior of a nonlinear, lossy material. The power loss during this cycle (the color shaded area) is approximately equal to the hysteresis loss (the area within the blue lines). The hysteresis curve for a material with a constant, real permeability (the straight yellow line) is shown as a reference.



When the nature of losses is also due to magnetic hysteresis, Maxwell allows you to model such effects using complex permeability by allowing the specification of the tangent of magnetic loss. When a linear material exhibits hysteresis effects, it should be characterized using a complex permeability, as below:

$$\underline{\mu} = \mu' - j\mu'' = \mu'\left(1 - j\tan\delta\right)$$

where $\tan\delta$ is the magnetic loss tangent, $\frac{\mu''}{\mu'}$

Enter the imaginary relative permeability of a material, *μ''*, in the **Imag. Permeability** field. The default imaginary permeability of zero is that of a material that exhibits no magnetic loss in a time-varying field.

Ferrite Materials

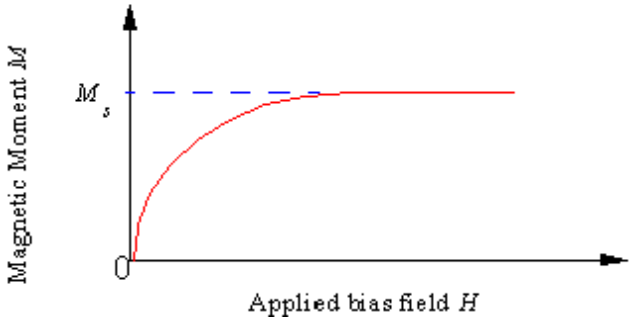
Ferrite materials are used to model the interaction between a microwave signal and a material whose magnetic dipole moments are aligned with an applied bias field. The gyrotropic quality of the ferrite is evident in the permeability tensor which is Hermitian in the lossless case. The Hermitian tensor form leads to the non-reciprocal nature of the devices containing microwave ferrites. If the microwave signal is circularly polarized in the same direction as the precession of the magnetic dipole moments, the signal interacts strongly with the material. When the signal is polarized in the opposite direction to the precession, the interaction will be weaker. Because the interaction between the signal and material depends on the direction of the rotation, the signal propagates through a ferrite material differently in different directions.

If you assign a ferrite material to an object, you must assign a magnetic bias source to the object.

Magnetic Saturation

A material with a non-zero magnetic saturation is considered to be a ferrite. When a ferrite is placed in a uniform magnetic field, the magnetic dipole moments of the material begin to align with the field. As the strength of the applied bias field increases, more of the dipole moments align. The magnetic saturation, M_s, is a property that describes the point at which all of the magnetic dipole moments of the material become aligned. At this point, further increases in the applied bias field

strength do not result in further saturation. The relationship between the magnetic moment, *M* and the applied bias field, *H*, is shown below.



The magnetic saturation, $4\pi M$, is entered in gauss.

Lande G Factor

The Lande *g* factor is a ferrite property that, on a microscopic level, describes the total magnetic moment of the electrons according to the relative contributions of the orbital moment and the spin moment. When the total magnetic moment is due entirely to the orbital moment, *g* is equal to one. When the total magnetic moment is due entirely to the spin moment, *g* is equal to two. For most

microwave ferrite materials, *g* has a range from 1.99 to 2.01. The Lande *g* factor is dimensionless.

Delta H

Delta H is the full resonance line width at half-maximum, which is measured during a ferromagnetic resonance measurement. It relates to how rapidly a precessional mode in the biased ferrite will damp out when the excitation is removed. The factor ΔH doesn't appear in the permeability tensor; instead, the factor α appears. The factor α is computed from

$$\alpha = -\frac{\gamma \mu_0 \Delta H}{2\omega}$$

The factor α changes the κ and χ terms in the permeability tensor from real to complex, which makes the tensor complex non-symmetric (where it had been hermitian for lossless ferrites).

Enter the full resonance line width at half maximum in the **Delta H** value box. Delta H is measured at a specific frequency. That frequency needs to be entered by the user at the interface. 9.4 Ghz is the frequency where Delta H is typically measured.

Anisotropic Materials

Anisotropic materials have characteristics that vary with direction. These characteristics are defined by their anisotropy tensors. You must define three diagonals each for anisotropic permittivity, electric loss tangent, conductivity, permeability, and magnetic loss tangent. Each diagonal represents a tensor of your model along an axis. The alignment of the materials axis with respect to the object is discussed in Assigning Material Property Types.

The following anisotropic characteristics can be defined:

- Anisotropic relative permeability tensors
- Anisotropic relative permittivity tensors
- Anisotropic conductivity tensors
- Anisotropic dielectric loss tangent tensors
- Anisotropic magnetic loss tangent tensors
- Anisotropic materials and ports

Anisotropic Relative Permeability Tensors

The relative permeability tensor for an anisotropic material is described by

$$[\mu] = \begin{bmatrix} \mu_1\mu_0 & 0 & 0 \\ 0 & \mu_2\mu_0 & 0 \\ 0 & 0 & \mu_3\mu_0 \end{bmatrix}$$

where

- μ_1 is the relative permeability along one axis of the material's permeability tensor.
- μ_2 is the relative permeability along the second axis.
- μ_3 is the relative permeability along the third axis.
- μ_0 is the permeability of free space.

The relationship between *B* and *H* is:

$$\begin{matrix} x \rightarrow \mu \\ y \rightarrow v \\ z \rightarrow w \end{matrix} \quad \begin{bmatrix} B_x \\ B_y \\ B_z \end{bmatrix} = [\mu] \begin{bmatrix} H_x \\ H_y \\ H_z \end{bmatrix}$$

To specify the relative permeability for an anisotropic material, enter the μ_1, μ_2, and μ_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. If the relative permeability is the same in all directions, use the same value for μ_1, μ_2, and μ_3. These values can also be entered as variables.

