User Interface Quick Links

Use the following links for quick information on the following topics.

The Maxwell Desktop	Working with Ribbons
General Purpose Keyboard Shortcuts for Maxwell	Running Maxwell From a Command Line

For detailed information on these and many other topics:

- Use **F1** on any open dialog to open the Help for that dialog.
- With the cursor, hover over any menu command, icon, or window and press **F1** for help on that selection.
- With the Help **Contents tab** selected, navigate the help topic hierarchy.
- With the Help **Index tab** selected, search the help index.
- In the Help **Search** box, search the full help text.

Modeling Quick Links

Use the following links for quick information on the following topics.

Set the model's units of measurement.	Setting Modeler Drawing Options
Assign transparency to an object.	Selecting Items in the Modeler Window
Subtract objects.	Drawing Objects
Measuring Objects	Choosing the Cursor Movement Mode
Drawing Bondwires	Importing Files
Keyboard shortcuts for the 3D Modeler Window.	Modifying Objects
Modifying the Model View	

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the Search Function.

Boundaries/Excitations Quick Links

Use the following links for quick information on the following topics.

Defining Boundary Conditions	Defining Excitations
Setting Eddy Effects and Displacement Current	Setting Core Loss
Setting Up Motion for Transient Projects	Functional Boundaries and Excitations
Defining Boundary Conditions in 2D	Defining 2D Excitations

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Meshing Quick Links

Use the following links for quick information on the following topics.

Defining Mesh Operations	Plot the finite element mesh
Detecting and Addressing Model Problems to Improve Meshing	Handling Complicated Models

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Analysis Quick Links

Use the following links for quick information on the following topics.

Specifying the Analysis Options	Remote Analysis
Configuring Distributed Analysis	Specifying Solution Settings
Selecting an Optimal Configuration for Distributed Analysis	Setting Adaptive Analysis Parameters

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Optimetrics Quick Links

Use the following links for quick information on the following topics.

Setting up a Parametric Analysis	Setting up an Optimization Analysis
Setting up a Sensitivity Analysis	Tuning a Variable
Setting up a Statistical Analysis	Setting a Range function
Setup Calculations for Optimetrics	Adding a cost function

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Results Quick Links

Use the following links for quick information on the following topics.

View solution data	Creating Reports
Plot field overlay	Working with Traces
Plot the finite element mesh	Adding Data Markers to Traces
Create animations	Creating a Quick Report
Specifying Output Variables	Dynamically Updating Reports During Solution
Using the Fields Calculator	

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Scripting Quick Links

Use the following links for quick information on the following topics.

Recording a Script	Running a script
Stopping Script Recording	Pausing and Resuming a Script

Stopping a Script	

The help system provides different ways to find information and navigate quickly:

- Press **F1** on any open dialog to open the Help for that dialog.
- A *hierarchical table of contents* – You can browse through the table of contents, expand entries, and close entries. Click on an entry to see it in the content area.
- A *full text search* – To locate every occurrence of a word or phrase that may be contained in the help, use the search function.

Maxwell Getting Started Guides

Maxwell documentation includes the following *Getting Started Guides*:

- *3D Rotational Actuator with Parametrics*

  This Getting Started Guide is written for Maxwell beginners and experienced users who would like to quickly familiarize themselves with the capabilities of Maxwell 3D. This guide leads you step-by-step through creating, solving, and analyzing the results of solving a 3D rotational actuator magnetostatic problem.

  By following the steps in this guide, you will learn how to perform the following tasks:
  - Draw a geometric model.
  - Modify a model's design parameters.
  - Assign variables to a model's design parameters.
  - Specify solution settings for a design.
  - Validate a design's setup.
  - Run a Maxwell simulation.
  - Plot the magnetic flux density vector.
  - Run a parametric analysis.
  - Create an animation using saved parametric field data.
- *3D Transient Rotational Actuator Problem with Motion*

  This Getting Started Guide is written for Maxwell beginners and experienced users who would like to quickly familiarize themselves with the capabilities of Maxwell 3D. This guide leads you step-by-step through creating, solving, and analyzing the results of solving a Transient rotational actuator problem with motion. This Getting Started Guide builds on the problem and techniques presented in the 3D rotational actuator magnetostatic problem.

  By following the steps in this guide, you will learn how to perform the following tasks:
  - Import a geometric model.
  - Modify a model's design parameters.
  - Assign variables to a model's design parameters.
  - Specify solution settings for a design.
  - Validate a design's setup.
  - Run a Maxwell simulation.
  - Plot the magnetic flux density vector.
  - Include motion in the simulation.

- *2D Magnetostatic Solenoid Problem with Parametrics*

  This Getting Started Guide is written for Maxwell beginners and experienced users who would like to quickly familiarize themselves with the capabilities of Maxwell 2D. This guide leads you step-by-step through creating, solving, and analyzing the results of solving a 2D asymmetric solenoid magnetostatic problem with parametric analysis.

  By following the steps in this guide, you will learn how to perform the following tasks:
  - Draw a geometric model.
  - Modify a model's design parameters.
  - Assign variables to a model's design parameters.
  - Specify solution settings for a design.
  - Validate a design's setup.
  - Run a Maxwell 2D simulation.
  - Plot the simulation results.
  - Set up a parametric sweep analysis varying multiple solution variables.
  - Plot families of curves of the parametric results.
- *Skin Depth Seeding*

  By following the steps in this guide, you will learn to use Skin Depth-Based mesh refinement for HFSS or Maxwell Modelers to specify a number of layers and a skin depth as an alternative to modeling physical layers. The guide also shows how to use mesh plots with cut planes, as well as a repurposed **Model Analysis** dialog box to view and obtain statistics on layering success.

2 - Getting Started with Maxwell and RMxprt

Maxwell is an interactive software package that uses finite element analysis (FEA) to solve three-dimensional (3D) electrostatic, magnetostatic, eddy current, and transient problems.

Using Maxwell you can compute:

- Static electric fields, forces, torques, and capacitances caused by voltage distributions and charges.
- Static magnetic fields, forces, torques, and inductances caused by DC currents, static external magnetic fields, and permanent magnets.
- Time-varying magnetic fields, forces, torques, and impedances caused by AC currents and oscillating external magnetic fields.
- Transient magnetic fields caused by electrical sources and permanent magnets.

RMxprt™ is an interactive software package used for designing and analyzing electrical machines.

Maxwell and Rmxprt are integrated into the Ansys Electronics Desktop.

Ansys Electronics Desktop Student

Ansys Electronics Desktop Student is a free Windows version of the Electronics Desktop that allows you to model, mesh, solve, and post-process in HFSS, Q3D Extractor, 2D Extractor, Maxwell 3D and Maxwell 2D, RMxprt, and Icepak. The following list of limitations applies to all supported design types in Ansys Electronics Desktop Student.

> **Note:** Unsupported design types (e.g., Mechanical) do not open in Ansys Electronics Desktop Student.

- Geometry export not supported
- Import of DXF and STEP files only
- Local solve only (remote configuration not supported)
- High Performance Computing limited to 4 cores
- Integration with Ansys Workbench not supported
- Beta features not supported

HFSS Student Limitations

- SBR+ not supported
- Mesh assemblies not supported
- Mesh element count limit (analysis and post-processing)
    - 3D volume: 64,000 elements
    - 3D surface: 8,000 elements
    - 2D: 2,000 triangles

Q3D Extractor and 2D Extractor Student Limitations

- Mesh element count limit (analysis and post-processing)
  - 3D volume: 64,000 elements
  - 3D surface: 8,000 elements
  - 2D: 2,000 triangles

Maxwell and RMxprt Student Limitations

- Mesh element count limit (analysis and post-processing)
  - 3D volume: 64,000 elements
  - 3D surface: 8,000 elements
  - 2D: 2,000 triangles
- 3D and 2D Transient simulations

Icepak Student Limitations

- Mesh element count limit (analysis and post-processing): 512,000 elements

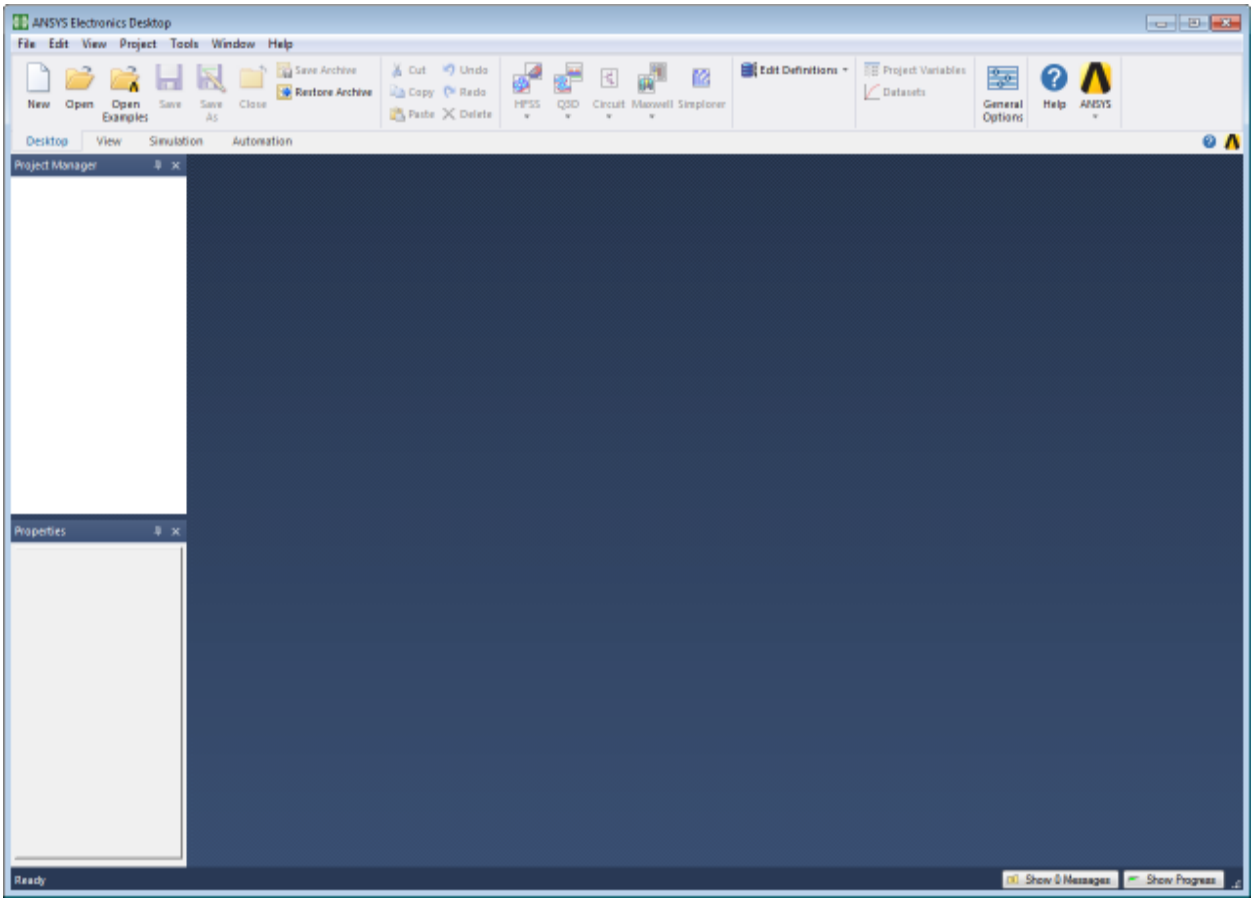
Welcome to Ansys Electronics Desktop

The Ansys Electronics Desktop, illustrated in the following figure, provides a comprehensive environment for designing and simulating various electronic components and devices. The Ansys Electronics Desktop consists of a unified user interface where a wide variety of design types can be created. Typically, you can create or import a design, set up the simulation, validate your design, run the analysis, and post process the results.



The desktop has the following design types and features:

- HFSS - a general purpose 3D interface for the design, analysis, and simulation of electromagnetic components.
- HFSS 3D Layout - a full-wave layout-based electromagnetic simulator with a specialized interface for geometries created in layout.
- HFSS-IE - a full wave Integral Equation solver for large open problems.
- Q3D Extractor - a quasi-static 3D solver for extracting lumped RLGC parameters and Spice models.
- 2D Extractor - a 2D solver for extracting per-unit-length RLGC parameters of transmission lines.
- Circuit - a schematic-based interface to the Nexxim circuit simulator.
- Circuit Netlist - a netlist (text-based) interface to the Nexxim circuit simulator.
- Maxwell 3D - uses finite element analysis (FEA) to solve three-dimensional (3D) electrostatic, magnetostatic, eddy current, and transient problems.
- Maxwell 2D - uses finite element analysis (FEA) to solve two-dimensional (2D) electrostatic, magnetostatic, eddy current, and transient problems.

- RMxprt - a template-based electrical machine design tool that provides fast, analytical calculations of machine performance and 2-D and 3-D geometry creation for detailed finite element calculations in Ansys® Maxwell®.
- Maxwell Circuit Design - sets up external circuit designs to supply excitations to coil terminals for Maxwell 2D and 3D Eddy Current and Transient designs.
- Twin Builder - an integrated, multi-domain, mixed-signal simulator for complex technical systems.
- Icepak - a general purpose 3D interface for the design, simulation, and thermal analysis of electronic components
- Launch Savant - a tool for simulating near-field, far-field, and coupling performance of antennas installed on platforms and within other complex and electrically large environments.
- Launch EMIT - a simulation tool for the prediction of radio frequency interference (RFI) in complex environments.

If you go to the **Project** menu, you can access all of the design types. Any combination of these design types can be inserted into a single project file. The schematics can be used to wire up the different field solver models and create a model of a high-level system. The Ansys Electronics Desktop provides an efficient way to manage complicated projects that require several different analysis tools to model all of its pieces. Designs can also be parameterized. With the help of the Optimetrics feature the best design variations can be made available to other modules when the designs are linked into a higher level simulation. This lets you study the effect of varying a design parameter on the behavior of the entire system.

"Launching Ansys Electronics Desktop" below

Launching Ansys Electronics Desktop

After you have installed Ansys Electronics Desktop, start the program by one of the following methods:

Maxwell contains the following menus, which appear at the top of the desktop:

- Double-click the **Ansys Electronics Desktop** icon on your desktop.
- Click **Ansys Electronics Desktop** on the Windows Start menu.
- Click **Start>All Programs>Ansys EM Suite 2023 R1>Ansys Electronics Desktop 2023 R1** on the Windows Start menu.

"Welcome to Ansys Electronics Desktop " on page 2-2

Obtaining Information about the Software and Release

To obtain information about the software:

1. Click **Help>About Ansys Electronics Desktop** to open the **About Ansys® Electromagnetics Suite [release number]** dialog.
2. Click the **Installed Components** tab to view a list of software installed.
3. Click the **Client License Settings** tab to view information about the following:
   - Provider Name
   - ANSYSLI Version
   - FlexNet Publisher Servers
   - Admin Directory
   - Customer Number
   - FLEXlm Version
   - Redirect Info
4. To export the software information:
   a. Click **Export**.
   The **Save As** dialog box appears.
   b. Browse to the location where you want to save the information as a text file.
   c. Type a name for the file in the **File name** text box. The **Save as type** pull-down list is already specified as **Export (*.txt)**.
   d. Click **Save**.
5. Click **OK** to close the **About Ansys® Electromagnetics Suite [release number]** dialog.

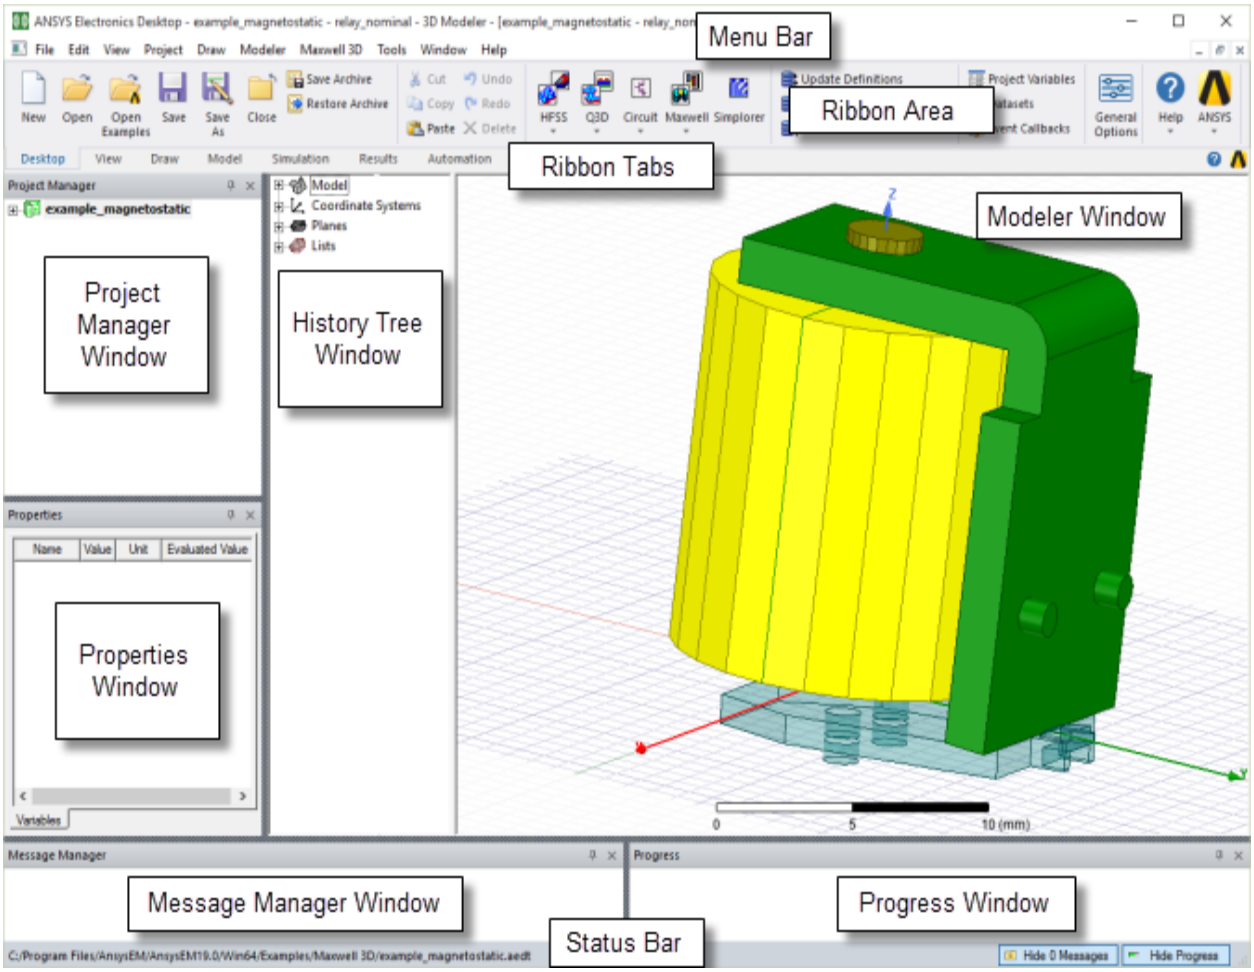
System Requirements

Maxwell supports certain versions of Windows and Linux. For supported platforms and system requirements, go to:

http://www.ansys.com/Solutions/Solutions-by-Role/IT-Professionals/Platform-Support

The Maxwell Desktop UI

The Maxwell desktop consists of several windows, a menu bar, ribbons, and a status bar. You can open multiple windows in Maxwell to display different parts of the model. For instance, one window can remain fixed on the winding, one on the diagram, and one on the main desktop window. To open a new window, click **Window>New Window**. To move back and forth between windows, select the **Windows** menu, and select the window you want to view.



Click a link below to view more information about that desktop component.

Menu Bar	Message Manager
Ribbon Area/Ribbon Tabs	Progress Window
Project Manager Window	Modeler Window
Properties Window	History Tree Window
Status Bar	

Working with the Menu Bar

The menu bar enables you to perform all Maxwell tasks, such as managing project files, customizing the desktop, drawing objects, and setting and modifying all project parameters.

Maxwell contains the following menus, which appear at the top of the desktop:

File menu	Use the **File** menu commands to manage Maxwell project files and printing options.
Edit menu	Use the **Edit** menu commands to modify the objects in the active model and undo and redo actions.
View menu	Use the **View** menu commands to display or hide desktop components and model objects, modify **2D** and **3D Modeler** window visual settings, and modify the model view. The **ACT Extensions**command opens the ACT Extensions window which lets you work with ACT integration tools.
Project menu	Use the **Project** menu commands to insert a Maxwell or RMxprt design (as well as other Desktop designs) to the active project, define datasets, and define project variables.
Draw menu	Use the **Draw** menu to draw the elements that make up a model.
Modeler menu	Use the **Modeler** menu commands to import, export, and copy 2D Modeler files and 3D Modeler files; assign materials to objects; manage the **3D Modeler** window's grid settings; define a list of objects or faces of objects; control surface settings; perform Boolean operations on objects; and set the units for the active design.
Maxwell3D, Maxwell2D, or RMxprt menu	Use these menu commands to change solution type, assign boundaries and excitations, set up parameters, add analysis setups, set up Optimetrics, post process solutions, export equivalent circuits, define datasets, and other design tasks.
Tools menu	Use the **Tools** menu to modify the active project's material library, arrange the material libraries, run and record scripts, update project definitions from libraries, display options, and modify many of the software's default settings.
Window menu	Use the Window menu commands to rearrange the **Modeler** windows.
Help menu	Use the **Help** menu commands to access the help system and view the current Maxwell version information.

Working with Windows

The **Window** menu allows you to manage the currently open windows in the **Maxwell** Desktop user environment.

In addition to the standard functions listed in the table, the menu also contains a list of currently open windows for easily switching between them. This is important in multiple window environments where the desktop make become crowded with open windows and some may be partially or completely obscured. Minimized windows are automatically opened when selected in this list.

Command	Description

New Window	Open a new window. New windows shows the model by default.
Cascade	Arranges all non-minimized windows in a cascade with the window title bar visible.
Tile Horizontally	Arranges all non-minimized windows to use the maximum horizontal size of the desktop.
Tile Vertically	Arranges all non-minimized windows to use the maximum vertical size of the desktop.
Arrange Icons	Arranges the icons of any minimized windows along the bottom of the Desktop.
Close All	Close All currently open desktop windows.

Moving and Resizing Desktop Windows

You can customize the appearance of the desktop by moving and resizing the Status Bar, the Message Manager, the Project Manager, the docked Properties window, and the Progress window.

To move one of these windows:

1. Click and hold on the title bar.
2. Drag the cursor toward the region where you want to place the window.

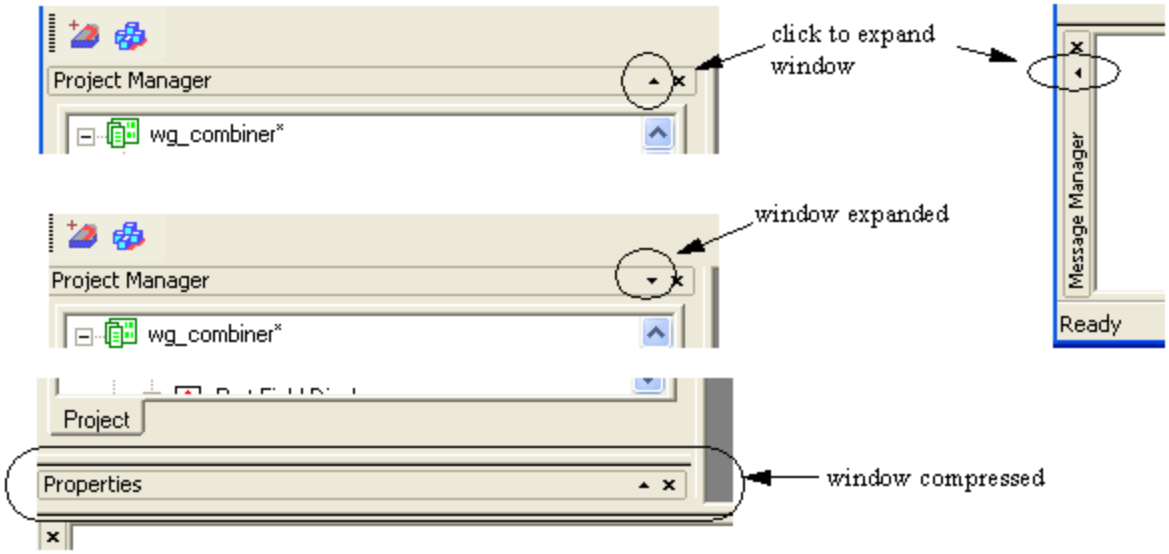
   A rectangle shape follows the cursor. As you drag the rectangle to different parts of the desktop, the changes in dimension show when you have reached a location where you can place the window. This can be at the top, left, bottom, and side of the modeler window. You can place a window next to another, as well as above or below another.

   If you drag the window to the center of the 3D Modeler window, you can place it there as a floating window.
3. Release the mouse button to place the window.

You can also resize the windows in two ways.

- To size a desktop window, place the cursor over an edge of the window. Over the inner-edges, for sizing a window within the desktop, the cursor changes to a double bar with arrows pointing each direction. Over the outer-edges, for sizing the desktop, the cursor changes to a line with arrows pointing each direction. Press and drag to size the window.
- To expand a window to fill the horizontal or vertical space it shares with another window, click the triangle in the window title bar. When you expand a window, the triangle appears as inverted and any other windows in the same horizontal or vertical space are compressed to only the title bar. If a window does not share a horizontal or vertical space with another,

the triangle does not appear.



Window Layouts

You can create and save specific window layouts for rhe desktop and apply them when needed. For example, you can create a layout that shows a large component window. There are options to apply a saved layout, restore the default window layout, and remove saved layouts.

To save a wndow layout:

1. On the **View** menu, click **Window Layouts>Save Current Layout**.
2. Enter the layout name in the **Layout Name** dialog box, and click **OK**. The layout is saved and added to the list of layouts on the **Window Layouts** submenu.

To apply a saved layout:

1. On the **View** menu, click **Window Layouts** and select from the listed saved layouts.

To restore the default window layout:

1. On the **View** menu, click **Window Layouts>Default**.

To remove window layouts:

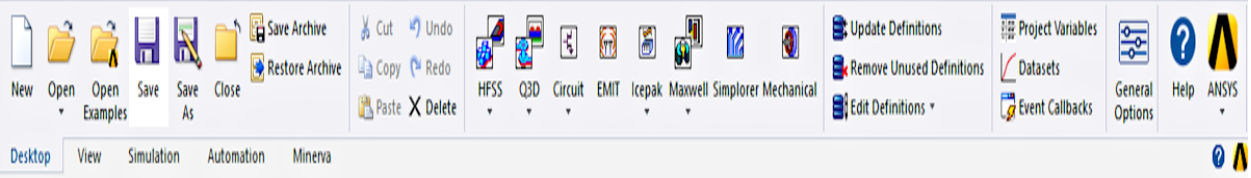
1. On the **View** menu, click **Window Layouts>Remove Saved Layouts**.
2. In the **Modify Layouts** dialog box, select one or more layouts and click **Delete**, or click **Delete All**.

Working with Ribbons

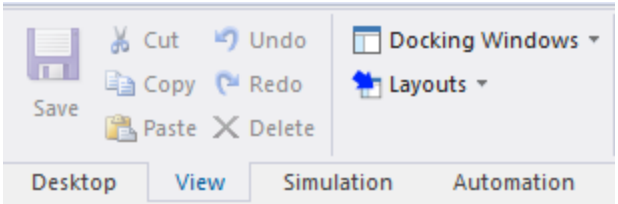
The ribbon is the rectangular area across the top of the application. It comprises various tabs, each one representing a subset of commands available from the menus. The initial set of tabs (Desktop, View, Simulation, Automation) offers commands for adding and opening projects,

selecting solvers, configuring the Desktop display (window choice, size, and position), configuring the simulation environment, setting scripted Event Callbacks or General Options, and showing Automation features for recording and using scripts. The **Desktop, View, Simulation, Automation,** and **Minerva** tabs appear for all design types.

Desktop Tab Selected



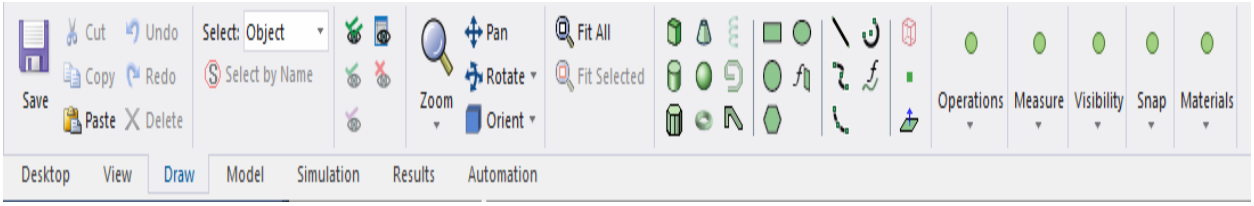
View Tab Selected without a Project



The Docking Windows and Layouts areas contain drop-down menus with additional selections.

If you have inserted a Project, for example, an HFSS project, the **View** ribbon displays commands appropriate for the active editor. For instance, the View tab will show different commands for the modeler (shown below) and the report viewer.

If you compress the Desktop window, each tab display shows fewer available features than an expanded display, with priority given to the most used features.

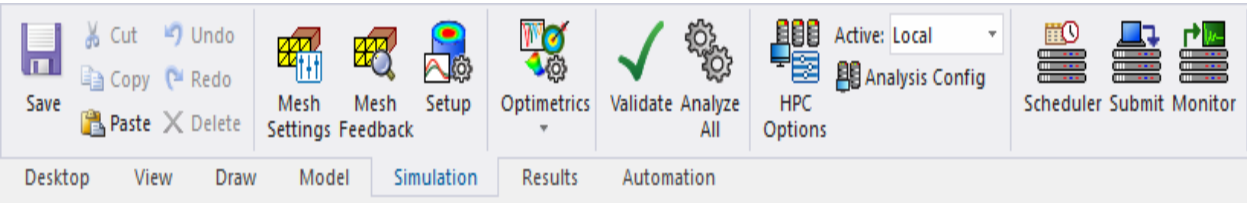


Draw Tab Selected

Model Tab Selected

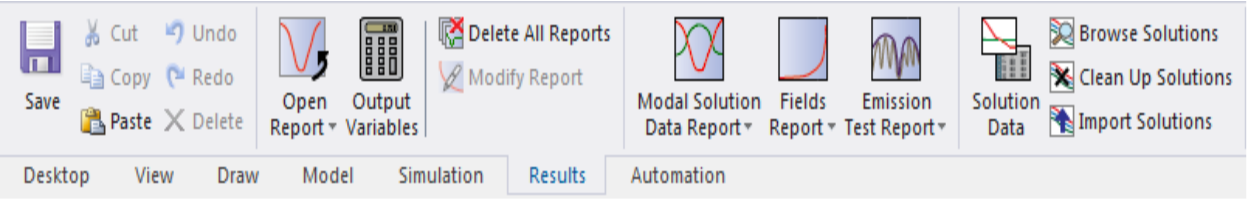
Simulation Tab Selected

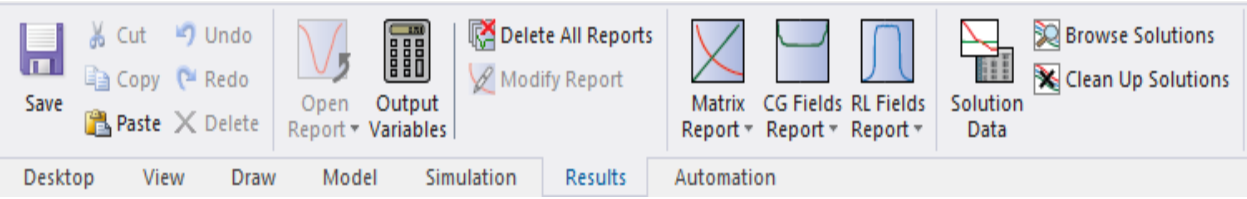
In this example, the **Simulation** tab contains commands appropriate for the currently active design.



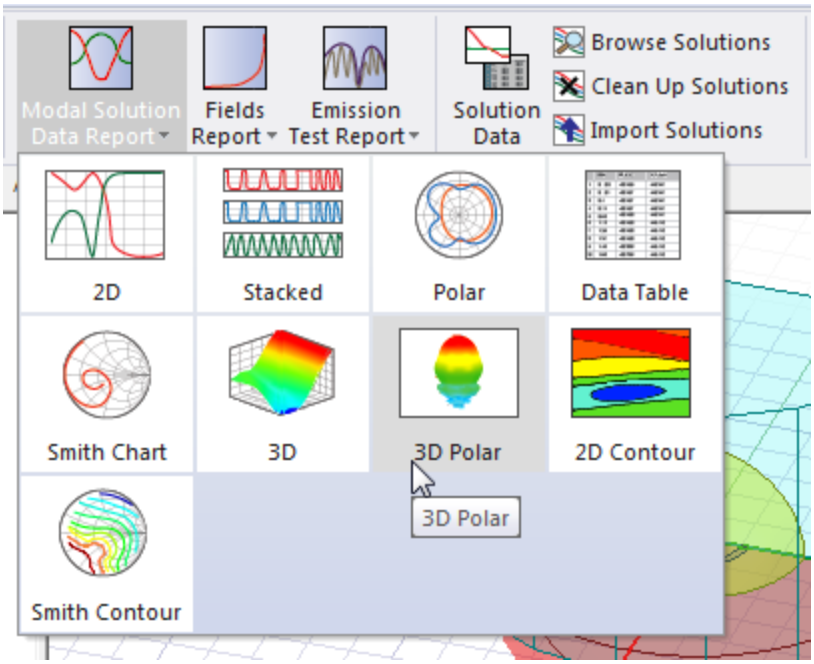
Results Tab Selected

In these examples, each **Results** tab contains commands appropriate for the currently active design.



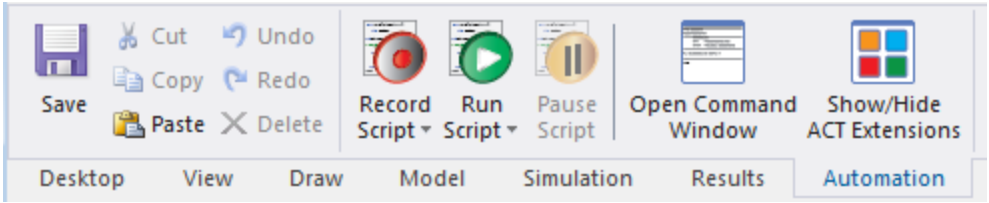


The drop-down menus under the Report icons let you select from available report types:



Automation Tab Selected

This tab includes controls for recording and running scripts, as well as access to the Command window, and display of ACT Extensions.



Related Topics

The Maxwell Desktop

External User Tools

To add an external user tools menu to Maxwell:

1. Click **Tools>External Tools**
2. This displays the **Customize User Tools Menu** dialog.

   If a **User Tools** menu has been defined, its contents are displayed. Navigation buttons let you Move Up, Move Down, Add, and Delete.
3. Click the **Add** button in the **Customize User Tools Menu** dialog.

This enables the following fields:

Menu Text field -- this displays [new tool] as text you will replace with the text you want to appear in the User Tools menu.

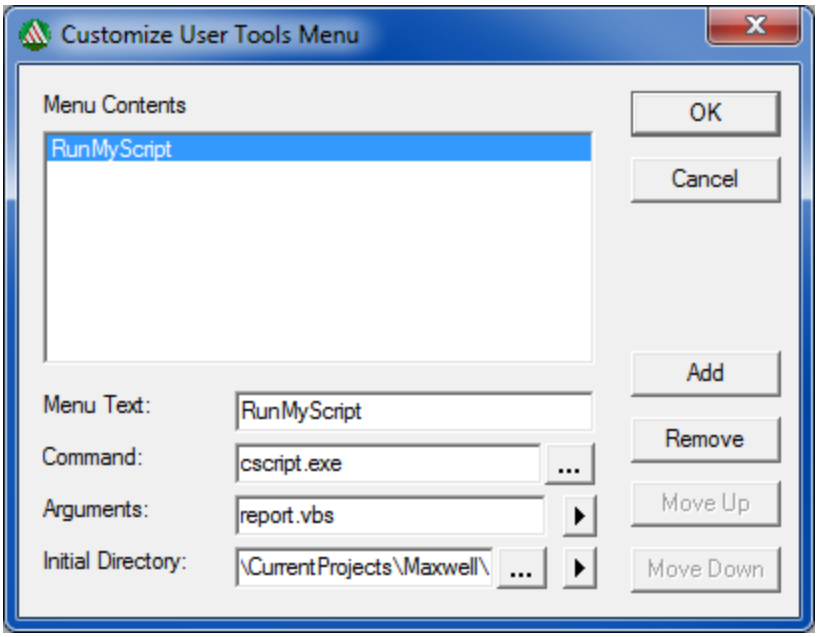
Command field -- this will display the external executable. An ellipsis button [...] lets you navigate to the file location.

Arguments field -- this field accepts command arguments from the **>** button menu selections for File Path, File Directory, File Name, File Extension, Project Directory, or Temp Directory.

Initial Directory – this field specifies the initial directory for the command to operate. The ellipsis button {...] displays a dialog that lets you navigate folders in your desktop, or across the network.

4. Click **OK** to add the External Tools menu to Maxwell or **Cancel** to close the dialog without changes.

You can also add scripts to the **Tools** menu. Assuming you have a script to generate custom reports called report.vbs, use the cscript.exe program to execute your script.



This example shows the cscript.exe program added to the **Tools** menu as **RunMyScript**. The command line argument to the csscript.exe program is report.vbs. You can also name the directory in which it will be run.

Working with the Shortcut Menus

A variety of shortcut menus — menus that appear when you right-click a selection — are available in the ribbons area of the desktop, in the **Modeler** window, and in the **Project Manager** window.

Shortcut menu in the Modeler window	Use the shortcut menu in the **Modeler** window to select, magnify, and move options (zoom, rotate, etc.), change the view, perform boolean operations, assign materials, or mesh operations to objects, and work with field overlays.
Shortcut menus in the Project Manager window	Use the shortcut menus in the **Project Manager** window to manage Maxwell project and design files and design properties; assign and edit excitations, and mesh operations; add, analyze, and manage solution setups; add optimetrics analyses; create post-processing reports; edit project definitions.
Shortcut menus in the History Tree	Use the shortcut menus in the History tree to expand or collapse groupings. If you select particular objects in the history tree, the shortcut menu lists the commands that you can apply to the selected object or objects.

Note	All of the commands on the shortcut menus are also available on the menu bar.

Shortcut Menu in the Modeler Window

Use the shortcut menu in the **Modeler** window to select, magnify, and move options (zoom, rotate, etc.), change the view, assign materials, nets, excitations, or mesh operations to objects, work with field overlays, and plot objects.

To access the shortcut menu in the **Modeler** window:

- Right-click in the **Modeler** window (grid area).

Shortcut Menus in the Project Manager Window

Each node, or item, in the project tree has a shortcut menu.

To access the shortcut menu in the **Project Manager** window, for a particular node:

- Select a node or item.
- Right-click in the **Project Manager** window.

General Purpose Keyboard Shortcuts for Maxwell

The following keyboard shortcuts apply to Maxwell and RMxprt in general

- F1: Help
- F1 + Shift: Context help
- F4 + CTRL: Close program
- CTRL + C: Copy
- CTRL + N: New project
- CTRL + O: Open...

- CTRL + P: Print...
- CTRL + V: Paste
- CTRL + X: Cut
- CTRL + Y: Redo
- CTRL + Z: Undo
- CTRL + 0: Cascade windows
- CTRL + 1: Tile windows horizontally
- CTRL + 2: Tile windows vertically

To customize the shortcut assignments, use Tools>Keyboard Shortcuts.

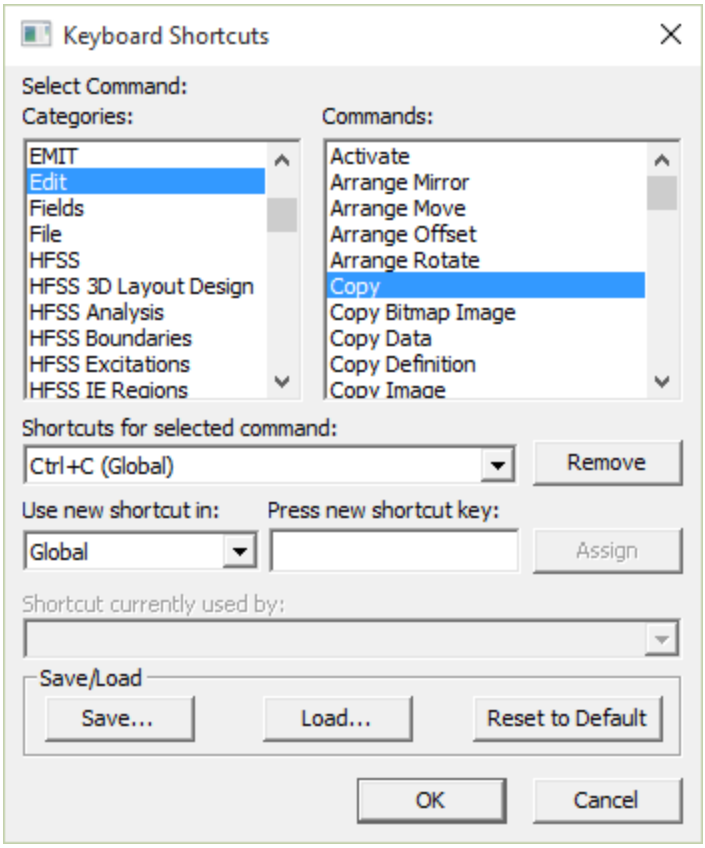
Related Topics

Keyboard Shortcuts for the 3D Modeler Window

Custom Keyboard Shortcuts

Custom Keyboard Shortcuts

Click **Tools>Keyboard Shortcuts** to display a dialog that lets you view existing assignments, create new shortcuts, save and load assignment files.



Selecting a Command category lists the available Commands for that category. If the command has an assigned shortcut, it is displayed in the **Shortcuts for selected command** field. You can use the **Remove** button to disable the shortcut for the selected command. If the selected command does not have an assigned shortcut, the **Shortcuts for selected command** field and the **Remove** button are grayed out.

To create a new shortcut key:

1. Select the Category and Command.
2. If you want disable a current assignment for the selected command, click **Remove**.
3. To assign a keyboard shortcut, place the cursor in the **Press new shortcut key** field.

   The field displays the keystrokes you make. When you have made keystrokes, the dialog enables the **Assign** button. If you combine keystrokes these are displayed with a "+" between them. For example, Ctrl + p or Alt +o.
4. The **Use new shortcut in** field displays **Global** by default, which means that the shortcut will apply to all applicable contexts. If a limited context exists, the menu will offer a selection.
5. When you have made the desired assignments, you can save the assignments to a named file.

   Clicking the **Save...** button displays a browser window that lets you navigate the file structure and assign a name, using an **aks** suffix for Ansoft Keyboard Shortcut file.

   Buttons on the browser window let you designate the file location as **Use Path**, **Personallib**, **Syslib**, **UserLib**, or **Project** folder.

   If you have an existing **aks** file, you can use the **Load...** button to display a browser window to locate the desired file.
6. You can **OK** the current settings, or **Reset to Default**.

Working with the Status Bar

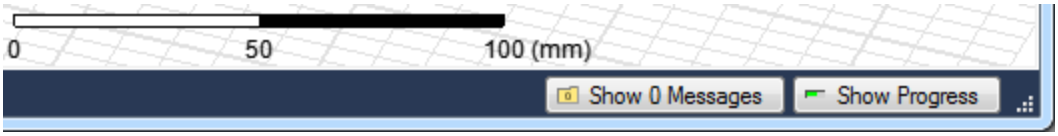
The status bar is located at the bottom of the application window. It displays information about the command currently being performed.

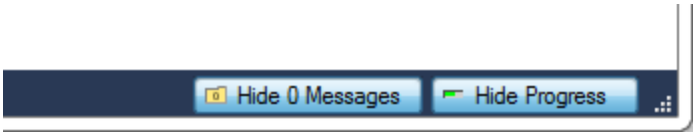
To display or hide the status bar:

- Click **View>StatusBar**.

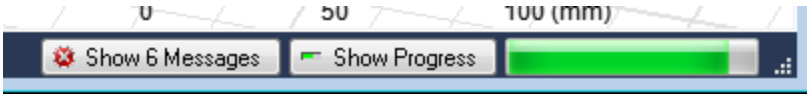
  A check box appears next to this command if the status bar is visible.

  When visible, the status bar contains buttons to show or hide the message window and progress window.





When more than one progress bar is active, the top progress bar is represented on the status bar with a progress indicator.



Depending on the command being performed, the status bar can display the following:

- **X**, **Y**, and **Z** coordinate boxes.
- A pull-down list to enter a point's absolute, relative, cartesian, cylindrical, or spherical coordinates.
- The model's units of measurement.

When creating object in the model window, you may jump to the coordinate entry boxes by pressing the **Tab** key. In addition, the **Tab** key moves the focus to the next coordinate box when performing manual data entry.

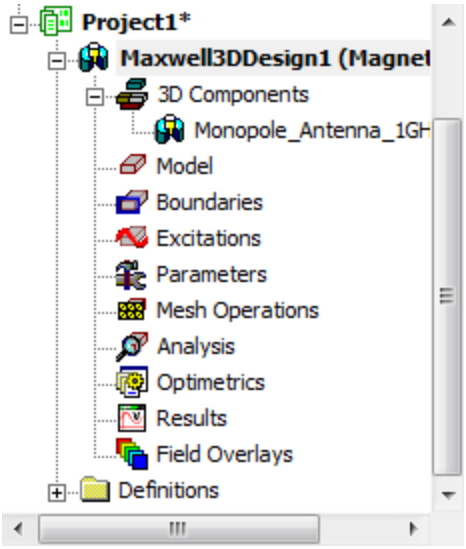
Exiting the Desktop

To exit the desktop, use **File>Exit**.

If simulations are running, a message informs you that if you continue, the simulations will be aborted. If you choose **OK**, Maxwell does a clean abort before going on with the Exit.

Working with the Project Manager

The **Project Manager** window displays the open project's structure, which is referred to as the project tree.



The **Project Manager** window displays details about all open Maxwell projects. Each project ultimately includes a geometric model, its boundary conditions and excitations, and field solution and post-processing information. Any 3D Components appear under the 3D Components icon.

To show or hide the **Project Manager**:

- Click **View>Project Manager**.
  A check box appears next to this command if the **Project Manager** window is visible.

Related Topics

Working with the Project Tree

Shortcut Menus in the Project Manager Window

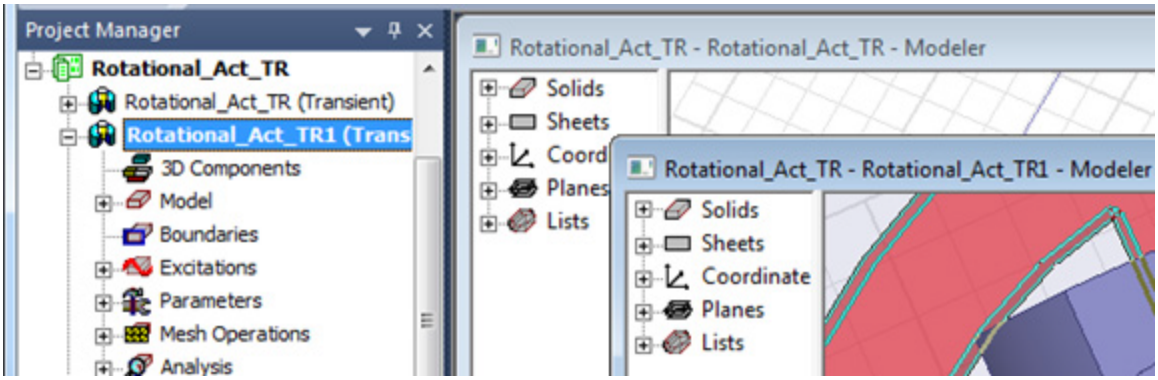
"Working with the RMxprt Project Manager" on page 26-12

Working with the Project Tree

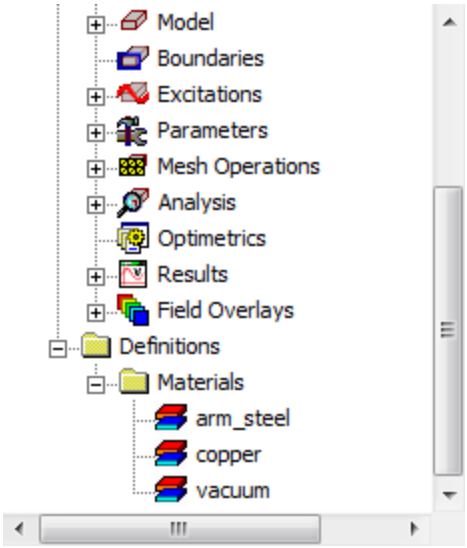
The project tree is located in the **Project Manager** window and contains details about all open Maxwell projects.

The top node listed in the project tree is the project name. It is named **Projectn** by default, where *n* is the order in which the project was added to the current session of Maxwell. Expand the project icon to view the project's Maxwell design information, 3D Components (if any) and material definitions.

By default, the Project tree icon for the active window is highlighted, as shown in the following figure. (See User Interface for the options.) With the option disabled, **Rotational_Act_TR (Transient)** in the Project tree would not be highlighted.



When the Project tree is taller than the window, if you mouse has a scroll wheel, you can click in the Project manager and use the wheel to scroll up and down. If the Project tree is larger than the window size, there is also a scroll bar can control with the mouse cursor.



In the project tree, an "unknown" section lists objects that do not fit one of the following dimensionality types: solid, sheet, or wire.

Viewing Maxwell Design Details

Setting the Project Tree to Expand Automatically

You can set the project tree to automatically expand when an item is added to a project.

1. Click **Tools>Options>General Options**.

   The **Options** dialog box appears.

2. Click the **Project Options** tab.
3. Under **Additional Options**, select **Expand Project Tree on Insert**.
4. Click **OK**.

Viewing Maxwell Design Details

Once you insert a Maxwell design into a project, it is listed as the second node in the project tree. It is named MaxwellModel*n* by default, where *n* is the order in which the design was added to the project. Expand the design icon in the project tree to view specific data about the model.

The MaxwellModel*n* node contains the following project details:

3D Components	Lists any 3D components added to the design.
Model	Allows you to display the design list, define motion setup, and set the symmetry multiplier. For Transient solutions only, when the Model icon is selected, the Properties window displays a Motion Variables tab showing Speed and Direction variables values (not user-editable) if a motion setup has been defined.
Boundaries	Allows you to define boundary conditions on selected faces.
Excitations	Allows you to define voltage and current sources on selected objects.
Parameters	Allows you to assign executive parameters to solve for (such as force and torque).
Mesh	Displays the mesh operations specified for objects or object faces. Mesh operations are optional mesh refinement settings that are specified before a mesh is generated.
Analysis	Displays the solution setups for a Maxwell design. A solution setup specifies how Maxwell computes the solution.
Optimetrics	Displays any Optimetrics setups added to a Maxwell design.
Results	Displays any post-processing reports that have been generated.
Field Overlays	Displays field overlay plots, which are representations of basic or derived field quantities on surfaces or objects. Plot folders are listed under **Field Overlays.** These folders store the project's plots and can be customized. See *Setting Field Plot Defaults* for information on how to customize the plot folders.

Note	To edit a project's design details: • In the project tree, double-click the design setup icon that you want to edit. A dialog box appears with that setup's parameters, which you can then edit.

In the project tree, an "unknown" section lists objects that are not solid, sheet, or wire.

Design List Dialog Box

You can view the design list for a model in the following ways:

- By clicking **Maxwell3D**, **Maxwell2D**, or **RMxprt** and then selecting **List**.
- By double-clicking **Model** in the project tree.
- By right-clicking items in the project tree and selecting **List** from the shortcut menu.

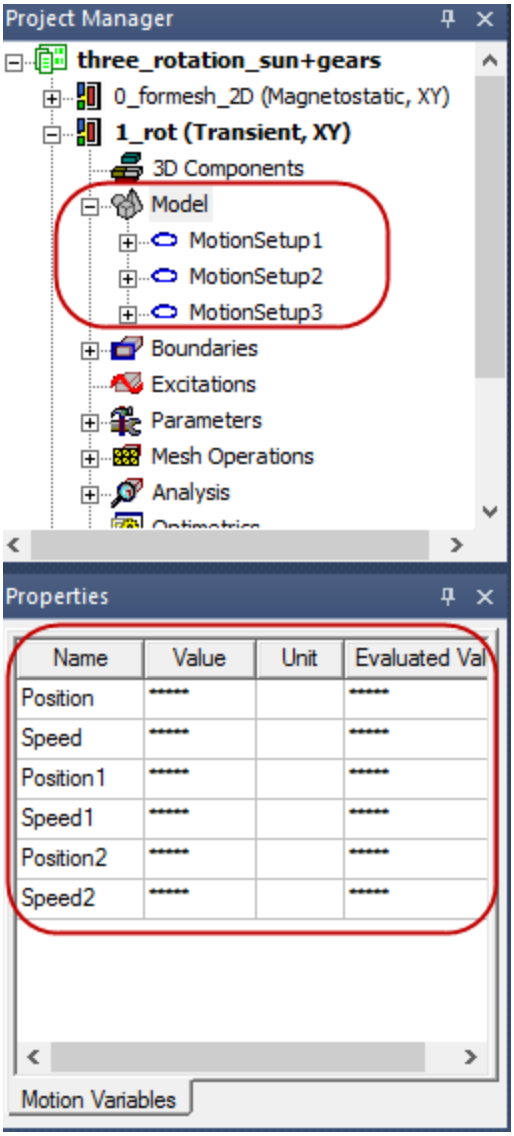
Information about the model, boundaries and excitations, mesh operations, and analysis setup can be viewed in the **Design List** dialog box that appears, with the following tabs available:

- **Model**
- **Machine** (for RMxprt projects)
- **Motion**
- **Boundaries**
- **Excitations**
- **Parameters**
- **Mesh Operations**
- **Analysis Setup**

In the **Design List** dialog box, all objects are shown, regardless of the type of dimensionality (solid, sheet, wire, or unknown); whereas, in the project tree, an "unknown" section lists objects that are not solid, sheet, or wire.

Motion Variables Tab

For 3DTransient solutions, when the Model icon in the project tree is selected, the **Properties** window displays a **Motion Variables** tab showing **Speed** and **Position** variables values if a motion setup has been defined. Similarly, for 2D transient solutions, which support multiple motion setups, the tab shows speed and position variables corresponding to each motion setup: **Position** and **Speed** for MotionSetup1; **Position1**, **Speed1** for MotionSetup2; **Position2**, **Speed2** for MotionSetup3, and so forth. Below is an example with three motion setups.



Note	Position and speed variables are treated as intrinsic variables and are not user-editable. Their values are dynamically calculated during solve time and are expressed in standard SI units. While these variables are *related* to motion setups, they are not necessarily *used* in motion setups. For example, they may also be used with the transient design's excitations. Like other variables, they can be used in expressions and reports.

Working with the Properties Window

The **Properties** window displays the attributes, or properties, of an item selected in the project tree, the history tree, or the **Modeler** window. The **Properties** window enables you to edit an item's properties. The properties, and the ability to edit them in the **Properties** window vary depending on the type of item selected. The tabs available in the **Properties** window also vary depending the selection.

You can choose to show or hide a docked **Properties** window as part of the desktop. You can move and resize the docked Properties window within the desktop to suit your work style. When you have a docked Properties window, it displays the properties of any item you select in the Project tree, the History Tree, or the Modeler window. You select **View>Properties Window** to toggle the viewing of the docked properties window.

Regardless of the whether you display a docked **Properties** window, you can still open an undocked **Properties** window for any item in the project tree, the history Tree, or the 3D Modeler window by double-clicking.

Auto-Complete for Variables and Properties in Electronics Desktop

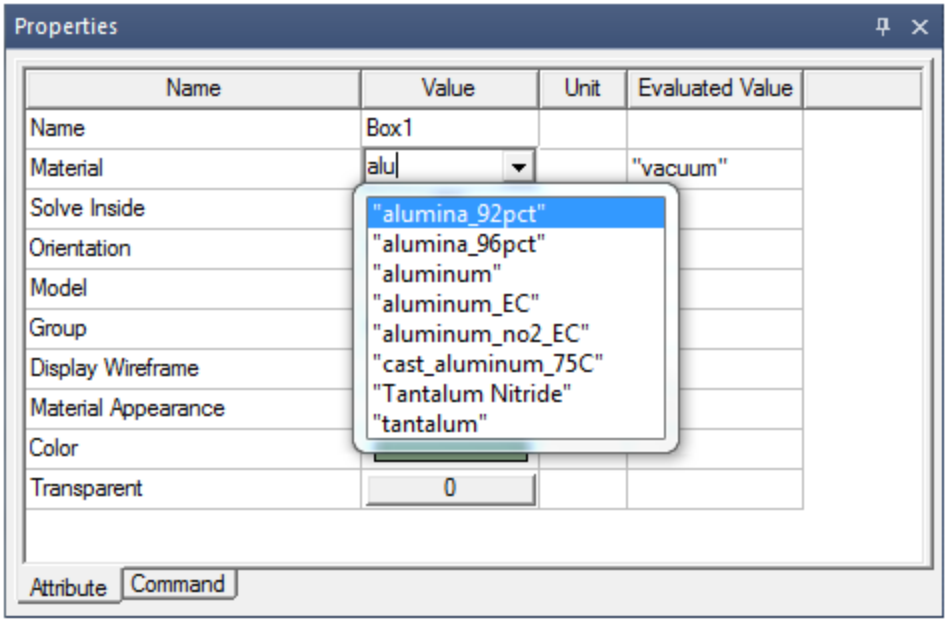
When you edit a properties or variable text field, Ansys Electronics Desktop can display possible matches for what you type. This can help if, for example, a variable or material name is long. You can save time by selecting a predetermined match rather than typing out the entire name. The following figure shows an example of auto-complete for material names:



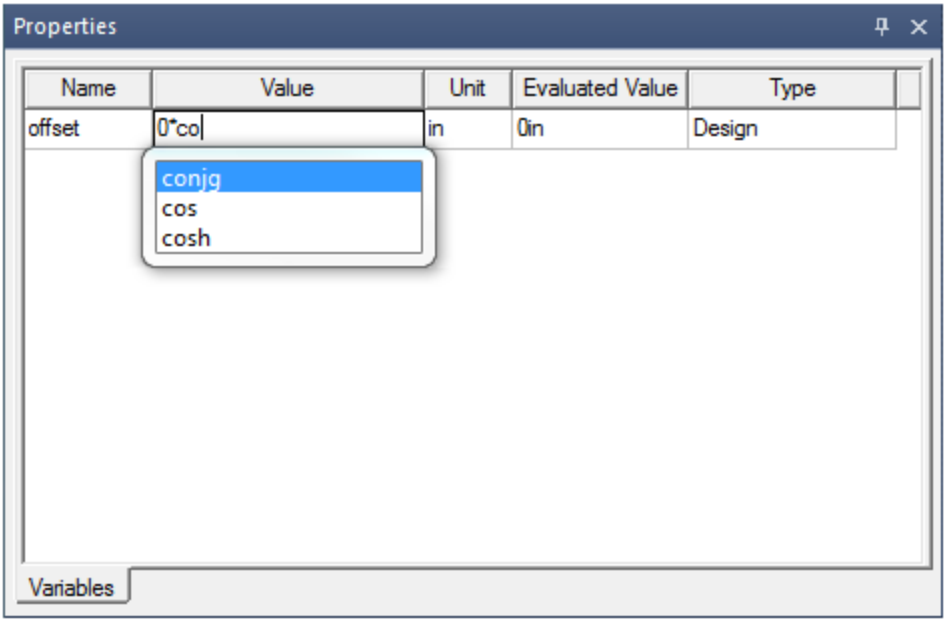
Using Auto-Complete

Certain commonly used text fields have auto-complete configured. (Not all editable fields are configured to work with auto-complete.) When you start typing in a field that is configured to work with auto-complete, items that match display in a list window below the text field. If there is no matching text, then no list window displays. With 10 matches or fewer, the list window is vertically sized according to the number of matches. The width of the window is based on the width of the text field. You can re-size the list window, and the new size is "remembered" when doing further auto-complete matching in the same text field. Switching to a different text field resets the sizing.

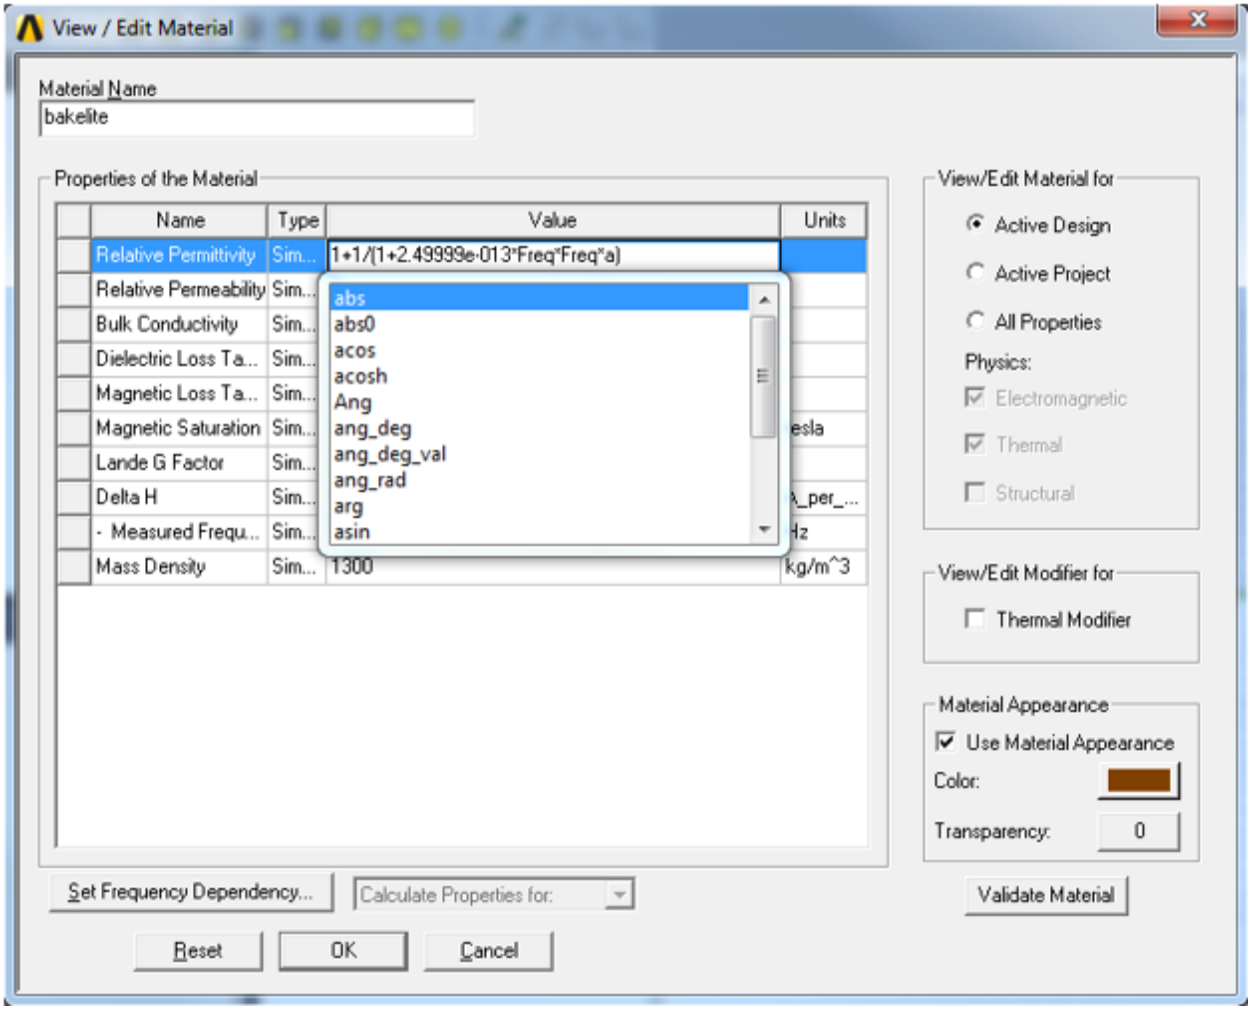
Pressing **[Tab]** or **[Enter]** accepts the current selection and hides the list window. Otherwise, hitting the escape key **[Esc]** hides the auto-complete list window.

For example, the properties window (shown in the picture above for a box drawn in HFSS) has auto-complete configured for both the Material property choices and the Group property choices. When you click in the Material value cell, the drop-down list is displayed, but as you begin to type text, this list is replaced by the auto-complete list if there are matches. For materials, not only are the choices from the drop-down list available for matching, but the full set of material definitions in all loaded libraries is searched for possible matches.

When selecting design properties, auto-complete works with expressions for the values, providing matches for the names of constants, intrinsic variables, functions, project variables (prefixed with “$”), and design properties. When project variables are displayed (that is, you select the project in the Project tree), auto-complete also works for value expressions, but without matching design properties. Properties of other items may also have auto-complete configured to work with value expressions, for example: properties of a CreateBox command or of a circuit component. Below is an example of s design property with auto-complete matching:



Auto-complete also works with value expressions for material properties:



Note the scroll bar, indicating that there are more matches than those currently displayed. Auto complete also works with thermal modifier expressions for Materials.

Modifying Object Attributes using the Properties Window

Modifying Object Command Properties Using the Properties Window

Modifying Object Command Properties Using the Properties Window

The **Command** tab in the **Properties** window displays information about an action selected in the history tree that was performed either to create an object, such as the **Draw>Box** command, or to modify an object, such as the **Edit>Duplicate>Mirror** command.

Not all command properties can be modified. The command properties you can typically modify include the numeric values, such as position values (base position, normal position, start position,

etc.), size values (height, radius, etc.), and various other coordinate values. You can also modify many of the unit settings for a command property.

1. In the history tree, select the command for which you want to edit its properties.

Hint	Press and hold **Ctrl** to select multiple commands. If you select multiple commands, only the common, or shared, properties are displayed under the **Command** tab.

2. Under the **Command** tab in the **Properties** window, edit the command's properties.

   Depending on the property type, you can edit it by doing one of the following:

   - Select the check box to apply the property; clear the check box to disable the property.
   - Click in the field and edit the numeric values or text, and then press **Enter**.
   - Click the button and then edit the current settings in the window or dialog box that appears.
   - Click the attribute, and then select a new setting from the menu that appears.

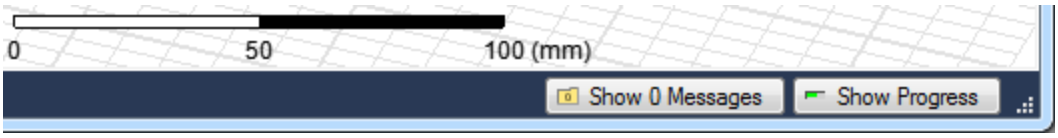
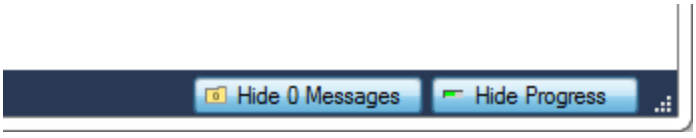
Working with the Progress Window

The **Progress** window monitors a simulation while it is running.

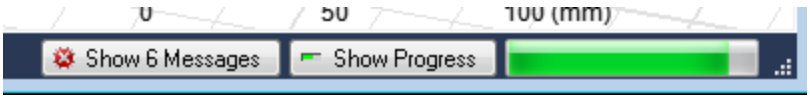
To display or hide the **Progress** window, do one of the following:

- Click the **Show Progress** or **Hide Progress** buttons on the status bar:





When more than one progress bar is active, the top progress bar is represented on the status bar with a progress indicator.



- Click **View> Progress Window**.

  A check box appears next to this command if the **Progress** window is visible.

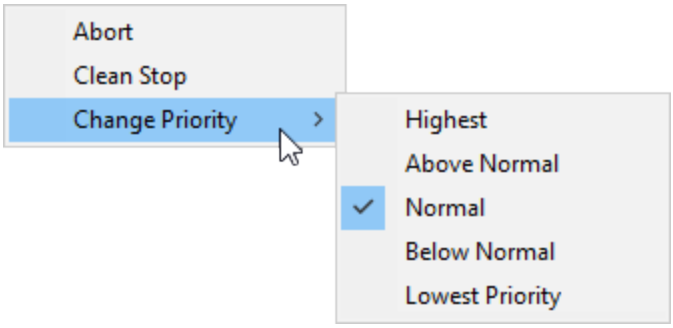
- Right-click the history tree, and then click **Progress** on the shortcut menu.
  A check box appears next to this command if the **Progress** window is visible.

Related Topics

Stopping or Aborting Simulation Progress
Viewing Distributed Analysis Subtasks

Stopping or Aborting Simulation Progress

- To abort progress, right-click in the Progress window, and select **Abort**.
- To stop the simulation cleanly between time steps, right-click in the **Progress** window, and select **Clean Stop**.
- To change priority, right-click. From the **Change Priority** submenu, select from **Highest**, **Above Normal**, **Normal**, **Below Normal**, and **Lowest**.



Stopping and Restarting Time Decomposition Method Analyses

- For Time Decomposition Method (TDM) analyses, invoking **Clean Stop** stops the analysis after completion of the current time subdivision, instead of after completion of the current time step. As a result, continuation of the solution process will start from the next time subdivision after clicking **Analysis**. In such a case, the stop time cannot be modified when TDM is used.
- When **Clean Stop** is invoked for projects in which a TDM transient source design is linked to a transient target design, after completion of the source design the solution process can continue from the target design. In such a case, the target design must be non-TDM.

Viewing Distributed Analysis Subtasks

While a distributed analysis is running, you can access parent and child progress bars. By default, only the main progress bar is displayed, while the child progress bars (or subtasks) remain hidden. You can toggle between showing and hiding the child progress bars.

To show the child progress bars:

- Right-click the progress window, and select **Show Subtask Progress Bars**.

To hide the child progress bars:

- Right-click the progress window, and select **Hide Subtask Progress Bars**.

Working with the Message Manager

The **Message Manager** displays messages associated with a project's development, such as error messages about the design's setup or informational messages about the progress of an analysis.

Messages in the **Message Manager** window are organized first by project, then by circuit. Because a design can contain multiple circuits and subcircuits, sometimes with multiple analyses for each, this organization helps you to quickly determine where errors have occurred. The following icons appear next to a message to indicate information, warnings, errors, or actions:

	Indicates an informative message.
	Indicates a warning message that may require your attention.
	Indicates an error message that may require your attention.
	Indicates the existence of an action that is associated with the message. Click on the message to invoke the action (the cursor will change to a hand icon when it is placed over the action message).

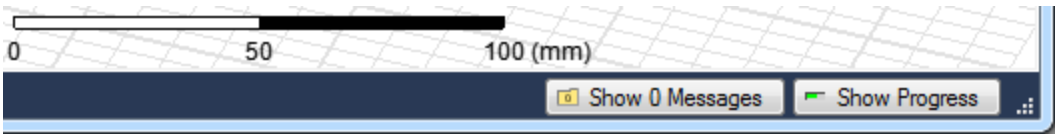
The Message Manager window is a dockable window similar to the Project Manager window. Like the Project Manager window, it can be moved and sized as needed. It can also be attached (docked) to any edge of the desktop. Message text wraps within the window. A vertical scrollbar displays as needed allowing you to move through the list message-by-message.

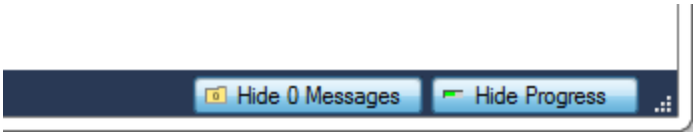
- You can drag the window by its title bar to undock, move, and dock it.
- You can resize the window by dragging its edges.
- You can maximize or minimize the window by clicking the triangle in the title bar.
- You can close the window by clicking the “X” in the title bar.
- You can right-click on a message and select **Details** to show message details.

Note	If a message is too large to fit in the window, clicking the scrollbar to page-up or page-down will have no effect. To view such messages in their entirety, you can resize the window or right-click on the message and select **Details** to show message details.

To display or hide the Message Manager:

- Click **View>Message Manager**.
  A check box appears next to this command if the Message Manager is visible.
- Click the **Show Messages** or **Hide Messages** buttons on the Status bar. The number of messages currently in the Message Manager is also shown in the button.





If you right click in the **Message Manager** window, you see a popup menu that lets you:

- Clear the messages for the current model.
- Copy the messages to the clipboard. This can be helpful for sending the messages to application engineers.
- Details. This brings up a information dialog with the project and design for specific message.

After you run a validation check, you can right-click on an intersection error message in the Message window, and select **Go to reference** from the shortcut menu. This selects the intersecting objects.

Showing new messages

Showing errors and warnings

Showing new messages

You can set the **Message Manager** to automatically be brought up when a new message appears.

1. Click **Tools>Options>General Options**.

   The **General Options** dialog box appears.

2. Under **General>Interface Options**, select **Show Message Window on new messages**.
3. Click **OK**.

Showing errors and warnings

You can set the **Message Manager** to automatically expand when an item is added to a project.

1. Click **Tools>Options>General Options**.

   The **General Options** dialog box appears.

2. Under **General>Interface Options**, select **Ensure that new messages are visible in the Message Window Tree**.
3. Click **OK**.

Clearing Messages for the Project

You can clear all the messages for a particular project.

To clear messages:

1. Right-click the *project#* in the **Message Manager**.

   A pop-up appears.

2. Click **Clear messages for Project#**.

Clearing Messages for the Model

You can clear all the messages for a particular model.

To clear messages:

1. Right-click the *MaxwellModel#* in the **Message Manager**.
   A pop-up appears.
2. Click **Clear messages for MaxwellModel#**.

Copying Messages

You can copy all the messages for a particular project.

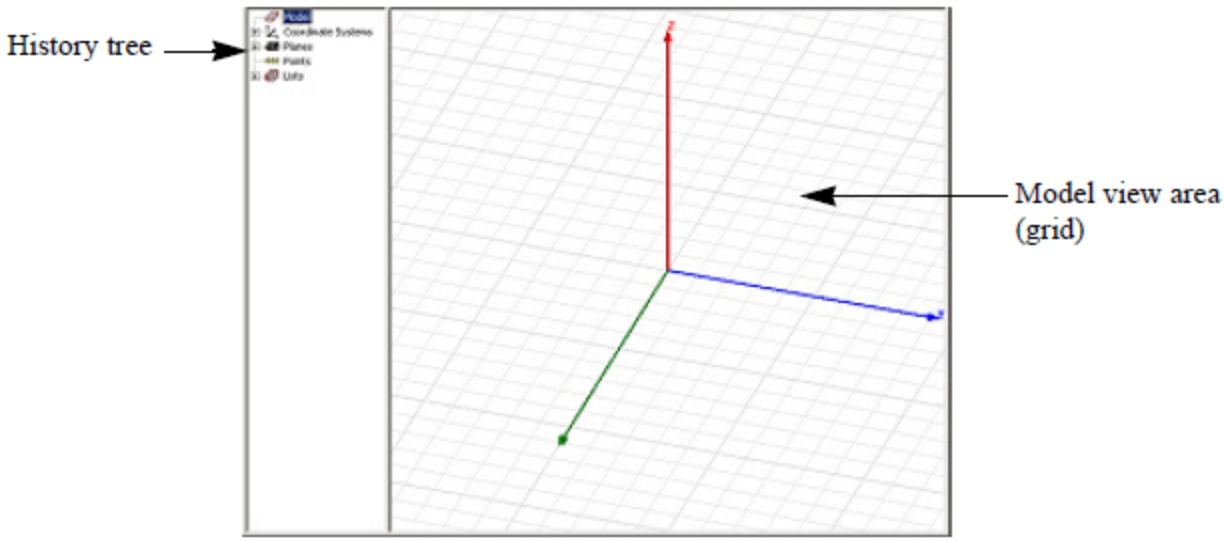
To copy messages:

1. Right-click in the **Message Manager**.
   A pop-up appears.
2. Click **Copy messages to clipboard**.

Working with the Modeler Window

The **Modeler** window is the area where you create the model geometry. It appears to the right of the **Project Manager** window *after* you insert a Maxwell design into a project.

The **Modeler** window consists of the model view area, or grid, and the history tree, as shown below:



To open a new Modeler window, do one of the following:

- Insert a Maxwell design into a project.
- Double-click a Maxwell design in the project tree.

The model you draw is saved with the current project when you click **File>Save**.

Objects are drawn in the **Modeler** window. You can create 3D objects by using Maxwell's **Draw** menu commands, or you can draw 1D and 2D objects and then manipulate them to create 3D objects. For more information, see *Drawing a Model*.

You can modify the view of objects in the **Modeler** window without changing their actual dimensions or positions. For more information, see *Modifying the Model View*.

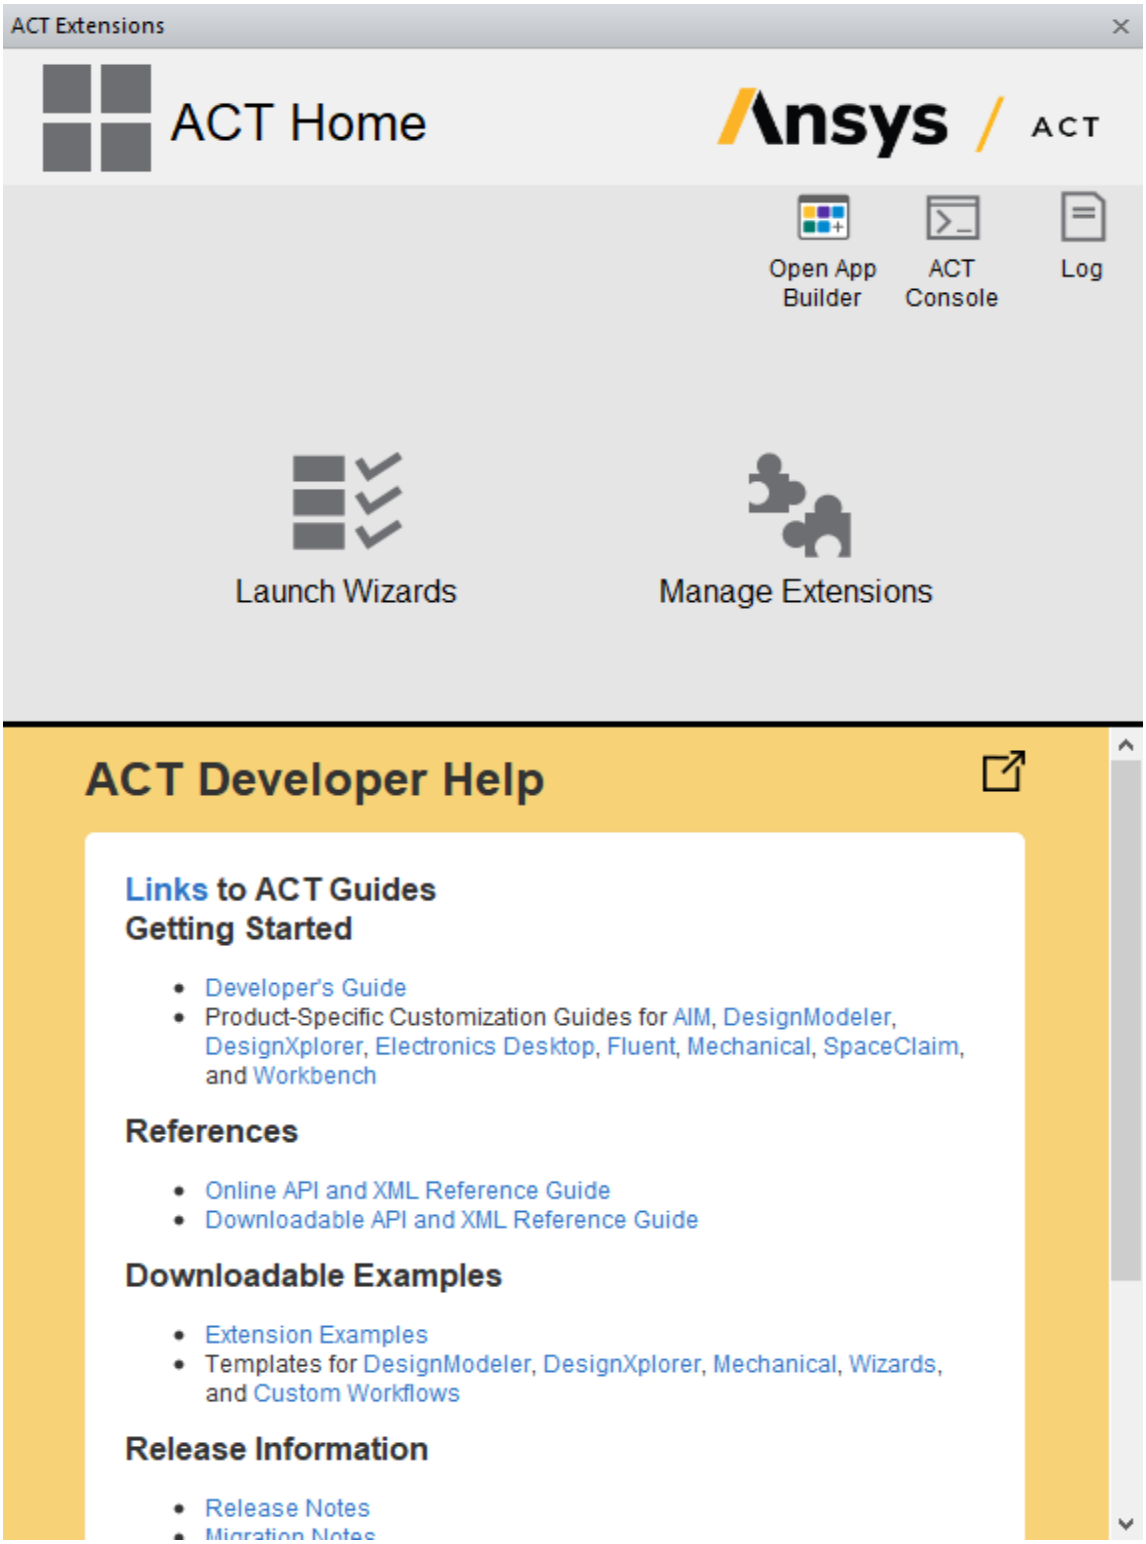
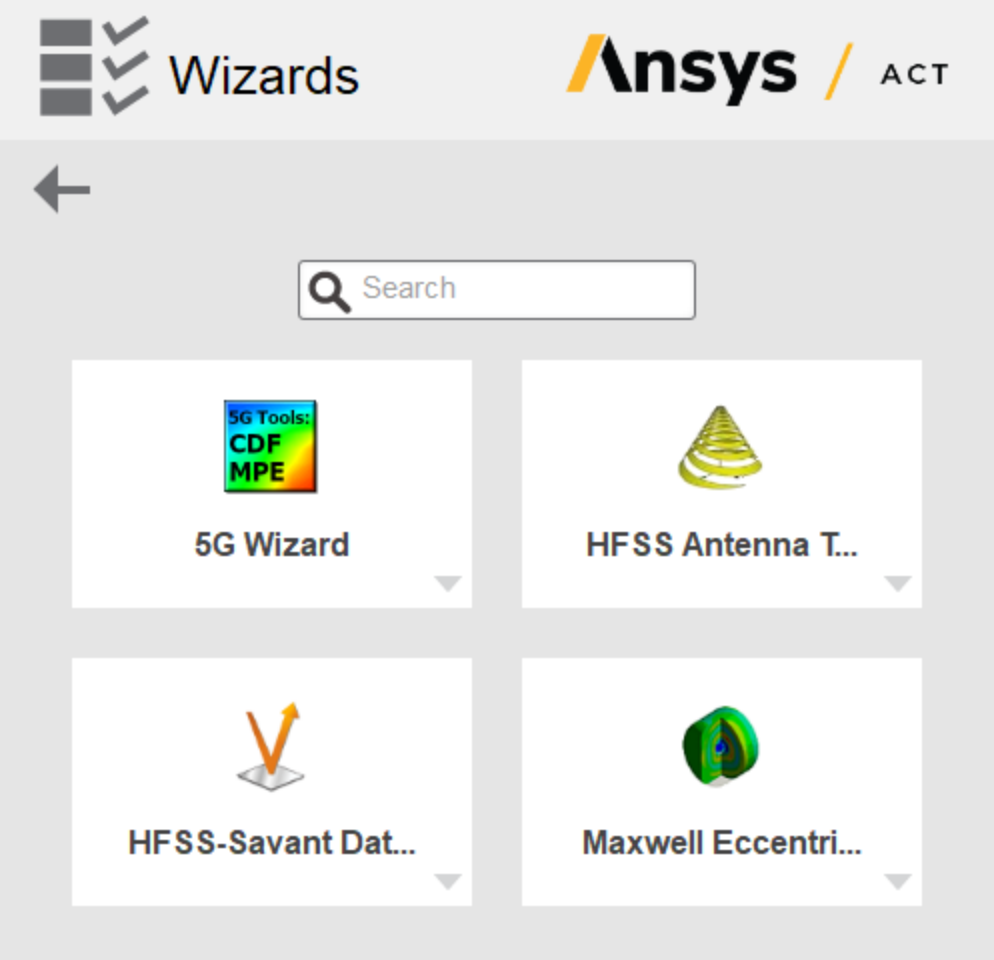
Working with the ACT Extensions Window

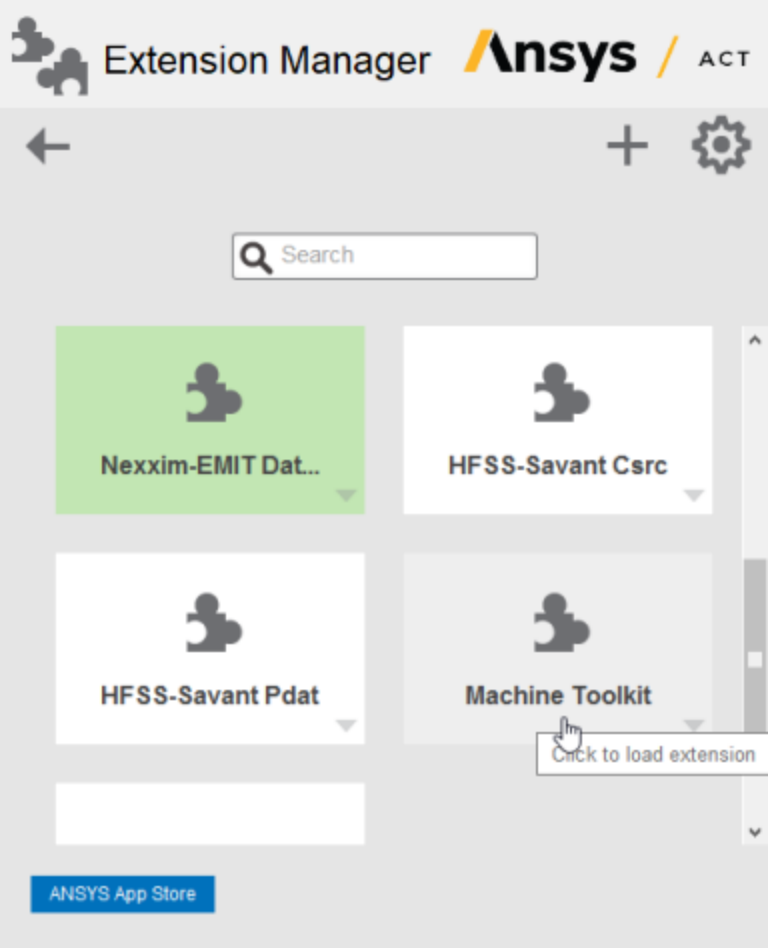
The **View** > **ACT Extensions** command opens the ACT Extensions window for extensions – known as **Wizards** – that have been implemented via Ansys ACT. Depending on how you size and arrange the desktop, the appearance of the window may vary. You may also choose to detach and size it as a floating window to suit your needs.



1. Click on the **Launch Wizards** icon to view active wizards in the **Wizards** view.

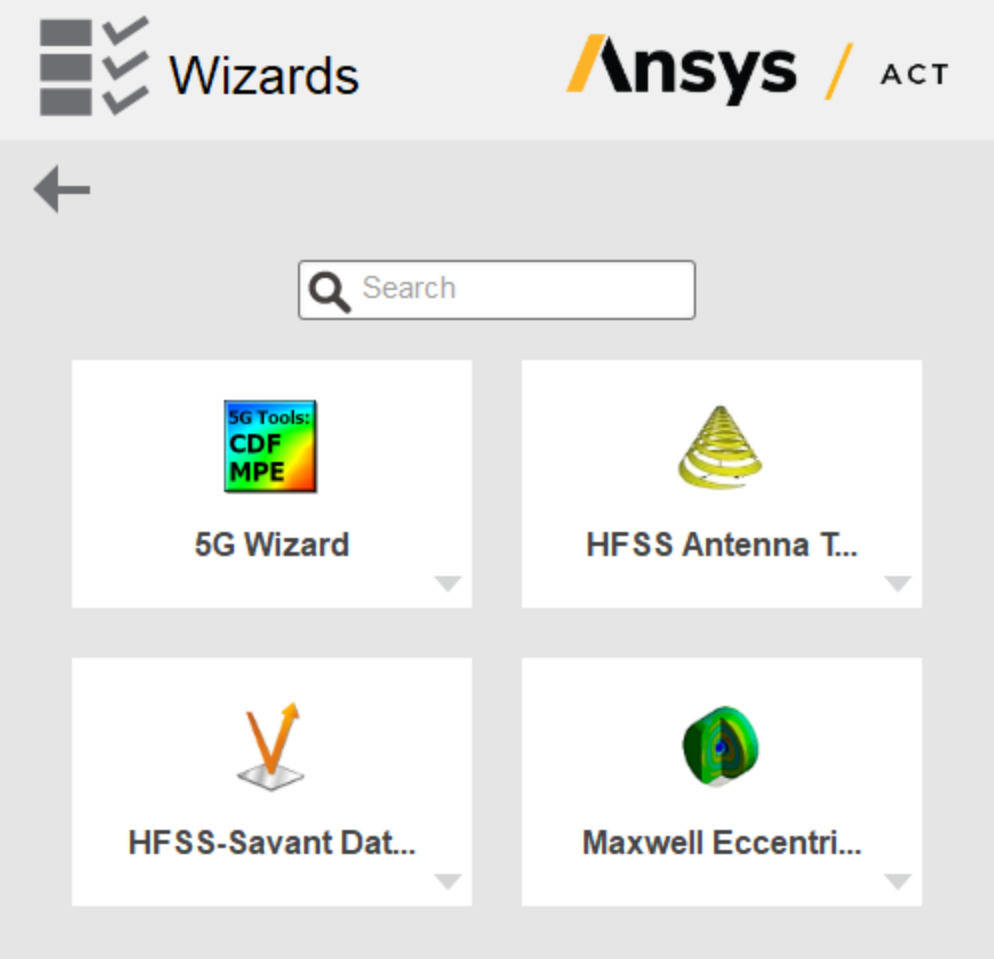


2. To add and use an existing Wizard, you must activate it by clicking on the **Manage Extensions** icon. This changes the view to show the installed extensions. If there are many available extensions, you can either scroll or use the **Search** field to find the ones you want. **Search** is not case sensitive. Click the desired extension to activate it. The extension is then loaded and highlighted to show the change in status. You can also unload (deactivate) an extension by clicking on it. In the following image, the Nexxim extension has been activated, but the HFSS and Machine Toolkit extensions are not activated for use.

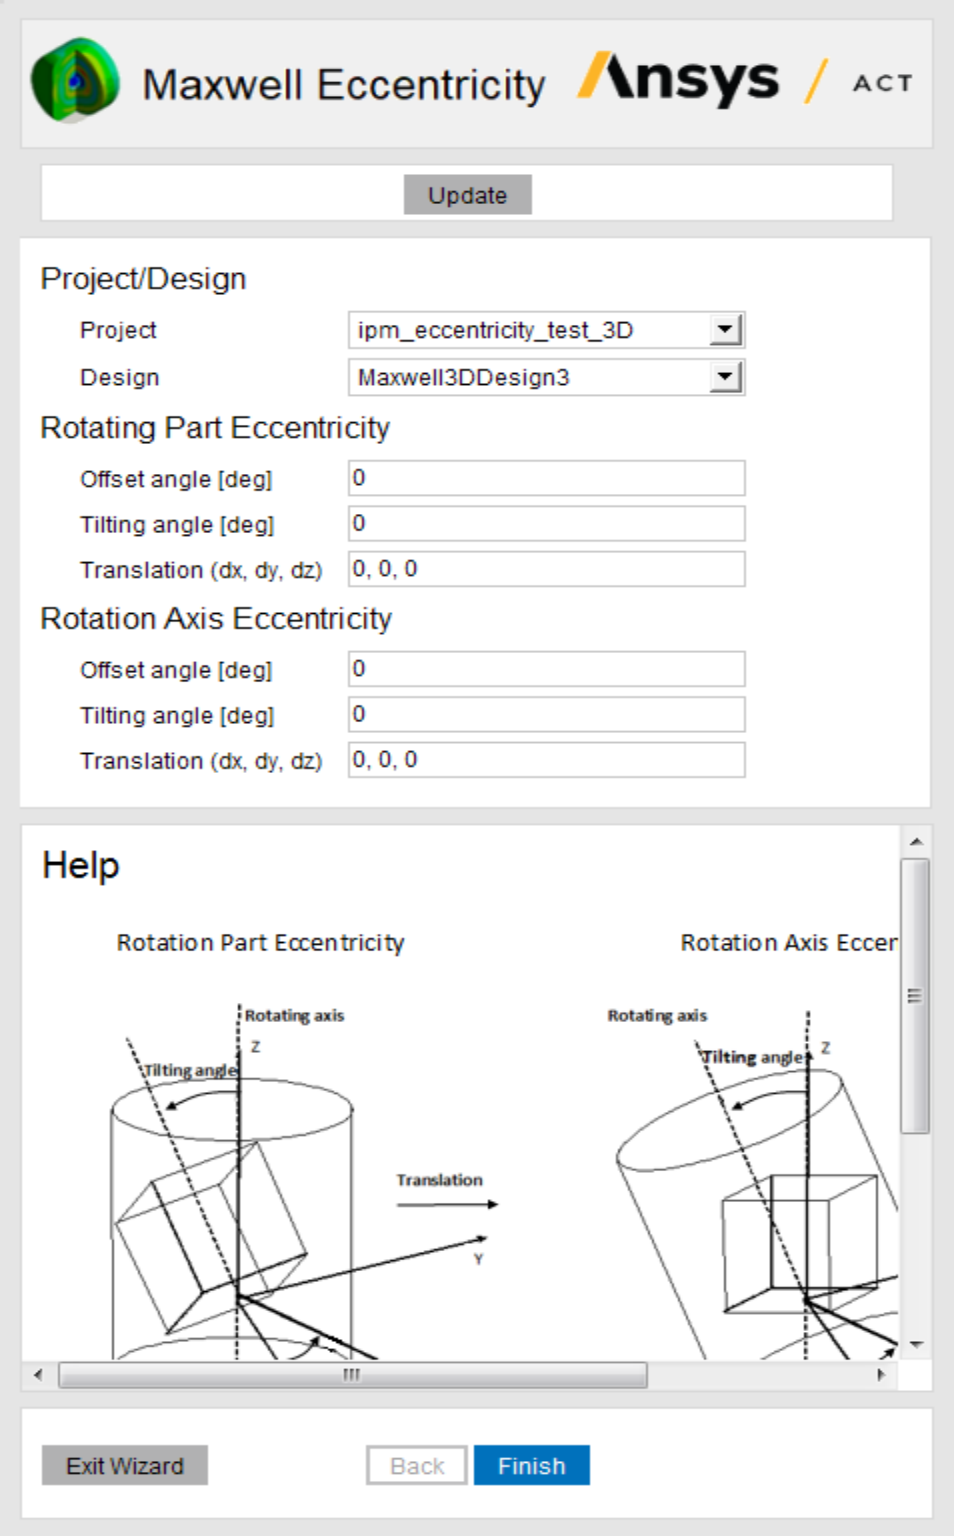


3. Click the back arrow icon to return to the ACT start page,

then click the **Launch Wizards** icon to open the **Wizards** view.