Anisotropic Relative Permittivity Tensors

The relative permittivity tensor for an anisotropic material is described by

$$\varepsilon = \begin{bmatrix} \varepsilon_1\varepsilon_0 & 0 & 0 \\ 0 & \varepsilon_2\varepsilon_0 & 0 \\ 0 & 0 & \varepsilon_3\varepsilon_0 \end{bmatrix}$$

where

- ε_1 is the relative permittivity of the material along one tensor axis.
- ε_2 is the relative permittivity along the second axis.
- ε_3 is the relative permittivity along the third axis.
- ε_0 is the permittivity of free space.

The relationship between *E* and *D* is then

$$\begin{matrix} x \rightarrow \mu \\ y \rightarrow v \\ z \rightarrow w \end{matrix} \quad \begin{bmatrix} D_x \\ D_y \\ D_z \end{bmatrix} = [\varepsilon] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the relative permittivity for an anisotropic material, enter the ε_1, ε_2, and ε_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as variables.

Anisotropic Conductivity Tensors

The conductivity tensor for an anisotropic material is described by

$$[\sigma] = \begin{bmatrix} \sigma_1 & 0 & 0 \\ 0 & \sigma_2 & 0 \\ 0 & 0 & \sigma_3 \end{bmatrix}$$

where

- σ_1 is the relative conductivity along one axis of the material's conductivity tensor.
- σ_2 is the relative conductivity along the second axis.
- σ_3 is the relative conductivity along the third axis.

The relationship between *J* and *E* is then:

$$\begin{matrix} x \rightarrow \mu \\ y \rightarrow v \\ z \rightarrow w \end{matrix} \quad \begin{bmatrix} J_x \\ J_y \\ J_z \end{bmatrix} = [\sigma] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the conductivity for an anisotropic material, enter the σ_1, σ_2, and σ_3 values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. The values of σ_1 and σ_2 apply to axes that lie in the xy cross-section being modeled. The values of σ_3 apply to the z-component. These values affect current flowing in dielectrics between the conductors. These values can also be entered as variables.

Anisotropic Dielectric Loss Tangent Tensors

The dielectric loss tangent tensor for an anisotropic material is described by

$$[\tilde{\varepsilon}] = \begin{bmatrix} \varepsilon'_1(1 - j\tan\delta_1) & 0 & 0 \\ 0 & \varepsilon'_2(1 - j\tan\delta_2) & 0 \\ 0 & 0 & \varepsilon'_3(1 - j\tan\delta_3) \end{bmatrix}$$

where

- $\tan\delta_1$ is the ratio of the imaginary relative permittivity to the real relative permittivity in one direction.

$$\tan\delta_1 = \frac{\varepsilon''_1}{\varepsilon'_1}$$

- $\tan\delta_2$ is the ratio of the imaginary relative permittivity to the real relative permittivity in the second direction.

$$\tan\delta_2 = \frac{\varepsilon''_2}{\varepsilon'_2}$$

- $\tan\delta_3$ is the ratio of the imaginary relative permittivity to the real relative permittivity in the third orthogonal direction.

$$\tan\delta_3 = \frac{\varepsilon''_3}{\varepsilon'_3}$$

ε'_1

- ε'_2 ε'_3

, , and are the real relative permittivities specified earlier.ε

The relationship between *D* and *E* will then be

$$\begin{matrix} x \rightarrow \mu \\ y \rightarrow \nu \\ z \rightarrow w \end{matrix} \quad \begin{bmatrix} D_x \\ D_y \\ D_z \end{bmatrix} = [\bar{\varepsilon}] \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}$$

To specify the electric loss tangent for an anisotropic material, enter the $\tan\delta_1$, $\tan\delta_2$, and $\tan\delta_3$ values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as variables.

Anisotropic Magnetic Loss Tangent Tensors

The magnetic loss tangent tensor for an anisotropic material is described by

$$[\bar{\mu}] = \begin{bmatrix} \mu'_1(1 - j\tan\delta_{M1}) & 0 & 0 \\ 0 & \mu'_2(1 - j\tan\delta_{M2}) & 0 \\ 0 & 0 & \mu'_3(1 - j\tan\delta_{M3}) \end{bmatrix}$$

where

- $\tan\delta_{M1}$ is the ratio of the imaginary relative permeability to the real relative permeability in one direction.

$$\tan\delta_{M1} = \frac{\mu''_1}{\mu'_1}$$

- $\tan\delta_{M2}$ is the ratio of the imaginary relative permeability to the real relative permeability in the second direction.

$$\tan\delta_{M2} = \frac{\mu''_2}{\mu'_2}$$

- $\tan\delta_{M3}$ is the ratio of the imaginary relative permeability to the real relative permeability in the third orthogonal direction.

$$\tan\delta_{M3} = \frac{\mu''_3}{\mu'_3}$$

μ'_1

- μ'_2 μ'_3

, , and are the real relative permeabilities specified earlier.

The relationship between *B* and *H* will then be

$$\begin{matrix} x \rightarrow \mu \\ y \rightarrow v \\ z \rightarrow w \end{matrix} \begin{bmatrix} B_x \\ B_y \\ B_z \end{bmatrix} = [\bar{\mu}] \begin{bmatrix} H_x \\ H_y \\ H_z \end{bmatrix}$$

To specify the magnetic loss tangent for an anisotropic material, enter the $\tan\delta_{M1}$, $\tan\delta_{M2}$, and $\tan\delta_{M3}$ values in the **Value** boxes of the **T(1,1)**, **T(2,2)**, and **T(3,3)** rows, respectively. These values can also be entered as functions.

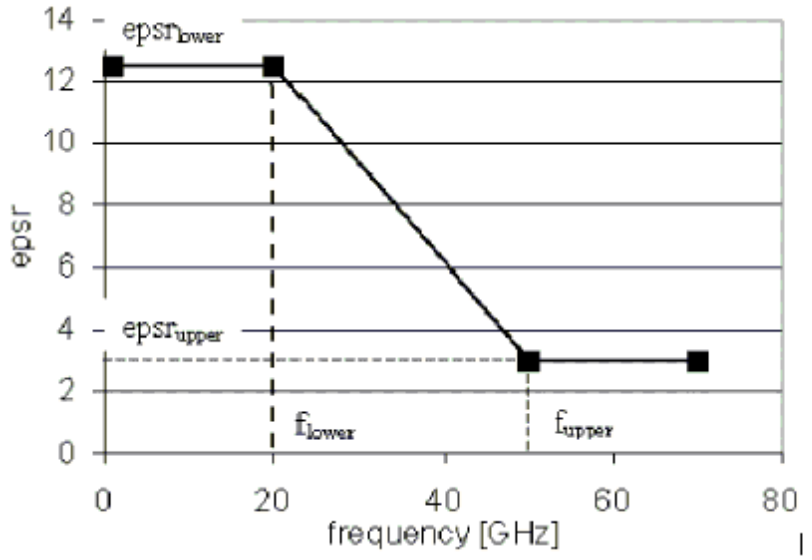
Anisotropic Materials and Ports

An anisotropic material can be in contact with a port under the following conditions:

- One principal axis of the anisotropic material is aligned normal to the port.

Frequency-Dependent Material Properties

The properties of some materials vary with the frequency of the field excitation. This frequency dependence is often linear within a certain frequency range and constant outside of the frequency range, as shown below,



where

- $epsr_{lower}$ is the relative permittivity of a material below the frequency range 20 - 50 GHz.
- $epsr_{upper}$ is the relative permittivity of a material above the frequency range 20 - 50 GHz.
- f_{lower} is the lower frequency, below which the material property is constant.
- f_{upper} is the upper frequency, above which the material property is constant.

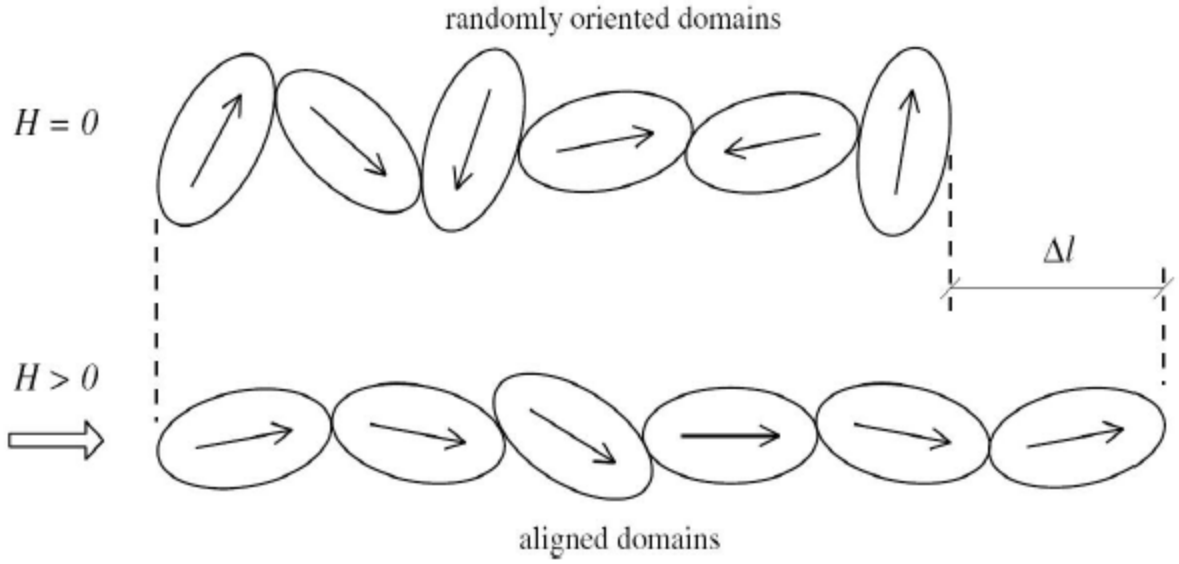
In general, to account for this variance within a given frequency range, use the **Piecewise Linear Material Input** window dialog box to specify a property's values at frequencies below and above the frequency range. Based on these values, Maxwell automatically creates a linear dataset that specifies the property's values at the desired frequencies during solution generation. This dataset can be modified with additional points if desired.

> **Note:** The 3D AC conduction solver only solves the function inserted in the material property field and does not check the upper and lower limits.

Magnetostriction Modeling of Magnetic Material

Magnetostriction was first observed by J. Joule in 1842. Currently it is typically described as "deformation of a body" as a result of its magnetization. The elongation or contraction in the direction of applied magnetic field is usually between 10^{-5} and 10^{-3} and accompanied by the opposite sign changing in the transverse direction, so that the volume remains almost the same. The phenomenon of magnetostriction can be regarded as an energy transduction (or transformation) from mechanical to magnetic and vice-versa. It can be described as a bidirectional magneto-mechanical coupling between the mechanical and magnetic fields in the magnetostrictive material. The origin of this phenomenon can be traced to the alignment of the

magnetic domains inside the material. The following figure is a schematic of the effect simplified to one dimension. When no magnetic field is applied to the system, the series of domains have randomly oriented magnetic moments. Whereas when a magnetic field is applied, the series of domains rotate to partially align themselves to the magnetic field direction resulting in a change in length Δl. Applying a sufficiently high magnetic field will result in perfectly aligned domains, in which case the material achieves the maximum magnetically induced strain (i.e. peak magnetostriction). Magnetostriction requires the magnetic domains to be longer in one dimension than the other two to obtain a change in length when the domain rotates. This, in general, results in anisotropy of the crystal structure of the material.