4. Click on the icon for the wizard you want to use to open it in the window.



5. You can click the **Exit Wizard** button to exit the wizard and return to the Wizards view.

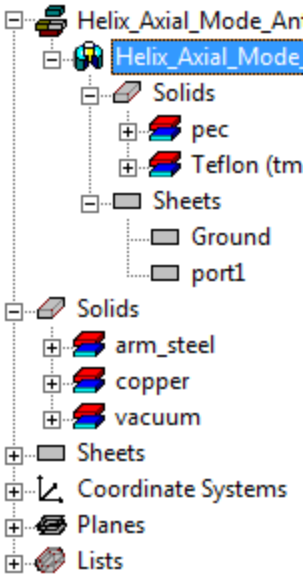
"Modeling Maxwell Motion Eccentricity " on page 13-9

Working with the History Tree

The history tree in the **Modeler** window lists the active model's structure and grid details, including the model's objects, coordinate systems, default planes, and any object or face lists.



You can perform the following tasks with the history tree.

- Expand or Collapse Groupings in the History Tree
- History Tree Layout Commands
- Group Commands for Modeler Objects
- Selecting Objects in the History Tree
- Use Shortcut Menus in the History Tree
- View Properties for History Tree Objects
- History of Commands on History Tree Objects
- Control the View of Objects in the History Tree
- Selecting All Objects in a History Tree Folder
- Upgrade Version

The history tree contains the following model details:

Invalid	Lists all invalid objects
3D Component Names	Lists any 3D components added to the design, listing their Solids, Coordinate Systems, and Planes, separately from objects drawn in the modeler, or imported to the modeler.

Solids	Displays all the model's solid objects and a history of the commands carried out on each object.
Sheets	Displays all the sheets in the model 3D design area. By default, all sheet objects are grouped by boundary assignment.
Lines	Displays all line objects included in the active model. See *Drawing a Line* for information on how to draw a line object.
Points	Displays all point objects included in the active model. See *Drawing a Point* for information on how to draw a point object.
Groups	Displays folders for Groups you have created or imported. See Group Commands for Modeler Objects.
Coordinate Systems	Displays all the coordinate systems for the active model. See *Setting Coordinate Systems* for more information on this model detail.
Planes	Displays the planes for all the coordinate systems. When you create a coordinate system, default planes are created on its xy, yz, and xz planes.
Lists	Displays the object or face lists for the active model. By default, a list called "AllObjects" appears. Creating an object list is a convenient way to identify a group of objects for a field plot or calculation. Creating a face list is a convenient way to identify a specific set of surfaces for a field plot or calculation. See *Creating an Object List*.

Note	While objects created in Maxwell can always be classed in the history tree as either a solid, sheet, or wire, some imported objects may have mixture of these. Such objects are placed in an Unclassified folder in the history tree.

Expand or Collapse Groupings in the History Tree

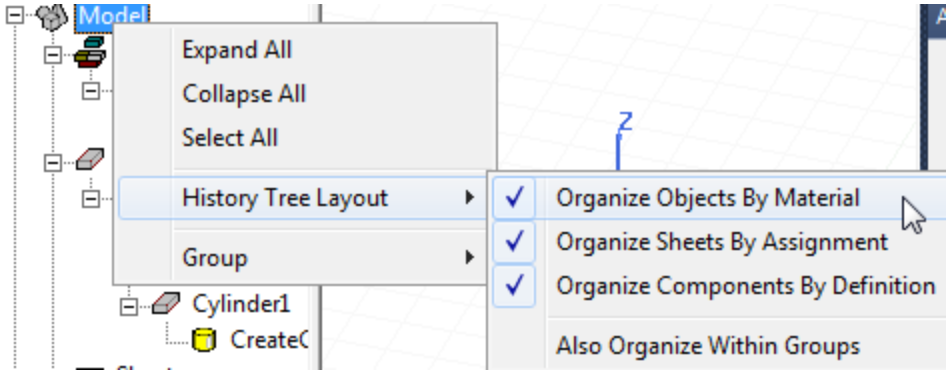
You can expand or collapse object groupings in the history tree by left clicking the + or - respectively. In addition, right-clicking on any group icon opens a pull-down to **Expand All** groupings or **Collapse All** groupings.

Related Topics

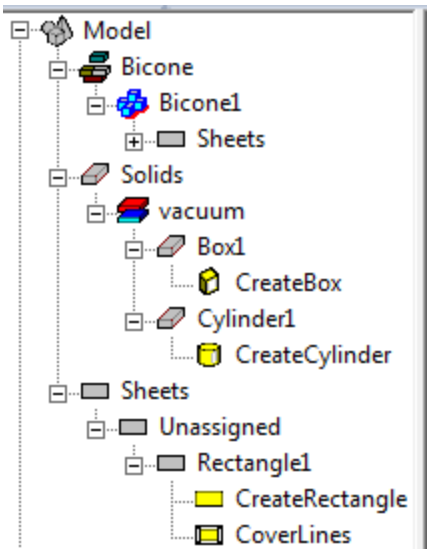
Selecting Objects in the History Tree

History Tree Layout Commands

A set of History Tree Layout commands lets you organize objects by material, assignment, or by component definition. By default there is no further organization within groups. You can select **Also Organize Within Groups** to extend organize settings within groups.



If the design does not contain material assignments, sheets, components, or groups, the menu items are disabled. You can access the History Tree Layout commands by clicking **Modeler>History Tree Layout** or by right-clicking on the Model icon in the history tree (as shown above). You click on [-] to close a hierarchy and [+] to open one.



Related Topics

Select Objects in the History Tree

Group Commands for Modeler Objects

History of Commands on Objects

The history tree also lists the history of all commands carried out a model's objects. This history is displayed in the order in which it occurred. Note in the above image the expanded air object and

its history of commands.

Selecting a command in the history highlights the object in the Modeler window and shows that object's properties (if available) in the docked Properties window. You can look at the fields in the Properties window to see any editable fields for that command, such as coordinate system, line type, coordinates, or units.

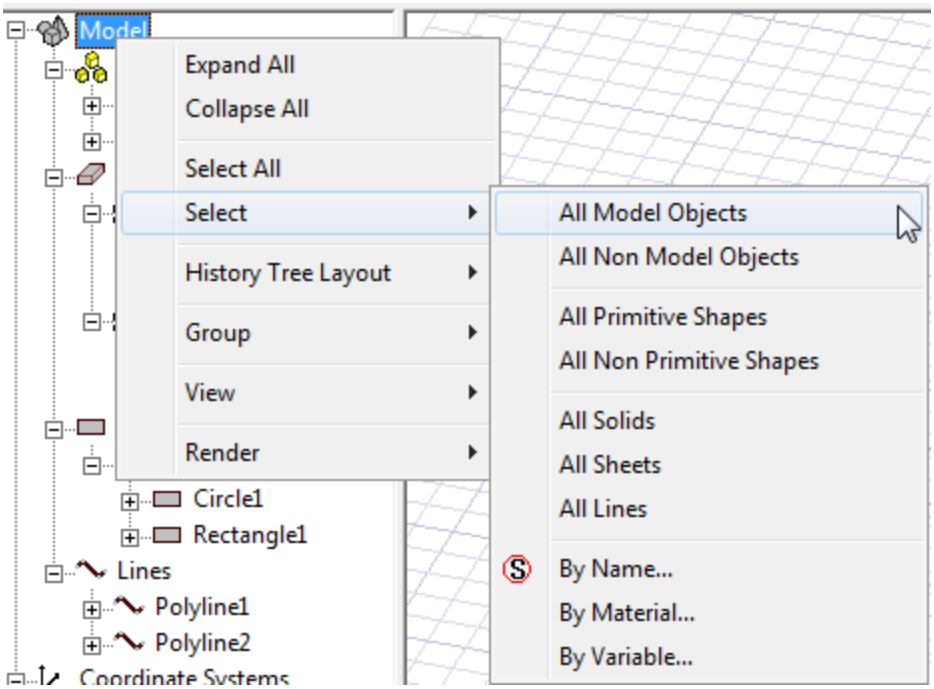
For some commands, such as **Edit>Arrange>Move**, or boolean operations, selecting them in the history tree enables the X (Delete) icon on the ribbons and the **Edit>Delete** menu. In these cases, you can delete those commands from the history tree as a way of undoing those operations. As an alternative to deletion, you can check **Suppress** command in the Properties window for that command. This undoes the effect of a command on an object without removing it from the History tree.

Selecting Objects in the History Tree

Selecting objects in the History tree also selects them in the View window. This can be useful for complex objects, when it may be easier to find the objects of interest by name or material, if the object of interest is inside or behind others.

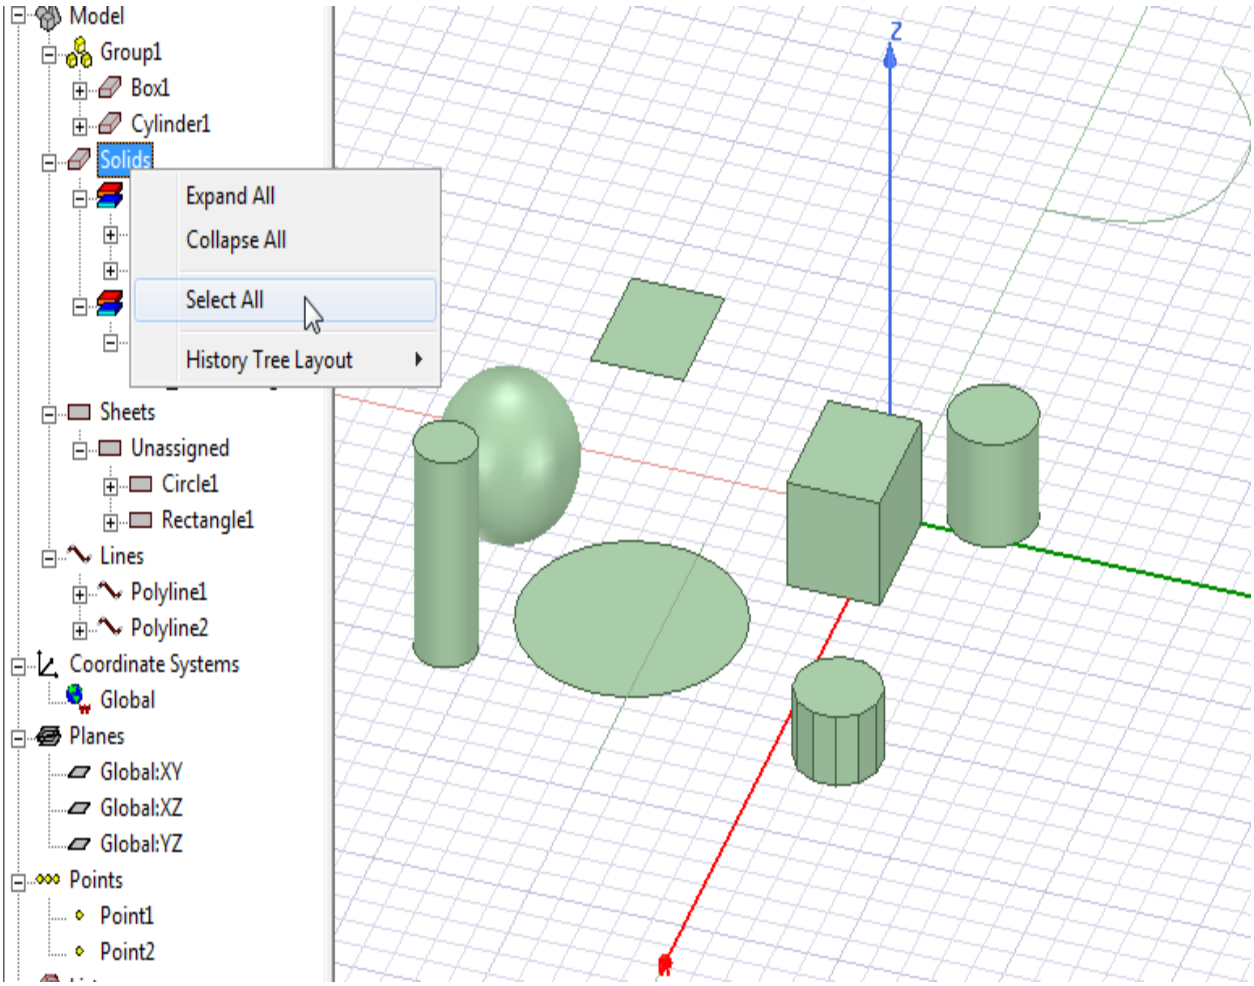
You can use CTLR-click to make multiple selections. You can select a range of objects by a click on the first, and then SHIFT-Click to select all in the range. You can also click and drag the mouse to make rubber band selections. Only visible objects are selected. That is, if the hierarchy is closed under the selection, any operand parts are ignored and do not interfere with cut and paste operations.

If you select Model in the History tree and right-click the shortcut menu offers these choices:

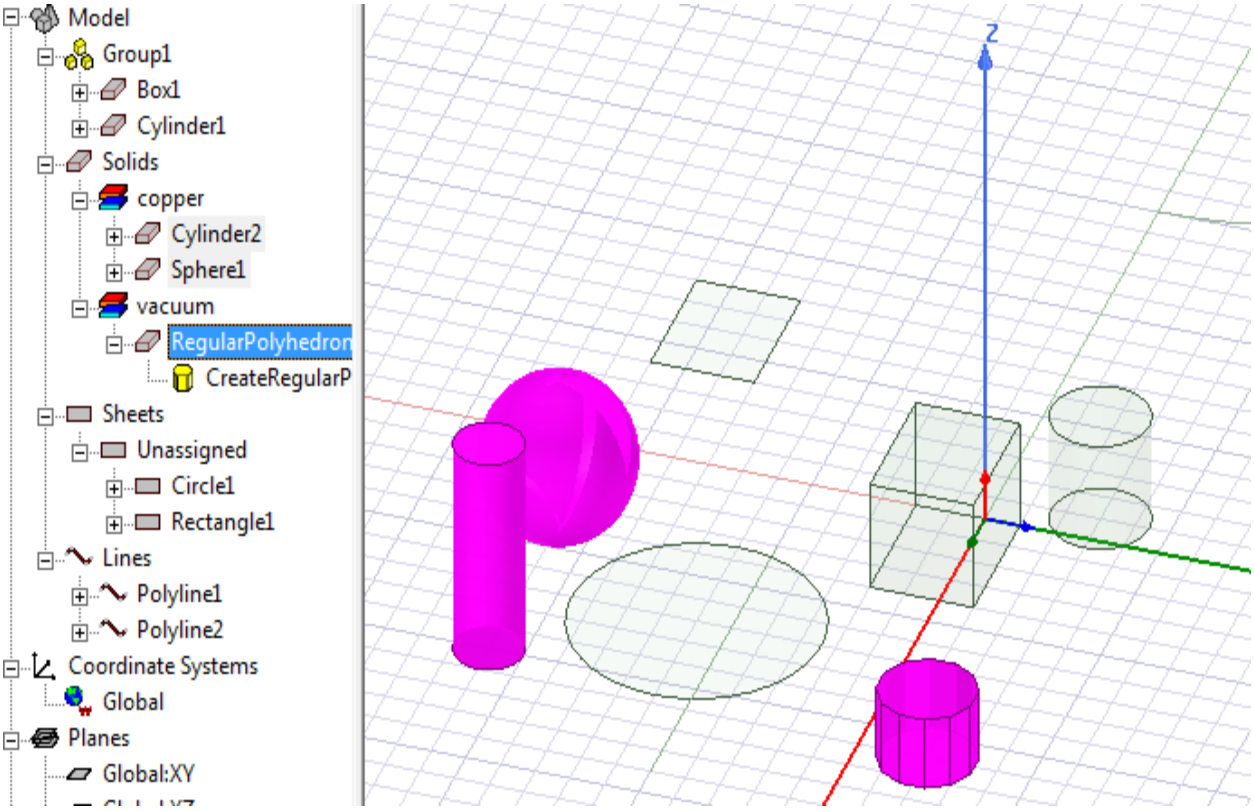


You can also right click on any History tree object or grouping and right click to display a shortcut menu with a **Select All** command. This lets you select at one time all solids, sheets, lines, non-model objects, or all unclassified objects, as well as all non-grouped objects assigned to specific materials.

For example, right-click on Solids and then **Select All**:



After clicking **Select All**, the History tree and the **Model** window highlight the selected Solid Objects. Notice that Box1 and Cylinder1 are not selected because they are in Group1.



If you select a geometric object, such as a Box or Cylinder, the shortcut menu **Select** command offers choices to select **All Faces**, **All Edges**, or **Sheet Edges** for that object.

Running Ansys Electronics Desktop From a Command Line

Ansys Electronics Desktop includes line arguments that can be included when launching from a command line or terminal prompt. All command-line arguments are case-insensitive. The commands associated batch options can also be used with a Job Management Interface for submitting jobs to Ansys or RSM and other supported schedulers. See

RSM Integration with Job Management UI

Integration with Microsoft Windows® HPC Scheduler

Integration with Platform's Load Sharing Facility (LSF)

Integration with Grid Engine (GE)

Command-line syntax

```
ansysedt <options> <run command(s)> <project file/script file>
```

It is good practice to put quotation marks around the path to the solver executable, and around the full path to the project. This ensures that spaces in the path or project will not be an issue. The same is true of the design name, if there are spaces.

Run Commands

The following command line run commands are available for Ansys Electronics Desktop. Of the commands (BatchSave, BatchSolve, BatchExtract, RunScript, RunScriptandExit), one or none must be specified as arguments after the solver executable. When none is specified, you may specify a project or archive to open when Electronics Desktop launches, and can only use the **-Iconic** and **-Help** options. The commands are further described below:

- **-BatchSave** [options] *file or folder specifier***>**

  Saves a named project or folder containing one or more project files or folders to the current version. This can be helpful for the change from ACIS to Parasolid. The Parasolid migration of aedt projects does not overwrite the existing project. Instead a copy is created through save-as with _converted suffix and then that copy is migrated to Parasolid. You can run this command with the **-Iconic**, **-Logfile**, and **-ng** options.

- **-BatchSolve <***project filename***>**

  By default, this run command solves all adaptive setups, Optimetrics setups, and sweeps found in the project file. You can run this command with the **-Iconic**, **-Logfile**, **-ng**, and **-WaitForLicense** options. If parallel solve is possible, you can use the **-Distribute** option.

  If you wish to specify which setups **-BatchSolve** completes, you can use additional parameters:

  - **[*designName*]** – batch solve all setups for the specified design in the project file.
  - **[*designName*]:Nominal** – batch solve all nominal setups for the specified design in the project file.
  - **[*designName*]:Optimetrics** – batch solve all Optimetrics setups for the specified design in the project file.
  - **[*designName*]:[*Nominal/Optimetrics*]:[*SetupName*]** – batch solve the specified Nominal or Optimetrics setup in the specified design.

  If you wish to specify whether **-BatchSolve** setups are completed locally or remotely, you can use the following options:

  - **-Local** – performs the **-batchsolve** on the local machine.
  - **-Remote -machineList** – performs the **-batchsolve** on a remote machine. The <*machineList*> should provide a single hostname.

- **-Distributed -machineList** – performs a distributed **-batchsolve** using a specified machine list.

  The **-machineList** parameter for a **-Distributed** setup can be formatted three ways:

  - **-MachineList list="<***machine1***>, <***machine2***>, ..."** – machine names (either by IP address or hostname) are separated by commas. If the list contains any whitespace, it must be enclosed in quotes. The number of distributed COM engines run on each host is equal to the number of times the hostname appears in the list. That is, if host1 appears in the list once, and host2 appears twice, then one COM engine will run on host1 and two COM engines will run on host2.

    list= accepts the following additional modifiers:

    <*MachineName***>:<***NumTasks***>:<***NumCores***>:<***RAM Limit in %***>:<***Number of GPU***>**

    Example:

    ```
    list="Orion:4:8:90%:1, Aries:3:12, Pluto:6:12"
    ```

    > **Note:**
    >
    > Duplicate machines are not allowed when specifying these additional modifiers. The number of cores must be greater than the number of tasks.

  - **-MachineList file="<***machineListFilepath***>"** – machine names (either by IP address or hostname) are listed in a file (one per line), and you specify the filepath. The number of distributed COM engines run on each host is equal to the number of times the hostname appears in the file. That is, if host1 appears in the file once, and host2 appears twice, then one COM engine will run on host1 and two COM engines will run on host2.

    file= accepts the following additional modifiers, in the file itself:

    <*MachineName***>:<***NumTasks***>:<***NumCores***>:<***RAM Limit in %***>:<***Number of GPU***>**

    Example:

    ```
    "Orion:4:8:90%:1",
    "Aries:3:12",
    "Pluto:6:12",
    ```

> **Note:**
>
> Duplicate machines are not allowed when specifying these additional modifiers. The number of cores must be greater than the number of tasks.

- **-MachineList num="<***numberofDistributedEngines***>"** – This format is used when a scheduler (such as LSF, PBS, SGE or HPC) is used to manage the jobs sent to a cluster of hosts. In a scheduler environment, you can specify the number tasks for distributed processing. In this case, you do not specify the machine names after the flag because the names are provided by the scheduler. For example, in the Windows HPC environment, you can write the number of tasks as follows:

```
-MachineList num=4
```

-Distributed setups can also take the following optional arguments. When these are not present, the behavior defaults to single-level distributed solutions with no change in order of precedence among possible distribution types.

The arguments are:

- **includeTypes=<***default***>|<***distribution type 1, distribution type 2***, ...>** – If included distribution types are specified, only the listed distribution types are enabled. If default is specified, the default set of enabled distribution types is used. To see a valid distribution types for your design, click **Simulation** > **Analysis Config** to open the **Analysis Configuration** window and view the types on the **Job Distribution** tab.
- **excludeTypes=<***default***>|<***distribution type 1, distribution type 2***, ...>** – If excluded distributed types are specified, all distribution types except those listed will be enabled. If default is specified, the default set of enabled distribution types is used. To see a valid distribution types for your design, click **Simulation** > **Analysis Config** to open the **Analysis Configuration** window and view the types on the **Job Distribution** tab.
- **maxLevels=<***1/2***>** – the maximum number of levels of job distribution (the current maximum is 2). See: Selecting Optimal Configurations for Distributed Analysis.
- **numLevel1=** – when two-level distribution is selected (**maxLevels=2**), this specifies the number of level 1 tasks.

You can also specify how a **-BatchSolve** distributes Optimetrics variations:

- **-auto** – Without additional parameters, the batch log file will specify that Optimetrics variations be solved sequentially.
- **-auto NumDistributedVariations=<***num***>** – You can specify an integer value greater than 1. This is the number of variations that will be solved in parallel.

- **-BatchExtract <***BatchExtract script filename***><***project filename***>** – allows the following commands to be executed non-graphically via script and without checking out any GUI licenses:
  - ExportProfile
  - ExportConvergence
  - ExportMeshStats
  - ExportNetworkData
  - ExportNMFData
  - ExportEigenmodes
  - ExportTransientData
  - Update Reports
  - ExportToFile

  A project file *must* be specified when **-BatchExtract** is used. Commands in the script file will only be executed in the specified project.

  > **Note:**
  >
  > - **-ng** must be used with **-BatchExtract**, or it will fail.
  > - Only the scripts listed above are supported for **-BatchExtract**. Including unsupported script commands will terminate script execution.

- **-RunScript <***script filename***>** – runs the specified script. You can use the **-ScriptArgs** option to add one or more arguments to this command, and the **-Iconic** option.
- **-RunScriptAndExit <***script filename***>** – runs the specified script and exits Electronics Desktop. You can use the **-ScriptArgs** option to add one or more arguments to this command. You can also use **-Iconic**, **-Logfile**, and **-WaitForLicense**.

  > **Note:**
  >
  > **-BatchSolve <***DesignName***>** is mutually exclusive with **-RunScriptAndExit <***ScriptName***>**.

- **-monitor** – during non-graphical analysis, you can monitor progress and messages. Progress, warning and info messages are logged to the standard output stream. Error and fatal messages are logged to the standard error stream. Schedulers intercept these streams and provide commands for display of this output. See individual scheduler documentation for specifics.

Job Management from the Command Line

- **-showmonitorjob** – Launch the monitor job dialog.
- **-showsubmitjob** – Launch the submit job dialog.

- **-showselectscheduler** – Launch the select scheduler dialog.

Run Command Examples

A distributed **-BatchSolve** of a specified design's Optimetrics setups, with a specified machine list:

```
C:\Program Files\AnsysEM\v231\Win64\ansysedt -distributed -
machinelist list="255.255.1.1,255.255.1.2" -batchsolve
myDesign:Optimetrics
"%UserProfile%\Documents\Ansoft\myProject.aedt"
```

A **-BatchExtract** operation using paths to a script file and a project file:

```
ansysedt -ng -batchextract exportToFile.py "C:\Program
Files\AnsysEM\AnsysEM23.1\Win64\Examples\ElectronicsDesktop\HFS
S\RF Microwave\OptimTee.aedt"
```

Where exportToFile.py contains:

```
oDesktop.RestoreWindow()
oProject = oDesktop.SetActiveProject("OptimTee")
oDesign = oProject.SetActiveDesign("HFSSDesign1")
oModule = oDesign.GetModule("ReportSetup")
oModule.UpdateReports(["XY Plot 1"])
oModule.ExportToFile("XY Plot 1", "exportToFilePy.csv")
```

A **-BatchSolve** of a specified design's nominal setups, run in a minimized window, with a specified log file:

```
ansysedt -Iconic -LogFile "H:\Logs\mylog.log" -BatchSolve
myDesign:Nominal "H:\Projects\MyProject.aedt"
```

Specifying Project Files

Specifying a project file opens that project when Electronics Desktop launches. If **-BatchSolve** is set, the project will also be solved.

You can specify an archive file instead of a project file. If **-Batchsolve** is set, the project will be automatically restored and solved. Otherwise, you are prompted for a restore location, and the project will be restored and opened.

When a **-Batchsolve** is being performed on an archive file, you may also specify **-archiveoptions**:

- **overwritefiles** – allows non-project/results-extracted files to overwrite existing files.
- **path=<***projectFilepath***>** – extracts the project file and associated files to the specified path. If not specified, the archive will be extracted into the same directory as the archive file.
- **winpath=<***windowsProjectFilepath***>** – specifies the Windows-specific path to the extracted project file. This is used when a batch job is to be run on a Linux system, but monitored on Windows.

Options

The following options can be associated with one or more of the run commands:

- **-autoextract** – exports profile (as text), convergence (as text), and report data (as CSV) for the requested project/design/setup in a batch job. Once the solve is complete, an export directory is created (for example, "Project1.aedtexport" for a project named "Project1.aedt") that contains a sub-directory for each design name. You can also specify `-autoextract "reports, fieldplots"` to also generate *.aedtplt files for each field plot and possible *.avz file (for import and display in Ensight) for all valid field plots. Export files reside within each design-name directory, and include setup name, design variation, job ID, and problem type, as applicable.

  > **Note:**
  >
  > - The -autoextract option is only valid when used with -BatchSolve
  > - The -autoextract option is automatically added for all Ansys Cloud jobs submitted from Electronics Desktop. There is also an additional "reports" and/or "fieldplots" option that immediately follow "-autoextract". This causes all reports to be exported as CSV files at the end of the batch solve, after the profile and convergence have been exported.
  > - For example, you can specify `-autoextract "reports, fieldplots"` to also generate *.aedtplt files for each field plot and possible *.avz file for all valid field plots.

- **-batchoptions** – for batch jobs, specifies any of the options in **Tools** > **Options**. See additional information.
- **-batchoptionhelp** – opens a window showing -batchoptions help. The paths shown in this window can be used with batchoptions and the Update Registry Get and Set commands. See: Setting or Removing Option Values in Configuration Files: UpdateRegistry Command.
- **-distribute** – distributes a batch solve to multiple machines. This option must be combined with the **-BatchSolve** run command. See: Distributed Analysis.
- **-help** – opens a window displaying command line options. This can only be used without a run command.
- **-iconic** – runs Electronics Desktop with the window iconified (minimized).
- **-logfile<***filePath***>** – specifies a log file. If none is specified, <project_name>.log will be written to the <project_name>.batchinfo directory.
- **-monitor** – enables batch job output to standard output and standard error streams.
- **-ng** – runs Electronics Desktop in non-graphical mode. This *must* be used with the **-BatchExtract** command.
- **>-useElectronicsPPE** – selects Electronics Pro/Premium/Enterprise licensing. Allowed values: <none>, true, "= 1", true, "=0" false.

- **-validateonly** – If true, validation will be performed, but none of the setup will be solved. Allowed values: 0 (false), 1 (true).
- **-waitforlicense** – directs Electronics Desktop to wait for unavailable licenses.
- **-scriptargs** – used in conjunction with **-RunScript** or **-RunScriptAndExit**, adds arguments to the specified script. You can pass multiple arguments to **-scriptargs** by surrounding the arguments in double quotes. For example:

  ```
  ansysedt.exe -scriptargs "MaxwellDesign1 Setup1" -
  RunScriptAndExit C:\temp\test.py
  ```

  In Python, the command line parameter following **-scriptargs** is passed without modification as a single string in the ScriptArgument python variable.

  In VBscript, the command line parameter following **-scriptargs** is split into multiple strings and converted to a VBscript collection which is accessible via the **AnsoftScript.Arguments** collection. To access these arguments, for example:

  ```
  msgbox AnsoftScript.Arguments(0) // Returns MaxwellDesign1
  msgbox AnsoftScript.Arguments(1) // Returns Setup1
  ```

  In either case, **Design1** is taken into Maxwell as the first argument, and **Setup1** as the second argument. If you failed to use quotation marks, **Design1** would be taken as the first argument and **Setup1** would not be understood by Maxwell.

-Batchoptions

All options that are specified through **Tools** > **Options** go into the user-level registry. You can override these registry entries via the **-batchoptions** command line. These overrides apply only to the current Desktop session. The registry setting overrides may be specified on the command line, or may be in a file with the file pathname specified on the command line. Batch jobs can be submitted from the command line or through Electronics Desktop's job submission window.

Large Scale DSO offers two new batchoptions related to the redistribution ability.

- `LargeScaleDSO/VarRedistribution`, where 0 disables redistribution (default), and 1 enables it.
- `LargeScaleDSO/RedistributionLimit`, is a positive integer specifying the minimum estimated remaining time (in minutes) for variations to redistribute to another task. The default is 3.

> **Note:**
>
> **-batchoptions** is only valid for batch jobs. It is ignored if you have not specified **-BatchSolve**, **-BatchSave**, or **-BatchExtract**.

-Batchoptions Examples

The batchoption **CreateStartingMesh** is available for all 3D products (HFSS, HFSS-3DLayout, Q3D, Q2D, Maxwell3D and Maxwell2D). When this option is set, only the initial mesh and manual mesh operation making portion of the setup are completed for the batch solve.

This example enables CreateStartingMesh for HFSS, and runs a batch solve on the specified project:

```
ansysedt -batchoptions "'HFSS/CreateStartingMesh'=1" -
batchsolve "D:\projects\MyProject.aedt"
```

See: Additional Examples of -Batchoptions Use.

Export Options Files

The **Tools** > **Options** > **Export Options Files** command writes XML files containing the options settings at all levels to the specified directory. This feature is intended to make it easier for different users to use Ansys Electromagnetics Suite 2023 R1 installed on shared directories or network drives. See: Example Uses for Export Options Features.

Examples and Further Explanations of -batchoptions Use

This section provides examples and further explanations of -batchoptions.

- Example with registry settings specified on the command line
- Example with registry settings specified in a file
- When to use the -batchoptions Desktop command line option

The following examples use general Desktop and Maxwell-specific settings. This feature is available for all desktop products.

- The registry path separator is the slash (/) character.
- Each complete registry key (that is, a registry path and option name) is enclosed in single quotes.
- Registry string values are enclosed in single quotes.
- After the -batchoptions switch, the set of registry keys and values that follows it must be enclosed in double quotes. However, if a batchoptions file is referenced (instead of listing the options directly on the command line), the double quotes are not used around the filename.
- Backslashes in registry key string values must be escaped with another backslash (\\ ), since a backslash by itself is an escape code within strings.

Example with registry settings specified on the command line

```
ansysedt.exe -batchsolve -batchoptions
"'Desktop/Settings/ProjectOptions/NumberOfProcessors'=4
'Maxwell3D/NumCoresPerDistributedTask'=2    (* This option is not
currently available from the Add Batchoption dialog box.)
'Desktop/ProjectDirectory'='C:\\projects\test'" projectname.aedt
```

This command line overrides registry values of the NumberOfProcessors (Desktop/Settings/ProjectOptions key) and ProjectDirectory (Desktop key) options.

> **Note:**
>
> - Multiple registry settings may appear in a single -batchoptions value, separated by whitespace.
> - The -batchoptions value must be enclosed in double quotes if it contains any whitespace.

Example with registry settings specified in a file

```
maxwell.exe -batchsolve -batchoptions filename projectname.aedt
```

where the referenced file, <*filename*> contains:

```
$begin 'Config'
  'Desktop/Settings/ProjectOptions/NumberOfProcessors'=4
  'Maxwell3D/NumCoresPerDistributedTask'=2
  'Desktop/ProjectDirectory'='C:/projects/test'
$end 'Config'
```

This command overrides the registry values of the NumberOfProcessors (Desktop/Settings/ProjectOptions key), UpdateReportsOnSolve (Desktop/Settings/ProjectOptions/Maxwell3D key), and ProjectDirectory (Desktop key) options. These overrides apply only to the current Electronics Desktop session.

> **Note:**
>
> - The -batchoptions ***<filename>*** value must be enclosed in double quotes if it contains whitespace
> - The **$begin 'Config'** and **$end 'Config'** lines are required

For additional options you can override for the command line with -batchoptions, see

- For -batchoptions Use: Project Directory and Lib Paths
- For -batchoptions Use: TempDirectory
- For -batchoptions Use: Various Desktop Settings
- For -batchoptions Use: Maxwell2D and Maxwell3D Options

When to use the -batchoptions Desktop Command Line Option

You can set analysis parameters for batch mode jobs using the graphical user interface (GUI). For example, you can set all options for a batch job using the **Add Batch Option** dialog box, which is accessed through the **Submit Job To** dialog box. These parameter settings include the following solver options (several examples, not a complete list):

- HPCLicenseType
- tempdirectory
- Desktop/AutoExtractReports
- Desktop/Settings/ProjectOptions/MumberOfProcessors
- <*design_type*>/DefaultProcessPriority
- <*design_type*>/EnableGPU – Applicable to Maxwell 3D
- <*design_type*>/MPIVendor (either “Intel” or “Microsoft”) – Applicable to Maxwell 2D and Maxwell 3D

For graphical analyses that do **not** use batch mode, you specify the analysis parameters using the GUI (**Tools** > **Options** > **General Options** or **HPC and Analysis Options**). These settings are written to the registry when you exit the Electronics Desktop program. The settings are read from the registry when the application is started. Therefore, when you start the Electronics Desktop application, all settings retain the values from the previous session of the same user on the same machine. If there was not a previous session of the same user on the same machine, then the values are obtained from other registry configuration files or from a default value.

When running a batch analysis, any setting that is not specified using the **-batchoptions** command line option is taken from the registry. This value is typically the setting from the last session of the same user on the same machine. However, the **-batchoptions** command line option allows you to override the parameter with values specified on the command line or in a batchoptions file. The values specified using the **-batchoptions** command line option only apply to the batch job, and do not affect the parameter values stored in the registry.

If important **-batchoptions** values are not specified when running a batch job, the paramaters could be affected by an interactive session running on the same host by the same user. Parameter changes can occur if the user sets an option in the GUI and then exits the program, or if another process that accesses the registry exits. To be sure of the desired batch job outcome, avoid changing options in concurrent interactive sessions or include the desired -batchoptions in the command line.

For -batchoptions Use: Project Directory and Lib Paths

The PersonalLib, syslib and userlib settings are a little different from other settings. If the final directory name is different from what is expected, then PersonalLib, syslib or userlib is appended as a final directory. In addition, these settings may come from a different registry value if the registry values shown above are not set.

Registry Key	Default Value	Units or Values	Description
Desktop/ProjectDirectory	Ansoft subdirectory of user's HOME directory or "Documents" directory	Directory pathname	Directory where new projects are created
Desktop/PersonalLib	PersonalLib subdirectory of user's HOME directory or	Directory pathname	Directory PersonalLib is appended if final

Registry Key	Default Value	Units or Values	Description
	"Documents" directory		directory is not PersonalLib
Desktop/syslib	syslib subdirectory of installation directory	Directory pathname	Directory syslib is appended if final directory is not syslib
Desktop/userlib	userlib subdirectory of installation directory	Directory pathname	Directory userlib is appended if final directory is not userlib

Running Maxwell from a Command Line

For -batchoptions Use: Various Desktop Settings

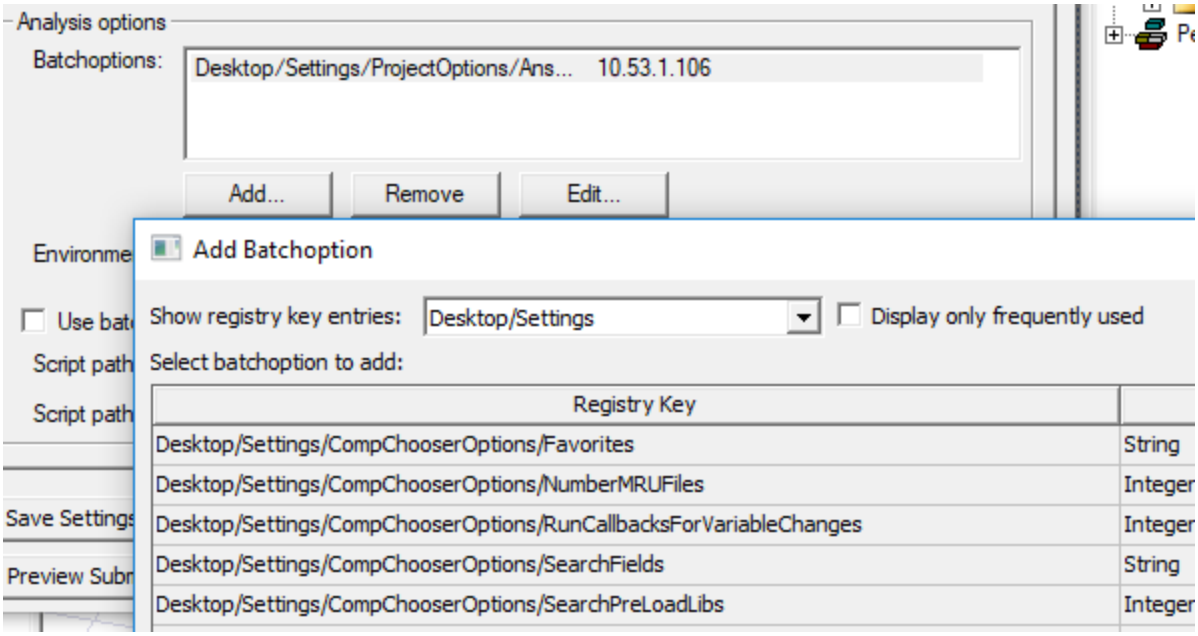
Note that most of these options only affect the GUI. To view these options from the *Submit Job To* window:

1. In the *Analysis options* area of the *Submit Job To* window, click **Add...**.
2. In the *Add Batchoption* window that appears, select **Desktop/Settings** from the **Show registry key entries** drop-down menu.



Registry Key	**Default Value**	**Units or Values**	**Description**
Desktop/Settings/ProjectOptions/AnimationMemory	200	Megabytes (MB)	Stop animations when available memory falls below this value
Desktop/Settings/ProjectOptions/AnsoftCOMPreferredIPAddress (see note below table)	“” (empty string)	IP address (as a string)	IP address used to connect from COM engines to ansysedt.exe

Registry Key	Default Value	Units or Values	Description
Desktop/Settings/ProjectOptions/AnsysEMPreferredSubnetAddress (see note below table)	“” (empty string)	IP address (as a string)	Subnet used to connect COM engines to ansysedt.exe – allowed formats are: • IPv4 network prefix in CIDR notation Example: 123.123.123.0/24 • IPv4 network prefix with /subnet mask appended Example: 123.123.123.0/255.255.255.0
Desktop/Settings/ProjectOptions/AutoSaveInterval	10	edits	Number of edits to allow between autosaves
Desktop/Settings/ProjectOptions/AutoShowMessageWindow	1 (true)	0 (false) or 1 (true)	Show message window on new messages
Desktop/Settings/ProjectOptions/AutoShowProgressWindow	0 (false)	0 (false) or 1 (true)	Show progress window when starting a simulation
Desktop/Settings/ProjectOptions/DiskLimitForAbort	0	Megabytes (MB)	A warning is issued when available disk space falls below this value
Desktop/Settings/ProjectOptions/DoAutoSave	1 (true)	0 (false) or 1 (true)	Enables autosaves if true
Desktop/Settings/ProjectOptions/DrawStateIconsInProjectTree3	1 (true)	0 (false) or 1 (true)	Change icon when selection does not match active window
Desktop/Settings/ProjectOptions/ExpandMessageTreeOnInsert	1 (true)	0 (false) or 1 (true)	Ensure that new messages are visible in the message window tree

Registry Key	Default Value	Units or Values	Description
Desktop/Settings/ProjectOptions/ExpandOnInsert	0 (false)	0 (false) or 1 (true)	Expand project tree on insert
Desktop/Settings/ProjectOptions/HighlightActiveContextInProjectTree2	1 (true)	0 (false) or 1 (true)	Emphasize active command context (menu and toolbars)
Desktop/Settings/ProjectOptions/SavePreviewImagesInProjectFile	1 (true)	0 (false) or 1 (true)	Save preview images in project file
Desktop/Settings/ProjectOptions/UpdateReportOnFileOpen	0 (false)	0 (false) or 1 (true)	Update reports on file open

Note:

The preferredIP address and preferred subnet address settings are mutually exclusive. If both are specified to be non-empty strings, then the preferred IP address takes precedence, and the preferred subnet address is ignored. This feature is typically used for cluster environments using batch solves. The setting can be made via batchoptions but can also be done via UpdateRegistry.

For -batchoptions Use: Maxwell2D and Maxwell3D Options

Running Maxwell from a Command Line

For -batchoptions Use: Maxwell 2D and Maxwell 3D Options

Here are the Maxwell Options with the complete registry keys (that is, the registry paths and option names). You can access a help window with information covering most available design-

type-specific batchoptions using the **-batchoptionhelp** switch when launching Electronics Desktop from a command line:

Registry Key	Default Value	Units or Values	Description
Maxwell 2D (or 3D)/DesiredRAMLimitInGB	0 (No Limit)	GB	Preferred memory use in GB. Type: Floating Point, Min: 0, Max: 1000000.
Maxwell 2D (or 3D)/MaxRAMLimitInGB	0 (No Limit)	GB	This setting specifies the absolute maximum memory usage in GB. Type: Floating Point, Min: 0, Max: 1000000.
Maxwell 2D (or 3D)/HPCLicenseType	"pack"	"pool" or "pack"	For Maxwell 2D Designs: "pool" = multiprocessing enabled by HPC licensing; "pack" = multiprocessing enabled by HPC Pack licensing
Maxwell 2D(or 3D)/DefaultProcessPriority	Normal	Allowed values: "Critical", "Above Normal", "Normal", "Below Normal", "Idle"	Specifies the default priority of distributed tasks.
Maxwell 2D(or 3D)/HPCLicenseType	“pack”	“pool” or “pack” or "none"	Specifies if HPC license is used and which type.
Maxwell 2D(or 3D)/MPIVendor		“Microsoft”, “Intel”.	Which MPI libraries to use for remote communication. Type: String,
Maxwell 2D(or 3D)/MPIVersion	"Default"	"Default", "2018", "2021"	This setting specifies the MPI version. If not specified, then the default version for the MPI vendor will be used. The valid values depend on the MPI vendor. Allowed values: "Default", "2018", "2021"
Maxwell 2D(or 3D)/RemoteSpawnCommand			This setting specifies the command that will be used to launch distributed solver jobs. The value Scheduler is only

Registry Key	Default Value	Units or Values	Description
			valid for jobs running under an LSF or SGE scheduler, and only if the MPI Vendor is Intel. Type: String, Allowed Values: "RSH", "SSH", "Scheduler".
Maxwell 2D(or 3D)/DistribLicense		"DSO", "Solver"	This setting specifies which license feature to use for distributed variations. Type: String
Maxwell 2D(or 3D)/NumCoresPerDistributedTask		Min: 1, Max: 1000	This setting specifies the number of cores that will be used per distributed task when using a machine list provided by the scheduler. Type, Integer.
Maxwell 2D(or 3D/SolveAdaptiveOnly		0 (False), 1 (True).	If true, only the adaptive portion of the setup will be solved. Applies only if a single setup is selected.
Maxwell 2D(or 3D)/CreateStartingMesh		0 (False), 1 (True)	If true, the starting mesh (with mesh operations if applicable) will be created, but none of the setup will be solved. Type: Integer
Maxwell 2D(or 3D)/RAMLimitPercent		Min: 1, Max: 99	This setting specifies the percent of total RAM to be used on each machine for solving. Please be sure to leave sufficient RAM for the operating system and applications. Type: Integer
Maxwell 2D(or 3D)/RAMLimitPerCoreInGB		Min: 0, Max: 10000	This setting specifies the maximum amount of RAM used for each core allocated by the scheduler in GB. This cannot be combined with RAM limit percent and is only valid when solving in a scheduler environment. Type: Floating Point
Maxwell 2D(or 3D)TotalNumOfCores		Min: 1, Max: 1000	This setting specifies the total

Registry Key	Default Value	Units or Values	Description
			number of cores that will be used across all tasks when using machine list provided by the scheduler. Type: Integer
Maxwell 2D(or 3D)/SolveAdaptiveOnly	1	Allowed values: 0 (false), 1 (true)	If true, only the adaptive portion of the setup will be solved. Applies only if a single setup is selected.
Maxwell 2D(or 3D)/CreateStartingMesh	0	Allowed values: 0 (false), 1 (true)	If true, the starting mesh (with mesh operations if applicable) will be created, but none of the setup will be solved. Applies only if a single setup is selected.
Maxwell 2D/RAMLimitPercent		Min: 1, Max: 99	This setting specifies the percent of total RAM to be used on each machine for solving. Please be sure to leave sufficient RAM for the operating system and applications. Type: Integer
Maxwell 2D(or 3D)/RAMLimitPerCoreInGB		Min: 0, Max: 10000	This setting specifies the maximum amount of RAM used for each core allocated by the scheduler in GB. This cannot be combined with RAM limit percent and is only valid when solving in a scheduler environment. Type: Floating Point
Maxwell 2D(or 3D)/DefaultProcessPriority	Normal	"Critical", "Above Normal", "Normal", "Below Normal", "Idle"	Specifies the default priority of distributed tasks.
Maxwell 3D/EnableGPU	0	0 (False), 1 (True).	Allow GPU to be used for eddy current solves. GPU acceleration will be disabled when automatic setting is selected in Analysis

Registry Key	Default Value	Units or Values	Description
			Configuration. Type: Integer

Running Maxwell from a Command Line

Running from a Windows Remote Terminal

When running Maxwell from a remote terminal, there are some performance and behavior issues to consider. These issues are due to the interaction of bandwidth/opengldrivers/remote-terminal-protocol

- Showing axes when interactively drawing objects will slow the performance.
- Remote OpenGL performance will be slower in general. Graphics card and driver quality helps.
- All 3D windows will be closed when you switch from remote PC to a console or from a console to remote. This is to avoid display/opengl instability during the switch.
- Grid will not be turned off while viewing a plot from a remote desktop. The mouse over highlights on 2D plots may appear as not totally overlapping the line color or as thin dotted lines.

Modifying the Model View

Windows HPC Commands

HPC Integration allows you to submit jobs directly using Ansys Electromagnetics command line arguments for batchsolves. The supported HPC software is described in the Ansys Electromagnetics Installation Guide. Ansys Electromagnetics products must be accessible from the same directory on all machines. The Ansys Electromagnetics command line syntax is documented here. You must pass in a -distributed flag as part of the Ansys Electromagnetics command line arguments if you want to run a distributed simulation.

Before running a job you must select **Tools>JobManagement>Select Scheduler** and use the dialog to designate the head node of a cluster. You can then select**Tools>Job Mangement>Submit Job** to submit the batch commands for the job.

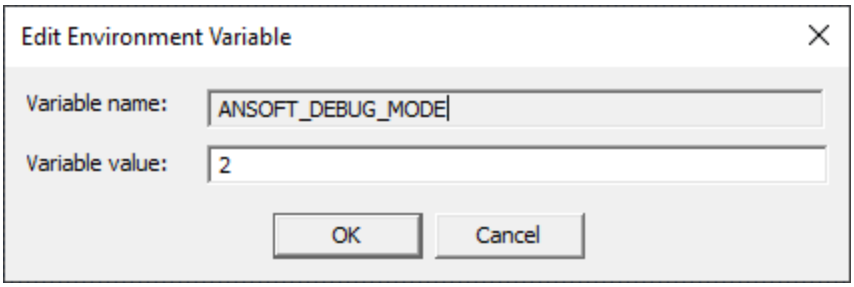
Debug Logging

Electronics Desktop provides error logging capabilities.

To begin logging errors:

1. Click **Tools** > **Debug Logging**.

   The **Edit Environment Variable** window appears, showing the ANSOFT_DEBUG_MODE variable.

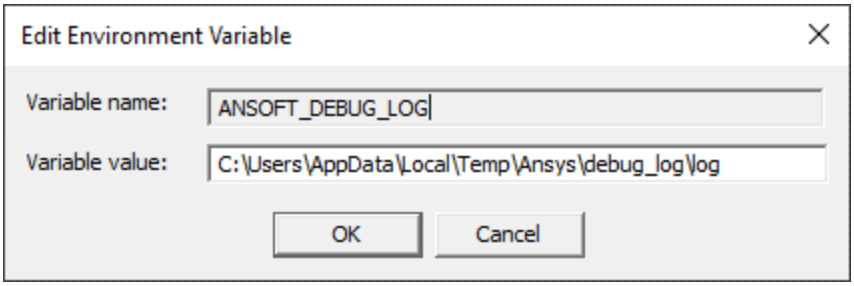


2. Enter a **Variable value**.

   The default value is 2, and should not be changed unless directed by technical support.

3. Click **OK**.

   The **Edit Environment Variable** window updates to display the ANSOFT_DEBUG_LOG variable.



4. Enter a folder path where log files (*.log) will be stored.
5. Click **OK**.

   Errors are logged to the specified folder until you disable logging.

To stop logging errors:

- Click **Tools** > **Stop Debug Logging**.

3 - Help Menu Options

The Help Menu displays different selections depending upon the type of design inserted to the active project (such as Maxwell, HFSS). The following describes the basic selections displayed on the Help Menu.

- **Maxwell Help** opens to the Maxwell help within the Electronics help system. You can also access PDF versions from within the help system.
- **Maxwell Scripting Help** opens to Maxwell's scripting help.
- **Maxwell Getting Started Guides** opens to a list of links to the Maxwell Getting Started Guides. These Getting Started Guides walk you through projects that demonstrate features of the product solvers.
- **Maxwell PDFs**provides access to PDFs for Maxwell, including the main help, scripting guide, and Getting Started Guides.
- **Maxwell Components** is enabled when you insert a Maxwell Circuit design into the active project, and opens the Maxwell Components help to a section that pertains to the component type.
- **Ansys Customer Support** opens a browser page to the Ansys Customer Portal. At the website you can learn more about Ansys products and services and log on to contact Ansys technical support staff.
- **What's New in this Release** opens a PDF that describes *What's New in Ansys Electronics Desktop* for the release.
- **Ansys Product Improvement Program** opens a dialog that describes the Product Improvement Program option.

Note	You can disable the Ansys Product Improvement Program for all users so that each user is not prompted to enable the Program when they first start Electronics Desktop. To do this after installing the software, run the following command as a user with permissions to modify the installed fileset: **UpdateRegistry.exe -set -ProductName ElectronicsDesktop2023.1 -RegistryKey Desktop/Settings/ProjectOptions/ProductImprovementOptStatus -RegistryLevel install -RegistryValue 1**

- **About Ansys Electronics Desktop** opens a dialog that displays the Ansys® Electromagnetics Suite release number and contains tabs that show information about the **Installed Components** and **Client License Settings**.

F1 Context-Sensitive Help

To access **F1** help from the Ansys Electronics Desktop user interface, do one of the following:

- To open a help topic about a menu option, hover the cursor over the item and press F1. You can also press **Shift**+**F1** on the item.
- To open a help topic about a dialog box, open the dialog box, and then press **F1**.

Scripting in Maxwell

Conventions Used in the Help

Please take a moment to review how instructions and other useful information are presented in this documentation.

- Procedures are presented as numbered lists. A single bullet indicates that the procedure has only one step.
- Bold type is used for the following:
  - Keyboard entries that should be typed in their entirety exactly as shown. For example, "**copy file1**" means you must type the word **copy**, then type a space, and then type **file1**.
  - On-screen prompts and messages, names of options and text boxes, and menu commands. Menu commands are often separated by greater than signs (>). For example, "click **HFSS** > **Excitations** > **Assign** > **Wave Port**."
  - Labeled keys on the computer keyboard. For example, "Press **Enter**" means to press the key labeled **Enter**.
- Italic type is used for the following:
  - Emphasis
  - The titles of publications
  - Keyboard entries when a name or a variable must be typed in place of the words in italics. For example, "**copy** *filename*" means you must type the word **copy**, then type a space, and then type the name of the file.
- The plus sign (+) is used between keyboard keys to indicate that you should press the keys at the same time. For example, "Press Shift+F1" means to press the **Shift** key and, while holding it down, press the **F1** key also. You should always depress the modifier key or keys first (for example, Shift, Ctrl, Alt, or Ctrl+Shift), continue to hold it/them down, and then press the last key in the instruction.

Accessing Commands: *Ribbons, menu bars,* and *shortcut menus* are three methods that can be used to see what commands are available in the application.

- The *Ribbon* occupies the rectangular area at the top of the application window and contains multiple tabs. Each tab has relevant commands that are organized, grouped, and labeled. An example of a typical user interaction is as follows:

  "Click **Draw** > **Line**"

  This instruction means that you should click the **Line** command on the **Draw** ribbon tab. An image of the command icon, or a partial view of the ribbon, is often included with the instruction.

- The *menu bar* (located above the ribbon) is a group of the main commands of an application arranged by category such File, Edit, View, Project, etc. An example of a typical user interaction is as follows:

  "On the **File** menu, click the **Open Examples** command" means you can click the **File** menu and then click **Open Examples** to launch the dialog box.
- Another alternative is to use the *shortcut menu* that appears when you click the right-mouse button. An example of a typical user interaction is as follows:

  “Right-click and select **Assign Excitation> Wave Port**” means when you click the right-mouse button with an object face selected, you can execute the excitation commands from the shortcut menu (and the corresponding sub-menus).

Getting Help: Ansys Technical Support

For information about Ansys Technical Support, go to the Ansys corporate Support website, http://www.ansys.com/Support. You can also contact your Ansys account manager in order to obtain this information.

All Ansys software files are ASCII text and can be sent conveniently by e-mail. When reporting difficulties, it is extremely helpful to include very specific information about what steps were taken or what stages the simulation reached, including software files as applicable. This allows more rapid and effective debugging.

Help Menu

To access help from the Help menu, click **Help** and select from the menu:

- **[product name] Help** - opens the contents of the help. This help includes the help for the product and its *Getting Started Guides*.
- **[product name] Scripting Help** - opens the contents of the *Scripting Guide*.
- **[product name] Getting Started Guides** - opens a topic that contains links to Getting Started Guides in the help system.

Context-Sensitive Help

To access help from the user interface, press **F1**. The help specific to the active product (design type) opens.

You can press **F1** while the cursor is pointing at a menu command or while a particular dialog box or dialog box tab is open. In this case, the help page associated with the command or open dialog box is displayed automatically.

Finding Information in the Help

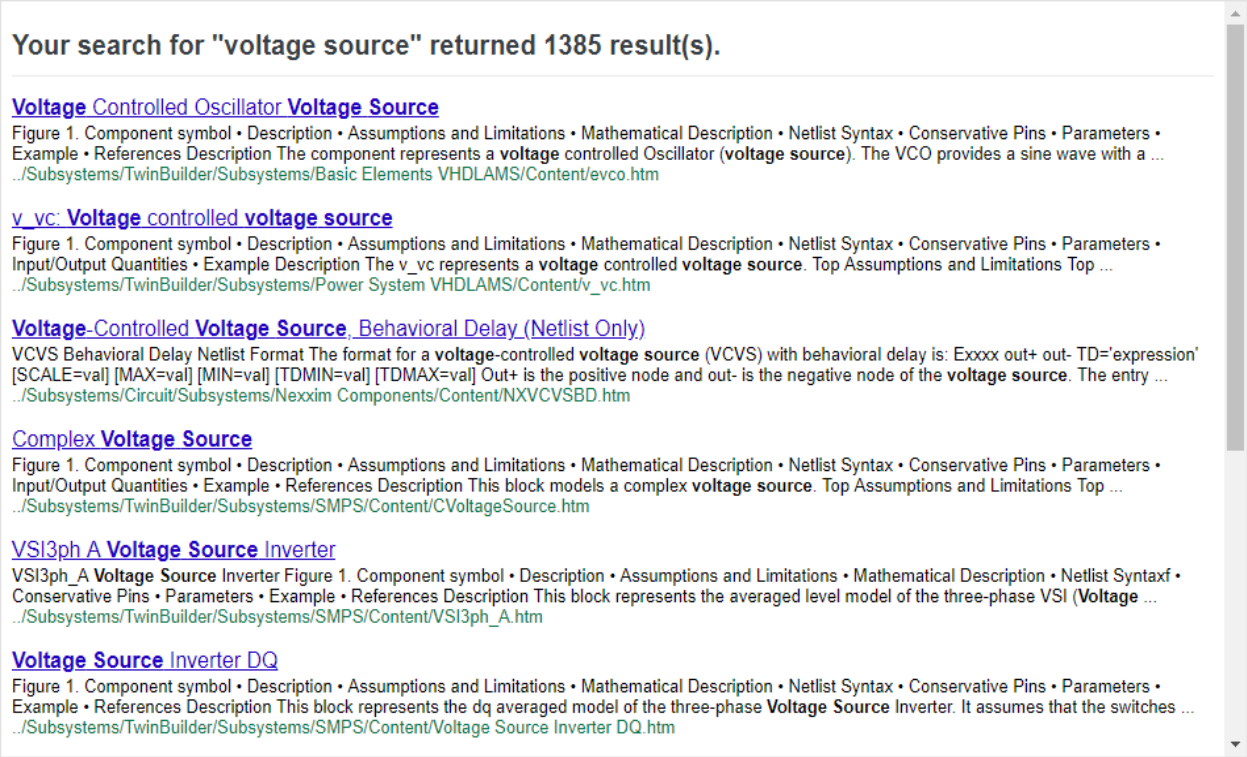
The help system provides four ways to find information and navigate quickly:

- A hierarchical table of contents - To browse through the table of contents, click the **Contents** tab. The table of contents is an expandable list of important topics. You can expand or collapse the list, and then jump to detailed information for a topic by clicking the topic title.

- A full text search - you can type text, and search the entire help. Items are listed according to rank in discussing the search text. For more information, see Using the Search Function in the Help.

Using the Search Function in the Help

When you enter words or strings to search for in the help, the search engine, by default, lists all topics in which any of the words occur. For example, if you enter “voltage source” without the quotation marks, the results show all topics that contain “voltage” or “source.”

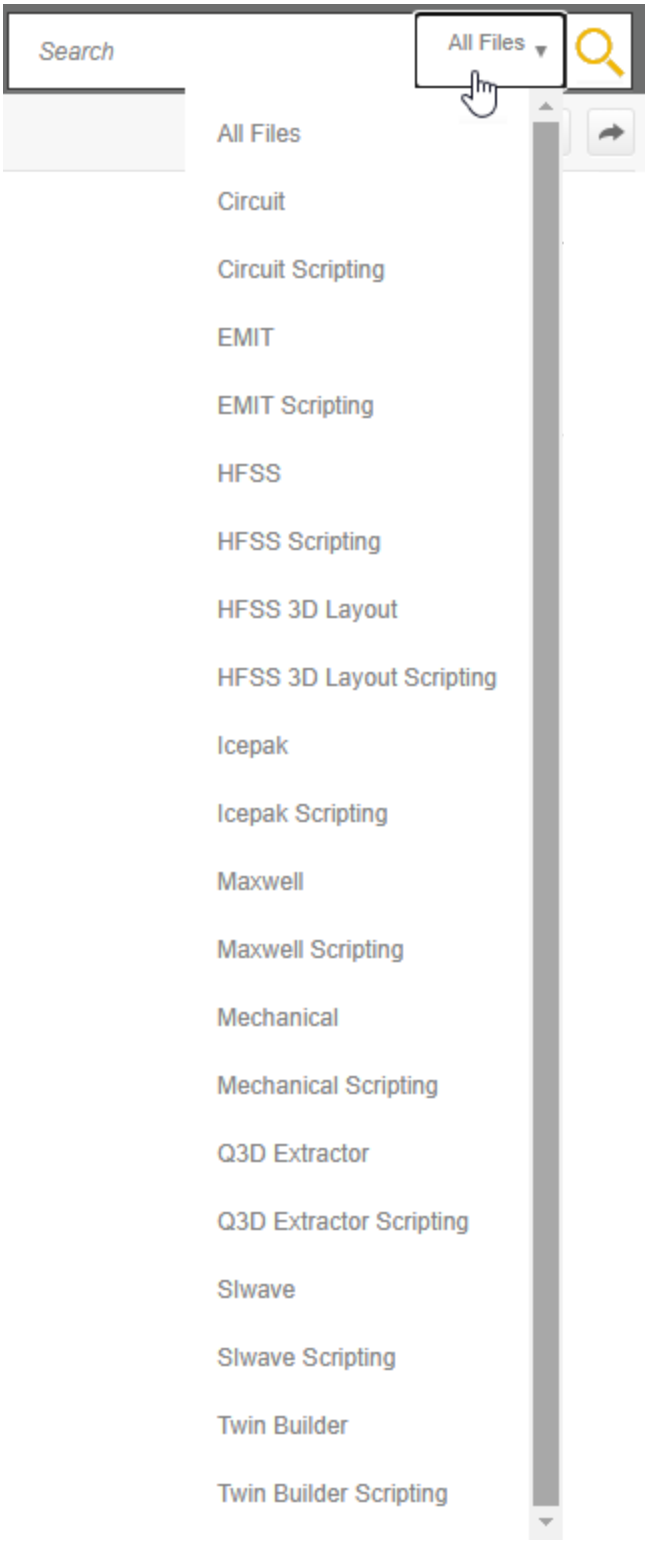


This method probably provides more hits than you want. The Search function in the help provides several methods for making searches more specific.

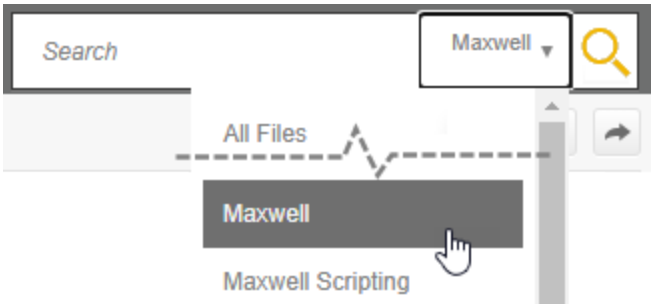
Performing a Basic Search

1. Type the words or string you are searching for in the search box.
    - If you are searching within the full Electronics help system, the search box includes a drop-down filter for specifying a product but not including its scripting guide, specifying a product's scripting guide, or searching across all products. When you

change the filter, the results dynamically reflect the selected filter.



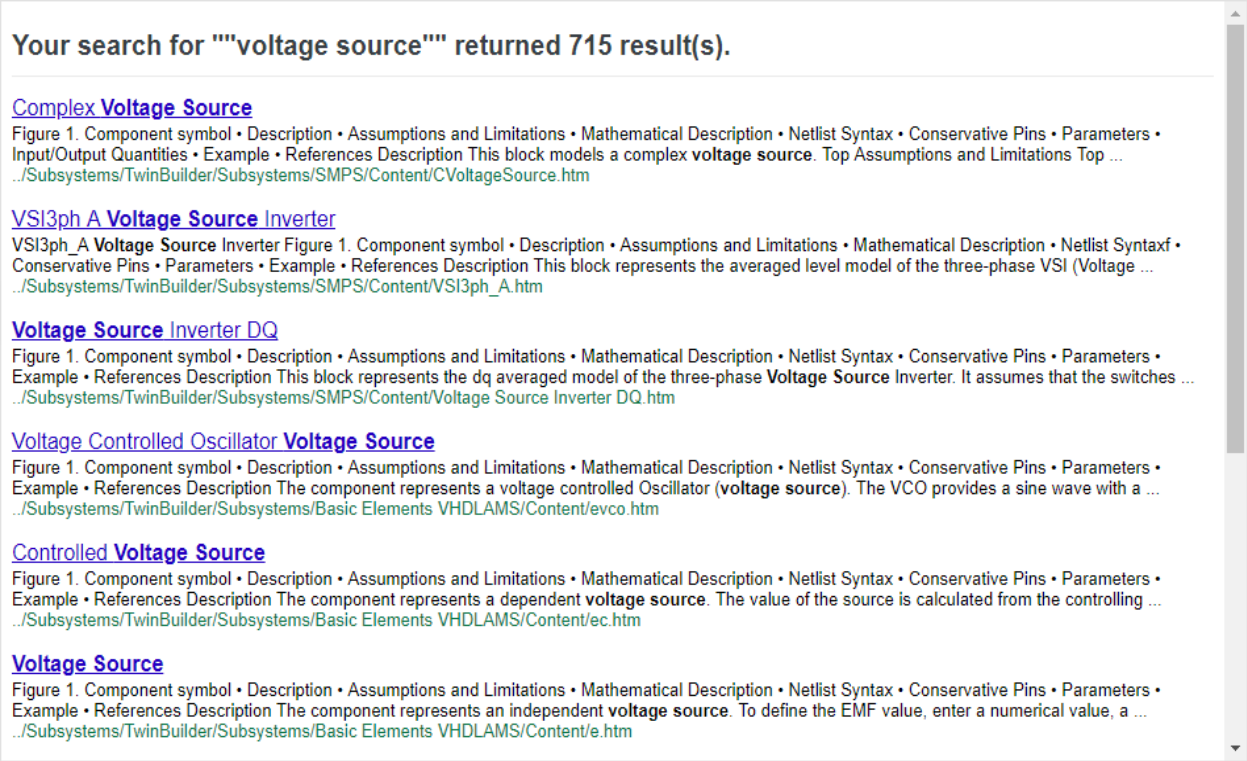
- If you used F1 from Maxwell, you see a search box that permits searches for all files in Maxwell (for example, *All Files*), all files except the Maxwell scripting guide (for example, *Maxwell*), or just files in the *Maxwell* scripting guide (for example, *Maxwell Scripting*).



2. Click on the topic you want in the list results.
   - If you want to view a different topic, press your browser's back button to return to the list results.
   - To turn off highlighting on the page you are viewing, click the Remove Highlights icon

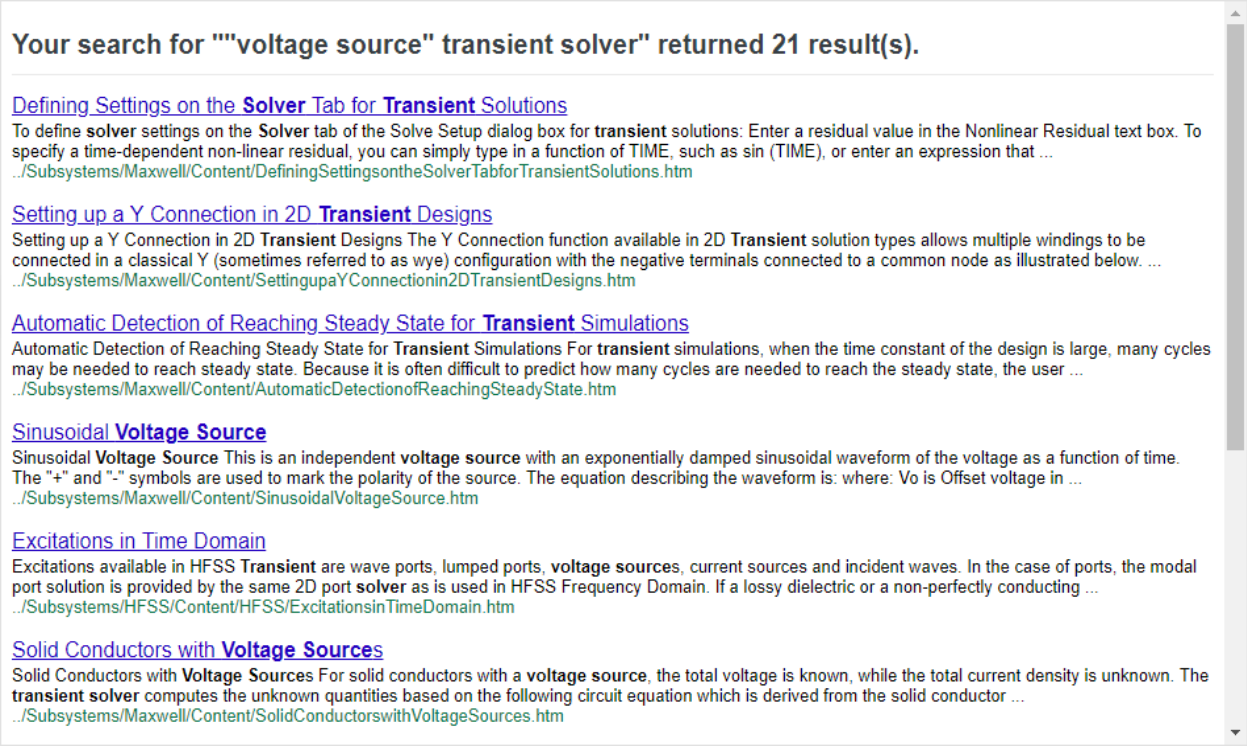
Searching with Quotation Marks

If you enter “voltage source” with quotation marks, the results show all topics that include the phrase.



As you can see, this returns far fewer results than the basic search.

To further limit the results, you can enter additional words, such as: “voltage source” transient solver



Note:

- Searches are not case sensitive, so you can type your search in uppercase or lowercase characters.
- You may search for any combination of letters (a-z) and numbers (0-9).
- Punctuation marks (period, colon, semicolon, comma, hyphen) are ignored during a search.
- When searching for a file name with an extension, group the entire string in quotation marks (for example, "filename.ext").

Using Boolean Operators

You can also use boolean operators to affect the number of topics listed.

Operator (s)	Usage	Example(s)
AND + &	Lists all topics that contain all of the terms.	Net AND Selection Net + Selection Net & Selection
OR |	Lists all topics that contain any of the terms.	Net OR Selection Net | Selection

Operator (s)	Usage	Example(s)
NEAR	Lists all topics that contain the terms near the other terms.	Net NEAR Selection
NOT ! ^	Lists all topics that contain the first term but not the second.	Net NOT Selection Net ! Selection Net ^ Selection

Use parentheses to group terms and operators. For example:

- solver AND (Circuit) NOT HFSS NEAR dynamic
- solver AND (HFSS OR Circuit) NOT (Q3D OR 2d) NEAR dynamic
- “dynamic link” ! (HFSS | circuit)

> **Important:**
>
> Because the characters +, &, |, !, and ^ are used as operators, you cannot search for them in the help. Doing so will result in an error.

The Ansys Product Improvement Program

This product is covered by the Ansys Product Improvement Program, which enables ANSYS, Inc., to collect and analyze anonymous usage data reported by our software without affecting your work or product performance. Analyzing product usage data helps us to understand customer usage trends and patterns, interests, and quality or performance issues. The data enable us to develop or enhance product features that better address your needs.

How to Participate

The program is voluntary. To participate, select **Yes** when the Product Improvement Program dialog appears. Only then will collection of data for this product begin.

How the Program Works

After you agree to participate, the product collects anonymous usage data during each session. When you end the session, the collected data is sent to a secure server accessible only to authorized Ansys employees. After Ansys receives the data, various statistical measures such as distributions, counts, means, medians, modes, etc., are used to understand and analyze the data.

Data We Collect

For all products that offer the Ansys Product Improvement Program, we only collect anonymous data such as session statistics, hardware information, types of loading, solution types, solution statistics, and similar data. The specific data collected varies from product to product.

For Ansys Electronics, we collect the following information:

- Application

    - Build information
    - System information
        - Country
        - Country code
        - CPU architecture
        - CPU brand
        - CPU identifier
        - Graphics card
        - Operating system
        - Operating system version
        - Processor count
        - Time zone
        - Total RAM value
- Session
    - Workbench session
    - Total CPU time
    - Execution mode
    - Start method
    - Number of processes
    - Number of compute nodes (HPC)
    - Session begin
    - Session end
- Mesh
    - Number of nodes
    - Number of elements
    - Number of zones
    - Number of faces

Data We Do Not Collect

The Product Improvement Program does not collect any information that can identify you personally, your company, or your intellectual property. This includes but is not limited to names, addresses, file names, part names, geometry- or design-specific inputs, material property values, etc. We make no record of where we collect data from.

Opting Out of the Program

You may stop your participation in the program any time you wish. To do so, select **Ansys Product Improvement Program** from the Help menu. A dialog appears and asks if you want to continue participating in the program. Select **No** and then click **OK**. Data will no longer be collected or sent.

The ANSYS, Inc., Privacy Policy

All Ansys products are covered by the ANSYS, Inc., Privacy Policy, which you can read here.

Frequently Asked Questions

1. *Am I required to participate in this program?*

   No, your participation is voluntary. We encourage you to participate, however, as it helps us create products that will better meet your future needs.
2. *Am I automatically enrolled in this program?*

   No. You are not enrolled unless you explicitly agree to participate.
3. *Does participating in this program put my intellectual property at risk of being collected or discovered by ANSYS?*

   No. We do not collect any project-specific, company-specific, or model-specific information.
4. *Can I stop participating even after I agree to participate?*

   Yes, you can stop participating at any time. To do so, select **Ansys Product Improvement Program** from the Help menu. A dialog appears and asks if you want to continue participating in the program. Select **No** and then click **OK**. Data will no longer be collected or sent.
5. *Will participation in the program slow the performance of the product?*

   No, the data collection does not affect the product performance in any significant way. The amount of data collected is very small.
6. *How frequently is data collected and sent to Ansys servers?*

   The data is collected during each use session of the product. The collected data is sent to a secure server once per session, when you exit the product.
7. *Is this program available in all Ansys products?*

   Not at this time, although we are adding it to more of our products at each release. The program is available in a product only if this Ansys Product Improvement Program description appears in the product documentation, as it does here for this product.
8. *If I enroll in the program for this product, am I automatically enrolled in the program for the other Ansys products I use on the same machine?*

   Yes. Your enrollment choice applies to all Ansys products you use on the same machine. Similarly, if you end your enrollment in the program for one product, you end your enrollment for all Ansys products on that machine.
9. *How is enrollment in the Product Improvement Program determined if I use Ansys products in a cluster?*

   In a cluster configuration, the Product Improvement Program enrollment is determined by the host machine setting.

Getting Help from Ansys Technical Support

For information about Ansys Technical Support, go to the Ansys corporate Support website, www.ansys.com/Support. You can also contact your Ansys account manager to obtain this information.

E-mail can work well for technical support. All Maxwell software files are ASCII text and can be sent conveniently by e-mail. When reporting difficulties, it is extremely helpful to include very specific information about what steps were taken or what stages the simulation reached. This allows more rapid and effective debugging.

4 - Working with Maxwell Projects and Designs

A Maxwell project is a folder that includes one or more Maxwell models, or *designs*. Each design ultimately includes a geometric model, its boundary conditions and material assignments, and field solution and post-processing information.

A new project called *Projectn* is automatically created when the software is launched, where *n* is a number. If you select the **Insert a design of type** radio button on the Desktop Configuration options panel, a design of the specified type is automatically created for the new project. You can also open a new project by clicking **File>New**. In general, use the **File** menu commands to manage projects. If you move or change the names of files without using these commands, the software may not be able to find information necessary to solve the model.

Maxwell Files

When you create an Ansys Electronics Desktop project, it is given an **.aedt** file extension and stored in the directory you specify. Any files related to that project are also stored in that directory.

Some common file and folder types are listed below:

.aedt	Maxwell project.
project_name. **aedtresults**	Maxwell folder containing results data for a project.
design_name. **results**	Maxwell folder containing results data for a design. This folder is stored in the *project_name.* **aedtresults folder.**
design_name. **asol**	Maxwell results data for a design. This file's contents may be empty if a solution is unavailable. This file is stored in the *project_name.* **aedtresults** folder.
.cls	Ansoft legacy EM projects.

Creating Projects

1. Click **File>New**  .

   A new project is listed in the project tree. It is named Project*n* by default, where *n* is the order in which the project was added to the current session.

   Project definitions, such as material assignments, are stored under the project name in the project tree.

2. Click **Project>Insert Maxwell (2d or 3D) Design**.

You specify the name of the project when you save it using the **File>Save** or **File>Save As** commands.

Note	To insert an RMxprt design, click **Project>Insert RMxprt Design**.

Creating New 2D Designs from 3D Designs

The Maxwell system contains both 2D and 3D projects. Often, you may want to take a cross-section of a 3D model to perform a 2D analysis. The following cases represent the scenarios available for automatically converting models.

- 3D model to 2D XY model
- 3D model to 2D RZ model

You must keep the following points in mind before you convert any project:

- A 2D design is created in the same project.
- All 3D geometry is used, you cannot select which geometry to include in the conversion.
- If there are any sheet objects in 3D, only those sheets that lie in the same plane as the section plane are converted.
- 1D objects are not converted from 3D to 2D.

Related Topics

Converting a 3D Model to 2D

Converting a 3D Model to 2D

To create a 2D design from an existing 3D design:

1. Click **Maxwell3D>Create 2D Design**.
   The **Create 2D Design** dialog box appears.
2. Select the **Coordinate System** to be used for creating sections in the 3D model.
3. Choose the **Section Plane** within the chosen coordinate system. You can choose XY, YZ, or ZX.
4. Select the **Geometry Mode**, to use for the target 2D design. You can choose either XY or RZ.
5. Click **OK** to create the 2D design.

The modeler creates a new design within the current project and generates the 2D model within the new design. All material properties and material assignments are copied to the new design.

Related Topics

Creating a Cross-Section

Creating New 3D Designs from 2D Designs

The Maxwell system contains both 2D and 3D projects. Often, you may want to sweep or rotate a 2D model to create a full 3D design. The following cases represent the scenarios available for automatically converting models from 2D to 3D.

- 2D XY model to 3D model
- 2D RZ model to 3D model

You must keep the following points in mind before you convert any project:

- A 3D design is created in the same project.
- All 2D geometry is used, you cannot select which geometry to include in the conversion.
- 1D objects are converted from 2D into 3D sheet objects.

Related Topics

Converting 2D XY Model to 3D
Converting 2D RZ Model to 3D

Converting 2D XY Model to 3D

To create a 3D design from an existing 2D XY design:

1. Click **Maxwell2D>Create 3D Design**.
   The **Sweep Along Vector** dialog box appears.
2. Enter a value in the **Length along z-axis** box to obtain a swept length of the model.
3. Choose the desired **Dimension** of the sweep distance entered from the pull-down menu.
4. Click **OK** to create the 3D design.

The modeler creates a new design within the current project and generates the 3D model within the new design. All material properties and material assignments are copied to the new design.

Related Topics

Sweeping Along a Vector

Converting 2D RZ Model to 3D

To create a 3D design from an existing 2D RZ design:

1. Click **Maxwell2D>Create 3D Design**.
   The **Sweep Around Z Axis** dialog box appears.
2. Enter the **Angle of Sweep** to obtain a full 360° 3D-model or a wedge model to a selectable degree.
3. Enter the desired **Draft Angle** and **Draft Type**.

Note	Entering a draft angle for a model where objects touch the z axis results in a error

	due to an invalid object being requested. Draft angles may only be used when no objects are touching the z axis.

4. Enter the **Number of Segments** to use in creating the 3D model. If you do not change the default value (=0), the project will be created with true surfaces.
5. Click **OK** to create the 3D design.

The modeler creates a new design within the current project and generates the 3D model within the new design. All material properties and material assignments are copied to the new design.

Sweeping Around an Axis

Opening Projects

Open a previously saved project using the **File>Open** command.

1. Click **File**>**Open**.

   The **Open** dialog box appears.
2. Use the file browser to find the Maxwell project file.

   By default, Maxwell files are displayed. To see other files, change the file filter in the **Files of type** pull-down list.
3. Select the file you want to open.
4. Click **OK**.

   The project information appears in the project tree.

   If you open another project without editing the automatically-created project, Maxwell removes the automatically-created project.

You can also open a saved project by:

- Dragging a Maxwell project file icon to the Maxwell icon.
- Dragging a Maxwell project file icon to the Maxwell desktop.
- Double-clicking on a Maxwell project file icon.

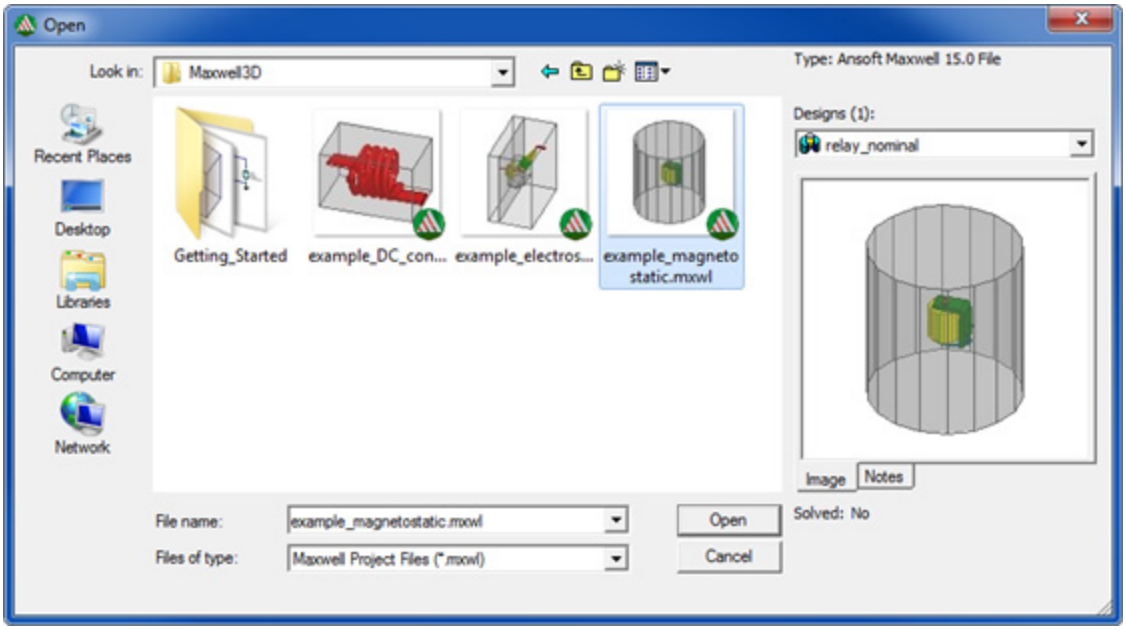
Opening Legacy Maxwell Projects

Opening Example Projects

Opening Example Projects

You can directly access and open example projects included with product install by using **File>Open Examples**. This displays a browser open to the Examples folder in the product install. You can select from various display styles for the folders and projects.



The help contains additional descriptions of these projects.

Related Topics

Example Projects

Opening Recent Projects

To open a project you recently saved in Maxwell:

- Click the name of the project file at the bottom of the **File** menu.

Note	If you open another project without editing the automatically-created project, Maxwell removes the automatically-created project.

Opening Legacy Maxwell Projects

Legacy Project Translation Considerations

When you open a legacy project, virtually all of the project's pre-processing data is translated. Solution results and Optimetrics setup data are unavailable; however, the nominal model created for Optimetrics is translated.

Objects that were considered non-model in the legacy project (**Model Object** check box was cleared in the Properties dialog) are translated but remain non-model objects in the translated project.

Following are additional notes about the translation of legacy project information:

Model Geometry	• The translated geometry's construction history is unavailable; therefore, the original object properties you defined cannot be modified in the **Properties** window. However, you can modify the geometry using Maxwell's modeling features. • For units unavailable in the older version, such as yards, the nearest available units are used; the model will be scaled slightly to fit the new units..
Excitations and Boundaries	• Boundaries assigned to named interface selections or rectangle selections are not translated. • For a boundary assigned to the intersection of two faces, Maxwell will create a new 2D sheet object from the intersecting area and assign the boundary to that object.
Materials	• Functions defined in legacy projects become project variables; therefore, functional material properties and functional material assignment angles are *not* translated. • Perfect conductors become regular materials with conductivity values of 1E30. Maxwell uses a conductivity threshold that treats all conductors over the threshold as perfect conductors. • Object coordinate systems are created for objects assigned anisotropic materials in legacy projects. The coordinate system is defined at the same origin as the global coordinate system, with the same orientation defined when the anisotropic material was assigned to the object in the legacy project. • Nonlinear materials from legacy projects that have magnetic saturation values greater than zero are treated as ferrite materials. Their properties are not modified. • When translating a legacy project, Maxwell does not import any variables that depend on intrinsic variables. For material properties depending on intrinsic variables, the variable reference is replaced with its expanded expression.
Mesh	• Mesh refinement operations performed on arbitrary boxes in legacy projects are ignored. • Area-based and volume-based mesh operations are translated as length-based mesh operations by taking their square roots and cube roots, respectively.
Optimetrics	• Setup information, including design variables, is not supported; however, the nominal model can be translated. • Parameterizing a translated model is limited because geometry construction history is unavailable.
Solution Setup	• The design's initial mesh is used for the solution. Meshes are not translated.
Solutions	• Solution data is not translated; therefore, you must solve legacy projects again.

Saving Projects

Use the **File>Save As** command to do the following:

- Save a new project.
- Save the active project with a different name or in a different location.

Use the **File>Save** command to save the active project.

Maxwell has a "Save before solving" setting located in the **Tools>Options>Maxwell** *(3D, or 2D)* **Options** or **Tools/Options/RMxprt Options** menu. By default this is on. However, for efficiency reasons, the project is only saved if it has been modified since its last save.

A prompt appears when you attempt to save a previously versioned file. If you agree to the prompt, the file is upgraded to the Maxwell version in which you are running the software. In this case the file may no longer be compatible with previous versions. If you do not agree to the prompt, the file is not saved, so the file retains the previous compatibility.

If you have a simulation running, you see a warning that if you continue, Maxwell will abort the simulation. If you OK the warning, Maxwell aborts the simulation and saves the project.

Path Name Length Issues for Windows

For most Windows programs, the current directory pathname length is limited to 259 characters on startup. Thus, the pathname length of the directory containing installed programs should be limited to no more than 259 characters because double-clicking on an application in Windows Explorer will set the working directory to the directory containing the application when the application is started.

Win32 Long Paths Not Enabled

If win32 long paths are not enabled on the analysis host, then essentially all files are limited to a maximum absolute pathname length of 259 characters. Directories may be limited to a maximum absolute pathname length of about 246 characters.

Win32 Long Paths Are Enabled

If win32 long paths are enabled on the analysis host, then many files are not subject to the maximum absolute pathname length limit of 259 characters. Here is a partial list of files that are still subject to this limit even if win32 Long Paths are enabled:

- Project Files.
- Project Archive Files.
- Ansys EDB (Electronics DataBase) files: These files are typically stored in the `ProjectName.aedb` folder.
- The temporary directory and most temporary files. Because some of the temporary files and temporary directories have automatically generated names that may be moderately long, it is **best to use a short pathname for the temporary directory**.
- Although most temporary files are created within the temporary directory, there may be some temporary files created within the project directory that are limited to a maximum absolute pathname length of 259 characters. As a result, the **project file directory pathname should be well below this limit**.

To enable Long Path support on Windows, both of the following requirements must be met:

- The application manifest must have the longPathAware setting specified as true, and
- Long paths must be enabled on the machine: There are two ways to do this; either may be used:

  Registry setting: `HKLM\SYSTEM\CurrentControlSet\Control\FileSystem : LongPathsEnabled=1`

  Via Group Policy Tool: The “Enable Win32 long paths” setting is in the folder: `Computer Configuration > Administrative Templates > System > Filesystem`

Saving a New Project
Saving the Active Project
Saving a Copy of a Project

Renaming a Project

To rename an existing, active project:

1. Select the project in the Project tree.
2. Right-click to display the short-cut menu.

3. Select **Rename**.

   This activates the text field for the project name.

4. Type the new project name and press enter.

   The new project name appears in the directory and the project remains in the original location.

Saving Project Data Automatically

Maxwell stores recent actions you performed on the active project in an Ansys Electronics Desktop auto-save file in case of a sudden workstation crash or other unexpected problem. The auto-save file is stored in the same directory as the project file and is named Project*n*.aedt .auto by default, where *n* is the order in which the project was added to the current session. After you have done a **Save As**, the autosave file name is <*name*>.aedt.auto, where <*name*> is the name you gave the project when saving.

Ansys Electronics Desktop automatically saves all data for the project to the auto-save file, except solution data. By default, Ansys Electronics Desktop automatically saves project data after every ten edits. An "edit" is any action you perform that changes data in the project or the design, including actions associated with project management, model creation, and solution analysis.

With auto-save activated, after a problem occurs, you can choose to re-open the original project file (Project*n*.aedt) in an effort to recover the solution data or to open the auto-save file. If a crash recovery file contains 0 bytes, the other file is opened instead.

To modify the auto-save settings:

1. Click **Tools>Options>General Options**.

   The **Options** dialog box appears.

2. Under the **General>Desktop Configuration** tab, verify that **Do Autosave** is selected.

   This option is selected by default.

3. In the **Autosave interval** box, enter the number of *edits* that you want to occur between automatic saves. By default, this option is set at 10.

Note	Auto-save *always* increments forward; therefore, even when you undo a command, Ansys Electronics Desktop counts it as an edit.

4. Click **OK** to apply the specified auto-save settings.

   Once the specified number of edits is carried out, a "model-only" save will occur. This means that Ansys Electronics Desktop does not save solutions data or clear any undo/redo history.

   When Ansys Electronics Desktop auto-saves, an ".auto" extension is appended to the original project file name. For example, "Project1.aedt " is automatically saved as "Project1.aedt .auto".

Warning	When you close or rename a project, Ansys Electronics Desktop deletes the auto-save file. Ansys Electronics Desktop assumes that you have saved any desired changes at this point.

Recovering Project Data in an Auto-Save File

Save Before Solving Option

The **Tools>Options>Maxwell 3D Options**, **Tools>Options>Maxwell 2D Options** or **Tools/Options/RMxprt Options** commands each display a dialog with a check box for an automatic **Save before solving** option. The main purpose is to force a full save before running the solve.

In the case where you start a solve while another solve is running, and the **Save before solving** option is set, Maxwell asks if you want solve without saving first. This lets you do multiple solves, and if you have not edited the project in between solves, crash recovery will work. In any case, you can start a new solve while running another without having to abort the running solve.

Recovering Project Data in an Auto-Save File

Following a sudden workstation crash or other unexpected problem, you can recover the project data in its auto-save file.

Warning	When you recover a project's auto-save file you *cannot* recover any solutions data; recovering an auto-save file means you will lose any solutions data that existed in the original project file.

To recover project data in an auto-save file:

1. If Ansys Electronics Desktop has crashed, launch Ansys Electronics Desktop from your desktop.
2. Click **File>Open**.
3. Select the original Project*n*.aedt project file for which you want to recover its Project*n*.aedt .auto auto-save file.

   The **Crash Recovery** dialog box appears, giving you the option to open the original project file or the auto-save file.
4. Select **Open project using autosave file to recover project data in the auto-save file, and then click OK.** Maxwell replaces the original project file with the data in the auto-save file.

   Ansys Electronics Desktop immediately overwrites the original project file data with the auto-save file data, removing the results directory (solutions data) from the original project file as it overwrites to the auto-save file.

Warning	If you choose to recover the auto-save file, you cannot recover the original project file that has been overwritten; recovering data in an auto-save file is *not* reversible.

Related Topics

Saving Project Data Automatically

Saving a Project From a Previous Version

When you open a Maxwell project from a version earlier than version 11, Maxwell creates a new project. The v10 or earlier project is not modified.

Archiving Projects

Use the **File>Archive...** command to “bundle” a project – and any other files related to the project that you want to include – in an **.mxwlz** file or **.zip** format archive. You can include notes about the contents of the archive and specify whether to include results and solution files, or related external files. The Archive command attempts to automatically detect the necessary files for linked projects and automatically include them in the archive. For example, if a project linked to the main project also has linked or associated files, you can add them.

Archive File Types

Internally, project archive files are .zip files, and are compatible with any program that can read .zip files (e.g. WinZip, 7Zip). The naming convention is that project archive files will have an extension that is unique for each product. The extension is generated by adding a 'z' to the project file extension (e.g..hfssz, .mxwlz). This extension will be displayed as the default when saving and restoring archive files. Note that .zip files are also included as a possible filter in file selection dialogs.

File Relocation Considerations

In a project to be archived, external files can be located anywhere on the user's system. One of the goals is for the restored project to be relatively self contained, and NOT to allow the restoration of an archived project to haphazardly write files anywhere on the restoring user's system.

To achieve this, it is sometimes necessary to change the location of files in the archived project such that the external files are now located in the project directory. At archive time, any external files not located in the project directory are relocated to the **restored_files** subdirectory of the project directory in the archived project. Any external files located in the user library or system library will be relocated to the personal library directory. Note that the project file that is written into the archive will be updated to refer to the files at the new locations, and the original project file will remain unaltered.