Magnetostriction is considered to be one of the main sources of noise in Transformers. When an alternating voltage is applied to one or more windings of a transformer, a magnetic flux is generated in the transformer core laminations made of grain oriented electrical steel. The nonlinear anisotropic property of magnetostriction implying alternating changes of the core dimensions due to the varying magnetic flux in the laminations. Those magnetostrictive forces cause core vibrations which are transmitted to the tank via the insulation oil and the core clamping points. Part of the mechanical energy is eventually radiated by the tank walls as noise. In electric motors, magnetostrictive forces also contribute to motor vibration and noise.

On the other hand, magnetostrictive materials convert energy between the mechanical and magnetic domains (inverse magnetostriction). They deform in response to applied magnetic fields and change their magnetic state when stressed. Some materials (such as Terfenol-D, Galfenol) have the ability to produce large magnetostrictive strains at moderate fields. Short response times (in the millisecond range) combined with resolutions in the order of microstrains make these materials well-suited to precision sensing and actuation mechanisms.

Due to the complexity of the mechanism of magnetostriction, it is very difficult to predict it with analytic models. In general, empirical methods based on statistics and dimensional basic parameters are used by most transformer manufacturers and sensor producers. Those

approaches present limitations when applied to new designs and do not enable accurate parametric studies. Therefore, prediction models based on finite element formulations will be utilized to describe accurately the complex interactions of the various design parameters and the coupling of the physical fields.

The finite element method (FEM) is widely used in engineering practice because using the irregular grids it can model complex inhomogeneous and anisotropic materials and represent complicated geometry. The FEM discretization produces a set of matrix differential equations. Because of the nonlinearity, the matrices generally are dependent of the solution vectors, so an iteration method such as Newton-Raphson method should be used to solve these nonlinear matrix equations. Namely, the nonlinear matrix equations are linearized for each nonlinear iteration. The linearized matrix equations may be solved by either a direct or iterative matrix solver.

The governing equation of magnetic field is given by:

$$\sigma \frac{\partial A}{\partial t} + \nabla \times \left(\frac{\nabla \times A}{\mu} \right) = J$$

(equation 1)

Where **A** is the magnetic vector potential, **σ** is the electrical conductivity, and **μ** is the magnetic permeability of material. **J** represents the current density.

The magnetic flux density **B** can be expressed as:

$$B = \nabla \times A$$

(equation 2)

The relationship between **B** and **H** (magnetic field) is based on the constitutive law:

$$B = \mu H$$

(equation 3)

For a discretized mechanical system, the governing equilibrium equation can be written as

$$Kr + R_0 = R$$

(equation 4)

Where K is the system stiffness matrix, is the body force vector, and R the vector of external force, r is vector of node displacement. The strain-displacement relationship can be written as

$$S = \nabla r$$

(equation 5)

Where **S** is the strain tensor. And the stress-strain relationship can be described by

$T=CS$ (equation 6)

where **T** is the stress tensor, and **C** is stiffness matrix.

When a magnetic field is applied to a magnetostrictive material, strain occurs within the material placed in a magnetic field in response to the flux density within the material, while the stress gives feedback to affect the magnetic field. For coupled method, we have:

$$\begin{bmatrix} B \\ S \end{bmatrix} = \begin{bmatrix} \mu & d \\ d^T & C^{-1} \end{bmatrix} \begin{bmatrix} H \\ T \end{bmatrix}$$

(equation 7)

$$d^T = \left. \frac{\partial \lambda}{\partial H} \right|_T$$

(equation 8)

$$d = \left. \frac{\partial B}{\partial T} \right|_H$$

(equation 9)

Where **d** and $\mathbf{d^t}$ are magneto-mechanical coupling coefficients, **λ** is magnetostriction induced by magnetic field **H**. The magnetic field and mechanical stress field are solved together, which means both fields are solved on the same mesh simultaneously by using the one matrix solver.

For decoupled method, the magnetostriction may be determined once the magnetic field distribution is obtained from FEM simulation. Hence an elastic analysis is reduced to the problem of finding the stress due to an external load caused by a force applied to a material with a previously known magnetostriction, the latter unrelated to the stress. Magnetostriction is transformed into stress with the usage of Hooke's law. Equation (7) can be rewritten as:

$$B = \mu H + dT$$

(equation 10)

$$S = C^{-1}T + d^T H$$

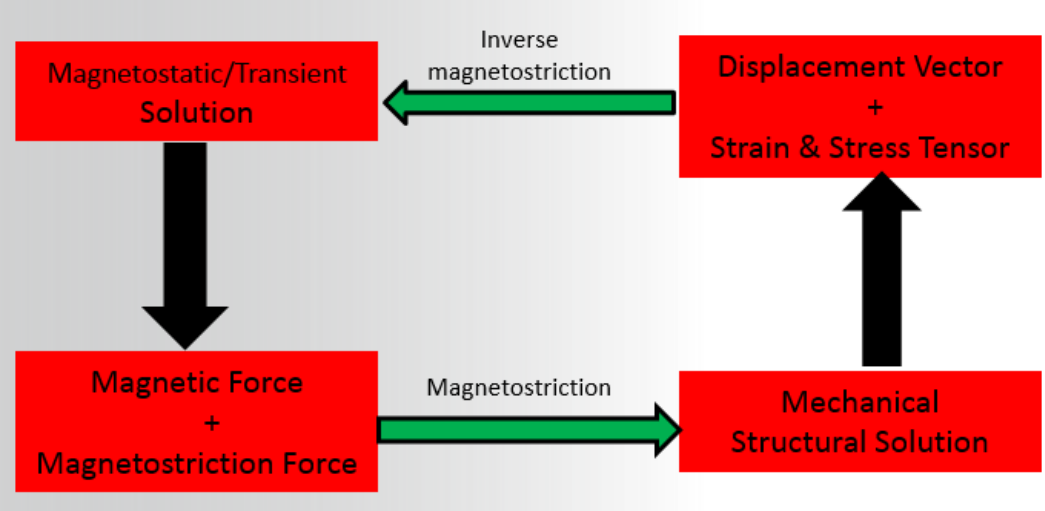
(equation 11)

where

$d^T H$: magnetostrictive, deformation induced by magnetic field **H**.

dT: inverse magnetostriction, impact of stress **T** on magnetic field **B**.

By using the decoupled method, the magnetic field and stress field can be solved independently with different mesh and different solver, and magnetostriction and inverse magnetostriction can be involved in either one or both. Compared to the coupled method, the decoupled method is more flexible and general. The process for the decoupled method is shown in the following figure:



30 - Maxwell Examples

Maxwell provides numerous examples for customer use.

- Maxwell 2D and 3D examples are stored in the **Examples\Maxwell** sub-directory within the **AnsysEM** installation directory.
- Rmxprt examples are stored in the **Examples\RMxprt** sub-directory within the **AnsysEM** installation directory.

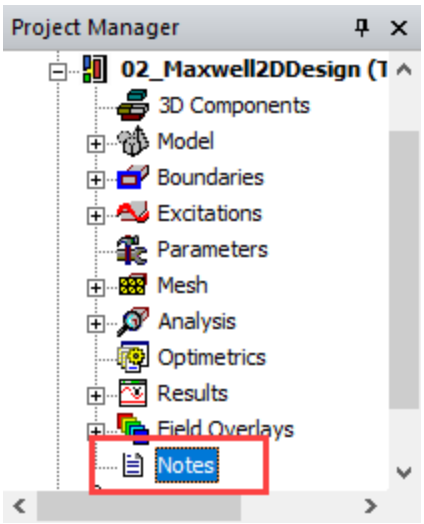
RMxprt Examples

Maxwell 2D and 3D Examples

Maxwell 2D and 3D example designs are stored in the **Examples\Maxwell** sub-directory within the **AnsysEM** installation directory. Detailed information for each design is included in the **Notes** in the design's project tree.

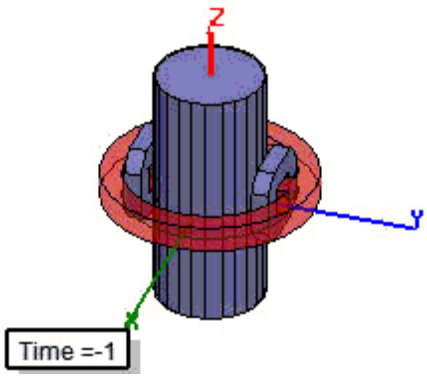


> **Note:** The **Ex_MS_4_ECE_Linear_Movement.aedt** and **WirelessCharging.aedt** designs cannot be used on Linux platforms because they contain **TwinBuilder** designs. **TwinBuilder** is not supported on Linux.

The designs below, found in the **Examples\Maxwell\Actuators** sub-directory, are those modeled in the three Maxwell *Getting Started Guides*.

Examples\Maxwell\Actuators	The solenoid model shown is a 2D axisymmetric

Solenoid.aedt 	simulation of a 3D actuator that demonstrates rotational symmetry about a central axis. The problem is a magnetostatic model that uses parametric analysis to determine the force on the core as various locations along the length of the stroke. This is a non-linear problem incorporating both non-linear steel and a permanent magnet. This problem is used in *Getting Started with Maxwell: A 2D Magnetostatic Solenoid Problem*.
Examples\Maxwell\Actuators\ Rotational_actuator.aedt 	The rotational actuator is another magnetostatic example usable for the parametric study of the torque and inductance characteristics vs. position. Possible variation (s) of the setup can include using ferromagnetic materials with different magnetic (non-linear) characteristics and the respective impact on torque and inductance characteristics. This model is used in the *Getting Started with Maxwell: Designing a Rotational Actuator* guide.
Examples\Maxwell\Actuators\ Rotational_Act_TR.aedt	This model is a modified version of the Rotational Actuator model listed above. It is configured with a motionband for rotating the inner armature. It is a transient problem using an external circuit to drive the coils with a pulse voltage. The results demonstrate the torque, position, and current versus time as the inner armature object moves with time. This model is used in the *Getting Started with Maxwell: Transient Problem* guide.

Examples\Maxwell\Actuators\ ExternalCircuit.aedt 	This project is the Maxwell Circuit Editor model used in the transient rotational actuator problem to drive the coils with a pulse input.

31 - Maxwell Terminology

This section defines the terminology used in the Ansys Maxwell® help topics. Terms are listed in alphabetical order.

Glossary: A

advanced nonlinear options

For the magnetostatic solution type, the advanced nonlinear options allow you to perform more sophisticated simulations of the magnetostatic field. (Nonlinear materials are materials in which the magnetic flux density varies nonlinearly with the magnetic field.)

anisotropic materials

Anisotropic materials exhibit different values of the respective material property in different directions of the three-orthogonal coordinate system used to define it. Any of the material properties can be anisotropic: electric conductivity, dielectric permittivity, magnetic permeability. Mathematically, tensors are used to express the respective anisotropic properties.

Glossary: B

B-H curve

In nonlinear materials, when a material has a permeability that varies with the flux density, a B-H curve is used to describe the material's nonlinear behavior. The B refers to the magnetic flux density. The H refers to the magnetic field intensity.