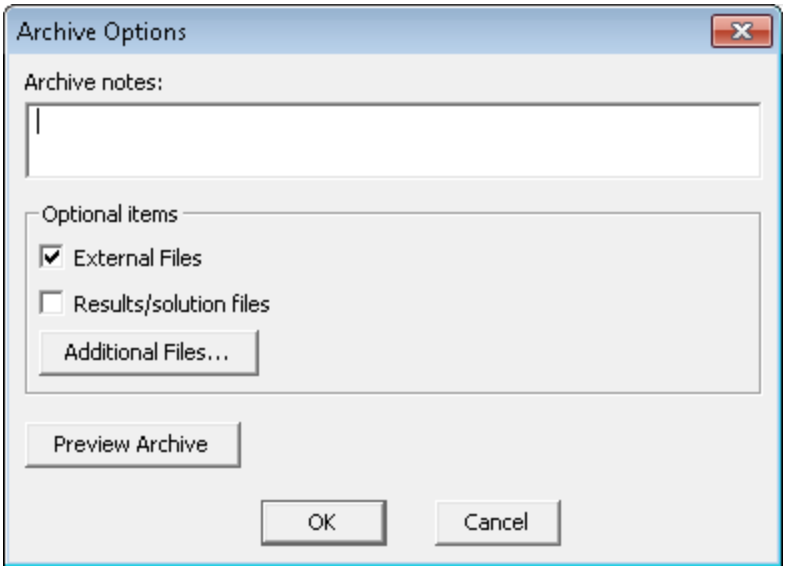
Archive Preview

The Archive command includes a preview feature that lets you review the contents of a planned archive.

To archive the current project:

1. Click **File>Archive...**

   The **Archive Options** dialog opens.

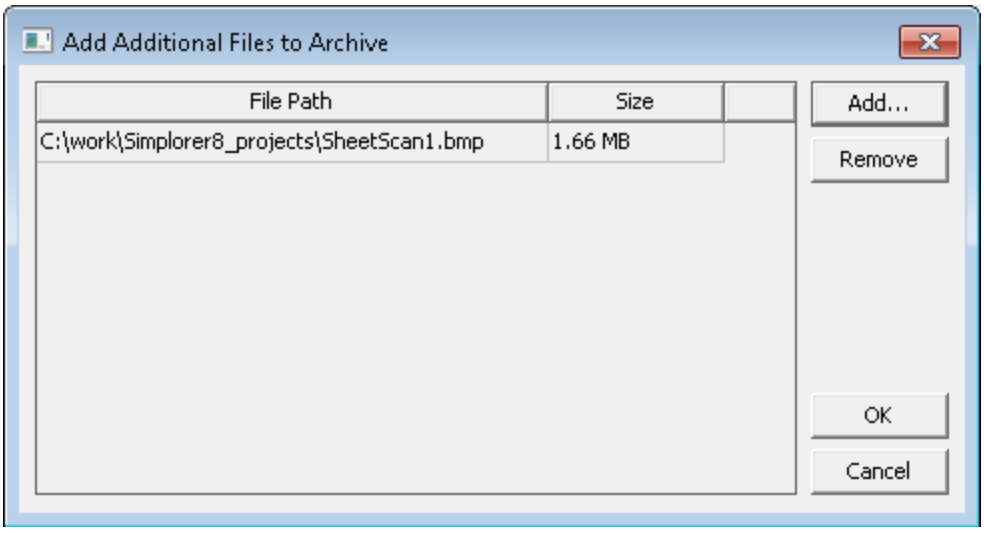


Archive notes: you can specify notes that will be visible when previewing the archive. These notes can be viewed from the preview dialog without actually restoring the archive.

External Files: selecting this check box will cause all external files to be included in the archive. The External Files check box refers to any existing files associated with the project, such as linked files, or files added through the **Project>Insert Documentation File** command or **Project>Data Set command**.

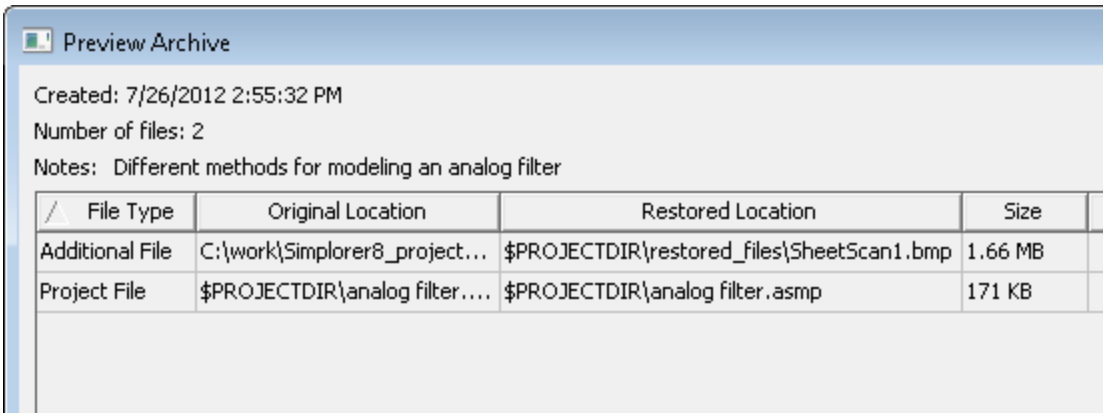
Results/solution files: selecting this check box will cause the entire results directory to be included in the archive. This may greatly increase the size of the archive file.

Clicking **Additional Files...** opens the **Add Additional Files to Archive** dialog.

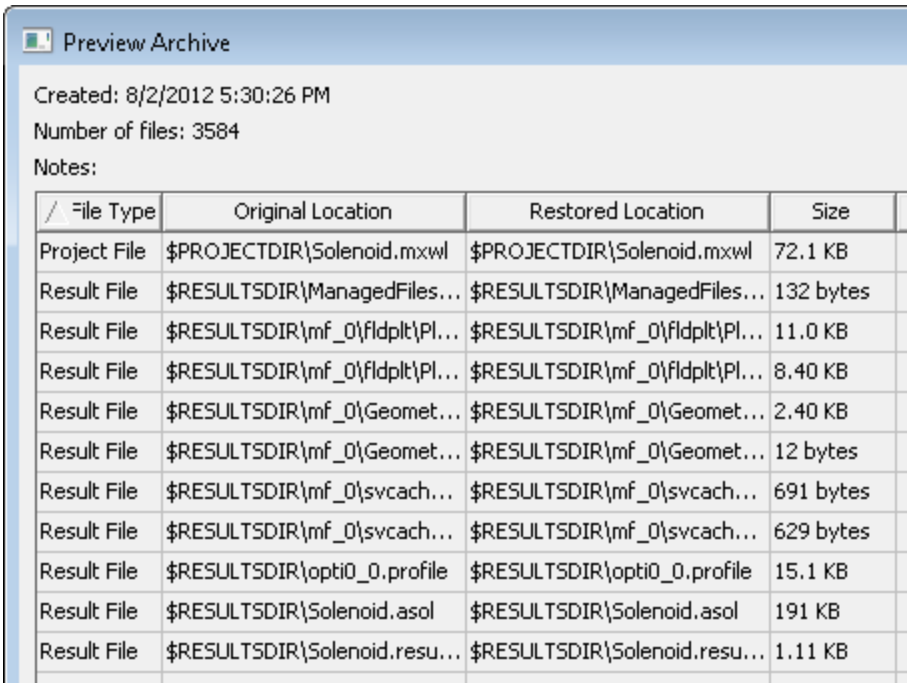


Here, you can click **Add...** to open a file browser to locate any additional files (such as documentation files or datasets) you want to include in the archive. You can also select and then **Remove** any files listed, and **OK** or **Cancel** any proposed changes.

2. Select any optional items, and make any desired archive notes in the text field.
3. When you have made your selections for optional items, you can select **Preview Archive** to look at the archive contexts, and the locations where restoring from the archive would place them.



Check the **Results/solution** option if you want to archive those files. Below is a preview showing some included results files.



To read longer locations, you can drag the column headers to expand the columns. Use the scroll bar to view longer lists.

Previewing an archive before creating the archive can be helpful in order to see exactly what files will be included in an archive, as well as how those files are being relocated. Another purpose of previewing an archive is to view warnings and consider if any additional files need to be added to the archive.

The preview dialog also displays the archive notes, creation date, and the number of included files.

4. When you are ready to create the archive, close the preview, and specify the format you want to use, **.mxwlz** or **.zip**, and specify the archive location and name. Click **OK** to create the archive.

Restoring Archives

Restoring Archives

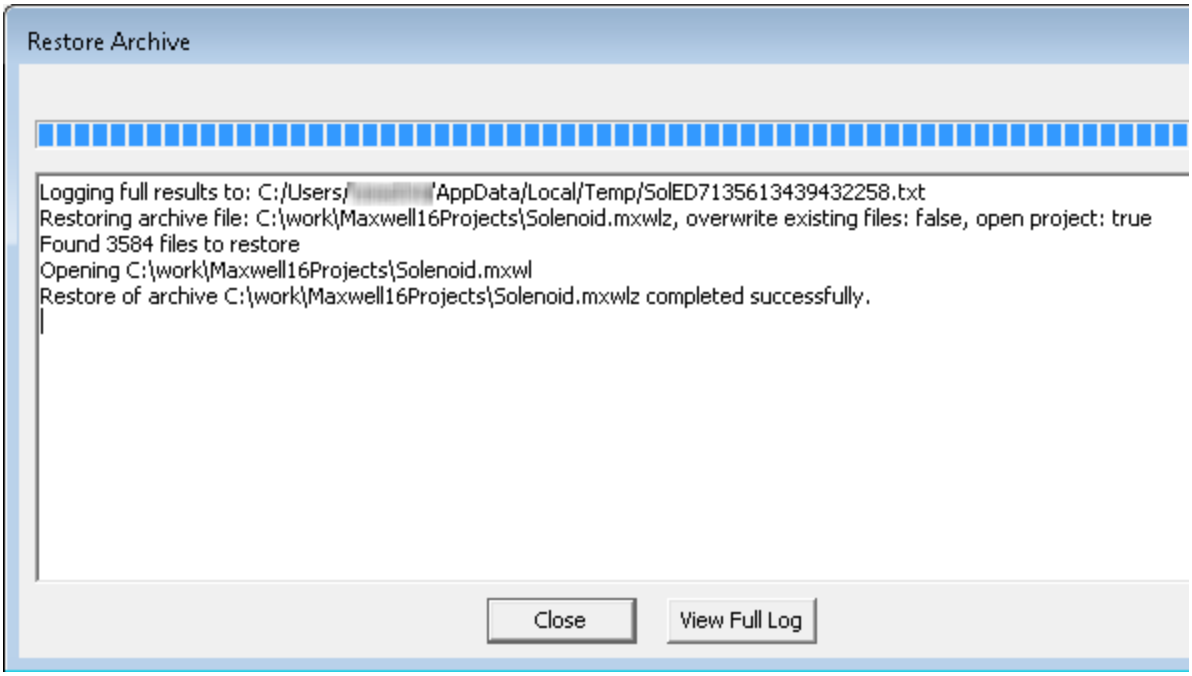
To restore an existing archive created with **File>Archive**:

1. Click **File>Restore Archive**

   This displays an **Archive to Restore** browser window that lets you navigate your file system for archive files of type **.mxwlz** or **.zip**.
2. After selecting a valid archive file, you can click **View Archive** to preview the contents.

   The preview dialog shows the same warnings that were generated at archive time. These warnings may be useful to identify additional steps that are needed to update any files to refer to files which had to be manually added to the archive.
3. Click **Open** to display a **Project File Restore Location** browser and navigate to the place where you want to restore the file.

   You can edit the file name, and check options to **Overwrite existing files** and to **Open project after restoring**.
4. Click **Save** to restore the archived file. A dialog displays progress and results of the restoration process.



A full log file is also generated which contains detailed information about the restore process. The first line in the text window displays the location of the full log file. After the restore has been completed, you can click **View Full Log** to display a detailed log of the restoration.

Archiving Projects

Closing a Project

To close a Maxwell or RMxprt project:

- Click **File>Close**.

If the project has not been saved since the last change, a message appears asking if you want to save the project before closing it. Do one of the following:

- Click **Yes** to save the project.
- Click **No** to close the project *WITHOUT* saving it.
- Click **Cancel** to keep the project open.

Deleting Projects

To delete a project:

1. Select the project in the project tree.
2. Click either **Edit>Delete**, or right click to display the short-cut menu and select **Delete**.

   A dialog displays the message: "The project selected and all its files will be deleted from the permanent storage medium. Click OK to proceed."
3. Click **OK** to delete the files or **Cancel** to retain them.

Exiting Maxwell and RMxprt

To exit the Maxwell and RMxprt interfaces:

- Click **File>Exit**.

Undoing Commands

Use the **Undo** command on the **Edit** menu to cancel, or undo, the last action you performed on the active project or design. This is useful for undoing unintended commands related to project management, model creation, and post-processing.

1. In the **Project Manager** window, do one of the following:
   - To undo the last action you performed on the *active project*, such as inserting a design or adding project variables, click the project icon.
   - To undo the last action you performed on the *active design*, such as drawing an object or deleting a field overlay plot, click the design icon.

Note	You cannot undo an analysis that you have performed on a model, that is, the **Maxwell>Analyze** command.
2. Click **Edit> Undo**, or click the **Undo** icon on the ribbons.

   Your last action is now undone.

Note	When you save a project, Maxwell always clears the entire undo/redo history for the project and its designs.

Related Topics

Redoing Commands

Redoing Commands

Use the **Redo** command on the **Edit** menu to reapply, or redo, the last action that was canceled, or undone. You can redo a canceled action related to project management, model creation, and post-processing.

1. In the **Project Manager** window, do one of the following:
   - To redo the last action you canceled on the *active project*, such as inserting a design or adding project variables, click the project icon.

- To redo the last action you canceled on the *active design*, such as drawing an object or deleting a field overlay plot, click the design icon.

2. Click **Edit>Redo**, or click the **Redo** icon on the ribbons.

   Your last canceled action is now reapplied.

Note	When you save a project, Maxwell always clears the entire undo/redo history for the project and its designs.

Undoing Commands

Removing Unused Components from a Project

To remove unused components from a project:

1. Click **Tools>Project Tools>Remove Unused Definitions**.

   The **Unused Definitions** dialog box appears.
2. Select the **Delete** check box for any components you want to remove.
   - You can also click the **Select All** button to select all components listed.
3. Click **Apply**.

   A warning message appears, telling you that the undo/redo history will be cleared for the project.
4. Click **OK** to continue, or click **Cancel** to cancel the deletion.
5. When you are finished removing components, click **OK** to close the **Unused Definitions** dialog box.

Updating Design Components

To update components defined in the current design:

1. Click **Tools>Project Tools>Update Definitions**.

   The **Update Definitions** dialog box appears.
2. Select one of the following two radio buttons.
   - Show Items with newer definitions
   - Show All Items
3. From the **Show Types** list in the **List Options** section, select the types of definitions you want to show in the **Item List** list.
4. Select the item you want to update from the **Item List** list.
5. Click the **Select All** or **Unselect All** buttons to select or clear all items listed.
6. Click **Update**.

   A message appears telling you the update was successful. Click **OK** to close the message.
7. When you are finished updating definitions, click **Close**.

Managing Projects and Designs

Copy and Paste a Project or Design

To **copy** a project or design:

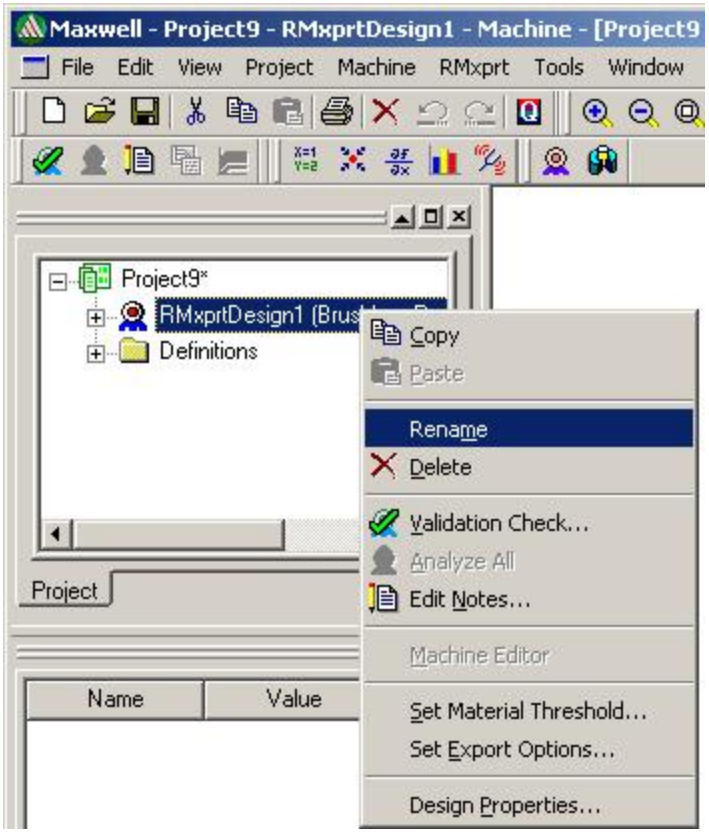
1. Select a project or design in the project tree in Project Manage Window to enable the menu command **Edit>Copy**.
2. Click **Edit>Copy**. The project or design is copied for pasting.

To **paste** a project or design:

1. Select a project or design in the project tree in Project Manage Window to enable the menu command **Edit>Paste**.
2. Click **Edit>Paste**. The project or design is pasted under the selected project, an icon is added to the project tree.

Rename a Project or Design

1. Right click the design icon to display the shortcut menu, as shown.



2. Click **Rename** in the shortcut menu.

3. Define the new name for the design by typing it directly into the Project Window.
4. Press **Enter** to complete the rename.

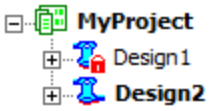
Delete a Project or Design

1. Select a project or design in the project tree in Project Manage Window to enable the menu command **Edit>Delete**.
2. Click **Edit>Delete**, or the **Delete** key.
3. Confirm the warning box to complete the delete operation, the icon is removed from the project tree.

Setting Read Only Designs

Designs can be set as either Read Only or Full Access. Full Access is the default status of a design and allows you to modify the design. In Read Only mode, you may only run the design or link it to another design. Setting a design as Read Only protects it from accidental modification.

Read Only designs are marked with a red lock in the Project Manager:



To change a single design's designation:

1. In the **Project Manager**, right-click the design.
2. Select either **Convert to Read Only** or **Convert to Full Access**.

To change the designation of *every design* in a project:

1. In the **Project Manager**, right-click the project.
2. Select either **Convert All Designs to Read Only** or **Convert All Designs to Full Access**.

> **Note:**
>
> Read Only settings are not saved when you save the project file.

Validating Designs

Before you run an analysis on a model, it is very important that you first perform a validation check on the design. When you perform a validation check on a design, Maxwell runs a check on all setup details of the active design to verify that the necessary steps have been completed and their parameters are reasonable.

To perform a validation check on the active design:

1. Click **Maxwell3D** or **Maxwell2D,** and then select **Validation Check**. You can also click the **Validate** button on the **Simulation** ribbon.

Maxwell checks the project setup, and then the **Validation Check** window appears.

2. View the results of the validation check in the **Validation Check** window.

   The following icons can appear next to an item:

	Indicates the step is complete.
	Indicates the step is incomplete.
	Indicates the step may require your attention.

3. View any messages in the **Message Manager** window.
4. If the validation check indicates that a step in your design is incomplete or incorrect, carefully review the setup details for that particular step and revise them as necessary.
5. Run a validation check after you have revised any setup details for an incomplete or incorrect design step**.**
6. Click **Close**.

Exporting 2D Modeler Files

When you export a 2D Modeler file, the geometry located within the xy plane is exported. You can choose to export only the selected parts of the geometry, or all of the parts.

Note	If you want to export a plane that does not coincide with the global xy plane, you must create a relative coordinate system to redefine the location of the origin and xy plane. See *Creating a Relative Coordinate System* for more information.

To export a file:

1. Click **Modeler**>**Export** .
   The **Export File** dialog box appears.
2. Use the file browser to find the directory where you want to save the file.
3. Type the name of the file in the **File name** box.
4. Select the desired model export format from the **Save as type** pull-down list.
5. Click **Save**. The file is exported to the specified location.

Related Topics

Exporting 2D AutoCAD Drawing Interchange Format Files
Exporting 3D Model Files

Exporting 2D AutoCAD Drawing Interchange Format Files

When you export a file in the AutoCAD Drawing Interchange Format (**.dxf**), the 2D geometry located within the xy plane on the working coordinate system is exported. You can choose to export only the selected parts of the geometry, or all of the parts.

Note	If you want to export a plane that does not coincide with the global xy plane, you must create a relative coordinate system to redefine the location of the origin. See *Creating a Relative Coordinate System* for more information.

To export a file to a **.dxf** format:

1. Click **Modeler**>**Export**.
   The **Export File** dialog box appears.
2. Use the file browser to find the directory where you want to save the file.
3. Type the name of the file in the **File name** box.
4. Select **AutoCAD DXF Files(*.dxf)** from the **Save as type** pull-down list.
5. Click **Save**. The file is exported to the specified location as a **.dxf** file.

Related Topics

Exporting 2D Model Files

Exporting 3D Model Files

You can export 3D models to the 3D model file formats listed below. You can choose to export only the selected parts of the geometry, or all of the parts.

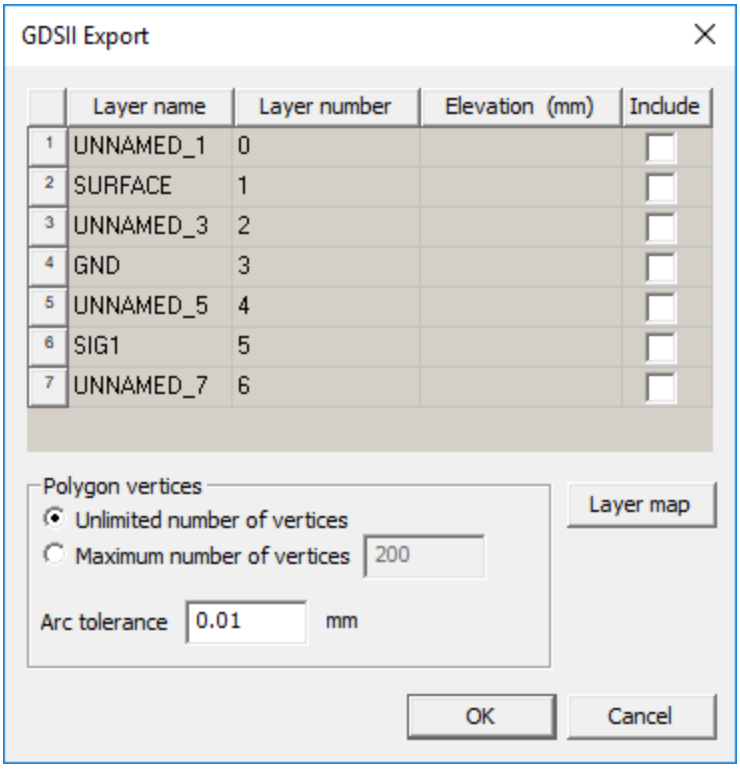
Type	Extension(s)
ACIS SAB	*.sab
ACIS SAT	*.sat
Ansys 3D Modeler	*.sm3
AutoCAD	*.dxf
CATIA	*.exp, *.model
GDSII	*.gds
IGES	*.iges, *.igs
OBJ Files (for importing models to Ensight.)	*.obj
Parasolid	*.x_t, *.x_b
STEP	*.step, *.stp

To export a file to a 3D model format:

1. Click **Modeler** > **Export**.
   The **Export File** window appears.
2. Browse to and select a location to save your file.
3. In the **File Name** field, name the file.
4. From the **Save as Type** drop-down menu, select the desired 3D filetype.
5. Click **Save**.
   The file is exported to the specified location with the appropriate file format.
   There is one additional option for *.sat files:

   - Use the **ACIS SM3 or SAT Version** drop-down menu to select an ACIS version.

   There are additional options for *.gds files:



- Use the **Include** check boxes to select layers for export.
- Click **Layer map** to define a *.layermap file, if desired. This is a text file that maps GDSII layer numbers to layer names in the stackup. The *.layermap file can have the same format as the .tech file used in GDSII import, but it only needs the layer name and number. Any other information is ignored.
- In the **Polygon Vertices** area, select either **No Limit to the number of vertices** or **Limit the number of vertices** and specify a value.
- For **Arc Tolerance**, leave the default or specify a value.

Importing GDSII Format Files

Exporting Graphics Files

You can export the following graphics formats:

Extension	Contents
.bmp	Bitmap files.
.gif	Graphics Interchange Format files.
.jpeg	Joint Photographics Experts Group files.
.tiff	Tagged Image File Format files.
.wrl	Virtual Reality Modeling Language (VRML) files.

To export a file to a graphics format:

1. Click **Modeler**>**Export** to save the file in a graphics format.
   The **Export File** dialog box appears.
2. Use the file browser to find the directory where you want to save the file.
3. Type the name of the file in the **File name** box.
4. Select the desired graphics file format from the **Save as type** pull-down list.
5. Click **Save**. The file is exported to the specified location as a graphics file.

To export an image file to specified high resolution, use the scripting commands. Fonts and line thickness is not scaled. Only the image. You will have to iteratively increase font sizes till you find a suitable output.

```
oEditor.ExportModelImageToFile
("C:/Users/kmchrist/Documents/highresexample_image.jpg", 7680, 4320,
[
"NAME:SaveImageParams",
"ShowAxis:=" , "True",
"ShowGrid:=" , "True",
"ShowRuler:=" , "True",
"ShowRegion:=" , "Default",
"Selections:=" , ""
])
```

Exporting 3D Model Files

Exporting Data Table Files

You must have an existing plot open to see the **Report2D** menu.

1. Click **Report2D**>**Export to File**.

- Alternatively, right-click on the data table, and then click **Export to File** on the shortcut menu.

The **Export plot data to file** dialog box appears.

2. Use the file browser to find the directory where you want to save the file.
3. Type the name of the file in the **File name** box.
4. Select one of the following file formats from the **Save as type** pull-down list:

Extension	Contents
.txt	Post processor format file
.csv	Comma-delimited data file
.tab	Tab-separated file
.dat	Ansoft plot data file

5. Click **Save**. The file is exported to the specified location as a data table file.

Importing Files

You can import the following types of files to Maxwell:

- 2D model files
- 3D model files

Related Topics

Exporting Files

Importing 2D Model Files

You can import 2D model files directly into the active **Modeler** window:

Note	If you import a file into an active **Modeler** window that contains an existing model, the file is added to the existing model; it will not replace it.

If you want to import a model in a specific orientation other than the current XY or XZ plane, you must first create a relative coordinate system with the planes in the desired orientation. See *Creating a Relative Coordinate System* for more information.

To import a 2D model file:

1. Click **Modeler**>**Import**.

   The **Import File** dialog box appears.
2. Select a file type from the **Files of type** pull-down list.
3. Use the file browser to find and select the file you want to import.

4. Click **Open**.
   The file is imported into the active **Modeler** window.

Related Topics

Importing 3D Model Files

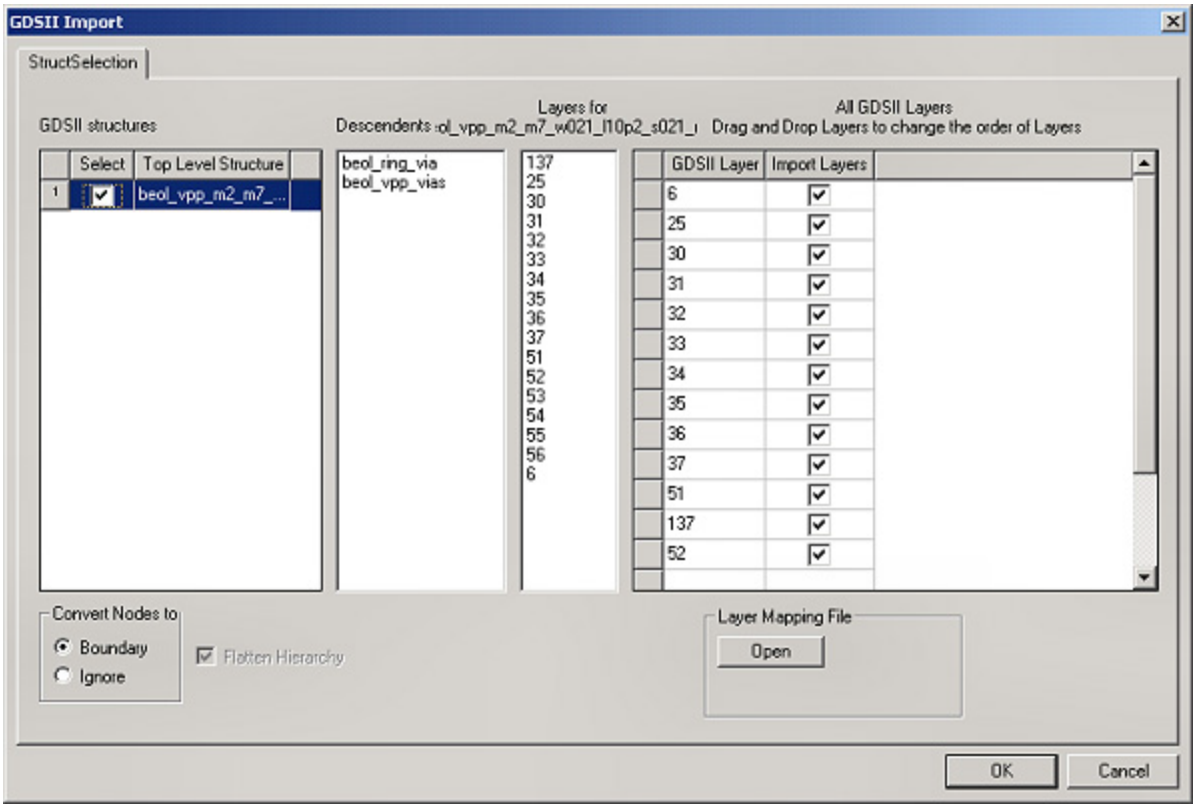
Importing GDSII Format Files

Importing GDSII Format Files

A GDSII format file is one type of 2D model file that can be read directly into the active Modeler window.

To import a GDSII format file:

1. Click **Modeler>Import**.
   The **Import File** dialog box appears.
2. Select **GDSII Files (*.gds)** from the **Files of type** pull-down list.
3. Use the file browser to find and select the GDSII format file you want to import.
4. Click **Open**.
   The **GDSII Import** dialog box appears.



5. Select the desired check boxes in the **GDSII structures** section of the dialog box.

   GDSII Structures Panel:

   The GDSII file may contain several top-level structures. You can do one of the following:

   - Click a structure name in the **GDSII Structures** panel to highlight it.
   - Clicking the **Select** check box in the **GDSII Structures** panel highlights the structure and selects that top-level structure to be imported.

   When multiple structures are imported, Maxwell creates multiple designs under the current project, one for each GDSII structure.

6. View the sub-layouts in the **Descendants** section of the dialog box.

   Descendants Panel:

   The GDSII file is hierarchical and may contain many sub-layouts. The **Descendants** panel shows the sub-layouts in the selected top-level designs.

7. In the **Layers for *structurename*** section, view the layers for the top-level structure.

   Layers for *structurename* Panel:

   The **Layers for *structurename*** panel shows the layers for the most recently highlighted top-level structure [*structurename*]. GDSII layers are identified by layer numbers.

8. In the **All GDSII Layers** section, select the layers you want to import.

   All GDSII Layers Panel:

   The **All GDSII Layers** panel lists all the layers from all the structures in the file.

   Use the **Import Layers** check boxes in the **All GDSII Layers** panel to select the layers to import. You can drag and drop the layers in the list to change the vertical stackup of layers.

9. In the **Convert Nodes to** section, convert or ignore objects that use the "nodes" data type.

   Convert Nodes to Panel:

   GDSII supports nodes and boundaries as separate data types. Normally, boundaries represent polygons. Maxwell can do one of the following: Convert objects that use the nodes data type to boundary types, or ignore them. You can do one of the following:

   - Use the **Convert Nodes to** radio buttons to select **Boundary** or **Ignore**. The default is to convert data type nodes to the data type boundary.
   - The **Flatten Hierarchy** check box is automatically selected. Maxwell always flattens any hierarchical geometry in the GDSII.

10. In the **Layer Mapping File** section, create a mapping to use for the import.

    Layer Mapping File Panel:

    If desired, you can create a mapping of the GDSII layer numbers to layer names in the design stackup. To create and use the mapping, do the following:

    - Use a text editor to create a text file that maps the GDSII layer numbers to layer names in the stackup. The layer mapping file must have a **.tech** suffix. The format of a **.tech** format layer mapping file lists includes the layer number and corresponding layer name, color, elevation, and thickness. For example, a layer mapping file may look like the following:

```
//#
//#  Layer        Color      Elevation        Thickness
//#  Name         Purpose       [nm]             [nm]
//#-------------------------------------------------------------------------
0    ref          red            0.000           0.000
17   POLYG        blue2        420.0           180.0
18   POLY2        blue2        420.0           180.0
25   PIMP         tan          400.0             0.000
26   NIMP         blue3        400.0             0.000
29   RPO          green        400.0             0.000
30   CONT         white        400.0           490.0
31   METAL1       red          890.0           280.0
```

- Click the **Open** button in the **Layer Mapping File** section to locate and open an existing layer mapping file.

11. When you are finished viewing and selecting options in the **GDSII Import** dialog box, click **OK**.

    The file is imported into the active **Modeler** window.

Parasolid	*.x_t, *.x_b	9.0 through 34.0.153
SOLIDWORKS	*.SLDPRT, *.SLDASM	98 through 2022
STEP	*.step, *.stp	ISO standard 10303-21:2016, AP203 STEP files and AP214 (geometry only)
STL	*.stl	2.0

Note	
	• Object, material, and parameter names with non-ASCII characters are not allowed for data transfer. Such transfers fail and produce an error message. • If you import a file into an active **Modeler** window that contains an existing model, the file is added to the existing model; it will not replace it.

To import a 3D model file:

1. Click **Modeler>Import**.

   The **Import File** dialog box appears.
2. Select the file type you want from the **Files of type** drop-down menu.
3. Select any import options available for the selected file type. Option may include:
   - **Validation and Healing Options** – See Healing an Imported Object.
   - **Import Material Names** – use the check box to import material names.
   - **Import Free Surfaces** – for Creo Parametric files, use the check box to import surfaces as well as parts.
   - **Stitch Tolerance and Units** – For STEP and IEGS files, you can specify a Stitch tolerance and units. The default value (auto) comes from Healing options.
   - **STL Import Options** – for STL files for Modal or Terminal solutions, select the modeling units to which the imported model is scaled and whether to merge faces that are on the same plane, and whether to Heal on import. Heal attempts to remove common issues while importing stl files, including closing solids when they are open due to minor cracks in triangulation and removing self-intersections.

     

     The generic format specification for STL does not include units. When “Auto” is chosen for the file units, the current Model units are normally used. The exception is for *.stl files saved from SpaceClaim, for which units have been specified.

     Checking **Reduce** enables fields for specifying Reduce Max Error and Reduce Percentage.
   - **Create Groups for Sub Assembly** – for formats that allow importing MCAD Assemblies as groups, use the check box to retain the assembly structure of objects using groups. For every subassembly in the model, a group is created and it retains hierarchical information by creating group hierarchy. See: Group Commands for Modeler Objects.
4. Use the file browser to find the file you want to import.
5. Click **Open**.

   The file is imported into the active **Modeler** window.

For tips on dealing with very complex models, see Technical Notes: Handling Complicated Models.

Note	While objects created in Maxwell can always be classed in the history tree as either a solid, sheet, or wire some imported objects may have mixture of these. Maxwell places such objects in an **Unclassified** folder in the history tree.

Technical Notes: Handling Complicated Models

Importing DXF and DWG Format Files

You can import AutoCAD versions 2.5 (AC1002) through 2012 (AC1024) on Linux and versions 2.5 (AC1002) through 2017 (AC1027) on Windows. The entities are imported as 2D, not 3D. The types of entities imported are:

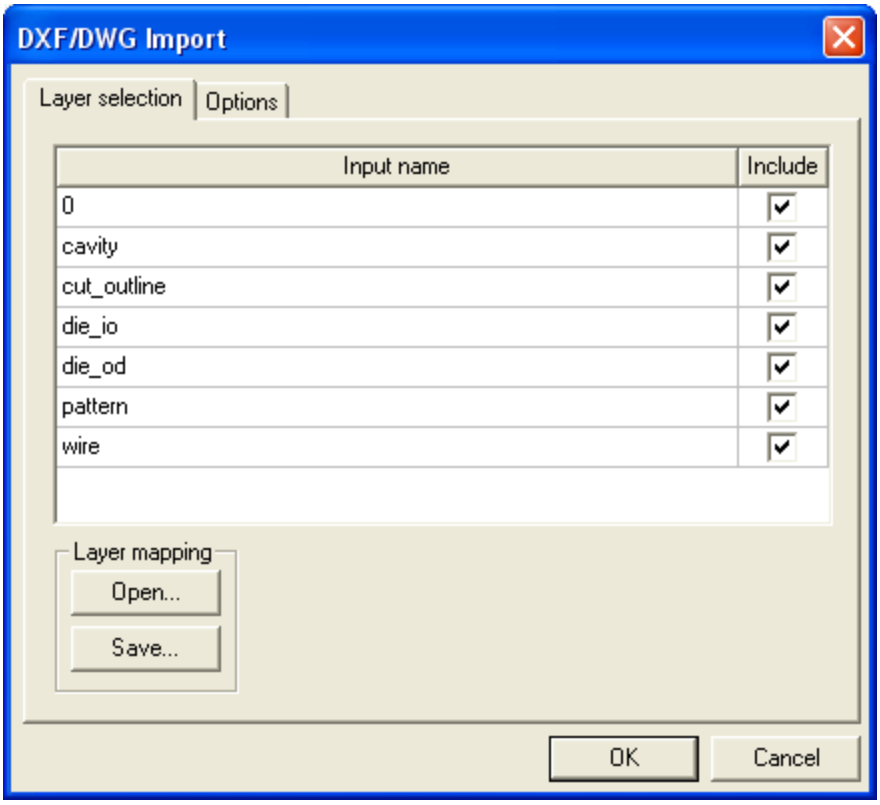
- 2D Polyline
- Polyline
- Line
- Arc
- Circle
- Ellipse
- Solid
- Block

To import a **.dxf** or **.dwg** model file (which may use an associated .tech file):

1. Click **Modeler**>**Import**.

   The **Import File** dialog box appears.
2. Select **AutoCAD Files (*.dxf;*.dwg)** from the **Files of type** pull-down list.
3. Use the file browser to find the file you want to import.
4. Select the **.dxf**/**.dwg** model file you want to import.
5. Click **Open**.

   Initially, the **DWG/DXF Import** dialog opens with the **Layer selection** tab displayed.

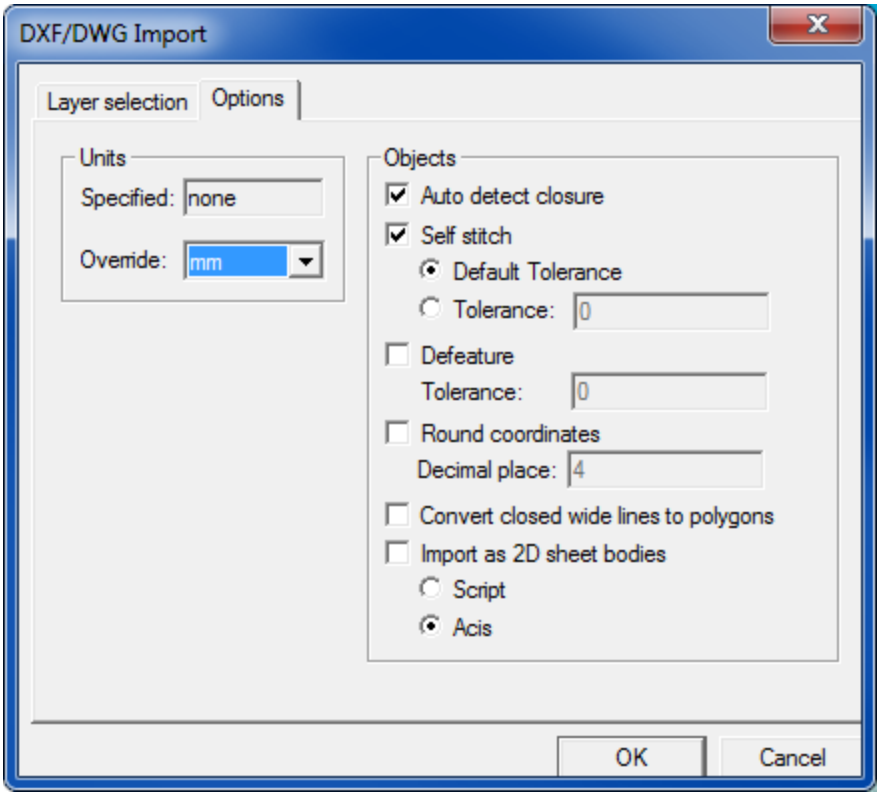


The **Input name** field shows the name of the layer in the DXF/DWG file (not editable).

6. Use the **Include** check boxes to specify which layers to import from the selected file.
7. You can use the browse button [...] to locate a Layer mapping file. The layer mapping file is a plain text file that includes units, layer names, color, elevation, and thickness information.

```
units um
//Layer_Name Color Elevation Thickness
BOTTOMLAYER purple 0 200
MIDLAYER green 500 200
TOPLAYER blue 1000 200
```

8. Click the **Options** tab.



9. Use the **Override** pulldown to select the layout units for the imported file (default is **mm**).
10. Use the Objects check boxes to fine-tune the import:
    - **Auto detect closure** causes polylines to be checked to see whether or not they are closed. If a polyline is closed, the modeler creates a polygon in the design.
    - **Self stitch** causes multiple straight line segments to be joined to form polylines. If the resulting polyline is closed, a polygon is created in the modeler.
        - **Default Tolerance/Tolerance** specifies whether you can specify a self stitch Tolerance value. If particular features in a model are outside of a normal tolerance allowance, you can set a Tolerance for importing that specific model.
    - **Defeature Tolerance** removes certain small features in the imported geometry to reduce complexity. The features that are removed include: multiple points placed within the specified distance; thin or narrow regions (“thins” and “spikes”); and extraneous points along straight line segments.
    - **Round coordinates** to **Decimal place** rounds all imported data to the specified number of decimal points.
    - **Convert closed wide lines to polygons** imports wide polylines as polygons. You have more flexibility to change the shape of such an object when it is imported as a polygon.
    - **Import as 2D sheet bodies** causes imported objects to be organized in terms of 2D sheets.

11. For Import method, select **Script** or **Acis**.
12. When you have completed selections on all tabs, click **OK** on any tab.

    The file is imported into the active **Layout** window.

Importing Data Tables

You can import data table files that contain data in the following formats:

- Tab-separated. Maxwell will recognize complex data if the values are separated by a comma (e.g. *real, imaginary*).
- Comma-separated. Maxwell will recognize complex data if the values are separated by a space (e.g. *real imaginary*).

1. Click **Maxwell**>**Results**>**Import Solutions**.
   - Alternatively, right-click **Results** in the project tree and then click **Import Solutions** on the shortcut menu.

   The **Imported Data** dialog box appears.
2. Click **Import Table**.

   The **Table Import** dialog box appears.
3. In the **File Name** text box, type the name of the data table file you want to import or click **Browse** and use the file browser to locate the file.
4. If the data in the table is complex, select the format — real/ imaginary, or magnitude/ phase — in which to import the data.

   If the data is simple, this option will be ignored.
5. Click **Load File**. Note that the file has not been imported yet.
6. Optionally, type a new name in the **Source Name** box that indicates the origin or the data table, or accept the default name.
7. Optionally, type a new name in the **Table Name** box that describes the data in the table, or accept the default name
8. In the **All Columns** list, the headings of each column in the data file are listed. Optionally, specify a new name for a column heading by doing the following:
   a. In the **All Columns** list, click the heading you want to change. The heading appears in the **Column Name** box.
   b. Type a new name in the **Column Name** box, and then click **Set Column Name**. The heading is changed to the new name in every place it appears in the **Imported Data** dialog box.
9. In the **Independent Data Columns** list, the first heading in the data table file is listed by default. In the **Dependent Data Columns** list, the second and subsequent headings in the data table file are listed by default. Optionally, click a heading name and then click an arrow button to move it from one column to another.
10. If the data in the **Dependent Data Columns** list contains matrix data, select **Matrix Data**. If it contains field data, select **Field Data**.
11. Click **Import**.

    You return to the **Imported Data** dialog box.

12. Click the data you want to import in the **Current Imports** list, and then click **OK**.
    The solution data is now available for post processing.

Adding Datasets

Inserting a Documentation File into a Project

To insert a documentation file so that it can be accessed from the project tree:

1. Click **Project>Insert Documentation File**.
   The **Open** dialog box appears.
2. Find and select the file you want to insert.
3. Click **Open**.
   The documentation file appears in the project tree for the current project.

Importing and Converting Materials

To preserve custom materials, you need to import them from a Maxwell **.mat** file (from a previous version of Maxwell) into the latest version of a Maxwell user library (**.amat** file).

To import these materials from previous versions, you must have at least one Maxwell design loaded in the project window.

To translate custom materials to the latest Maxwell version:

1. From the menu, click **Maxwell3D** or **Maxwell2D**, and then select **Translate Material Database**.
   The **Translate Legacy Material Database** appears.
2. Enter the name of the old database in the **Legacy Material DB Name** box. You can also click the **[...]** button to locate the database (**.mat** file).

Note	The **.mat** extension displays as a shortcut in the file browser.

3. Enter a name for the new database in your current project in the **User Material DB Name** box.
4. Click **Translate**. The dialog displays a Translation completed message when done. The imported materials are stored in a file with an **.amat** extension in the **userlib**.

Assigning Materials.

Importing a Model from the Clipboard

You can import a model from the Clipboard in order to use a geometry from a different design. To use a geometry with datalink, the geometry ID must be preserved. The **Import from Clipboard** command preserves geometry IDs.

To import a model from the Clipboard, the model for the current design must be empty. If the design it not empty, existing geometry is deleted.

The geometry model is imported from the Clipboard with the ID preserved.

1. Select the objects you want to copy. For selecting all objects, you can use **Edit>Select All** or **Ctrl-A**.
2. Click **Edit**>**Copy**  .

   The objects are copied to the Clipboard, a temporary storage area. The selected items are not deleted from the source location.
3. Select the design into which you want to paste the objects. It can be the same design from which you copied the items.
4. Click in the **3D Modeler** window.
5. Select the working coordinate system. Objects are imported relative to the current working coordinate system.
6. Click **Modeler**>**Import From Clipboard**.

The geometry model is pasted from the Clipboard with the ID preserved.

Setup Link Dialog

Selecting Items in the Modeler Window

Importing Tabular Arrays

Array data in tabular format can be imported from a file using the **Array Import** wizard that is invoked by selecting **Tools > Import Array from Table** and specifying a .csv file from the dialog that opens.

The tabular array .csv file should contain the following formatting:

```
arrIndex1 arrIndex2 arrIndex3
c1 "a0" d1
c2 "a2" d8
c3 "a3" d9
```

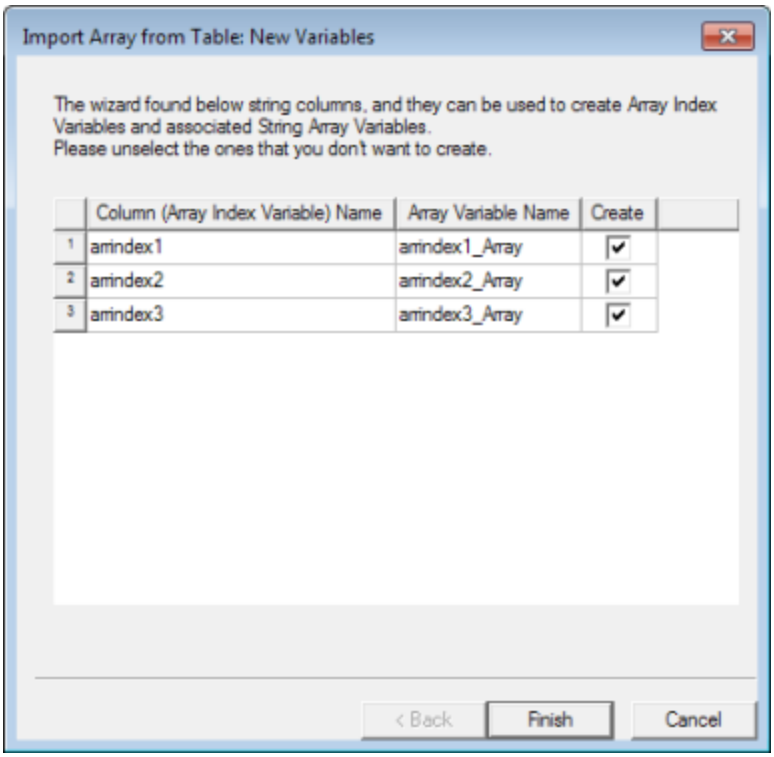
- First row consisting of list of Array Index Variable names separated by tabs or commas
- Remaining rows consisting of a list of string values separated by tabs or commas

- Double quotation marks (“ “) for string values are optional

After you select a .csv file to open:

- If no existing array variables are present in the design, the **Import Array From Table: New Variables** dialog opens.
- If one or more existing array variables are present in the design, the **Import Array From Table: Existing Variables** dialog opens.

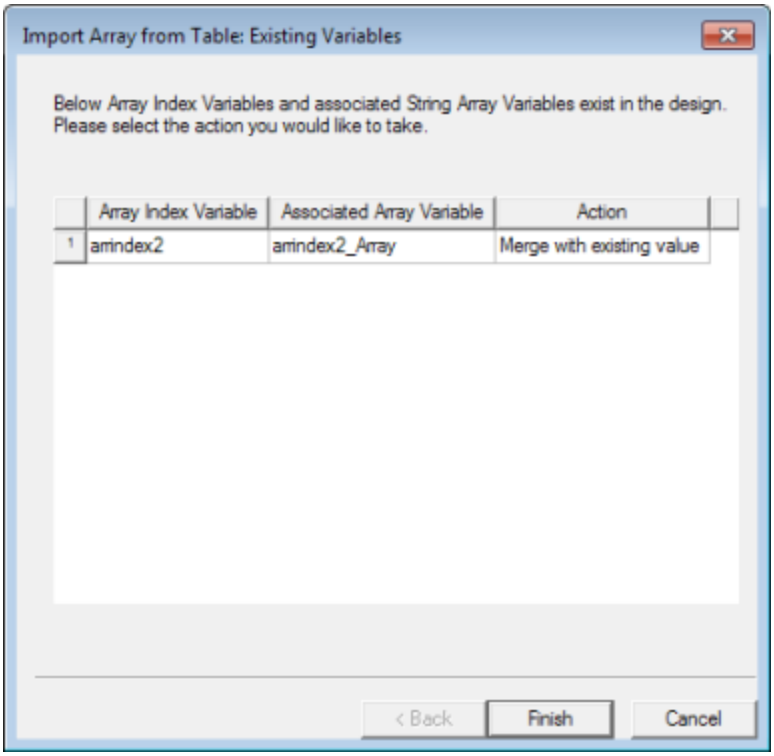
The **Import Array From Table: New Variables** dialog is shown below.



The following controls are available:

- **Column (Array Index Variable) Name** cannot be modified and is used to create the array index variable.
- The associated **Array Variable Name** has the default name “<*ColumnName*>_Array". You can modify the **Array Variable Name**, but variable uniqueness and validity is checked upon closing the wizard.
- Click the **Create** checkbox to specify that the array index variable should be created.
- Use the control buttons at bottom to go **Back** to the previous wizard dialog box, proceed to **Finish** and close the wizard dialog box, or click **Cancel** to close the dialog without making changes.

If one or more existing array variables are present in the design, when you click **Next** in the above wizard dialog box, the **Import Array From Table: Existing Variables** dialog opens.



The following controls are available:

- **Array Index Variable** name can *not* be modified.
- **Associated Array Variable** can be modified, but variable uniqueness and validity is checked upon closing the wizard.
- The following choices appear in the **Action** pulldown menu:

  – **Merge with existing value**

  – **Replace existing value**

  – **No Action**

  If you select **Replace existing value**, you are then prompted for verification.

- If you import a file to a design where a string column already exists as an **ArrayIndexVariable**, the value of the variable is checked when imported. If the existing array value is a superset of new array values, the array variable will not appear in the **ExistingVariables** dialog.

You can also use the same .csv tabular array file to setup a parametric analysis. When the parametric analysis is set up, the **ArrayIndexVariable** is searched and its index is used to create the table. Whether the **ArrayIndexVariable** refers to a double array or a string array, you must use the array element from the imported file - rather than the index value itself - to set up the **Parametric from File** analysis.

Printing

The printing commands enable you to send an image of the active window to the printer.

To print the project:

1. Click **File**>**Print**.

   The **Print** dialog box appears.
2. You can change the printer (if other printer names are listed on the drop down), set the print range, number of copies, or use the check box to Print to file.
3. Do one of the following:
   - Click **OK** to print the project.
   - Click **Cancel** to dismiss the window without printing.
   - Click **Properties** to define printer settings.

You can also access the printer properties by clicking **Printer** in the **Page Setup** dialog box.

Previewing the Printout

To preview how the page will look when printed:

1. Click **File>Print Preview**.
   The preview window appears.
2. To print the project after seeing the preview, click the **Print** button.
   The **Print** dialog box appears.
3. To navigate through the preview, click the **Next Page**, **Prev Page**, and/or **Two Page** buttons.
4. To zoom in or out on the preview, click the **Zoom In** or **Zoom Out** button.
5. To close the preview and return to your project, click **Close**.

Changing the Page Setup

To set or change the page setup:

1. Click **File>Page Setup**.
   The **Page Setup** dialog box appears.
2. Under **Paper**, select a **Size** and **Source** for the paper.
3. Under **Orientation**, select either **Portrait** or **Landscape**.
4. Under **Margins**, change the values as desired in the **Left**, **Right**, **Top**, and **Bottom** text boxes.
5. Click **OK**.

You can also access the printer properties by clicking **Printer** in the **Page Setup** dialog box.

Saving Design Notes

You can save notes about a design, such as its creation date and a description of the device being modeled. This is useful for keeping a running log on the project.

To add notes to a project:

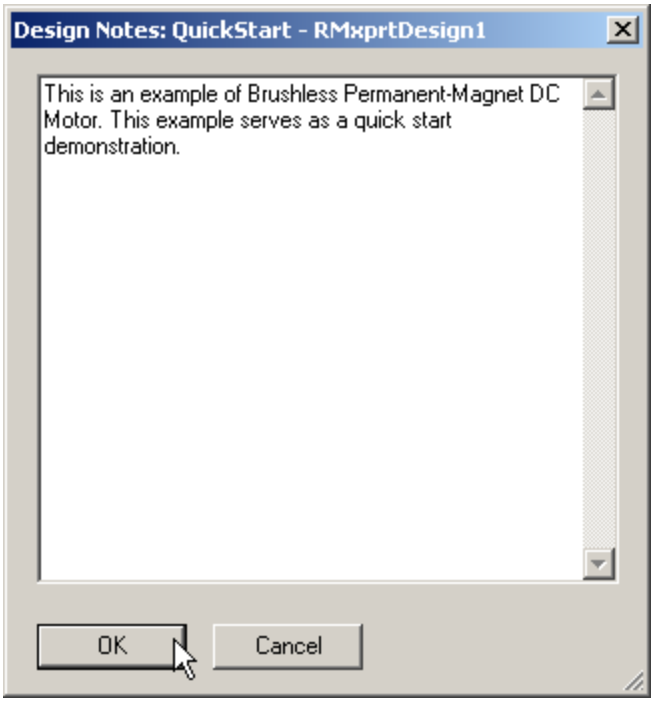
1. Click **Maxwell3D, Maxwell2D, or RMxprt, and then select Edit Notes**. Alternatively, right-click a design icon in the project tree and select **Edit Notes…** from the shortcut menu.

   The **Design Notes** dialog box appears.
2. Click in the window and type your notes.
3. Click **OK** to save the notes with the current project.

To edit existing design notes you may:

- Double-click the **Notes** icon in the project tree.
- Click **Maxwell3D, Maxwell2D, or RMxprt, and then select Edit Notes**.
- Right-click a design icon in the project tree and select **Edit Notes…** from the shortcut menu.

The **Design Notes** window appears, in which you can edit the design's notes as shown in the following example.



To delete the existing notes for a design:

1. Select the icon **Notes** in the project tree, click **Edit>Delete**.
2. Right-click the icon **Notes** in the project tree, click **Delete** from the shortcut menu.

The Notes icon is removed from the project tree.

Note	Notes are used to document aspects of designs only. For project level documentation, you can insert a documentation file into a project with the Project>Insert Documentation Files command.

Using the Password Manager to Control Access to Resources

Maxwell and RMxprt allow you to specify library resources that require password access and encryption. The same password can apply to multiple resources.

To access the Password Manager, click **Tools>Password Manager**.

Specifying a New Password Protected Resource

To specify a new password protected resource:

1. Click **Tools>Password Manager**.

   The **Password Manager** dialog box appears.
2. Click the **New** button.

   The **New Encrypted Resource** dialog box appears.
3. Specify the name of the resource that you want to protect, and click **OK**.

   The **Enter Passwords** dialog appears.
4. Select one of the following radio buttons:
   - **Enter password** - and confirm for **Full Access** or for **Execute Only Access**.
   - **Use Ansoft Password (Execute Only)** - This does not require you to enter a password, but it still encrypts the library.
5. After you have selected a radio button, and, if necessary, specified passwords correctly, click **OK** to return to the **Password Manager** dialog box in which the new resource is now listed.

Encrypting a Resource

To encrypt a resource:

1. Click **Tools>Password Manager**.

   The **Password Manager** dialog box appears.
2. Select an existing resource to highlight it and enable the **Encrypt File** button.
   A file browser window appears.
3. Select the desired **Circuit files (*.lib)** file you wish to encrypt.

   Any existing resources in the selected directory appear.
4. Click **OK**.

   The resource is encrypted.

Setting Options in Maxwell

You can use **Tools>Options>General Options** to open the **Options** dialog and set options for Maxwell as well as the Ansys Electronics Desktop. The following options are pertinent to Maxwell:

- General Options, such as project directory, WebUpdate options, and distributed analysis options.
- Maxwell 3D Options, such as the default solution type.
- Report Setup Options, including advanced mode editing, the number of significant digits to display, and drag and drop behavior.
- Maxwell 2D Options, such as the default solution type.
- RMxprt Options, such as the default solution type and material thresholds.
- Report2D options, such as formatting and cell size.
- Modeler options, such as coordinate system settings, color, and grid settings.
- Fields Reporter options, such as field overlay and phase animation settings.
- Schematic Editor options, such as fonts, colors ,etc. used by the Maxwell Circuit Editor.

You can use HPC and Analysis Options to specify design-specific options.

Additionally, the Tools>Options>Export Options Files command writes xml files containing the Options settings at all levels to the specified directory. This feature makes it easier for different users to use Ansys Electromagnetics tools installed on shared directories or network drives. The Example Uses for Export Options Features section outlines some use cases enabled by this feature.

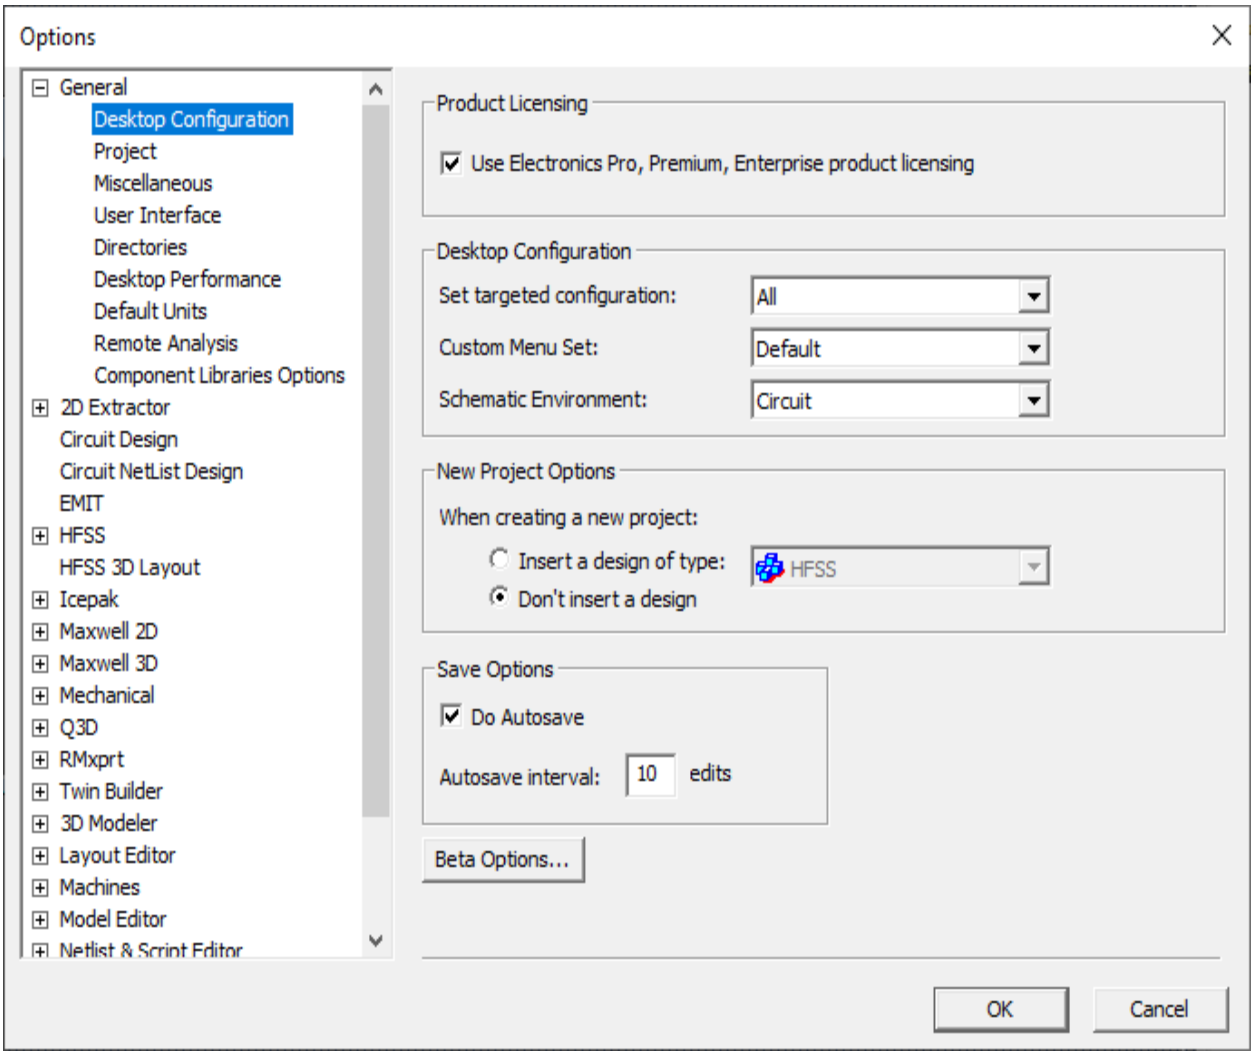
Setting General Options

To set general options in Maxwell:

1. Click **Tools>Options>General Options**.
   When the **Options** dialog appears, clicking the + next to **General** expands the list to show the following:
   - Desktop Configuration
   - Project
   - Miscellaneous
   - User Interface
   - Directories
   - Desktop Performance
   - Default Units
   - Remote Analysis
   - Component Libraries Options
2. Click each entry, and make the desired selections.
3. Click **OK** to apply your preferences.

General Options: Desktop Configuration

Under General Options, **Desktop Configuration** options allow you to customize Electronics Desktop in a way that suits your work priorities. These include options for product licensing, menus, new projects, save intervals, and beta features.



In the **Product Licensing** area, select whether to disable the Electronics Pro, Premium, Enterprise (PPE) product licensing mode. The PPE model is a portfolio of products that enable broad capabilities at each level, without requiring the purchase of add-ons and options. For example, features like Optimetrics, CAD translation, and circuit simulation are included directly in the PPE product levels.

In general, the Pro, Premium, Enterprise products use the same prep/post licensing as the traditional products. You can open and edit designs within the Electronics Desktop regardless of which product licensing has been selected. Simulation, and some other features like translation, use new licenses for the PPE products. If the **Use Electronics Pro, Premium, Enterprise**

product licensing option is not set appropriately these features will fail to check out their licenses.

When the PPE option is enabled, HPC licensing is used to enable all cores, GPUs, and distributed tasks. DSO is no longer used to distribute Optimetrics variations, as it was under the traditional product licensing model. ACL license sharing context manages license sharing of Electronics products. This allows design point (variation) distribution for external tools (WorkBench and optiSLang) to be based upon HPC licensing. A single set of solve and level licenses are checked out, instead of a set of solve and level licenses being checked out for each distributed design point. License sharing can be between applications (for example, Siwave and 3D layout), between designs (for example, datalink, cosim and dynamic link) and within a design (for example, distributed variations). The sharing context will always be used when the Pro, Premium, Enterprise (PPE) license model is active, and will never be used when PPE is not active. For more details, see Setting HPC and Analysis Options.

The **Desktop Configuration** section contains the following: **Set targeted configuration**, **Custom Menu Set**, and **Schematic Environment**.

- **Set targeted configuration** Each selection here also affects the default selections for the **Custom Menu Set** and **Schematic Environment** options (described below), as well as the default design type for a new project. Select the desired targeted configuration from the **Set targeted configuration** drop-down menu.
  - **All** – Default option. Sets the **Custom Menu Set** to **Default**, the **Schematic Environment** to **Circuit**, and the default design type to **HFSS**.
  - **EM** – Electromagnetic focus. Sets the **Custom Menu Set** to **EM**, the **Schematic Environment** to **Twin Builder**, and the default design type to **Maxwell 3D**.
  - **RF** – Radio Frequency focus. Sets the **Custom Menu Setto** RF, the **Schematic Environment** to **Circuit**, and the default design type to **HFSS**.
  - **SI** – Signal Integrity focus. Sets the **Custom Menu Set** to **SI**, the **Schematic Environment** to **Circuit**, and the default design type to **HFSS 3D Layout**.
  - **Twin Builder** – Sets the **Custom Menu Set** to **Twin Builder**, the **Schematic Environment** to **Twin Builder** and the default design type for a new project to **Twin Builder**.
- **Custom Menu Set** choices are:
  - **Default** – All solvers appear on the **Project** menu.
  - **EM** – Only electromagnetics solvers appear on the **Project** menu.
  - **RF** – Only radio frequency solvers appear on the **Project** menu.
  - **RF.0** – All solvers appear on the **Project** menu. The **HFSS RF Setup** menu appears.
  - **SI** – Only signal integrity solvers appear on the **Project** menu.
  - **SI1.0** – Only signal integrity solvers appear on the **Project** menu. The **Import**, **Solution Setup**, **Automation**, and **Definitions** menus appear.

- **SI2.0** – All solvers appear on the **Project** menu. The **HFSS SI Setup** menu appears.
- **Twin Builder** – Only Twin Builder appears on the **Project** menu.

NOTE: The default menu set selected depends on the selected targeted configuration.

- **Schematic Environment** – Select **Circuit**, **Twin Builder**, or **Maxwell**

New Project options specifies whether a design of a particular type is inserted when you create a new project. For example, if you define EM in **Set targeted configuration**, the default for **Insert a design of type** is Maxwell 3D. You can select other options from the drop-down list, or select the **Don't insert a design** option. The default is based on the selected targeted configuration.

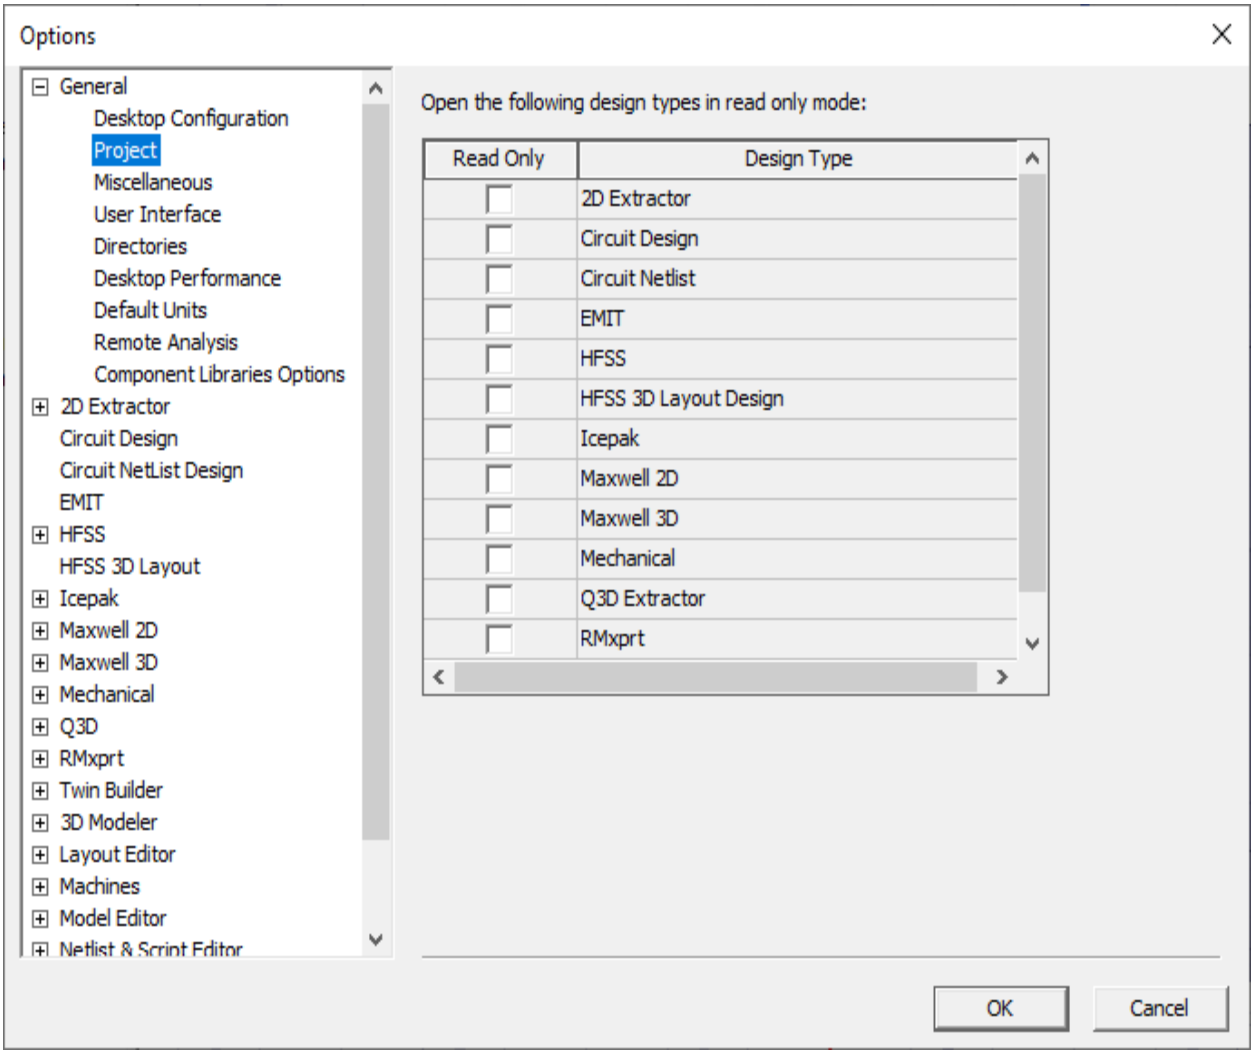
Save Options defines if autosave is enabled and the interval in edits for autosaving. To enable autosave, select the **Do Autosave** check box. Set the number of editing actions after which a backup file is automatically saved to your hard drive in the **Autosave interval** text box. The default is **10**. The backup file is given the same name as your project and has an "**aedt.auto**" file extension.

Beta Options opens a **Beta Options** dialog in which you can check any Beta Options you want to use, then click OK to close the dialog box. If you have selected any options, when you close the main Options dialog box, Ansys Electronics Desktop will prompt you to restart the desktop application to enable the selected beta features.

When all information on **Desktop Configuration** is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: Project

These options are set on the **Project** panel under **General** in the **Options** dialog box. They allow you to select design types to open in read-only mode. This can help prevent accidental changes.



When all information on the **Project** panel is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: Miscellaneous

These options are set on the **Miscellaneous** panel under **General** in the **Options** dialog.

Ansys Workbench Application

The Ansys Workbench Application **Path** lets you specify a path to an Ansys Workbench installation, if you have one. This path can be used to open the Icepak application when you create an Icepak design in RMxprt. It can also be used by the Optimetrics feature for connecting to the Design Xplorer.

MATLAB Optimization

If you have an installation of MATLAB installed you can use it as an Optimizer. This MATLAB path setting must to point to the version of MATLAB to be used for performing the optimization. .

Note	The platform (64 bit) of the specified version of MATLAB must match the platform of this application.

Save Preview Images

Click **Save preview images in project file** if you want the images to be saved in your projects.

When all information on **Miscellaneous** is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: User Interface

These options are set on the **User Interface** panel under **General** in the **Options** dialog.The **User Interface** panel contains the following sections:

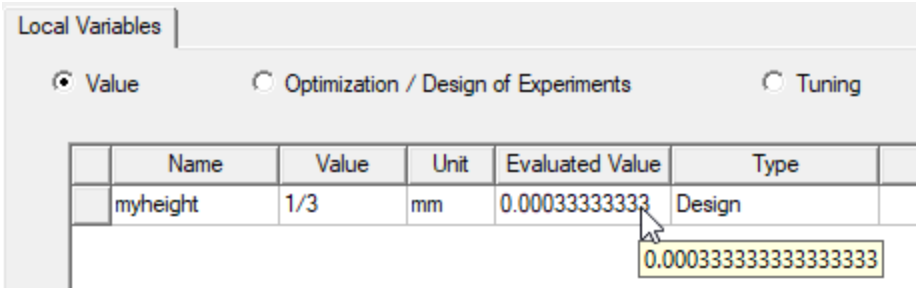
General

- **Show Message Window on new messages** – when selected, the message window automatically opens if a message arrives.
- **Ensure that new messages are visible in the Message Window Tree** – when selected, the message window expands as needed to display messages.
- **Show Progress Window when displaying progress bars** – when selected, the progress window automatically opens while simulations are in progress.

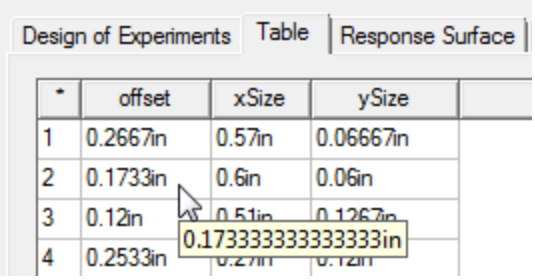
Project Tree Visualization Options

- **Emphasize active command context** – when selected, active elements in the Project Tree display in bold text.
- **Change icon when selection does not match active window** – when selected, a small, window-shaped overlay icon displays in the corner of the selected Project Tree element. This icon changes when the data in the active window is unrelated to the selected project item (data affecting the same model is considered to be related). Clicking the icon opens the window and brings it into focus.
- **Expand Project Tree on Insert** – when selected, the Project Tree automatically expands when you insert a new design.

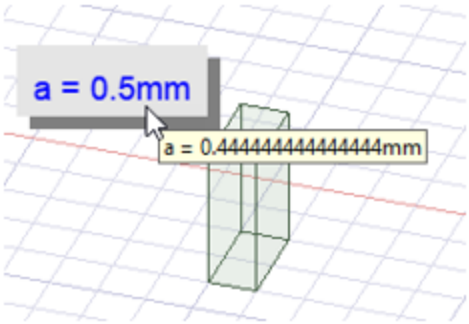
In the **Display Options** area, specify the **Maximum Number of Significant Digits** to display. The default is 8 and the maximum is 20. This affects the digits displayed in the Solutions dialog box, evaluated variable values, Animation dialogs, Optimetrics, Reports, and so forth. You can still see the full precision values in the tooltips by holding a cursor over the displayed value.

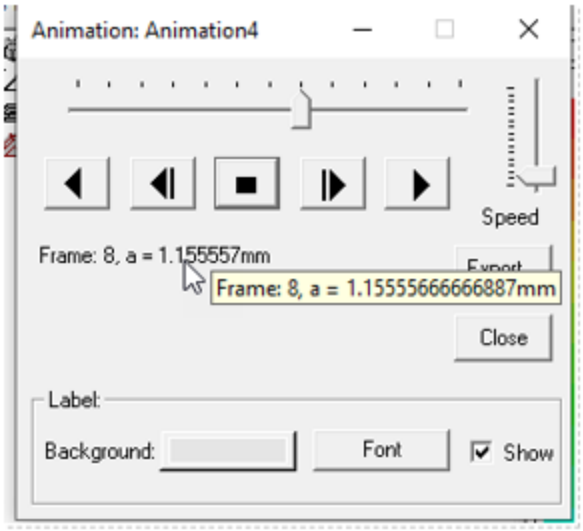


In the case of variable values, if you have assigned more significant digits, you will see these when editing the variable value. In the case of table displays of values, the tooltip display shows all available digits when the mouse pointer is over a result:



The tooltip functions to show internal digits in throughout the Ansys Electronics Desktop interface, including the Model window, animation dialogs and so on.





Color Scheme

You can select the color scheme of Blue, Silver, or Black.

Welcome Message

Select **Show welcome message at startup** if you want to see a welcome message when Electronics Desktop opens.

When all information on the **User Interface** panel is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: Directories

1. For each directory, Project, Syslib, UserLib, and PersonalLib, enter a path in the **Directory** text box, or click the ellipsis button ("**...**") to find and select the desired directory. If you modify SysLib, UserLib or PersonalLib paths through **Tools>General** options, the User Defined Primitives menu should reflect those changes on next startup or on **Draw>User Defined Primitive>Update Menu**.
2. If you want to enter a directory path in the **Temp Directory** text box, you must check Override to enable the path text field and the ellipsis button ("**...**") for finding and selecting the desired directory.
3. To reset the library directories to the default, click **Reset Library Directory**.

General Options: Desktop Performance Tab

These options are set on the **Desktop Performance** panel under **General** in the **Options** dialog box.

Report Update Options for Design Type:

- Select a **Design type** to which the report update options apply.
- Select or clear **Dynamically update reports and field overlays during edits**.

  If selected, report plots and overlays update dynamically.
- **Dynamically update postprocessing data for new solutions**.

  Updating numerous reports may take a significant amount of time. Updating reports during the analysis process can impact the overall time to solution. You may want to vary the times when your reports get updated relative to the impact on overall solve time.
- **Update reports on file open –** specifies that reports be automatically updated whenever an existing file with solution data is opened for viewing/editing. Enabled by default.

  Five options exist for updating reports during solutions:
  - **Automatically** - the default. It means update most things immediately.

    For “AdaptivePass” plot context, plots are updated at the end of each solution pass. For “LastAdaptive” or “Transient” the plot is updated at the end of the transient or adaptive solution. This option balances report and field plot updating with solution time. For example, reports may be updated after each adaptive pass but field plots will not be updated until the solution is complete.
  - **Immediately** - update reports and plots as soon as data comes from the solver.

    This option will have the greatest impact on the overall solution time but will have the most rapid updating of reports and field plots. Caution should be used in selecting this option. Some types of reports and field plots may take a long time to update, especially as the mesh size increases.
  - **Never** - only manual intervention updates reports.

This option will prevent updates from impacting the solution time.

- **On Completion** - as with **Never**, but a single update is done when the solve completes.

Note	Reports that are updated on completion are done after the solve has been completed. The time for that update is not included in the solve profile.

- **After Each Variation** - when performing an Optimetric or parametric analysis, all reports are updated after analysis of each variation has been completed.

Animation

Computing animated plots requires significant memory which depends upon the complexity of the plot type. The animation setting is used to prevent problems related to low memory should an animation require large memory allocation.

The Animation setting lets you set a limit to **Stop computing animation frames when available memory is less than** the set value in megabytes. The default is 100.

Desktop Pre/Post Processing settings:

- **Number of Processors** – The default is determined by the number of logical processors on the machine. This option is common for both pre-processing and post-processing. This option only affects pre/post processing in desktop (not solve or simulation).

  More details regarding the default core usage.

  - The default core usage per desktop session (UI + solve) is set to 2/3 of the logical processors on the machine.
  - The cores for default local config is max{4, 1/3 of the logical processors on the machine}
  - The default number of processors for pre/post is min{1, 2/3 of the logical processors - default_cores_for_local_config}
  - When the core usage per desktop session cannot be evenly distributed between solve and pre/post, more cores will be assigned to solve.

  Example 1:

  - logical processors = 24
  - cores usage per desktop session = 16
  - local HPC set to 4 cores
  - processors for pre/post set to 12

  Example 2:

  - logical processors = 20
  - cores usage per desktop session = 13
  - local HPC set to 4 cores
  - processors for pre/post set to 9

  Example 3:

  - logical processors = 5
  - cores usage per desktop session = 3
  - local HPC set to 2
  - processors for pre/post set to 1

The following pre-processing algorithms can take advantage of multiple processors:

- Visualization/faceting of 3D models for 3D products
- Model validation for 3D products
- Auto net identification for Q3D only

Disk Space Warning

You can set a value to **Warn when available disk space is less than** the specified number of gigabytes.

When all information on the **Desktop Performance** panel is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: Default Units

These options are set on the **Default Units** panel under **General** in the **Options** dialog.

The **Default Units** panel of the **General Options** dialog box allows you to set the default unit values for the following metrics: **Length**, **Frequency**, **Resistance**, **Angle**, **Power**, **Inductance**, **Time**, **Voltage**, **Capacitance**, **Temperature**, **Current**, **Force**, **Torque**, **Speed**, **Angular Speed**, **Magnetic Induction**, **Weight**, **Mag**netic **Field Strength**, **Pressure,** and **Conductance**.

Note	Units specified in the **Default Units** panel are generally for problem definition. The Post Processor displays output in the unit that scales best for plotting, however, the user may change the unit when creating the plot. Also, the Fields Calculator always works with SI units.

When all information on the **Default Units** panel is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

General Options: Remote Analysis

Under General Options, **Remote Analysis** options allow you to launch all analyses as a service or specified user rather than as the current user.

In the **RSM Service Options** area, options include:

- **Ansoft Service Port** – Click **Change** to update the port number. Ansys Electromagnetics RSM Service should be running on this port for all distributed machines.
- **Send Analysis Request As** – Select either **Service User** or **Specified User**. Selecting **Specified User** enables the **User Name**, **Password**, and **Domain/Workgroup** fields.

  > **Note:**
  >
  > If any of the remote machines is Unix-based, you must specify the current user.

- **Disable Access By Remote Machines** – If desired, select to disable access for remote machines.

When multiple IP addresses are available, the **Desktop-Engine Connection** area allows you to specify the preferred IP address for communication:

- **Use Default** – your system's default IP address.
- **Specified Address** – an IP address you specify.
- **Specified Subnet** – a subnet you specify. Subnet may be network prefix and prefix length (123.12.123.0/22), network prefix and subnet mask (123.12.123.0/255.255.252.0), or network prefix only (123.23.123.0).
- **Use Loopback Address for Local Solves** – modifies how Electronics Desktop connects to the simulation engine when solving on a local machine. Selecting this option can make the connection more reliable and avoid interruptions associated with connecting and disconnecting with VPN.

Changing the Listening Port used by Ansys RSM Service

To change the listening port used by the RSM Service, you must change the ansoftrsmservice.cfg file as follows:

Specify the ListenPort within a 'CommDetails' block, which must be within a 'Default:CommDetails' block, which must be within the top level block of the file (the 'AnsoftCOMDaemon' block). The following example changes the listen port from 32958 to 32957, with these blocks at the beginning of the file:

```
    $begin 'AnsoftCOMDaemon'
$begin 'Default:CommDetails'
  $begin 'CommDetails'
  ListenPort='32957'
  $end 'CommDetails'
$end 'Default:CommDetails'
. . . .
    $end 'AnsoftCOMDaemon'
```

For the second level block, ensure that there is a single colon character and no spaces or tabs separating the two parts of the block name 'Default:CommDetails'. The third level block, with name 'CommDetails' is also required. Use caution when editing this file by hand, because any typos in the block or value names may cause the data to be ignored.

Remote Analysis

General Options: Component Libraries Options

These options are set on the **Component Libraries Options** panel under **General** in the **Options** dialog.The **Component Libraries Options** panel contains the following sections:

You can select to **Use extractor mode by default for separate dynamic link desktops** by using the check box.

You can select to **Run affected property callbacks when variable changes value** by using the check box.

The **Component Tree Options** panel contains the following controls:

- **Show Favorites** specifies that a list of favorites, in the form of an expandable tree, is displayed in the Component Libraries's Components tab window.
- **Show Most Recently Used** specifies that a list of the components you have most-recently used is displayed in the project window.
- **Most Recently Usedlist contains** specifies the number of recently used components to display.

The **Search Options** panel contains the following controls:

- Use **Set** to determine whether searches are performed on **All components**, **Current list only**, or **Append to current list**.
- **Load Libraries at Initialization** – When checked, Twin Builder pre-loads all system and configured libraries into the Component Libraries search database when the Component Libraries is initialized at Twin Builder startup. Clear this option to reduce the startup time of Twin Builder, in which case the libraries are loaded at first search.

When all information on the **Component Libraries Options** panel is defined, select another option under **General** in the **Options** dialog or click **OK** to put your settings into effect.

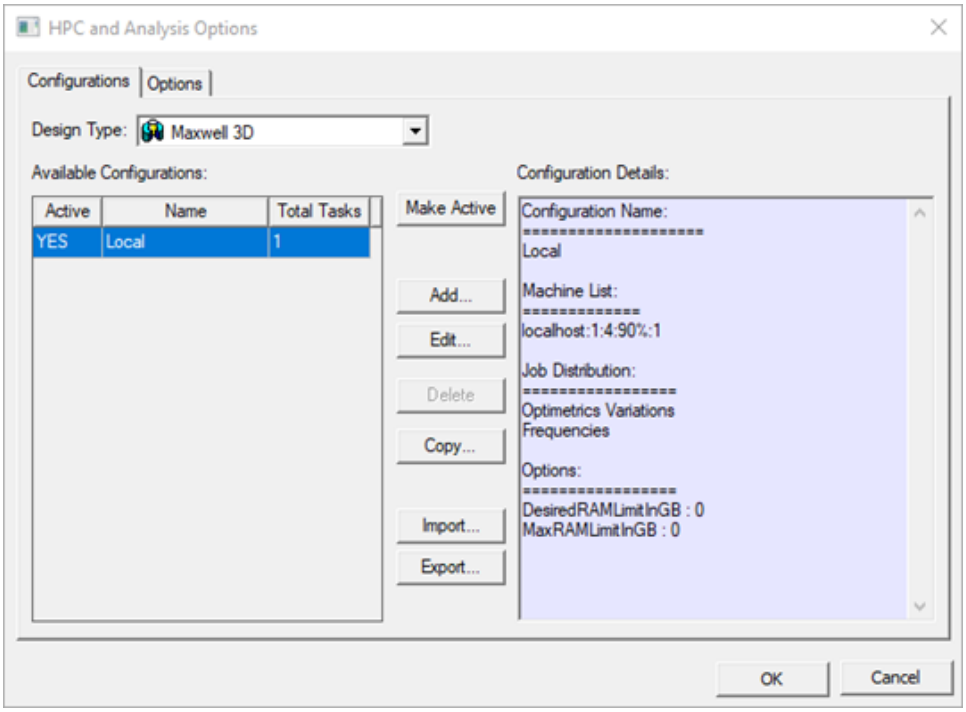
Setting HPC and Analysis Options for Maxwell and RMxprt Designs

HPC and analysis parameters are accessed via a single dialog. Machine list and options settings are integrated into analysis configurations. The default configuration is for solving on a single, local machine. You can create many analysis configurations for remote and distributed solutions, and switch between them, depending on the job being solved. Multiprocessing is integrated into the machine lists.

To set the HPC and Analysis Options:

1. Click **Tools>Options>HPC and Analysis Options.**

The **HPC and Analysis Options** dialog appears, displaying two tabs.



Configurations tab

In the **Configurations** tab, you can select the Design Type, and select from a list of available configurations. Selecting a Design Type displays a list of the Available configurations for that type. Selecting a configuration from the list displays the details of that configuration in the text fields. A Name can describe the use for which a configuration has been defined. The Total Tasks column shows the number of tasks that the analysis configuration can execute.

Design Type

Defines configurations for the selected design type. If you want to use similar analysis parameters for a different design type, you must create a separate analysis configuration for that design type. The Active configuration is used when solving an analysis for the design type.

Available Configurations List

From the lists of Available Configurations for each design type, click the desired configuration in the list to select it, then click **Make Active**. The active configuration is indicated with a YES in the Active column.

- **Add...** button – launches a dialog to create a new analysis configuration.
- **Edit...** button – launches a dialog to edit the currently selected analysis configuration.
- **Delete** button – deletes the currently selected analysis configurations.

Note	You cannot delete the Local configuration.

- **Copy...** button – creates a new analysis configuration, and launches a dialog to edit it. If the dialog is canceled, the new analysis configuration is not created.
- **Import...** button – allows the user to import an .acf file to create an analysis configuration.

Note	Importing analysis configurations always adds the imported analysis configurations to the current design type. Also, if there is a name conflict between an imported analysis configuration and an existing analysis configuration, the imported configuration is renamed and you are notified.

- **Export...** button – allows the user to export the selected analysis configurations to an **.acf** file. Users can then import the configurations into a different design type, or import them on a different machine.

Options Tab

Note	Options for Maxwell 2D, Maxwell 3D, and RMxprt design types are described below. Options for other design types, such as HFSS, are described in the *Ansys Electronics Desktop Help*.

The Options tab in the **HPC and Analysis Options** dialog contains design type specific options. These options are not part of an analysis configuration: instead they are always in effect for the given design type when the following is true:

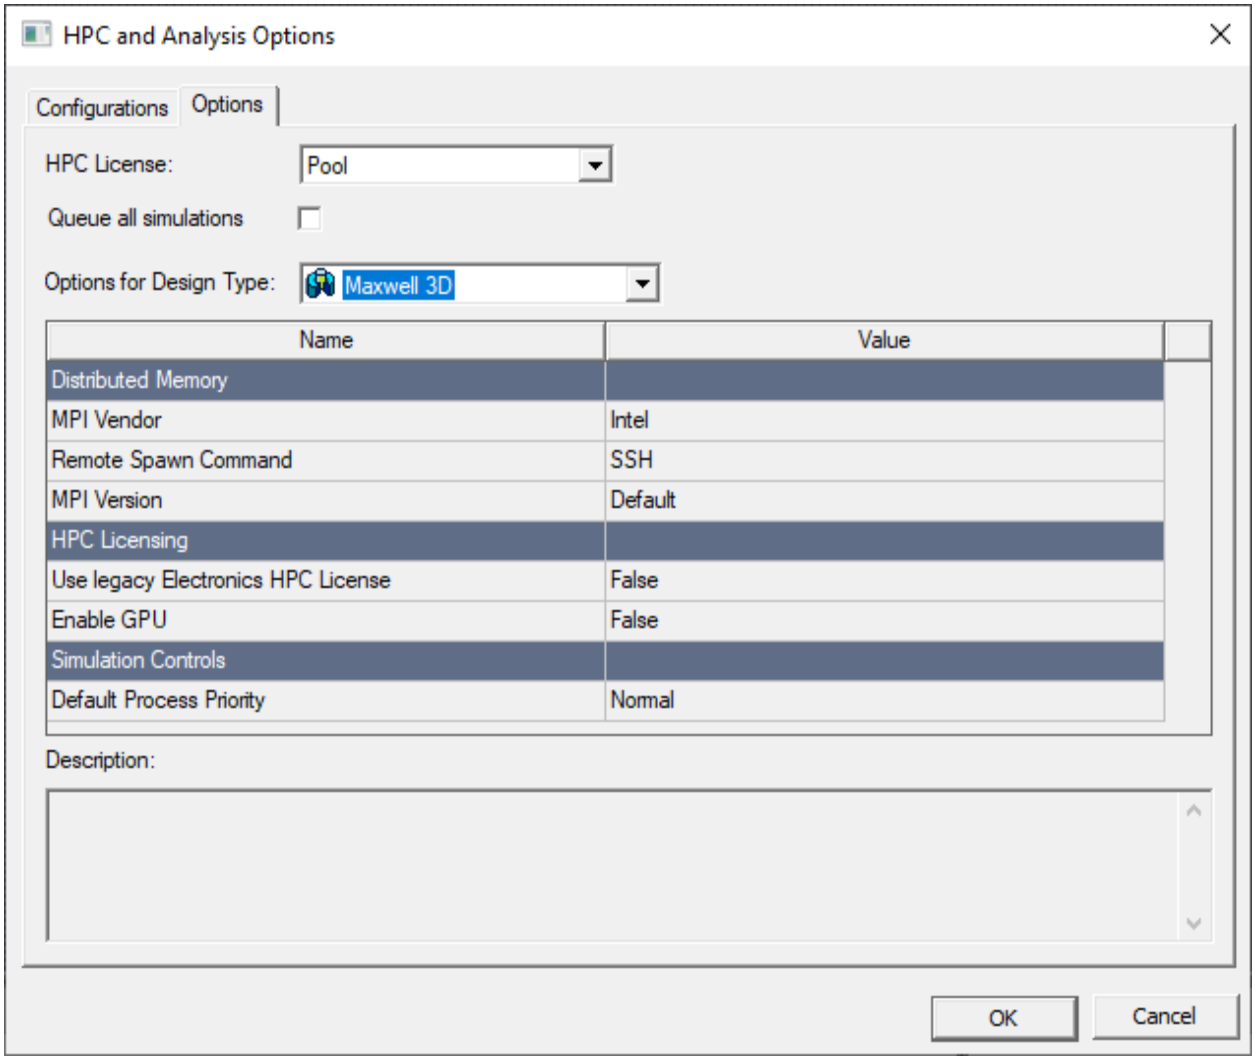
- A design of the matching design type is being solved
- You have not specified corresponding overriding batch options on the command line.

In the **Options** tab you can enable queuing by clicking the **Queue all simulations** check box, and set the design type.