Glossary: C

capacitance

Capacitance is a quantity used to describe the ability of a pair of corresponding electrodes to store electric energy. In an equivalent formulation, the storage of energy corresponds to charge accumulation on the respective armatures while a voltage is established between them. Mathematically, capacitance is the positive defined ratio between the charge accumulated on one of the armatures and the voltage between the two armatures.

cascaded windows

Cascaded windows are a set of partially overlapping windows stacked on top of each other.

coil terminals

A coil terminal is used to apply excitations to coils. It can be a 2D sheet object obtained, for example via a section command (for closed coils that are totally contained within the region where the field problem solution is being computed), or it can be materialized by the intersection between the problem region and open-ended conductors. It is assumed that the current flow is perpendicular to the coil terminal.

conduction path

The conduction path is a sequence of conductors (objects with non-zero conductivity) through which current flows.

conductivity

Conductivity (electric) represents the ability of a material to allow electric current to flow through it.

conductor

Conductor are, in general, objects with non-zero value of conductivity. The way such objects are treated by the software depends upon the user-defined conductivity threshold value.

cost function

In an optimization setup, a cost function is calculated based on goal values specified for one or more solution quantities. The chosen Optimetrics engine automatically changes the design parameter values to fulfill the objective of the optimization. The cost function can be based on any quantity that can be computed directly by Maxwell or by the field calculator.

current density terminals

This refers to any terminal used to specify the current density of an object.

cutplane

A cutplane is any plane that cuts through the model. Cut planes can cut through the model at any angle and may be moved to a new position to observe a difference in plotted fields.

Glossary: D

damping (linear motion)

A value for damping for linear motion can be calculated by the windage and friction loss in Watts divided by the speed in m/sec (at which those losses are defined); this is Damping with resulting units of (W / (m/sec)^2) or (N*m * sec/m).

damping (rotational motion)

A value for damping for rotational motion (for electric machines) can be calculated by the windage and friction loss in Watts divided by the speed in rad/sec (at which those losses are defined); this is Damping with resulting units of (W / (rad/sec)^2) or (N*m * sec/rad).

design variation

A single combination of variable values that is solved during a parametric or optimization setup.

dielectric loss tangent

The dielectric loss tangent is a material property characteristic for lossy dielectrics, i.e. dielectrics which exhibit power losses.

Dirichlet boundary

The Dirichlet boundary (or value boundary) allows you to prescribe the value of the function (solution) on the respective surface of the solution domain where it is applied. Alone or together with other applied boundary conditions, it ensures the uniqueness of the field solution calculated by Maxwell.

Glossary: E

eddy current

Eddy currents are the currents due to the electric field induced by the time varying magnetic field in conductors.

eddy effect

The eddy effect refers to the current flow induced by the time-varying magnetic field in conductors. It can be turned on or off depending on the characteristics of the application. Turning the eddy effect off in conductors (when their effects are estimated to be negligible) can save significant computing resources.

electric coercivity

This refers to the electric field that exists when the electric flux is zero.

electric retentivity

The electric retentivity refers to the value of the electric flux density when the electric field is zero.

electric flux

Electric flux is defined as the integral of the electric flux density vector over a specified surface. According to Gauss's law, the electric flux calculated for a closed surface is equal to the total electric charge enclosed by the respective surface.

electric susceptibility

This material property refers to a material's ability to become polarized.

executive parameters

Executive parameters are parameters of great practical significance that are calculated directly by the Maxwell solvers for all specified objects.

Glossary: F

finite element analysis

Finite element analysis (FEA) is a numerical method of solving physical domain partial differential equations (such as Maxwell's equations for electromagnetic fields) by which the solution domain is divided into a set of geometric entities such as tetrahedrons.

finite element mesh

The finite element mesh for a Maxwell problem is the assembly of all tetrahedral finite elements used to discretize the solution space where the respective electromagnetic fields are calculated.

floating boundaries

In electrostatics, floating boundaries are similar to Dirichlet boundaries in that the entire surface is at a single potential, except that you need not specify the potential as a known a value. This is used to model conductors at unknown potentials.

floating conductor

Floating conductors are conductors at which the potential is unknown.

Glossary: G

Genetic Algorithm

Optimization method of the experiment tool with automatic parameter variation and target function determination.

goal

In an optimization setup, a goal is the value of a solution quantity that you want to be achieved during the optimization. A goal is represented as one row in the cost function table. Each cost function defined in an optimization setup must include at least one goal.

grid plane

The grid plane is the plane on which you want to display the grid in the active view window. Also called the drawing plane.

Glossary: H

hotkeys

Hotkeys are keystroke combinations that execute more complex commands without the need for accessing the commands in the menu bars or tool bar icons.

Glossary: I

imaginary permeability

This material property refers to the imaginary component of the permeability of a material. See **permeability**.

imaginary anisotropic relative permeability

This material property refers to the imaginary component of the anisotropic relative permeability of an object. See **anisotropic permeability**.

imaginary relative permeability

This material property refers to the imaginary component of the relative permeability of a material. See **relativepermeability**.

impedance

Impedance represents the characteristic of an electric circuit element to impose a certain dependency between the voltage between a pair of terminals and the corresponding AC current flowing between the two terminals.

independent generator

The generator supplies electrical power to a load inductor. For an AC generator, the resistance and inductance of the load inductor are determined by the rated output power, the rated voltage, and the rated power factor. For a DC generator, the resistance of the load resistor is determined by the rated output power and the rated voltage.

inductance

Inductance represents the property of a magnetic circuit to relate its magnetic flux to the current which produced it. It is the expression of the property of magnetic devices to store magnetic energy.

infinite bus

When the generator is connected to an infinite bus of the power system, the terminal voltages remain constant and the output power is determined by the output currents.

insulating boundary

An insulating boundary is a convenient way of preventing the current flow across the boundary. This boundary condition is placed between conductors and allows you to avoid creating small separating spaces between conductors for insulation purposes.

insulator

An insulator refers to a material that does not allow the current to flow through it (typically with zero electric conductivity). The way such objects are treated by the software depends upon the user-defined insulation threshold value.

isotropic materials

Isotropic materials refer to materials with properties independent of the direction (orientation) of the axes of the coordinate system in which they are defined.