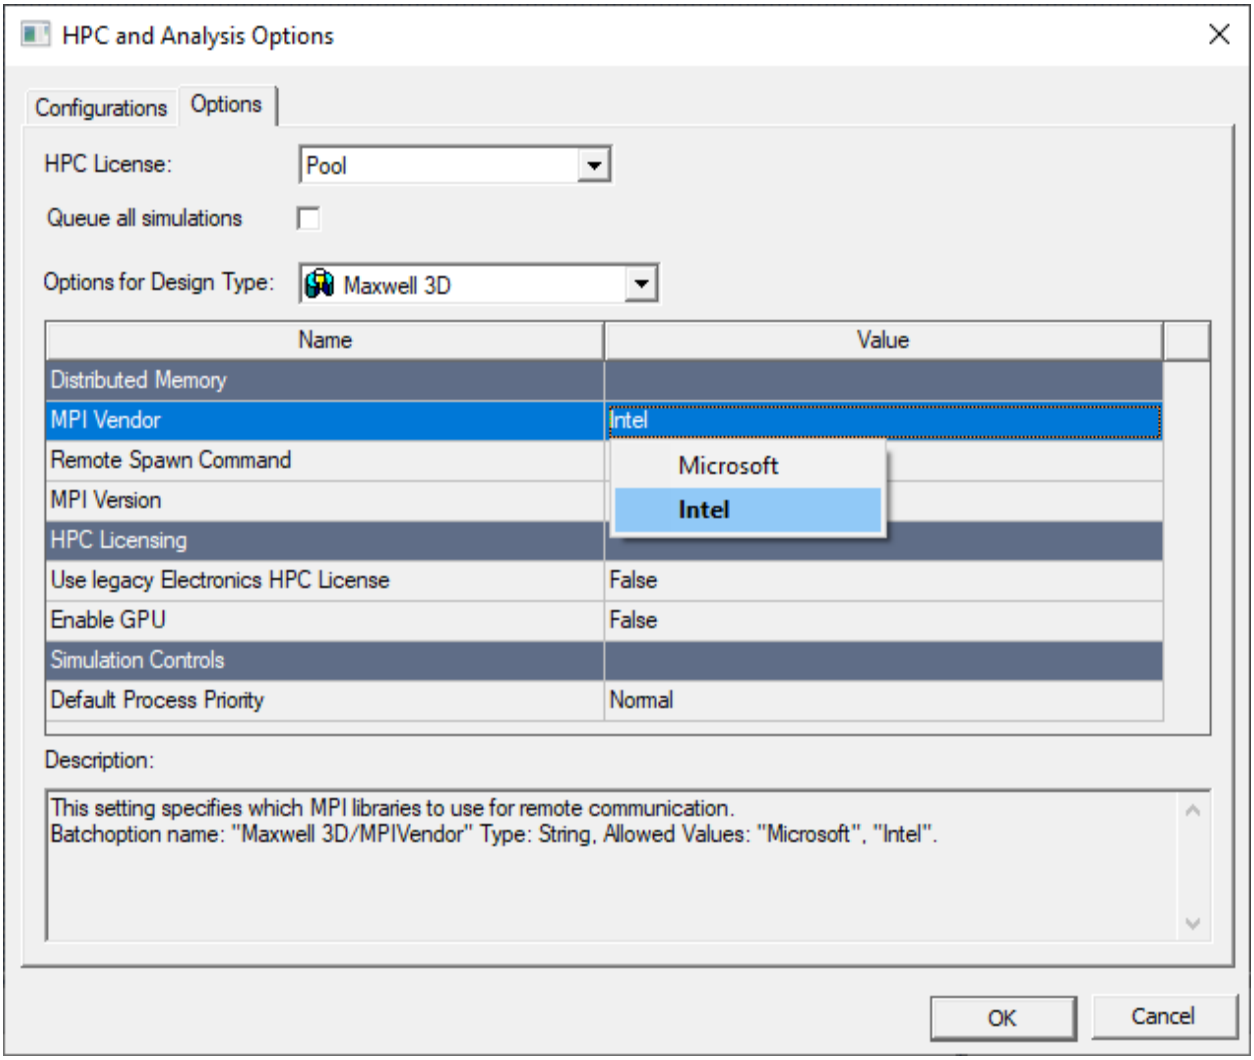
- For Maxwell 2D and 3D design types, you can specify the Distributed Memory MPI (Message Passing Interface) vendor, specify the Remote Spawn Command, set the HPC license type, and set the Default Process Priority.
- For the Maxwell 3D design type only, you can also Enable GPU (if installed) for Eddy Current solves.
- For the RMxprt design type, you can only set the Default Process Priority.

Solving on a single Windows machine does not require MPI installation; and users running on Linux do not need to install MPI manually.

If the **Queue all simulations** check box is selected, the Desktop queues any active simulations for design types that have **Save before solving** turned off in **General Options** and then processes them in order. You can view and change the queue by using Show Queued Simulations.



2. For Distributed Memory options, use the drop-down menu to select the MPI Vendor for the selected Design type.



The solvers use the standard Message Passing Interface (MPI), and can perform solutions that distribute memory use across machines in a cluster or network. Memory used by the MPI-enabled solver is therefore limited by the set of machines that are available rather than the shared memory available on any single machine. This allows you to simulate larger structures, and to optimally reconfigure the cluster of machines for the problem at hand. For solving on a single machine, MPI is not required, nor does it provide an advantage.

To use the distributed memory solution you must install MPI software from one of the supported third party vendors on all the machines you intend to use.

You may need to set passwords depending on the MPI vendor for authentication on the machines. Settings within each design type turn on distributed memory solutions and define the list of machines you intend to use.

You can also specify the MPI version. If not specified, then the default version for the MPI vendor will be used. This setting is ignored if there is only one supported version for the selected MPI Vendor. Multiple versions are only supported for Intel MPI, as follows:

- The value "Default" indicates that the default Intel MPI version should be used. This is Intel MPI 2018 in most cases.
- The value "2018" indicates that Intel MPI 2018 should be used.
- The value "2021" indicates that Intel MPI 2021 should be used.

InfiniBand Support for Windows

By default, the MPI vendors use the fastest interconnect (typically InfiniBand is faster than Ethernet). If you want to override the default behavior and force the use of Ethernet, you can set the **ANSOFT_MPI_INTERCONNECT** environment variable to **eth** for the job.

3. For Linux authentication, you can specify the Remote Spawn Command as RSH or SSH (the default).
4. For **HPC License** select either the **Pool**, **Pack** or **None** license option.

   HPC licensing enables the use of cores and GPUs to accelerate simulations. In general, each core requires one unit of HPC, while each GPU requires eight units. The selected HPC license type determines which license is used, and how units of HPC are converted to license counts.

   - **Pool** - One HPC pool license enables one unit of HPC.
   - **Pack** - One HPC pack license enables eight units of HPC. Additional packs multiply by four, enabling 32, 128, 512, etc., in the context of a single simulation.
   - **None** – Disables the use of HPC in some scenarios (see below). Since the Electronics Pro, Premium, Enterprise (PPE) products (the default in General Options: Desktop Configuration) use HPC to enable all parallel and distributed simulations, the **None** option is not shown under **HPC License** when using PPE.

   The Electronics Desktop products include four units of HPC for each licensed simulation. This means that up to four units can be used without requiring HPC licenses; license counting will begin with the fifth unit. For example, a simulation that uses 36 cores requires 32 HPC units after subtracting the four included cores. This simulation will check out 32 HPC pool licenses, or two HPC pack licenses.

   When using traditional Electronics product licensing, variations are distributed via the Distributed Solve Option (DSO). Distributing N variations requires N-1 licenses of DSO. The HPC units are then calculated on a per variation basis. In other words, the HPC licenses will enable HPC for a single variation, and then DSO extends this HPC to all distributed variations. If you do not have HPC licenses, choose **None** under **HPC License**. You can still use DSO to distribute variations, with up to the four included HPC units per variation.

   A significant advantage of the Electronics Pro, Premium, Enterprise products is that the HPC products enable all parallel and distributed simulations, *including distributed variation*s. As a result, DSO licenses are not compatible with the PPE products.

   When the PPE option is enabled, HPC licensing is used to enable all cores, GPUs, and distributed tasks. DSO is no longer used to distribute Optimetrics variations, as it was under the traditional product licensing model. ACL license sharing context manages license sharing of Electronics products. This allows design point (variation) distribution for external tools (WorkBench and optiSLang) to be based upon HPC licensing. A single set of solve

and level licenses are checked out, instead of a set of solve and level licenses being checked out for each distributed design point. License sharing can be between applications (for example, Siwave and 3D layout), between designs (for example, datalink, cosim and dynamic link) and within a design (for example, distributed variations). The sharing context will always be used when the Pro, Premium, Enterprise (PPE) license model is active, and will never be used when PPE is not active.

In prior releases, a distributed parametric with a HPC config of [3 tasks, 16 cores] always required 20 hpc-pool, even when there are only 2 variations to be solved. With ACL context, license checkouts are on-demand and distributing 2 variations with [3 tasks, 16 cores] only checkouts 11 hpc-pool. With ACL, enabled by PPE, required licenses are held for the full course of a simulation. The value of this improved behavior can be amplified in a cluster simulation of large Optimetrics.

For externally driven solves: the driving application creates a context and all instances of Electronics Desktop run under that context. This means that PPE and solve licenses will only incur a single checkout. HPC checkouts are distributed and done on demand.

For WB - Each instance is counted as a single variation using a single core. Behavior should be the same as in earlier versions.

For LSDSO - A context is passed through different levels of desktopjob down to the ansysedt.exe. Behavior should be the same as earlier versions with regard to license counts, except HPC checkouts are distributed and done on demand instead of being done in a single checkout.

For OptiSlang - Single PPE and solve license checkouts, and HPC checkouts distributed and done on demand.

For Remote solves: remote solves on different machines can all run under the same context. PPE and solve licenses incur a single checkout and HPC checkouts are done on demand.

For Twin Builder - PPE is not supported by Twin Builder. However, you can still select to use PPE licensing in an Electronics design (for example, Maxwell or HFSS) that is coupled to a Twin Builder design. When coupled with a Twin Builder simulation, electronics designs are expected to share its PPE licenses. For example, during a distributed variations simulation of the Twin Builder design, the electronics solve features that are requested in parallel should ey supported by HPC Parametric (8 ans_hpc per variation) instead of one copy of the solve feature per variation. For appropriate sharing of ans_hpc (pool and pack), Twin Builder stops using DSO to distribute variations when “use PPE” is selected.

For HPC Pool, distributing *N* variations requires 8**N* pool licenses and enables up to four HPC units per variation. Each additional *N* pool licenses will enable one additional HPC unit per variation. For HPC Pack, distributing *N* variations requires *N* pack licenses and enables up to four HPC units per variation. Each additional *N* pack licenses will enable 8, 32, 128, etc., additional HPC units per variation. Since the PPE products use HPC to enable all parallel and distributed simulations, the **None** option is not shown under **HPC License** when using PPE.

Solution setups with domains, such as transient designs using the Time Decomposition Method, always use HPC licensing. Even though domains are distributed and may use multiprocessing, they do not use distributed solve or multiprocessing licenses – all of this is included in the HPC licensing when solving domains.

When variations are not distributed, core capping is done by including the first four cores from the machine/task entries in the user specified hpc setup. If the first entry has four or more cores, then only that machine/task is included, with its cores capped at four. If the first entry has fewer than four cores, all of its cores are included, and cores from additional entries add in the same manner until the overall cap of four cores is reached.

Note	Do not select **None** if the simulation requires more than four cores HPC. For **None**, see step 5.

5. If you choose to opt out of HPC licensing by selecting None, the Ansys Electronics Desktop enables four cores for all solvers. The four cores are not limited to a single node, meaning that features such as distributed frequencies, DDM, and TDM can all be used without HPC licenses, as long as the total core count is four or less. The four cores scale with DSO. For example, a user with 2 DSO can distribute 2 variations with 4 cores each, for a total of 8 cores, without requiring HPC licenses.
6. The **Use legacy Electronics HPC License** option defaults to **True**, meaning that legacy HPC licenses are checked out by default. These licenses are reported in the log. If the option is set to **False**, then the anshpc and anshpce_pack licenses are checked out.
7. For 2D projects, select the **License model for distributed variations** as either **DSO** or **Solver**. The Optimetrics variations can be distributed by the solver licenses. One solver license will be consumed for each variation being solved in parallel.
8. Optionally, users with one HPC pack or 8 HPC pool licenses, and who have an NVIDIA® graphics card installed, can use GPU acceleration for Maxwell 3D Eddy Current designs. For details on the requirements for GPU use, see Using GPU Acceleration for Maxwell 3D Eddy Current Designs.

   To enable use of GPU acceleration, set **Enable GPU** to **True** in the HPC and Analysis Options dialog; and set **Use Automatic Settings** to **off** in the Analysis Configuration dialog box. The matrix solver automatically determines if all cores should be used, or if one GPU should be used to give the best performance. For example, if you specify 4 cores for the simulation, the 3D Eddy current solver will use 4 cores in parallel during matrix assembly while the matrix solver will use either 4 cores or 1 GPU.

	Name	Tasks	Cores	GPUs	RAM Limit (%)	Enabled
	localhost	1	4	1	90	☑

You can determine if a GPU is being used for acceleration by viewing the Solutions dialog box, Profile tab. If a GPU is successfully locked for use by the solver process, the profile shows the GPU's CUDA device ID and its name.

If the GPU is not used, the Profile indicates that, and the fallback to using the CPU cores.

Enable/Disable GPU Acceleration from the Command Line

GPU acceleration can be toggled by the -batchoptions command line argument:

```
EnableGPU =[0/1]
```

For example, the following command turns on GPU acceleration:

```
ansysedt.exe -batchsolve -batchoptions "Maxwell 3D/EnableGPU' =1"
projectname.aedt
```

When the GPU is Used:

- GPU must be enabled for Maxwell.
- Both Windows and Linux are supported.
- Only complex symmetric matrices can be solved by CUDA.
- Matrix must be large. By default, its dimension should be larger than 2,000,000.
- The times using CUDA and CPU only are estimated. If the GPU is faster, it will be used. If not, the solver will fall back to multi-core CPU.

Time Estimation for GPU and CPU Usage:

- Time estimation is based on the structure of the matrix, not just the dimension.
- The generation and model of GPU are considered. The newer the model is, the faster the GPU estimation is.
- The clock rate and number of cores of CPU are considered. The higher the rate is, and the more the cores there are, the faster the CPU estimation is.
- The faster device (either GPU or CPU) will be selected based on the estimated time.

Why the GPU May Not Be Used:

- The time estimation is based on the entire matrix, not just the size. Having larger matrices doesn't necessarily mean GPU will be used.
- The bandwidth does not necessarily determine usage either. It is possible to have two matrices of exactly the same size and bandwidth, one favoring GPU and the other CPU.
- If GPU is an older model while CPU is newer, the GPU may not be used.
- If CPU has a high clock rate, the GPU may not be used.
- If CPU has many cores, the GPU may not be used.

Multiple GPUs

When there are multiple GPU cards in the same machine, the first 3D eddy solver process locks the first GPU card available (that is, one that is not already locked or used by other processes, not used for display, etc.). The second process locks the second available card, and so on. If all cards are locked, the solver uses the CPU only.

9. Optionally, you can select one of the following from the Default Process Priority pull-down list:

   - Critical (highest) Priority (not recommended)
   - Above Normal Priority (not recommended)
   - Normal Priority
   - Below Normal Priority
   - Idle (lowest) Priority

   To edit configurations, see Editing Distributed Machine Configurations.

High Performance Computing (HPC) Integration

"Using GPU Acceleration for Maxwell 3D Solvers " on the next page

Specifying the Remote Spawn Command as RSH or SSH (Linux)

An important step in using a high performance cluster is setting up authentication across machines in such a way that the machines can be accessed without a password. By default Maxwell 2D and Maxwell 3D use SSH authentication on Linux to spawn commands on the remote machines but also supports RSH. The selection of which to use is made on the **Options** tab of the Tools>Options>HPC and Analysis dialog.

SSH

You will need to set up passwordless access to useMaxwell on a Linux cluster with SSH or RSH. In general, for SSH, this is accomplished as follows:

1. Verify that you have working SSH servers and clients on your machines.
2. Verify that the server will accept passwordless logins. You may need to edit the /etc/ssh/ssh_d file to allow RSAAuthentication and PubkeyAuthentication.
3. Generating keys on the client system using the ssh-keygen program. Do not use a passphrase so that you can access the machine without a password.
4. Copy the public key generated in step 1 from the ~/.ssh directory to the server. The easiest way to transfer the keys is to use the ssh-copy-id program. Alternately, you can use any file

transfer utility. If the server already has a list of existing keys for other clients add the new public key to the list.

5. Test the connection. Login to the client machine using the username that you used to create the identity keys. Open a new shell terminal and attempt to open an SSH login session. For example type: ssh 192.168.0.4 (where the IP address is the address of the machine you are attempting to connect to). The server should allow you to login without requesting a password.

RSH

If you choose to use RSH you will need to make sure RSH is installed on all the machines and set the machines up so that you are not prompted for a password. There are different ways to set up password-less RSH so be sure to see the documentation for your machines and network for detailed instructions.

Machine access using RSH without a password is often set up by editing the /etc/hosts.equiv file and adding entries for the hosts you would like to use without a password. This file lists hosts and users that are granted "trusted" access to the system.

If you look at the contents of the `/etc/hosts.equiv` file you should have something similar to the following:

```
job1.n1.com
job2.n1.com
job3.n1.com
```

The machines job1, job2 and job3 can connect without a password. You may also need to verify that the files /etc/hosts.allow and /etc/hosts.deny are empty. See your local documentation for detailed instructions and troubleshooting suggestions.

Using GPU Acceleration for Maxwell 3D Solvers

Maxwell 3D solvers can be accelerated by using an NVIDIA® GPU accelerator. Numerical factorization of symmetric matrices is supported for GPU acceleration.

You can also enable distributed GPUs for Eddy Current Frequency Sweeps.

Hardware Requirements

GPU acceleration for the Maxwell 3D Eddy Current solver has been developed for NVIDIA cards and is officially supported with the Tesla® series. NVIDIA Tesla cards are recommended for the best performance when using several cards on one machine to solve using HPC. The following cards are supported:

- NVIDIA Tesla K20c (both workstation and server)
- NVIDIA Tesla K40c (both workstation and server)
- NVIDIA Tesla K80 (server with GPU cooling solution only, 2 GPUs consume 2 Ansys HPC licenses)
- NVIDIA Quadro K5000, K5200, M6000
- NVIDIA Quadro K6000 (both workstation and server, will be slow in graphic processing when used for GPU acceleration)

Note	NVIDIA Tesla M2090 (Not supported in Release 17), a previous generation (code Fermi) GPU card, doesn't work for Workstation since it has no fan for active cooling, but rather needs a server with GPU cooling solution (passive cooling) similar to the NVIDIA Tesla K80.

To obtain the best performance, the GPU used for running simulation jobs should not be attached to any display. Only GPU cards with CUDA® Compute Compatibility 2.0 and above should be used. To improve the speedup of visualization, you should install the GPU card on a system with PCI-E 3.0 slots. A mixture of interface cards with lower PCI-E versions may result in the data not being transferred from GPU to CPU at the highest speed.

Setup for Windows

1. After you install GPU cards and Nvidia graphics drivers, you should be able to find the cards in Windows Display Manager**.**
2. Run `nvidia-smi.exe` at C:\Program Files\NVIDIA Corporation\NVSMI to check if GPU cards are installed successfully. (The executable `nvidia-smi.exe` should be available after the display driver is installed.)
3. To further set up the configuration of GPU cards, open a command window as an administrator.
4. To improve the performance of GPU acceleration, it is recommended that you turn off the Error Correction Code (ECC) support using the `-e 0` option of nvidia-smi.

   ```
   nvidia-smi.exe -e 0
   ```

   New ECC settings become effective only after system reboot.
5. (Optional) For remote execution of GPU accelerated jobs (e.g., through Windows Remote Desktop Connection or RSM options), it is necessary to turn on the Tesla Compute Cluster (TCC) mode using the `-dm 1` option of nvidia-smi.

   ```
   nvidia-smi-exe -dm 1
   ```

   New TCC settings become effective only after system reboot.

Note	• The above step is unnecessary if you run Maxwell 3D Eddy Current from a local machine. • Only Tesla cards support TCC. • You cannot run GPU accelerated jobs on remote GeForce and Quadro cards.

Setup for Linux

1. After you install an NVIDIA GPU card and graphics drivers, you should be able to find the card using the command:

   ```
   /sbin/lspci | grep -i nvidia
   ```

   You can also use the following command to check if a GPU card can be recognized by the system:

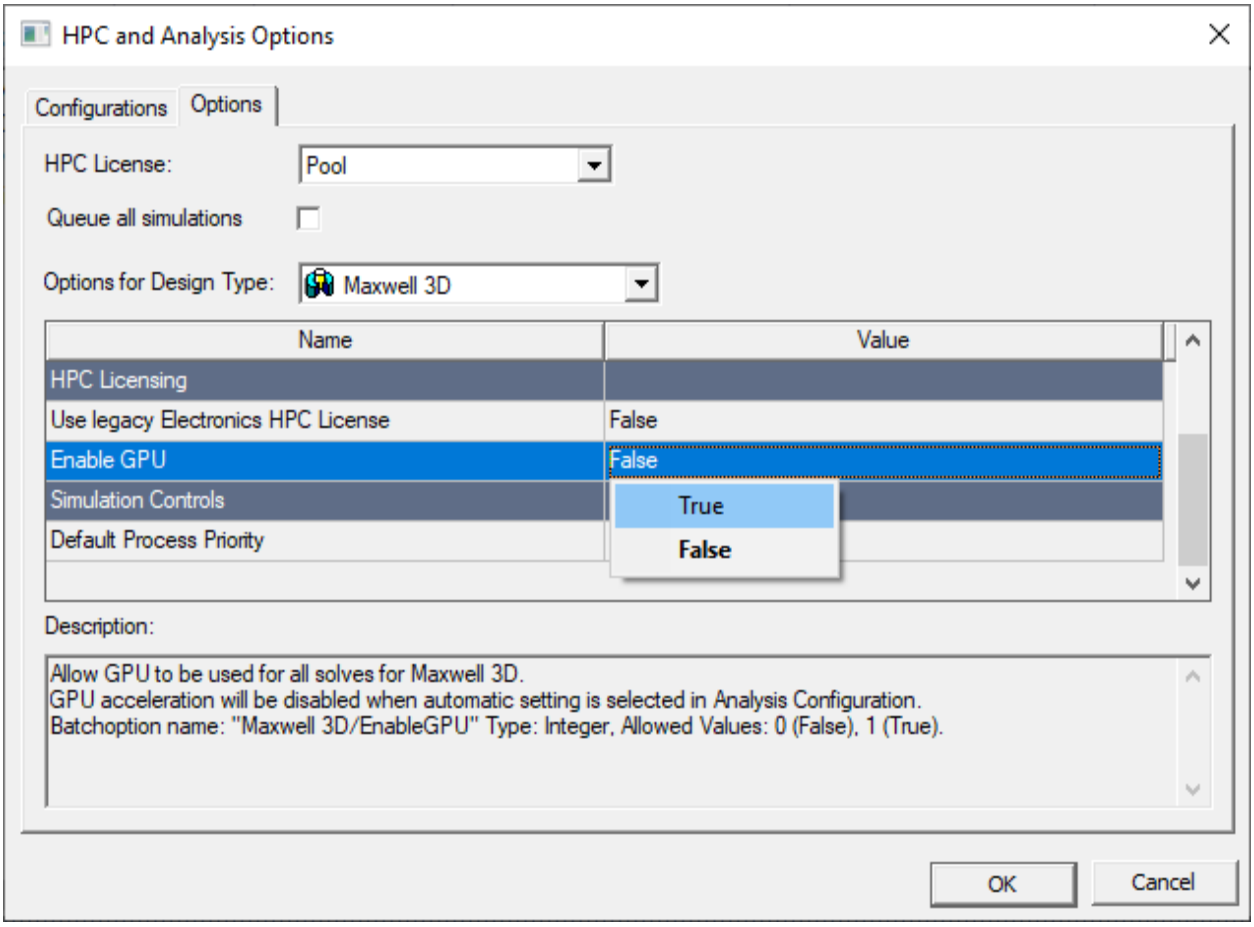
   ```
   /usr/bin/nvidia-smi
   ```

2. (Optional) The setting of GPUs to disable ECC (for performance), enable TCC (for remote execution), and enable Exclusive_Process (for GPU-distributed) are similar to Windows. You need the administrative rights to make such changes.

   ```
   sudo nvidia-smi -e 0
   sudo nvidia-smi -dm 1
   sudo nvidia-smi -c 3
   ```

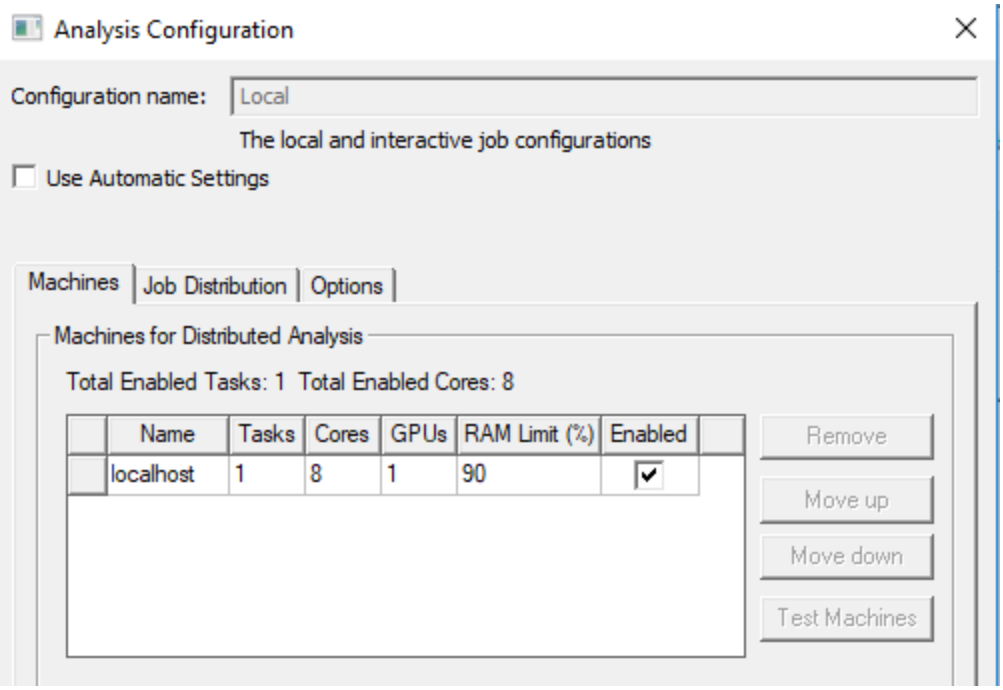
Enabling GPUs for Maxwell 3D solvers

1. Go to **Tools>Options>HPC and Analysis Options**.
2. In the Options tab, set the **Enable GPU** option to **True**.



Setting Up Non-distributed GPU for Maxwell 3D Solvers

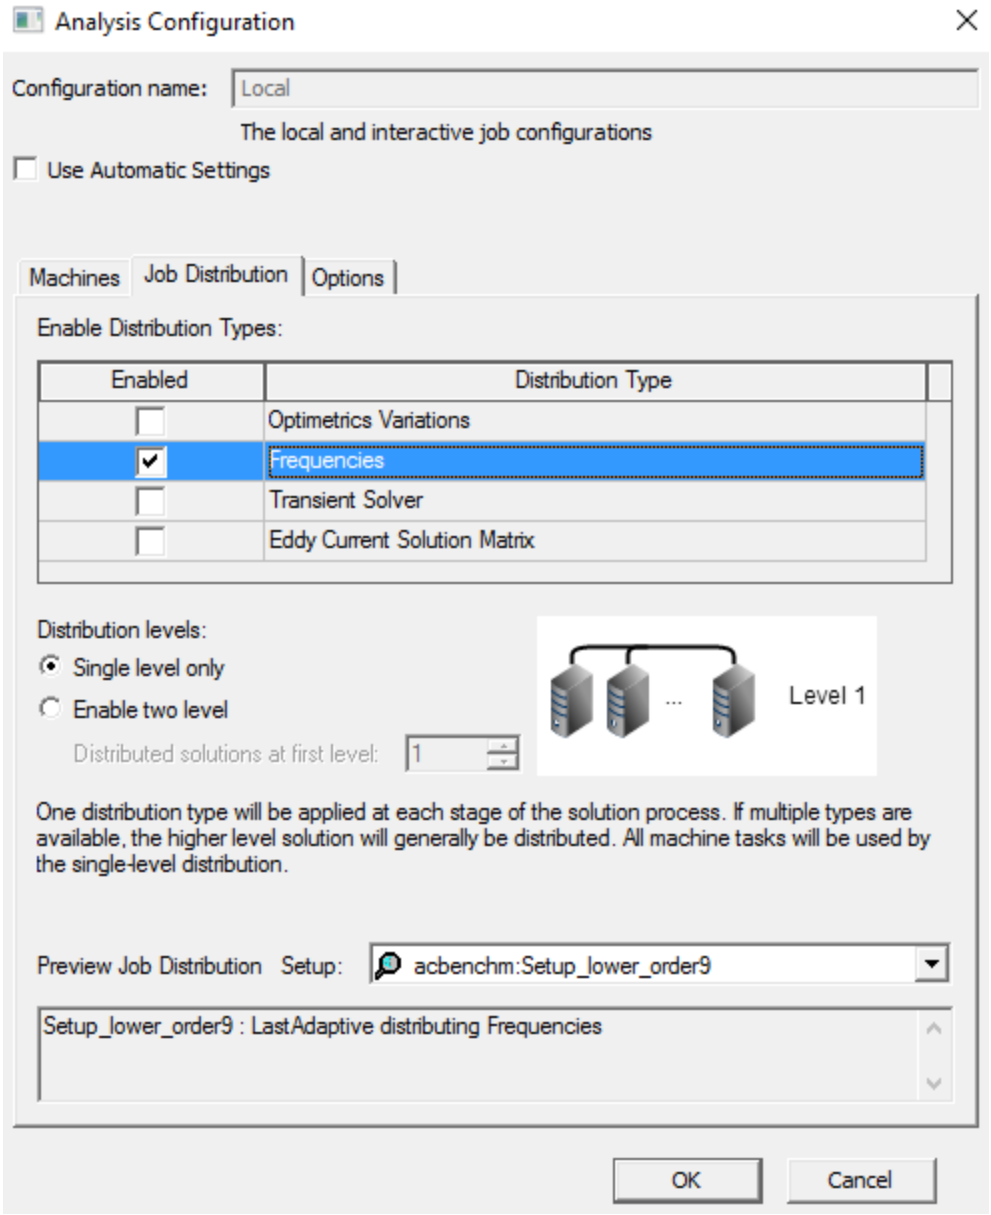
In the **Analysis Configuration** dialog box **Machines** tab, in the **Machines for Distributed Analysis** section, set **GPUs** to 1.



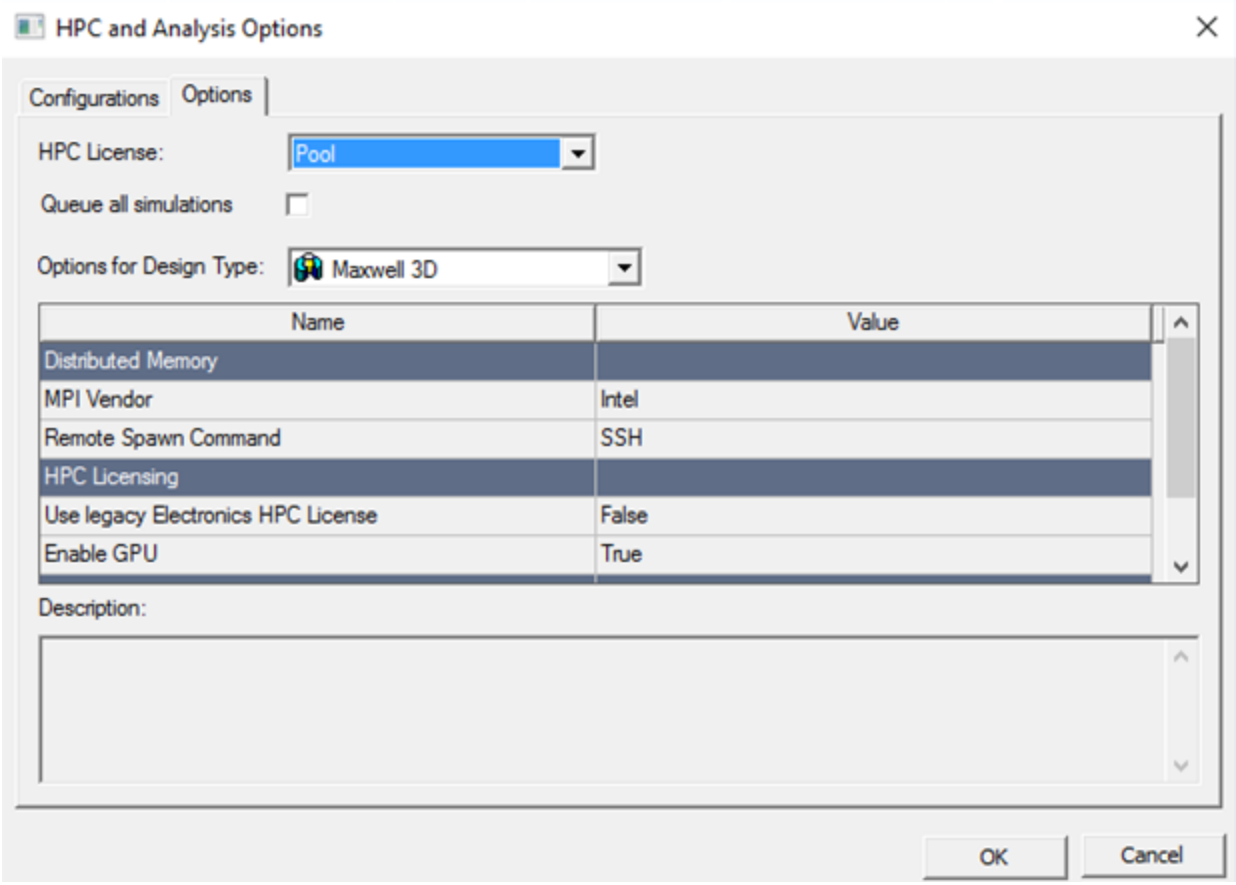
Enabling Distributed GPUs for Eddy Current Frequency Sweep

To set up distributed GPUs for eddy current frequency sweeps:

1. Go to **Tools>Options>HPC and Analysis Options** and click **Edit** in the dialog box, or select the **Simulation** tab of the ribbon, and click **Analysis Config** to edit Analysis Configurations.
2. Uncheck **Use Automatic Settings**, select the **Job DIstribution** tab, then select **Frequencies**.



3. Go to **Tools>Options>HPC and Analysis Options**, select the **Options** tab, and set **Enable GPU** to **True**.



4. Set up the Machines for distributed GPU usage.

   For example, the following figure shows two simulation jobs set to run on the local host; and up to two GPUs can be used for acceleration depending on the availability of licenses and GPU cards.

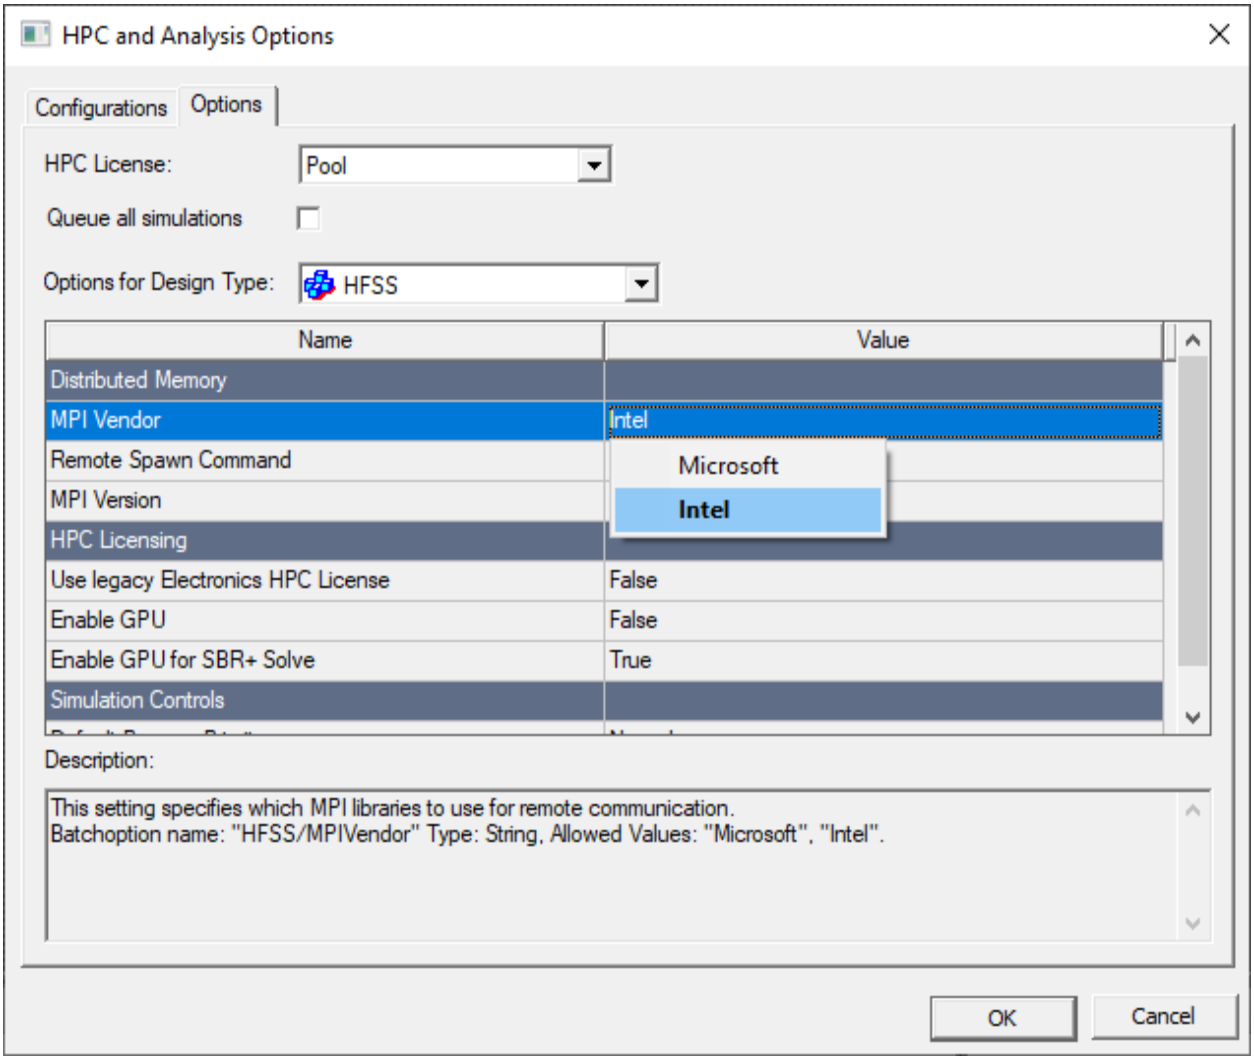
"Setting HPC and Analysis Options for Maxwell and RMxprt Designs" on page 4-54

Select the MPI Vendor

Aafter installing MPI on your machine from a particular vendor such as Microsoft or Intel, you need to set which type of MPI you are using: Microsoft or Intel. Go to the **Options** tab of the **HPC and Analysis Options** dialog box, and select the design type and the MPI Vendor type.



Maxwell 2D/3D Options

Select the **Options** page of interest:

Maxwell 3D Options

Maxwell 2D Options

Setting Maxwell 3D Options

To set Maxwell 3D options:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Maxwell 3D** to show the following choices: **General**, **Solution Type**, **Material Threshold**, **Boundary Assignment**.
2. On the **General** panel, select or clear the following check boxes:

- **Save before solving**

Note	When you enable the **Save before solving** setting, the project is saved only if it has been modified since its last save.

- **Save Optimetrics field solutions**
- **Apply variation deletions immediately**

3. On the **Solution Type** panel:
   - To change the default solution type when you initially insert a design, select one of the following from the **Default solution type** pull-down list: **Electrostatic**, **Magnetostatic**, **Eddy Current**, **Transient**, **DC Conduction**, **ElectroDCConduction**, **Electric Transient**, **TransientAPhiFormulation**.
4. On the **Material Threshold** panel, enter the **Default perfect conductor** and **Default insulator/conductor** values in siemens/m.

Note	Setting the material threshold affects the default setting for the current and all future projects/designs. To change the material threshold for the current design only, use the **Maxwell>Design Settings** command and change the material thresholds on the **Set Material Thresholds** tab.

5. On the **Boundary Assignment**panel, select or clear the following check boxes:
6. **Use Wizards for data input when creating new boundaries**

   When this is checked, the creation of boundaries and excitations use Wizards to guide you through the process. When this is not checked, the creation of boundaries and excitations displays a Properties dialog with tabs for different kinds of information.
   - **Duplicate boundaries/mesh operations with geometry**

     When this is checked, you can duplicate a boundary or excitation when its geometry is pasted or duplicated. See Duplicating Boundaries and Excitations.
   - **Visualize boundaries on geometry**

     When checked, enables visualization of boundaries on geometry.

Setting the Material Threshold

Report Setup Options

To set up general options for Reports

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Reporter** to expand the list and select **Report Setup**.
2. In the **Report Setup** panel, set the **Maximum number of significant digits to display in the reporter when displaying numeric quantities**.
3. In the **Drag and Drop** section, select either **Drag Item Data**, or **Drag Item Definition**.

4. The **Quantity selection** value specifies the matrix size for using a tree display for matrix quantities. This is helpful when dealing with larger matrices. The default is 50. When the number of matrix elements is larger than the number, the Quantities field uses a tree structure to divide matrix quantities into groups by their first element name. The initial display shows groups, without initially listing group members.

   A folder Node is not selectable. A click on a folder node toggles (Expand or collapse) the node. When any of a folder's child nodes is selected it becomes bolded.

   Mouse Click on Quantity Node (Tree leaf node). Shift and Ctrl key only apply to multiple selection dialogs:

   - Without Shift and Ctrl key – Select the quantity and unselect all previous selected quantities.
   - Only with Ctrl key down – Toggle the selection of the quantity. No effect on other selected quantities.
   - Only with Shift key down – Do range selection, deselect any selected quantity that is outside of the range.
   - Both Shift and Ctrl key down – Do range selection, but don't deselect any selected quantity.
   - Ctrl+a – Select all quantities in a multiple selections dialog.

   Range selection: Select quantity nodes between the last mouse clicked quantity node and the newly clicked-on quantity node. Folder nodes in between won't be selected but their children will be selected. So those folder nodes will be in a bolded state.

5. Click **OK**.

Setting Maxwell 2D Options

To set Maxwell 2D options:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Maxwell 2D** to show the following choices: **General**, **Solution Type**, **Material Threshold**, **Boundary Assignment**.
2. On the **General** panel, select or clear the following check boxes:
   - **Save before solving**

Note	When you enable the **Save before solving** setting, the project is only saved if it has been modified since its last save.

   - **Save Optimetrics field solutions**

- **Apply variation deletions immediately**
- **Generate model history when importing legacy 2D projects**

3. On the **Solution Type** panel:
   - To change the default solution type when you initially insert a design, select one of the following from the **Default solution type** pull-down list: **Magnetostatic**, **Eddy Current**, **Transient**, **Electrostatic**, **DC Conduction**, **AC Conduction**.
   - To change the default geometry mode when you initially insert a project, select one of the following from the **Default geometry mode** pull-down list: **XY**, **about Z**.
4. On the **Material Threshold** panel, enter the **Default perfect conductor** and **Default insulator/conductor** values in siemens/m.

Note	Setting the material threshold affects the default setting for the current and all future projects/designs. To change the material threshold for the current design only, use the **Maxwell>Design Settings** command and change the material thresholds on the **Set Material Thresholds** tab.

5. On the **Boundary Assignment** panel, select or clear the following check boxes:
   - **Use Wizards for data input when creating new boundaries**

     When this is checked, the creation of boundaries and excitations use Wizards to guide you through the process. When this is not checked, the creation of boundaries and excitations displays a Properties dialog with tabs for different kinds of information.
   - **Duplicate boundaries/mesh operations with geometry**

     When this is checked, you can duplicate a boundary or excitation when its geometry is pasted or duplicated. See Duplicating Boundaries and Excitations.

Setting the Material Threshold

Setting RMxprt Options

To specify settings for RMxprt options:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **RMxprt** to show the following choices: **General**, **Machine Type**, **Threshold**
2. In the **General** options panel, select or clear the following check boxes:
   - **Save before solving**

Note	When you enable the **Save before solving** setting, the project is only saved if it has been modified since its last save.

   - **Apply variation deletions immediately**
3. On the **Machine Type** panel, to change the default machine type when you initially insert a design, select one of the following from the **Default machine type** pull-down list:

- Three Phase Induction Motor
- Single Phase Induction Motor
- Three Phase Synchronous Machine
- Brushless Permanent-Magnet DC Motor
- Adjust-Speed Synchronous Machine
- Permanent-Magnet DC Motor
- Switched Reluctance Motor
- Line-Start PM Synchronous Motor
- Universal Motor
- DC Machine
- Claw-Pole Synchronous Machine
- Three Phase Non-Salient Synchronous Machine
- Generic Rotating Machines

4. On the **Threshold** panel, enter the **Default conductivity** and **Default permeability** values in siemens/m.

Note	Setting the material thresholds under **Tools>Options** impacts the default setting for the current and all future projects/designs. To change the material threshold for the current design only, use the **RMxprt>Design Settings** command and change the material thresholds on the **Set Material Thresholds** tab.

5. Click **OK** to close the dialog box.

Setting Report2D Options

To set Report2D options in Maxwell:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Reporter** to expand the list and select **Report2D** to display the following list:
   - Curve
   - Axis
   - Grid
   - Header
   - Note
   - Legend
   - Marker
   - Marker Table
   - X-Y Markers
   - Stacked
   - Digital
   - General
   - Table

For properties controlled by check boxes, you can set values for all curves by clicking the column header cell that contains the property title. Right-clicking on a text field cell displays a context menu that lets you cut, copy and paste values. Right-clicking on a menu cell displays a context menu that lets you copy and paste entire rows.

You can use a **Restore Defaults** button.

2. Click each list item, and make the desired selections.
3. Click **OK**.

Report 2D Options: Curve

These options are set on the **Curve** panel under **Report2D** in the **Options** dialog.

- **Line style** – select the options from the drop down menu. The options are Solid, Dot, Dash, and Dot dash.
- **Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Width** – set the line width by editing the real value in the text field.
- **Arrows** – use the check box to use arrows on the curve ends.
- **Symbol** – use the check box to have symbols mark the locations of data points on the curve.
- **Sym Freq** – set the symbol frequency by editing the integer value in the text field.
- **Sym Style** – select the symbol to display for the designated data points. The sym style can be box, circle, vertical ellipse, horizontal ellipse, vertical up triangle, vertical down triangle, horizontal left triangle, horizontal right triangle.
- **Fill Sym** – use the check box to set the symbol display as a solid or as hollow.
- **Sym Color** – set the color for the symbol by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.

Report2D Options: Axis

These options are set on the **Axis** panel under **Report2D** in the **Options** dialog.

- **Axis Name** – this describes the axis to which the following options refer.
- **Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Font color** – set the font color of the axis by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Edit Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Font Description** – displays the chosen font properties.

Report2D Options: Grid

These options are set on the **Grid** panel under **Report2D** in the **Options** dialog.

- **Grid Name** – lists the name or letter of the grid. Not editable.
- **Line Style** – select the options from the drop down menu. The options are Solid, Dot, Dash, and Dot dash.
- **Line Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.

Report2D Options: Header

These options are set on the **Header** panel under **Report2D** in the **Options** dialog.. For the Title and SubTitle, you can independently specify the following:

- **Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.

Report2D Options: Note

These options are set on the **Note** panel under **Report2D** in the **Options** dialog.

- **Note Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Note Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Background Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Background Visibility** – use the check box to toggle the background for the note on or off.
- **Border Line Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Border Visibility** – use the check box to toggle the visibility of the note border.
- **Border Line Width** – set the line width by editing the real value in the text field.

Report2D Options: Legend

These options are set on the **Legend** panel under **Report2D** in the **Options** dialog.

- **Show Trace Name** – use the check box to toggle the visibility of the trace name.
- **Show Solution Name** – use the check box to toggle the visibility of the solution name.
- **Show Variation Key** – use the check box to toggle the visibility of the variation key.

- **Text Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Text Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Background Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Border Line Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Border Line Width** – set the line width by editing the real value in the text field.
- **Grid Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.

Report2D Options: Marker

These options are set on the **Marker** panel under **Report2D** in the **Options** dialog.

- **Marker Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Marker Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Arrow Direction** -- set the arrow direction by choosing Up, Down, Left, or Right from the drop-down menu.

Related Topics

Modifying Markers on Point Plots

Report2D Options: Marker Table

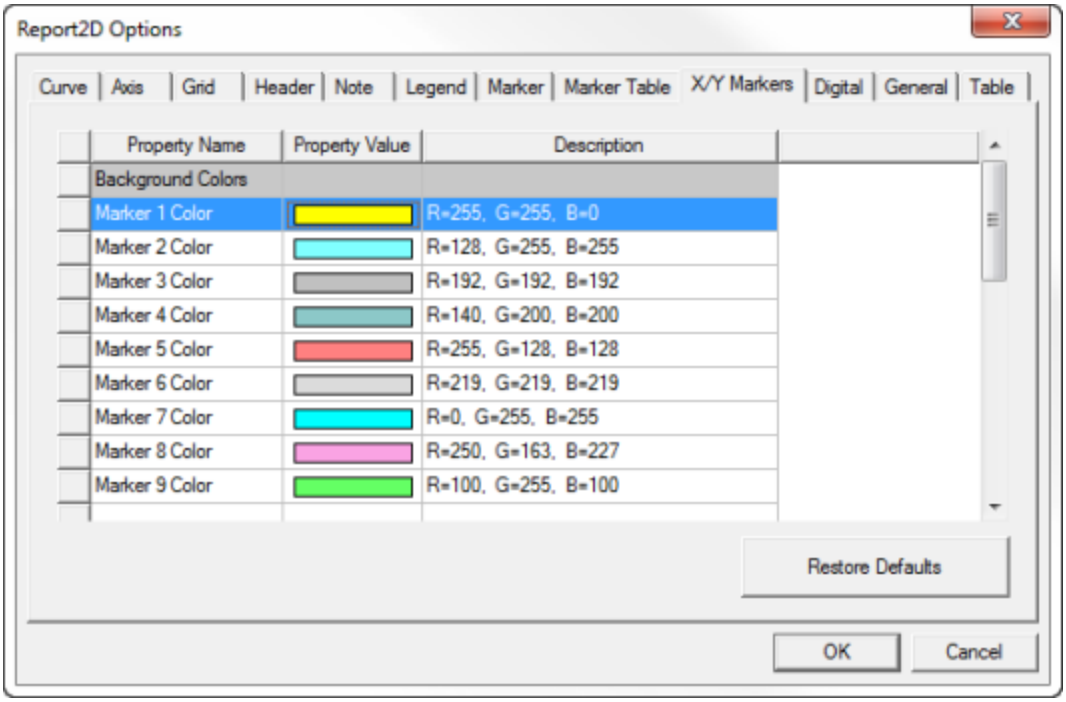
These options are set on the **Marker Table** panel under **Report2D** in the **Options** dialog.

- **Text Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Text Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Background Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Border Line Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Border Line Width** – set the line width by editing the real value in the text field.
- **Grid Color** – set the color by double clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Grid Line Width** – set the line width by editing the real value in the text field.

Report 2D Options: X-Y Markers

These options are set on the **X-Y Markers** panel under **Report2D** in the **Options** dialog.

You can set background colors for Markers 1 through 10 by clicking the current color to open a color selection dialog box.



In addition to marker colors, properties you can set include:

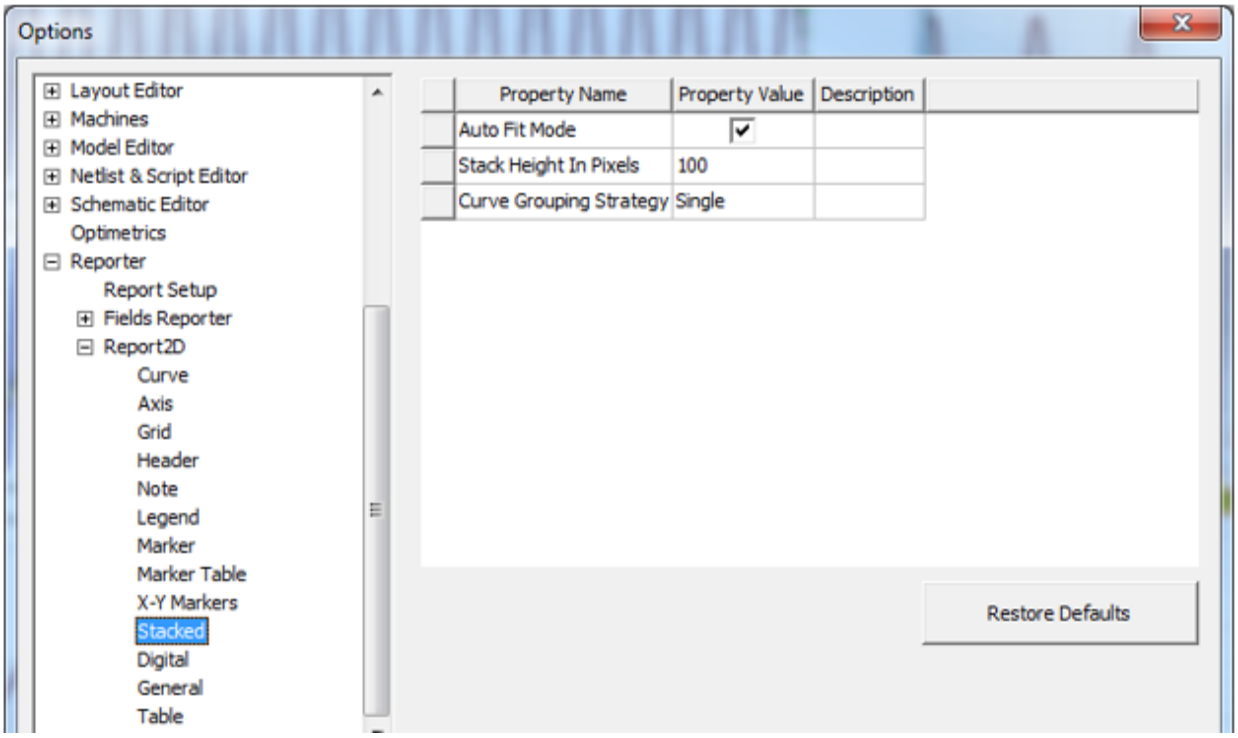
- On-screen intersection
- Marker Font
- Text color
- Line color
- Line style
- Line width
- Whether to Show Name
- Whether to Snap to Vertex

Inter marker delta properties include:

- Whether to show Delta
- Delta font
- Delta text color
- Line color
- Line style
- Line width

Report 2D Options: Stacked

These options are set on the **Stacked** panel under **Report2D** in the **Options** dialog.



- Auto Fit Mode – **On** or **Off**
- Stack Height in Pixels – sets the default stack height
- Curve Grouping Strategy -- can be **Single**, **By Trace**, or **By Units**. **Single** means that a new stacked plot shows a single curve per stack. **By Trace** means that all curves are grouped by their trace. **By Units** means that all curves are grouped by their unit type.

If you change the **Curve Grouping Strategy** set by default, existing stacked plots remain unaffected. The new default will apply only to new stacked plots.

When a project containing stacked plots saved in versions before 19.0 is opened in version 19.0, **Curve Grouping Strategy** will default to **Single** and the stacked plots remain unaffected.

Related Topics

Creating a 2D Rectangular Stacked Plot

Report2D Options: Digital

These options are set on the **Digital** panel under **Report2D** in the **Options** dialog.

- Digital Literal Foreground color
- Whether to Expand Arrays/Records

Digital Stack Height in Pixels can be set for the following:

- Analog
- Digital
- Enum
- Event
- Literal

Report2D Options: General

These options are set on the **General** panel under **Report2D** in the **Options** dialog.

- **Background Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Plot Area Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Highlight Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Accumulate Depth** – enter a value; the default is 4..
- **Enable Y Axis Stripes** – select the check box to add stripes to the Y axis; deselect to remove stripes.
- **Auto Scale Fonts** – on by default and when enabled scales text in plots and color key (contour plot, field plots in 3D modeler) for high resolution screens.

Curve Tooltip

- **Show Trace Name** – select the check box to display trace names in the tooltip when hovering the cursor over a curve.
- **Show Variation Key** – select the check box to display the variation key in the tooltip when hovering the cursor over a curve.
- **Show Solution Name** – select the check box to display the solution name in the tooltip when hovering the cursor over a curve.

Clipboard Option

- **Capture Aspect Size Ratio** – this can be As Shown or Full Screen.
- **Capture Background Color** – this can be As Shown or White.

Format

- **Field Width** – set the number of digits to display by editing the real value field.
- **Precision** – set the precision for marker placement by editing the real value field.
- **Use Scientific Notation** – use the check box to toggle scientific notation on or off.

Report2D Options: Table

These options are set on the **Table** panel under **Report2D** in the **Options** dialog.

- **Rows Per Page** – set to 2500 by default.
- **Text Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.

- **Text Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
- **Border Width** – set to 2 by default.
- **Border Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Grid Width** – set to 1 by default.
- **Grid Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Background Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Page Link Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Arrow Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Header Row** – use the following properties to set the header row format:
  a. **Text Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
  b. **Text Font** – click the cell to display the Edit Text Font dialog box. The dialog lets you select from a list of available fonts, styles, sizes, effects, colors, and script. The dialog also contains a preview field. **OK** the selections to apply the font edits and to close the dialog.
  c. **Background Color** – set the color by clicking to display the Set color dialog box. Select a default or custom color and click **OK**.
- **Format** – use the following properties to set the format:
  a. **Field Width** – set the table field width by editing the real value in the text field.
  b. **Precision** – set the table precision by editing the real value in the text field.
  c. **Use Scientific Notation** – use the check box to toggle scientific notation on or off.
- **Copy to Clipboard** – use the following check boxes to toggle the following properties for table copy operations:
  a. **With Header**
  b. **With Tab Separator**

Setting 3D Modeler Options

To set 3D modeler options:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options.
2. Click the + next to **3D Modeler** to display the following choices:
   - Drawing
   - Operation
   - Snap
   - Display

- Group
- SpaceClaim Link
- Advanced

2. Click each option, and make the desired selections.
3. Click **OK**.

3D Modeler Options: Drawing

These options are set on the **Drawing** panel under **3D Modeler** in the **Options** dialog.

1. The **Drawing Data Entry Mode** section controls whether you draw new objects directly via the mouse (**Point**), or whether a **Properties** dialog opens for you to enter dimensions for the object. The **Dialog** mode drawing feature works with the equation based line, and all two and three dimensional objects. You can also use **F3** to switch to Point mode and **F4** for dialog mode.
2. In the **Relative Coordinate System Creation Mode** radio buttons control whether the default uses **Axis/Position** or **Euler Angle** to create a new relative coordinate system. You can use the F3/F4 keys to switch between the modes.
   - For the **Axis/Position** setting, **Modeler> Create> Relative CS>[Offset | Rotated | Offet and Rotated]** enters **Draw** mode, displaying a point selection cursor and the **Measure Data** dialog box. Also the **Status** bar fields for setting X, Y and Z values, as **Coordinate System** settings are active.
   - For the **Euler Angle** setting, **Modeler>Create>Relative CS>[Offset | Rotated | Offset and Rotated]** displays a dialog in which you type in the needed values and select units.
3. In the **Polyline Creation** section, select or clear the **Automatically cover closed polylines** check box.

   By default, surface objects created with the **Polyline** command will be created with a cover so that they become sheet objects. You can choose to leave the polyline as an uncovered object to perform further operations prior to creating a sheet object
   - If checked, closed polylines become sheet objects, and are listed as such in the History tree.
   - If not checked, closed polylines are listed under lines in the History tree.
4. Select or clear the **Show measures dialog during drawing** check box. This specifies whether a Measure dialog appears on the creation of a new primitive. The dialog shows the coordinates of the current cursor position.
5. To have a Properties dialog display whenever you create a new object in the modeling window, check the box for **Edit properties of new primitives**.

3D Modeler Options: Operation

These options are set on the **Operation** panel under **3D Modeler** in the **Options** dialog.

1. By default, the modeler will delete tool objects when performing tasks such as Uniting, Subtracting, or Intersecting objects. The user may specify that the modeler should make a copy (clone) of the tool object prior to the operation, allowing the object to remain available for subsequent operations. To specify when to clone tool objects, select or clear the following check boxes in the **Clone** section:
   - **Clone tool objects before uniting**
   - **Clone tool objects before subtracting**
   - **Clone tool options before intersecting**
   - **Clone tool objects before imprinting**
   - **Clone tool objects before projecting**
2. In the **Coordinate System** section, select or clear the **Automatically switch to face coordinate system** check box.

   By default, the modeler operates within the user selected coordinate system. If this option is enabled, you can select a face and when a new object creation is started, the modeler first creates a face coordinate system consistent with the selected face and the new object is created within the face coordinate system. With this selection, unchecked, you must manually create a Face Coordinate System before creating an object related to it.
3. For the **Model Edit** section:
   - If **Delete invalid objects created during split operation** is checked, the modeler deletes invalid objects created during split operation. If not checked, invalid objects can be created. Validation issues warnings.
   - Select or clear **Automatically imprint wrapped sheets**.
4. In the **Model Save** area, you can enable/disable being prompted for model history cleanup. You can also specify the number of actions on a part that will cause a prompt. The default value is 50.

3D Modeler Options: Snap

These options are set on the **Snap** panel under **3D Modeler** in the **Options** dialog.

1. To specify snap settings, select or clear the following check boxes in the **Snap Mode** section:
   - Grid
   - Vertex
   - Edge Center
   - Face Center
   - Quadrant
   - Arc Center
2. Enter how near the mouse needs to be to click a grid item in the **Mouse Sensitivity** box, in pixels.

3D Modeler Options: Display

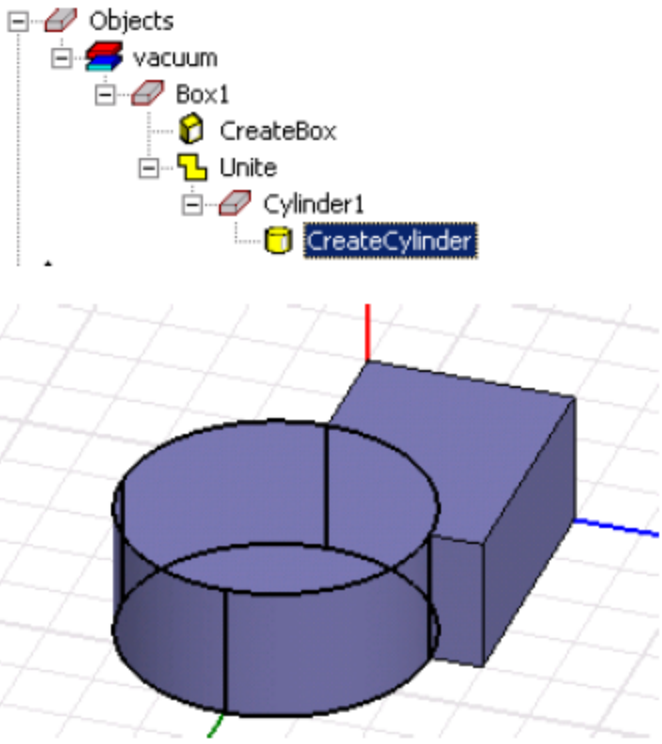
Under **3D Modeler** in the **Options** dialog box, the **Display** options settings are in three sub-groups:

- **General**
- **Rendering**
- **History Tree**

General

1. Under **Operations History Visualization**, select or clear the **Visualize history of objects** check box.

   This option lets you view an outline of each part that comprises an object when the given part is selected in the model history tree. This can help you visualize an object that has been merged with another object. A change to the option takes effect only when you restart Ansys Electronics Desktop. Clearing this selection removes visualization of objects that are part of the model history. For large models, this is faster and uses less memory. The following figure shows an example history tree with an object selected and the outline view of that object in the Main window.



2. Select or clear **Show coordinate system of selected operations**.

3. Under Selection:
    a. Select or clear the **Show orientation of selected objects** check box.
    b. Select or clear the **Highlight selection dynamically** check box. This option causes objects or faces (depending on the selection mode) to be highlighted when you pass the mouse pointer over them. You may want to turn this off for complicated models as it can reduce responsiveness. For large models, the dynamic highlighting option is automatically ignored, and a message is displayed.
4. Select or clear **Display UV Isolines for wireframe display**.

    For models with curved faces, you may prefer to clear this selection to simplify the wire-frame display, so the rendering will be faster.

Rendering

1. To specify a default color for a Modeler drawing object or action (such as on select):
    - Select the object or action from the **Default color** pull-down list. Then click the color button to open the **Color** window.
    - Select a color, and click **OK**.
2. To specify how to render an object, select **WireFrame** or **SmoothShade** from the **Default view render** pull-down list.

    When dealing with complicated geometries, choose **WireFrame** rendering. This is faster than shaded rendering.
3. To use pre-defined material appearance if available, check the **Use material appearance if available** box. When this option is selected, the default color and transparency used for newly created objects come from material settings. It is possible that some materials, like custom materials, may not have a default appearance specified, in which case the default color and transparency specified under **Object Appearance** are used.
4. To set the **Default transparency**, move the slider, or enter a numerical value.
5. To set the **Default color**, click the color button to open the **Color** window.
6. To set the **Show Object Outline** , use the checkbox. Unchecking shows the objects but without the outline.
7. To set the **Object Visualization Outline** contrast, use the slider.The current value, on a range from 0 to 1 displays in the text field.

History Tree

1. Under **Default tree layout**:
    a. Select or clear the **Group objects by material** check box. This feature is the same as selecting or clearing the **Group Objects By Material** toggle command from the **Modeler** menu.
    b. Select or clear **Group components by definition**.
2. Under **Selection**, for the **Select last command on object select** option:
    - If checked, the history tree is expanded after operations on object properties, even if the tree is collapsed for the item.

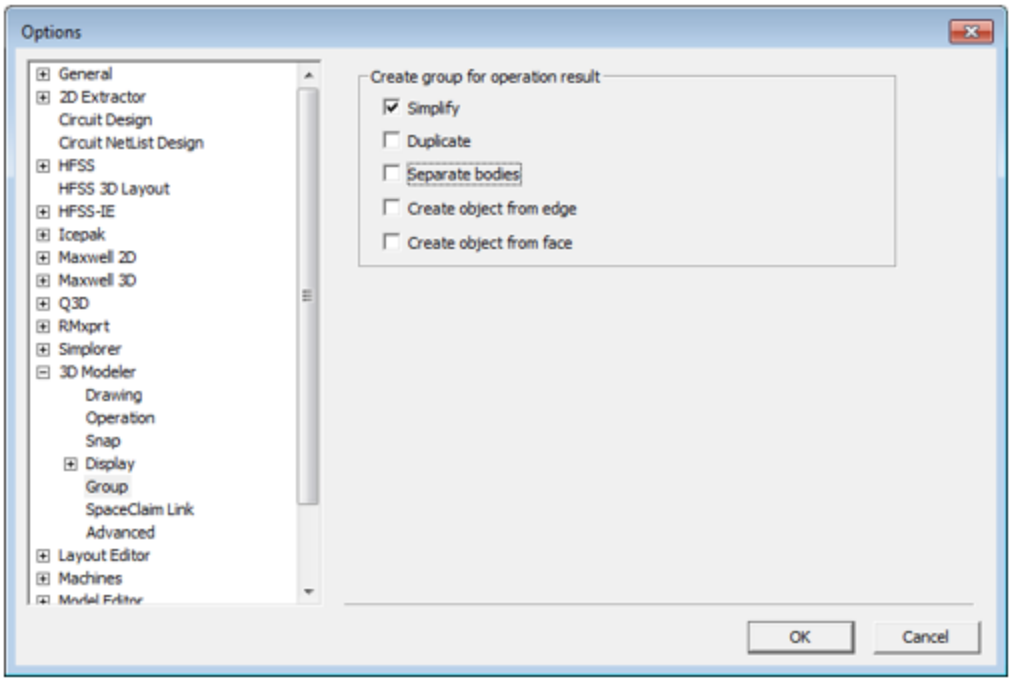
- If not checked, when you select an object in 3D view, only the object selected, and current tree collapse/expand state is preserved

3. Under **Selection**, for the **Expand history tree on object select** option:
   - If not checked, the history tree does not open on object selection. This can be useful for speeding the display of multiple object selections, or complex objects.
   - If checked, selecting an object automatically opens the history tree.

3D Modeler Options: Group Options

To set the Group creation for operation result settings for the 3D Modeler, use **Tools>Options>General Options** to open the **Options** dialog and select **3D Modeler**. Under **3D Modeler** options, select **Group**.

1. To specify Group creation for operation settings, select or clear the following check boxes in the **Snap Mode** section:
   - Simplify
   - Duplicate
   - Separate Bodies
   - Create object from edge
   - Create object from face



3D Modeler Options: SpaceClaim Link

These options are set on the **SpaceClaim Link** panel under **3D Modeler** in the **Options** dialog.

Import Options

- Select or clear **Import Solid Bodies**.
- Select or clear **Import Surface Bodies**.
- Select or clear **Import Parameters**, and enter the desired **Parameter Key**.
- Select or clear **Import Rendering Attributes**.
- Select or clear **Import Material Assignments**.
- Select or clear **Import suppressed for physics objects**. By default, this is unchecked and objects suppressed for physics are not imported.

3D Modeler Options: Advanced

These options are set on the **Advanced** panel under **3D Modeler** in the **Options** dialog.

Faceting

1. Select or clear **Incremental faceting (facet only modified faces of object)**.
2. Select or clear **Facet bodies by face using multiple processors**.

UDM/UDP Geometry Computation for Optimetrics Analysis

Select either **Engine computes the geometry** or **Desktop computes the geometry**.

Note	Geometry computation with CAD Integration (dynamic links) and geometry sharing in Ansys Workbench is always by Desktop.

Setting Fields Reporter Options

To set the **Fields Reporter** options:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Reporter** to expand the list and select **Fields Reported** to display the following list:
   - **Animation**
   - **Mesh Plot**
   - **Streamline Plot**
2. On the **Animation** panel:
   a. Specify whether to **Group Field Overlays by Type** (default, yes).
   b. Set the default Phase Animation settings for **Scalar Plots** and **Vector Plots.**

   Each of these accepts values for **From** and **To** in degrees, and the number of **Steps**.
3. On the **Mesh Plot** tab, in the **Clipping of volume mesh plot** section, choose the conditions under which the plot is updated dynamically while dragging the clip plane. Options are: **Never**, **Always**, and **When number of mesh element is less than** (default number is 50000).
4. On the **Streamline Plot** panel:

a. Set the **Streamline drawing stopping criteria.**
b. Set the **Streamline marker spacing** for the **Number of marker per bounding box diagonal**. The default value is 100.

Exporting Options Files

The options files at all levels that may affect a product running as a specific user on a specific host may easily be exported. You can export options files by selecting **Tools>Options>Export Options Files.** This brings up a browser dialog that you use to select the destination directory for the options files. Pressing the Cancel button will cancel the export command. Pressing the Open button will copy all of the config files for the current user and current host to the specified directory. Config files for the install, install_machine, user, and user_machine levels will be copied, if they exist. One additional file, admin.XML, will also be copied to the destination directory. This file does not contain user configurable options.

Setting Options via Configuration Files

> **Note:**
>
> Because Maxwell can interact with other Ansys products, the following sections on setting options via configuration files include examples and information applicable to various other Ansys products.

In addition to setting options from the Desktop UI, you can also set options in several configuration files.

Option settings in configuration files may apply to all users or only to a specific user, and may apply to all hosts or only to specific hosts. There are four levels, listed below from most specific (highest precedence) to most general (lowest precedence):

- Host-dependent user options (apply to the specified user on the specified host only)
- Host-independent user options (apply to the specified user on all hosts)
- Host-dependent default options (apply to all users on the specified host)
- Installation default (default for all users on all hosts)

A setting at any level will override settings at lower levels in the list above. If there is no setting in any file, the application default value will be used. See UpdateRegistry for instructions on selecting these levels.

> **Important:**
>
> Options set from the Desktop UI will override settings in configuration files.

Behavior Examples

Consider running an application as user **jsmith** on host **host123**. Also, assume the following conditions apply:

- There is no *host-dependent user setting* for the **Expand Project Tree on Insert** option in the *host-dependent user options* config file for user **jsmith** on host **host123**.
- But, the option exists in the *host-independent user options* config file for user **jsmith**.

In this situation, the latter setting is used (if it is not overridden using the Desktop UI). Any settings in the *host-dependent default options* config file or the *installation default* config file are ignored.

As another example, consider running an application as user **jdoe** on host **host123**. Also, assume that the following conditions apply:

- There is no setting for the **Expand Project Tree on Insert** option in the *host-dependent user options* config file for **jdoe** on **host123**.
- There is no setting in the *host-independent user options* config file for user **jdoe**.
- And, there is no setting in the *host-dependent default options* config file for host **host123**.

In this situation, the value from the *installation default* config file is used, if present.

Rules for Modifying Option Settings

Option settings displayed in the Desktop UI follow the above rules. That is, if there is a setting in any of the option config files, then the setting from the highest priority config file is displayed in the Desktop UI. If there is no setting in any of the option config files, then the global default value is used.

You can modify settings using the various **Options** dialog boxes accessed via the **Tools** > **Options** menu. If a dialog box is closed with the **Cancel** button, then changes made to any settings are discarded. If the dialog box is closed with the **OK** button, then any settings that have been changed become immediately effective. These changes are written to the host-dependent user options config file when you exit the Electronics Desktop application. The changed values written to this file are then used the next time that the application is launched by the same user on the same host. The Desktop UI option settings are not written to any of the other option config files.

Configuration File Locations

The configuration files for host-dependent and installation **default** options reside at: <*installation_directory*>\<*version*>\<*platform*>\config. The configuration files for host-dependent and host-

independent **user** options reside in a subfolder of the user's Documents folder (for Windows) or the user's HOME folder (for Linux). See the tables below for specific Windows and Linux file names and paths.

Products with Multiple Desktop Versions

For products that have multiple Desktop versions, each version has a separate user-specific **config** folder with a different value for <*ApplicationName&Version*> (the parent folder name). Simarly, each version has a separate **config** folder for the *host-dependent default* and *installation default* config files. This folder is under the path, <*InstallationDirectory*>\<*version*>\<*platform*>. See the tables below for specific Windows and Linux file names and paths.

Table of Directories and Files

The following table shows the directories and files, where the *Level Name* is the name used to describe an options config file when using the UpdateRegistry tool.

Config File	Level Name	File Name	Windows Directory Path	Linux Directory Path
host-dependent user options	user_machine	<*hostname*>_user.XML	%UserProfile%\Documents\Ansoft\<*ApplicationName&Version*>\config	$HOME/Ansoft/<*ApplicationName&Version*>/config
host-independent user options	user	user.XML		
host-dependent default options	install_machine	<*hostname*>.XML	<*InstallationDirectory*>\v<*version*>\Win64\config	<*InstallationDirectory*>/v<*version*>/Linux64/config
installation default	install	default.XML		

Note:

- ***<hostname>*** is the name of the computer on which the Electronics Desktop software is installed
- **%UserProfile%** is a Windows variable that represents the currently active user's profile (for example, C:\Users\JohnDoe)
- ***<ApplicationName&Version>*** is the product name (without spaces) followed by the four-digit year of the version, a decimal point, and the minor release number (such as ElectronicsDesktop2023.1)
- **$HOME** is the user's home directory on Linux
- ***<InstallationDirectory>*** is the root folder where the Electronics Desktop software is installed (typically, C:\Program Files\AnsysEM, on Windows, or /opt/AnsysEM, on Linux)
- ***<Version>*** is the last two digits of the product version's year followed by the minor release number, without a decimal point (such as 231)

The following table shows an example of specific file names and directory names for a typical Ansys Electronics Desktop installation on Microsoft Windows and on Linux. These are the files that apply to software version **2023 R1**, user "**jsmith**," and hostname "**host123**":

Config File	Level Name	File Name	Windows Directory Path	Linux Directory Path
host dependent user options	user_machine	host123_user.XML	C:\Users\jsmith\Documents\Ansoft\ElectronicsDesktop2023.1\config	/home/jsmith/Ansoft/ElectronicsDesktop2023.1/config
host independent user options	user	user.XML		
host dependent default options	install_machine	host123.XML	C:\Program Files\AnsysEM\v231\Win64\config	/opt/AnsysEM/v231/Linux64/config
installation default	install	default.XML		

Note:

As with the temporary file location configuration files, the settings in these options files have precedence in the following sequence: user_machine (highest precedence), user, install_machine, install (lowest precedence). The first time you start and then exit the application, the file at the "user_machine" level is created (<*hostname*>_user.XML). The other files are only created if you use the UpdateRegistry tool to specify an option at the "user," "install_machine," or "install" level. If the temporary directory is set to an empty string in a configuration file, then that setting is ignored.

Setting or Removing Option Values in Configuration Files: UpdateRegistry Command

UpdateRegistry is a command line tool used to modify option settings in the options config files. You can use this command to add, change or remove settings from any of the option config files. This tool is included in the installation directory of each product. This feature makes it easier for different users to use Ansys Electromagnetics tools installed on shared directories or network drives.

The UpdateRegistry command has multiple command line formats, as shown below.

The following command line options are *mutually exclusive*:

- `-Set`
- `-Get`
- `-GetKeys`
- `-Delete`
- `-FromFile`

UpdateRegistry -Set Command

This command is used to add or modify an option setting in an option config file. If the option config file does not exist, it will be created. If the setting does not exist in the specified config file, it will be added. If the setting already exists in the specified config file, then the value will be changed to the specified value.

Example:	`UpdateRegistry -Set -ProductName <name> -RegistryKey <keyPath> -RegistryValue <value> [ -RegistryLevel <level> ]`

Required:	<name>	The application or product name and version. For example, ElectronicsDesktop2023.1. If the name contains spaces, it must be quoted. The name can be found in the ProductList.txt file in the install directory: ...\AnsysEM\<version>\Win64\config\
	<keyPath>	The pathname of the option setting. This includes the same analysis-related registry keys and values that are displayed by the -batchoptions help. For example, Desktop/Settings/ProjectOptions/AnimationMemory
	<value>	The new value of the option, typically a string or a number. If the value contains spaces, it must be quoted.
Optional:	<level>	When specifying -RegistryLevel, this is a string denoting which config file to modify. One of: install, install_machine, user, and user_machine. If the level is not specified, the user_machine (host-dependent user options) file is modified.

UpdateRegistry -Get Command

This command is used to view an option value in an option config file. If the setting exists in the specified config file or files, then the value, the value type and the config file where the value was found will be reported. If no value is found, then that will also be reported.

Example:	UpdateRegistry -Get -ProductName <name> -RegistryKey <keyPath> [-RegistryLevel <level>]
Required:	<name> The application or product name and version. For example, ElectronicsDesktop2023.1. If the name contains spaces, it must be quoted. The name can be found in the ProductList.txt file in the install directory: \AnsysEM\<version>\Win64\config\
	<keyPath> The pathname of the option setting. This includes the same analysis-related registry keys and values that are displayed by the -batchoptions help. For example, Desktop/Settings/ProjectOptions/AnimationMemory.

Optional:	<level>	When specifying -RegistryLevel, this is a string denoting which config file to modify. One of: install, install_machine, user, and user_machine. If the level is not specified, then all config files are searched in order of precedence.

UpdateRegistry -GetKeys Command

This command is used to view the allowed key names for all of the option settings, or to view a subset of the key names that match a string. For each key displayed, the current value, if any, is also reported. If a key has a value in multiple config files, then only the highest precedence value is reported.

Example:	UpdateRegistry -GetKeys [<pattern>] -ProductName <name> [-Case]	
Required:	<name>	The application or product name and version. For example, ElectronicsDesktop2023.1. If the name contains spaces, it must be quoted. The name can be found in the ProductList.txt file in the install directory: \AnsysEM\<version>\Win64\config\
Optional:	<pattern>	If no pattern is specified, then all allowed key names are reported. If a pattern is specified, then only keys that match the pattern are shown. For example, Settings/Project. If the name contains spaces, it must be quoted. By default, the pattern match is case insensitive.
	-Case	If this command line option is specified, then the pattern match is case sensitive.

UpdateRegistry -Delete Command

This command is used to remove an option setting from an option config file. If the setting does not exist in the specified config file, the file will not be changed. If the setting exists in the specified config file, then it will be removed. A setting may need to be removed from an option config file, to allow the setting from a lower priority file to be used by the application.

Example:	UpdateRegistry -Delete -ProductName <name> -RegistryKey <keyPath> [-RegistryLevel <level>]

Required:	`<name>`	The application or product name and version. For example, ElectronicsDesktop2023.1. If the name contains spaces, it must be quoted. The name can be found in the ProductList.txt file in the install directory: \AnsysEM\<version>\Win64\config\
	`<keyPath>`	The pathname of the option setting. This includes the same analysis-related registry keys and values that are displayed by the -batchoptions help. For example, Desktop/Settings/ProjectOptions/AnimationMemory.
Optional:	`<level>`	When specifying `-RegistryLevel`, this is a string denoting which config file to modify. One of: install, install_machine, user, and user_machine. If the level is not specified, the user_machine (host-dependent user options) file is modified.

UpdateRegistry -FromFile Command

You can use this form of the UpdateRegistry command to set multiple key-value pairs from a file with a single UpdateRegistry command. You specify the -FromFile command line option. This option must be followed by a filename. The file may contain multiple entries, where each entry contains a registry key and a registry value. The key-value pairs are added to the registry level specified by the -RegistryLevel command line option; if no -RegistryLevel is specified, then the default registry level (user_machine) is used.

UpdateRegistry File Format

> **Note:**
>
> Functionality featured in the example(s) in this section applies to multiple design types.

The file format is similar to the -batchoptions file format. An example UpdateRegistry file is shown below:

```
    $begin 'AddEntries'
'TempDirectory'='C:/temp/AnsysEM'
'Desktop/Settings/ProjectOptions/HPCLicenseType'='Pool'
    $end 'AddEntries'
```

Additional notes on the file format:

- The file may contain an arbitrary number of entries, one per line.
- Leading whitespace on each line is ignored. Spaces or tabs may be used to make the file more readable.

Registry key pathname:

- The registry key pathname appears before the equal sign "=" on each line.
- Each registry key pathname must be enclosed in single quotes.
- This includes the same analysis-related registry keys and values that are displayed by the -batchoptions help.

Registry value:

- The registry value appears after the equal sign on each line.
- Integral registry values must not be enclosed in quotes.
- All other registry values are treated as strings, and must be enclosed in single quotes.
- The forward slash "/" may be used as a directory separator on Windows and Linux. The back slash "\" may be used as a directory separator on Windows only.
- The back slash "\" is used as an escape character in the value string. That it, this character removes the special meaning of the following character.
- The single quote character normally ends the value string. The back slash may be used to remove this special meaning, and include a single quote in the string.
- To use a back slash as a directory separator on Windows, it must be escaped. That is, a double back slash "\\" is used to denote a single directory separator.

Alternative UpdateRegistry File Format:

- Analysis Configuration File format, which is exported from the HPC and Analysis Options dialog box.

> **Note:**
>
> If a current registry does not exist, Ansys Electronics Desktop can detect earlier minor versions of same application on the same machine. If such a registry exists (and does not involve -help, -batchoptionhelp, IsBatchMode(), -regserver, -unregserver, running a script, or non graphical mode), a prompt displays allowing you to port the registry from an earlier version.

Example Uses for Export Options Features

The **Tools** > **Options** > **Export Options** feature is intended to make it easier for different users to use Ansys Electromagnetics tools installed on shared directories or network drives. This section

outlines some use cases enabled by this feature.

> **Note:**
>
> Functionality featured in the examples in this topic apply to multiple design types.

Options that Apply to All Users

In many cases, an Ansys Electromagnetics tool installation is administered and maintained by a single user or group and used by a number of other users or groups. The permissions of the Ansys Electromagnetics tool installation may be set so that the administrator may add, delete or modify files, but other users may only read or execute these files. The administrator may set the recommended option settings in the installation default config file and/or the host dependent default options config file. These config files reside within the installation directory hierarchy, and should generally have the same permissions as other Ansys Electromagnetics tool installation files. This allows that administrator to control these settings, but does not allow other users to add, remove, or change these settings.

Each user can override any of these settings, if needed. This may be done using the Desktop UI, which affects the host-dependent user options config file. It may also be done using the host-independent user options config file. If user has overridden an option setting in either of the user files, the user may revert back to the option settings provided by the administrator by removing the setting of the same option in the host-dependent user option config file and/or the host-independent user option config file.

For global defaults, the administrator may set a value in the installation default config file. These settings will to apply to all users on all hosts.

In some cases, there are significant differences between the capabilities of different hosts. The host-dependent default config file may be used to specify different default values on some hosts. Any setting in a host dependent default config file would affect all users running on the specified host. The installation default value is used if there is no value specified for the setting in the host-dependent default config file for the current host. Note that the host-dependent default config file is named <*hostname*>.xml, where *hostname* is the name of the host computer.

Example: Searching for a Registry Key Pathname

Both administrators and ordinary users may occasionally use the UpdateRegistry command line tool to add, change or delete settings. To use this tool, the registry key pathname must be known by the user. The -GetKeys option may be used to quickly search for a key pathname if some information is known about it. For example, if the administrator knows that there is a setting related to issuing warning messages when available disk space is low, but does not know the exact key name, the following command may list some of the keys related to disk space:

```
UpdateRegistry -GetKeys disk -ProductName
ElectronicsDesktop2023.1
```

This will display a list of all keys that match the string "disk" case insensitively.

Typical output may look like the following:

```
Registry keys matching pattern <disk> case insensitively:
```

```
Desktop/Settings/ProjectOptions/DiskLimitForAbort: value is <0>
at level <user_machine>
```

Example: Setting an Installation Default Value

The normal default for the Options/General/Desktop Performance/Warn when available disk space is less than setting is 0 MB. If the administrator is concerned that running out of disk space might be a common problem, the administrator could set the installation default for the warn setting setting to 1000 MB, for example. This limit would then apply to all users running on all hosts. The administrator could use the following command to change this setting for Ansys Electronics Desktop:

```
UpdateRegistry -Set -ProductName ANSYSElectronicsDesktop2023.1
 -RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort
 -RegistryValue 1000
 -RegistryLevel install
```

Example: Setting a Host-Dependent Default Value

For this example, assume that all hosts have two cores, except for three hosts: bighost1, bighost2, and bighost3, which have eight cores each. The administrator has set the Desktop/Settings/ProjectOptions/NumberOfProcessors option value to 2 in the installation default config file. The administrator may set the Desktop/Settings/ProjectOptions/NumberOfProcessors option value to 8 in the host-dependent default config files for the three hosts having 8 cores: bighost1, bighost2 and bighost3. The administrator may log in to host bighost1 and run the following command to change this setting for the host-dependent default options config file for host bighost1:

```
UpdateRegistry -set -ProductName ElectronicsDesktop2023.1
 -RegistryKey
Desktop/Settings/ProjectOptions/NumberOfProcessors
 -RegistryValue 8
 -RegistryLevel install_machine
```

To make this change for the other two hosts, the administrator would log in to bighost2 and bighost3, and run the same command on each of those hosts.

Example: Reverting from a User-Defined Option Value to the Administrator Default

Consider the case in which Electronics Desktop was installed and the administrator initially did not set a value for the Desktop/Settings/ProjectOptions/DiskLimitForAbort setting in the default installation config file. User jsmith (who always uses host jshost) wanted to be warned before disk space dropped to zero, so he set the Desktop/Settings/ProjectOptions/DiskLimitForAbort to 100 MB using the UI. This setting is recorded in the host dependent user options config file for host jshost and user jsmith. Now the administrator learns that many users are running into disk space issues, so that administrator sets the installation default value for the setting Desktop/Settings/ProjectOptions/DiskLimitForAbort to 1000 MB, as in the above example.

When user jsmith runs Electronics Desktop on host jshost, the disk limit is 100 MB, not 1000 MB, because the host-dependent user options config file overrides all of the other config files. User jsmith may revert to the administrator provided default by removing this setting from the host

dependent user options config file for host jshost and user jsmith. The following command may be run by user jsmith on host jshost to remove this setting:

```
UpdateRegistry -Delete -ProductName ElectronicsDesktop2023.1
 -RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort
 -RegistryLevel user_machine
```

If user jsmith had added a value for this setting to the host-independent user options config file, then user jsmith would also run the following command to remove this setting from the host-independent user options config file:

```
UpdateRegistry -Delete -ProductName ElectronicsDesktop2023.1
 -RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort
 -RegistryLevel user
```

User Options and the Update Registry Tool

When you change an options value using the Desktop UI, the new value is stored in the host-dependent user options config file. You can also use the UpdateRegistry tool to add or modify settings in the host-dependent user options config file. You cannot use the Desktop UI to remove settings from the host-dependent user options config file, however. You must use the UpdateRegistry tool to remove settings from the host-dependent user options config file.

If a user has not explicitly created a host-dependent user options config file or a host-independent user options config file, then when a user first runs an Ansys Electromagnetics tool on a host, all settings will come from the host-dependent default options config file or the installation default options config file. Any settings for another host in a host-dependent user options config file will not be carried over to the new host. This may be inconvenient if the user has preferred option settings that differ from the settings that apply to all users, especially if the user runs the Ansys Electromagnetics tool on a number of different hosts. In this case, the user may set these option values in the user's host-independent user options config file. Then, these option values will be used on all new hosts, overriding any values set by the administrator to apply to all users. Any changes made in the UI will only affect the user's host-dependent user options config file for the current host.

Getting a Value from a Specific Configuration File

Getting a Value Using Precedence Rules

Example of Removing a Host Dependent User Option Setting

Example Adding a Host Independent User Option Setting

Setting the Temporary Directory

Temporary Directory Configuration File Format

Example Temporary Directory Configuration File Format

Setting the Temporary Directory Using the GUI

Setting or Removing Temporary Directory Values in Configuration Files: UpdateRegistry Command

Getting a Value from a Specific Configuration File

In the previous example, the user jsmith may decide to check the Desktop/Settings/ProjectOptions/DiskLimitForAbort setting in the host independent user configuration file before making any changes to this setting. The following command may be used to quickly view this setting before making the change:

```
UpdateRegistry -Get -ProductName ElectronicsDesktop2023.1 -
RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort -
RegistryLevel user
```

Getting a Value Using Precedence Rules

In may cases, the user is more interested in the value of a setting that will be applicable when running the product than in the setting in a single configuration file. If the -Get option is used with no -RegistryLevel specified, then the value reported is the value found in the highest precedence configuration file. If the user jsmith is interested in the highest precedence value for the Desktop/Settings/ProjectOptions/DiskLimitForAbort setting, then the following command may be used to report this information:

```
UpdateRegistry -Get -ProductName ElectronicsDesktop2023.1 -
RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort
```

Example of Removing a Host Dependent User Option Setting

For this example, user **jsmith** always uses host **jshost** to run Electronics Desktop. At some point, **jsmith** set the Autosave interval in the **General Options** dialog box, **Project Options** tab to 1000 edits, and this value was written to the jsmith's host dependent user options config file for host jshost. Now, **jsmith** wants to remove this setting and return to the default value of 10. User **jsmith** may run the following command on host jshost to remove the **Desktop/Settings/ProjectOptions/AutoSaveInterval** option value from this config file:

```
UpdateRegistry -Delete -ProductName ElectronicsDesktop2023.1
-RegistryKey Desktop/Settings/ProjectOptions/AutoSaveInterval
-RegistryLevel user_machine
```

Setting the Temporary Directory

Example Temporary Directory Configuration File Format

Setting the Temporary Directory Using the GUI

Example Adding a Host Independent User Option Setting

Consider the case in which there is no value set for the **Desktop/Settings/ProjectOptions/DiskLimitForAbort** setting for all users. The default is then 0 MB. User **jsmith** uses a variety of hosts and wants to be warned whenever disk space drops to 250 MB on any host. User **jsmith** may use the following command to set the **Desktop/Settings/ProjectOptions/DiskLimitForAbort** option value to 250 MB for all hosts:

```
UpdateRegistry -set -ProductName ElectronicsDesktop2023.1
-RegistryKey Desktop/Settings/ProjectOptions/DiskLimitForAbort
-RegistryValue 250 -RegistryLevel user
```

Setting the Temporary Directory

Temporary Directory Configuration File Format

Setting the Temporary Directory Using the GUI

Setting the Temporary Directory

The temporary directory may be viewed or set using the Electronics Desktop user interface (UI), or from the command line.

To set the directory via the UI:

Navigate to **Tools** > **Options** > **General Options**. In the tree at the left side of the dialog box, expand the **General** branch and select **Directories**. Then, use the **Temp** field and **Override** check box to enter a desired directory path. Values set in this manner are written to the user_machine level configuration file for the temporary directory. If the **Override** check box is cleared, clicking **OK** changes the user_machine level setting for the temporary directory to an empty string. This enables settings from the next highest precedence configuration file. The file that provides the currently active temporary directory setting is shown under the **Temp** edit box.

To set the temporary directory from the command line, using the -batchoptions command line option. See: Running Ansys Electronics Desktop from a Command Line and -Batchoptions Command Line Examples.

The temporary directory may be configured with an installation default value, as well as a host-dependent default value, a host-independent user-specified value and a host-dependent user-specified value. Temporary directory settings are stored in different files from the other option settings. These files are located in the same directories as the configuration files for the other option settings. The following table shows the directories and files used to store temporary directory settings.

Config File	Level Name	File Name	Windows Directory Path	Linux Directory Path
Host-dependent, user-specific temporary directory	user_machine	<*hostname*>.cfg	%UserProfile%\Documents\Ansoft\<*ApplicationName&Version*>\config	$HOME/Ansoft/<*ApplicationName&Version*>/config
Host-independent, user-specific temporary directory	user	default.cfg		
Host-dependent, default temporary directory	install_machine	<*hostname*>.cfg	<*InstallationDirectory*>\v<*version*>\Win64\config	<*InstallationDirectory*>/v<*version*>/Linux64/config
Installation default temporary directory	install	default.cfg		

Note:

- **<*hostname*>** is the name of the computer on which the Electronics Desktop software is installed
- **$HOME** is the user's home directory on Linux
- **<*ApplicationName&Version*>** is the product name (without spaces) followed by the four-digit year of the version, a decimal point, and the minor release number (such as ElectronicsDesktop2023.1)
- **%UserProfile%** is a Windows variable that represents the currently active user's profile (for example, C:\Users\JohnDoe)
- **<*InstallationDirectory*>** is the root folder where the Electronics Desktop software is installed (typically, C:\Program Files\AnsysEM, on Windows, or /opt/AnsysEM, on Linux)
- **<*Version*>** is the last two digits of the product version's year followed by the minor release number, without a decimal point (such as 221)

As with other options, the settings in these files have precedence in the following sequence: user_machine (highest precedence), user, install_machine, install (lowest precedence). The installer creates the file at the "install" level (default.cfg). The first time you start and then exit the application, the file at the "user_machine" level is created (<*hostname*>.cfg). The other files are only created if you use the UpdateRegistry tool to specify an option at the "user" or "install_machine" level. If the temporary directory is set to an empty string in a configuration file, then that setting is ignored.

Related Topics

User Options and the Update Registry Tool
Example Adding a Host Independent User Option Setting
Example Temporary Directory Configuration File Format
Setting the Temporary Directory Using the GUI
Temporary Directory Configuration File Format

Temporary Directory Configuration File Format

This section describes the format of the Temporary Directory configuration files. The format is the same for files at all four levels: user_machine, user, install_machine, and install. These files are text files, so any text editor may be used to modify or create Temporary Directory configuration files.

An example temporary directory configuration file is shown below:

```
$begin 'Config'
```

```
tempdirectory='C:/TEMP/AnsysEM'
$end 'Config'
```

The temporary directory specified by this configuration file is C:/TEMP/AnsysEM.

Additional notes:

The string containing the pathname of the temporary directory must be enclosed in single quotes.

The forward slash "/" may be used as a directory separator on Windows and Linux. The back slash "\" may be used as a directory separator on Windows only.

The back slash "\" is used as an escape character in the tempdirectory string. That it, this character removes the special meaning of the following character.

The single quote character normally ends the tempdirectory string. The back slash may be used to remove this special meaning, and include a single quote in the string.

To use a back slash as a directory separator on Windows, it must be escaped. That is, a double back slash "\\" is used to denote a single directory separator.

On Windows, a UNC path normally begins with two back slash characters. In a tempdirectory string, each of these back slash characters must be doubled, so four consecutive back slashes "\\\\" are used in the config file.

UNC Example

Config file:

```
$begin 'Config'
tempdirectory='\\\\hostxyz\\TEMP\\abc'
$end 'Config'
```

Here hostxyz is a host with a sharename TEMP having subdirectory abc used as the Temporary Directory. This shows that four back slashes are required for UNC names and that back slashes used as directory separators must be doubled.

Single Quote Example

Config file:

```
$begin 'Config'
tempdirectory='C:/TEMP/ab\'cd'
$end 'Config'
```

Temporary directory is C:/TEMP/ab'cd. This shows how to include a single quote in a tempdirectory pathname. It also shows that forward slashes may be used as directory separators on Windows.

Related Topics

User Options and the Update Registry Tool

Example Adding a Host Independent User Option Setting

Example for Setting the Temporary Directory

Setting the Temporary Directory Using the GUI

As for other options, the Temporary Directory may be viewed or set using the Desktop GUI. In the **Tools>Options>General Options** dialog box, the Temp Directory setting appears in the Directories group box on the **Project Options** tab. Activating the **Override** check box allows you to enter a desired directory pathname in the edit box or to click on the [...] button to bring up a directory file browser dialog box, from which you can select a temp directory. Values set in this manner are written to the user_machine level configuration file for the Temporary Directory. If the **Override** check box is unchecked, then when the **OK** button is pressed, the **user_machine** level setting for the Temporary Directory is changed to an empty string. This enables setting from the next highest precedence config file. The config file which provides the currently active Temporary Directory setting is shown under the Temp Directory edit box in the **Project Options** tab of the **General Options** dialog box, if the **Override** check box is unchecked.

Setting the Temporary Directory From the Command Line

The temporary directory may be set from the command line, using the **-batchoptions** command line option. See Running Maxwell from a Command Line. The Batchoptions Command Line Examples section below includes examples that show how to set the Temporary Directory from the command line.

Setting or Removing Temporary Directory Values in Configuration Files: UpdateRegistry Command

The UpdateRegistry command line tool, described above, may be used to view, add, change or remove the Temporary Directory setting from any of the Temporary Directory config files. The registry key for viewing or modifying the Temporary Directory is TempDirectory. The -Get, -Set, and -Delete options are valid for viewing a Temporary Directory setting, adding or changing a

Temporary Directory setting, or deleting a Temporary Directory setting. The -GetKeys option does not list the Temporary Directory key.

User Options and the Update Registry Tool

Batchoptions Command Line Examples

The **-batchoptions** entries command line argument may be used to specify one or more batchoptions settings on the command line. To specify multiple entries using a single **-batchoptions** argument, the entries should be enclosed in double quotes. Alternatively, the batchoptions may be specified in a file using the **-batchoptions** <filename> command line argument format. In this case, the filename is an absolute or relative pathname of the file containing the batchoptions, as described above. The two approaches may not be combined: either all batchoptions must be in a file or all batchoptions must be specified explicitly on the command line.

Batchoptions File Format

Example -BatchOptions with -Remote (Windows)

Example -Batchsolve with -Machinelist (Windows)

Example -Batchsolve with -Machinelist (Linux)

Example -Batchsolve for Local (Windows)

Related Topics

Running Maxwell From a Command Line

Batchoptions File Format

> **Note:**
>
> Functionality featured in the example in this section applies to multiple design types.

An example batchoptions file is shown below:

```
$begin 'Config'
  'Desktop/ProjectDirectory'='C:/test/projects'
  'Desktop/Settings/ProjectOptions/NumberofProcessors'=2
$end 'Config'
```

Additional notes on the file format:

- The file may contain an arbitrary number of batchoption entries, one per line.
- Leading whitespace on each line is ignored. Spaces or tabs may be used to make the file more readable.
- The **Registry Key** appears before the equals sign (=) on each line and must be enclosed in single quotes ('). The registry key includes the key path and the name of the registry value.
- The registry value (or option value) appears after the equals sign on each line.
- Registry keys are case-insensitive.
- There are two supported types of registry values—string and integer:
  - Each **string** value must be enclosed in single quotes (').
  - Do **not** enclose **interger** values in quotes.
- For file paths within string values, the forward slash (/) may be used as a directory separator on both Windows and Linux systems.
- Alternatively, on Windows only, the customary backslash (\ ) may be used as a directory separator. However, in string values, the backslash is used as an escape code for indicating special characters that cannot be typed directly (such as \n for a new line). Therfore, if you use the backslash as a directory path separator, each instance must be doubled (\\ ). An example is: '\\\\host3\\temp\\Ansoft'. In this case, each double backslash is interpreted as a single backslash (\\host3\temp\Ansoft).
- The single quote character (') normally ends a string value. If you need to include a single quote (or apostrophe) within a string, use the backslash-apostrophe (**\'**) escape sequence. For example, the string '%UserProfile%/Documents/Ansoft/John\'s_Files', is interpreted as: %UserProfile%/Documents/Ansoft/John's_Files.

Example -BatchOptions with -Remote (Windows)

> **Note:**
>
> Functionality featured in the examples in this section applies to multiple design types.

In this example, we run a batch Maxwell analysis of project file project1.aedt which contains a 3D design. We want all temporary files and directories created in directory C:\temp\Maxwell instead of using the installation default for the Temporary Directory. We decide that the analysis will be done on a remote host, at IP address 12.34.56.78. Because of limited memory on the remote host, we decide to run the analysis using only a single COM engine. Because the remote host has four cores, we decide to use four processors for the analysis. We can use the **-Remote** option to specify that there will be a single remote COM engine.

Here is a sample command line for this analysis, where the project file \\somehost\projects\project1.aedt is located in a shared directory specified using a UNC path:

```
ansysedt -BatchSolve -Remote -Machinelist list=12.34.56.78
 -batchoptions "'TempDirectory'='C:/temp/Maxwell'
 'Desktop/Settings/ProjectOptions/NumberofProcessors'=4"
 \\somehost\projects\project1.aedt
```

An alternative is to use the **-Distributed** command line option. Because the -Machinelist list contains only one host, there is a single remote COM engine in this case also.

```
ansysedt -BatchSolve -Distributed -Machinelist list=12.34.56.78
 -batchoptions "'TempDirectory'='C:\\temp\\Maxwell'
 'Desktop/Settings/ProjectOptions/NumberofProcessors'=4"
 \\somehost\projects\project1.aedt
```

The second line of the first example shows that you can use the forward slash "/" as a Windows directory separator within option value 'strings'. In this case, it is used in the TempDirectory path. You can also use the customary backslash "\" as a Windows directory separator, but it must be doubled to "\\" because the backslash is also an escape character within parameter strings. This usage is demonstrated in the second line of the second example, again in the TempDirectory path.

Related Topics

Batchoptions Command Line Examples

Example -Batchsolve with -Machinelist (Windows)

Example -Batchsolve with -Machinelist (Linux)

Example -Batchsolve for Local (Windows)

Example -Batchsolve with -Machinelist (Windows)

Suppose that we want to run a batch Maxwell analysis of project file project1.aedt. Because all of our hosts have multiples of 2 cores, we specify that we will use two threads for multiprocessing for both the distributed (NumberOfProcessorsDistributed) and non-distributed (NumberOfProcessors) parts of the job. The analysis contains a sweep that will be distributed across three hosts, adam, bill, and charlie. The hosts adam and bill have four cores each, so we run two distributed COM engines on each of these hosts, each using two threads. Host charlie has only two cores, so we specify only one distributed COM engine on this host. This COM engine will also use two threads. We specify a desired RAM limit of 6 GB and a maximum RAM limit of 8 GB for this analysis. The RAM limits are specified in KB, so the desired RAM limit is 6291456 KB, and the maximum RAM limit is 8388608 KB.

Here is a sample command line for this analysis, where the project file \\dennis\projects\project1.aedtis located in a shared directory specified using a UNC path:

```
maxwell -BatchSolve -Distributed
-Machinelist list=adam,adam,bill,bill,charlie
-batchoptions "Maxwell/Preferences/MemLimitHard=8388608
Maxwell/Preferences/MemLimitSoft=6291456
Maxwell/Preferences/NumberOfProcessors=2
Desktop/Settings/ProjectOptions/NumberOfProcessors=2"
\\dennis\projects\project1.aedt
```

Related Topics

Batchoptions Command Line Examples

Example -BatchOptions with -Remote (Windows)

Example -Batchsolve with -Machinelist (Linux)

Example -Batchsolve for Local (Windows)

Example -Batchsolve with -Machinelist (Linux)

In this example, we run a batch Maxwell analysis of project file project2.aedt, which contains an Maxwell design. We have four identical hosts **host1**, **host2**, **host3**, and **host4** for analysis, and each host has 4 cores. We do not use multiprocessing for the distributed analysis, so **NumberOfProcessorsDistributed=1**. As each host has four cores, we specify multiprocessing using 4 threads for the non-distributed part of the analysis, so **NumberOfProcessors=4**. Because we do not use multiprocessing for the distributed analysis, we will run four distributed COM engines on each host, with a singe core available for each engine. As in Example 1, we specify a desired RAM limit of 6 GB and a maximum RAM limit of 8 GB for this analysis. The RAM limits are specified in KB, so the desired RAM limit is 6291456 KB, and the maximum RAM limit is 8388608 KB.

Here is a sample command line for this analysis, where the project file **/home/jsmith/projects/project2.aedt** is located in a shared directory:

```
maxwell -BatchSolve -Distributed
-Machinelist file=/home/jsmith/hosts/list2
-batchoptions "Maxwell/Preferences/MemLimitHard=8388608
Maxwell/Preferences/MemLimitSoft=6291456
Maxwell/Preferences/NumberOfProcessors=4
Desktop/Settings/ProjectOptions/NumberOfProcessors=1"
/home/jsmith/projects/project2.aedt
```

For this example, the hostnames are in the text file **/home/jsmith/hosts/list2**. Here are the file contents:

```
host1
host1
host1
host1
host2
host2
host2
host2
host3
host3
```

```
host3
host3
host4
host4
host4
host4
```

Batchoptions and Analysis Configurations in the Registry

Analysis configurations are used to specify machines and options for local, remote, and distributed analysis, including capabilities that are enabled by HPC licenses.

How Analysis Configurations are Stored in the Registry

A configuration contains information beyond the machine or machines to use for a solution. Examples are the number of processors to allocate to the analysis for each machine in the list, memory limits, directory locations for personal libraries and temporary files, and many other preferences.

Note:

- Options are arranged as keys and values (in a structure similar to the *Windows Registry*). However, these options are not a part of the *Windows Registry* but are separately stored and maintained by the Ansys Electronics Desktop software. For more information concerning the configuration files comprisisng the options registry, see the following topics:

  Setting Options Via Configuration Files
  Setting the Temporary Directory
- For access to options and functionality beyond what is directly accessible via the user interface or batch options, refer to the documentation of the **UpdateRegistry** tool. This tool is discussed in the following help topic and in the topics that follow it in the same branch of the product help:

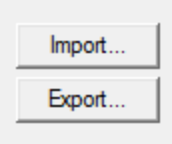
  Setting or Removing Option Values in Configuration Files: UpdateRegistry Command

General settings are associated with the Desktop application or 3D Editor. "HPCLicenseType" and "tempdirectory" values are at the root level of the registry. Other options are specific to a particular product or design type. For example, certain mesh, boundary, and memory limit settings as well as many other preferences are product-specific and are therefore associated only with the applicable design types. Such options appear with a consistent value name but in a different registry path for each applicable design type.

Copying a Configuration from one Design Type or Product to Another

To copy a configuration from one design type (or product) to another:

1. Click **Tools** > **Options** > **HPC and Analysis Options**. The *HPC and Analysis Options* dialog box appears.
2. On the **Configurations** tab of the **HPC and Analysis Options** dialog box, use the **Export…** button to export the configuration to a file.



3. Switch to the destination design type (or product) and use the **Import…** button to import the configuration data.

Any data that is not applicable to the destination design type is ignored; any settings present in the destination design type that were not present in the source configuration will be assigned default values. The user may then edit the copy, as desired.

Using HPC and Analysis Options for Configurations

Due to the complexity of the registry values for the configurations we do not recommend directly editing these values using the *UpdateRegistry* tool. Instead, use the **HPC and Analysis Options** dialog box to edit or create a configuration. (See: Setting HPC and Analysis Options.) Configurations created or edited using the GUI are stored in the **user_machine** level of the registry. You can create a configuration for one of the other registry levels the following steps:

1. Create the configuration using the Analysis Configurations GUI, then export the configuration to a file.
2. Delete the configuration using the GUI so that it will not be present in the **user_machine** level. Then, exit the GUI.
3. Use the **UpdateRegistry** tool to import the data into the desired registry level using the **-FromFile** option to specify the file exported via the GUI, and using the **-RegistryLevel** option to specify the registry level where the configuration is to be stored. For example, an administrator may use this approach to create a configuration at the **install** level that may be used by any user on any machine.

Batch Options

There is a large number of both general and product-specific options supported by the software. These options have evolved over time. Therefore, older batchoptions files may no longer be valid, and the options listed in the user interface of the current software may differ from earlier versions you have used. Additionally, there are options beyond those listed within the user interface (that is, the UI provides a subset of the available options). You can generate a more complete list of options by running the UpdateRegistry tool with the -GetKeys switch and piping the output to a text file, as detailed in the following Windows procedure:

1. In a command window, navigate to the following folder:

   <*installation_directory***>\v<***version***>\Win64**

2. Type and enter the following command:

   UpdateRegistry -GetKeys -ProductName ElectronicsDesktop20*xx.y* **>** <*text_file_path*>**\Batchoptions.txt**

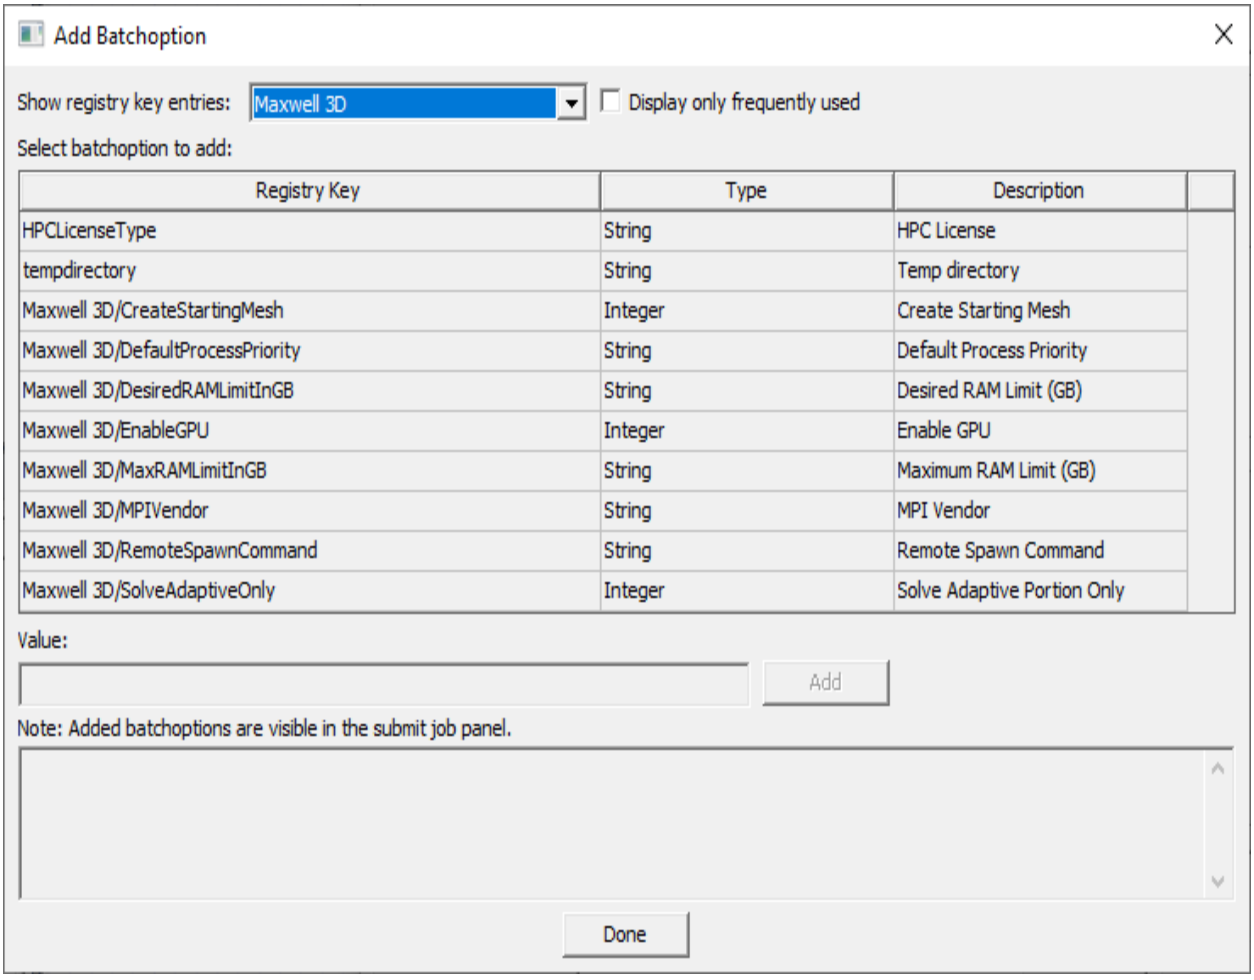
   Substitute the last two digits of the installed product version year and the minor release number for *xx.y* (such as **22.1**). Also, substitute the desired *text_file_path* (such as **%UserProfile%\Desktop**).

   The resulting **Batchoptions.txt** file will contain a nearly complete list of available options.

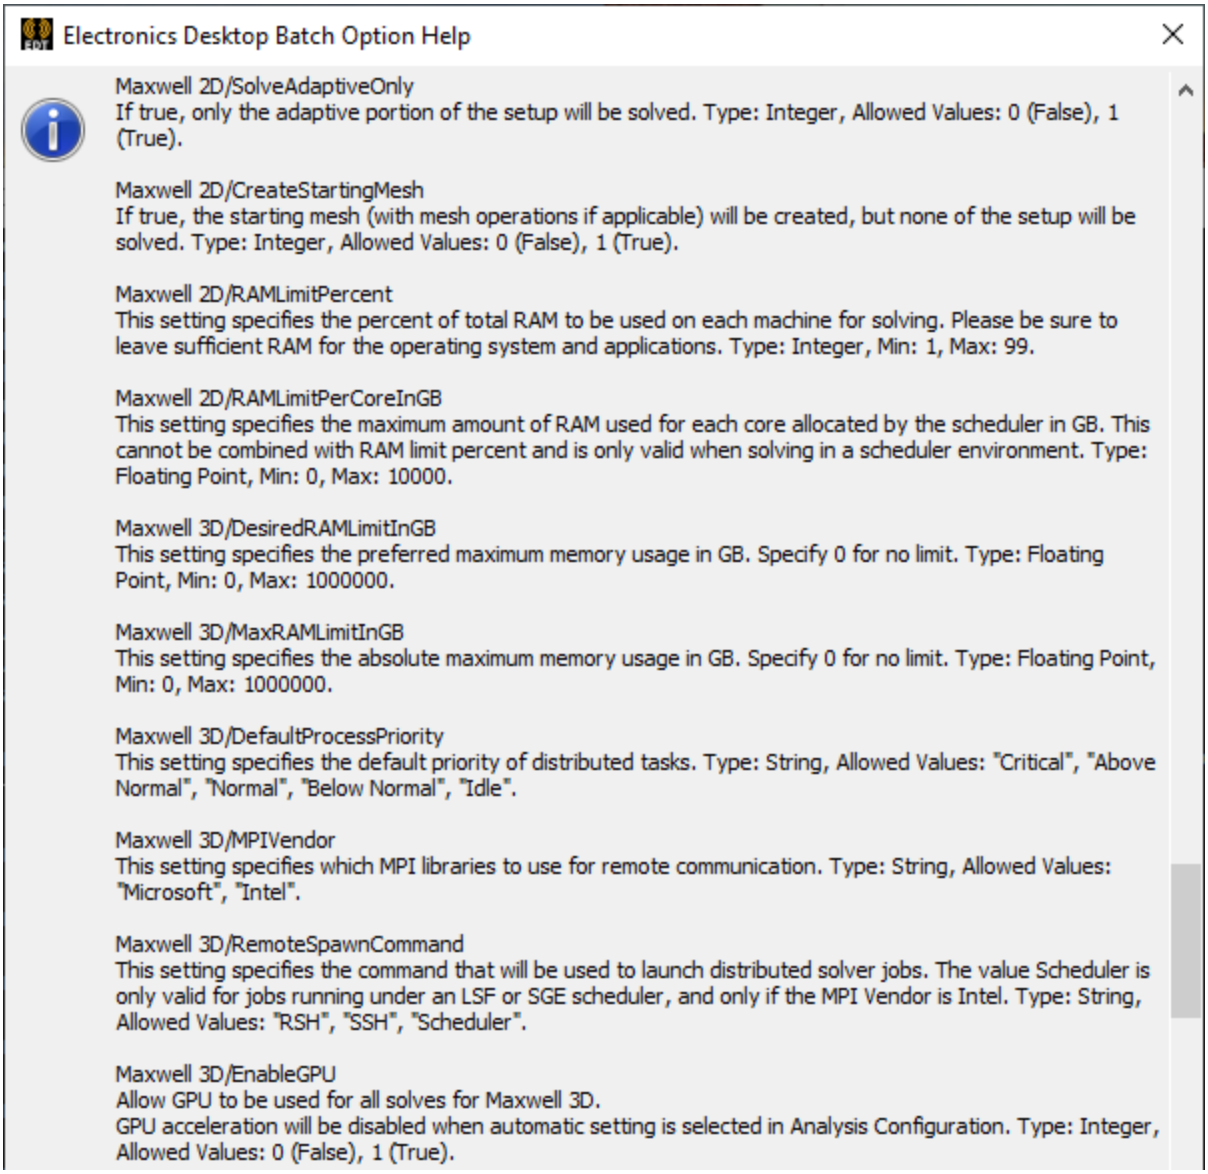
This procedure also works from the <*installation_directory*>/v<*version*>/Linux64 folder on the Linux platform.

> **Note:**
>
> For special product-specific options that are neither available from the GUI nor listed by the UpdateRegistry tool, see Special Batch Options. Even though the -GetKeys switch does not list these special options, you can still use the UpdateRegistry tool to set them.

When you submit jobs to a remote computer or cluster, you can specify batch options using the job submission GUI. When using the GUI, you select the batch options from a list and therefore avoid typographical errors. For the most commonly used batch options, there is detailed information about the allowed values. Click **Submit** on the **Simulation** ribbon tab to access the *Submit Job To* dialog box. Then, click **Add** to access the **Add Batchoption** dialog box pictured below:



To assist users who need to specify batch options and are unable to use the job submission GUI, a new help option has been added. If the Electronics Desktop application is launched with the **-batchoptionhelp** command line argument, a message box is displayed which lists and describes the most common design type-specific batch options:



Setting Analysis Configurations Using the User Interface

The Desktop User Interface may be used to select the configuration to be used for each design type. Each configuration is identified by a unique name. These settings may be viewed and modified using the **HPC and Analysis Options** dialog and modified using the **Analysis Configuration** dialog box.

See Setting HPC and Analysis Options.

Working with PEmag Designs

If **PEmag** is installed on your system, you can launch the PEmag desktop directly from the main Maxwell **Tools** menu. After you have created or opened a design in PEmag, PEmag can be used to generate both Maxwell 2D Electrostatic designs, and Eddy current designs. Also, provided that both Maxwell and PEmag desktops remain open, you can modify the related Maxwell design using PEmag.

The first time you invoke PEmag from Maxwell, an “About PExprt Modeler [PEmag]” dialog displays, informing you that modeling of magnetic components is disabled when PEmag is invoked from Maxwell. Uncheck the “I want to see this message...” checkbox to prevent this dialog from displaying again.

Note	Please refer to the documentation included with PEmag for detailed information on how to use that application to work with PEmag designs.

Related Topics

Creating Maxwell Designs Using PEmag

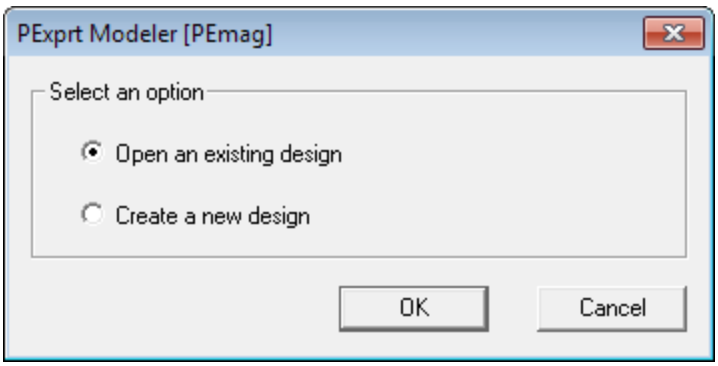
Modifying Maxwell Designs Using PEmag

Solving Maxwell Designs Generated by PEmag

Creating Maxwell Designs Using PEmag

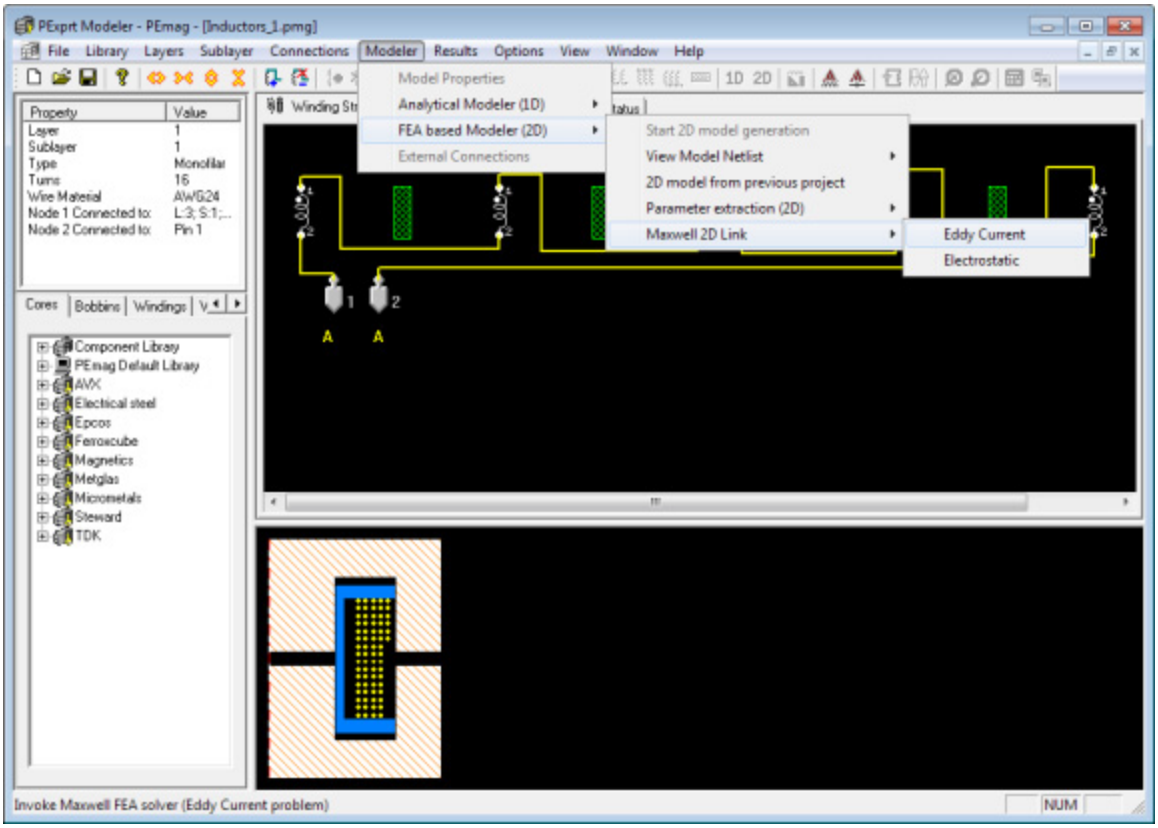
To create a Maxwell Design using PEmag:

1. Select **Tools>PEmag** to launch the PEmag desktop application.
2. In PEmag, choose either to **Open an existing design**, or to **Create a new design**.

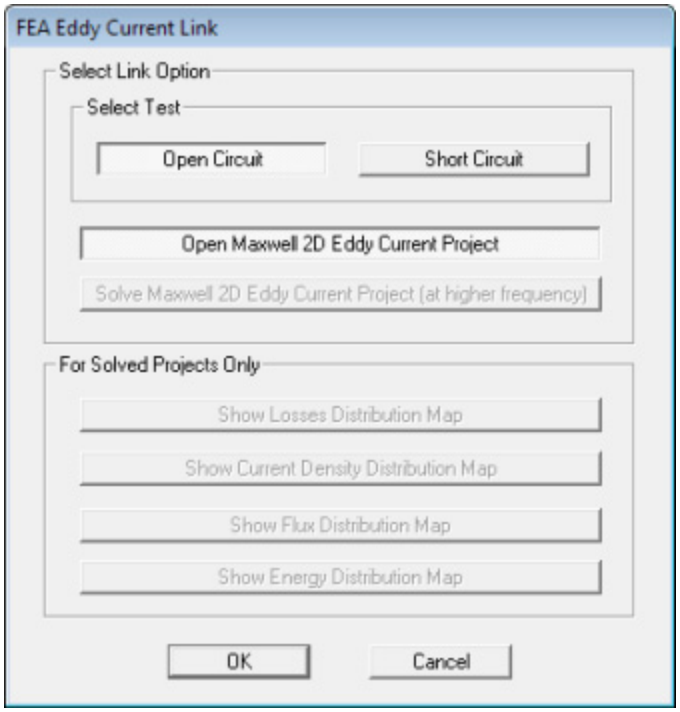


3. When finished creating the PEmag design, you can choose either **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Eddy Current** or **Modeler>FEA based Modeler (2D)>Maxwell 2D Link>Electrostatic** to have PEmag generate a corresponding design for Maxwell.

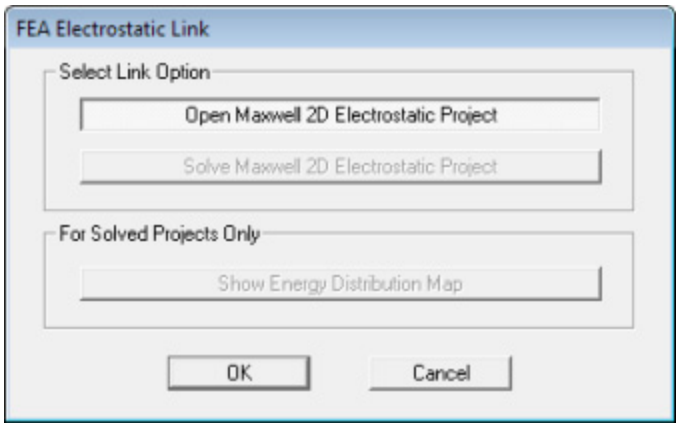
   You can also click on the **FEA Eddy Current** or **FEA Electrostatic** toolbar icons.



a. If you choose **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Eddy Current** a dialog similar to the following displays.



b. If you choose **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Electrostatic** a dialog similar to the following displays.



4. Click **OK** to close the dialog box. PEmag generates a Maxwell 2D design and adds it to the Maxwell Project Manager and desktop. The new design is created corresponding to the PEmag model. The project is immediately saved on disk with the name, *<PEmag project name>*.aedt, in a new folder named *<PEmag project name>*.pjt, which is under the same directory as the PEmag project.

Note	• Adding a Maxwell 2D design via PEmag is not undo-able. • After a Maxwell design is created through PEmag, attempting to close Maxwell while PEmag is still open, displays a message to inform that the

	Maxwell desktop cannot be closed while PEmag is still open.

Related Topics

Modifying Maxwell Designs Using PEmag

Solving Maxwell Designs Generated by PEmag

Modifying Maxwell Designs Using PEmag

After a Maxwell project is created through PEmag, the Maxwell project and design can be modified in the Maxwell desktop while the PEmag desktop is still open. The PEmag model can also be modified through PEmag desktop while the Maxwell desktop is open.

Note	• Modifying a Maxwell 2D design via PEmag is not undo-able. • After a Maxwell design is modified through PEmag, attempting to close Maxwell while PEmag is still open, displays a message to inform that the Maxwell desktop cannot be closed while PEmag is still open. • Modifications made in the Maxwell project are not updated in the PEmag project.

- If you modify the Maxwell 2D design, or add a new Maxwell design to the project in Maxwell; or if you modify the PEmag model in the PEmag desktop and regenerate the Maxwell design (by selecting either **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Eddy Current** or **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Electrostatic**), PEmag will pop up a dialog to ask whether to open the existing Maxwell2D project.

  a. If you select **Yes**, the Maxwell 2D project is reloaded from disk, and any changes made in Maxwell to the Maxwell 2D design and project are lost.
  b. If you select **No**, the Maxwell design and project on the Maxwell desktop will be overwritten by the design and project generated through PEmag with the latest changes in the PEmag model. The Maxwell 2D project is immediately saved to the disk.

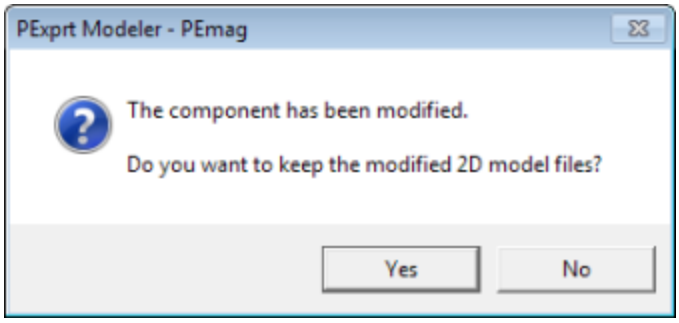
- If you launch PEmag from Maxwell with no Maxwell projects loaded; then open an existing PEmag project which has previously been used to generate a Maxwell project, modify the PEmag model and regenerate the Maxwell design (by selecting either **Modeler>FEA based Modeler(2D)>Maxwell 2D Link>Eddy Current** or **Modeler>FEA**

based Modeler(2D)>Maxwell 2D Link>Electrostatic), PEmag will pop up a dialog (see above) to ask whether to open the existing Maxwell 2D project.

a. If you click **Yes**, the Maxwell 2D project on disk is loaded to the Maxwell desktop.

b. If you click **No**, PEmag generates a Maxwell project and design on the Maxwell desktop, corresponding to the modified PEmag model. The project is immediately saved to the disk, overwriting the previous project on disk and deleting the previous solutions (if any).

- If you modify a PEmag model and regenerate the Maxwell design; then attempt to close PEmag, a dialog pops up asking whether to keep the modified 2D model files.



a. If you click **Yes**, PEmag closes and nothing is changed.

b. If you click **No**, PEmag closes, the Maxwell design and project is deleted from disk, but the modified Maxwell design remains on the Maxwell desktop, and you can save the project to disk, if desired. If not, closing Maxwell will permanently lose the project.

Related Topics

Creating Maxwell Designs Using PEmag

Solving Maxwell Designs Generated by PEmag

Solving Maxwell Designs Generated by PEmag

Maxwell designs generated by PEmag are fully setup and are ready for analysis.

- After solving the Maxwell design generated by PEmag, if you subsequently modify the PEmag model and regenerate the Maxwell design, the old Maxwell design is overwritten and the solutions are deleted.
- While the Maxwell design is being solved on the Maxwell desktop, if you modify the corresponding PEmag design on the PEmag desktop and invoke PEmag to regenerate the Maxwell design, the solver process on the Maxwell desktop will be aborted and the Maxwell design that has been modified by PEmag is loaded into Maxwell and saved to the disk simultaneously.

Modifying Maxwell Designs Using PEmag

Working with Variables

A variable is a numerical value, mathematical expression, or mathematical function that can be assigned to a design parameter in Maxwell. You can assign a variable to any dimensional or material property, or output value. Variables are useful in the following situations:

- When you expect to change a parameter often.
- When you expect to use the same parameter value often.
- When you intend to run a parametric analysis, in which you specify a series of variable values within a range to solve.
- When you intend to optimize a parameter value by running an optimization analysis.
- When you intend to run a convergence on an output variable.

There are two types of variables in Maxwell:

Project Variables	A project variable can be assigned to any parameter value in the project in which it was created. Maxwell differentiates project variables from other types of variables by prefixing the variable name with the **$** symbol. You can manually include the **$** symbol in the project variable's name, or Maxwell can automatically append the **$** after you define the variable. Project variables can be used in any design within the project.
Design Variables	A design variable can be assigned to any parameter value in the Maxwell design in which it was created. Design variables are not available to other designs within the same project.

Clicking **View** > **Variables** brings up a dockable variable window that is associated with the active project and/or design. When there is an active project, there will be a corresponding project variable tab. When there is an active design, there will be a corresponding design variable tab. Each tab contains an **Add...** button allowing creation of new variable of this type. If variables exist for the Project or Design, they are shown in the corresponding tab.

Adding a Project Variable

A project variable can be assigned to a parameter value in the Maxwell project in which it was created. Maxwell differentiates project variables from other types of variables by prefixing the variable name with the following symbol: **$**. You can manually include the symbol **$** in the project variable's name when you create it, or Maxwell automatically appends the project variable's name with the symbol after you define the variable. Project variables can be used in any design within the project.

1. Click **Project**>**Project Variables**.

- Alternatively, right-click the project name in the project tree, and then click **Project Variables** on the shortcut menu.

  You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

The **Properties** dialog box appears.

2. Under the **Project Variables** tab, click **Add**.

   The **Add Property** dialog box appears.

3. In the **Name** box, type the name of the variable.

   Project variable names must start with the symbol **$** followed by a letter. Variable names may include alphanumeric characters and underscores (_). The names of intrinsic functions and the predefined constant pi (π) cannot be used as variable names.

   You can sort the project variables by clicking on the Name column header. By default, variables are sorted in original order. Clicking once sorts them in ascending order, noted by a triangle pointing up. Clicking against sorts in descending order, noted by a triangle pointing down. Clicking a third time sorts in original order, with no triangle.

4. Select a radio button for the variable use:

Selected Use	Setable Properties
Variable	Unit Type, Units, Value.
Separator	Value
Array Index Variable	Associate Array variable, Value

   Each selection affects the settable options.

5. For Project Variables in the **Unit Type** text box you can use the drop-down menu to select from the list of available unit types. “None” is the default.

   When you select a Unit Type, the choices in drop-down menu for the Units text box adapt to that unit type. For example, selecting Length as the Unit Type causes the Unit menu to show a range of metric and english units for length. Similarly, if you select the Unit Type as Resistance, the Units drop down lists a range of standard Ohm units.

6. In the **Value** text box, type the quantity that the variable represents. If you did not specify the Unit Type and Unit, you can also optionally, include the units of measurement.

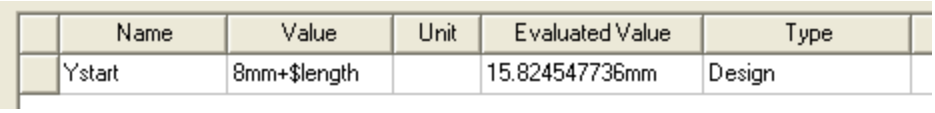
Warning	If you include the variable’s units in its definition (in the **Value** text box), do not include the variable’s units when you enter the variable name for a parameter value.

   The quantity can be a numerical value, a mathematical expression, or a mathematical function. The quantity entered will be the *current,* (or *default) value* for the variable. If the mathematical expression includes a reference to an existing variable, this variable is treated as a dependent variable. The units for a dependent variable will automatically change to

those of the independent variable on which the value depends. Additionally, dependent variables, though useful in many situations, cannot be the direct subject of optimization, sensitivity analysis, tuning, or statistical analysis.

7. Click **OK**.

   You return to the **Properties** dialog box. The new variable and its value are listed in the table. If the value is an expression, the evaluated value is shown. Updating the expression also changes the evaluated value display. The evaluated values of any dependent variables also are changed.



8. Optionally, type a description of the variable in the **Description** box.
9. Optionally, select **Read-Only**. The variable's name, value, unit, and description cannot be modified when **Read-only** is selected.
10. Optionally, select **Hidden**. If you clear the **Show Hidden** option, the hidden variable does not appear in the **Properties** dialog box.
11. You can also designate a variable as Sweep. You may need to use the scroll bar or resize the dialog to view the check boxes.

   The Sweep check box lets you designate variables to include in solution indexing as a way to permit faster post processing. Variables with Sweep unchecked are not used in solution indexing. If a solution exists, checking or unchecking a variable's Sweep setting produces a warning that the change will invalidate existing solutions. To continue, click **OK** to dismiss the warning dialog.

   If a variable has dependent variables, the Sweep check box is disabled and cannot be changed.

12. Click **OK**.

The new variable can now be assigned to a parameter value in the project in which it was created.

Deleting Project Variables

To delete a project variable:

1. Remove all references to the variable in the project, including dependent variables.
2. **Save** the project to erase the command history.
3. Click **Project>Project Variables** to display the **Properties** dialog with list of variables. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.
4. Select the variable and click **Remove** and **OK**.

To remove all unused project variables that are not in use (that is, not in the undo/redo command history):

1. Remove all references to unused project variables, including dependent variables.
2. **Save** the project to erase the command history.
3. Click **Project>Project Variables** to display the **Properties** dialog with list of variables. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.
4. Click **Remove** and from the drop-down menu, select **Remove All Unused** and click **OK**.

   All variables that are not in use (not in undo/redo history) are removed.

To force remove all unused project variables:

1. Remove all references to unused project variables, including dependent variables.
2. Click **Project>Project Variables** to display the **Properties** dialog with list of variables. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.
3. Click **Remove** and from the drop-down menu, select **Force Remove All Unused** and click **OK**. A warning message asks whether you want the unapplied changes in the property dialog to be applied, and clear undo/redo history. If you select No, nothing happens. If you

select Yes, all unapplied changes are applied first, and undo/redo history is cleared; all variables that are not used are removed (including those that are only in undo/redo history before this command is executed).

Adding a Design Variable

A design variable is associated with a Maxwell or RMxprt design. A design variable can be assigned to a parameter value in the design in which it was created. Design variables are only available within the design where they are created and are not available to other designs within the same project.

1. Click **Maxwell3D, Maxwell2D, or RMxprt, and then select Design Properties**.
   - Alternatively, right-click the design name in the project tree, and then click **Design Properties** on the shortcut menu.

     You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   The **Properties** dialog box appears opened on the **Local Variables** tab. From the Properties dialog you can Add, Add Array, Edit, or Remove variables. This section describes **Add**. Use the links for descriptions of Add Array, Edit and Remove,

   Any existing Design variables are listed in the **Properties** dialog with the name followed by cells for Value, Unit, Evaluated Value, Type, Description, and Read-only and Hidden check boxes. A Show Hidden check box on the lower right of the Properties dialog controls the appearance of any Hidden variables.

   Initially, leave the radio button with Value selected until you have defined a variable. The other radio buttons let you enable defined variables for Optimization/Design of Experiments, Tuning, Sensitivity or Statistics. Selecting one of these radio buttons adds a new column to the Variable definition row for which you can check or uncheck Include for regular variables for that kind of Optimetrics simulation. For further discussion, see Optimetrics.

2. Click **Add**.

   The **Add Property** dialog box appears.

3. In the **Name** box, type the name of the variable.

   Variable names must start with a letter, and may include alphanumeric characters and underscores (_). The names of intrinsic functions and the predefined constant pi (π) cannot be used as variable names.

   You can sort the variables by clicking on the Name column header. By default, variables are sorted in original order. Clicking once sorts them in ascending order, noted by a triangle

pointing up. Clicking against sorts in descending order, noted by a triangle pointing down. Clicking a third time sorts in original order, with no triangle.

4. Select a radio button for the variable use:

Selected Use	Setable Properties
Variable	Unit Type, Units, Value
Array Index Variable	Associate Array variable, Value
Separator	Value
Post Processing Variable	Unit Type, Units, Value

Each selection affects the settable options.

5. In the **Unit Type** text box you can use the drop down menu to select from the list of available unit types. “None” is the default.

   When you select a Unit Type, the choices in drop down menu for the Units text box adapt to that unit type. For example, selecting Length as the Unit Type causes the Unit menu to show a range of metric and english units for length. Similarly, if you select the Unit Type as Resistance, the Units drop down lists a range of standard Ohm units.

6. In the **Value** box, type the quantity that the variable represents. Optionally, include the units of measurement.

Note	If you include the variable's units in its definition (in the **Value** box), do not include the variable's units when you enter the variable name for a parameter value.

   The quantity can be a numerical value, a mathematical expression, or a mathematical function. The quantity entered will be the *current* (or *default value)* for the variable. If the mathematical expression includes a reference to an existing variable, this variable is treated as a dependent variable. The units for a dependent variable will automatically change to those of the independent variable on which the value depends. Additionally, dependent variables, though useful in many situations, cannot be the direct subject of optimization, sensitivity analysis, tuning, or statistical analysis.

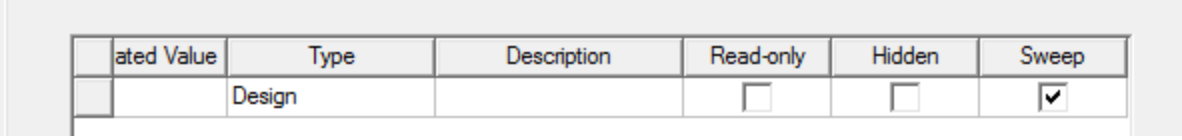
Note	Complex numbers are not allowed for variables to be used in an Optimetrics sweep, or for optimization, statistical, sensitivity or tuning setups.

7. Click **OK**.

   You return to the **Properties** dialog box. The new variable and its value are listed in the table. If the value is an expression, the evaluated value is shown. Updating the expression also changes the evaluated value display. The evaluated values of any dependent variables also are changed.

	Name	Value	Unit	Evaluated Value	Type
	Ystart	8mm+$length		15.824547736mm	Design

8. Optionally, type a description of the variable in the **Description** box.
9. You can designate a variable as Read-only, Hidden, or Sweep. You may need to use the scroll bar or resize the dialog to view the check boxes.



The Sweep check box lets you designate variables to include in solution indexing as a way to permit faster post processing. Variables with Sweep unchecked are not used in solution indexing. If a solution exists, checking or unchecking a variable's Sweep setting produces a warning that the change will invalidate existing solutions. To continue, click **OK** to dismiss the warning dialog.

If a variable has dependent variables, the Sweep check box is disabled and cannot be changed.

10. Click **OK**.

    The new variable can now be assigned to a parameter value in the design in which it was created.

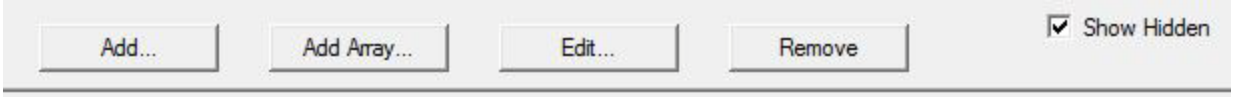
Add Array of Values for a Design Variable

A design variable is associated with a Maxwell design. You can also add a variable defined with an array of values.

1. Click **Maxwell 3D** or **Maxwell 2D**>**Design Properties**.
   - Alternatively, right-click the design name in the project tree, and then click **Design Properties** on the shortcut menu.

The Local Variables **Properties** dialog box appears. From the Properties dialog you can Add, Add Array, Edit... or Remove variables. This section describes Add Array. Use the links for descriptions of Add,.Edit and Remove,



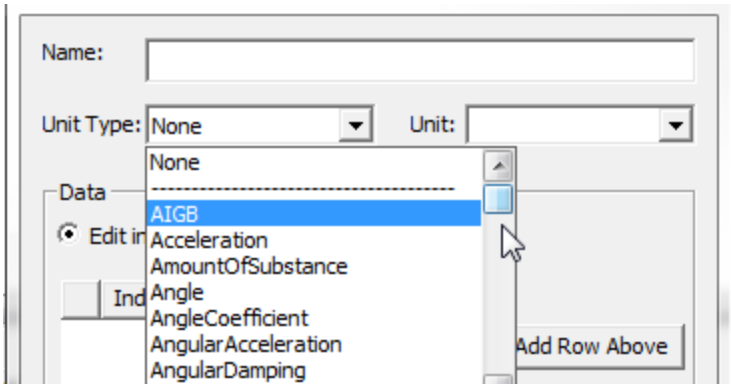
Any existing Design variables are listed in the **Properties** dialog with the name followed by cells for Value, Unit, Evaluated Value, Type, Description, and Read-only and Hidden check boxes. A Show Hidden check box on the lower right of the Properties dialog controls the appearance of any Hidden variables.

Initially, leave the radio button with Value selected until you have defined a variable. The other radio buttons let you enable regular variables for Optimization/Design of Experiments, Tuning, Sensitivity or Statistics. Array variables cannot be enabled for Optimetrics use.

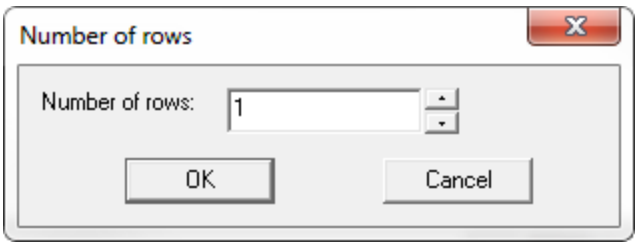
2. Click the **Add Array...**. button.

   The **Add Array** dialog displays.

3. Specify a variable Name in the text field.
4. Select a Unit Type and Units from the drop-down menus.



5. To specify the array with Edit in Grid Selected, you can begin by clicking the **Append Rows...** button to display the **Number of Rows** dialog box. (For Edit in plain text field, see below.)



6. Specify a value and click OK.

This displays a list of indexed data rows in the **Add Array** dialog box. You can type any data value in the cells. If you enter alphanumeric text in a cell it must be delimited by double quotes. You can edit the rows relative a row selection by clicking buttons to Add Row Above, Add Row Below, or Remove Row. All cells must contain a value.

7. When you have completed the array, click **OK** to close the dialog,

   The Array variable is listed in the **Design Properties** dialog as a Local Variable. The array variable value field includes the array contents in brackets with the unindexed data values delimited by commas.

   If you elected to edit the array Edit in plain text field in the **Add Array** dialog, the bracketed and comma delimited format is used.

Editing a Design Variable

A design variable is associated with a Maxwell design. A design variable can be assigned to a parameter value in the Maxwell design in which it was created. You can also add a variable defined with an array of values.

1. Click **Maxwell**>**Design Properties**.
   - Alternatively, right-click the design name in the project tree, and then click **Design Properties** on the shortcut menu. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   The Local Variables **Properties** dialog box appears. From the Properties dialog you can Add, Add Array, Edit, or Remove variables. This section describes **Edit**. Use the links for descriptions of Add, Add Array and Remove.

   Any existing Design variables are listed in the **Properties** dialog with the name followed by cells for Value, Unit, Evaluated Value, Type, Description, and Read-only and Hidden check boxes. A Show Hidden check box on the lower right of the Properties dialog controls the appearance of any Hidden variables.

   Initially, leave the radio button with Value selected until you have defined a variable. The other radio buttons let you enable defined variables for Optimization/Design of Experiments, Tuning, Sensitivity or Statistics. Selecting one of these radio buttons add a new column to the Variable definition row for which you can check or uncheck Include a regular variable for that kind of Optimetrics simulation. Array variables cannot be Enabled for Optimetrics. For further discussion, see Optimetrics.
2. Select a variable to highlight it.
3. Click the **Edit** button.

   For regular variables, the **Add Property** dialog for that variable opens, and for array variables, the **Edit Array** variable dialog for that variable opens.
4. Complete the edits and **OK** the dialog to apply them.

Deleting Design Variables

To delete a design variable:

1. Remove all references to the variable in the design, including dependent variables.
2. **Save** the project to erase the command history.
3. Click **Maxwell>Design Properties** to display the **Properties** dialog with list of local variables.
4. Select the variable and click **Remove** and **OK**.

To remove all unused design variables (that is, not in the undo/redo command history):

1. Remove all references to unused variables in the design, including dependent variables.
2. **Save** the project to erase the command history.
3. Click **Maxwell 2D** or **Maxwell 3D>Design Properties** to display the **Properties** dialog with list of local variables.
4. Select the variable and click **Remove** and from the drop-down menu, select **Remove All Unused** and click **OK**. All variables that are not in use (not in undo/redo history) are removed.

To force remove all unused design variables:

1. Remove all references to unused variables in the design, including dependent variables.
2. Click **Maxwell 2D** or **Maxwell 3D>Design Properties** to display the **Properties** dialog with list of local variables.
3. Select the variable and click **Remove** and from the drop-down menu, select **Force Remove All Unused** and click **OK**. A warning message asks whether you want the unapplied changes in property dialog to be applied, and clear undo/redo history. If you select No, nothing happens. If you select Yes, all unapplied changes are applied first, and undo/redo history is cleared; all variables that are not used are removed (including those that are only in undo/redo history before this command is executed).

Deleting Project Variables

Adding Datasets

Datasets are collections of plotted data points that can be extrapolated into an equation based on the piecewise linear makeup of the plot. Each plot consists of straight line segments whose vertices represent their end points. A curve is fitted to the segments of the plot and an expression is derived from the curve that best fits the segmented plot. The created expression is then used in a piecewise linear intrinsic function such as: pwl, pwlx or pwl_periodic. You can add datasets at either the Project Level or the Design level. They can be for various purposes, including to define frequency dependent port impedances or frequency dependent global variables, and boundary definitions.

Project level datasets are used typically for defining various material properties at the project level (applicable to all designs in the project). Otherwise, project level datasets are not supported for design level assignment.

Note	The descriptions of the various controls and fields for working with datasets are also applicable to the **BH Curve** dialog box when *Specifying BH Curves for Nonlinear Relative Permeability*.

Design level datasets can be used in geometry entities like part commands, coordinate systems, points, and planes. Design level datasets do not work with equation-based surfaces or curves. Design level datasets can be used directly with piecewise linear functions in expressions or indirectly through variables that can refer to the dataset.

Design level datasets can be used in the following operations.

- **Creating or editing geometry** – when a geometry uses a dataset directly, edit dataset invalidates the solution. When a geometry uses a variable that is defined by dataset, editing the dataset does not invalidate the solution.
- **Creating an Animation** – based on a variable which can index in datasets.
- **Copying and Pasting Geometry** – if a part refers to a design dataset, it will be pasted to destination design.

The following procedure describes how to add a dataset manually. You can also add datasets:

- By importing data from an external file.
- By using the SheetScan tool.

1. For a Project level dataset, click **Project>Datasets**. For a Design level dataset, click **Maxwell 2D>Design Datasets**, **Maxwell 3D>Design Datasets**, or **RMxprt>Design Datasets**.

   The Datasets dialog box appears, listing any project or design-level datasets.

2. Click **Add**.

Note	If you are adding either a project-level or a design-level dataset, you will be presented with the option to add either a 1D Dataset or 3D Dataset. See: Adding 3D Datasets for specifics on this type of dataset.

   The **Add Dataset** dialog box appears. The dialog contains fields for the Dataset name, and a table for x- and y- coordinates. It contains a graphic display that draws a line for the coordinates you add. It also includes buttons for the following functions:

   - **Swap X-Y Data** – this swaps the x- and Y- coordinates and adjusts the graphical display.
   - **Import Dataset** - this provides a way to import data sets from an external source. The format is a tab separated points file. Clicking the button opens a file browser window.
   - **Export Dataset** -- this provides a way to export the current dataset to a tab separated points file. Clicking the button opens a file browser window.
   - **Add Row Above** – adds a new row to the table above the selected row.
   - **Add Row Below** – adds a new row to the table below the selected row/
   - **Append Row** – opens a dialog that lets you specify a number of rows to add to the table.
   - **Delete Row** – deletes the selected row or rows.

3. Optionally, enter a name other than the default for the dataset in the **Name** box.

Note	Project-level datasets must begin with a dollar sign character ($). If you do not type one, it will be added for you.

4. Enter the x- and y- coordinates by one of the following methods

   Type the x- and y-coordinates for the first data point in the row labeled **1**.Type the x- and y-coordinates for the remaining data points in the dataset using the same method.

   After you type a point's coordinates and move to the next row, the point is added to the plot, adjusting the display with each newly entered point.

Note	• The x-coordinate values for successive data points must increase within ten significant digits. • You can also use the **Import Dataset** button to import data coordinates. Doing so will overwrite any existing values in the Coordinates panel.

5. When you are finished entering the data point coordinates, click **OK**.
6. Click **Done** in the **Datasets** dialog box.

The dataset plot is extrapolated into an expression that can be used in parametric analyses, boundary definitions, or assigned to a material property value.

You can now edit, remove, clone, or export the dataset. You can also change the plot display properties.

Adding 3D Datasets

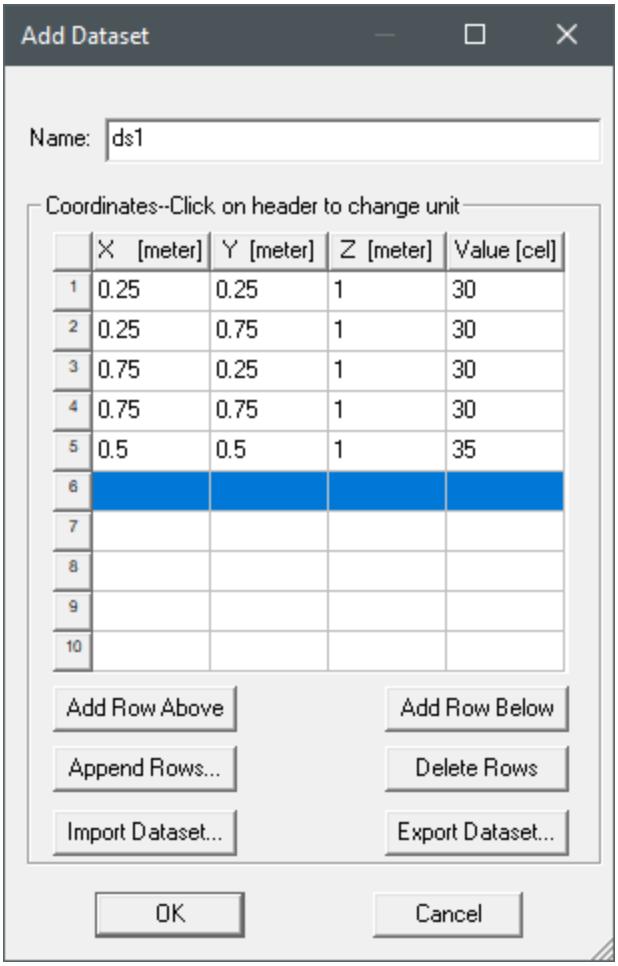
In Maxwell designs, you can define both project-level and design-level 3D datasets. Use a project-level 3D dataset to define material properties that vary according to the spatial coordinates. Use a design-level 3D dataset to define temperatures that vary according to the spatial coordinates.

To define a 3D dataset, specify a list of **X**, **Y**, and **Z** coordinates and the corresponding **Values** in the **Add Dataset** window. For example, the first line in the image below specifies a temperature of 30° C at (0.25, 0.25, 1). The data specifies a variation of temperature on the plane $0.25 \le X \le 0.75$, $0.25 \le Y \le 0.75$, $Z = 1$. In this example, the values in the **Values** column are temperature, but can be set to a different unit depending on the property you wish to assign. To change the unit, click the **X**, **Y**, **Z**, or **Value** header row.



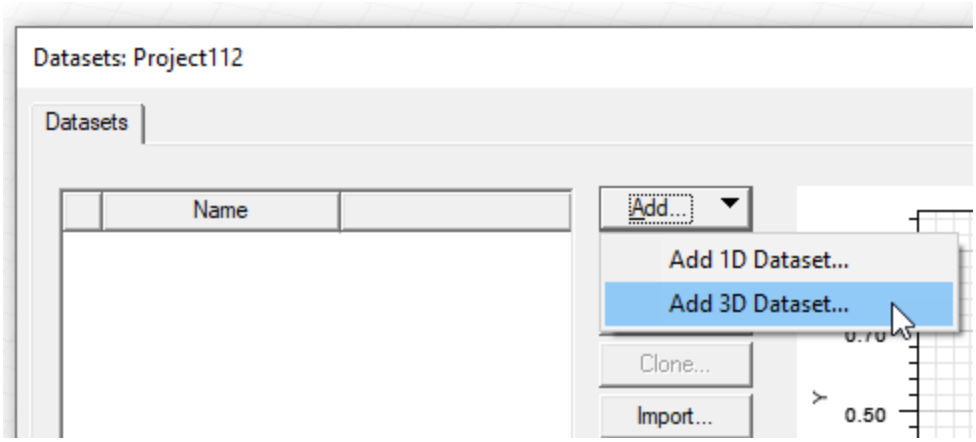
1. Depending on whether you are defining a project-level or design-level 3D dataset, choose the appropriate one of the following two options:
   - For project-level datasets (material properties):

     Using the menu bar, click **Project** > **Datasets** or, on the **Desktop** ribbon tab, click **Datasets**.
   - For design-level datasets (temperatures):

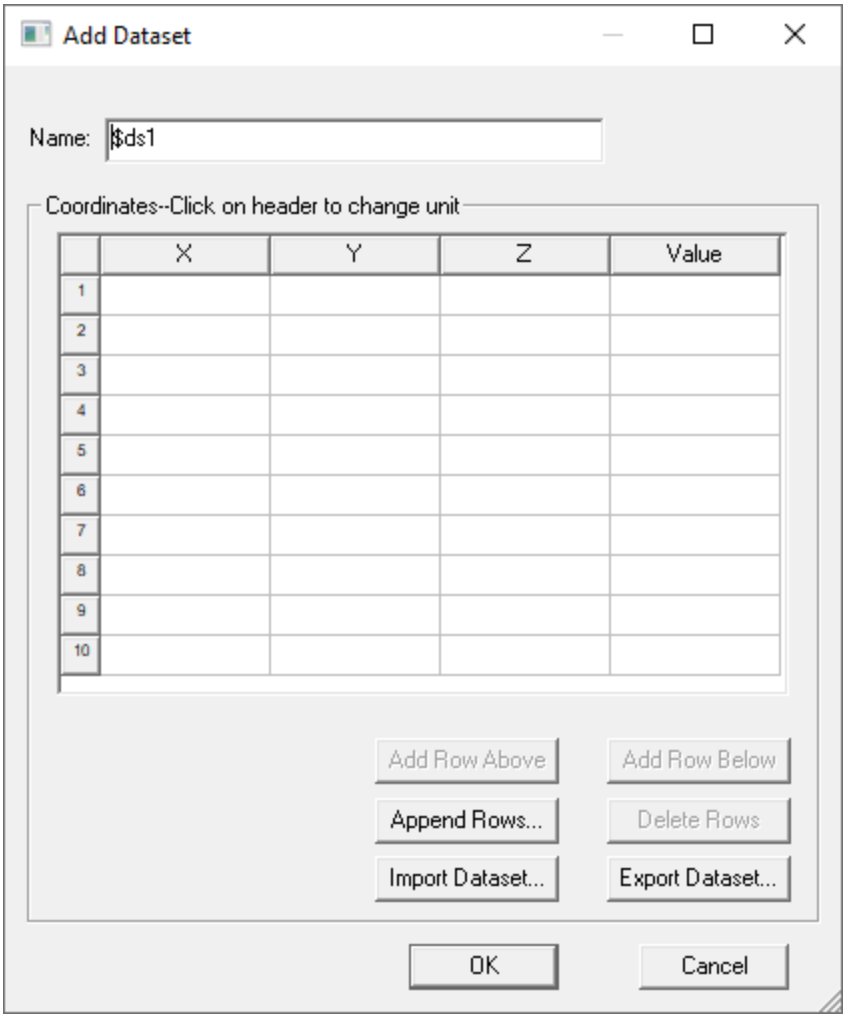
     Using the menu bar, click **Maxwell** > **Design Datasets**.

   The **Datasets** dialog box appears. This lists any existing datasets.

2. Click **Add** > **Add 3D Dataset**.



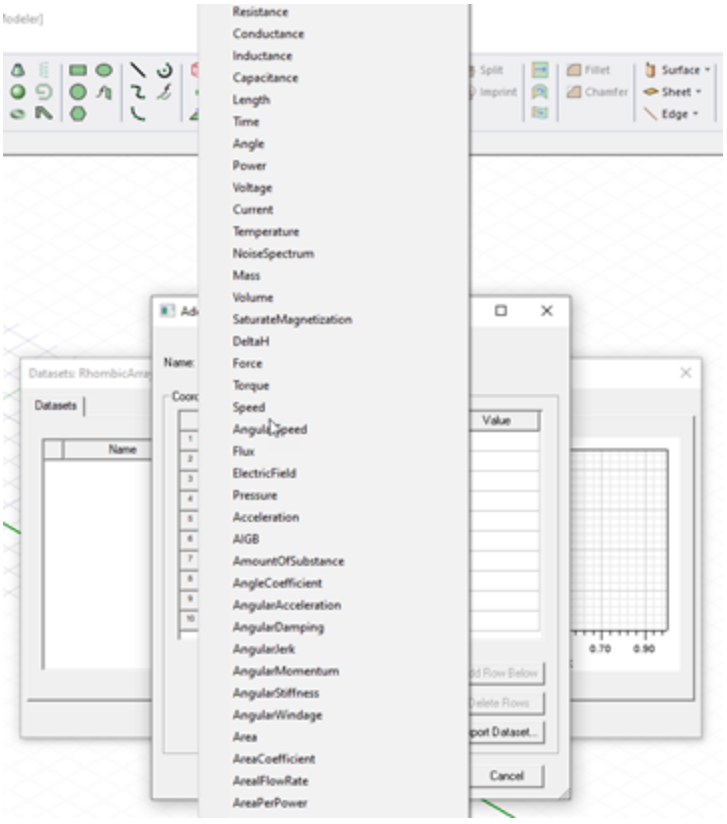
The **Add Dataset** window appears.



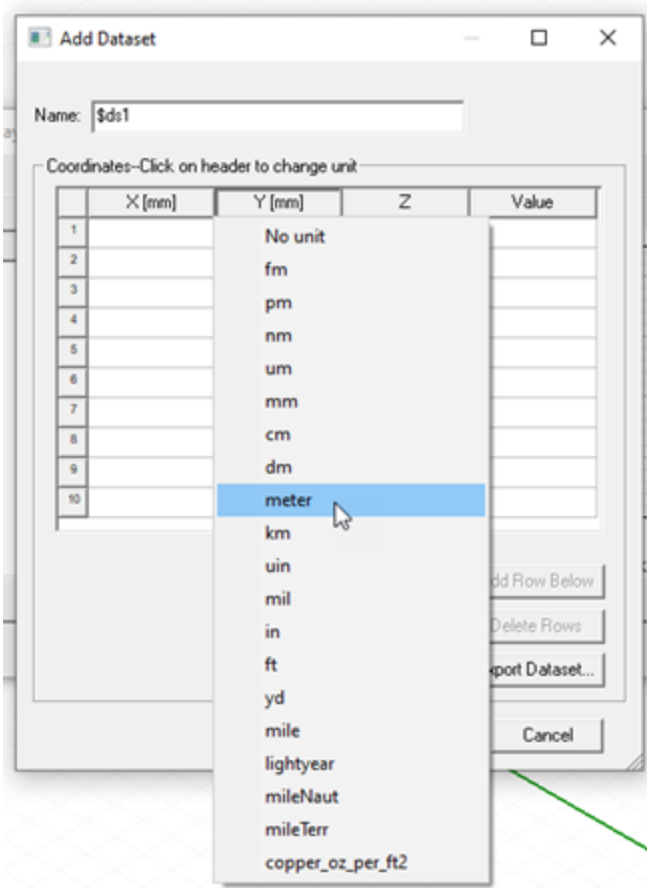
The window contains fields for the dataset name and a table for X, Y, and Z coordinates and corresponding values. It can be resized to display additional rows and columns, and includes buttons for the following functions:

- **Add Row Above** – adds a new row to the table above the selected row.
- **Add Row Below** – adds a new row to the table below the selected row.
- **Append Row** – opens a dialog box that lets you specify a number of rows to add to the table.
- **Delete Row** – deletes the selected row or rows.
- **Import Dataset** – this provides a way to import data sets from an external source. The format is a tab separated points file. Clicking the button opens a file browser window.
- **Export Dataset** – this provides a way to export the current dataset to a tab separated points file. Clicking the button opens a file browser window.

3. Optionally, type a name other than the default for the dataset in the **Name** field.
4. Click the **X**, **Y**, **Z** and **Value** column headers to select a unit category. The default is No Unit.



Click the header again to select a unit in that category. You can select No unit.



Selected units are displayed for each column in the header cell.

5. Enter the X, Y, and Z coordinates and the corresponding values by one of the following methods:
   - **Import Dataset**
   - Type coordinates and associated value in the **X**, **Y**, **Z**, and **Value** columns.
6. When you are finished entering the data point coordinates and values, click **OK**.

Note	When used with a clp function (Closest point interpolation) in an expression, performance will degrade with large 3D datasets.

Datasets Dialog Box

The **Datasets** dialog box provides a browsable listing of all datasets currently defined for the project or design. A preview window displays a plot of the currently selected dataset. Controls allow you to **Add**, **Edit**, **Remove**, and **Clone** datasets; to **Import** and **Export** characteristics data; and to launch the **SheetScan** tool that you can use to extract data from graphics such as data sheets.

Add - Opens a blank **Add Dataset** window in which you can define a dataset by entering data coordinates directly, or by importing data from a file.

Edit - Opens the selected dataset in an **Edit Dataset** window for editing.

Remove - Removes the selected dataset from the project.

Clone - Copies the selected dataset to an editing window for modification. The original dataset remains intact.

Import - Opens an **Import Dataset** window in which you can locate and import characteristics data from several file types including data exported from the **SheetScan** tool.

Export - Opens an **Export Dataset** window in which you can export the selected dataset to a tab-delimited file.

SheetScan - Opens the SheetScan tool in which you can extract characteristics data from graphics such as data sheets.

Dataset Preview Plot Properties

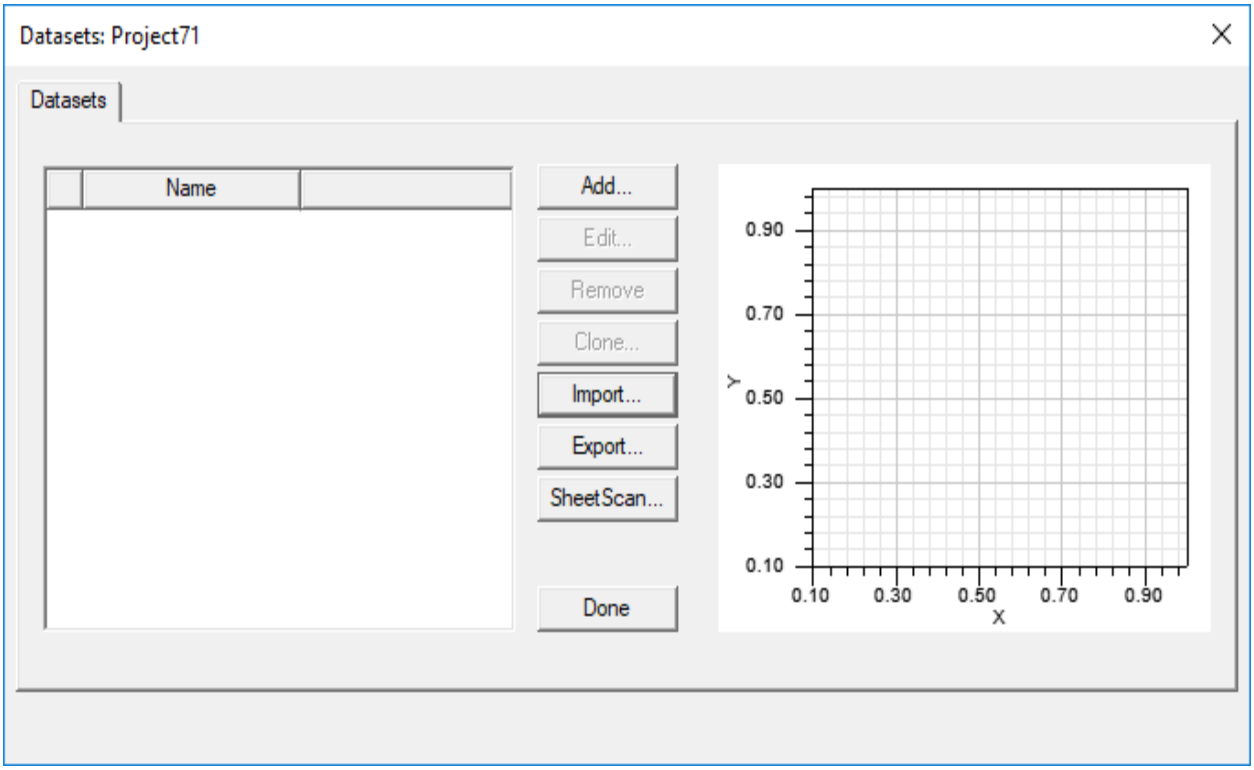
1. You can change the properties of various elements of the preview plot such as the major and minor grid colors, title font, and trace line style by double-clicking the element to open its properties dialog box.
2. Depending on the type of element selected, tabs allow you to set the **Color**, **Font**, **Line Style**, **Scaling**, **Title**, and **Legend** properties.
3. Right-clicking inside the plot window opens a context menu containing commands to add and delete data markers and labels, change trace type, and print the plot.
4. Click **Save as Defaults** to make the changes the default values.
5. Click **OK** to apply the changes only while the current dataset plot window is open. Click Save as Defaults to keep the changes.

Importing Datasets

To import data for a dataset from a file:

1. For a Project level dataset, click **Project**>**Datasets**. For a Design level dataset, click **Maxwell 2D>Design Datasets**, **Maxwell 3D>Design Datasets**, or **RMxprt>Design Datasets**.

The **Datasets** dialog box appears.



2. Click the **Import** button.
3. In the file browser window that appears, choose the data file you wish to import from the following file types:

Note	The table below lists the file types supported for *Project level datasets*. For *Design level datasets*, only **.tab** files are supported.

.mdx, .mda	Twin Builder Characteristic format
.xls, .xlsx	Microsoft Excel
.txt	text file
.csv	Comma-separated value
.out	Maxwell SPICE (read-only - reads data inside the KW_DATA section)
.cfg	Comtrade (IEEE Std C37-111-1999)
.dat	TEK Oscilloscope
.tab	tab delimited data files

- If you select a file type other than .**xls**, .**xlsx**, .**txt**, .**dat**, .**out**, or .**csv** the data is imported immediately into the **Add Dataset** dialog box.

Note	Importing an .xls or .xlsx file requires Microsoft Excel to be available.

- Selecting an .xls or .xlsx file containing multiple sheets opens a **Table Properties** dialog box where you can choose the desired sheet from a drop-down list. Otherwise, selecting an .xls or .xlsx file imports the data immediately into the **Add Dataset** dialog box.

Note	Only the first two columns of data are imported, the left-most column containing the X-coordinate values. The x-coordinate values for successive data points must increase within ten significant digits. Non-numeric entries are assigned a value of zero. The first row of data is assumed to contain column headings and is ignored.

- Selecting a .**txt** or .**csv** file opens an **Import** dialog box in which you can specify how to settings for reading the data in the file for import. You can choose the **Separator**(s) and **Decimal Symbol**, as well as the line at which to begin the import. The dialog box shows both the original text and the text as it would appear when imported based on the current import settings.

When satisfied with the import settings, click **OK** to import the data.

4. After importing the data, you can modify it manually (see Editing Datasets).

Note	You can also import a dataset in the **Add Dataset** and **Edit Dataset** windows.

Editing Datasets

1. For Project level datasets, click **Project>Datasets**. For Design level datasets, click **Maxwell 2D>Design Datasets**, **Maxwell 3D>Design Datasets**, or **RMxprt>Design Datasets**.

   The **Datasets** dialog box appears.
2. Click the dataset name you want to modify, and then click **Edit**.

   The **Edit Dataset** dialog box appears.
3. Optionally, type a name other than the default for the dataset in the **Name** box.
4. Type new values for the data points as desired.

   The plot is adjusted to reflect the revised data points.

5. When you are finished entering the data point coordinates, click **OK**.
6. Click **Done.**

Using SheetScan

SheetScan allows you to extract characteristics data from graphics such as data sheets which have been scanned and saved in any of the following formats: .bmp, .dib, .jpg, .gif, .tif, .tga, .pcx, .htm, or .html. SheetScan can be accessed at the AEDT project level under **Project>Datasets>SheetScan**.

In addition to importing graphic files directly, SheetScan also can be used to browse the Internet for datasheet information and transfer a snapshot of the web page to the SheetScan editor where

you can map axes on the image as an overlay. You can then manually add datapoints to approximate the characteristic curve(s) on the datasheet.The sampled data can then be converted to Maxwell format, and the extracted data exported to a Maxwell dataset or saved to a tab-delimited file.

The process for creating a dataset using SheetScan involves four basic operations:

- Loading a datasheet into SheetScan.
- Defining a coordinate system for the imported datasheet picture.
- Defining a characteristic curve using the datasheet picture as reference.
- Exporting the characteristic curve data to a file or to a dataset.

Related Topics

Defining a Characteristic Curve in SheetScan

SheetScan Toolbars

Three toolbars are available in SheetScan. They provide convenient access to commands that are also found in the SheetScan main menu. Toolbars can be toggled on and off via the **View>Toolbar** sub-menu.

- The **Standard** toolbar includes access to basic Windows functions such as file Open and Save, Cut, Copy, Paste, Print, and Help.

- The **Curve** toolbar contains tools for working with curve values. A pull-down menu allows you to select the curve on which to work. Other tools allow you to: change curve settings, change the curve's coordinate system, and to select, append, delete, and insert points on the active curve

- The **Zoom** toolbar provides tools for scaling the current view, zooming in and out, resetting

the zoom to 100 percent, and toggling the display of the curve's grid on and off.

SheetScan Settings

Default settings are made by choosing **Options>Settings**. The **Settings** dialog box contains three tabs:

- The **Document** tab allows you to set the Width and Height of the sheet created when a picture imported into the SheetScan editor. You can either enter the dimensions manually, or allow SheetScan to adapt the dimensions to the picture being loaded.
- The **Axis** tab allows you to set the default **Name**, **Unit** of measure, **Scaling** factor, and **Offset** value for the X and Y axes. Checking **Monotonicity in X** automatically prevents you from adding consecutive data points whose X-values are not increasing.
- The **Representation** tab lets you choose whether to connect points on the characteristic curve and to choose the color of the connecting line. You can also choose to display markers for the point chosen when defining a curve, to set the color of displayed markers, and to set the color of markers when they are selected.

Note	You can also override the default settings on the Axis and Representation tabs for individual curves (see Defining a Characteristic Curve in SheetScan).

Loading a Datasheet Picture into SheetScan

By default, SheetScan opens a new, blank datasheet editing window. There are two ways to load a datasheet picture into the editor:

Loading a Datasheet Picture Directly

1. Browse directly to the datasheet picture file by choosing **Picture>Load picture** to open a file browser window.
2. When you have located the desired file, click **OK** to load the image into the SheetScan editor. Supported file types include: .bmp, .dib, .jpg, .gif, .tif, .tga, .pcx, .htm, and .html.

Loading a Datasheet Picture Using the HtmlViewer

1. Choose **Picture>Internet** to open the Sheetscan HtmlViewer.
2. Browse the Internet for the desired datasheet.
3. Resize the **HtmlViewer** window and adjust its scrollbars until the desired portion of the datasheet is in view
4. Click the **To SheetScan** button  to copy the visible contents of the HtmlViewer window into the SheetScan editor window.

Note	To hide the datasheet picture, choose **Picture** on the **View** menu.

After loading a datasheet picture into the SheetScan editor, the next step is Defining a coordinate system for the imported picture.

Loading a Datasheet Picture into SheetScan

Defining a SheetScan Coordinate System

Use this procedure to define a coordiante system typically for a graph on a datasheet picture that you have previously loaded into the SheetScan editor.

To define the coordinate system:

1. Select **Coordinate System>New** to open the **Coordinate System** dialog box.
2. Click the **Point1** button.

   The **Coordinate System** dialog box disappears temporarily and the cursor changes to a crosshairs.
3. Position the cursor over a corner of the datasheet graph and click the left mouse button.

   The **Coordinate System** dialog box reappears displaying the X- and Y-Coordinate values for the chosen point.
4. Enter the X-Value and Y-Value for this point. Typically, these values will correspond to the values taken from the axis scale values on the datasheet.
5. Select the desired scaling (linear, logarithmic, or decibel) for both the X and Y axes.
6. Repeat steps 2 through 4 for the **Point2** and **Point3** buttons.
7. Click **OK**. The grid is placed in the graphic.

Note	• You can edit the grid after placement either by selecting **Coordinate System>Properties** from the SheetScan main menu bar, by clicking the coordinate system icon on the Curve toolbar, or by right-clicking in the SheetScan editing window and selecting **Coordinate system** from the context menu. • You can hide the grid by selecting **Grid** on the **View** menu, or by clicking the grid icon on the **Curve** toolbar.
8. Proceed to *Defining a Characteristic Curve in SheetScan*.

Defining a Characteristic Curve in SheetScan

Defining a Characteristic Curve in SheetScan

Once you have loaded a datasheet picture in the editor and have defined a coordinate system, you can define one or more characteristic curves as follows:

1. Choose **Curve>New**.

   The **Curve Settings** dialog box opens.
2. Define the properties of the curve. Refer to SheetScan Settings for a detailed explanation of the settings you can make on the **Axis** and **Representation** tabs.
3. When finished defining curve properties, click **OK**.

   The cursor changes to cross hairs.
4. Click the points of the characteristic which you want to capture for the dataset. The points are connected automatically.
5. Repeat steps 1 through 4 for each additional characteristic curve you wish to define.

After characteristic curves have been defined, you can perform various operations on them. Refer to *Performing Operations on SheetScan Curves* for details.

Performing Operations on SheetScan Curves

You can perform the following operations on existing characteristic curves:

- select a curve for editing
- edit a curve
- delete a curve
- change curve settings
- check if a curve is monotonically increasing along the X-axis
- export the curve data to a dataset

Selecting a SheetScan Characteristic Curve

1. To select a SheetScan curve for editing, do one of the following:
   a. Select **Curve>Select** on the SheetScan menu bar.
   b. Right-click in the editor window and choose **Select Curve** from the context menu.

The **Select Curve** dialog box opens.

2. Click the desired curve name to highlight it, then click **OK** to select the curve.

Note	If the Curve Values window is open, you can also click the tab of the desired curve to select it.

Changing Characteristic Curve Settings

You can changes curve settings for a characteristic curve as follows:

1. Select the curve whose settings you wish to change.
2. Choose **Curve>Change Settings**.

   The **Curve Settings** dialog box opens.
2. Change the properties of the curve as desired. Refer to SheetScan Settings for a detailed explanation of the settings you can make on the **Axis** and **Representation** tabs.
3. When finished changing curve properties, click **OK**.
4. Repeat steps 1 through 3 for each additional characteristic curve you wish to change.

Editing a SheetScan Characteristic Curve

The following SheetScan curve editing functions are available either via the main **Curve** menu, the Curve toolbar, or the editor window context menu:

- Select points — click on a point to select it. **Ctrl+click** selects multiple points.
- Append points — click to add data points to the end of a curve.
- Delete points — click a data point to remove it from the curve.
- Insert points — click to insert new data points between existing data points.

Deleting a SheetScan Characteristic Curve

To delete a characteristic curve and all of its associated data points:

1. Select the desired curve.
2. Select **Curve>Delete**.

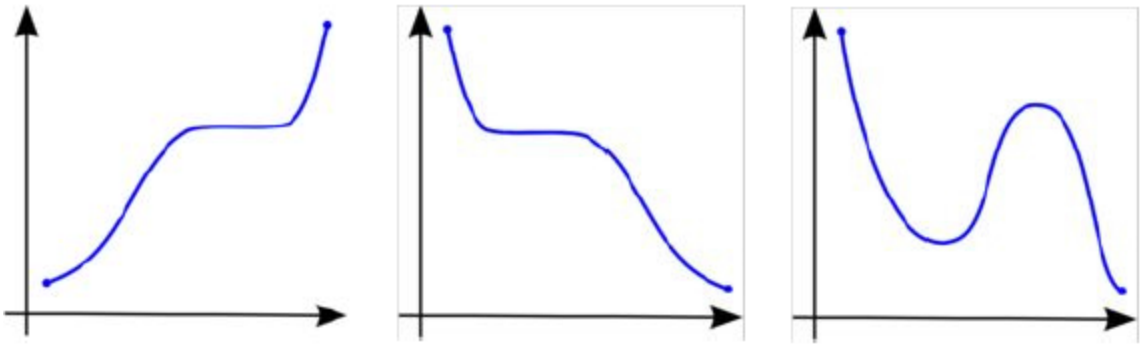
Warning	You cannot undo this action. If you delete a curve and its data points from the SheetScan editor, you must reconstruct it manually.

Checking for Monotonicity in X

Maxwell requires that characteristics be monotonically increasing along the X-axis. In other words, successive data points must have increasing X-values, while Y-values may both increase and decrease. You can check for monotonicity in X as follows:

1. Select **Curve>Check Monotonicity**.

   If the characteristic curve is monotonically increasing in X-value, the check completes without notice. Typical examples of curves that meet monotonicity criteria are shown below.



2. If the characteristic curve is not monotonically increasing in X-value, a dialog box displays informing you that errors were found. Click **Yes** to have SheetScan automatically correct the errors.

Defining a Characteristic Curve in SheetScan

Importing Characteristic Data into SheetScan

SheetScan supports data import from the following file types: Twin Builder Characteristic (*.mdx, *.mda), Microsoft Access (*.mdb), Microsoft Excel (*.xls), text (*.txt), comma separated value

(*.csv), Spice (*.out), Comtrade (*.cfg), and TEK Oscilloscope (*.dat).

1. To import characteristic curve data into SheetScan, select **File>Import**.
2. In the file **Open** dialog box, select the desired data file and click **OK**.
   a. Selecting a **.xls** file containing multiple sheets opens a **Table Properties** dialog where you can choose the desired sheet from a drop-down list. Otherwise, selecting a **.xls** file imports the data immediately into the **Add Dataset** dialog box.

Note	• Only the first two columns of data are imported, the left-most column containing the X-coordinate values. The x-coordinate values for successive data points must increase within ten significant digits. Non-numeric entries are assigned a value of zero. • The first row of data is assumed to contain column headings and is ignored.

   b. Selecting a **.txt**, **.tab**, or **.csv** file opens an **Import** dialog box in which you can specify how to settings for reading the data in the file for import. You can choose the **Separator** (s) and **Decimal Symbol**, as well as the line at which to begin the import. The dialog box shows both the original text and the text as it would appear when imported based on the current import settings.

   When satisfied with the import settings, click **OK** to import the data.

   A **Curve Settings** dialog box opens.

3. Change **Curve Settings** as needed and click OK to complete the data import.
   The new characteristic curve is added to the current SheetScan sheet.

Exporting SheetScan Data

You can export SheetScan curve data directly to a Maxwell or RMxprt Dataset.

1. To export the curve data, choose **File>Export**.
2. In the **Save**dialog box, choose **Current Curve** (default) to export current curve data, or **Curves** if you wish to choose the curve(s) whose data you wish to export. Choosing **Curves** reveals a list box showing all of the curves available for export. Check the **Export** box for the desired curves.

Note	The **Multidimensional Table** option is not currently supported.

3. Choose **Equidistant** if you want to set the **Start** and **StopX-Channel** values and a **Sample Rate** or **Number of samples** for the exported dataset(s),
4. Choose **Dataset** to export curve data directly to the project's dataset file.

Note	Exporting data to a file via the **File** button is not currently supported.

Defining Mathematical Functions

A mathematical function is an expression that references another defined variable. A function's definition can include both expressions and variables.

The following mathematical functions may be used to define expressions:

Basic functions	**/**, **+**, **-**, *****, mod (modulus), ****** (exponentiation), **-** (Unary minus), **==** (equals), **!** (not), **!=** (not equals), **>** (greater than), **<** (less than), **>=** (greater than equals), **<=** (less than equals), **&&** (logical and), **||** (logical or)
Intrinsic functions	**if**, **abs**, **exp**, **pow**, **ln** (natural log), **log10**, **sqrt**
Trigonometric expressions	**sin**, **cos**, **tan**, **asin**, **acos**, **atan**, **sinh**, **cosh**, **tanh**

The predefined variables X, Y, Z, Phi, Theta, R, and Rho must be entered as such. X, Y, and Z are the rectangular coordinates. Phi, Theta, and Rho are the spherical coordinates. R is the cylindrical radius, and Rho is the spherical radius.

If you do not specify units, all trigonometric expressions expect their arguments to be in radians, and the inverse trigonometric functions' return values are in radians. If you want to use degrees, you must supply the unit name **deg**. When the argument to a trigonometric expression is a variable, the units are assumed to be radians. These function names are reserved and may not be used as variable names.

As far as expression evaluation is concerned: units are conversion factors (that is, from the given unit to SI). Note also that the evaluated value of an expression) is always interpreted as in SI units.

Expressing Cartesian, Cylindrical or Spherical Coordinates

Defining an Expression

Expressions are mathematical descriptions that typically contain intrinsic functions, such as sin(x), and arithmetic operators, such as +, -, *, and /, well as defined variables. For example, you could define: x_size = 1mm, y_size = x_size + sin(x_size). Defining one variable in terms of another makes a dependent variable. Dependent variables, though useful in many situations, cannot be the subject of optimization, sensitivity analysis, tuning, or statistical analysis.

The Constants tab of the **Project Variables** dialog lists the available predefined constants.These may not be reassigned a new value.

Name	Value	Description
Boltz	1.3806503E-023	Boltzmann constant (J/K)
c0	299792458	Speed of light in vacuum (m/s)
e0	8.854187817e-012	Permittivity of vacuum (F/m)
elecq	1.602176462e-019	Electron charge (C)
eta	376.730313461	Impedance of vacuum (Ohm)
pi	3.14159265358979	Ratio of circle circumference to diameter
u0	1.25663706143582e-066	Permeability of vacuum (H/m)

Numerical values may be entered in Ansys' shorthand for scientific notation. For example, $5x10^7$ could be entered as **5e7**.

Note	Maxwell 2D, 3D, and RMxprt do not support expressions that include the combination of array and intrinsic variables.

Using Intrinsic Variables

Maxwell recognizes a set of intrinsic variables that can be used to define expressions. Intrinsic variable names are reserved and may not be used as user-defined variable names.

User-defined variables cannot depend on any intrinsic variables.

The following intrinsic variables (shown on the Intrinsic Variables tab after selecting **Project>Project Variables**) may be used to define expressions:

Variable	Units	Description
_Empty		Empty value
_I1 through _I9	mA	Terminal current in an interpretive user-defined model
_t		Variable to define a parametric equation based curve
_u		Variable to define a parametric equation

		based surface
_v		Variable to define a parametric equation based surface
_V1 through _V9	mV	Port voltage in an interpretive user-defined model
Ang	deg	Post-processing variable (cannot be set by the user)
Budget_Index		Post-processing variable (cannot be set by the user)
Distance	mm	
ElectricalDegree	deg	Electrical degree of the rotating machine (cannot be set by the user)
F	GHz	Frequency of the circuit/system analysis
F1	GHz	Frequency of tone 1 in the harmonic balance analysis
F2	GHz	Frequency of tone 2 in the harmonic balance analysis
F3	GHz	Frequency of

		tone 3 in the harmonic balance analysis
FNoi	GHz	Offset noise frequency in the harmonic balance noise analysis
Freq	GHz	Post-processing variable (cannot be set by the user)
Hmax	ns	
Hmin	ns	
Ia and Ib	mA	Post-processing variable (cannot be set by the user)
Index		Post-processing variable (cannot be set by the user)
IWavePhi	deg	Post-processing variable (cannot be set by the user)
IWaveTheta	deg	Post-processing variable (cannot be set by the user)
Normalized Deformation		
Normalized Distance		Post-processing variable (cannot be set by the user)

OP	mW	Post-processing variable (cannot be set by the user)
Pass		Post-processing variable (cannot be set by the user)
Phase	deg	Post-processing variable (cannot be set by the user)
Phi	deg	Post-processing variable (cannot be set by the user)
R	mm	Post-processing variable (cannot be set by the user)
Rho		Post-processing variable (cannot be set by the user)
RSpeed	rpm	Speed of the machine (cannot be set by the user)
Spectrum	GHz	Post-processing variable (cannot be set by the user)
Temp	cel/deg	Analysis temperature (deg)

Tend	ns	
Theta	deg	Post-processing variable (cannot be set by the user)
Time	ns	Time point in a transient analysis
Time0	ns	Time 0 point in a transient analysis
Vac	mV	Post-processing variable (cannot be set by the user)
Vbe	mV	Post-processing variable (cannot be set by the user)
Vce	mV	Post-processing variable (cannot be set by the user)
Vds	mV	Post-processing variable (cannot be set by the user)
Vgs	mV	Post-processing variable (cannot be set by the user)
X, Y, and Z	mm	Post-processing variable (cannot be set by the user)

ZAng and ZRho	deg	Post-processing variable (cannot be set by the user)

Not shown on the Intrinsic Variables tab are the **Speed** and **Position** variables that are available only in Maxwell 2D and 3D transient designs with Motion Setup. These variables are treated as intrinsic variables and are not user-editable. Their values are dynamically calculated during solve time and are expressed in standard SI units. While these variables are *related* to motion setups, they are not necessarily *used* in motion setups. For example, they may also be used with the transient design's excitations. See *Motion Variables Tab* for additional information.

Using Intrinsic Functions in Expressions

Maxwell recognizes a set of intrinsic trigonometric and mathematical functions that can be used to define expressions. Intrinsic function names are reserved and may not be used as variable names.