Glossary: L

lamination model

Lamination modeling allows you to specify a stacking factor and stacking direction, which represents the direction perpendicular to the plane of the lamination. This lamination model is an alternative way of specifying anisotropic behavior when using laminations.

line impedance

The line impedance of an object is the impedance of a single current loop.

LMB

This is an acronym for the left mouse button. The left mouse button is used to choose commands and select points, surfaces, and objects.

Lorentz force

The Lorentz force is the force on an object due to the currents in the magnetic field, neglecting forces due to the effects of material properties.

Lorentz torque

The Lorentz torque is the torque of an object due to the currents in a magnetic field, neglecting torques due to the effects of material properties.

lumped capacitance

Lumped capacitance is the capacitance between two conductors or groups of conductors.

Glossary: M

magnetic coercivity

This refers to the magnetic field that exists when the magnetic flux is zero.

magnetic flux

The magnetic flux is the total of all the lines of force in a magnetic field.

magnetic loss tangent

The magnetic loss tangent allows you to represent a dielectric that dissipates the power of a high-frequency magnetic field. The smaller the loss tangent, the less lossy the material.

magnetic retentivity

In nonlinear materials, the magnetic retentivity (or remanence) refers to the value of the magnetic flux density when the magnetic field is zero.

magnetic susceptibility

The magnetic susceptibility is a measure of the ability of the material to become magnetized.

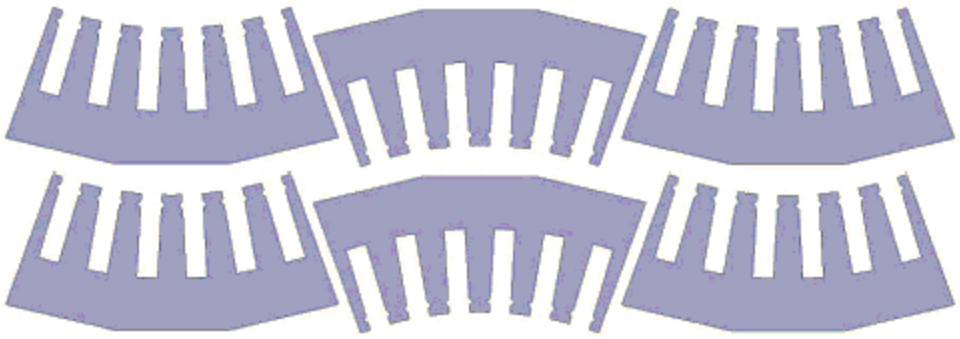
matching boundaries

Matching boundary conditions force the field solution at one surface (the Dependent surface) to match the magnitude and orientation (or opposite orientation) of the field at the Independent surface.

material consumption

Whole-circle laminations – Considers a minimum section of square “raw steel” from which the lamination could be cut. The calculation takes the rotor or stator diameter as the length of the square and calculates the weight based on the material density.

Lamination sectors – For large size machines, a lamination layer of the stator core may be laminated sector-by-sector, instead of a whole circle lamination. The number of Lamination Sectors indicates how many lamination sectors are needed to form a lamination layer. Lamination sectors are punched as shown below so that material consumption is minimized. There is a 3mm allowance in the edge and between two sectors.



material coordinate system

The material coordinate system is the coordinate system used to define the vector or anisotropic material property of objects. Maxwell supports the following three material coordinate systems: Cartesian, cylindrical, and spherical.

mesh refinement

Mesh refinement refers to the process of successively breaking down large error finite elements into smaller ones for the purpose of continuously increasing the accuracy of the finite element calculation. Maxwell uses proprietary adaptive mesh refinement algorithms designed to automatically detect and refine the mesh in regions with the largest field error.

multi-processing

Using more than one processor to solve a Maxwell design. Requires a multiple processor license. Using multiple processors (if physically available on the computer) speeds up the matrix solution process phase. Thus, shorter solution times can be achieved with significant saves in absolute terms, particularly for large models of 100,000 finite elements or more. There are no negative side effects if the number of processors to be used is set to more than are available on the respective computer. In this case, the actual number of available processors will be used in the matrix solution process.

Glossary: N

natural boundary

A natural boundary is a boundary condition at the interface between different objects. You do not need to apply this boundary condition yourself, as Maxwell enforces it internally. The natural boundary condition reflects the particular local form of Maxwell's equations at the interface between objects where there is an sudden change in the material properties. When crossing such a surface of discontinuity, Maxwell assumes the following behavior (in average):

- The normal component of B is continuous.
- The normal component of D has a jump equal with the local superficial charge density (on the discontinuity surface).
- The tangent component of H is continuous if there are no current sheets on the discontinuity surface (has a jump equal with the density of the current sheet if they are present on the discontinuity surface), and so on.

Neumann boundary

For magnetic problems with T-Omega formulation, the homogeneous Neumann boundary condition specifies that the normal component of the H field is zero. For magnetic problems with A-Phi formulation, the homogeneous Neumann boundary condition specifies that the tangential component of the H field is zero. In other words, this boundary condition confines the magnetic field within the space of the problem. If the out-most surfaces of the problem region are not assigned any boundary conditions, they automatically receive a Neumann BC. Because of this, as a rule, the solution space (region size) should be chosen such that the respective region walls are not close to field sources (currents and/or permanent magnets); this allows us to assume the field is a tangent at the region limits.

nodes

Nodes normally refer to the vertices of the tetrahedral finite elements. They can also refer to the connection points of branches in an electric circuit (if external circuits are used to drive coils).

nominal design

The original model on which Optimetrics analyses are based.

nonlinear materials

Nonlinear materials are materials with the constitutive relationship being nonlinear (such as is the case of the dependency between B and H for some magnetic materials).