The following intrinsic functions may be used to define expressions:

Function	Description	Syntax
abs	Absolute value (|x|)	**abs(x)**
sin	Sine	**sin(x)**
cos	Cosine	**cos(x)**
tan	Tangent	**tan(x)**
asin	Arcsine	**asin(x)**
acos	Arccosine	**acos(x)**
atan	Arc tangent. Takes a tangent value as an argument. Because there are two angles in a circle that can have the same tangent value, and atan can return only one value, it returns a value in the range between -90 degrees and +90 degrees (or between -pi/2 and pi/2 in radians).	**atan(x)**
atan2	A two-argument version of the **atan** function. Takes the y and x coordinates (including sign information) of a point as arguments and returns the angle from the X-axis. Can return angle values for the full circle (-180 degrees to +180 degrees or -pi to +pi in radians).	**atan2(y,x)**
asinh	Hyperbolic Arcsine	asinh(x)
atanh	Hyperbolic Arctangent	atanh(x)
sinh	Hyperbolic Sine	**sinh(x)**
cosh	Hyperbolic Cosine	**cosh(x)**
tanh	Hyperbolic Tangent	**tanh(x)**

even	Returns 1 if integer part of the number is even; returns 0 otherwise.	even(x)
odd	Returns 1 if integer part of the number is odd; returns 0 otherwise.	odd(x)
sgn	Sign extraction	sgn(x)
exp	Exponential ($\mathbf{e}^x$)	**exp(x)**
pow	Raise to power (x^y)	pow(x,y)
if	If	**if(cond_exp,true_exp, false_exp)**
pwl	Piecewise Linear with linear extrapolation on x. (pwl can be used with datasets for Design Variables but not for Project variables).	pwl **(dataset_exp, variable)**
pwlx	Piecewise Linear x with linear extrapolation on x	pwlx **(dataset_exp, variable)**
pwl_periodic	Piecewise Linear with periodic extrapolation on x	pwl_periodic **(dataset_exp, variable)**
sqrt	Square Root	**sqrt(x)**
ln	Natural Logarithm (The "log" function has been discontinued. If you use "log(x)" in an expression, the software automatically changes it to "ln(x)".)	**ln(x)**
log10	Logarithm base 10	log10(x)
int	Truncated integer function	int(x)
nint	Nearest integer	nint(x)
max	Maximum value of two parameters	max(x,y)
min	Minimum value of two parameters	min(x,y)
mod	Modulus	mod(x,y)
rem	Returns the fractional part of a decimal number such that rem(x) = x-int(x)	rem(x)
clp	Closest point interpolation. Note: If used with a large 3D dataset, clp function will degrade.	clp (*datasetName*, X,Y,Z)

Note	If you do not specify units, all trigonometric functions interpret their arguments as radians. Likewise, inverse trigonometric functions' return values are in given in radians.

	When the argument to a trigonometric expression is a variable, the units are assumed to be radians. If you want values interpreted in degrees, supply the argument with the unit name **deg**

Related Topics

Defining an Expression

Using Piecewise Linear Functions in Expressions

The following piecewise linear intrinsic functions are accepted in expressions:

```
pwl (dataset_expression, variable)
pwlx (dataset_expression, variable)
pwl_periodic (dataset_expression, variable)
```

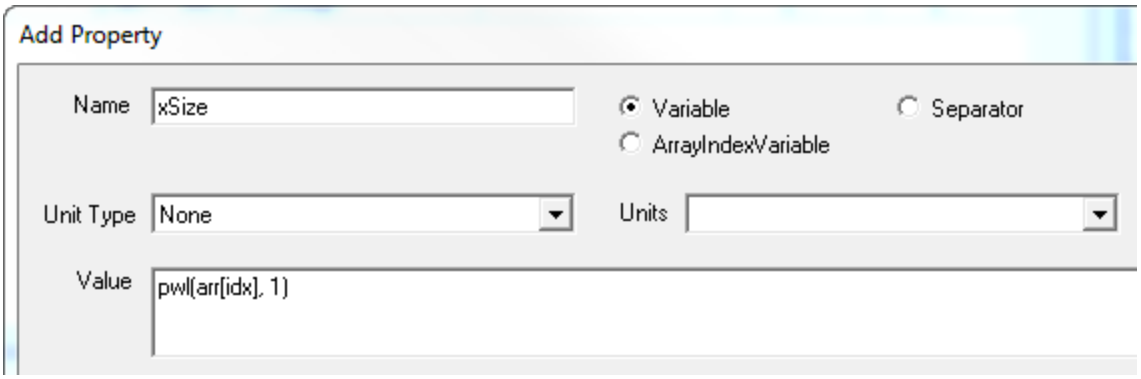
The **pwl** and **pwlx** functions interpolate along the x-axis and returns a corresponding y value. The **pwl_periodic** function also interpolates along the x-axis but periodically.

You can use **pwl** in an expression that uses array variables and datasets for uses such as a frequency dependent material property. (Refer to Adding Datasets for related information on working with datasets.) For example, you specify BulkConductivity as:

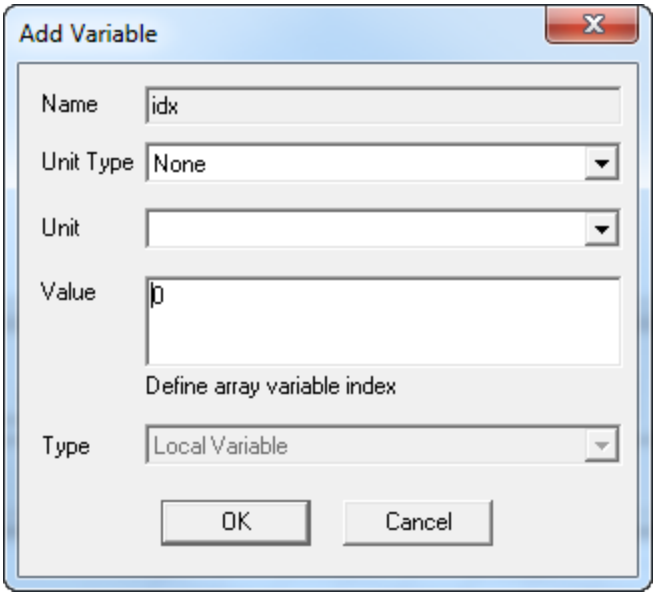
`pwlx($dsArr[$dsIndex], Freq)` where `$dsArr=["$ds1", "$ds2"]`

You can create a Design Variable representing dimension `xSize` as `pwl(arr[idx], 1)` where "`arr`" is an array variable and `idx` is an array index variable.

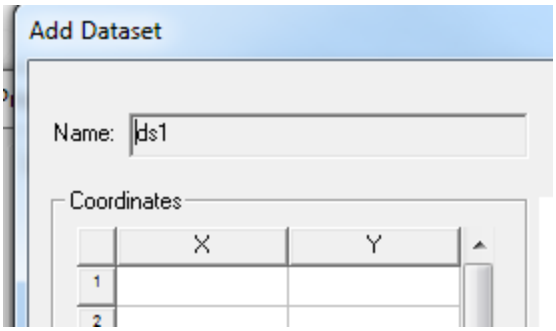
In this case, creating a variable named xSize with pwl(arr[idx], 1) like this:



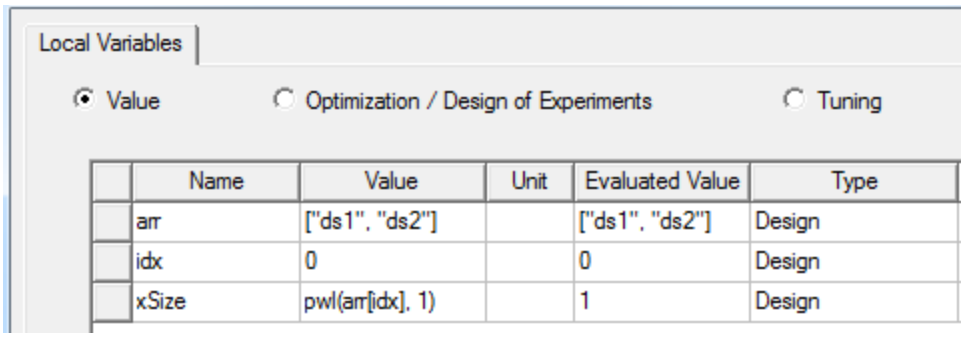
This value for xSize automatically opens a dialog first for the idx index variable:



And then dialogs automatically open for each dataset variable implicit for the predefined array variable:



Then the **Design Properties** dialog shows as follows:



Note	pwl can be used with datasets for Design Variables but not for Project variables.

Adding Datasets
Adding a Design Variable
Modifying Datasets
Using Dataset Expressions

Using Dataset Expressions

Dataset expressions take the following form:

$$\$ds1((x_0,y_0), \ldots, (x_n,y_n))$$

These expressions may be used as the first parameter to piecewise linear (**pwl**, **pwlx** and **pwl_periodic**) functions, and may also be assigned to variables, in which case the variable may be used as the second parameter to **pwl**, **pwlx** and **pwl_periodic** functions.

Dataset expressions are derived from a series of points in a plot created in the **Datasets** dialog box. (Refer to Adding Datasets for related information on working with datasets.) Each plot consists of straight line segments whose vertices represent their end points. A curve is fitted to the segments of the plot, and an expression is derived from the curve that best fits the segmented plot. The created expression is then used in the piecewise linear intrinsic functions.

Assigning Variables

To assign a variable to a parameter in Maxwell:

- Type the variable name or mathematical expression in place of a parameter value in a **Value** text box.

  If you typed a variable name that has not been defined, the **Add Variable to *DesignName*** dialog box will appear, enabling you to define the design variable.

  If you typed a variable name that included the **$** prefix, but that has not been defined, the **Add Variable** dialog box appears, enabling you to define the project variable.

Note	You can assign a variable to nearly any design parameter assigned a numeric value in Maxwell. See the Maxwell help about the specific parameter you want to vary to determine if can be assigned a variable.

Related Topics

Working with Variables

Choosing a Variable to Optimize

Before a variable can be optimized, you must specify that you intend for it to be used during an optimization analysis in the **Properties** dialog box.

1. If the variable is a design variable, click **Maxwell 2D** (or **Maxwell 3D**, or **RMxprt**)**>Design Properties**. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   If the variable is a project variable, click **Project>Project Variables**. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

   The **Properties** dialog box appears.
2. Click the tab that lists the variable you want to optimize.
3. Click the row containing the variable you want to optimize.

Note	Dependent variables cannot be optimized.
4. Select the **Optimization/ Design of Experiments** option.
5. For the variable you want to optimize, select **Include**.

   The selected variable is now available for optimization in an optimetrics setup defined in the current design or project.

Note	Complex numbers are not allowed for variables to be used in an Optimetrics sweep, or for optimization, statistical, sensitivity or tuning setups.

6. Optionally, override the default minimum and maximum values that Optimetrics uses for the variable in every optimization analysis. During optimization, the optimizer does not consider variable values that lie outside of this range.
7. Click **OK**.

Including a Variable in a Sensitivity Analysis

Before a variable can be included in a sensitivity analysis, you must specify that you intend for it to be used during a sensitivity analysis in the **Properties** dialog box.

1. If the variable is a design variable, click **Maxwell 2D** (or **Maxwell 3D**, or **RMxprt**)**>Design Properties**. You can also access the Design variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Design Variables**.

   If the variable is a project variable, click **Project**>**Project Variables**. You can also access the Project variables from a menu in the lower left corner of the following Optimization dialogs: **Parametric**, **Optimization**, **Sensitivity**, **Statistical**, **Design of Experiments**, and **Design Xplorer Setup**. Click **Edit Variables** and from the menu select **Edit Project Variables**.

   The **Properties** dialog box appears.
2. Click the tab that lists the variable you want to include in the sensitivity analysis.
3. Click the row containing the variable you want to include in the sensitivity analysis.

Note	Dependent variables cannot be included in a sensitivity analysis.
4. Select the **Sensitivity** option.
5. For the variable you want to include in the sensitivity analysis, select **Include**.

   The selected variable is now available for sensitivity analysis in a sensitivity setup defined in the current design or project.

Note	Complex numbers are not allowed for variables to be used in an Optimetrics sweep, or for optimization, statistical, sensitivity or tuning setups.

6. Optionally, override the default minimum and maximum values that Optimetrics uses for the variable in every sensitivity analysis. During sensitivity analysis, Optimetrics does not consider variable values that lie outside of this range.
7. Optionally, override the default initial displacement value that Optimetrics uses for the variable in every sensitivity analysis. During sensitivity analysis, Optimetrics will not consider a variable value for the first design variation that is greater than this step size away from the starting variable value.
8. Click **OK**.

Maxwell ACT Extensions Wizards

The following Maxwell extension Wizards implemented in Ansys ACT can be accessed through the **View>ACT Extensions** user interface.

- Maxwell Eccentricity
- Machine Toolkit

Related Topics

Using the Motion Eccentricity Wizard

Using the Machine Toolkit Wizard

Using the Maxwell Machine Toolkit Wizard (Windows only)

The Machine Toolkit wizard (Windows only) requires a valid 2D or 3D transient design with motion setup. The machine toolkit uses the original design to create a new design which is then used to perform the analysis. The machine toolkit supports five machine types:

- PM (Permanent Magnet) Synchronous Machines
- Induction Machines
- Synchronous Reluctance Machines
- Switched Reluctance Machines
- Wound-rotor Synchronous Machines

The machine toolkit can be used in the following four scenarios. Choose the one appropriate for your design needs.

- **Interactive Solve**
    1. For interactive solve, define the machine parameters, then click **Finish**. The toolkit will solve the parametric table sweep, and calculate efficiency maps immediately on

the same machine. Make sure you have set the analysis setting you wish to use (DSO/HPC).

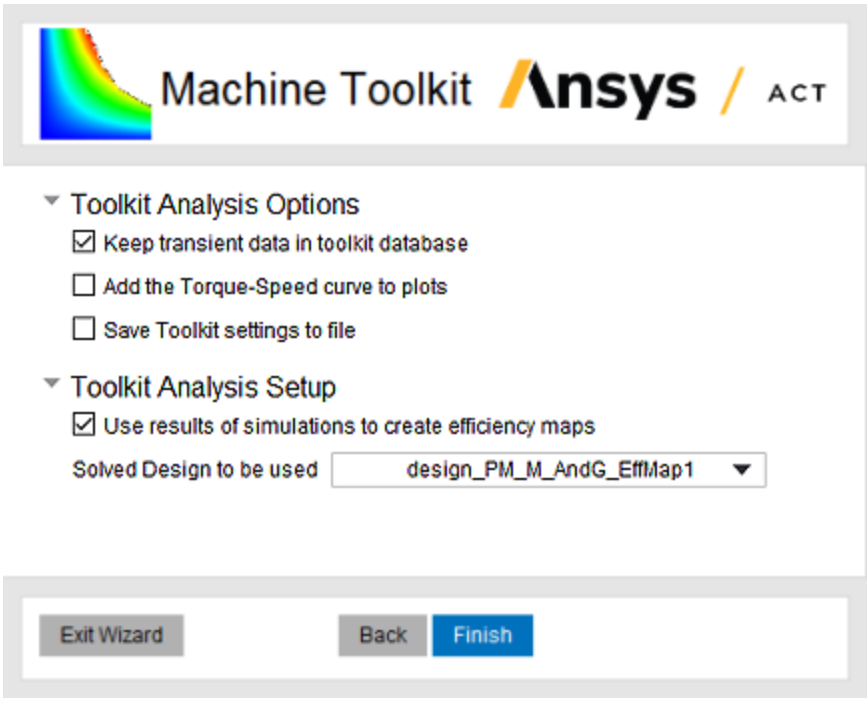
Note	The user does not have to solve the parametric sweep, it is solved automatically.

- The toolkit creates a new design.
- Parametric sweep is solved.
- For PM Synchronous machines, Synchronous Reluctance machines, and Wound-rotor Synchronous machines: If not provided by the user, the DQ initial alignment angle is calculated by solving an independent simulation.
- Results are extracted.
- Postprocessing is performed, and reports (contour plots) are created in the design.

- **Delayed Solve**
  1. For delayed solve, define the machine parameters, and check **Solve for initial angle then prepare new design (user to solve parametric table)**.

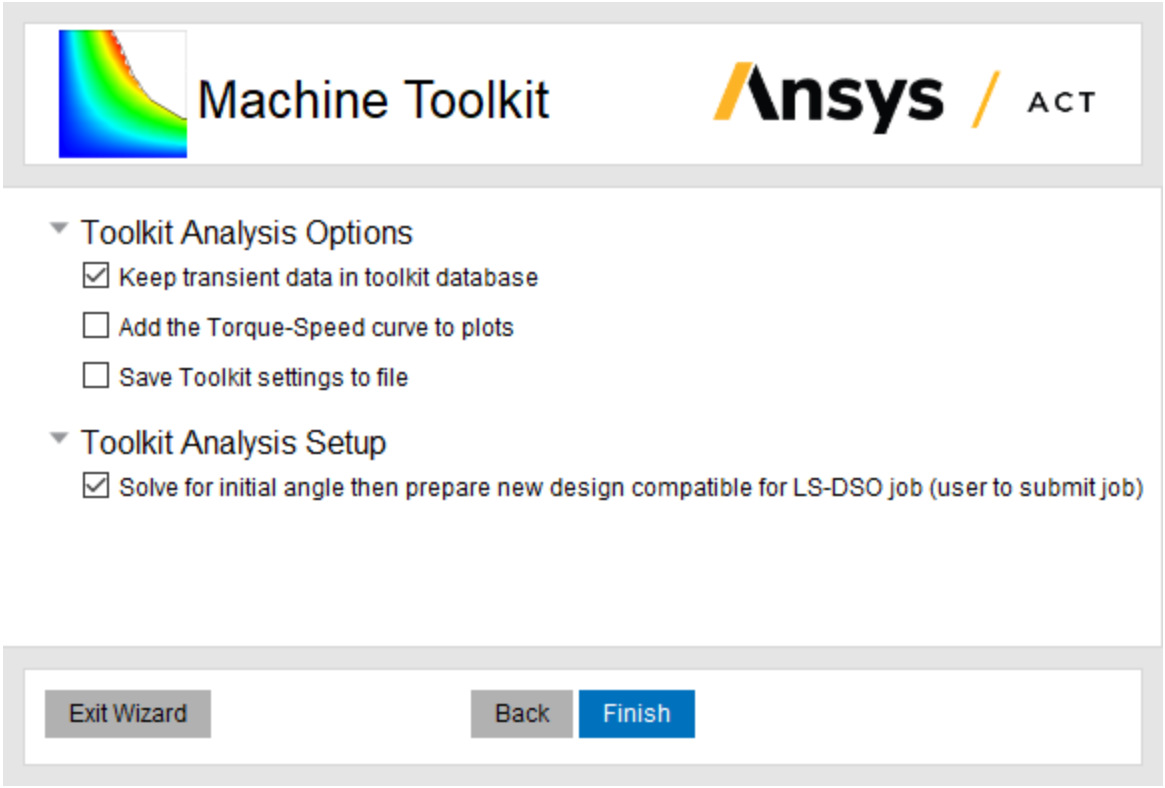
  2. Click **Finish**.
     - A new design is created.
     - For PM Synchronous machines, Synchronous Reluctance machines, and Wound-rotor Synchronous machines: If not provided by the user, the DQ initial alignment angle is calculated by solving an independent simulation.
     - The parametric sweep is then solved separately by the user.
  3. After solving, reopen the toolkit. The parameter entries will be prefilled.

4. Navigate to the last wizard page and select **Use results of simulations to create efficiency maps** and select the **Solved Design to be used**.

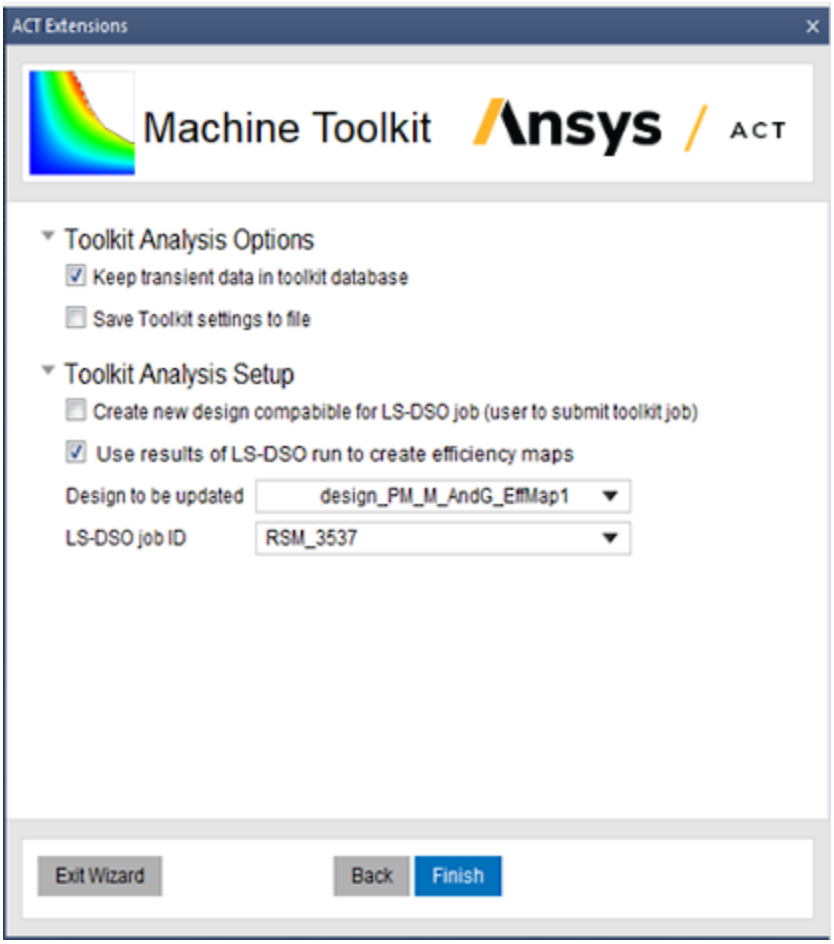


5. Click **Finish**.
    - Results are extracted.
    - Postprocessing is performed, and reports (contour plots) are created in the design.

- **Solve using LS-DSO**
    1. For solve using LS-DSO, define the machine parameters, and check **Solve for initial angle then prepare new design compatible for LS-DSO job (user to submit job)**.



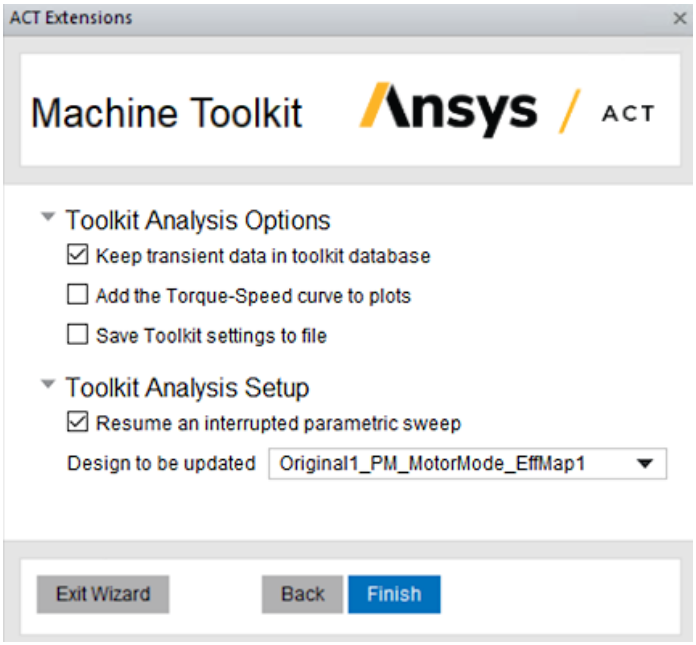
2. Click **Finish**.
    - A new design is created.
    - For PM Synchronous machines, Synchronous Reluctance machines, and Wound-rotor Synchronous machines: If not provided by the user, the DQ initial alignment angle is calculated by solving an independent simulation.
    - The new design contains a parametric sweep that needs to be solved.
    - The toolkit stops to let user solve the LS-DSO job separately.
3. Upon completion of the LS-DSO job, restart the toolkit. The parameter entries will be prefilled.
4. Navigate to the last wizard page and select **Use results of LS-DSO run to create efficiency maps**, then select the **Design to be updated** and also the **LS-DSO job ID** that was used for the job.



5. Click **Finish**.
    - Results are extracted.
    - Post-processing is performed, and reports (contour plots) are created in the design.

- **Resume an Interrupted Parametric Sweep Run**
    1. For this scenario, first select an existing original design. The parameters of the interrupted efficiency map design are automatically prefilled in the UI.
    2. Navigate to the last wizard page and select **Resume an interrupted parametric sweep** and select the **Design to be updated**.
    3. The parametric sweep of this design will start from where it was interrupted, and

efficiency maps will be generated in post processing.



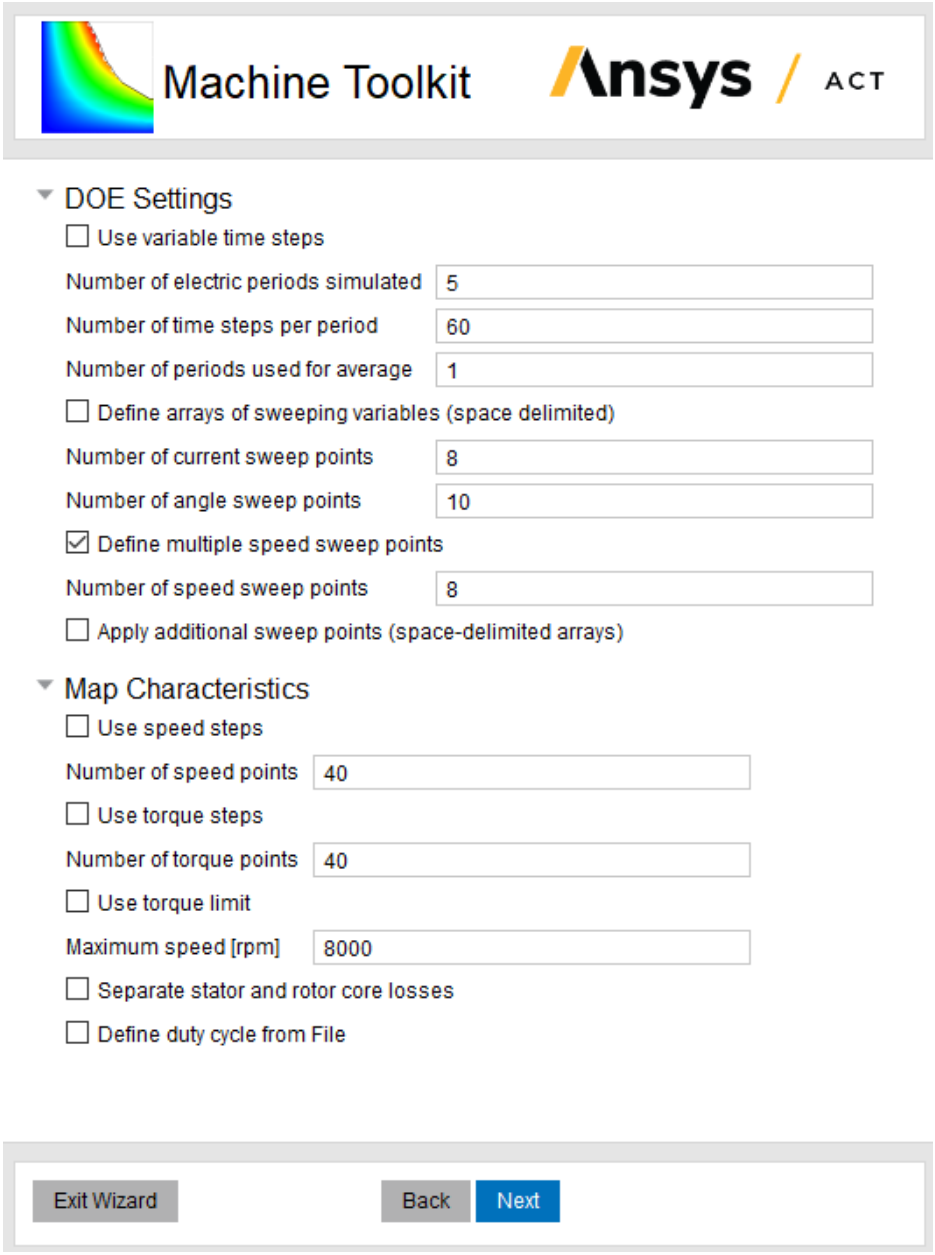
- **Generate Efficiency map only**
  1. For this scenario, first select an existing design. The parameter entries will be prefilled.
  2. Navigate to the last wizard page and select **Use results of simulations to create efficiency maps** and select the **Solved Design to be used**.
  3. Both general transient and periodic (or half-periodic) TDM can be used to conduct parametric analysis and create performance maps. Define the TDM option in the analysis setup of the original design. When conventional transient method or general transient TDM is used to extract performance data, it is necessary to define Number of electric periods simulated and Number of periods used for average in DOE settings. There is an option for the user to define two time intervals, and also specify the number of electric periods and number of time steps per period for each interval. When periodic or half-periodic TDM is enabled in the original design, such options are hidden in DOE settings, and the Machine Toolkit automatically defines the time duration for each simulation.

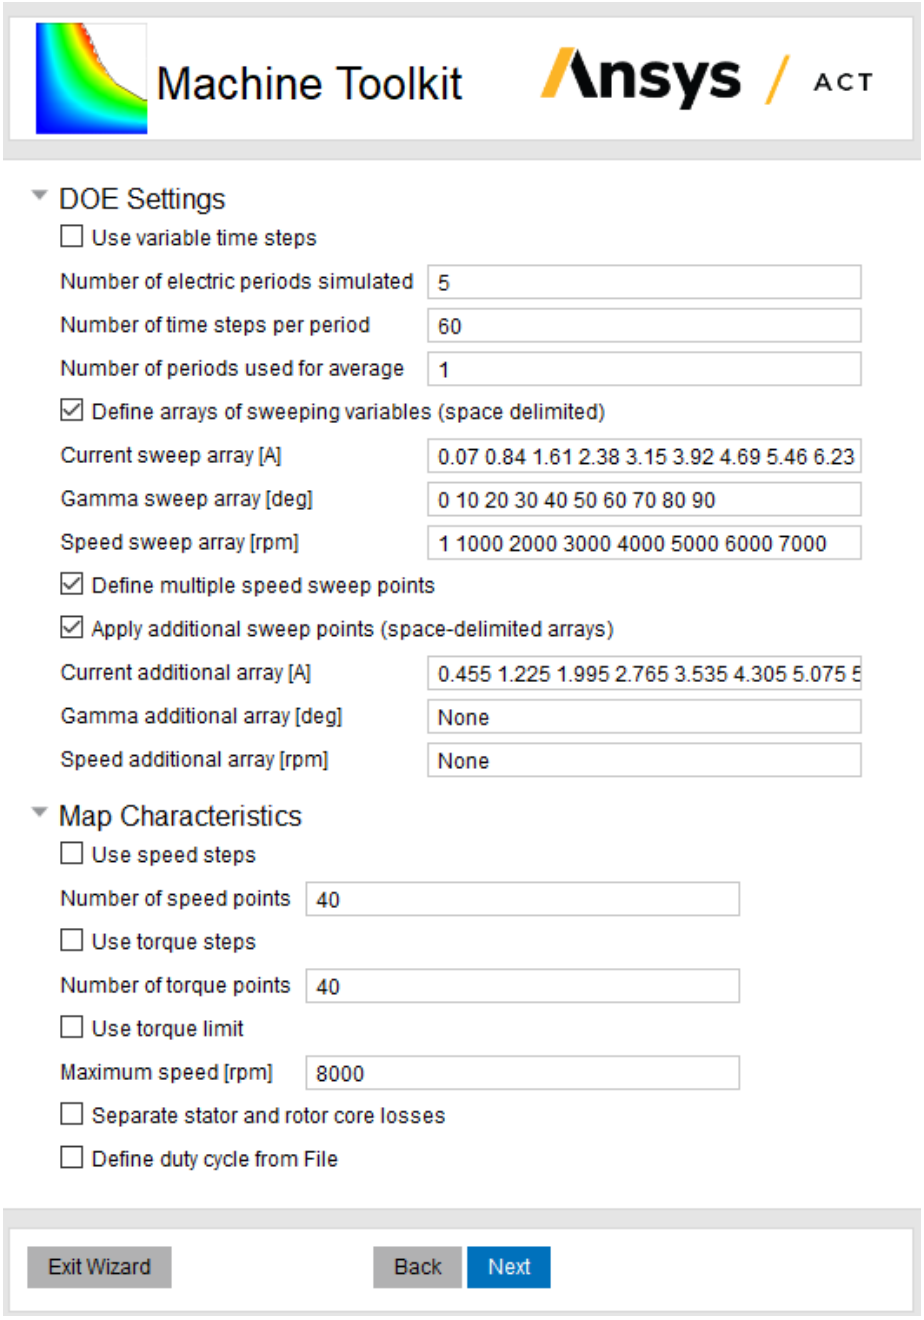
     Machine Toolkit provides two options for the user to determine sweep points in the parametric analysis. The first option is to define the number of sweep points for each independent variable, and then Machine Toolkit assigns the sweep points that are uniformly distributed in the solution domain. The second option is to define the numerical arrays of the sweeping variables, where each value is separated from its adjacent values by a single space character.

     Once the parametric analysis of the prior efficiency map simulation is completed, there is an option for the user to apply additional sweep points to the parametric

analysis. The operating points that are already computed in the prior parametric analysis are automatically skipped, and Machine Toolkit only simulates these additional points.

Note	• For an induction machine model with general transient analysis, the simulations of some operating points in the prior parametric sweep may not be skipped. • TDM options cannot be enabled for Switched Reluctance machines.





For induction machines, to use periodic TDM or half-periodic TDM, all sources including induced eddy current have to be in the same frequency. This means periodic TDM or half-periodic TDM is only applicable when rotor is locked at zero speed. To this end, we can introduce equivalent conductivity σ_eq associated with locked rotor to approximate the performance at original speed (σ_eq = σ * slip). For this kind of equivalence, fundamental component will be correctly modelled. This approximation is normally good enough to the simulated performances including

torque, current, voltage, etc with one exception that computed loss in the rotor needs to be rescaled in terms of slip.

Note	The following steps must be done before proceeding to use periodic TDM solver in the toolkit: a. Add a project parameter called **$slip**. The **Value** and **Evaluated Value** can be any number since the parametric sweep will override it. b. Modify the rotor bar's material, and change the conductivity from **X** to **X*$slip**. c. Modify the end connection resistance from **X** to **X/$slip**. d. Select **Enable two level**for HPC setting.

4. Click **Finish**.
   - Results are extracted.
   - Post-processing is performed, and reports (contour plots) are created in the design.

- **Create Efficiency Maps based on Reduced-Order Model**

  Machine Toolkit supports efficiency map generation based on the reduced-order model (ROM) for induction machines. This feature must be implemented in a design with Eddy Current solution type. The following parameters must be defined through the Machine Toolkit UI about the characteristics of the efficiency maps, including phase RMS voltage, maximum torque and speed, core loss correction factor, control strategy, simulation mode, friction loss, windage loss and their reference speed.

  Refer to the item ECEIM_Model for details about its input parameters and the mathematical representations of the ECE ROM for induction machines. All identified parameters of the ECE ROM are saved in the file `ece_table.txt`, and the Machine Toolkit needs this file to generate efficiency maps. There are three options for the user to obtain this file and define its directory in the Machine Toolkit. The first option is that the user directly specifies the file by checking **Specify the directory of the ECE table**. The second option is that the user first define an external circuit which includes an ECEIM_Model module, then the Machine Toolkit launches the analysis and automatically obtains the file `ece_table.txt`. The third option is that the Machine Toolkit creates an external circuit with the ECEIM_Model module and imports it to the definition of Excitations, then runs the simulation to get this table. Additional parameters must be input by the user if the third option is selected, including the skew angle, phase RMS current, number of current sweep points, and the resistance and end inductance of the windings. The user can also define the current sweep array for the ECEIM_Model.

Defining Machine Toolkit Parameters

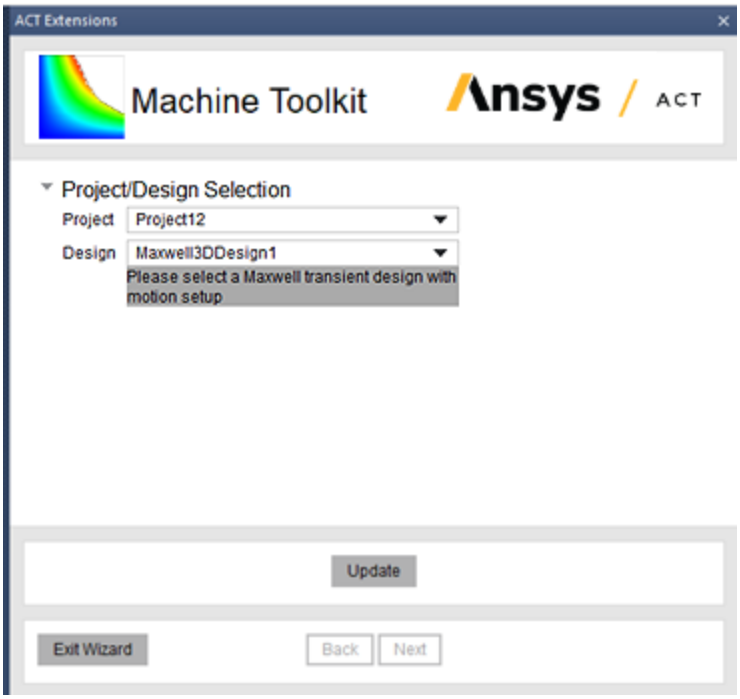
The machine toolkit supports five machine types:

- PM (Permanent Magnet) Synchronous Machines
- Induction Machines
- Synchronous Reluctance Machines
- Switched Reluctance Machines
- Wound-rotor Synchronous Machines

Note	The Machine Toolkit requires a valid 2D or 3D transient design with motion setup. The machine toolkit uses the original design to create a new design which is then used to perform the analysis.

The general workflow for using the Machine Toolkit to define machine parameters is as follows:

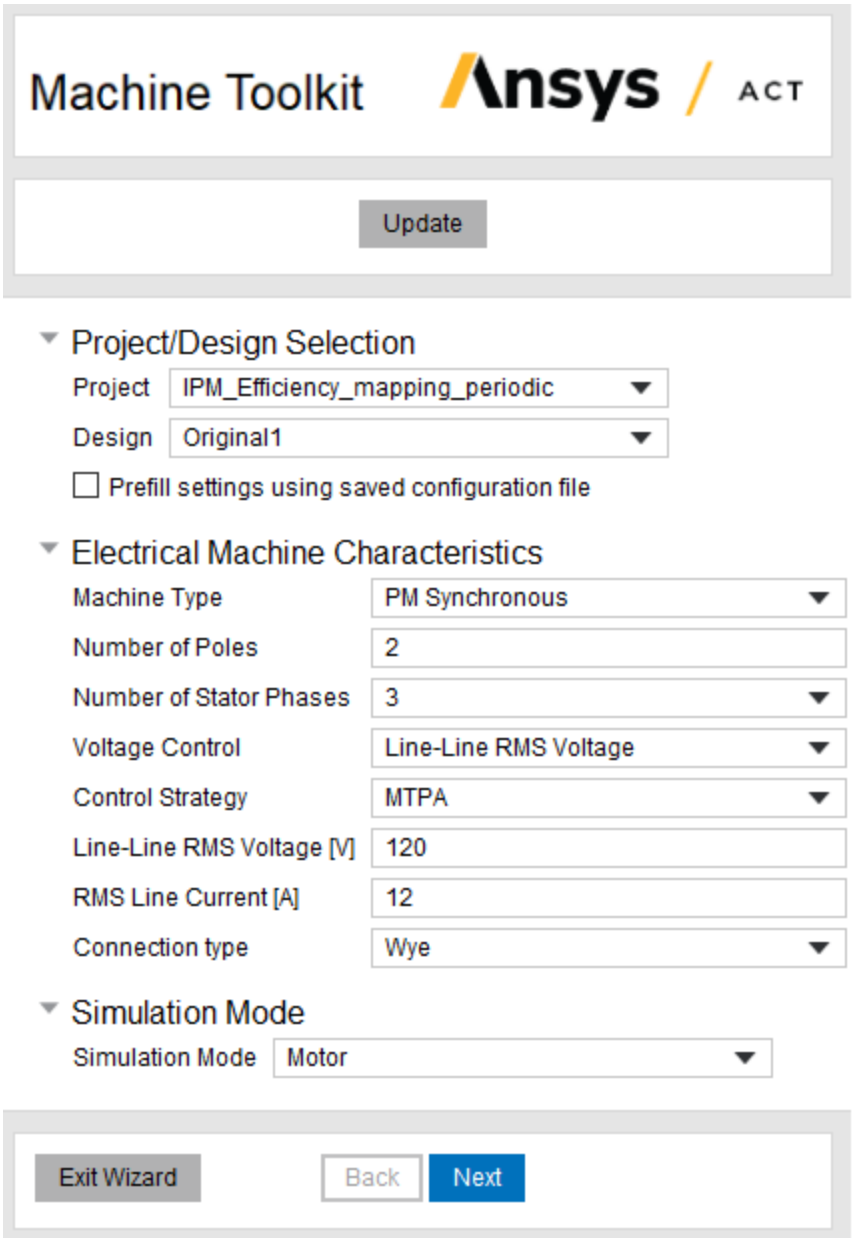
1. In the ACT Extensions Wizards window, click on the Machine Toolkit icon to launch the wizard, and select a valid transient design with motion.
2. You can open a project/design in the project manager if one is not already open.



After loading the project, select **Update** to refresh the Project/Design selections.

3. Select the desired Project and Design. Only designs that do not use reserved local variables are shown in the drop-down list. Reserved local variables are:

   Speed_TSC, Imax_TSC, Gamma_TSC, Vmax_TSC, Slip_TSC, Freq_TSC, and Field_TSC.



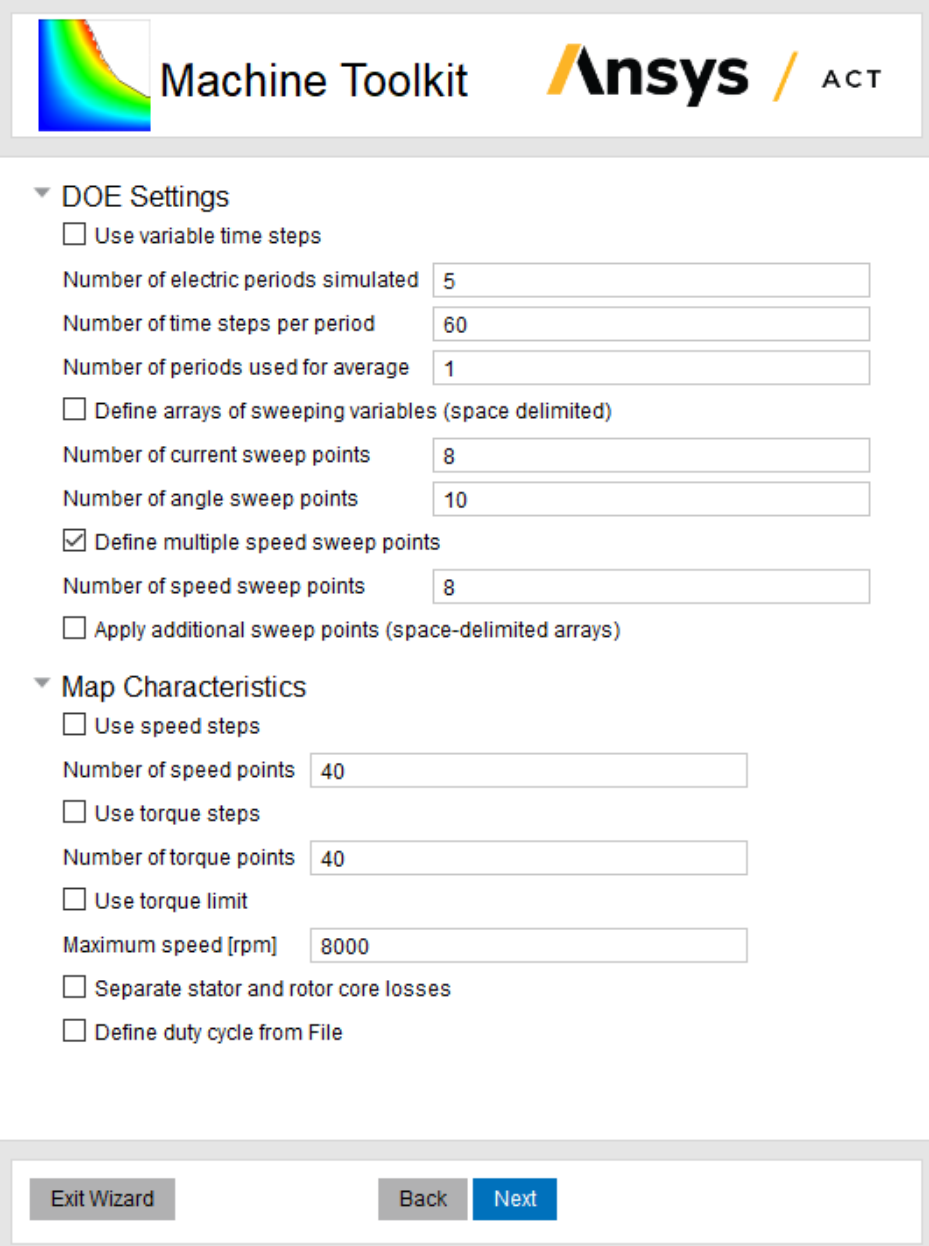
4. Enter all characteristics of the machine: **Machine Type** (**PM Synchronous**, **Induction**, **Synchronous Reluctance**, **Switched Reluctance**, or **Wound-rotor Synchronous**), **Number of Poles**, etc., in the various fields. Also select the desired **Simulation Mode** (**Motor** or **Generator**).

Note	• You can pre-fill all settings using a previously saved configuration `.sav` file by selecting **Prefill settings using saved configuration file**. • If you have previously used the toolkit with the current project, the toolkit prefills entries automatically.

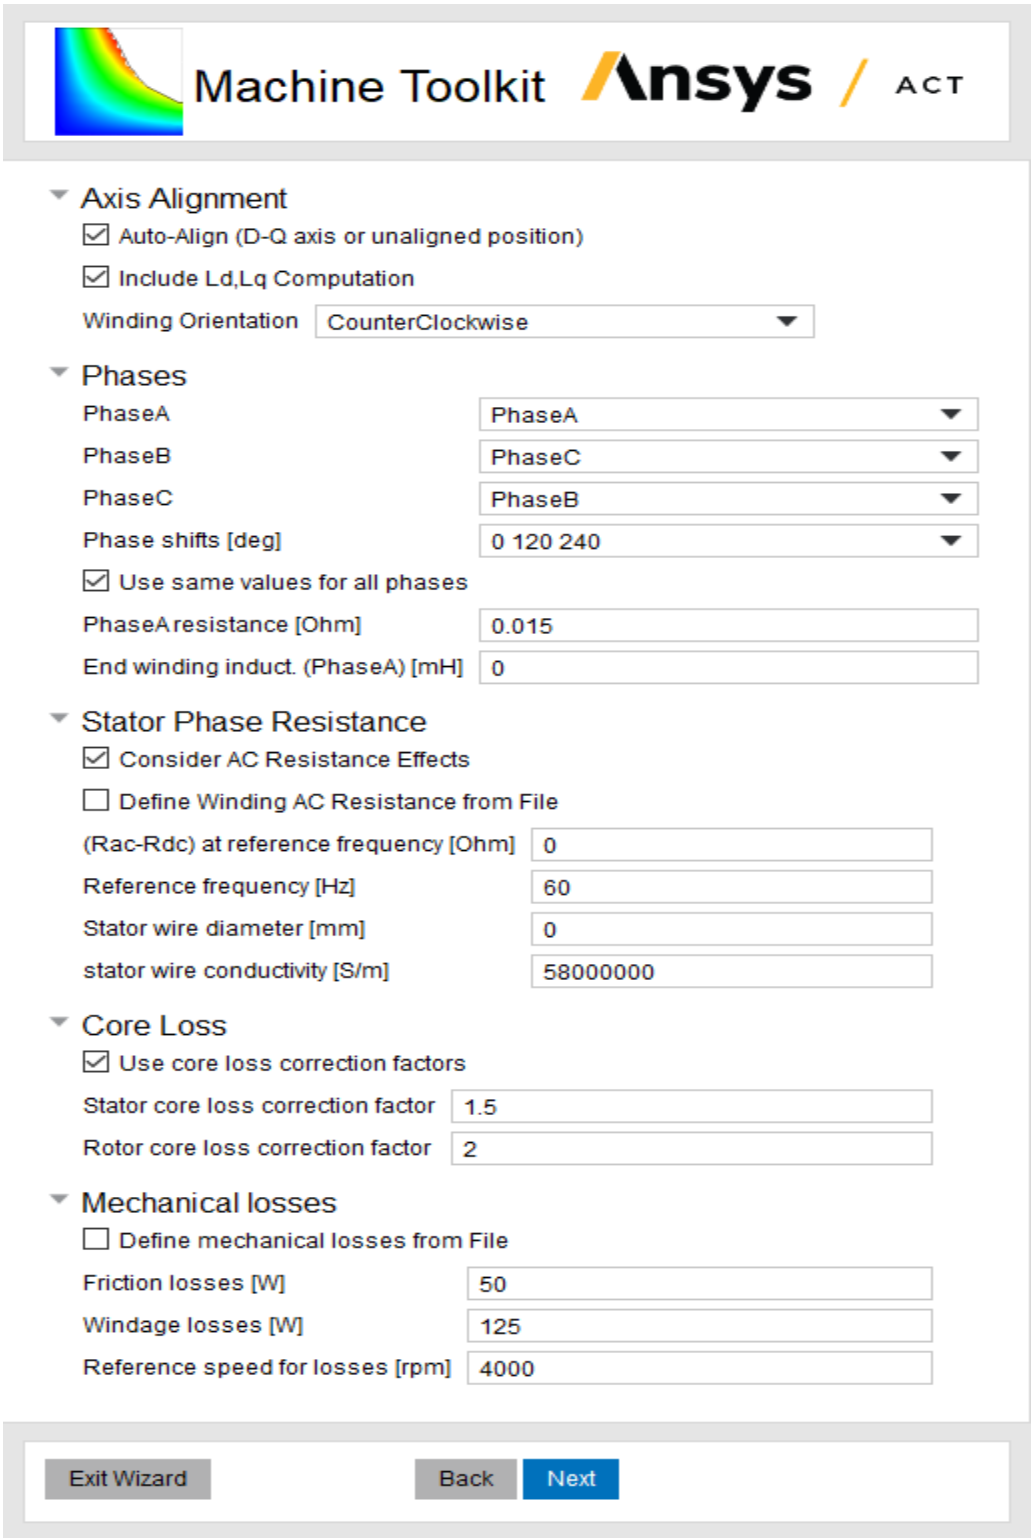
5. Click **Next** to go to the next page of the wizard. Here you enter the desired **DOE** (design of experiments) **Settings**, and the **Map Characteristics** used to generate the efficiency map when the design is solved.

Note	The content of the DOE Settings and Map Characteristics change based on which machine type you selected on the previous page.

Note that check boxes allow you to **Use speed steps** and **Use torque steps** instead of using the default speed and torque points. A parametric sweep will be created to account for the number of points (or steps).



6. When finished, click **Next** to move to the next page of the wizard.



- For PM Synchronous machines, Synchronous Reluctance machines, and Wound-rotor Synchronous machines, you can provide the alignment angle or have the toolkit calculate it. No matter which simulation mode is chosen, the initial angle must be determined first.
- For Phases, provide phase names, phase shifts, and other phase information.
- Optionally, provide custom loss information (Core Loss, Stator Phase Resistance winding losses, and Mechanical Losses).

Note	There are three options for AC winding loss calculation: • The first option is to apply the analytical AC winding loss model, and the user is required to input the stator wire diameter and conductivity, as well as AC resistance at the reference frequency. • The second option is to use the Litz wire model. • The third option is that the user can input a .txt file that provides a frequency vs. AC resistance table; in this file, the first line should include the names and units of frequency and resistance, e.g., "Freq [Hz] Rac[ohm]", followed by combinations of frequency vs. resistance data in each line, e.g., "60 1.5".

Note	Mechanical losses include friction and windage losses at a reference speed. You can optionally "Define mechanical losses from File", then specify the location of a user-defined “Mechanical loss vs speed table” text file. 
7. When finished, click **Next** to move to the next page of the wizard.
   - It is recommended to have the **Keep transient data in toolkit database** option enabled to retain the data because the extraction process can be lengthy.
   - Check **Save Toolkit settings to file** if you want to save all settings to a `.sav` file for use with another project. (For the current project, the settings are saved automatically.)
   - You can click **Back** to review or edit settings on previous pages.
   - If you choose to **Exit Wizard**, all settings are automatically saved and loaded the next time the current project is loaded.
   - **Toolkit Analysis Setup** options are used for the various scenarios described in *Using the Maxwell Machine Toolkit Wizard*.

8. Click **Finish** to complete the process for the various scenarios as described in *Using the Maxwell Machine Toolkit Wizard*.

Working with the ACT Extensions Window

Permanent-Magnet Synchronous Machines

Three-Phase Induction Machines

Using the Maxwell Eccentricity Wizard

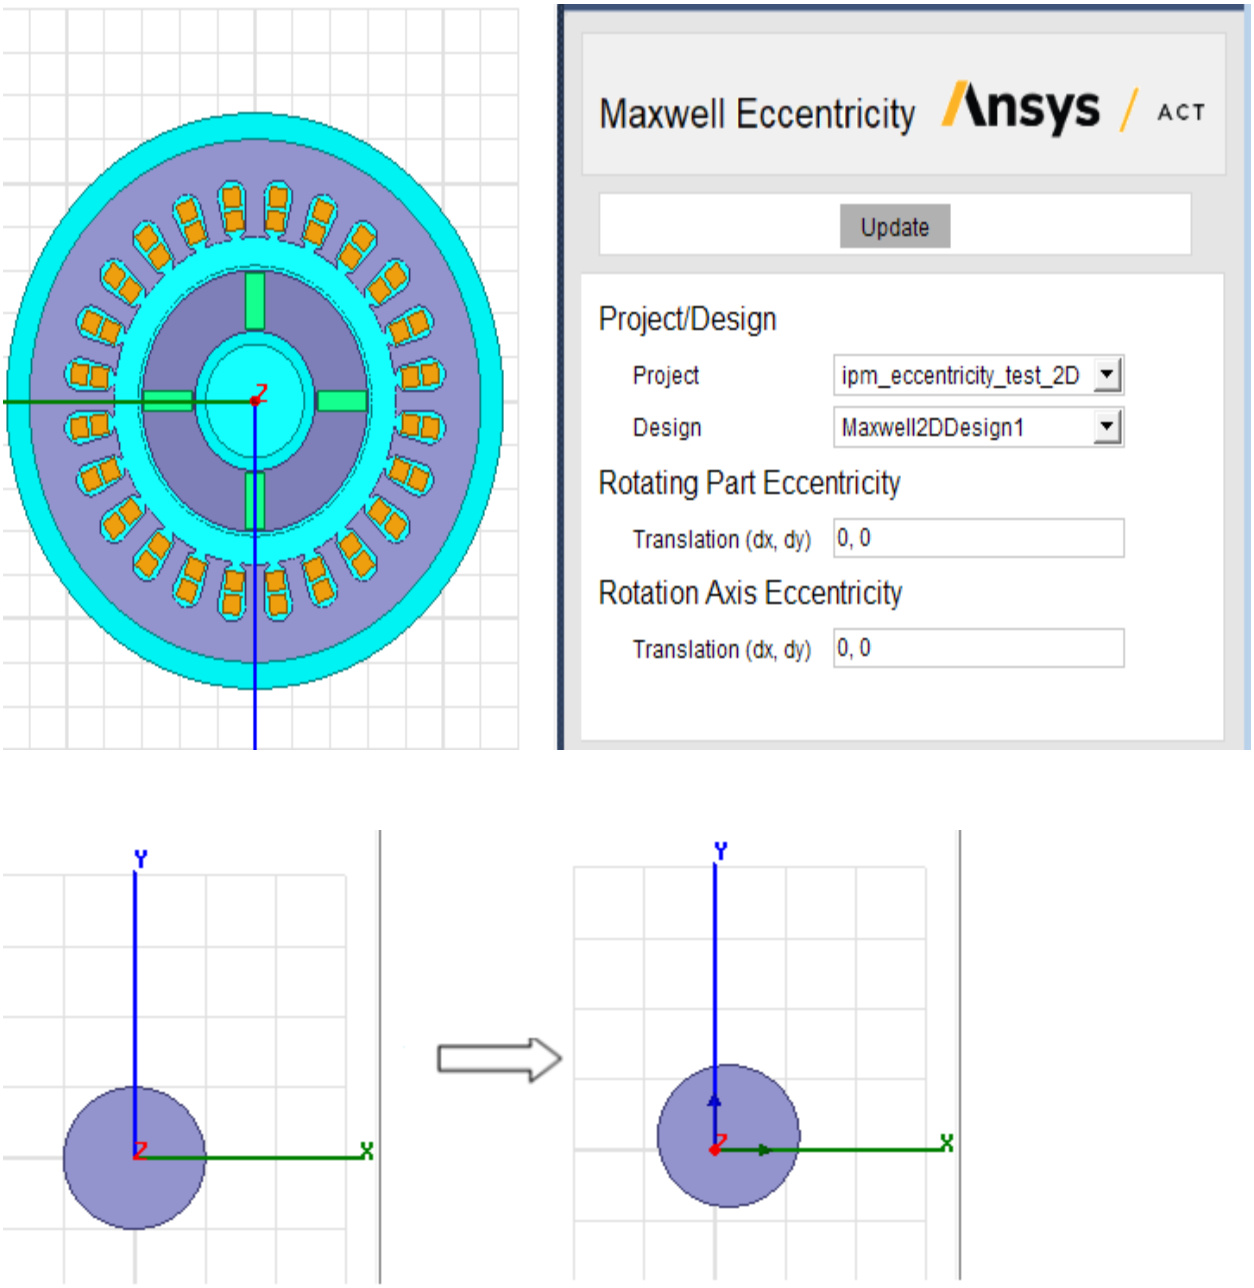
You can use the Maxwell Eccentricity wizard to model both 2D and 3D transient designs that have cylindrical rotational motion set up.

Note	If you want to generate a 3D rotational eccentricity motor design from an RMxprt-generated Maxwell 3D design, you must enter **Eccentricity 1** in the RMxprt **Design Setting** dialog **User Defined Data tab** for the RMxprt design *before* generating the Maxwell 3D design.

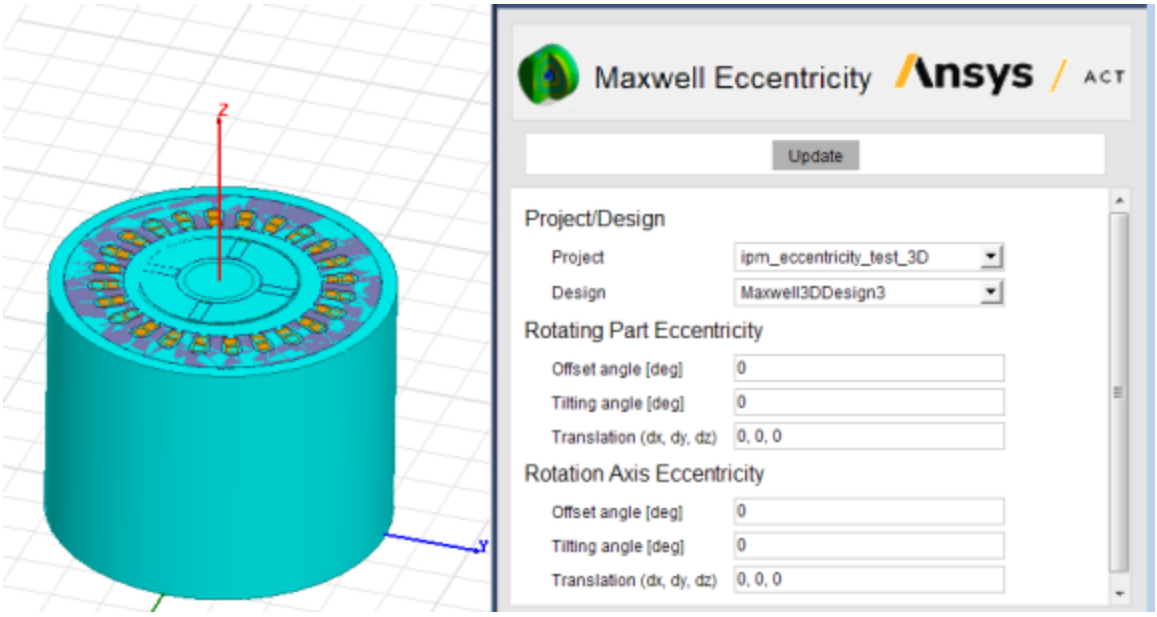
1. Select **View** > **ACT Extensions** to open the ACT Extensions window.
2. Click the **Wizards** button to open the Wizards page, then click **Maxwell Eccentricity** to load the Maxwell Eccentricity setup page.
3. Select the **Project** and **Design** you want to use.

Note	• The **Update** button synchronizes the Project and Design selection lists with those currently loaded in the Desktop. • You can click **Exit Wizard** to close the eccentricity wizard and return to the wizard start page without executing any changes.

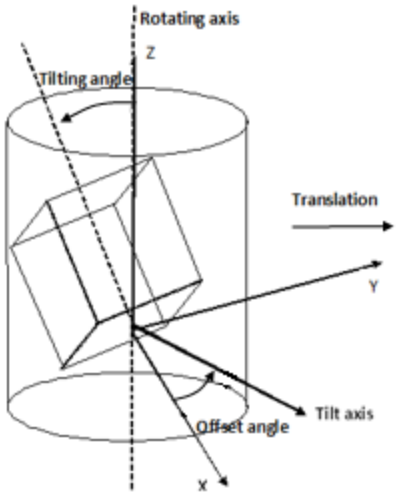
4. Depending on whether your design is 2D or 3D, do one of the following:
    - For a 2D Maxwell project, enter the desired dx and dy translation values to set up the Rotating Part Eccentricity and Rotation Axis Eccentricity. The unit of measure for translation values is the model's unit, which is set using **Modeler** > **Units**.



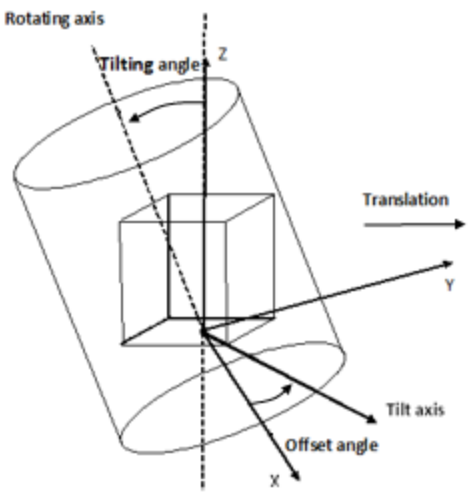
- For a 3D Maxwell project, enter the desired dx, dy , and dz translation values, the offset angle, and the tilting angle for the rotating part eccentricity axis and rotation axis. The unit of measure for translation values is the model's unit, which is set using **Modeler > Units**.



Rotation Part Eccentricity



Rotation Axis Eccentricity



5. Click the **Finish** button at the bottom of the page. The page closes and the wizard adds a new design in the same project, in which the Maxwell geometry has been updated in accordance with the eccentricity setup values you entered as follows:

For 2D designs

- Design variables are created for each of the data entered in the wizard.

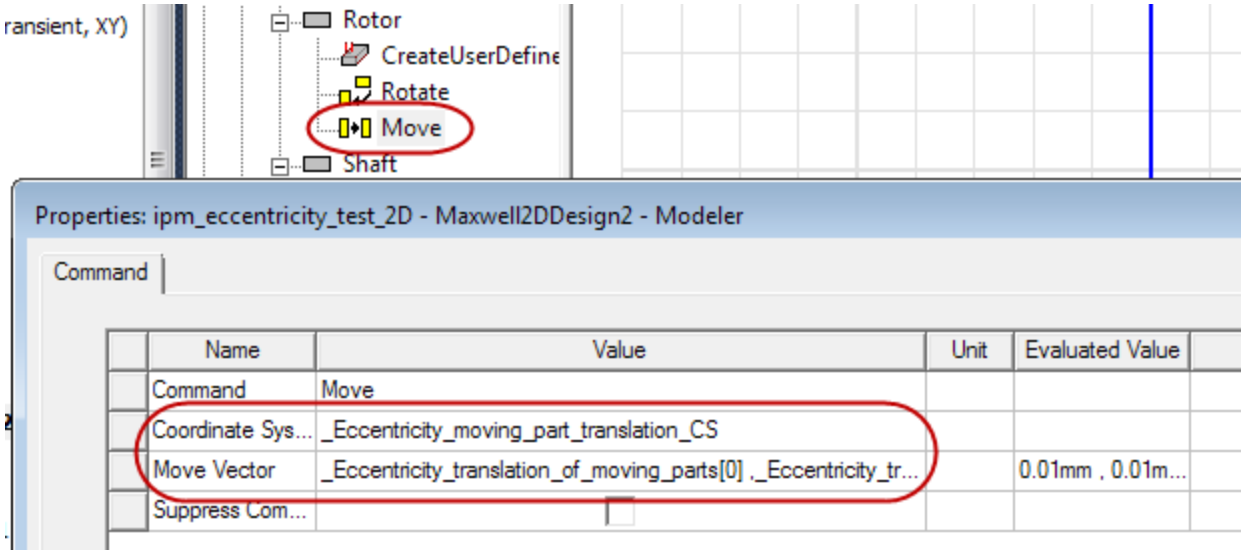
  For rotating part eccentricty:

_Eccentricity_translation_of_moving_parts

For rotation axis eccentricity:

_Eccentricity_translation_of_rotating_axis

- The moving parts in the design motion setup are shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.



- New design coordinate systems are created.

  _Eccentricity_rotating_axis_translation_CS

  _Eccentricity_moving_part_translation_CS

  _Eccentricity_moving_part_CS_*<part name>* – one for each moving part

Note	• All the above operations of translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables. • You can modify these design variables to adjust the eccentricity. • The newly added coordinate systems should not be changed manually by the user. • Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

For 3D designs

- Design variables are created for each of the data entered in the wizard.

  For rotating part eccentricty:

  _Eccentricity_offset_angle_of_moving_parts

  _Eccentricity_translation_of_moving_parts

  _Eccentricity_tilting_angle_of_moving_parts

  For rotation axis eccentricity:

  _Eccentricity_offset_angle_of_motion_axis

  _Eccentricity_translation_of_motion_axis

  _Eccentricity_tilting_angle_of_motion_axis
- The moving parts in the design motion setup are rotated and shifted according to the data defined for **Rotating Part Eccentricity** in the Wizard. New coordinate systems are generated as the object coordinate systems for moving parts, according to the same operations.
- The band is rotated and translated according to the data defined for **Rotation Axis Eccentricity** in the wizard.
- The **Moving Vector** entry in the design's motion setup is replaced with the new direction (represented by an axis of a new coordinate system) generated according to the data defined for **Rotation Axis Eccentricity** in the Wizard.
- New design coordinate systems are created.

  For the motion moving vector:

  _Eccentricity_motion_axis_CS

  _Eccentricity_motion_axis_tilting_axis_CS

  For the moving parts:

  _Eccentricity_moving_part_tilting_axis_CS

  _Eccentricity_moving_part_translation_CS

  _Eccentricity_moving_part_CS_*<part name>* – one for each moving part

Note	• All the above operations of rotation and translation, as well as the creation of new coordinate systems, are dependent on the eccentricity design variables. • You can modify these design variables to adjust the eccentricity. • The newly added coordinate systems should not be changed manually by the user. • Using the wizard to modify a design that has already been set up for eccentricity is not recommended.

Note	When modeling motion eccentricity, the position and direction of the moving objects and/or band are adjusted based on the eccentricity setup. In such cases, all the adjustments are referenced to the original position and direction of the geometry of each

	object, As a result, after you finish the eccentricity setup and click the **Finish** button, all the geometries in the design created by the wizard are updated to new positions based on the eccentricity setup. If you want to edit geometry, you should do so in the original design. After editing the geometry, you can then re-do the eccentricity setup to create a new design.

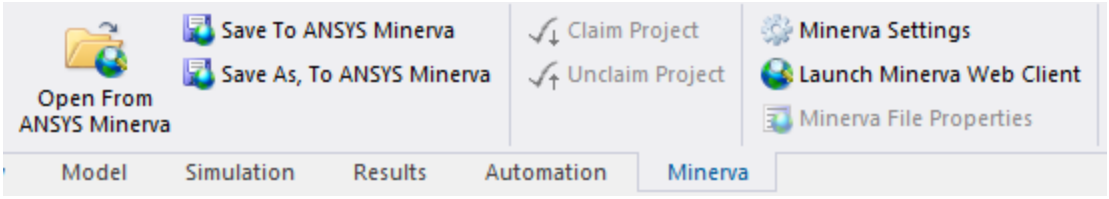
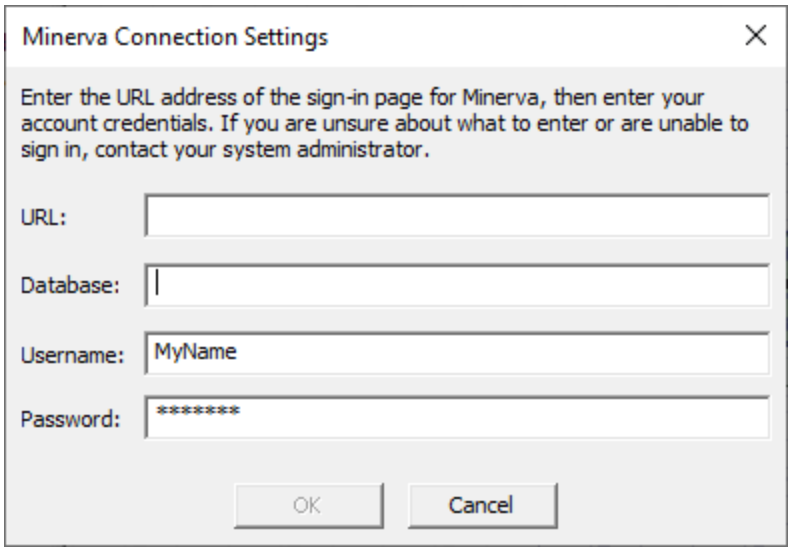
5 - Minerva Remote Storage Environment

Ansys Minerva is a remote storage environment where you can store Ansys project archive files. You can collaborate with other users by downloading a project, making changes, and then uploading the project. One of the features of Ansys Minerva is the ability to store and retrieve Ansys projects from the Minerva server. This ability has been integrated into Electronics Desktop so it is now possible to download and open a project stored on Minerva directly from the Electronics Desktop interface. In the same way, it is also possible to save a project to Minerva. The image below shows the Minerva ribbon containing Minerva commands accessible through the desktop.



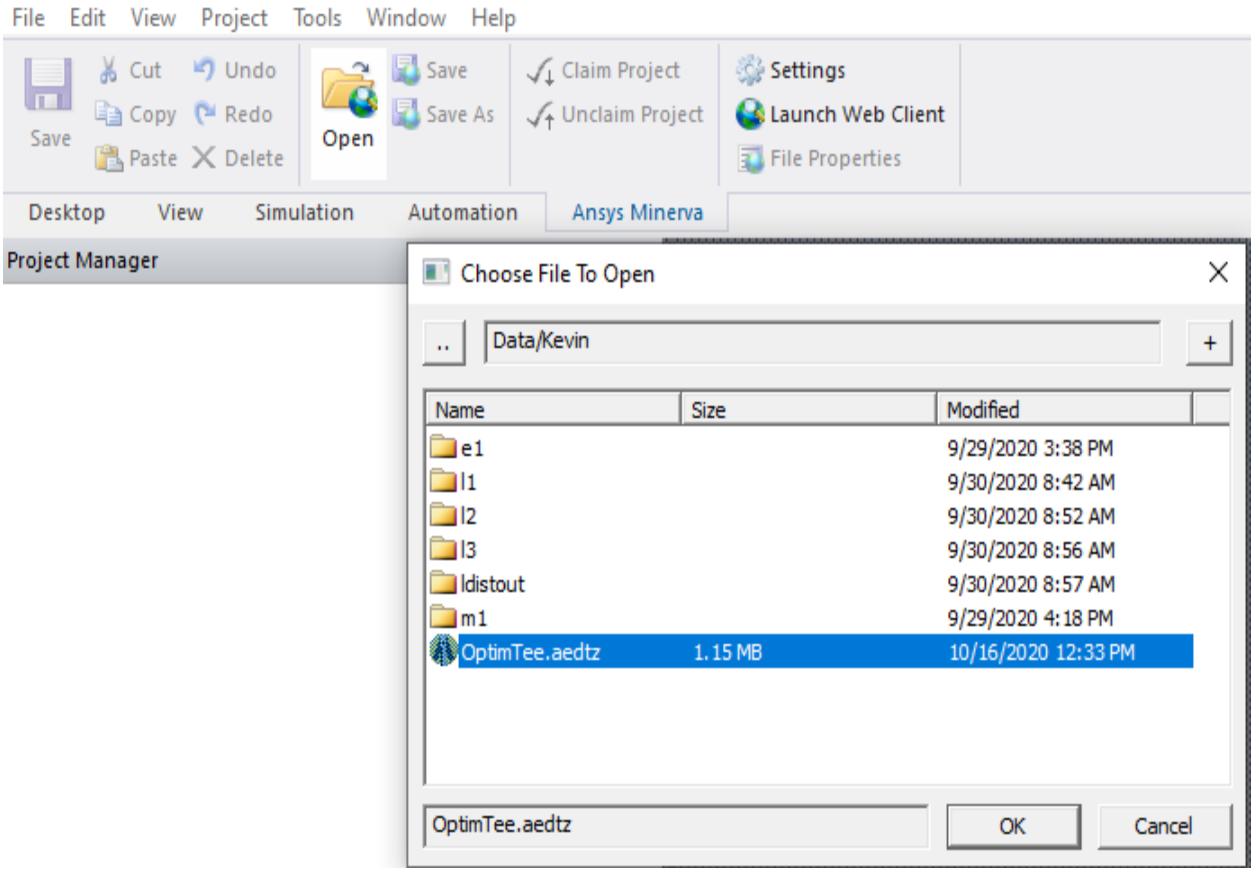
Minerva has its own HTML web interface with additional features as a knowledge management application that secures critical simulation data, and provides simulation process and decision support to simulation teams across geographies and functional silos.

Minerva Settings

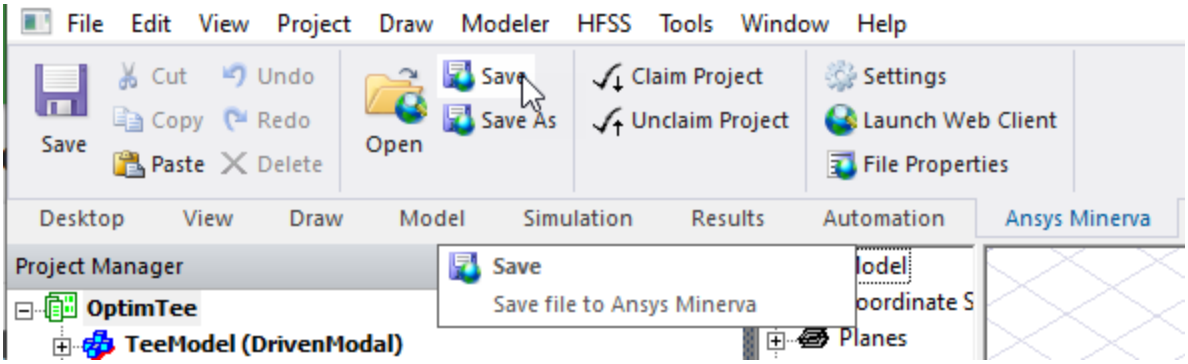


When you first login via the desktop, or to the Web Client, you must provide a Minerva URL, a database name, a user name, and a password. You will need to obtain these from your system administrator. Once you provide the connection settings, the other Minvera commands are enabled.

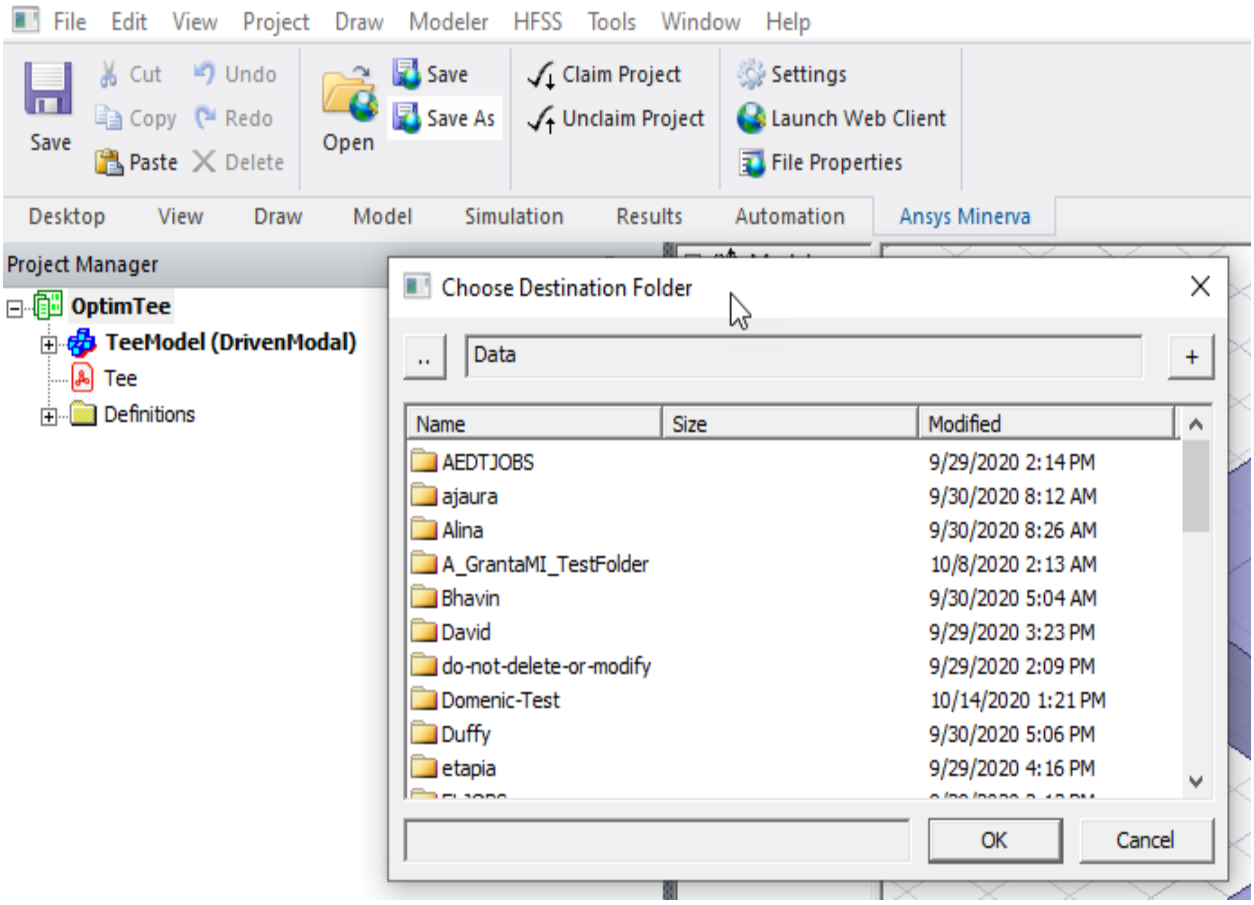
Open From Ansys Minerva: opens the Choose File to Open browser that lets you select and download an archive file, extract it, and open it. The [..] button moves up one level in the file hierarchy. The [+] button creates a new folder at the current level.



Save: archives the current project, and saves it to a remote Minerva system.



Save As...: prompt for remote file, archive project, save to remote Minerva system.



In order to prevent users from overwriting each other's work, Minerva has added the concept of claiming and unclaiming files. A file claimed by one user cannot be overwritten on the Minerva server by another user. Unclaimed files can be overwritten by anyone at any time. Once a file has been claimed by one user, it cannot be claimed by a different user until it has been unclaimed by the original claimer. Note: even if a project is claimed by one user, other users are free to download, open and edit the file locally.

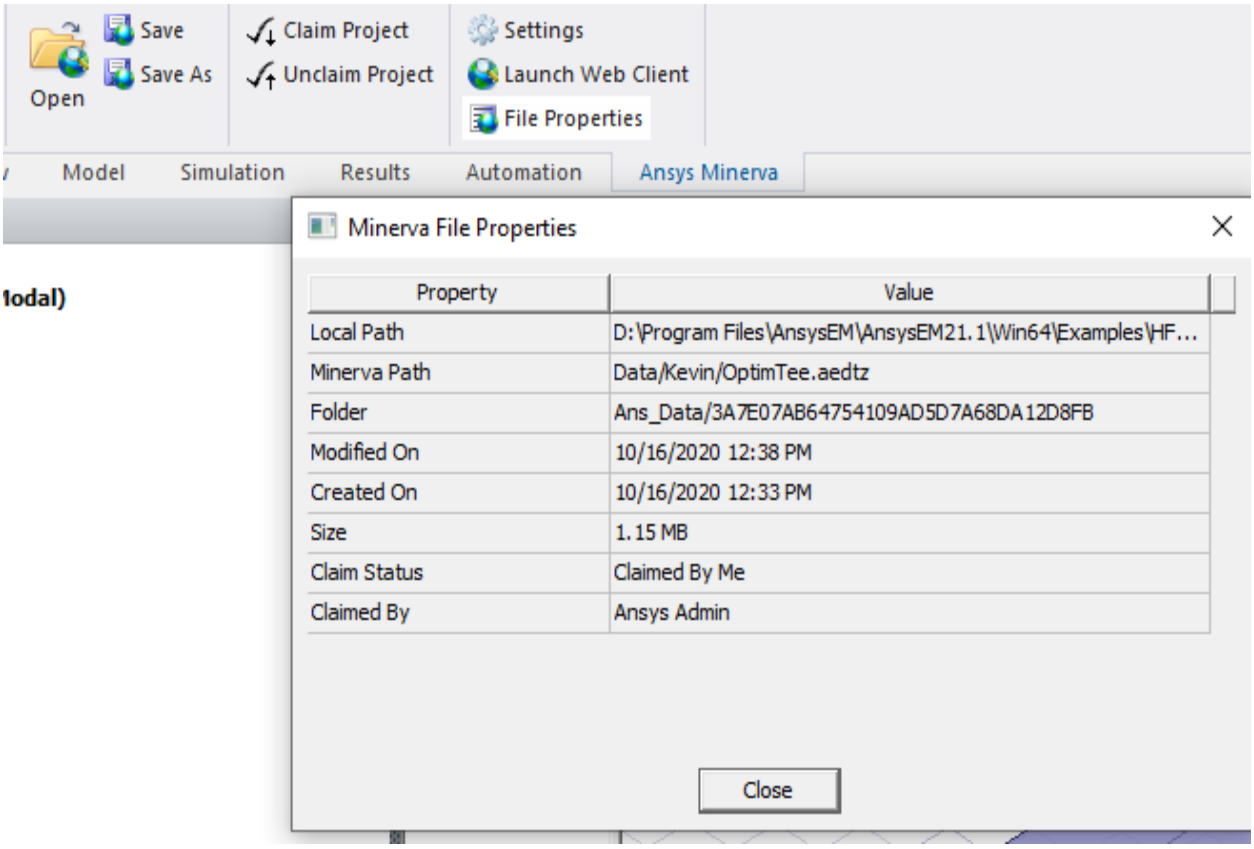
The recommended flow when working on a project is:

1. Claim the file, making sure you are working with the most recent version.
2. Make edits.
3. Save the file to Minerva.
4. Unclaim the file.

Claim Project: claims file so it cannot be modified by other users.

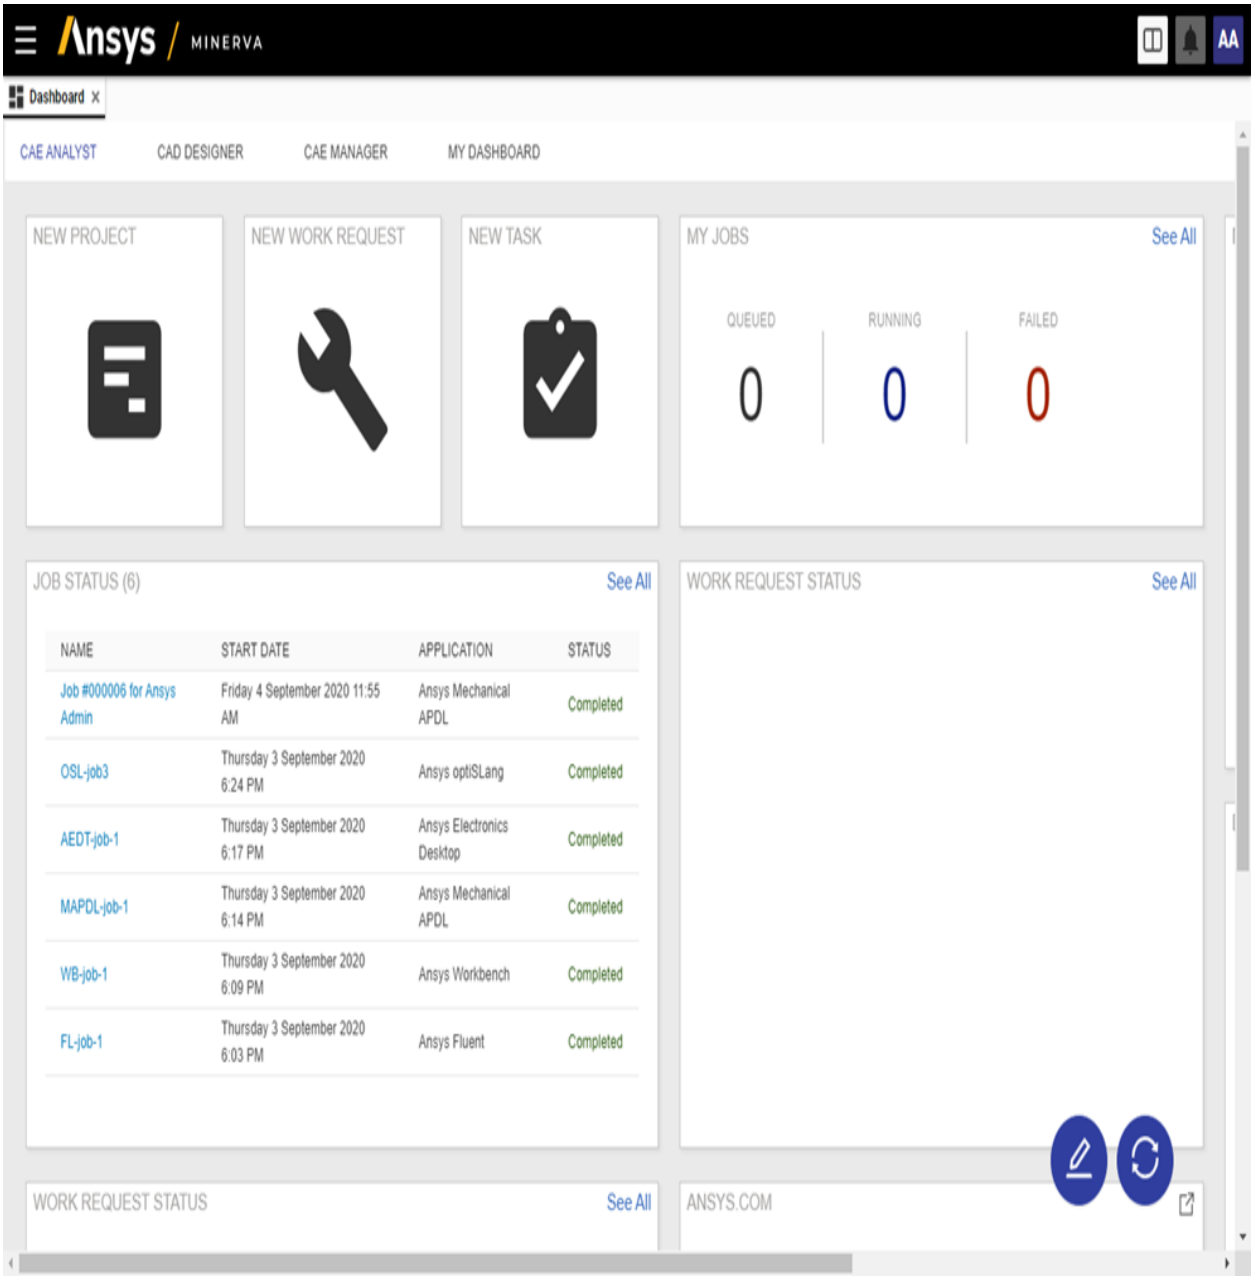
Unclaim Project: releases claimed file.

File properties: opens a dialog letting you view remote file properties. Notice the Claim Status and Claimed By properties.

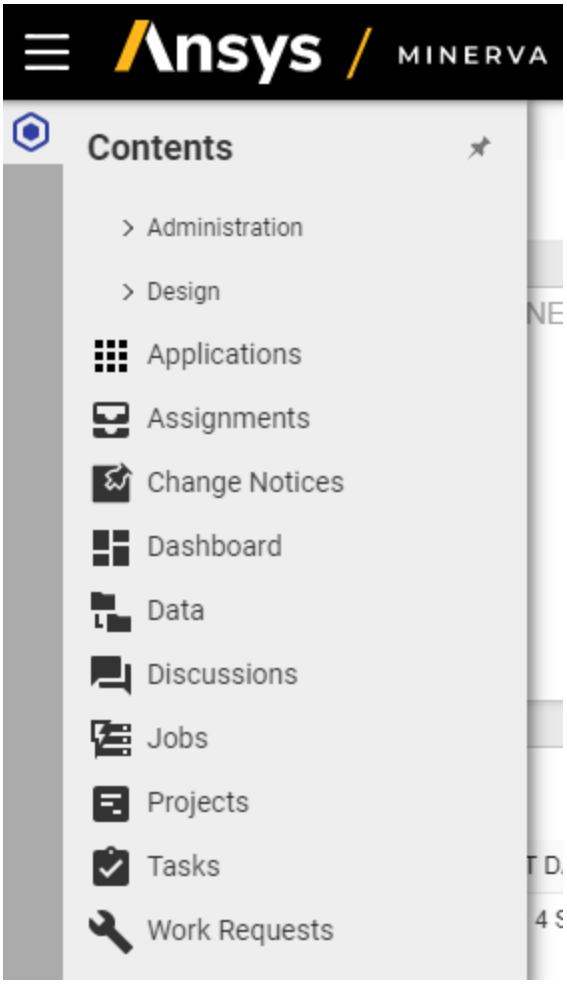


Launch Web Client:

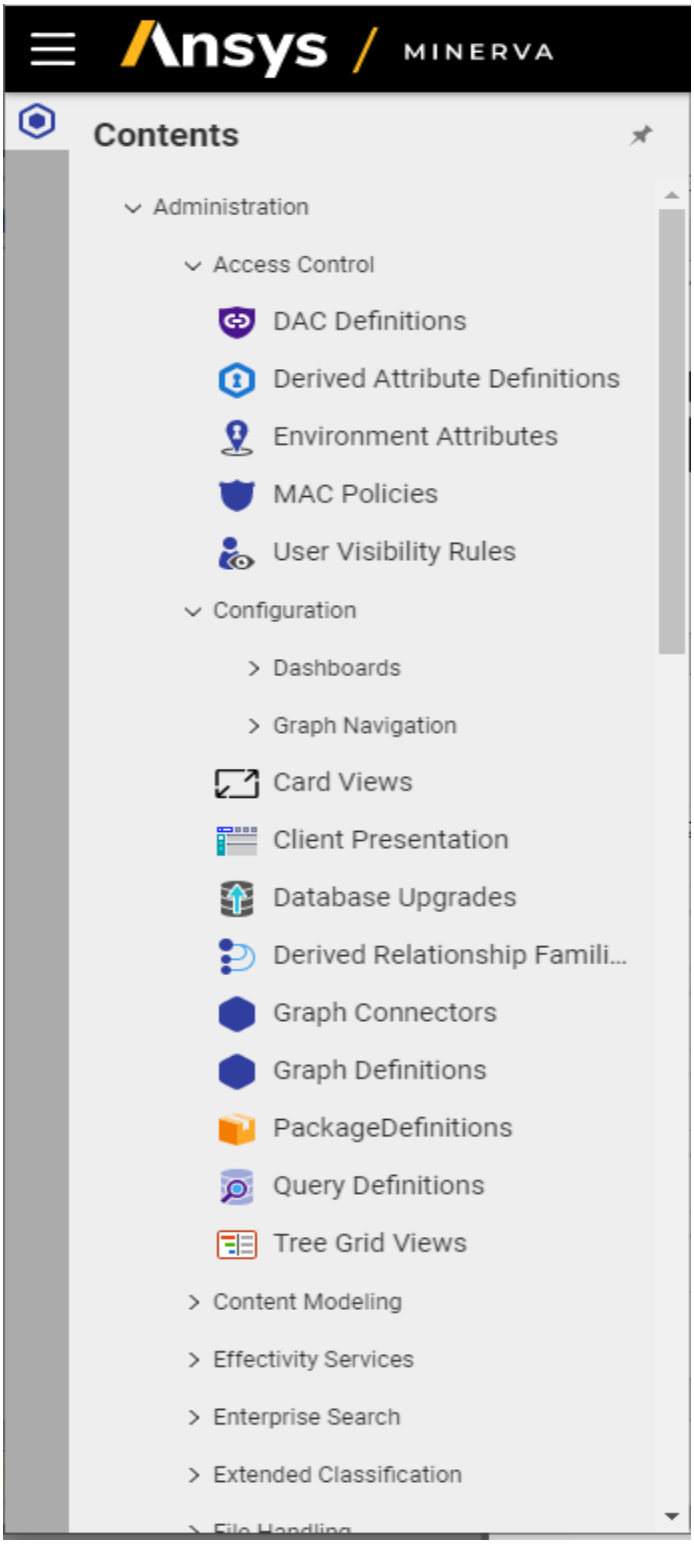
Ansys Minerva, powered by Aras, is a knowledge management application that secures critical simulation data, and provides simulation process and decision support to simulation teams across geographies and functional silos. Launching the Minverva Web Client gives access to these features. This opens a dialog calling for you to provide login information. It attempts to open a web browser window, so your default browser must be compliant.



Clicking on the triple bar icon left of the Ansys logo opens up access to the more robust Minerva Web Client functionality.



The angle icons for Administration open up further functionality.



6 - Setting Up a Maxwell Design

After you insert a design, you do not need to perform the basic steps sequentially, but they all must be completed before a solution can be generated.

To set up a Maxwell design, follow this general procedure:

1. Insert a Maxwell design into a project. After you insert the design, you can then set the model's units of measurement and the background material.
2. Draw the model geometry.
3. Specify the solver type.
4. Assign material characteristics to objects.
5. Assign boundaries and excitations.
6. (*For Transient Solutions Only*) Set up motion.
7. Add parameters for which you want to solve.
8. Specify mesh settings.
9. Specify how Maxwell will compute the solution.
10. (Optional) Set up any optimetrics you want to run.
11. Run the simulation.
12. View solution results, post-process results, view reports, and create field overlays.
13. (Optional) Export the circuit to generate a circuit equivalent of the model.

Inserting a Maxwell Design

The first step in setting up a Maxwell Project is to add a design to the active project.

To insert a design:

1. Click **Project and select one of the following:**
   - **Insert Maxwell 3D Design**
   - **Insert Maxwell 2D Design**
   - **Insert RMxprt Design**
2. The new design is listed in the project tree. It is named Maxwell3DDesign*n*, Maxwell2DDesign*n*, or RMxprtDesign*n* by default, where *n* is a number signifying the order in which the design was added to the project.

   The **Modeler** window appears to the right of the Project Manager. You can now create the model geometry.

Note	Click the plus sign to the left of the design icon in the project tree to expand the project tree and view specific data about the model.

Related Topics

Setting the Project Tree to Expand Automatically

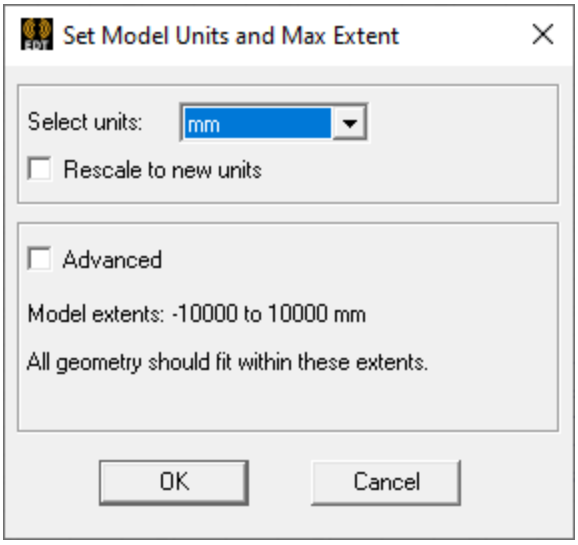
Setting Units of Measurement for the Model

You can specify the units of measurement for drawing geometric models. After the units of measurement have been specified, they are assigned to the objects in the **3D Modeler** window. You can then choose to display the model's dimensions in the new units, or rescale the model's dimensions to the new units.

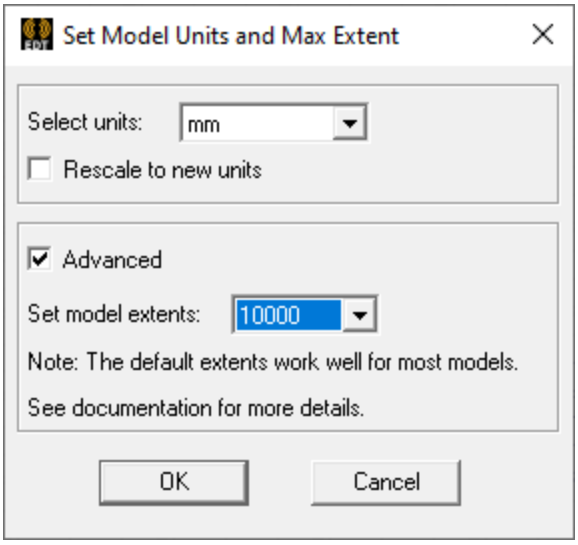
To set the model's units of measurement:

1. Click **Modeler>Units**.

   The **Set Model Units** dialog box appears.



2. Select the new units for the model from the **Select units** pull-down list.
3. Specify how the change in units affects the model:
   - Select the **Rescale to new units** option to rescale the dimensions to the new units. For example, selecting centimeters (cm) as the new unit of measurement results in a dimension of 10 millimeters (mm) becoming 10 cm.
   - Clear the **Rescale to new units** option (the default) to convert the dimensions to the new units without changing their scale. For example, selecting cm as the new unit of measurement results in a dimension of 10 mm becoming 1 cm.
4. While most models should fit the default, you can check **Advanced** to enable **Set model extents** to specify model extents in the 3D modeler.



Parasolid kernel has a strict size limit of +/- 500 units. As many AEDT models go beyond this limit in the desired units, we have implemented internal scaling to allow creation of models with a larger extent. With our default model extent of 10,000, all geometry will be internally scaled down by a factor of 100 to fit within parasolid size limit. We recommend using the default extent of 10,000 as much as possible. Modeling operations will output an error if model goes beyond 50,000 units.

A second extent option of 100 is available in the advanced options.

If model extent is set to 100, we do not scale geometry internally. Modeling operations will output an error if model goes beyond +/- 500 units. Extent of 100 should be only used in rare situations where it is determined that scaling is causing a failure, and there is no workaround.

5. Click **OK** to apply the new units to the model.

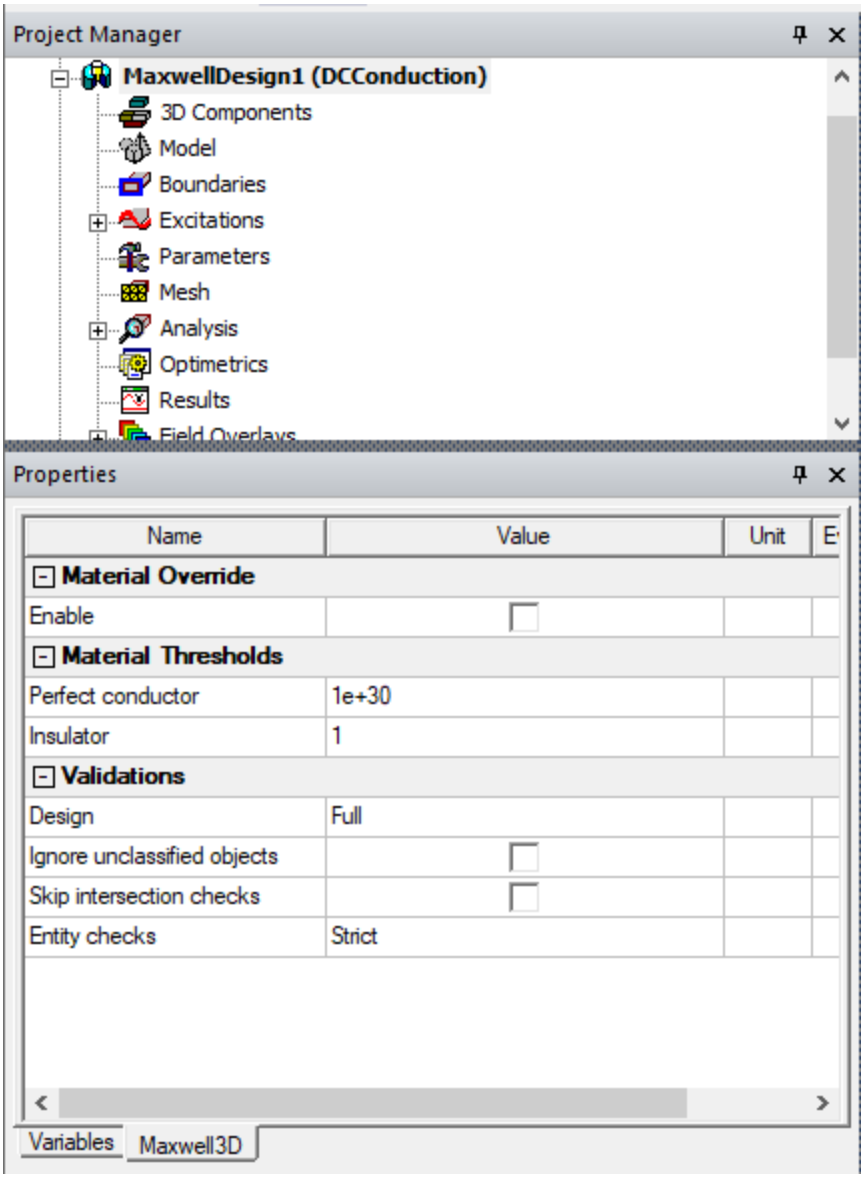
Design Settings

The Design Settings dialog allows you to specify how the simulator will deal with some aspects of the design. The tabs present in this dialog box, and the options available on each tab, vary with the solution type.

- Set the Material Thresholds for treating materials as conductors/insulators.
- Set the Model Depth Settings
- Set the Material Override (Maxwell3D only) to allow metals to automatically override dielectrics.
- Set the Matrix/Permeability Computation method for 3D Magnetostatic Solutions.
- Set the Inductance Computation method for 2D Magnetostatic Solutions
- Set the Matrix Computation to compute the inductance matrix for Transient solutions.
- Adjust model and design Validations settings.

- Set the Symmetry Multiplier for Transient and Eddy current solutions.
- Set Preserve Transient Solution options (Transient solutions Only).
- Set transient coupling with Twin Builder on the Advanced Product Coupling tab (Transient solutions Only).
- Set the Model Settings (Maxwell2D XY Transient, and 2D Eddy current solutions Only).
- Set Skew Model options (Maxwell2D XY Transient solutions with cylindrical rotational motion Only).
- Set the default Background material (Maxwell2D solutions only).
- Set Export Options (RMxprt Only).

You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.



Set Material Threshold Tab

Maxwell3D and Maxwell2D Material Thresholds:

The material thresholds tell the **Maxwell 2D** and **Maxwell 3D** solvers how to deal with conductors and insulators. Materials with conductivities above the **Perfect Conductor** threshold are treated as having infinite conductivity and surface current only. Materials with conductivity values below the **Insulator/Conductor** threshold are treated as insulators with no conductivity and no current carrying capability. Materials that fall between the two thresholds are treated as normal conductors that can carry current throughout the volume of the material.

1. Click **Maxwell>Design Settings.** The **Design Settings** dialog box appears.
   The material thresholds are set in the **Set Material Thresholds** tab. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Type a value in the **Perfect Conductor** text box.
3. Type a value in the **Insulator/Conductor** text box.
4. Click **OK**.

RMxprt Material Thresholds:

1. Click **RMxprt>Design Settings.**
   The **Design Settings** dialog box appears with the **Set Material Threshold** tab selected. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Type a value in the **Conductivity Threshold** text box (Default=10,000).
3. Type a value in the **Permeability** text box (Default=100).

Note	RMxprt will treat materials with conductivity greater than 10,000 as conductors, and materials with Permeability greater than 100 as steels.

4. If you want these values to be the default, change the values by clicking the **Tools>Options>RMxprt Options** menu and setting the material thresholds in the **RMxprt Options** dialog.
5. Click **OK**.

Setting RMxprt Options

Model Depth Settings

Maxwell 2D allows you to set the model depth for 2D magnetostatic, transient, and eddy current solutions. The model depth setting is retained when switching between magnetostatic and transient and eddy solutions.

To set the model depth:

1. Click **Maxwell>Design Settings**.
   - Alternate method: In the project tree, right-click **<***Design_name***>**, and select **Design Settings**.

     The **Design Settings** dialog box appears.

     > **Note:** You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

2. On the **Model Depth** tab, enter the model depth value and select the desired unit of measure. The model depth value must be greater than zero. The default setting is 1 meter.

   > **Note:** Changing the model depth invalidates the solution.

3. Optionally, if you check **Save as default**, newly inserted designs will be set to use the specified model depth setting.
4. When finished changing settings, click **OK**.

Related Topics

Design Settings

Set Material Override Tab

The **Maxwell3D>Design Settings** command brings up a dialog with text note and a check box to **Enable material override**. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

Normally, the modeler considers any intersection between 3D objects to be an error. But, if you check this option, the modeler allows a metal object to intersect a dielectric, and just gives a warning. Intersections between two metals or two dielectrics will still be errors.

In the mesher, the dielectrics are "subtracted" from the metals in the intersecting region. That is, the part of the dielectric that is inside the metal is removed, and if the dielectric is completely inside, the whole object disappears.

The purpose of this feature is to allow you to avoid doing explicit subtraction in the modeler. One example application is a via that passes through many dielectric layers--with the option turned on, the via does not have to be subtracted from the layers.

Note	Users must be careful: this setting changes the "ground rules" of the modeler, and may have unexpected results.

Matrix/Permeability Computation Tab Settings for 3D Magnetostatic Solutions

Maxwell 3D provides two **Matrix/Permeability Computation** methods for calculating the inductance of current-carrying coils for magnetostatic solutions: **Apparent** and **Incremental**.

- **Apparent** inductance is defined as the ratio of flux to current at a certain operating condition. Alternatively, this can be expressed as the slope of a line from the origin to the operating point on the BH curve. Apparent inductance is commonly used in nonlinear magnetic applications and in circuit analysis, and is the default method used by Maxwell.
- **Incremental** inductance is defined as the ratio of delta flux to delta current at a certain operating condition. This is equivalent to the slope of the tangent to the BH curve at the operating point. Incremental inductance is commonly used in physical design because it is easy to measure.

To set the matrix/permeability computation method:

1. Click **Maxwell>Design Settings**.
   - Alternate method: In the project tree, right-click **<***Design_name***>**, and select **Design Settings**.

   The **Design Settings** dialog box appears. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. On the **Matrix/Permeability Computation** tab, select the desired method: Apparent or Incremental.

Note	If you change the computation method after solving, all matrix results of both AdaptivePass and LastAdaptive solutions will be invalidated. Then, on the next simulation, the matrix of the last solved pass will be re-computed with the new method. If there are matrix expression caches for the AdaptivePass solution, then the cached values of previous passes will not be available because only the last pass is re-simulated.

3. Optionally, if you check Save as default, newly inserted designs will be set to use the specified computation method.
4. When finished changing settings, click **OK**.

Inductance Computation Tab Settings for 2D Magnetostatic Solutions

Maxwell 2D provides two **Inductance Computation** methods for calculating the inductance of current-carrying coils for magnetostatic solutions: **Apparent** and **Incremental**.

- **Apparent** inductance is defined as the ratio of flux to current at a certain operating condition. Alternatively, this can be expressed as the slope of a line from the origin to the operating point on the BH curve. Apparent inductance is commonly used in nonlinear magnetic applications and in circuit analysis, and is the default method used by Maxwell.
- **Incremental** inductance is defined as the ratio of delta flux to delta current at a certain operating condition. This is equivalent to the slope of the tangent to the BH curve at the operating point. Incremental inductance is commonly used in physical design because it is easy to measure.

To set the matrix computation method:

1. Click **Maxwell>Design Settings**.
   - Alternate method: In the project tree, right-click **<***Design_name***>**, and select **Design Settings**.

   The **Design Settings** dialog box appears. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. On the **Inductance Computation** tab, select the desired method: Apparent or Incremental.

Note	If you change the computation method after solving, all matrix results of both AdaptivePass and LastAdaptive solutions will be invalidated. Then, on the next simulation, the matrix of the last solved pass will be re-computed with the new method. If there are matrix expression caches for the AdaptivePass solution, then the cached values of previous passes will not be available because only the last pass is re-simulated.

3. Optionally, if you check Save as default, newly inserted designs will be set to use the specified computation method.
4. When finished changing settings, click **OK**.

Related Topics

Design Settings

Matrix Computation Tab Settings for Transient Solutions

Maxwell 2D/3D provides an option on the **Matrix Computation** tab for computing the inductance matrix for transient solutions. When the **Compute inductance matrix** option is selected, the computed matrix quantities will be available at all time steps. The matrix quantities are listed in the reporter and thus are available for post-processing, output variables creation, and Optimetrics studies.

Note	During the inductance calculation in the transient solver: • Eddy effects for all objects are turned-off even if “Eddy Effect” is checked in the

	"Set Eddy Effects" dialog box. However, the field solution and all other results will consider the eddy effects as set in the interface. • For a field system with multiple stranded windings, after all nonlinear materials are frozen, one winding is supplied with 1A DC current while the other winding is open (all other sources are turned-off).

The size of the computed inductance matrix is equal to the number of winding setups, i.e., the matrix will be *N* x*N* when there are *N* winding setups; and the total number of inductance-related quantities will be N^2. Components of the full matrix are available for plots and Optimetrics calculation even though the matrix will always be symmetric. You can choose to access only the upper right half of the matrix by selecting the corresponding quantities as listed in the reporter dialog box. For example, the upper half of a 2x2 matrix will be the L11, L12 and L22 quantities.

Maxwell 2D/3D provides two **Matrix Computation** methods for calculating the inductance of windings for transient solutions: **Apparent** and **Incremental**.

- **Apparent** inductance is defined as the ratio of flux to current at a certain operating condition. Alternatively, this can be expressed as the slope of a line from the origin to the operating point on the BH curve. Apparent inductance is commonly used in nonlinear magnetic applications and in circuit analysis, and is the default method used by Maxwell.
- **Incremental** inductance is defined as the ratio of delta flux to delta current at a certain operating condition. This is equivalent to the slope of the tangent to the BH curve at the operating point. Incremental inductance is commonly used in physical design because it is easy to measure.

To enable the matrix computation for transient solutions:

1. Click **Maxwell>Design Settings**.
   - Alternate method: In the project tree, right-click **<***Design_name***>**, and select **Design Settings**.

   The **Design Settings** dialog box appears.You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. On the **Matrix Computation** tab, select **Compute inductance matrix**, and select the desired method: **Apparent** or **Incremental**.

Note	
	• The default is NOT to compute the inductance matrix. Changing the setting for an existing design does not affect the solution for the previous simulation. For example, if a transient solve setup has 1 second set as the end time and is solved with the **Compute inductance matrix** option off (unchecked) and a plot of matrix quantities is created vs. time, the plot will not show any values because no matrix quantities were computed. Subsequently, if the compute option is enabled (checked) and the end time extended to 2 seconds, after simulation, matrix quantities will be available from > 1 second to 2 seconds, at all solved time steps. • If you change the computation method after solving, all matrix results of both AdaptivePass and LastAdaptive solutions will be invalidated. Then, on the next simulation, the matrix of the last solved pass will be re-computed with the new method. If there are matrix expression caches for the AdaptivePass solution, then the cached values of previous passes will not be available because only the last

	pass is re-simulated.

3. Optionally, if you check **Save as default**, newly inserted designs will use the specified setting.
4. When finished changing settings, click **OK**.

Inductance Computation for 2D and 3D Transient Solutions

Validations Tab

Model Settings

You can adjust the degree to which the software checks a model for faults that could jeopardize mesh accuracy. There are four levels of model validation that a user can specify for a given design: **Warning Only**, **Basic**, **Strict**, and **None**. Note that this setting affects only the "3D Model" stage of a design validation. The default Entity Check Level is **Strict**.

- The **Warning Only** entity check setting allows all models to pass 3D Model validation regardless of any faults that are found. These faults are posted in the message window as warnings.
- The **Basic** entity check setting allows most models to pass 3D Model validation. Some faults are flagged as model errors, thereby prohibiting a design from proceeding to the meshing stage of an analysis. You must correct such errors before attempting to analyze the design under the Basic setting, or you must change the entity check level to Warning Only.
- The **Strict** entity check setting enforces a tighter tolerance for model faults than the Warning Only and Basic settings. All model faults that are found during 3D Model validation are posted to the message window. These errors must be corrected before attempting to analyze the design under the Strict setting, or you must change the entity check level to Basic or Warning Only.
- The **None** setting disables model validation.

In addition, check boxes allow you to adjust model validation to:

- **Ignore Unclassified Objects** and to
- **Skip Intersection Checks**.

These settings are unchecked by default.

Maxwell2D and Maxwell3D Design Settings

For both 2D and 3D designs, you can choose either:

- **Perform full validations** (the default setting) – All design validations are performed.
- **Perform minimal validations** – All design validations except boundary overlap validation are performed.

For 3D designs only, you can select **Skip mesh checks** to prevent the solver from failing validation when the mesh has a few elements of poor quality.

Adjusting Settings

To adjust settings on the Validations tab:

1. Select **Maxwell>Design Settings** to open the **Design Settings** dialog box; then select the Validations tab.
2. Choose the desired level of Model validation from the **Entity Check Level** drop down box.
3. Optionally, adjust Model validation to **Ignore Unclassified Objects**, or to **Skip Intersection Checks**.
4. Optionally, select **Perform minimal validations** if you want to omit boundary overlap validation checking.
5. Optionally, **Skip mesh checks** to prevent the solver from failing validation when the mesh has a few elements of poor quality.
6. Optionally, click the **Save as Default** button to make the current selections the default settings.
7. Click **OK** to accept the selections and close the dialog.

> **Note:** You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

Setting a Symmetry Multiplier

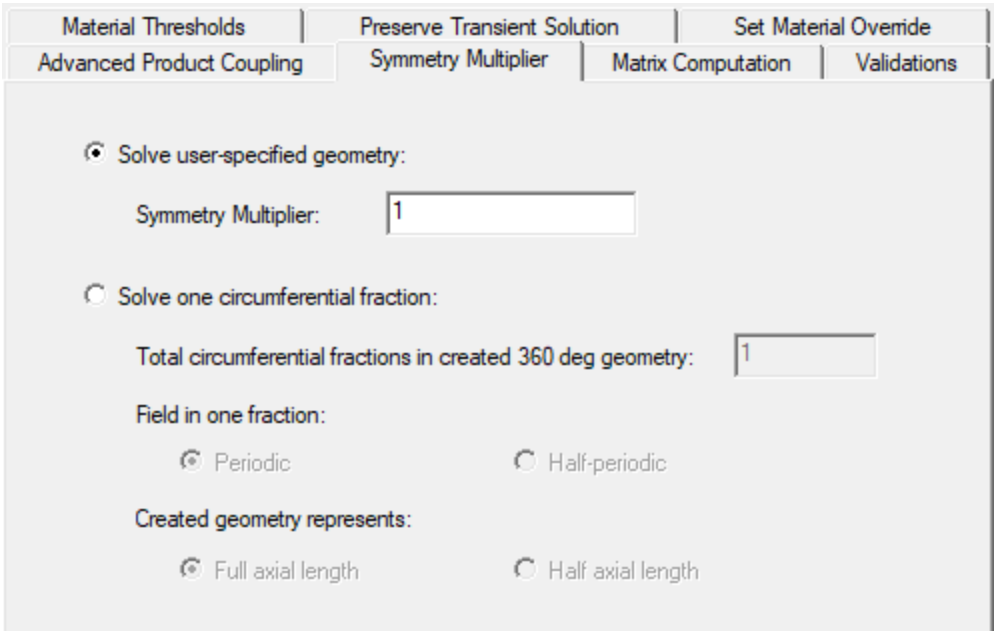
(Transient and Eddy Current Solutions Only)

If you are using symmetry and/or independent/dependent boundary conditions in your solution, you may need to specify a multiplier (so that the other part of the model, which is not included in the solution domain, can be properly taken into account). This symmetry multiplier will be automatically applied to all input quantities including: input voltage, inductance, resistance, load torque, mass, damping, external circuit; and all output quantities including: induced voltages, flux linkages in every winding, stranded loss, solid loss, core loss, and torque.

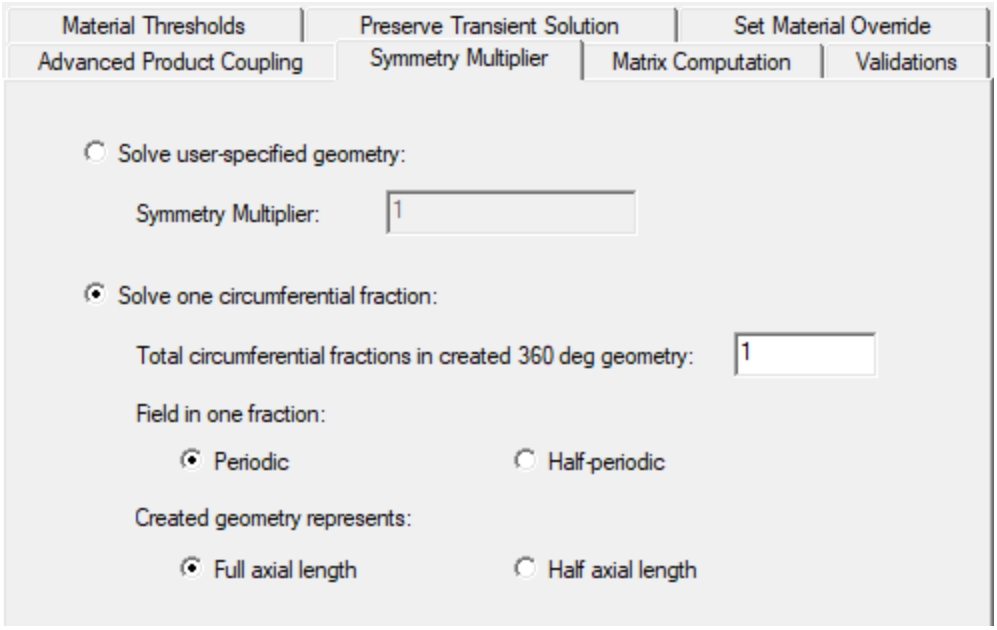
To specify a multiplier:

1. Select **Maxwell>Design Settings** from the main menu to open the Design Settings dialog box, then select the **Symmetry Multiplier** tab. You can also right-click **Model** in the Project Manager tree, and select **Set Symmetry Multiplier**; or select **Maxwell>Model>Set Symmetry Multiplier**, to open the Design Settings dialog to the **Symmetry Multiplier** tab.You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Depending on the design type, do one of the following:
   - For 2D and 3D Eddy Current, and 2D Transient designs, enter an integer value (or a variable that evaluates to an integer value) in the **Symmetry Multiplier** text box, and click **OK**.

   - For 3D Transient designs, you can select either:
     - **Solve user-specified geometry** and enter an integer value (or a variable that evaluates to an integer value) in the **Symmetry Multiplier** text box, then click **OK**.



- **Solve one circumferential fraction**, then enter an integer value for the **Total circumferential fractions in created 360 deg geometry**.



Select either **Full axial length** or **Half axial length** for **Created geometry represents**.

Select either **Periodic** or **Half-periodic** for **Field in one fraction**.

Click **OK**.

Note	When a symmetry multiplier has been set, the parameter values (moment of inertia, damping, load torque) specified on the **Motion Setup** dialog **Mechanical** tab are related to the full model.

Export Options Tab

You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver. To set the Export options for RMxprt:

1. Choose which options to use when exporting a design from RMxprt to Maxwell3D:
   - **Periodic**
   - **Difference**
   - **Band Arc**
   - **Teeth-Teeth**
   - **Segmented Arc**

Note	These options may also be set on the **Export Options** tab of the RMxprt Options dialog box. Using the **Tools>Options>RMxprt Options** command changes the default for the current design and all future designs.

You may also set the default **Design Sheet** for use with RMxprt by entering the path and filename or by browsing to the Excel file using the **ellipsis** button.

Related Topics

Generating a Custom Design Sheet for RMxprt

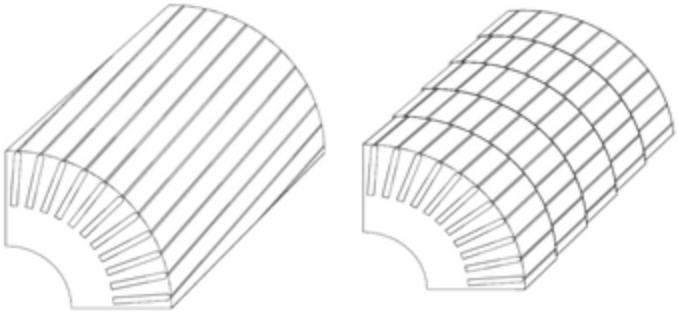
Model Settings Tab

(Maxwell2D XY Transient and 2D Eddy Current Designs Only)

For Maxwell2D XY transient and 2D Eddy current designs, torque, flux linkage, back EMF, etc. are scaled by the length provided in the **Model Depth** field on the **Model Settings** tab. The scaled results are used to calculate output quantities.

(Maxwell2D XY Transient solutions with cylindrical rotational motion Only)

For Maxwell 2D transient designs with cylindrical rotational motion setup, the transient solver can take into account the effects of skewed rotor slots by using a multi-slice model.

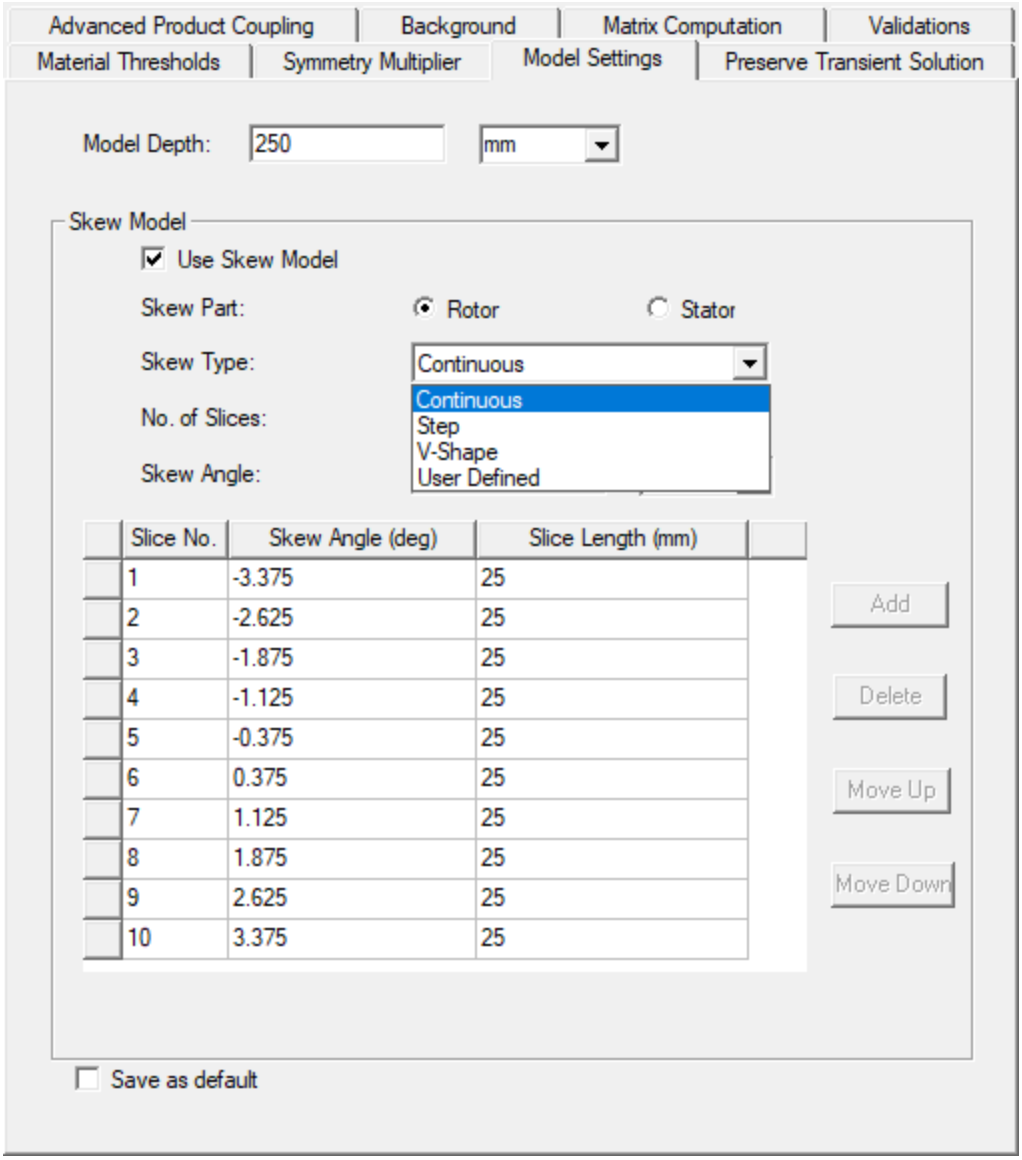


Skewed rotor Multi-slice model

Note: Maxwell 2D transient designs that use the skew model can use MPI HPC for distributed computing of multiple slices.

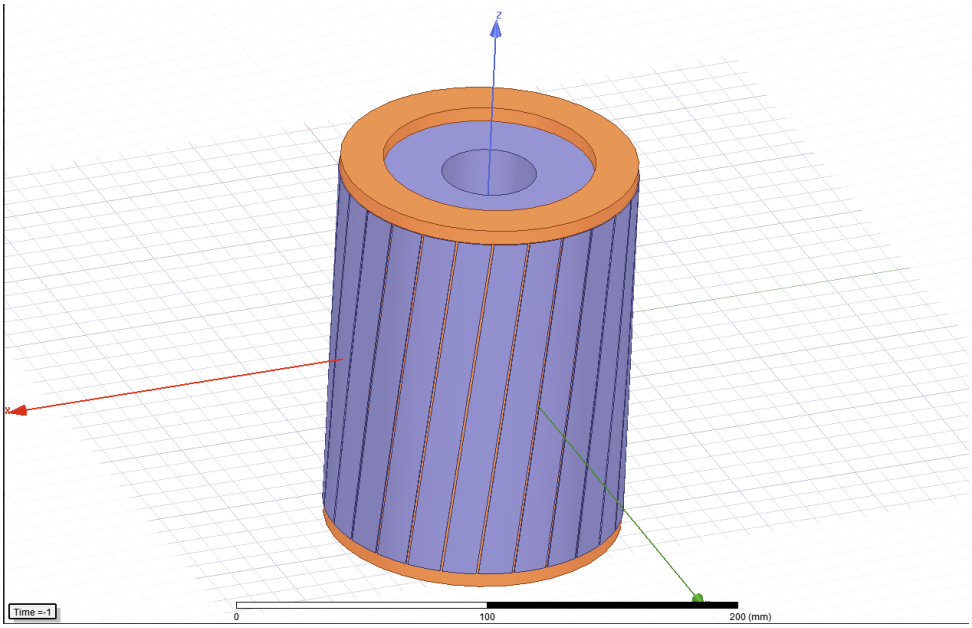
To enable use of the multi-slice skew model:

1. Right-click on **Model** in the Project Tree and select **Set Skew Model** on the context menu to open the **Design Settings** dialog to the **Model Settings** tab. You can also click **Maxwell 2D> Design Settings** to open the **Design Settings** dialog box, then select the **Model Settings** tab. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Check the **Use Skew Model** check box to enable the parameter fields below it.

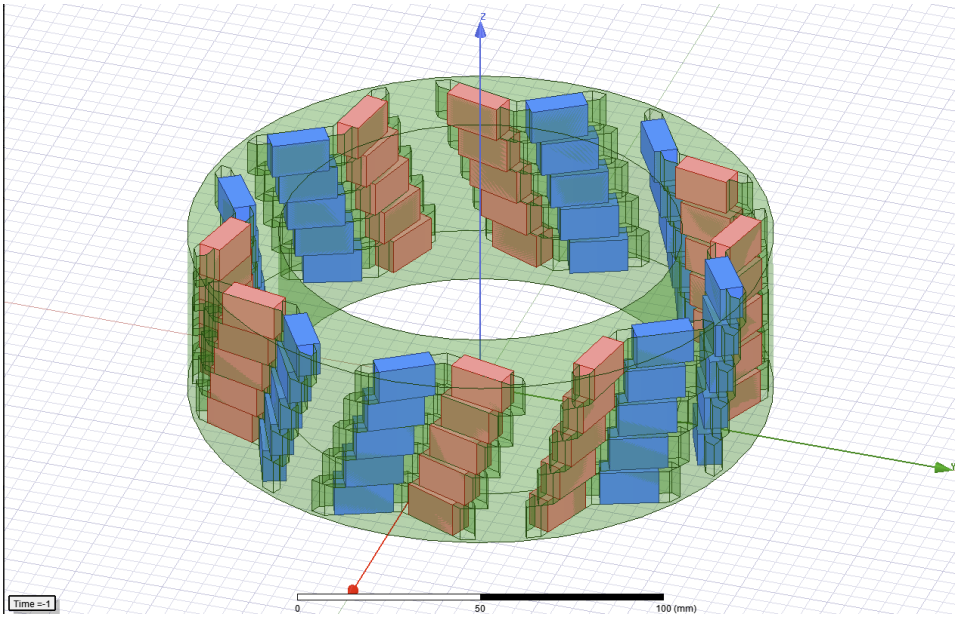


3. Select either **Rotor** or **Stator** as the **Skew Part** being modeled. Default is **Rotor**.
4. Select a **Skew Type**.

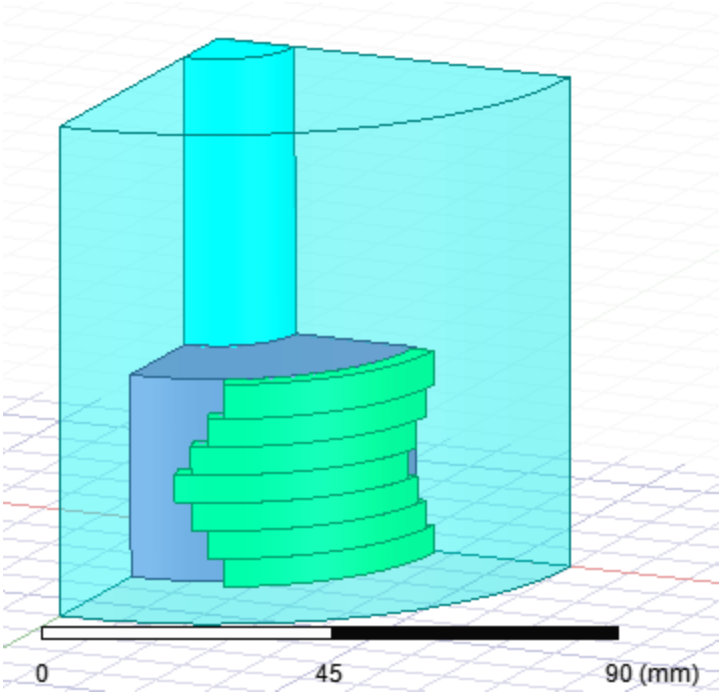
- **Continuous** (the default) - usually used in induction machines



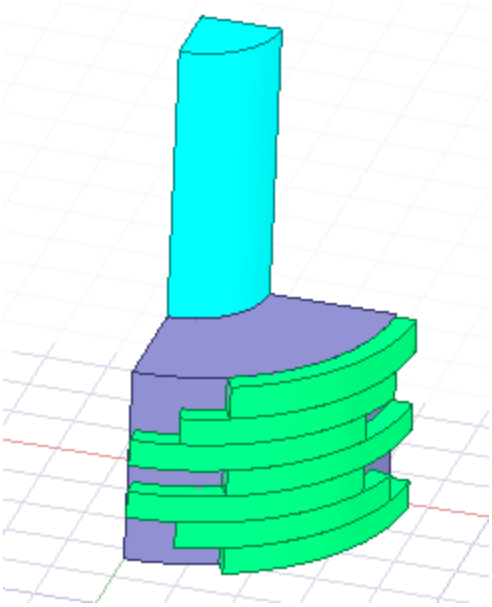
- **Step** - usually used in PM machines



- **V-Shape**

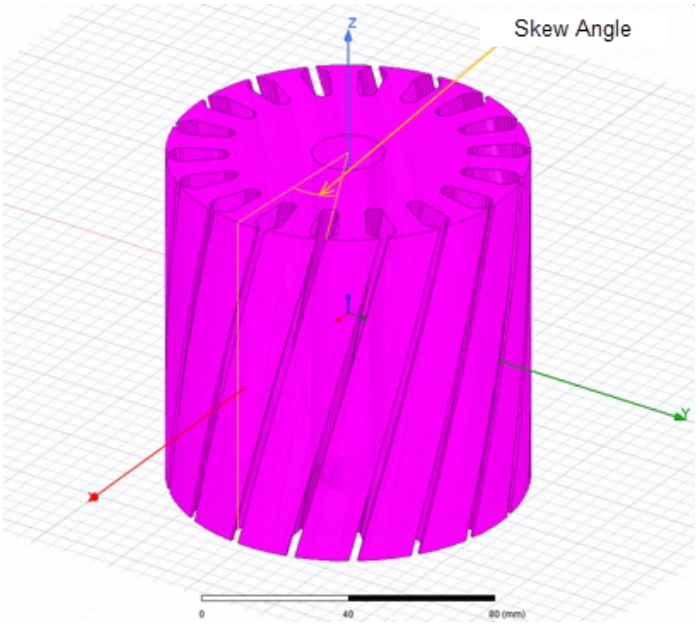


- **User Defined**

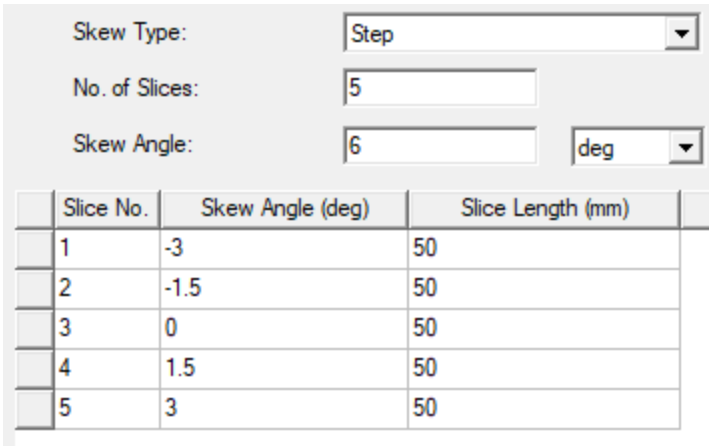


5. For **Continuous**, **Step**, and **V-Shape** skew types:
    a. Enter the **No. of Slices** that you want the model divided into in the Z-direction. The input must be a positive integer value greater than zero. The default is 5. You can also enter a variable name. (**No. of Slices** is not used for the **User Defined** skew type and is grayed out .)

b. Enter the **Skew Angle** and unit of measure of the part. The **Skew Angle** is the angle between first and last slice (not between two adjacent slices). Entries are non-negative real numbers in the range of 0 to 180 degrees inclusive (or equivalent values in units of measure such as radians). The default value is 5 degrees. You can also enter a variable name.

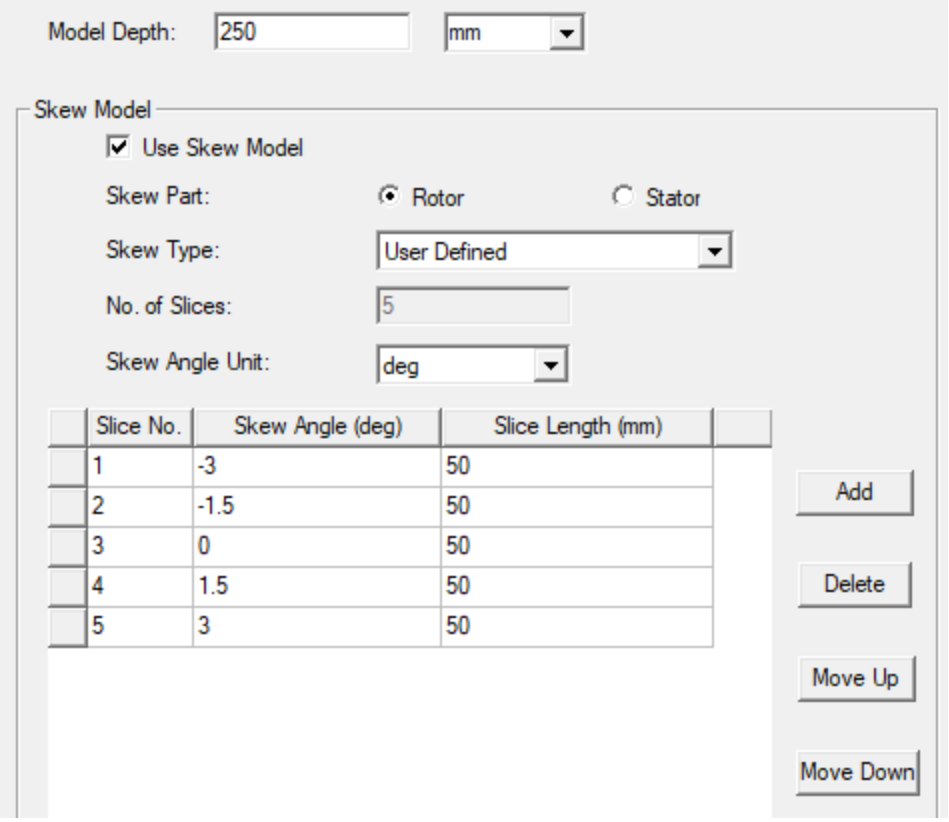


The Skew Angle and Slice Length values for each slice are calculated by the modeler and are listed in the (non-editable) table.



Slice No.	Skew Angle (deg)	Slice Length (mm)
1	-3	50
2	-1.5	50
3	0	50
4	1.5	50
5	3	50

6. For the **User Defined** skew type:
   a. Select a **Skew Angle Unit**, which will be applied to the Skew Angle values you enter in the table.



b. Enter the desired **Skew Angle** and **Slice Length** values for the selected skew part. If the total of the **Slice Length** values differs from the **Model Depth** value, a message informing you of the difference will display in the Message Manager. **Add**, **Delete**, **Move Up**, and **Move Down** buttons allow you to control the table row entries.

7. When finished, click **OK** to close the dialog box.

Related Topics

Harmonic Force Calculation in Maxwell 2D with Skew Model

User Defined Skew Type Computations

The phase angle of flux-linkage in a user defined skew part will change according to the slice skew angle.

For user defined skew type, solver will rotate all the slices at an additional angle β in order to keep flux-linkage with the same initial phase angle as that of the unskewed case.

The additional angle β can be calculated by

$$\beta = -\frac{1}{L}\sum_{i=1}^{i=N} \alpha_i * L_i$$

where:

- β is the additional rotate angle for all the slices
- N is the slice number
- α_i is the ith slice skew angle which user defines
- L_i is the ith slice length which user defines
- $L = \sum_{i=1}^{i=N} L_i$ is the model depth.

Thus, the slice skew angle for each slice will be:

$\alpha_i + \beta$

Related Topics

Background Material Tab

(Maxwell2D Designs Only)

The area of a model not enclosed within specific objects is termed the background. The material assigned to this area is vacuum by default.

To change the default setting:

1. Click **Maxwell2D>Design Settings**.

   The Design Settings dialog is displayed. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.
2. Select the **Background** tab.
3. Click the **Background** button listing the current material setting.

   The **Select Definition** dialog is displayed with the Material Database.
4. Locate the material desired and click on the **Name** in the table.
5. Click **OK** to return to the **Design Settings** dialog.
6. The **Background** button will now list the newly selected material indicating that it will be used as the background material.
7. Click **OK** to finalize the change and dismiss the dialog.

Preserve Transient Solution Tab

For **Transient** solutions, you have the option of enabling the **Preserve solution after dataset edits** function on this tab.

Datasets may be used to describe material and source behavior in Maxwell. Enabling the **Preserve solution after dataset edits** function allows source, material, or other parameters that depend upon datasets to be modified without deleting the transient solution data. The transient solver may then be restarted from the final time step of the previous simulation.

You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

Advanced Product Coupling Tab

For Transient solutions, this tab provides the option to **Enable transient-transient link with Twin Builder** components. You can also view and set design settings by selecting the current design, and then in the **Properties** window, select the tab for the solver.

Maxwell designs may be dynamically coupled to Twin Builder components through the Twin Builder user interface. The Twin Builder interface allows 2D, 3D, and RMxprt designs to be linked as dynamic components. Source windings set to **External** are available as conservative pins in Twin Builder.

Dynamically linked components provide the ability to have Twin Builder vary a variable in a Maxwell design and have Maxwell solve the design at the new design point and provide the solution data back to Twin Builder for use in the circuit simulation.

For more information, refer to the Twin Builder Help.

7 - Specifying the Solver Type

Before you begin to draw the models in your project, choose which field solver to use for it. Each solver requires a different type of problem setup. If you later change the solver, all problem setups become invalid, and all solutions are deleted. Because of this, it is a good idea to decide on a solver before starting.

To specify a solver:

1. Click **Maxwell 2D>Solution Type** or **Maxwell 3D>Solution Type**.
   The **Solution Type** window appears with the solvers generally split between **Magnetic** and **Electric** solver types.
2. For Maxwell 3D designs, select one of the following solver types:
   - **Magnetostatic**
   - **Eddy Current**
   - **Transient**
   - **Electrostatic**
   - **3D AC Conduction**
   - **DC Conduction** either with or without Insulator Field
   - **Electric Transient**
3. For Maxwell 2D designs, select one of the following solver types:
   - **Magnetostatic**
   - **Eddy Current**
   - **Transient**
   - **Electrostatic**
   - **2D AC Conduction**
   - **DC Conduction**

Note	For Maxwell2D designs, you must also specify the geometry mode, either **Cartesian, XY** or **Cylindrical about Z**.
4. Click **OK**.

Note	For information on the various material property types supported by each solver, refer to *Maxwell Solvers Material Properties*.

Magnetostatic Solver

The magnetostatic field simulator computes static magnetic fields in 2D or 3D. The source of the static magnetic field can be:

- DC currents in conductors.
- Static external magnetic fields represented by boundary conditions.
- Permanent magnets.

The quantities for which the magnetostatic field simulator solves are the magnetic field, **H**, and the current distribution, **J**; the magnetic flux density, **B**, is automatically calculated from the **H**-field. Derived quantities such as forces, torques, energy, and inductance may be calculated from these basic field quantities.

Eddy Current Solver

The eddy current (AC magnetics) field simulator computes electromagnetic fields in the frequency domain in 2D or 3D. The sources of the electromagnetic field can be:

- AC currents in conductors.
- Time-harmonic external magnetic fields represented by boundary conditions.

The quantity for which the eddy current field simulator solves is the magnetic field, **H**. The magnetic flux density, **B**, is automatically calculated from the **H**-field. Optionally, the eddy current solver can incorporate displacement currents into the solution even in non-conducting domains, thereby allowing the solution of the full system of Maxwell's equations and the recovery of the electric field **E** everywhere including the non-conducting regions. Derived quantities such as forces, torques, energy, losses, and impedances may be calculated from these basic field quantities at the solution frequencies.

Related Topics

Technical Notes: 3D Frequency Domain (Eddy Current) Solver

Transient Solver

The transient field simulator computes the time-domain magnetic fields in 2D or 3D. The source of the magnetic fields can be:

- Moving or non-moving time varying currents and voltages.
- Moving or non-moving permanent magnets and/or coils.
- Moving or non-moving external circuit coupling.

The quantities for which the transient field simulator solves are the magnetic field, **H**, and the current distribution, **J**; the magnetic flux density, **B**, is automatically calculated from the H-field. Derived quantities such as forces, torques, energy, speed, position, winding flux linkage, and winding induced voltage may be calculated from these basic field quantities.

Note	If **A-Phi Formulation** is selected as the 3D Transient solver, please refer to **Maxwell 3D Transient Solution Based on A-Phi Formulation** for details.

Maxwell 3D Transient Solution Based on A-Phi Formulation

The Maxwell 3D transient solver is currently based on T-Omega formulation. T-Omega formulation is a powerful method for solving a wide range of low frequency EM problems. However, there are some areas where the applicability of the method is limited – such as multiple (mixed) source excitations on a single conduction path and capacitive effect (displacement current). For simulation of such problems, the Maxwell 3D Transient A-Phi formulation is a more suitable solution type.

Please refer to the following sections for information on this feature:

- "Limitations" on the next page
- "Boundaries and Excitations" on the next page

Limitations

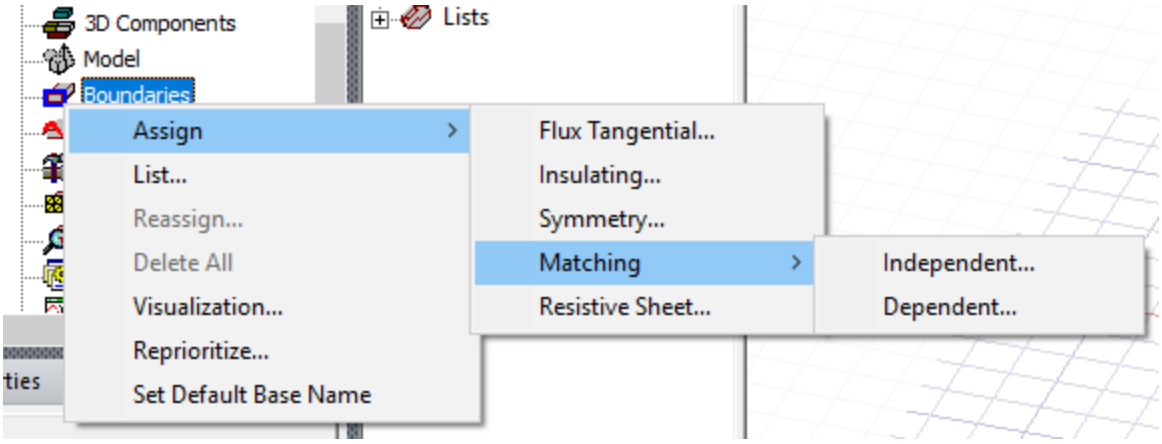
The following 3D Transient features are not supported/available for this release:

- Time Decomposition Method Option on the **Solver** tab of **Solve Setup**.
- Solver level of Auto HPC and MPI.
- Motion related features.

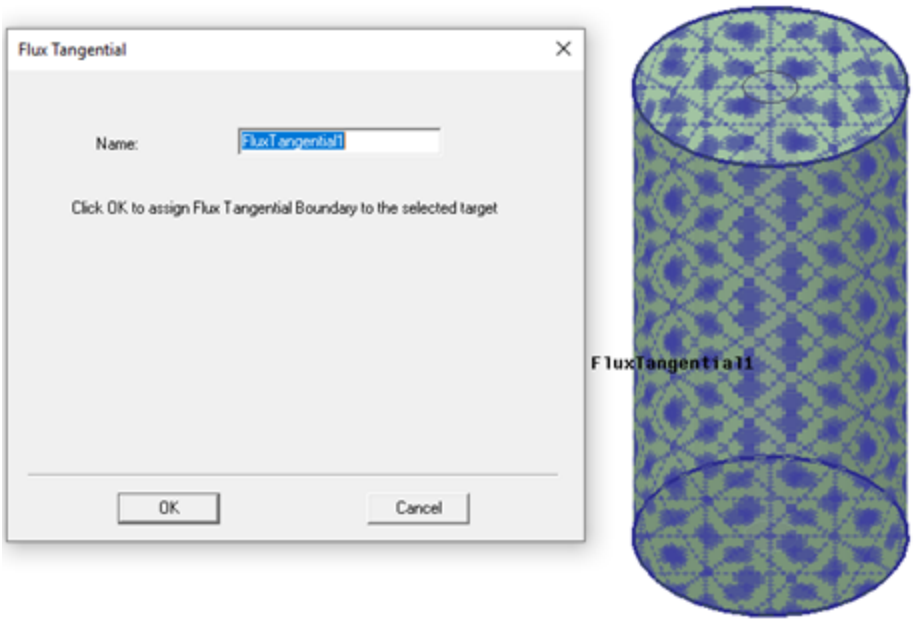
Boundaries and Excitations

Boundaries and Excitations supported are as follows:

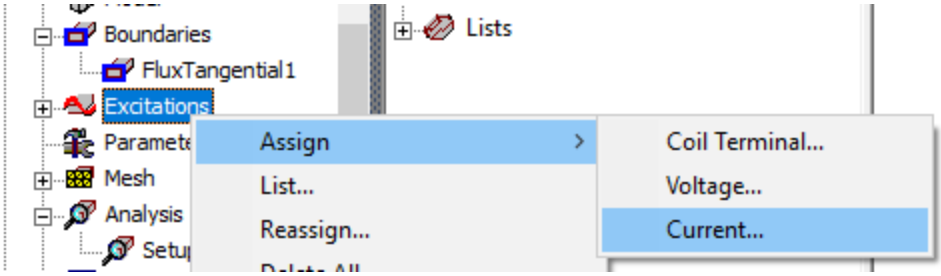
- Boundaries supported are: **Flux Tangential**, **Insulating**, **Symmetry**, **Independent**, **Dependent**, and **Resistive Sheet**.



Flux Tangential boundaries can only be applied to Face objects. Unlike T-Omega Formulation, the Neumann boundary condition on external faces is flux normal for A-Phi formulation. That is why a Flux Tangential boundary condition must be assigned when the magnetic field is tangential to the face.



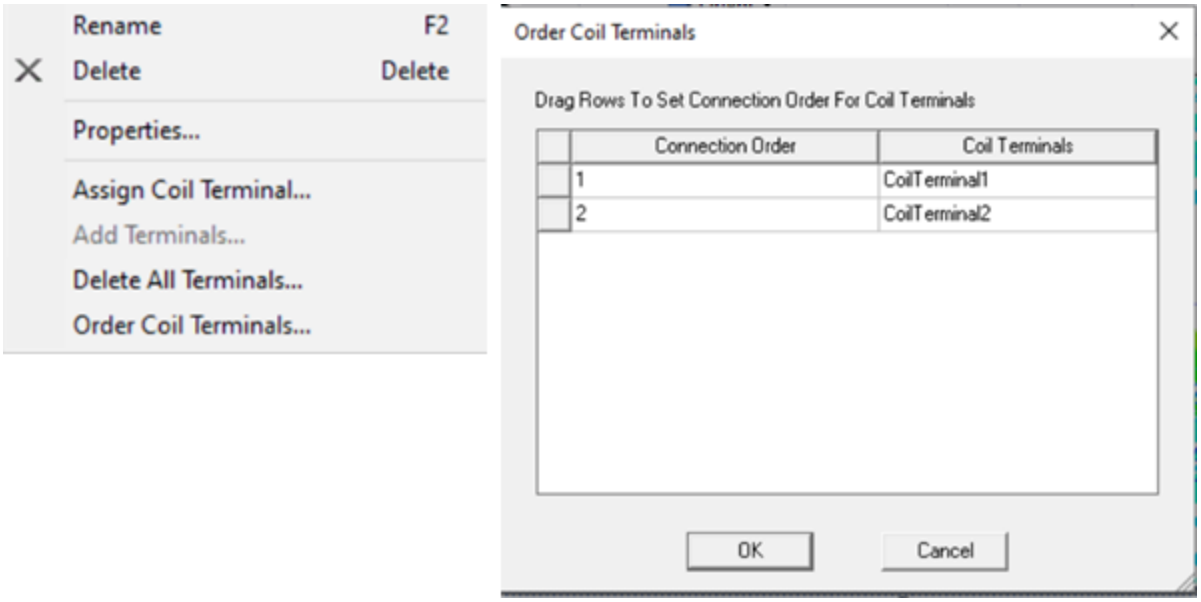
- Excitations supported are winding (via **Coil Terminal**), voltage, and current. Winding excitation is assigned as in the Transient solver (Refer to *Coil Terminals* for more information on winding assignments). **Voltage** and **Current** excitations are also included on the **Excitations>Assign** menu:



Winding Excitations for A-Phi Formulation

Winding excitation is assigned as in the Transient solver (Refer to *Assigning a Winding Setup for a Transient Solver* for more information on winding assignments). For winding excitations, the coil terminals must be ordered according to the physical potential distribution. To do this:

1. Right-click on the winding to open the context menu.
2. Click on **Order Coil Terminals** to open the **Order Coil Terminals** dialog box.



3. Order the terminals by dragging them in the **Order Coil Terminals** dialog box.

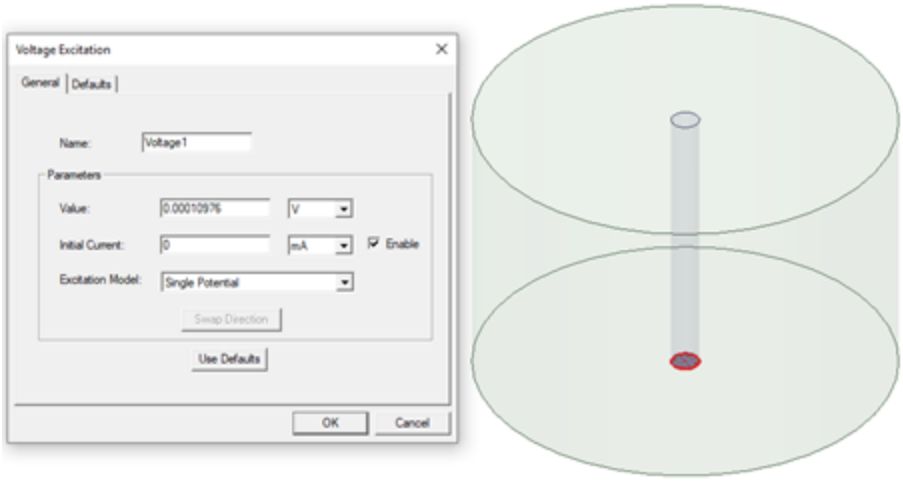
Voltage Excitations for A-Phi Formulation

For designs with known potentials, select and assign a Voltage excitation on each face.

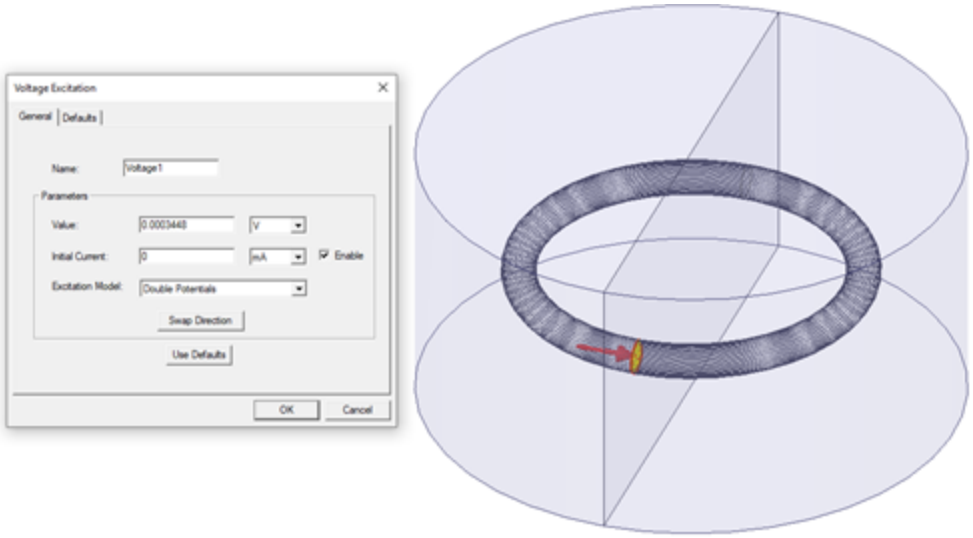
You can also define initial currents for Voltage Excitation by checking the **Initial Current** box. When Initial current is defined, the solver treats it as the Current excitation. The default value is 0A. You should select at least one voltage excitation without enabling the initial currents on a solid conduction path to set a reference potential. (If the path is touching the odd symmetry boundary, where the potential is set to 0 V, or if displacement effect is considered in the problem domain, then this rule does not apply on this path.)

Voltage excitation supports 3 different excitation models:

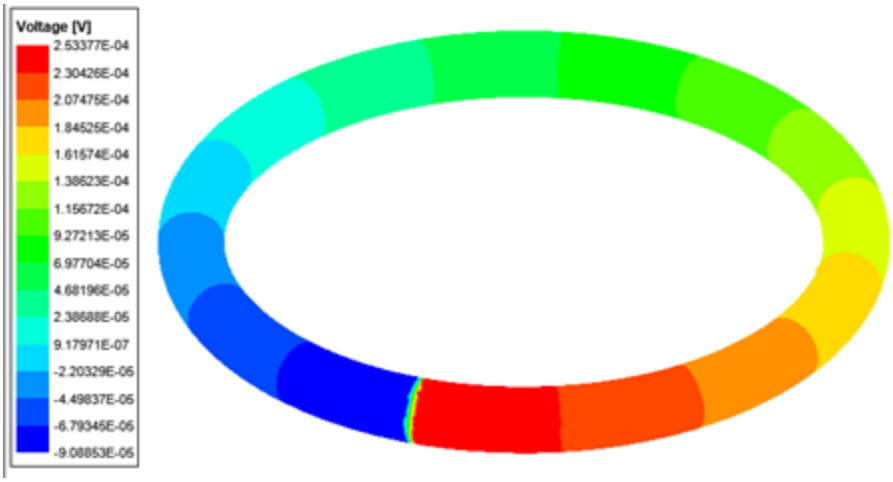
- **Single Potential**: The solver treats the terminal as an equi-potential terminal. Only one scalar electric potential DOF (Degree of Freedom) is assigned to the surface and the value of the DOF is set to the value that user inputs. *This model must be used only at the external boundaries of the problem domain.*



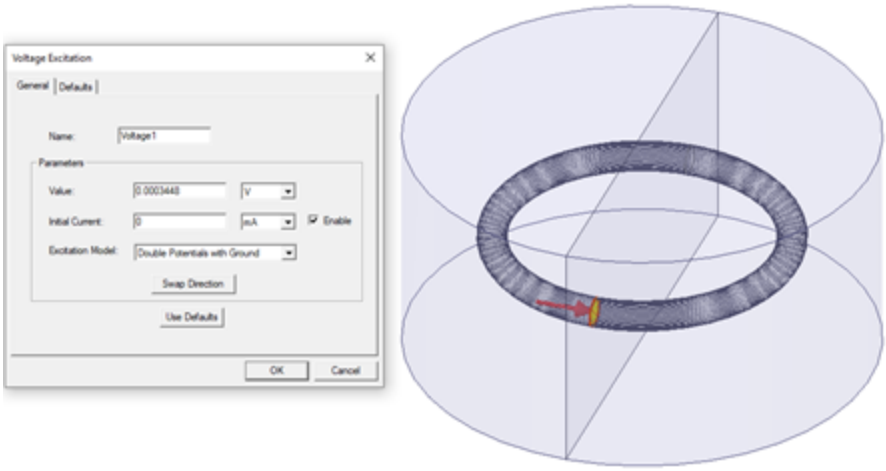
- **Double Potentials**: The solver treats the terminal as a voltage (potential difference) terminal. At the terminal face, two scalar electric potential DOFs are defined and the DOFs are unknown. The difference between those potentials equals the voltage value that the user specified. If the voltage value is a positive quantity, higher potential is in the specified direction. *This model must be used on faces inside the problem domain.*

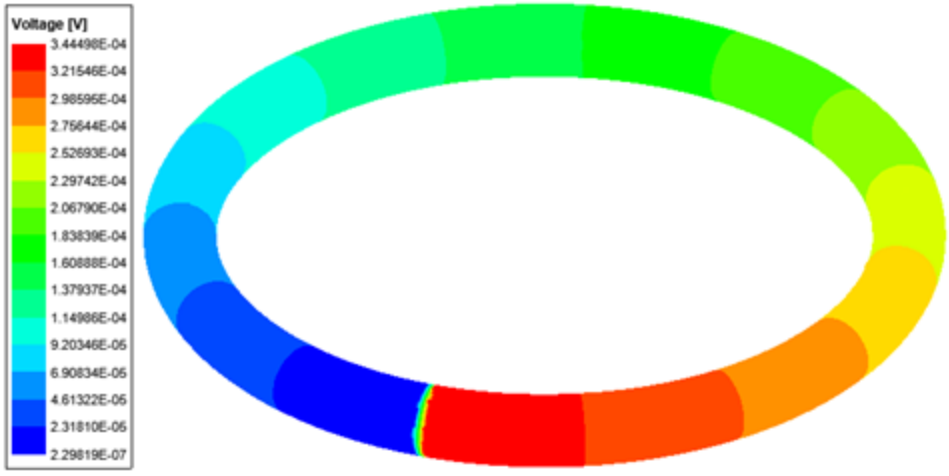


If the user does not define a reference potential on the same conduction path, the potentials at the terminal will be floating, so they are not unique. However, B, J, H, and all other quantities will be unique since they depend on the derivative of the potential.



- **Double Potentials with Ground**: The solver treats the terminal as voltage (potential difference) terminal. At the terminal face, two scalar electric potential DOFs are defined and both DOFs are known. The difference between those potentials equals to the voltage value that user specified. If the voltage value is a positive quantity, the DOF in the specified direction is set to the specified voltage value, and the DOF in the opposite direction is set to 0. *This model must be used on faces inside the problem domain.*

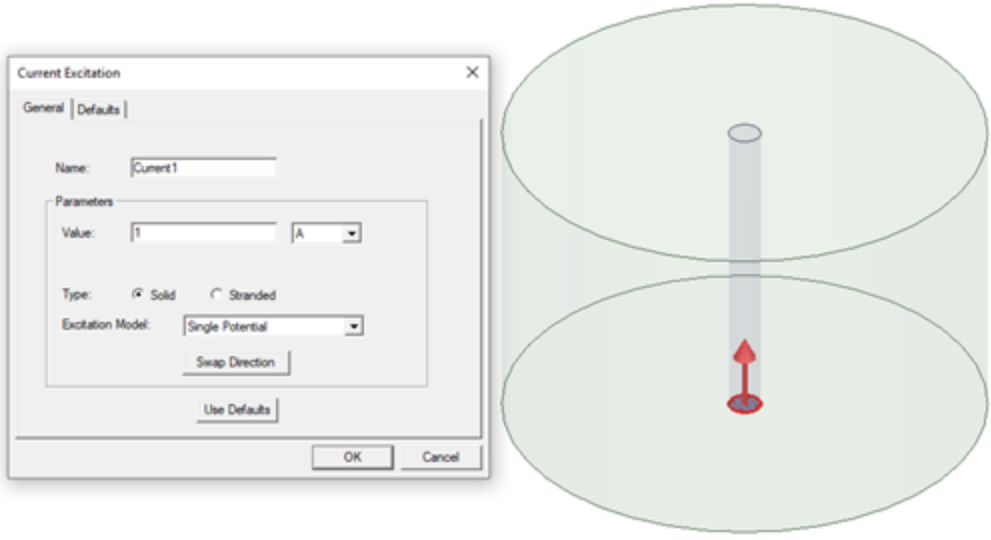




Current Excitations for A-Phi Formulation

For designs with known current values, the user selects and assigns a Current excitation on each face. The user also selects the type of conductor: solid or stranded. Current excitation supports 3 different excitation models for Solid conductor type based on how the potential DOF is assigned on the face:

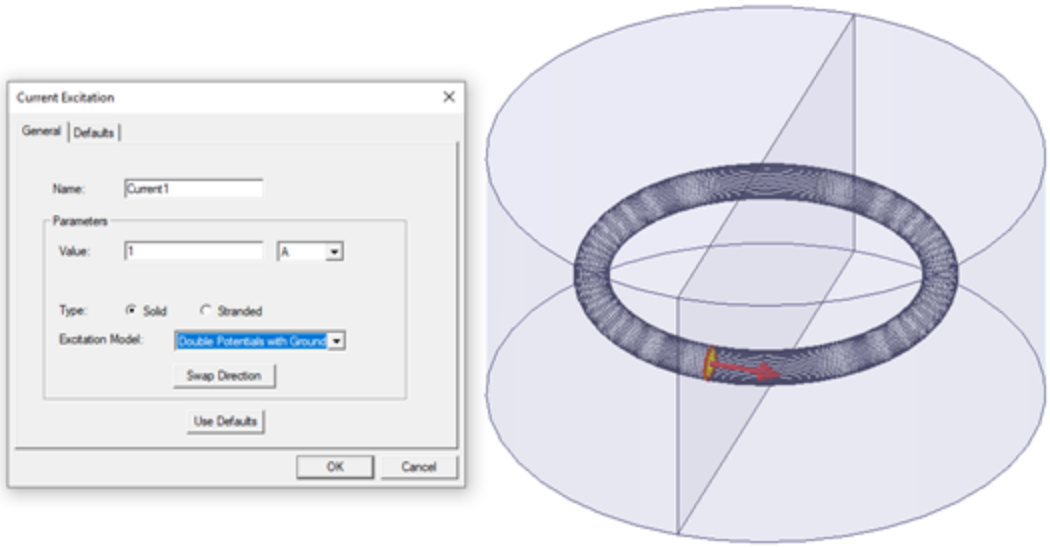
- **Single Potential**: Only one scalar electric potential DOF is assigned to the surface and it is unknown. *This model must be used only at the external boundaries of the problem domain.*

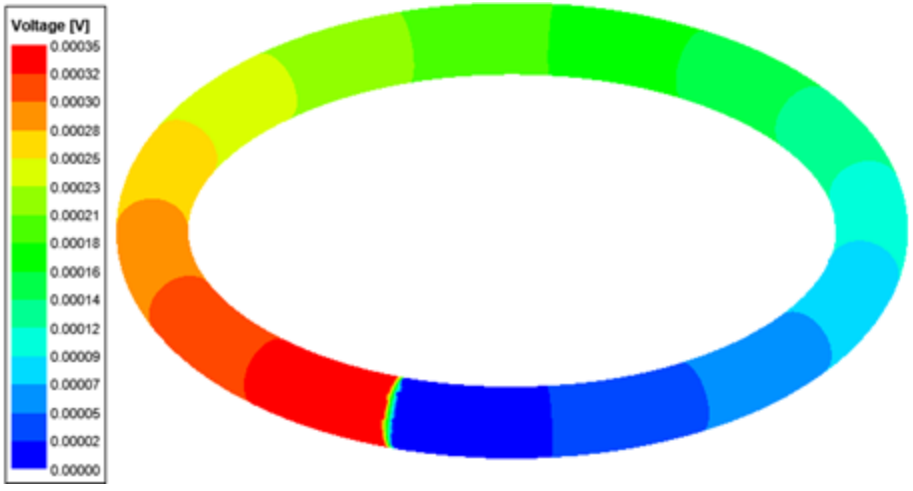


- **Double Potentials**: At the terminal face, two electric scalar potential DOFs are defined and the DOFs are unknown. There is a potential difference at the terminal. The current will be unidirectional, and it will flow in the direction that user specifies if

the current value entered is a positive quantity. *This model must be used on faces inside the problem domain.*

- **Double Potentials with Ground**: At the terminal face, two scalar electric potential DOFs are defined. The potential on the opposite side of the direction that user specified is set to 0. The current will be unidirectional, and it will flow in the specified direction if the current value entered is a positive quantity. *This model must be used on faces inside the problem domain.*





Rules/Limitations of Excitations on Conduction paths

Winding Excitations

- 1 or 2 terminals can be defined on a conduction path: if the path is a loop, then only one coil terminal per coil must be defined, else only 2 coil terminals per coil must be defined (for both solid and stranded cases).
- More than 2 coil terminals are not allowed on a conduction path.
- Coil terminals must be ordered according to the physical potential distribution. One potential degree of freedom (DOF) is assigned to each external coil terminal. Two DOFs are assigned to each internal coil terminal. For windings with external coil terminals, there are two coil terminals defined for each conduction path. The potential DOF of the second terminal on a conduction path is linked to the potential DOF of the first terminal on the next conduction path, which means the coils are serially connected. That is why it is essential to create the coil terminals in the order of the actual potential distribution on serially connected coils (conduction paths). The potential on the last Coil Terminal is set to zero. The same rule for linking the DOFs applies to the windings with internal coil terminals.

Current Excitations

- For stranded current excitation: More than 2 terminals are not allowed on a conduction path. For a loop conduction path, one terminal is defined. For other conduction paths, user must define 2 terminals (in and out). A voltage terminal and a stranded current terminal cannot be defined on the same conduction path.
- For solid current excitations: At least one voltage excitation is to be defined as a reference potential on the same conduction path of the current excitation. If a current excitation with Double Potentials with Ground selection exists in the path, or displacement current is enabled, this requirement does not apply. Multiple current excitations on a conduction path are allowed.

Voltage Excitations

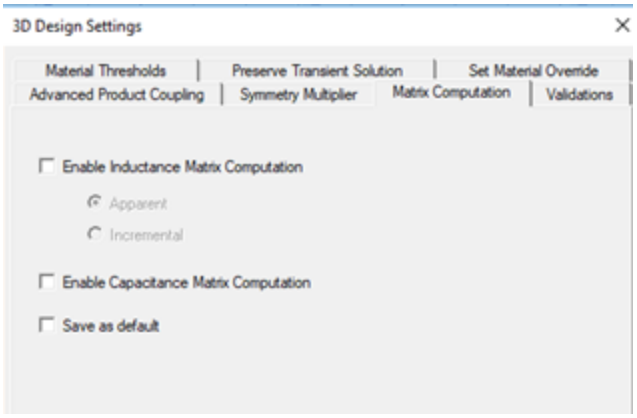
- There must be at least one voltage excitation on a conduction path with current/voltage excitations if displacement effect is not enabled (if the path is not touching the odd symmetry boundary, or there is no current/voltage excitation with Double Potentials with Ground selection, where the potential is set to 0 V).
- Winding excitation cannot be defined together with voltage or current excitations on the same path.
- On a conduction path there can be multiple solid voltage and current terminals defined.

Independent/Dependent and Odd Symmetry Boundaries

- Excitations cannot be defined on Independent/Dependent Boundaries.
- If a conduction path crosses an Odd Symmetry Boundary, Excitations must be defined at External Boundaries because the default electric potential value is zero on the Odd Symmetry Boundary. Voltage Excitation can be used to set a different potential value on the face intersecting with an Odd Symmetry Boundary. Also, any Excitation (Coil Terminal, Voltage, or Current Excitation) assignment is allowed on the face intersecting with an Odd Symmetry Boundary.
- if a conduction path crosses both Odd Symmetry and Independent/Dependent Boundaries, the User interface validation process does not allow one external terminal definition on the path. The user can select "Perform minimal validations" under Design Settings to simulate such designs at the user's own risk. Full model simulation is highly recommended for such designs.

Matrix Setup

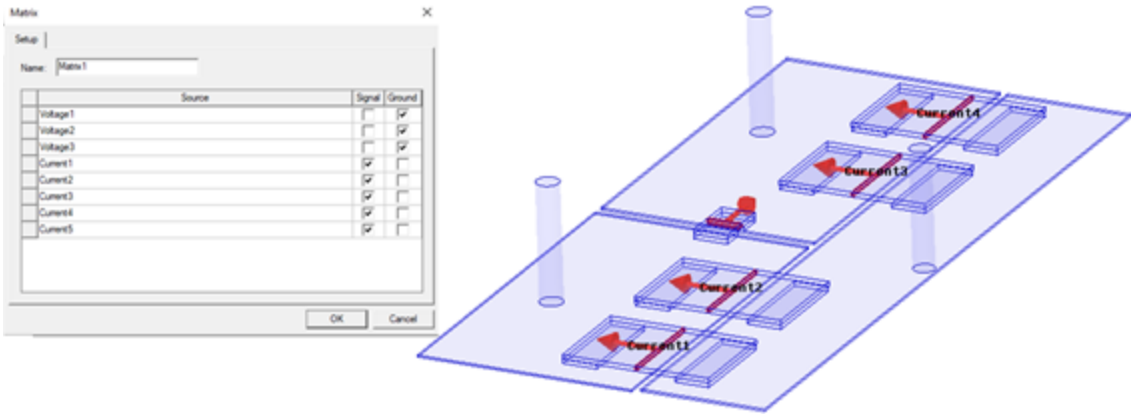
Parametric Matrix Setup is supported for the A-Phi transient solver. The user can define only one matrix setup for inductance or capacitance calculations. The user must select **Enable Inductance Matrix Computation** or **Enable Capacitance Matrix Computation** under **Design Settings** for computation of the defined matrix.



The user selects signals and grounds for the matrix of interest. For the inductance matrix, the followings are restrictions on ground selections:

- Ground selection is not allowed for windings, because they are internally grounded.
- Ground selection is not allowed for stranded current excitations since no potential is defined on the conduction path.
- Ground selection is not allowed for current excitations with double potentials and double potentials with ground.
- Ground selection is only available for Voltage excitation with Single Potential model. Ground selection is not allowed for voltage excitations with double potentials and double potentials with ground.

It is highly recommended that ground selection be as in the nominal problem setup, especially for designs with multi-terminal excitations on a conduction path. Other solver types do the matrix computation after the solution of nominal problem so it is fully post-processed, and the user can select different signal/ground/return path configurations. However, the transient solver is computing the matrix at each time step and the computation is highly dependent on how the current flows on a path, especially for designs with multiple excitations on the path.



The capacitance matrix is computed using the electrostatic energy stored in a system under 1V excitation for one selected signal and 0V for all others. Based on the selection of signals and grounds, the solver computes the capacitance matrix of the system. For the capacitance matrix, the following rule applies for the ground selection:

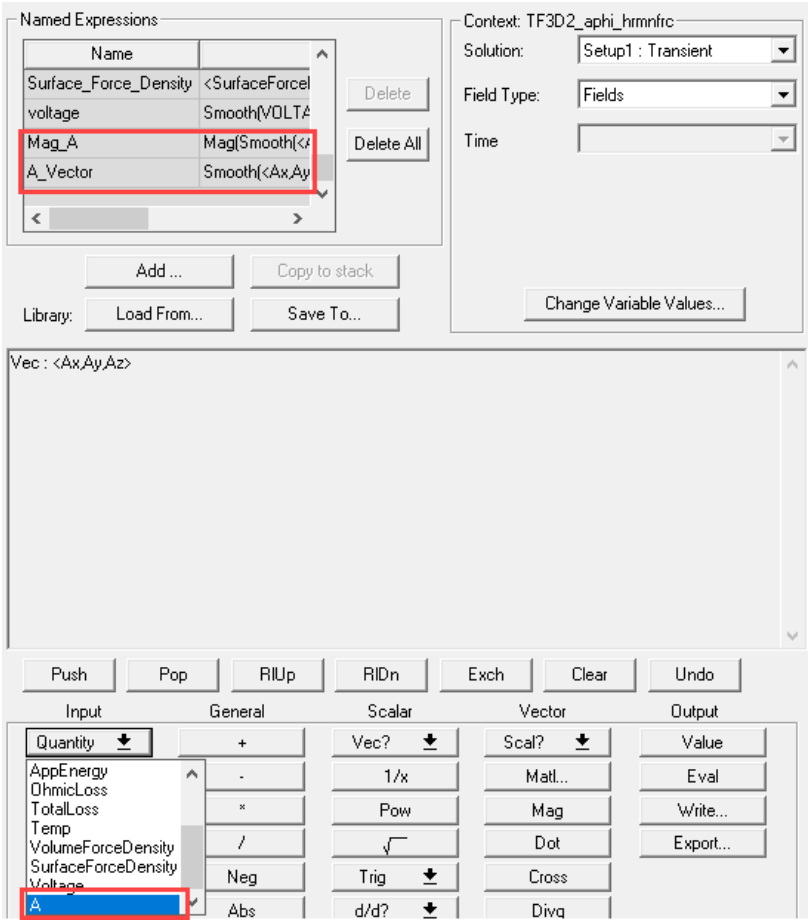
- There must be at least one ground selection in the Matrix setup if there is no internal zero reference potential defined in the design. Odd Symmetry, winding excitation, and double potentials with ground excitation model are examples of internal grounds.

Post-Processing Support

The A-phi transient solver supports all the post-processing features of the transient solver. Additionally, the following features are supported:

- Voltage in the Field Plot and in the Fields Calculator

  There are cases where no voltage is defined in an object (in a stranded object, or in an object with no eddy or displacement effect setting).
- Magnetic vector potential in the Fields Calculator



- Voltage and current quantities at the Voltage and Current Terminals
  The current computed at any terminal is assumed to be flowing into the problem domain.

Electrostatic Solver

The electrostatic field simulator computes static electric fields in 2D or 3D due to:

- Stationary charge distributions.
- Applied potentials.

The quantity for which the electrostatic field simulator solves is the scalar electric potential, ϕ; the electric field (**E**-field) and the electric flux density (**D**-field) are automatically calculated from the potential. Derived quantities such as forces, torques, energy, surface charge density, and capacitance matrix may be calculated from these basic field quantities.

Related Topics

Technical Notes: 3D Electrostatic Field Calculation

Technical Notes: 2D Electrostatic Field Simulation

2D AC Conduction

The 2D AC conduction field simulator computes steady-state 2D electric fields in conductors due to:

- Applied potentials.

The AC conduction field solver allows you to analyze conduction currents due to time-varying electric fields in conductors and lossy dielectrics. Use it to analyze current distributions, electric field distributions and potential differences, admittances, lossy materials, and stored energy. For instance, the admittance matrix associated with a structure can be computed using the AC conduction field solver. In addition, any quantity that can be derived from the basic electromagnetic quantities can then be analyzed.

The AC conduction field solver can compute conduction currents for cartesian (XY) and axisymmetric (Cylindrical about Z) models. It assumes that all sources are sinusoids oscillating at the same frequency. Optionally, you may specify different phase angles for different sources.

You are expected to specify material properties and the electric potential at one or more object interfaces or boundaries in the model. The AC conduction field solver then computes the electric

potential, $\phi(t)$, for the model. From the electric potential, it derives the electric field, **E**(t), the electric flux density, **D**(t), and the current density, **J**(t).

Related Topics

Technical Notes: *2D AC Conduction Field Simulation*

3D AC Conduction

AC conduction analysis is the study of:

- electric field
- current
- losses
- lumped parameters (CG)

The AC conduction field solver allows you to analyze both conduction and displacement currents due to time-varying electric fields in conductors and perfect and lossy dielectrics.

Use it to analyze current distributions, electric field distributions and potential differences, and CG parameters. For instance, the admittance matrix associated with a structure can be computed using the AC conduction field solver. In addition, any quantity that can be derived from the basic electrical quantities (Electric Field, current densities, etc.) can then be analyzed.

The AC conduction field solver assumes that all sources are sinusoids oscillating at the same frequency. Optionally, you may specify different phase angles for different sources.

You need to specify these related material properties: permittivity, conductivity (for lossy materials), frequency-dependent dielectric loss tangent. You also must specify the current, electric potential at one or more object interfaces or boundaries in the model. The AC conduction field solver then computes the electric potential for the model. From the electric potential, it derives the electric field, **E**, the electric flux density, **D**, and the current density, **J**.

The supported 3D material models can be found in the table in *Maxwell Solvers Material Properties*.

3D AC Conduction Boundaries and Excitations

Technical Notes: 3D AC Conduction Solver Theory

Maxwell Solvers Material Properties

DC Conduction Solver

The electric conduction field simulator computes steady-state 2D or 3D electric fields in conductors due to:

- Current excitations.
- Applied potentials.

The quantity for which the electric conduction field simulator solves is the electric potential, ϕ; the electric field (**E**-field**)** and the current density (**J**-field) are automatically calculated from the potential. The resistance matrix, a derived quantity, may be calculated from these basic field quantities. As an additional option, perfect insulators, that is, non-conduction regions, surrounding the conductors can also be added to the simulation domain allowing to calculate the electric field everywhere including the insulators.

Related Topics

DC Conduction Boundaries and Excitations

Technical Notes: 2D DC Conduction Field Simulation

Electric Transient Solver

The 3D electric transient field simulator computes time-varying electric fields excited by:

- Time-varying applied potentials.
- Total charge and volume charge density.
- Time-varying current excitations.

The quantity for which the electric transient field simulator solves is the electric potential, ϕ by solving the following equation:

$$-\nabla \cdot \left(\varepsilon \nabla \frac{\partial \Phi}{\partial t}\right) - \nabla \cdot (\sigma \nabla \Phi) = 0$$

The electric field (**E**-field), the current density (**J**-field), and the electric flux density (**D**-field) are automatically calculated from the potential.

Derived solution parameters such as the electric energy, Ohmic loss, surface charge density, and maximum electric field can be obtained for each solid.

The temporal discretization is adaptive and, besides the initial and maximum time step, it also depends on temporal tolerance. The default temporal tolerance is 0.005, but it depends on the problem to be solved.

Normally, problems with high time derivative field solutions would require smaller temporal tolerances.

In the case of non-linear problems, temporal tolerance also depends on the non-linearity of materials and its value needs to be set around 1e-12 or even smaller.

Maxwell Solvers Material Properties

The tables below list material properties supported by the Maxwell 2D and 3D solvers. Additional information may be found in the sections on *Adding Materials*, *Assigning Material Property Types*, and *Materials*.

Material Properties for Maxwell 3D Solvers

Material property	Electrostatic	DC Conduction	AC Conduction	Electric Transient	Magnetostatic	Eddy current	Magnetic Transient (T-Omega)	Magnetic Transient (A-Phi)

Specifying the Solver Type

Disconnected Solution Domains

There are two ways to create a problem that contains multiple disconnected solution domains:

- By not creating or by excluding (not solving in) the background object, when the included objects are not all touching.
- By using excluded objects or perfect conductors that cut the included objects into different regions.

The Maxwell solver identifies multiple disconnected solution domains.

For the electric solvers (electrostatic, conduction, and conduction+electrostatic), the solution is allowed even if multiple disconnected solution domains are detected. In this case, an error message appears only if a solution domain with inconsistent or unsolvable solution setup is detected.

For the magnetic solvers (magnetostatic, eddy current, and transient EM), an error message appears when multiple disconnected solution domains are detected.

8 - Drawing a Model

After you insert a design into the current project, you can draw a model of the electromagnetic structure. The general strategy is to build the model as a collection of 3D objects. You can assign any single material to each 3D object.

You can create 3D objects by using the modeler's **Draw** commands or you can draw 1D and 2D objects, and then manipulate them to create 3D objects. Objects are drawn in the **3D Modeler** window. You can also import objects from other systems.

To open a new **3D Modeler** window, do one of the following:

- Insert a new design into the current project.
- Double-click a design in the project tree.

If a **3D Modeler** window is not open, do one of the following:

- On the Maxwell menu, click **3D Model Editor**.
- Right-click the design name in the project tree, and then click **3D Model Editor** on the shortcut menu.

The model you draw is saved with the current project when you click **File>Save**.

Note	If you access your machine via Remote Desktop, if Maxwell is running and one or more modeler windows are open, those modeler windows automatically close. The message manager window displays a message indicating that Maxwell closed the modeler windows.

When working with multiple projects, or when a project has multiple designs, you may have multiple **Modeler** windows available. To switch to the modeler window associated with a specific design:

1. In the Project Manager window, select the **Design** of interest.
2. Click **Maxwell3D Model Editor** to focus the modeling window on the selected design.

Note	If the menu command is unavailable, then the selected design is already in the modeler window.

Drawing Objects

You can draw one-, two-, or three-dimensional objects using the **Draw** commands. You can alter objects individually or together to create the geometry of your structure. In the **Tools>Modeler Options, Drawing** tab, you can set a default to either draw objects directly with the mouse or by invoking a **Properties** dialog in which you can enter the values for the object dimensions. The **Dialog** mode drawing feature works with the equation based line, and all two and three dimensional objects. You can toggle to **Point** mode via the **F3** function key and to **Dialog** mode via the **F4** function key. When you use the **Dialog** mode for drawing objects the **Edit property of new primitives** setting is ignored.

One-dimensional (1D) objects in the modeler include straight line, arc line, center-point arc, and spline segments, or a combination of these - called polylines. One-dimensional objects are open objects; their boundaries do not enclose a region, unless you connect their endpoints. They have length, but no surface or volume. Generally they are used as temporary objects from which to create 2D objects.

Two-dimensional (2D) objects in the modeler include objects such as equation based surfaces, rectangles, ellipses, circles, and regular polygons. Two-dimensional objects are closed sheet objects; their boundaries enclose a region. You can create 2D sheet objects by covering the enclosed region. In many applications (FSS, antennas) it is essential to calculate net power flow through a surface.

You can also edit the properties of a polyline from the history tree to assign it a Cross Section property as line or rectangular. If you then assign it either a height or a width, the polyline becomes a sheet object.

By default, the history tree organizes sheet objects according to their boundary assignments. To change this, select the **Sheets** icon, and right-click to display the **Group Sheets by Assignment** check box. Within the calculator sheet objects are listed under surface.

Three-dimensional (3D) objects in the modeler include objects such as boxes, cylinders, regular polyhedra, cones, spheres, torii, and helices. These objects have boundaries that enclose a region with volume.

You can create 3D objects by manipulating 2D objects along a plane or by using the appropriate **Draw** commands. You can also edit the properties of a polyline from the history tree to assign it a Cross Section property as circle rectangular. If you then assign it an appropriate diameter or both height or a width, the polyline becomes a 3D object.

By default, the history tree organizes 3D objects by material. To change this, select the **Objects** icon, and right click to display the **History Tree Layout Commands**. You can also use Group Commands for Modeler Objects.

While you draw objects you can also:

- Select Movement Mode as 3D, In Plane, Out of Plane, Along X, Y or Z axis.
- Select Grid Plane as XY, YZ, or XZ.
- Set Snap Mode
- Set Reference Point for the movement mode
- Adjust the View

After you draw an object in the **3D Modeler** window, you can modify the object's properties, such as its position, dimensions, or color, in the **Properties** dialog box. Most object properties can be assigned to variables that can then be manipulated during the solve to test their effect on the solution.

Note	If you access your machine via Remote Desktop, if Maxwell is running and one or more modeler windows are open, those modeler windows automatically close. The message manager window displays a message indicating that Maxwell closed the modeler windows.

Drawing a Straight Line Segment

To create an object with one or more straight line segments, use the **Draw>Line** command.

1. Click **Draw>Line**  .
2. Select the first point of the line in one of the following ways:
   - Click the point.
   - Edit the point's coordinates in the **X**, **Y**, and **Z** boxes in the status bar.

   To delete the last point that was entered, click **Undo Previous Segment** on the shortcut menu. After using the undo feature, you can also use **Redo Previous Segment** on the shortcut menu.
3. Select the endpoint of the line by clicking the point or typing the coordinates in the text boxes in the status bar.

   The endpoint serves as the start point for a subsequent line segment.

   To delete all points and start over, press **ESC** or click **Escape Draw Mode** on the shortcut menu.
4. Complete the line in one of the following ways:

- Double-click the endpoint.
- Click **Done** on the shortcut menu.
- Press **Enter**.

If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line.

5. Click **OK to close the Properties dialog.**

Note	While drawing a polyline, you can switch between straight line, arc line, or spline segments using the **Set Edge Type** commands on the shortcut menu.

Drawing a Three-Point Arc Line

In the modeler, a three-point arc line segment is an arced line defined by three points on its curve. Use the **Draw>Arc>3 Point** command to create a polyline object with one or more arc line segments.

1. Click **Draw>Arc>3 Point**  .
2. Select the start point of the arc in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.
3. Select the midpoint of the arc by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.

   To delete the last point that was entered, click **Undo Previous Segment** on the shortcut menu. After using the undo feature, you can also use **Redo Previous Segment** on the shortcut menu.

   To delete all points and start over, press **ESC** or click **Escape Draw Mode** on the shortcut menu.

4. Select the endpoint of the arc by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.

   The endpoint serves as the start point for a subsequent arc line segment.

5. If the endpoint is the last point of the polyline object, double-click the point to complete the polyline or click **Done** on the shortcut menu.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line.

6. Click **OK**.

   Based on the three points you specified, the modeler calculates the center point and radius of the arc and draws an arced line through the three points.

Note	While drawing a polyline, you can switch between arc line, straight line, or spline segments using the **Set Edge Type** commands on the shortcut menu.

Drawing a Center-Point Arc Line

In the modeler, a center-point arc line segment is an arced line defined by a center point, start point and angle. Use the **Draw>Arc>Center Point** command to create a polyline object with one or more center-point arc line segments.

1. Click **Draw**>**Arc**>**Center Point**  .
2. Select the center point of the arc in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.
3. Select the start point, or radius, of the arc by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.

To delete the last point that was entered, click **Undo Previous Segment** on the shortcut menu. After using the undo feature, you can also use **Redo Previous Segment** on the shortcut menu.

To delete all points and start over, press **ESC** or click **Escape Draw Mode** on the shortcut menu.

4. Sweep the angle, or endpoint, of the arc by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.
5. If the endpoint is the last point of the polyline object, double-click the point to complete the polyline or click **Done** on the shortcut menu.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes.
6. Click **OK**.