Glossary: O

outer terminals

Typically, outer terminals are faces of 3D objects that lie on the surface of the problem region.

Glossary: P

parametric analysis

A parametric analysis consists of a sweep of one or more design or project variables for the purpose of analyzing one or more output quantities (Maxwell parameters or quantities calculated by the field calculator).

paste buffer

When you cut or copy an object, such as with the **Edit** commands, the object is stored in the paste buffer. The paste buffer itself is an area of resident memory that is erased and replaced with the newest item that has been cut or copied.

perfect conductor

Perfect conductors are idealized materials with very high conductivity (typically many orders of magnitude above the usual conductivity values). The actual value is influenced by the perfect conductivity threshold value you specify in the solve options.

permanent magnets

Permanent magnets are any materials that generate magnetic flux due to permanent magnetic dipoles in those materials.

permeability

Permeability is a material property characteristic of magnetic materials and relates magnetic flux density to magnetic field strength in objects with no permanent magnetization present.

permittivity

Permittivity is a material property characteristic for dielectrics and relates electric flux density to electric field strength in objects with no permanent electric polarization present.

phasors

Phasors represent a conventional way of representing sinusoidal (AC) quantities such as voltages and currents. In a phasor representation, the amplitude of the signal relates to the length of the rotating vector (phasor) while the initial phase is the starting angle at time t=0. The angular velocity of the phasor rotation relates to the frequency of the signal.

polyline

A polyline is an object composed of one or more straight or curved line segments.

post processing

Post processing is the phase of the analysis when information is extracted from the simulation. Typical results are 2D plots, contour and vector plots of field quantities, results from the field calculator, animations, etc.

press board (pressboard)

An optional material used above and below the lamination stack and as a spacer in manufacturing. In RMxprt, users can specify the press board thickness and whether it is magnetic or non-magnetic.

problem region

The problem region is the region where Maxwell calculates the field solution. This is an all-encompassing object with user-selected material properties and with surfaces that are used to apply the necessary boundary conditions (user-specified or default ones).

Glossary: R

relative permeability

Relative permeability relates the absolute permeability of a magnetic material to the permeability of vacuum ($4\pi 10^{-7}$ H/m).

relative permittivity

Relative permittivity relates the absolute permittivity of a magnetic material to the permittivity of vacuum($4\pi 10^{-7}$ H/m).

resistance

Resistance represents the characteristic of a DC electric circuit element to impose a certain dependency between the voltage between a pair of terminals and the corresponding DC current flowing between the two terminals.

RMB

This is an acronym for the right mouse button.

RMBM

This is an acronym for the right mouse button menu. This menu becomes visible when you hold the right mouse button down while the cursor is in a view window. Depending on the module you are in, you may use this menu to select or deselect objects, or accept or cancel selections or values.

Glossary: S

section

This refers to the **Surfaces/Section** command which creates a cross-section of 3D objects with the XY, YZ, or XZ planes.

seeding

Seeding refers to the process of adding points to your finite element mesh to create a finer one.

self-inductance

Self-inductance of an object or group of objects associates the current flowing in the respective object(s) with the own flux linkage.

skin depth

The skin depth of a material is the distance measured inside a conductor from the surface where the AC field (magnetic/electric) penetrating the conductor is reduced by a factor of 1/e (~ 1/2.71). As general rule is that at 5 skin depths from the surface, the AC fields penetrating inside conductors can be considered to be zero.

$$\delta = \sqrt{\frac{2}{\omega \sigma \mu_0 \mu_r}}$$

slot fill factor

The slot fill factor is the ratio between the cross-sectional area of all conductors in one slot and the entire slot area.

solver

Maxwell has a number of solvers allowing you to choose from electric, magnetostatic, eddy, and transient, depending upon the characteristics of the problem to be solved.

solver residual

The solver residual is an error term that measures the current accuracy of the solution process when using an iterative solver.

superposition

Superposition allows you to combine the results of field solutions, each corresponding to linear problems. Superposition should not be used when problems are nonlinear.

surface

A surface is an object face.

sweep

Sweep can refer to two different topics:

- In the 3D Modeler, sweeping a face or object along a path or vector creates a new 3D object. The object you sweep need not be orthogonal to the path or vector.
- In the Executive Parameters module, a parametric sweep refers a series of variables.

symmetry boundary

Symmetry boundaries model the planes of symmetry in a problem.

Glossary: T

terminal

As a terminal, you can use an exact cross-section of the conduction path, to apply an eligible excitation.

tile window

Existing windows, regardless of their contents, can be tiled either horizontally or vertically.

toolbar

A toolbar contains icons which can be used to shortcut commands.

Glossary: V

value boundary

See **Dirichlet boundary**.

variable sweep definition

A set of variable values within a range that Optimetrics drives Maxwell to solve when a parametric setup is analyzed. A parametric setup can include one or more sweep definitions.

vector functions

Vector functions are used to specify certain vector type properties. For instance, magnetization can be defined using vector properties in a chosen, previously defined coordinate system.

view window

In the 3D Modeler, the view window is the window in which you create your model. The view window gives a 3D view of the model. In this window, you can assign materials to objects, specify boundary conditions, set up any executive parameters, or post process data or fields in the model.

virtual force

Virtual force is the force calculated on an object or group of objects using a special mathematical algorithm that contains the effects of a virtual motion along a generalized coordinate (such as x, y, z). The movement does not actually take place; it is virtual.

virtual torque

Virtual torque is the torque calculated on an object or group of objects using a special mathematical algorithm that contains the effects of a virtual rotation around a coordinate axis (such as x, y, z). The movement does not actually take place; it is virtual.

visibility

Visibility refers to whether or not an object is displayed. You can show or hide an object using the **View>Active View Visibility** commands.