Note	While drawing a polyline, you can switch between arc line, straight line, or spline segments using the **Set Edge Type** commands on the shortcut menu.

Drawing a Spline

A spline is a curved line defined by three points. The modeler uses a natural spline type: a piece wise cubic spline with an end condition that has a derivative of zero. Use the **Draw>Spline** command to create a polyline object with one or more spline segments.

1. Click **Draw**>**Spline**  .
2. Select the spline's start point in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the **X**, **Y**, and **Z** text boxes in the status bar, and then press **Enter**.

   To delete the last point entered, click **Undo Previous Segment** on the shortcut menu.After using the undo feature, you can also use **Redo Previous Segment** on the shortcut menu.

   To delete all selected points and start over, press **ESC** or click **Escape Draw Mode** on the shortcut menu.

3. Select the midpoint of the spline by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.
4. Select the endpoint of the spline by clicking the point or typing the coordinates in the **X**, **Y**, and **Z** text boxes in the status bar.

   The endpoint serves as the start point for a subsequent spline segment.
5. Complete the spline in one of the following ways:
   - Double-click the endpoint.
   - Click **Done** on the shortcut menu.
   - Press **Enter**.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line.
6. Click **OK**.

Note	While drawing a polyline, you can switch between spline, straight line, or arc line segments using the **Set Edge Type** commands on the shortcut menu.

Converting Polyline Segments

Drawing a Polyline

A polyline is a single object that includes any combination of straight line, arc line, or spline segments. The endpoint of one segment is the start point for the next segment. Use the shortcut menu's **Set Edge Type** commands to switch between straight line, arc line, or spline segments while drawing a polyline.

In the **Polyline** section of **Operation** tab of the **Modeler Options**, select or clear the **Automatically cover closed polylines** check box.

If checked, closed polylines become sheet objects, and are listed as such in the History tree. If unchecked, closed polylines are listed under lines in the History tree.

1. Click **Draw**>**Line**  .
2. Right-click in the **3D Modeler** window to access the shortcut menu, and then point to **Set Edge Type**.
3. Click **Straight**, **Spline**, **3 Point Arc**, or **Center Point Arc** depending on which type of polyline segment you want to draw.
4. If you clicked **Straight**, follow the procedure for drawing a straight line.

   If you clicked **Spline**, follow the procedure for drawing a spline.

   If you clicked **3 Point Arc**, follow the procedure for drawing a three-point arc line.

   If you clicked **Center Point Arc**, follow the procedure for drawing a center-point arc line.
5. Repeat steps 2 and 3 for each segment of the polyline object. The endpoint of the previous segment serves as the start point for the next segment.

   The shortcut menu lets you do the following for each segment:

   Undo Previous Segment or **Redo Previous Segment**.
6. Complete the polyline in one of the following ways:
   - Double-click the endpoint of the final segment.
   - Click **Done** on the shortcut menu.

Note	To connect the polyline's start and endpoints, click **Close Polyline** on the shortcut menu.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line. Notice that by going to the History tree selecting Create Polyline for that object, you can assign a cross-section and dimensions to a polyline.
7. Click **OK**.

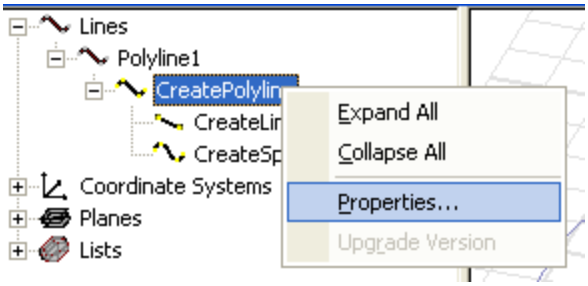
Assigning a Cross Section and Dimensions to a Polyline

By viewing the History tree property of a polyline, you can assign either a line, circle or rectangle or isosceles trapezoid cross-section to a polyline. This assignment enables editable dimension properties of width for a line, diameter for a circle, and height and width for a rectangle. To assign a cross-section to a polyline:

1. In the History tree of the Modeler window, right-click on the polyline that you want to give a cross-section.

   This selects the polyline, displays the polyline properties in the docked properties (if you have if displays) and displays a shortcut menu where you can choose **Properties...** to display the undocked Properties window for the polyline.



2. In a Properties window (either docked or undocked) for the selected polyline click on **None** on the **Type** line under Cross Section to display the choices for Line, Circle, Rectangle or Isosceles Trapezoid.
3. Select one of Line, Circle, Rectangle, or Isosceles Trapezoid as the cross-section.
   - Selecting **Line** causes the Cross Section area of the polyline properties to display editable fields for Orientation and Width.
   - Selecting **Circle** causes the Cross Section area of the polyline properties to display an editable field for diameter.
   - Selecting **Rectangle** causes the Cross Section area of the polyline properties to display editable fields for Orientation, Width and Height.
   - Selecting **Isosceles Trapezoid** causes the Cross Section area of the polyline properties to display editable fields for Orientation, Width/Diameter, Top Width and Height.
4. If you select Line, Rectangle or Isosceles Trapezoid, you can edit the Orientation as Auto, X, Y, or Z. This provides the direction in which the dimension extends.
5. Specify the dimensions and select the units for the Cross section.

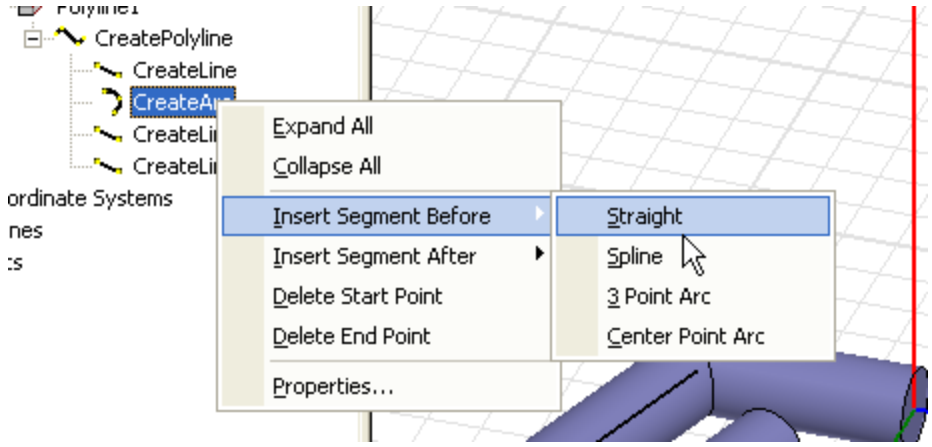
   Type a value in the dimension field(s) and select units from the drop down menu.

   The dimensions must be reasonable relative to the specified shape and orientation of the polyline. If the polyline cannot be extended into current Orientation for the given dimension

(s), you will receive a warning. If you receive a warning, check the Orientation, dimension and units.

When the modeler can extend the dimensions legally, it displays the modified object, and lists it in the History tree as either a Sheet object (Line or one dimensional Rectangle) or as a Solid object (Circle or two dimensional Rectangle).

6. You can modify the new polyline either by editing the properties, or by using the History tree to select one of the line objects that make up the polyline, and right clicking to display the popup menu showing commands to **Insert**, **Delete**, or display editable segment **Properties**.



A segment that you select in the Project tree is indicated in the Modeler window by a line in the dimensioned object. If you insert a new segment, it adopts the dimensions you specified for the polyline object.

Inserting Line Segments

You can insert line segments of various kinds for existing line objects.

1. Select the line object in the **History** tree (not the modeler window).

This highlights the object and enables the **InsertLine Segment** commands in the **Draw** menu and short-cut menu.

2. Use the cascade menu from the **Draw>Line Segment** command to or the right-click menu to select whether to **Insert Before Line Segment** or **InsertAfter Line Segment**.
3. Use the next cascade menu to specify the kind of segment to add. These can be: Straight, Spline. 3 Point Arc, or Center Point Arc.
4. If you clicked **Straight**, follow the procedure for drawing a straight line.

   If you clicked **Spline**, follow the procedure for drawing a spline.

   If you clicked **3 Point Arc**, follow the procedure for drawing a three-point arc line.

   If you clicked **Center Point Arc**, follow the procedure for drawing a center-point arc line.
5. Repeat steps 2 and 3 for each segment of the polyline object. The endpoint of the previous segment serves as the start point for the next segment.
6. Complete the polyline in one of the following ways:
   - Double-click the endpoint of the final segment.
   - Click **Done** on the shortcut menu.

Note	To connect the polyline's start and endpoints, click **Close Polyline** on the shortcut menu.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line.
7. Click **OK**.

Related Topics

Drawing a Center-Point Arc Line

Converting Polyline Segments

Drawing an Equation-Based Curve

Any line that can be described by an equation in three dimensions can be drawn.

1. Click **Draw**>**Equation Based Curve** .

   The **Equation Based Curve** dialog box opens.

2. Type equations for **X(_t)**, **Y(_t)**, and **Z(_t)**.

Note	You can also define an equation by doing the following: 1. Click the **...** button. The **Edit Equation** dialog box appears. 2. Do one or more of the following to define the equation: • Type a numerical value or expression directly in the text box. • Select a function to insert from the pull-down list, and select **Insert Function**. • Select an operator from the pull-down list, and select **Insert Operator**. • Select a quantity from the pull-down list, and select **Insert Quantity**. 3. When you are finished defining the equation, click **OK** to close the **Edit Equation** dialog box and return to the **Equation Based Curve** dialog box.

   - Any unitless value input in equation based curve is taken as model units. For example, for Y(_t) = 1, the y value is taken as 1 model units (say mm). If a value has units, then it is converted to model units and used. For example, if we specify Y(_t) = 1cm, then y value will be correctly taken as 10mm.
   - While parsing expressions, equation based curves convert each variable separately to model units and assume that the resulting expression is in model units.
   - Equation based curves depend on the variable value library to correctly evaluate the units of expression.
3. Select a start value from the **Start_t** pull-down list.
4. Select an end value from the **End_t** pull-down list.
5. Select the number of points in the curve from the **Points** pull-down list.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes. Those listed under the Command tab describe the commands used to create the object. These commands also appear in the History tree. The Properties listed as line attributes include Name, Orientation, whether a Model object, whether to Display Wireframe, Color, Transparency, and whether to Show Direction as arrows. The Show Direction property is most helpful to unambiguously show the line start orientation when plotting fields along a line.
6. Click **OK** on the **Properties** dialog box.

Setting the Reference Point

Assigning a Cross Section and Dimension to a Polyline

Drawing a Circle

Draw a circle by selecting a center point and a radius. Circles are drawn as true surfaces in the modeler.

1. On the **Draw** menu, click **Circle**  .
2. Select the center point of the circle in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Specify the radius by selecting a point on the circle's circumference in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the center point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes.
4. Click **OK**.

   If the **Automatically cover closed polyline** option is selected in the **Modeler Options** window, the circle will be covered, resulting in a 2D sheet object. Otherwise it will be a closed 1D polyline object.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. For details about these commands see: Technical Notes, "Surface Approximations" and related sections, "Modifying Surface Approximations," and "Guidelines for Modifying Surface Approximations"

Drawing an Ellipse

Draw an ellipse by specifying a center point, base radius, and secondary radius.

1. On the **Draw** menu, click **Ellipse**  .
2. Select the center point of the ellipse in one of the following ways:

- Click the point.
- Type the point's coordinates in the text boxes in the status bar.

3. Specify the base radius of the ellipse. If the current drawing plane is xy, then x is the base radius direction. If the drawing plane is yz, then y is the base radius direction. If the drawing plane is xz, then z is the base radius direction. Select the point in one of the following ways:
   - Click the point. Maxwell constrains mouse movement to the base radius direction.
   - Type the coordinates of a point relative to the center point in the **dX**, **dY**, or **dZ** box, where **d** is the distance from the previously selected point.
4. Specify the secondary radius of the ellipse. Select the point in one of the following ways:
   - Click the point. Maxwell constrains mouse movement to a point on the plane orthogonal to the base radius direction.
   - Type the coordinates of a point relative to the center point in the **dX**, **dY**, or **dZ** box.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.

   The **Ratio** value represents the aspect ratio of the secondary radius to the base radius.
5. Click **OK**.

   If the **Automatically cover closed polyline** option is selected in the **Modeler Options** window, the ellipse will be covered, resulting in a 2D sheet object. Otherwise it will be a closed 1D polyline object.

If the base radius is larger than the secondary radius, the ellipse's longer axis will lie along the default base radius direction. If the secondary radius is larger than the base radius, the ellipse's longer axis will lie perpendicular to the default base radius direction. To create an ellipse with an arbitrary orientation, rotate or move the ellipse after drawing it.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. Drawing a Rectangle

Draw a rectangle (or square) by selecting two diagonally opposite corners.

1. Click **Draw**>**Rectangle**  .
2. Select the first diagonal corner in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.

   To delete the selected point and start over, press **ESC** or click **Escape Draw Mode** on the shortcut menu.
3. Select the second corner of the rectangle in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the first diagonal corner in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.
4. Click **OK**.

   If the **Automatically cover closed polyline** option is selected in the **Modeler Options** window, the rectangle will be covered, resulting in a 2D sheet object. Otherwise it will be a closed 1D polyline object.

Drawing a Regular Polygon

A regular polygon is a 2D object with three or more equal sides. Regular polygons are useful for drawing faceted 2D objects.

1. Click **Draw**>**Regular Polygon**  .
2. Select the center point of the polygon in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Specify the polygon's radius, the distance from the center point to one of the polygon's vertices, in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the center point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

4. In the **Segment number** dialog box, enter the **Number of segments** in the polygon, and then click **OK**.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.

5. Click **OK**.

Note	The radius is measured from the center point to a corner of the polygon, or the intersection of two edges. It is *not* measured from the center point to the midpoint of an edge.

   If the **Automatically cover closed polyline** option is selected in the **Modeler Options** window, the polygon will be covered, resulting in a 2D sheet object. Otherwise it will be a closed 1D polyline object.

Drawing an Equation-Based Surface

Any surface that can be described by an equation in three dimensions can be drawn.

1. Click **Draw>Equation Based Surface** .

   The **Equation Based Surface** dialog box opens.

2. Type equations for **X(_u, _v)**, **Y(_u, _v)**, and **Z(_u, _v)**.

Note	You can also define an equation by doing the following: 1. Click the **...** button. The **Edit Equation** dialog box appears. 2. Do one or more of the following to define the equation: • Type a numerical value or expression directly in the text box. • Select a function to insert from the pull-down list, and select **Insert Function**. • Select an operator from the pull-down list, and select **Insert Operator**. • Select a quantity from the pull-down list, and select **Insert Quantity**. 3. When you are finished defining the equation, click **OK** to close the **Edit Equation** dialog box and return to the **Equation Based Surface** dialog box.

- Any unitless value input in equation based curve is taken as model units. For example, for Y(_t) = 1, the y value is taken as 1 model units (say mm). If a value has units, then it is converted to model units and used. For example, if we specify Y(_t) = 1cm, then y value will be correctly taken as 10mm.
- While parsing expressions, equation based curves convert each variable separately to model units and assume that the resulting expression is in model units.

- Equation based curves depend on the variable value library to correctly evaluate the units of expression.

3. Select start values from the **Start_u** and **Start_v** pull-down lists.

   Select end values from the **End_u** and **End_v** pull-down lists.If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.

4. Click **OK** on the **Properties** dialog box.

Drawing a Sphere

Draw a sphere by selecting a center point and a radius. Spheres are drawn as true surfaces in the modeler.

1. Click **Draw**>**Sphere**  .
2. Select the center point of the sphere in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Specify the radius by selecting a point on the sphere's circumference in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the center point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.
4. Click **OK**.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. For details about these commands see: Technical Notes, "Surface Approximations" and related sections, "Modifying Surface Approximations," and "Guidelines for Modifying Surface Approximations"

Drawing a Cylinder

Draw a cylinder by selecting a center point, radius, and height. Cylinders are drawn as true surfaces in the modeler.

1. Click **Draw>Cylinder**  .
2. Select the center point of the cylinder's base circle in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Specify the radius by selecting a point on the base circle's circumference in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the center point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.
4. Specify the cylinder's height by selecting a point on the axis perpendicular to the base circle's plane. Select the point by clicking the point or typing the coordinates in the **dX**, **dY**, and **dZ** boxes.

Note	If you create a cylinder with a height of zero, Maxwell draws a circular sheet object.

   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's attributes.
5. Click **OK**.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. Drawing a Torus

Draw a torus by selecting its center point, major radius, and minor radius. The modeler then sweeps a circle around a circular path. Toruses are drawn as true surfaces in the modeler.

1. Click **Draw>Torus**  .
2. Select the center point of the torus in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Specify the major radius by selecting a point in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the center point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   The major radius determines the diameter of the torus.
4. Specify the minor radius by selecting a point relative to the major radius point.

   The minor radius determines the diameter of the "donut hole".

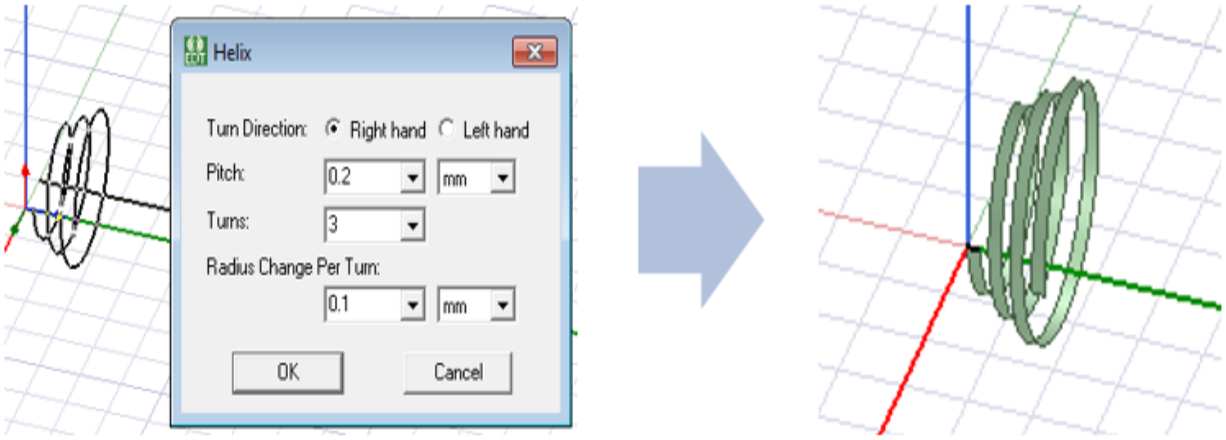
   If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.
5. Click **OK**.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. For details about these commands see:

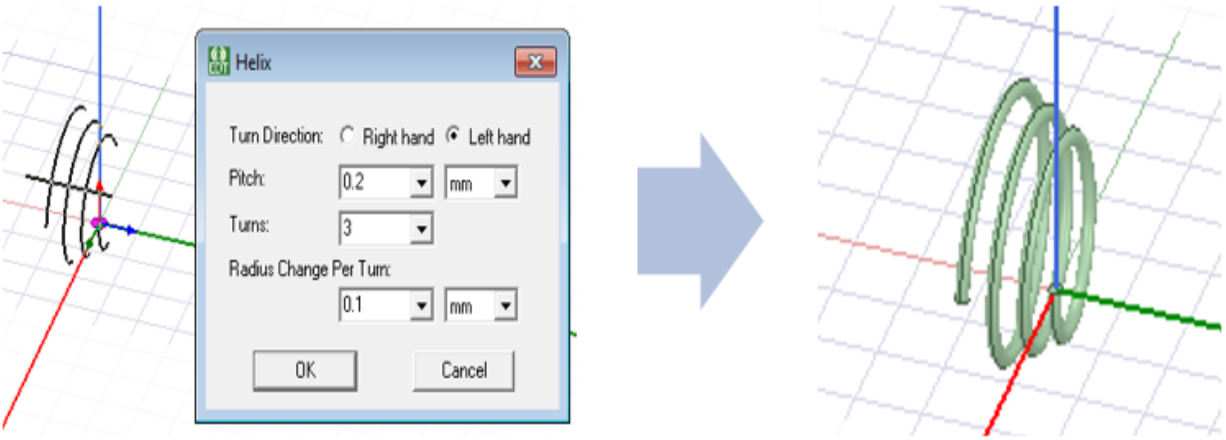
	Technical Notes, "Surface Approximations" and related sections, "Modifying Surface Approximations," and "Guidelines for Modifying Surface Approximations"

Drawing a Helix

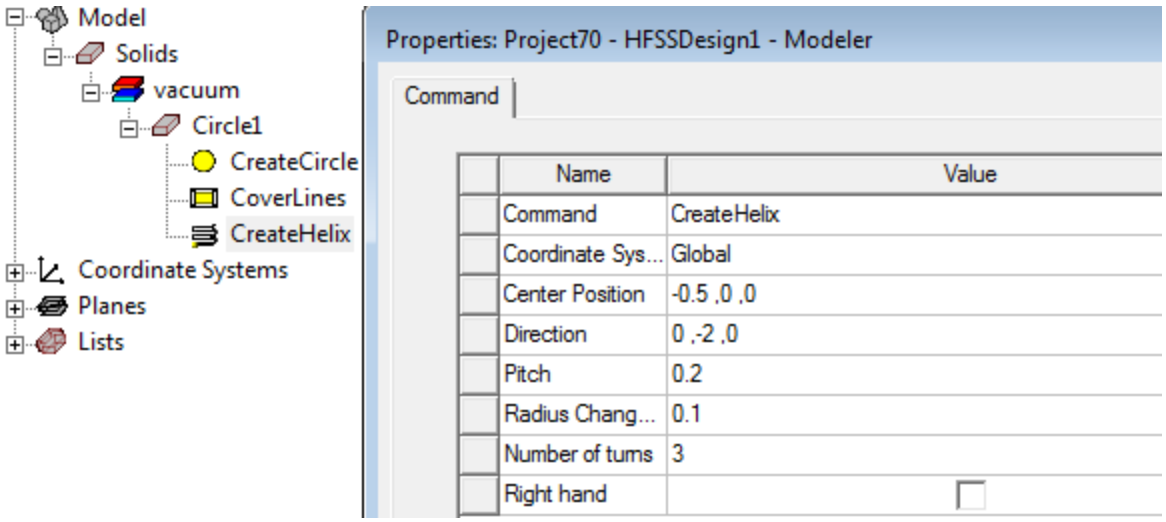
A helix is a 3D spiral object created by sweeping a line or 2D sheet object that you create along a vector that you define. The center of the helix is the defined by the placement of the vector relative to the swept object. You must define the vector so that the swept object will not self-intersect, the rule being, do not draw the vector so that it centers on or overlaps a selected 2D object. After you create the vector, the **Helix** dialog box opens, where you then specify the turn direction, pitch, number of turns, and radius of the turn to define the helix.



Sweeping a 2D object results in a hollow 3D object. Sweeping a 2D sheet object results in a 3D solid object.

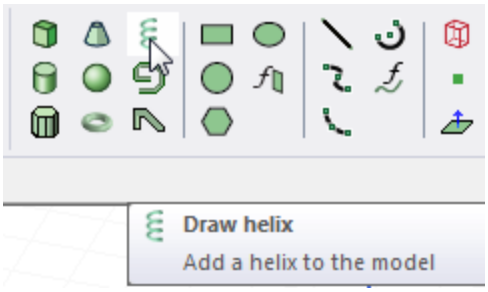


Once you have created a helix, you can changing it by edit the properties of the original object, and by editing the helix command properties for coordinate system, center position (which corresponds to the vector placement), direction, pitch, turns, radius change, and direction.



To create a helix:

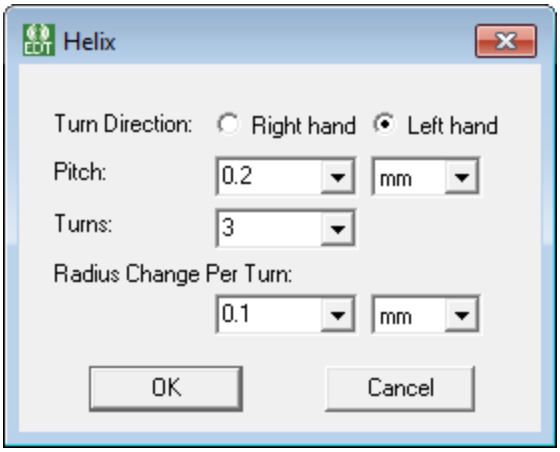
1. Create and select the line or 2D object you want to sweep to form a helix. Selecting a valid object enables the **Helix** icon on the **Draw** tab of the ribbon.
2. Click **Draw**>**Helix** or in the **Draw** tab of the ribbon, click the helix icon:



3. Draw the vector you want to sweep the object around. The two points that describe the vector affect axis location and direction only and not the helix length. (The vector definition corresponds to the **Center Position** and **Direction** properties in the **CreateHelix** command in the **History** tree.) The helix length is determined when you enter the pitch and number of turns in the **Pitch** and **Turns** text boxes. The initial radius of the helix is determined by the axis position relative to the object being swept. It is important that the swept object cannot intersect itself. For a 2D object, you should ensure that the vector you draw does not intersect the interior. If it does, the object cannot be drawn due to self-intersection and you receive a message that "Body could not be created because of invalid parameters."
   a. Select the start point by clicking the point or typing its coordinates in the **X**, **Y**, and **Z** text boxes. (Remember that you can also edit the parameters of a completed helix).

b. Select the endpoint by clicking the point or typing its coordinates relative to the start point in the **dX**, **dY**, and **dZ** boxes.

The **Helix** dialog box appears.



4. For **Turn Direction**, select **Right hand** if the turn direction is clockwise and **Left hand** if the turn direction is counter-clockwise.
5. In the **Pitch** text box, type the distance between each turn in the helix, and click a unit in the pull-down list.
6. In the **Turns** text box, type the number of complete revolutions the object will make along the vector.
7. In the **Radius Change per Turn** text box, type a number for the increase in the radius and select the units from the pull-down list.
8. After you set these values, the selected object is swept along the vector to form a helix. The original object you swept is deleted.
9. Click **OK** to create the Helix. If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, enabling you to modify the object's properties. You can also select the commands for the object and the helix command in the History tree to access and edit their properties.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. For details about these commands see: Technical Notes, "Surface Approximations" and related sections, "Modifying Surface Approximations," and "Guidelines for Modifying Surface Approximations"

Drawing a Spiral

A spiral is a 2D or 3D spiral object created by sweeping an object around a vector. Sweeping a 1D object results in a 2D sheet object. Sweeping a 2D sheet object results in a 3D solid object.

1. Select the 1D or 2D object you want to sweep to form a spiral.

1. Click **Draw**>**Spiral**  .
2. Draw the vector you want to sweep the object around:
   a. Select the start point by clicking the point or typing its coordinates in the **X**, **Y**, and **Z** text boxes.
   b. Select the endpoint by clicking the point or typing its coordinates relative to the start point in the **dX**, **dY**, and **dZ** boxes.
   The **Spiral** dialog box appears.
3. Select **Right hand** if the turn direction is clockwise and **Left hand** if the turn direction is counter-clockwise.

4. In the **Radius Change** text box, type the difference in radius between each turn of the spiral.

   The radius of the first turn is measured from the center point of the 1D or 2D object you are sweeping to the vector you drew.
5. Click a unit for the radius in the pull-down list.
6. In the **Turns** text box, type the number of complete revolutions the object will make around the vector.

   The selected object is swept around the vector to form a spiral. The original object you swept is deleted.If the Modeler option for editing properties of new primitives is checked, the **Properties** dialog box appears, in which you can modify the object's properties.
7. Click **OK**.

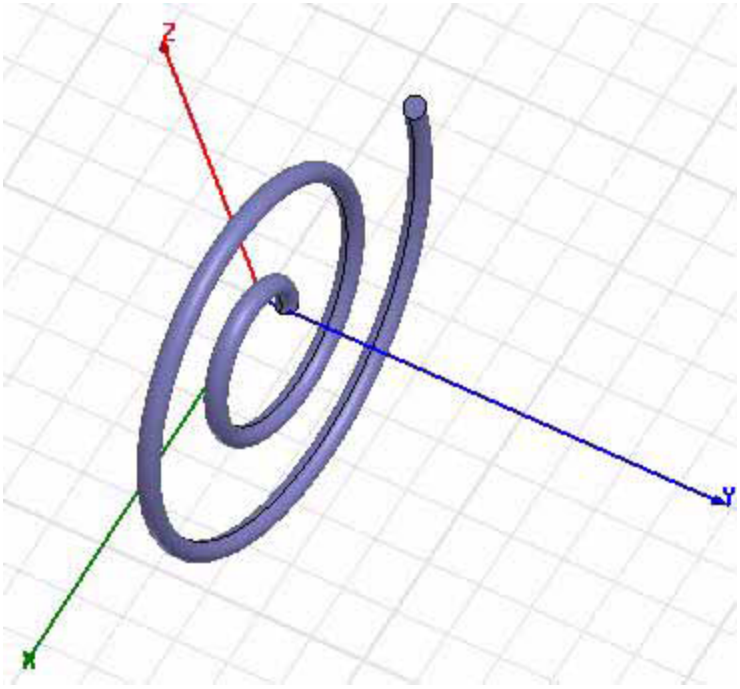

Figure 8-1 This 3D spiral was created from a 2D circle drawn at z = 0. The turn direction was right hand, the radius change was set at 2, and the number of turns was set at 2.

Note	The 3D Geometry Modeler permits drawing of true-curved objects. However, the solution will be obtained with a tetrahedral mesh which conforms to the true surface only within the limits identified by certain mesh settings. The modeler has default settings for this conformance which is a reasonable trade-off between solution speed and solution quality for most objects, but may not be ideal for all such objects. High-aspect ratio curves structures, such as helices with narrow and curved cross-sections, may benefit from user control of the faceting values. For details about these commands see:

Drawing a Spiral

Drawing a Geodesic Sphere Using a User Defined Primitive

Ansys provides you with a .py script to define the parameters of a geodesic polyhedron and draw a geodesic sphere. A geodesic polyhedron has straight edges and flat faces that approximate a sphere.

1. Click **Draw>User Defined Primitive>Examples>geodesic_sphere**.

   The **User Defined Primitive Operation** dialog box appears. The **Parameters** tab permits you to edit the parameters. An **Info** tab contains information about the user defined primitive, its purpose, the company/author who created it, the date created and the version number.
2. Specify the values for the following parameters:

radius	The radius of the sphere. Enter a positive number and desired unit of measure.
frequency	Indicates how many times each side of the base triangle is subdivided"

3. Click **OK**.

   This creates the primitive and displays the **Properties** dialog for the new object.

Sweeping Objects Around an Axis, Along a Vector, or Along a Path

Use the following three commands (found on the **Draw** menu in the desktop) to sweep a spiral or other object:

- **Draw>Sweep>Around Axis**
- **Draw>Sweep>Along Vector**
- **Draw>Sweep>Along Path**

Drawing a Bondwire

A bondwire is a thin metal wire that connects a metal signal trace with a chip. Please see the topic *Bondwires* in the *Technical Notes* before drawing a bondwire.

1. Click **Draw**>**Bondwire**  .
2. Select the bond pad point in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.
3. Select the lead point by clicking the point or typing the coordinates in the text boxes in the status bar.

   The **Bondwires** dialog box appears.
4. In the **Type** list, click the JEDEC modeling standard shape you want the bondwire to have: **JEDEC 4-point**, **JEDEC 5-point, or Low**.

The **Type** selection changes the dialog bondwire graphic, and shows options for that type.

5. Enter the number of facets in the bondwire in the **No. of Facets** text box.

   The minimum value is 3. The value describes the number of faces that make up the circumference of the bondwire.

6. In the diameter field, specify a diameter value and select the units from the pull-down menu.

7. Enter the height between the bond pad and the top of the loop in the **h1** text box. Include the height's unit of length.
8. The value in the **h2** text box is the height between the bond pad and the lead point. It was calculated by Maxwell based on the lead point you selected. If you modify the value of *h2*, the lead point will be modified.

   Optionally, type a new value in the **h2** text box. Include the height's unit of length.

9. If you selected **JEDEC 5-point or Low** do the following:
   a. Type the angle between the horizontal plane and the wire at the bond pad point in the **alpha** text box.
   b. Type the angle between the horizontal plane and the wire at the lead point in the **beta** text box.
10. Click **OK**.

Technical Notes:Bondwires

Drawing a Point

Drawing a point object within the problem region enables you to plot fields or perform field computations at that point. Points are always considered non-model objects by the modeler.

1. Click **Draw>Point**  .
2. Select the point in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.

   The point is listed under **Points** in the history tree.

Related Topics

Setting the Reference Point

Modifying Markers on Point Plots

Drawing Non-Model Objects

Drawing a Plane

A plane object is a cutplane through the problem region. You can plot fields or perform field computations on its surface. Planes are always considered non-model objects by the modeler.

1. Click **Draw>Plane**  .
2. Select the origin in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.

   To delete the selected point and start over, press **ESC**.
3. Select a normal point in one of the following ways:
   - Click the point.
   - Type the coordinates of the point relative to the origin in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   The plane is created. Its center point is located at the origin you specified and oriented perpendicular to the normal point you specified. The plane is listed under **Planes** in the history tree.

Note	You only need to draw a plane that does not lie on a predefined xy, yz, and xz plane. Default planes are created on the xy, yz, and xz planes of the global coordinate system as well as any new coordinate system you create.

Drawing Non-Model Objects

Inserting a Line Segment

To create an object with one or more straight line segments after another object, use the **Draw>Line Segment** command.

1. Click **Draw**>**Line Segment>Insert Segment Before** or **Draw**>**Line Segment>Insert Segment After**.
   A submenu appears.
2. Select one of the following:
   - **Straight**
   - **Spline**
   - **3 Point Arc**
   - **Center Point Arc**
3. Select the first point of the line in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the text boxes in the status bar.

4. Select the endpoint of the line by clicking the point or typing the coordinates in the text boxes in the status bar.

   The endpoint serves as the start point for a subsequent line segment.

   To delete all points and start over, press **Esc** or click **Escape Draw Mode** on the shortcut menu.
5. Complete the line in one of the following ways:
   - Double-click the endpoint.
   - Click **Done** on the shortcut menu.
   - Press **Enter**.

   The **Properties** dialog box appears, enabling you to modify the object's attributes.
6. Click **OK**.

Note	While drawing a polyline, you can switch between straight line, arc line, or spline segments using the **Set Edge Type** commands on the shortcut menu.

After drawing a polyline, you can select any segment in the history tree and edit it by changing coordinates, inserting a segment before or after, deleting the start or end point, and making other modifications.

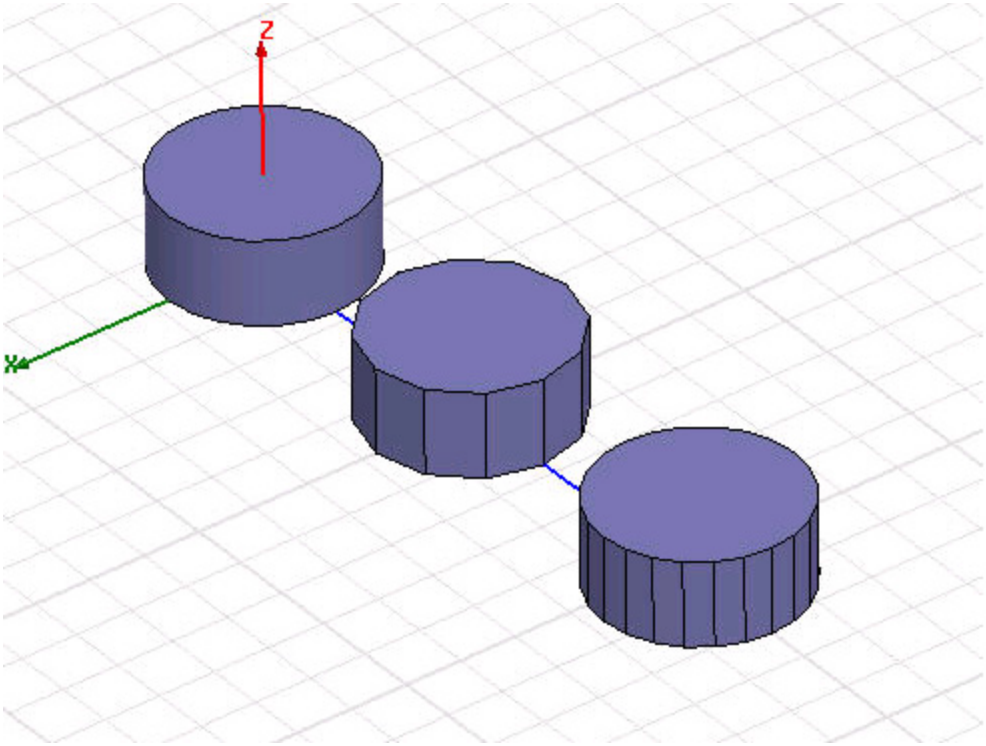
Related Topics

Deleting Polyline Segments

Converting Polyline Segments

Creating Segmented Geometry

For some structures, you may want to create segmented as opposed to smooth (or True) surfaces. The following figure shows a comparison of a cylinder created with true surfaces and with segmented surfaces.



The following model objects can be created as segmented structures:

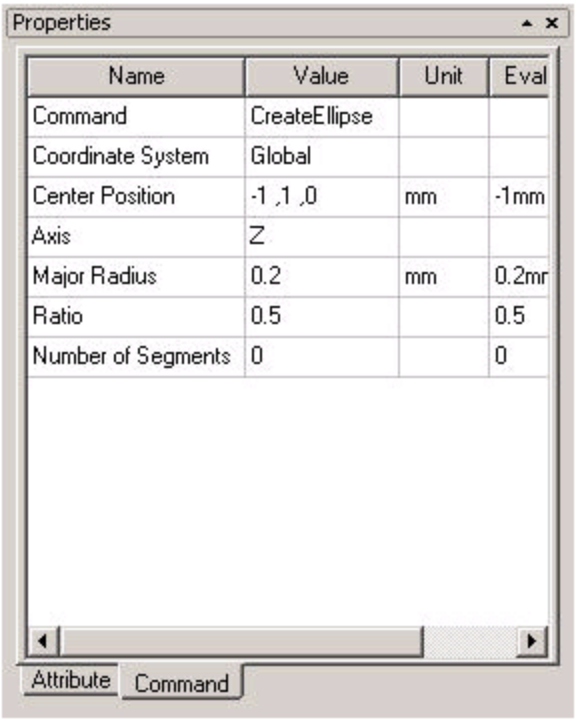
Circle, Ellipse, Cylinder	See Segmented Objects
Polyline, Arc, Line Segment	See Converting Polyline Segments

Segmented Objects

To create segmented circles, ellipses, and cylinders use the **Number of Segments** parameter on the Command Tab of the **Properties** dialog as shown below. To convert an object from true surface to segmented, do the following:

1. Select the **circle**, **ellipse**, or **cylinder** in the modeler window or in the history tree.
2. In the command tab of the properties window (shown docked below), change the **Number**

of Segments to an integer value of three or greater and press **Enter**.



Values of 1 and 2 are not valid values for the circle, ellipse, or cylinder command and will cause an error.

Creating Segmented Geometry

Drawing Non-Model Objects

If you want to create an object that does not affect the geometric model, define the object as *non model*. This ensures that the object is used for analysis only; it will not affect the solution process. After drawing the non-model object, assuming it lies in the problem region, you can use it in the reporter as a place on which to plot field quantities. For example, draw a non-model line across the design, then (in the reporter) plot Mag_E on every point along that line.

Following are examples of using non-model objects to analyze a solution:

- Draw a polyline along which to plot fields or perform field computations. Note that when you create a value versus distance plot, by default, the line will be divided into 100 equally spaced points. You can modify the number of points into which the line is divided in the **Edit Sweeps** dialog box.For more information, see *Specifying Variable Values for a Sweep Definition*.
- Draw a rectangle upon which to plot fields or perform field computations.

- Draw a volume box to analyze fields in areas of the problem region that are not occupied by an object or that consist of parts of several objects.
- Draw a plane, which is always a non-model object.
- Draw a point object, which is always a non-model object, in order to plot fields or perform field computations at that point.

What do you want to do?

Switch to non-model drawing mode. Objects you draw in non-model mode will not be included in the solution process.

Modify an existing model object to be a non-model object.

Selecting Non-Model Drawing Mode

To switch to non-model drawing mode:

1. Click **Modeler**>**New Object Type**>**Non Model**.
2. Draw the object.

Related Topics

Changing an Object to Non Model

Drawing Non-Model Objects

Changing an Object to Non-Model

To modify an existing object to be a non-model object:

1. Select the object you want to modify.
2. In the **Properties** dialog box, clear the **Model** option.

   The object will not be included in the solution process. If the object lies in the problem region, you can plot solution quantities on it.

Related Topics

Selecting Non-Model Drawing Mode

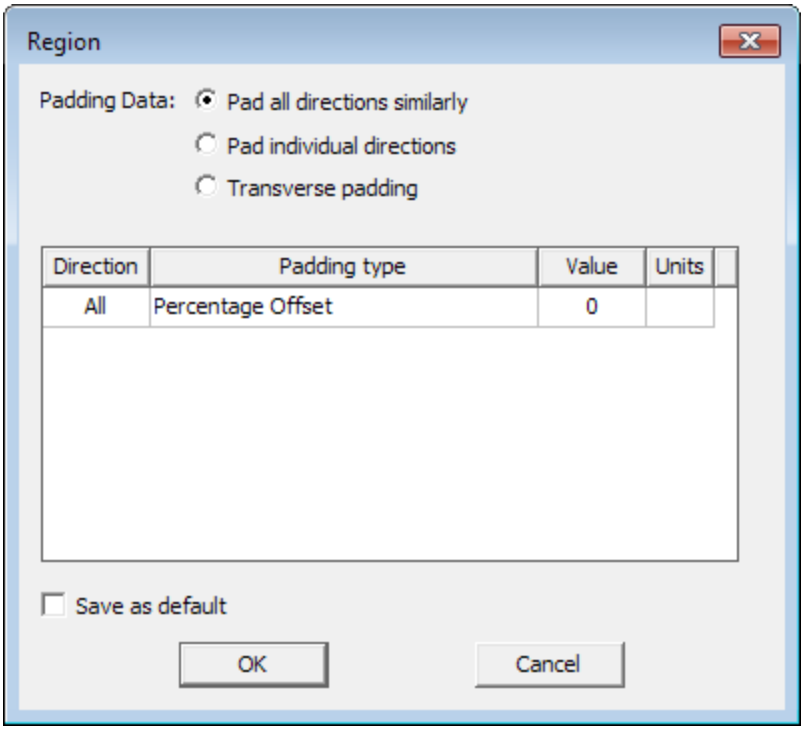
Drawing Non-Model Objects

Drawing a Region

To draw a region encompassing the objects in the current project:

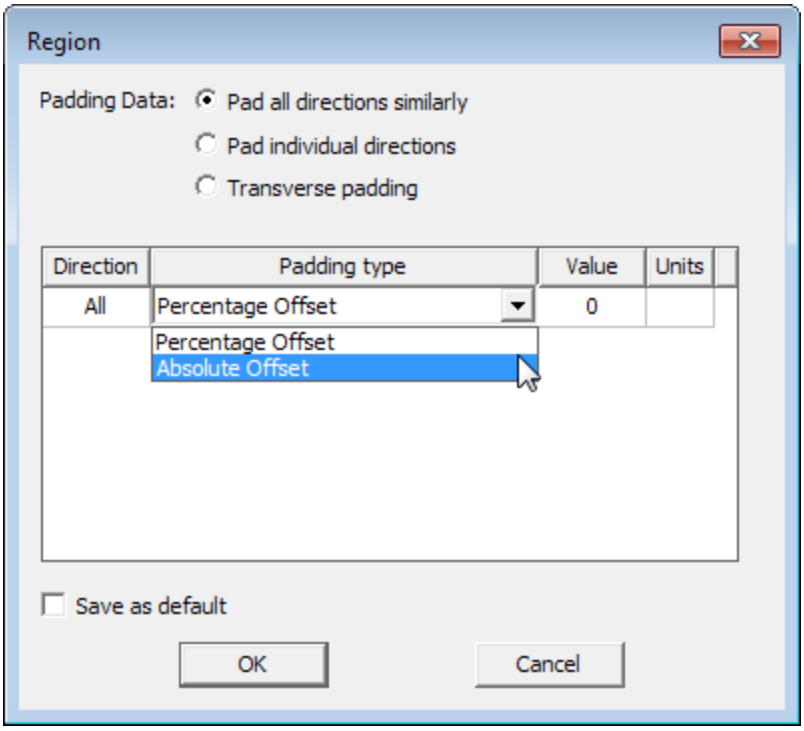
1. Click **Maxwell>Draw>Region** or click the  icon on the tool bar.

   This displays the **Region** dialog box. You can define the region padding as a percentage, relative position, or absolute position.

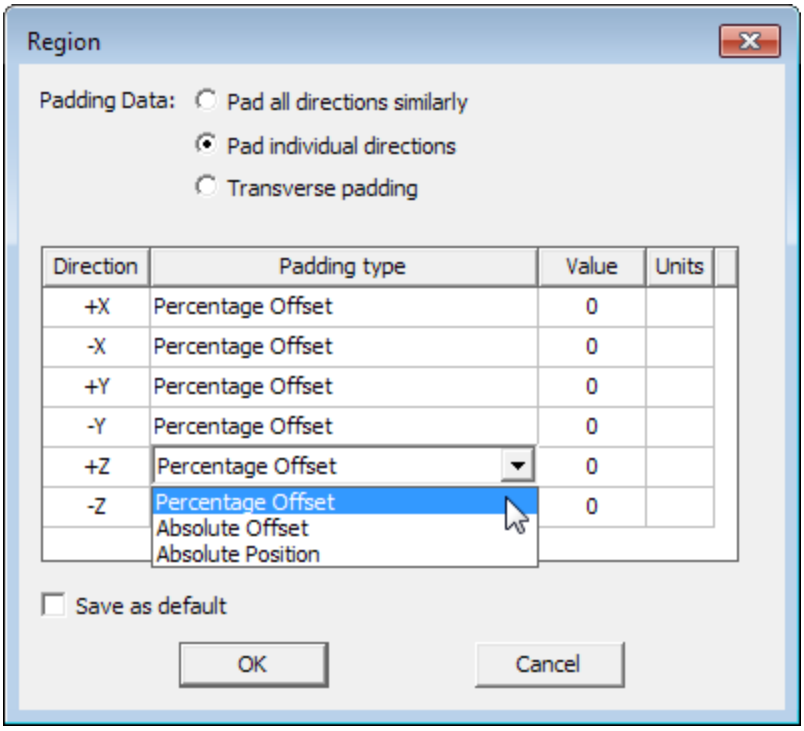


2. For the Padding data, you can select either **Pad all directions similarly**, **Pad individual directions**, or **Transverse padding**.

   If you select **Pad all directions similarly** you can specify the Padding type by selecting either **Percentage Offset** or **Absolute Offset** from the drop down menu, requiring a single Value that affects all directions. If you select **Absolute Offset**, you also specify the units by selecting from a drop down menu.



Selecting **Pad individual directions** displays the Padding Percentage as a table of Positive and Negative X, Y, and Z coordinates, permitting you to specify padding for each direction. In this case, you can specify the Padding type by selecting **Percentage Offset**, **Absolute Offset**, or **Absolute Position** from the drop down menu.



Selecting **Transverse padding** means that padding in one direction is controlled by dimensions in the other two directions. One direction (for example, X) is padded with a user-specified percentage of diagonal length of the other two directions (Y and Z).

3. Specify the Padding values in the fields and select the units from the drop-down list.
4. If desired, click the check box to save the values as Default.
5. Click **OK** to close the dialog and create the region.

   The region is drawn, selected, and displayed in the History tree. It is created using the current coordinate system. The Properties dialog for the region has a Commands tab that shows the coordinate system and Padding values, and the Attributes tab includes properties for Name, Material (Default, vacuum), Solve inside, Orientation, Model, Color, Display Wireframe, and Transparency. You can edit all of these values.

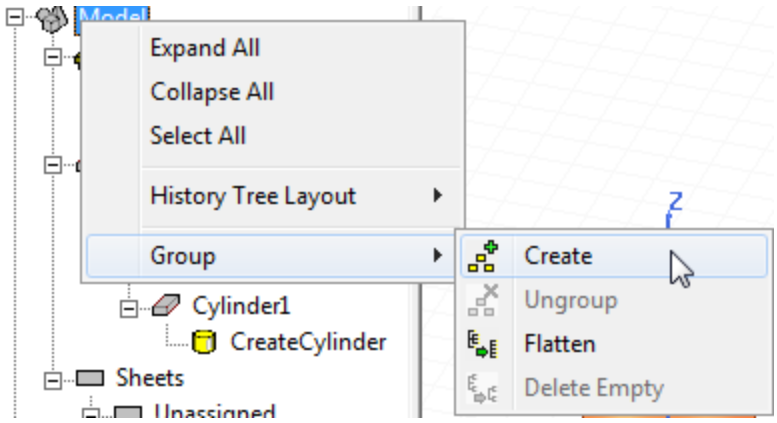
If you try to create a region that does not contain all of the objects in your model, the region is automatically expanded to cover all objects. The region also updates automatically as your geometry changes.

Only one region can be created for a single project using the **Draw>Region** command. If you try to create a second region, the **Properties** window appears for the existing region, allowing you to change operation parameters and attributes.

Group Commands for Modeler Objects

The 3D Modeler allows you to group objects in the History tree. Besides pre-defined folders under **History Tree Layout** for solids, sheets, and material assignments, a set of **Group** commands let

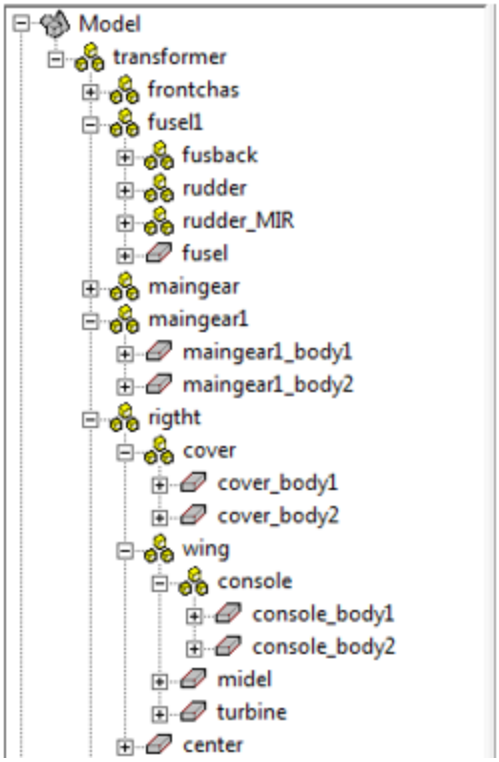
you create groups, un-group objects, flatten a selected group's hierarchy, and delete empty groups.



The **Group** commands support the following features:

- Group objects in the history tree. When objects are grouped, they show up under a sub-item in the history tree.
- Groups can contain sub-groups and sub-group containing further sub-groups.
- Groups permit moving objects from one group to any other group at any time.
- Groups are purely for organization of the history tree. They do not affect the solution in any way.

- Groups permit you to bring in MCAD assemblies and sub-assemblies as groups. See Importing 3D Model Files.



- Groups can contain objects, submodels (for example, UDM, 3D Component, CAD links) and groups. Coordinate systems, planes etc will not have any parent group.

Object groups have the following important differences from 3D components.

- Groups do not encapsulate history of objects. They do not encapsulate parameters used by those objects.
- Groups do not have history tree operations. For example, Arrange operations apply to all objects of the group rather than the group.
- Groups are not independent. Deletion of an object in one group could cause the object in another group to be deleted also.

Accessing the Group Commands

You can access the Group commands in several ways: via the **Modeler>Group** menu, by right-clicking on **Model** in the History tree to see the short-cut menu, the right-click context menu in the Modeler window, and using the Group icons on the Model ribbon.

Group Command Descriptions

Group>Create works with selection or no selections. If there are no selections, an empty group is created under model. If there are selections, then a new group is created under same group as all the selections, provided all selections are under one group. Once a group is created, all selections move under new group. If selections are under different groups, then a new group is created

under model. Selections could be objects, groups, 3D Components, or User Defined Model. The **Group> Create** command tries to find a more suitable group name where possible based on names of all selections. If not, default group names are Group1, Group2 and so on. You can edit group names later.

Group>Ungroup is enabled only when you select one or more groups. Upon ungroup, all the contents of the selected group move under group's parent and the selected group is deleted. Note that **Group>Ungroup** is not recursive; it only affects the selected group is and all its children groups remain intact. Ungroup is also different from **Delete** (under **Edit>Delete**) which deletes a selected group and everything under it.

Group>Flatten Flatten Group is enabled when you select a group selection. You can select multiple groups at different levels. All of the selected group's contents (that is, objects, sub-groups, and so forth) come directly under selected group. In a sense this is a recursive ungroup operation as all the children and grandchildren groups of selected group are ungrouped.

Group>Delete Empty deletes all empty groups under the selected group. If a selected group is empty it is deleted. This command is helpful to clean up empty groups after you have moved objects from one group to another.

Operations on Groups

Edit/Delete: Delete operations delete group and all the children, including sub-groups, under the group.

Copy and Paste of Objects in Groups

When you copy and paste objects with groups to another design, group information is carried over, that is, new group in target design is created. If a group with the exact name exists, then the objects are moved under that group and no new group is created. When pasted in the same design, the pasted object moves under same parent group as original object.

Copy and Paste of Groups

When you copy and paste one or more groups in same design or to another design, a new group is created with unique name derived from original group name. Everything under that group, including any sub-groups, is copy/pasted as well.

Copy and Paste of Groups and Objects

If you multi-select a few objects and groups, all of them are pasted correctly. If you select a group and a few objects under that group, copy and paste includes the complete group structure. This means that selection of objects under the selected group is ignored. If you want to only copy and paste few objects from group, you should only select those objects and NOT select the group.

Arrange Operations on Groups

You can select group to enable arrange operations like move, rotate and mirror. Note that arrange operations works directly on objects under selected group. So after arrange operation is done, the History tree shows the arrange operation under every object of that group.

Duplicate Operations on Groups

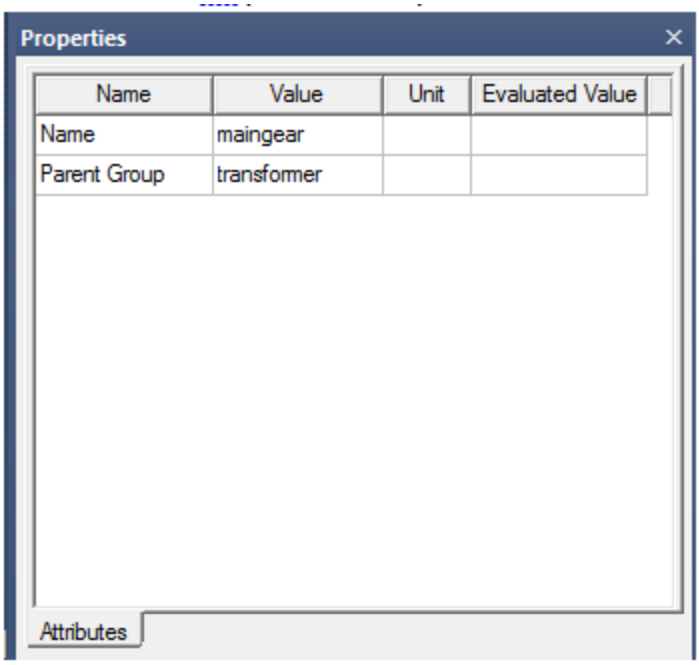
You can select groups to enable duplicate operations. Afterward, the History tree shows a duplicate operation under every object of that group. Newly created objects appear under a new group. There will be new group for every instance of duplicate.

Other Operations on Groups and Objects in Groups

Modeling operations that create new objects, such as Create from Face or Edge, as well as Simplify and Separate. The newly created objects appear under a new group created under the original object's group, based on the tool option settings. See 3D Modeler Options: Group Options.

Group Properties

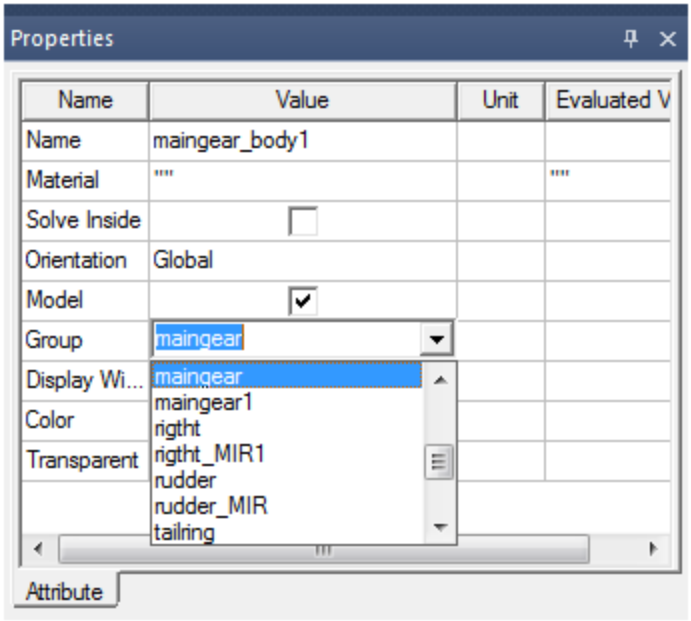
A Group's Property tab is shown when you select a group in the history tree. The Group's properties include Name and parent Group.



Group Property Window

Object, group and submodel properties have a Group property. You can edit the Group Property and this provides another way of setting an object's (or group's) group. You can select any of the

existing groups listed or create a new group.



Group assignment could be changed in Object's property window

User Customization through User Defined Primitives (UDPs)

User Defined Primitives (UDPs) allow users to add customized geometric modeling commands to the Maxwell Desktop. UDPs are C++ compiled or Python libraries that can be added to the desktop interface and shared between users with common modeling needs.

To create a UDP, see Creating a User Defined Primitive for requirements and the procedure for building a proper DLL or Python library.

In order to share UDPs between users, an existing DLL or Python library may be copied into the **userlib>User Defined Primitives** subdirectory which can be found in the Maxwell installation directory. Placing an appropriately constructed DLL or Python library in this subdirectory will automatically add a new menu item in the **Draw>User Defined Primitives** menu to allow access to the UDP.

If desired, users can also create a **User Defined Primitives** subdirectory in their **PersonalLib** directory, and store UDPs there. The **PersonalLib** directory path is specified on the **Directories** panel under **General** in the **Options** dialog.

Refer to *Maxwell User Defined Primitives* for additional information.

Creating a User Defined Primitive

The modeler allows you to generate user-defined primitives, primitives customized to suit any application. User-defined primitives are accessed using DLLs that you build and compile. When user defined primitives exist in your UserLib or Personal directory (given the paths specified in **Tools>General Options**Project Options tab), they appear in the **Draw>User Defined Primitives>** menu. Newly created UDPs will appear after a restart, or **Draw>User Defined Primitive>Update Menu.**

Example C++ source and header files that can be used to generate DLLs are located in the **UserDefinedPrimitives/Examples** subdirectory under the Ansys Electromagnetics Suite installation directory.

As an example, create the primitive **myUDP.dll** using Microsoft Visual C++ Developer Studio:

1. Create a directory to store all of the workspace information, call it `UDPDir`.
2. Use the sample workspace **RectangularSpiral.dsw** as a template:
   a. Copy **RectangularSpiral.dsw** and **RectangularSpiral.dsp** from the **`UserDefinedPrimitives/Examples`** directory to this new directory.
   b. Make sure the new files have write permissions.
   c. Rename the files to **myUDP.dsw** and **myUDP.dsp** respectively.
   d. Open the **.dsw** and **.dsp** files in a text editor, and replace every occurrence of **RectangularSpiral** with **myUDP**.
   e. Save **myUDP.dsp** and **myUDP.dsw**.
3. In the **`UDPDir`** directory, create a **`Headers`** subdirectory.
4. Copy the **UserDefinedPrimitiveStructures.h** and **UserDefinedPrimitiveDLLInclude.h** files from the **`UserDefinedPrimitives/Headers`** directory.

Note	The header files include information on the methods that are available for use in your source code. They must be included when you compile the DLL.

5. In the **`UDPDir`** directory, create a **`Sources`** subdirectory.
6. Use the sample source file **RectangularSpiral.cpp** as a template:
   a. Copy **RectangularSpiral.cpp** from the **`UserDefinedPrimitives/Examples`** directory to this new directory.

b. Make sure the new file has write permission.
c. Rename the file to **myUDP.cpp**.

The resulting directory structure will appear similar to the following:

```
UDPDir/
        myUDP.dsw
        myUDP.dsp
        Headers/
          UserDefinedPrimitiveDLLInclude.h
          UserDefinedPrimitiveStructures.h
        Sources/
          myUDP.cpp
```

7. Open **myUDP.dsw** using Microsoft Visual C++ Developer Studio, and edit the source code to create your desired primitive. You may also add additional headers and source files as appropriate.

   The UDP dll contains a data structure called UDPPrimitiveTypeInfo. This contains information about the udp, its purpose, company/author who created it, date created and the version number. When you select a primitive from your library, you see the **Create Primitive** dialog with a **Parameters** tab for setting the parameters, and an **Info** tab with the information from this data structure.
8. Build **myUDP.dll** using the **Win32 Release** configuration.
9. Copy the resulting file **myUDP.dll** to the **`[ProductInstallationPath]/userlib/UserDefinedPrimitives`** directory.

   Optionally, copy the resulting file to the `UserDefinedPrimitives` directory in your PersonalLib. The **PersonalLib** directory path is specified on the **Directories** panel under **General** in the **Options** dialog.
10. To view your primitives, click **Draw>User Defined Primitive>Update Menu** and then click **Draw>User Defined Primitive>UserLib**or **Draw>User Defined Primitive>PersonalLib**.

Note	On Linux, you may use the same example directory structure, source, and header files to build and compile a shared library using C++. The resulting shared library needs to be placed in the same **`/userlib/UserDefinedPrimitives`** directory. As with the Windows DLL, the compiled library will work only on the operating system on which it was built.

Specifying UDP Parameters

The **User Defined Primitive Operation** dialog box allows you to set the specific parameters required for a UDP.

In the **Parameters** tab, a list of the parameters associated with the UDP is displayed along with the value, unit, evaluated value, and description for each parameter. To change a parameter:

1. Select the **Value** cell in the row corresponding to the parameter to be changed. The cell becomes editable. Enter the desired **Value** for the parameter.
2. Click on the cell under **Unit** to obtain a list of the available units for the parameter. Select the desired **Unit**.
3. When the desired changes have been made, click **OK** to create the geometry defined by the UDP and the parameters you have entered.

The **Info** tab provides information about the UDP.

Updating the User Defined Primitives Menu

When new User Defined Primitives have been created or provided for your use, they should be placed in the **Maxwell/userlib/UserDefinedPrimitives** directory. Optionally, user defined primitives can be placed in your **PersonalLib**. The **PersonalLib** directory path is specified on the **Directories** panel under **General** in the **Options** dialog.The **Update Menu** command scans the disk and creates menu items for new UDPs. To create menu items for new UDPs:

1. Place new UDPs in either of the directories listed above. Organizing UDPs using subdirectories is permitted.
2. Select **Draw>User Defined Primitive>Update Menu**.

   The new UDPs may now be run directly from the **Maxwell** menu.

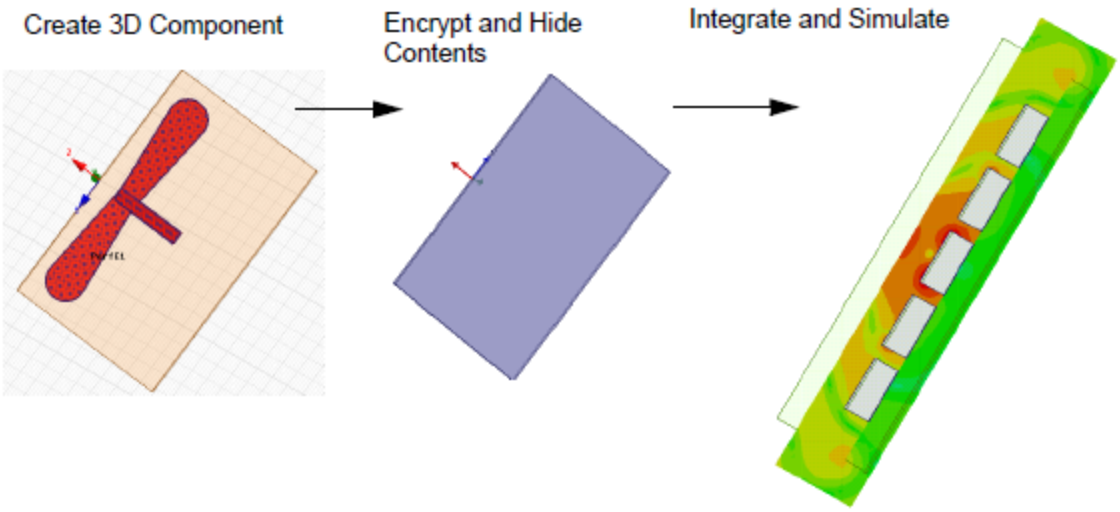
3D Component Library

The 3D Modeler lets you access predefined 3D component libraries and create 3D components with:

- Geometry – objects, parameters, and coordinate systems.
- Design data, boundaries, excitations and mesh operations.
- Material assignment and definition for components are separate from project material and other component materials. They do not appear in the Project Tree materials list under Definitions. Component materials cannot be edited in the project in which they are inserted.
- Component parameters, including variables used by geometries, design data, and material properties. These are displayed separately on the Parameters tab.
- Optional logo or icon image to display with components in the modeler window.

- Optional encryption with password definition, or internal key as a password.



The ability to create components from models lets you easily share and reuse components. You can add components to a library and share components with other users. Once you insert a component into the target design, you can directly manipulate whole components using Arrange operations such as **Move**, **Rotate** and **Mirror or** Duplicate operations like **Duplicate Along Line**, **Duplicate Around Axis** and **Duplicate Mirror**.

Note	3D Component Libraries can contain components created using the **Create 3D Component** menu command in both Maxwell 2D and Maxwell 3D projects. 3D Components created in Maxwell 2D projects cannot be used in Maxwell 3D projects, and vice-versa.

Instances of an inserted component are grouped by definition in the model history. Multiple instances of identical components permit mesh reuse.

Note	Except where noted, the following sections apply to component libraries and components created in both Maxwell 2D and Maxwell 3D projects.

The documentation includes the following sections:

Creating a 3D Component from an Existing Model

Replace Selection with 3D Component

Inserting a 3D Component into a Design

Using the Component Libraries Window

Viewing Properties of 3D Components

3D Components in the Project Manager Window

3D Components in the History Tree

Editing 3D Component Properties

Editing 3D Component Definitions

Updating 3D Component Definitions

Human Body Exteriors

Qi Wireless Power Transfer System

3D Component Agents

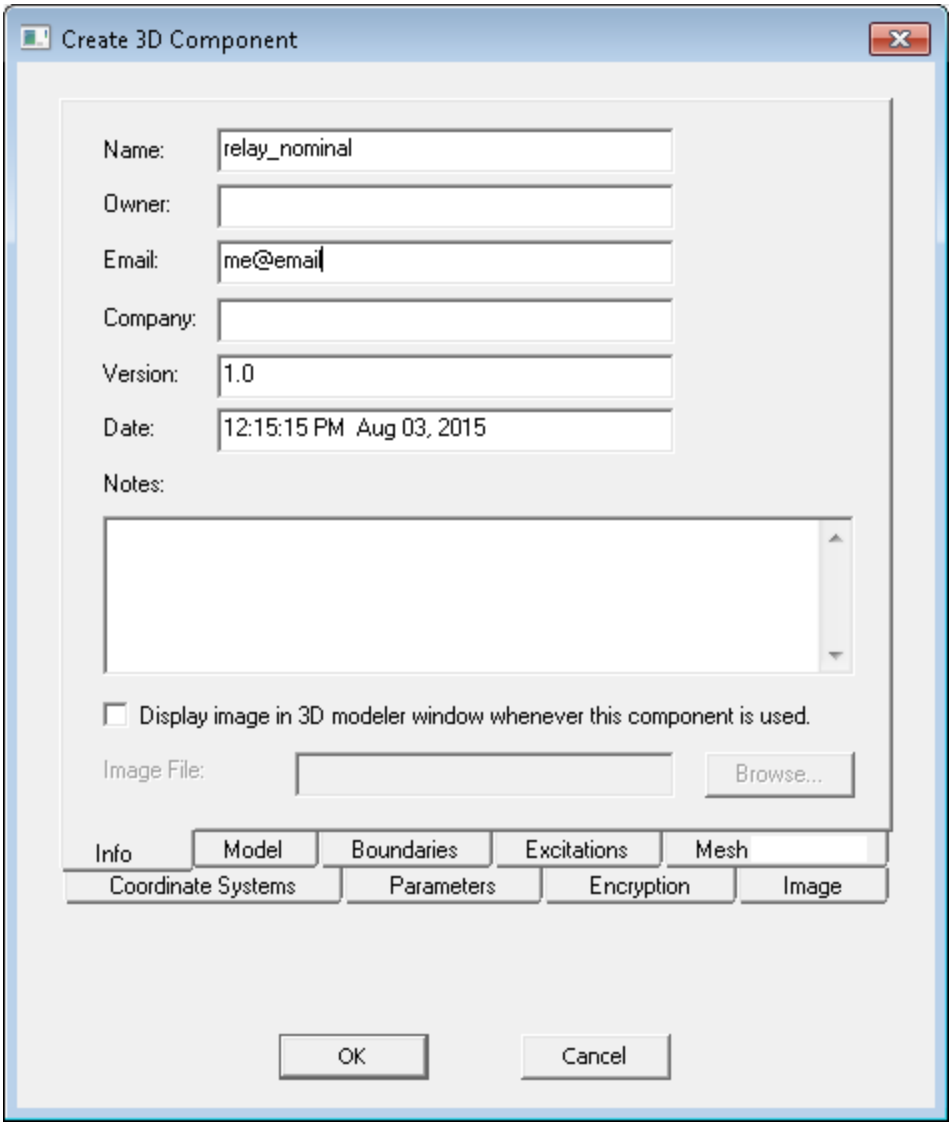
Creating a 3D Component from an Existing Model

To create a 3D component, select an existing object or model, right-click, and select **Create 3D Component**. You can also click **Draw>3D Component Library>Create 3D Component.**

This opens the **Create 3D Component** dialog box. The **Model** tab lists all of objects selected before you invoked **Create 3D Component**.

Note	The Create 3D Component menu command can be used to create components in both Maxwell 2D and Maxwell 3D projects. 3D components created in Maxwell 2D cannot be used in Maxwell 3D projects, and vice-versa.



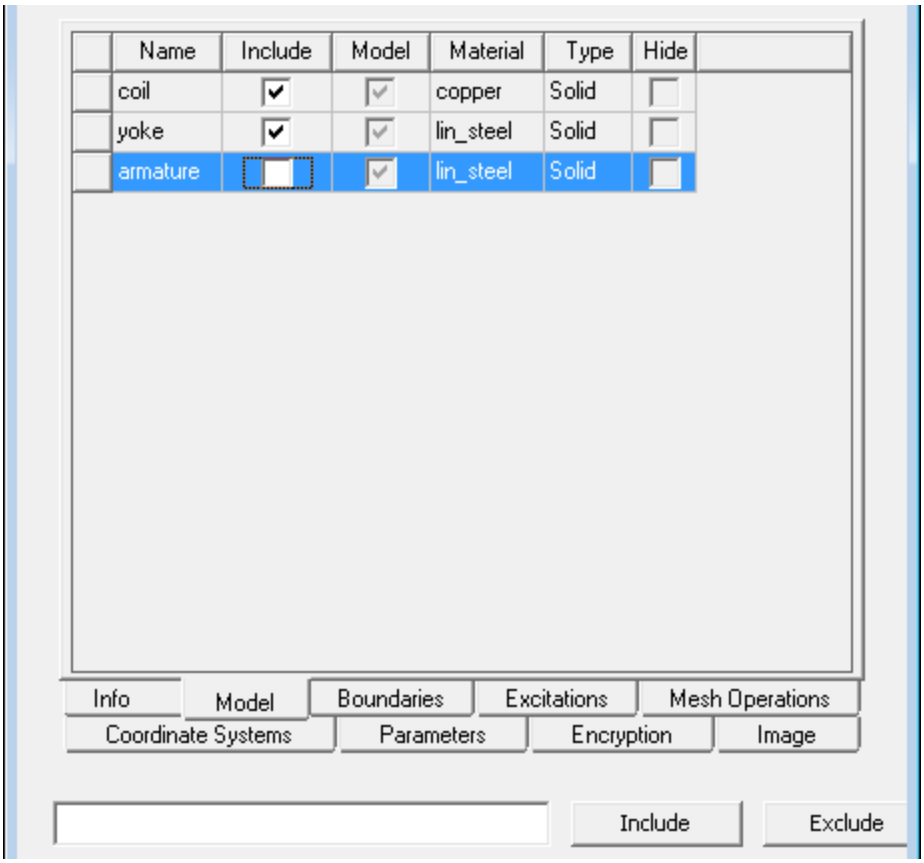
The tabs let you view the component features organized according to geometry, design data, and settings:

- Info tab
- Model tab
- Boundaries tab
- Excitations tab
- Mesh tab
- Coordinate Systems tab
- Parameters tab
- Encryption tab
- Licensing tab
- Image tab

Note	3D components selected from the SysLib libraries include tabs only for Parameters, Image, and Info.

Include or Exclude Feature from Component

You can view the various tabs and select which features to **Include** or **Exclude** in creating the component. You can use the check boxes in the Include column for this purpose. You can also use the text field. Type a feature Name which you can then use the command buttons to Include or Exclude.



Object selection for **Include** or **Exclude** impacts selection in other tabs. For example, if you exclude an object from the component creation, the design data, parameters, and coordinate systems corresponding to that object are also excluded.

Sorting Columns Using the Headers

The features listed for each tab include columns for the Name, check boxes for whether to include, and properties. You can click on the column headers to sort by Name, Model, or other feature listed for each tab. Click the column header to select the column to sort. Click again to invert the column.

You can sort lists by using all columns except Include.

Notes on Design Data

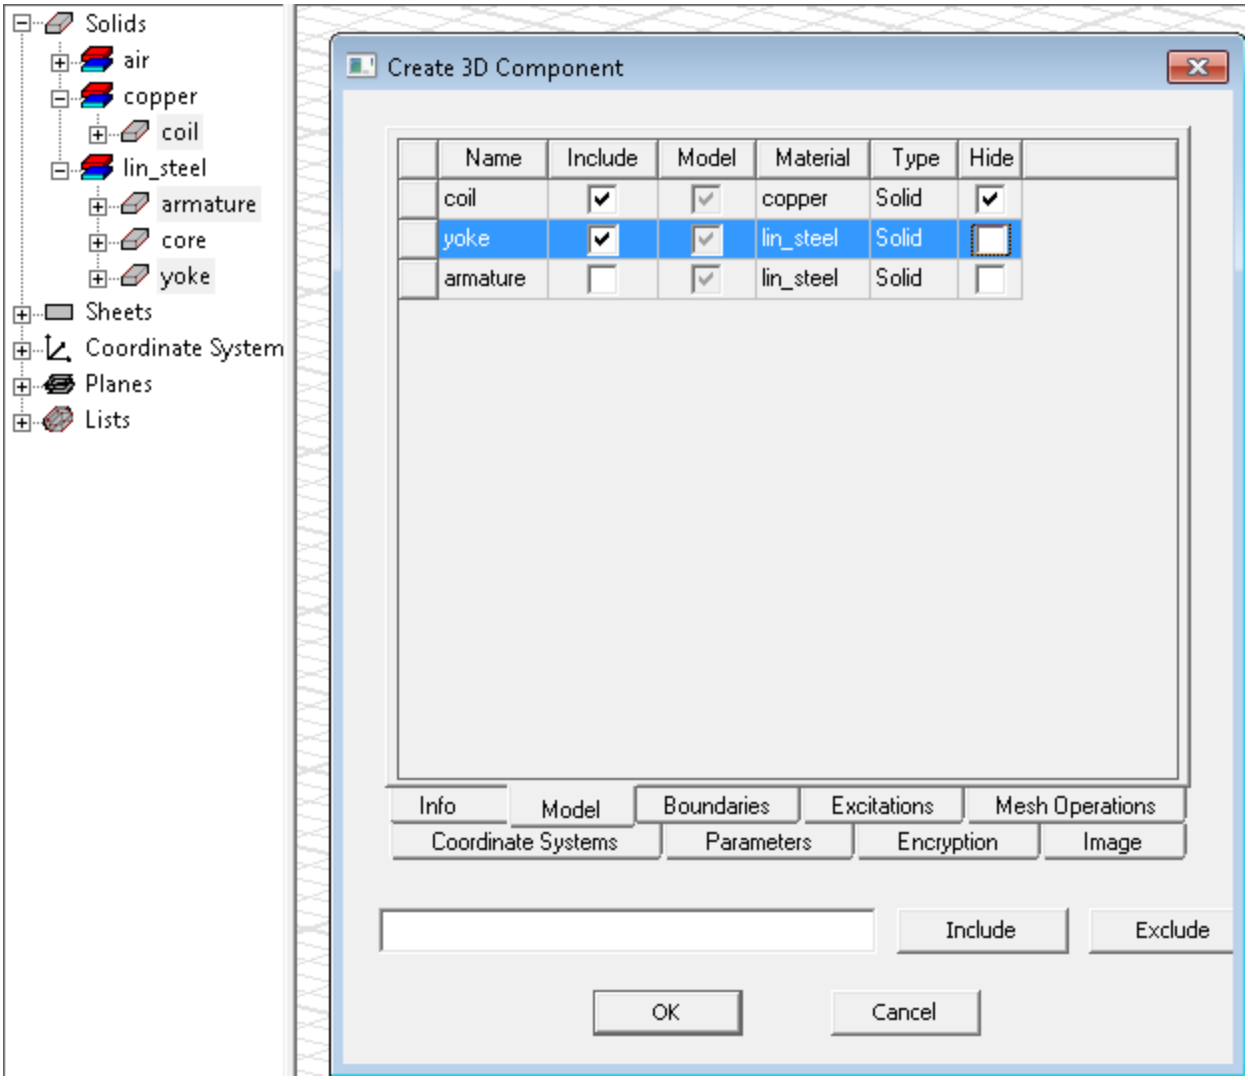
- DC thickness on selected objects is always included in components. It is not listed in **Boundaries** tab.
- The **Create 3D Component** dialog does not list design data without an assignment (for example, a winding in Maxwell).
- The parent of any included boundary/excitation is included, as long as the parent does not require assignment (for example, a winding in Maxwell).
- Design settings like material overrides are not included.

Once you have made the Include and Exclude settings, and have specified the Image and Info you click **OK** to Save 3D Component File. When you click OK, the component is validated for everything that is included in the component. For example, you cannot include boundaries if the object on which the boundaries have been created is not included. After validation, a dialog for saving the component to a location appears.

Create 3D Component: Model Tab

The **Model** tab lists all of objects selected before you invoked **Create 3D Component**. These correspond to the selected objects listed in the history tree.

- Use the check boxes or text field to Include or Exclude objects for the component.
- Material and Type columns are read only.
- For Encrypted components, you can also chose which objects to hide. The hide column is only enabled if you have the Hide Contained option selected on Encryption tab.

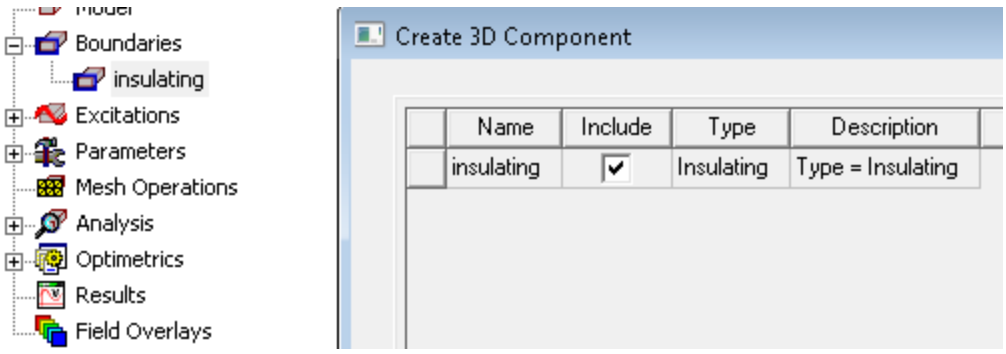


Create 3D Component: Boundaries Tab

The list is populated with all the boundaries for the selected objects.

- Use the **Include** check boxes to include (selected) or exclude (cleared) individual boundaries for the 3D component.

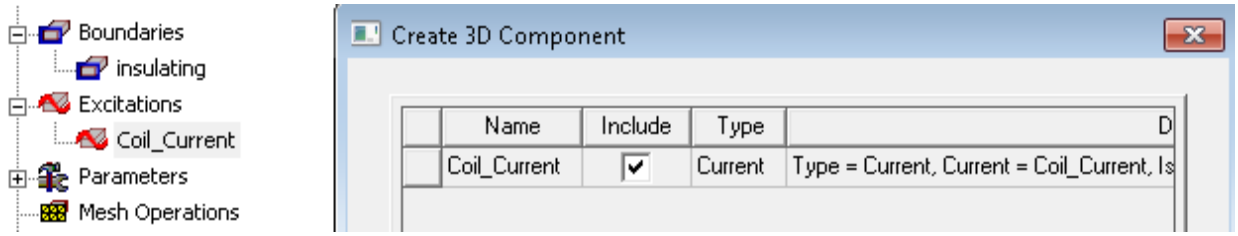
  Alternatively, you can type a boundary Name into the text box and click the **Include** or **Exclude** button. Wildcards (? and *) are supported when you use this method, so you can change the inclusion state of multiple boundaries with similar names in a single operation.
- Type and Description columns are read only.



Create 3D Component: Excitations Tab

The list is populated with all the excitations for the selected objects.

- Use the **Include** check box to include excitations in the 3D component (selected), or to Exclude them from the component (cleared). You can also use the edit box and **Include**/**Exclude** buttons to filter excitations.
- *Type* and *Description* columns are read only.

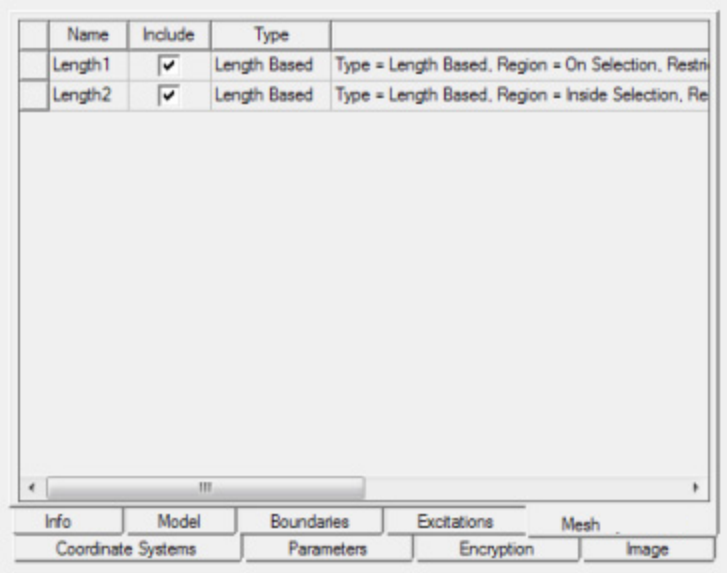


Create 3D Component: Mesh Tab

The list is populated with all the mesh operations for the selected objects.

- Use the Include check boxes to include (selected) or exclude (cleared) individual mesh operations.

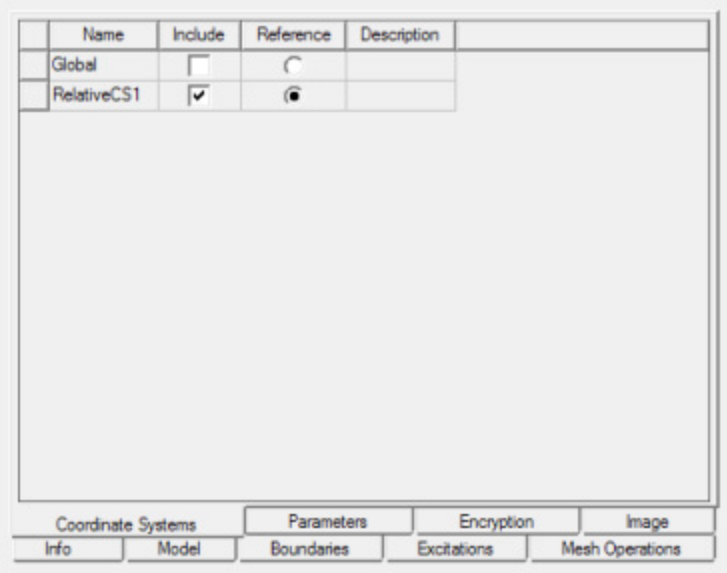
  Alternatively, you can type a mesh operation Name into the text box and click the **Include** or **Exclude** button. Wildcards (? and *) are supported when you use this method, so you can change the inclusion state of multiple mesh operations with similar names in a single operation.
- *Type* and *Description* columns are read only



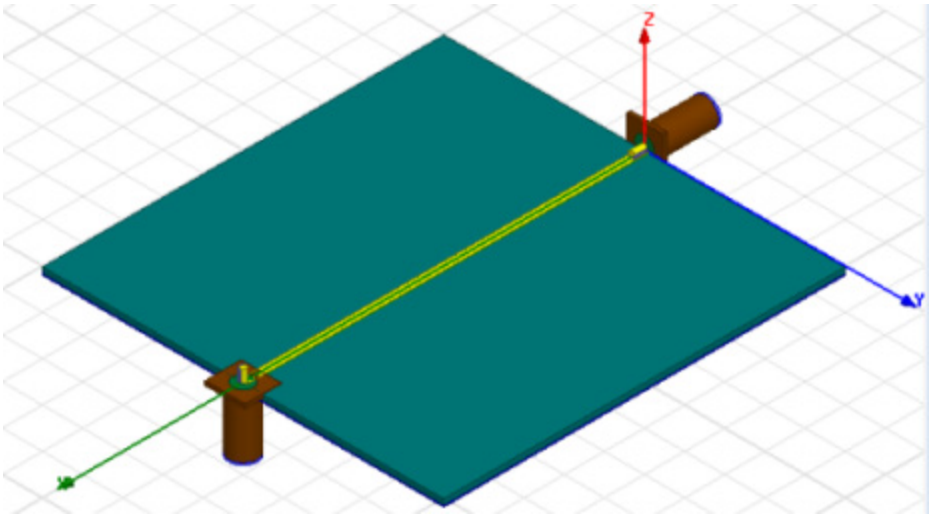
Create 3D Component: Coordinate Systems Tab

The list is populated with all the Coordinate Systems for the selected objects. By default, only the Coordinate Systems used to define the object orientations are included. You can include Coordinate Systems created on specific model parts.

- Use the checkbox to Include or Exclude coordinate systems. You can also use the text field and **Include**/**Exclude** buttons. Global CS cannot be included in the component.
- You can select any of the CS as a component reference.
- By default, the current working CS is the component reference CS.
- Reference CS must be included in the model (except for global).



The coordinate Reference system that you specify affects the orientation of the component upon insertion.

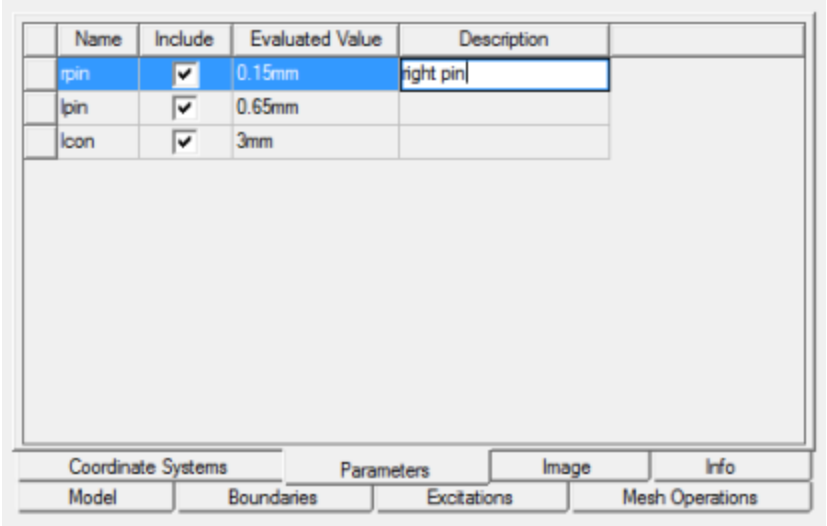


Create 3D Component: Parameters Tab

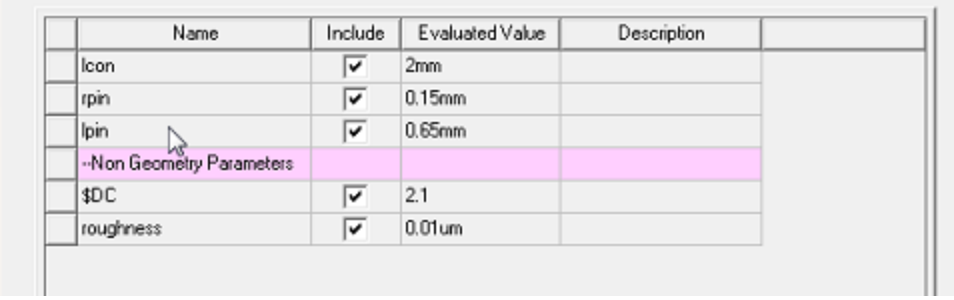
Component properties can be parameterized by assigning variables. The parameters list is populated with all the variables used by objects (and Coordinate Systems, design data, and material properties) included in the component.

- Use the **Include** check box to include parameters in the 3D component (selected), or to Exclude them from the component (cleared).

  Alternatively, you can type a parameter Name into the text box and click the **Include** or **Exclude** button. Wildcards (? and *) are supported when you use this method, so you can change the inclusion state of multiple parameters with similar names in a single operation.
- You can fill in the description field, if desired.



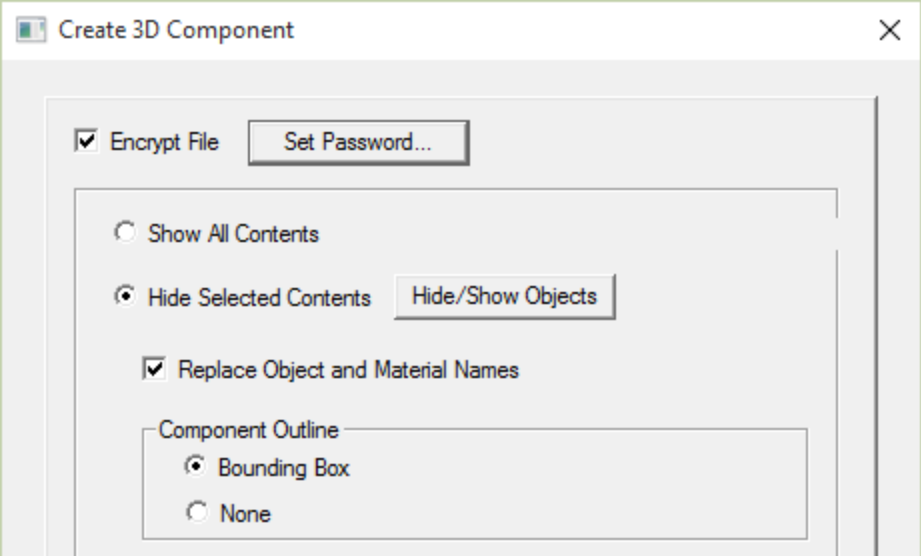
If you create non-geometry variables materials or boundaries, these are listed separately:



If you exclude any geometry, boundary or material associated with a variable, the associated variable is automatically excluded on the **Parameters** tab.

Create 3D Component: Encryption Tab

The **Encryption** tab includes a checkbox for you to define a user access password to use the component.



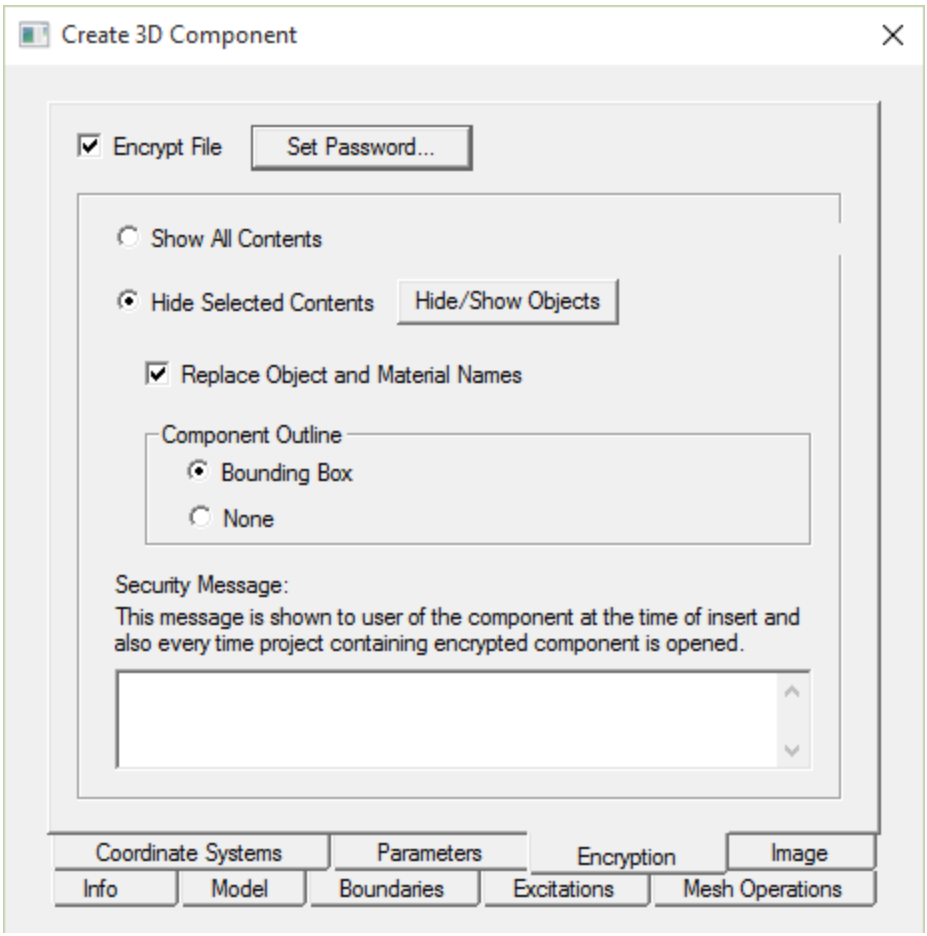
Encryption is a common technique for encoding information in a manner that is very difficult for unauthorized users to decode. When this option is enabled for 3D Components, the contents of the component file are encrypted to protect them from external viewing or editing.

- 3D Components use the Advanced Encryption Standard (AES) with a 256-bit key and password-based key derivation.
- If the encrypted component is created with an **Internal Key**, it can be used without additional authorization.
- If the encrypted component is created with a **User Password**, that password must be entered when the component is used in a design.

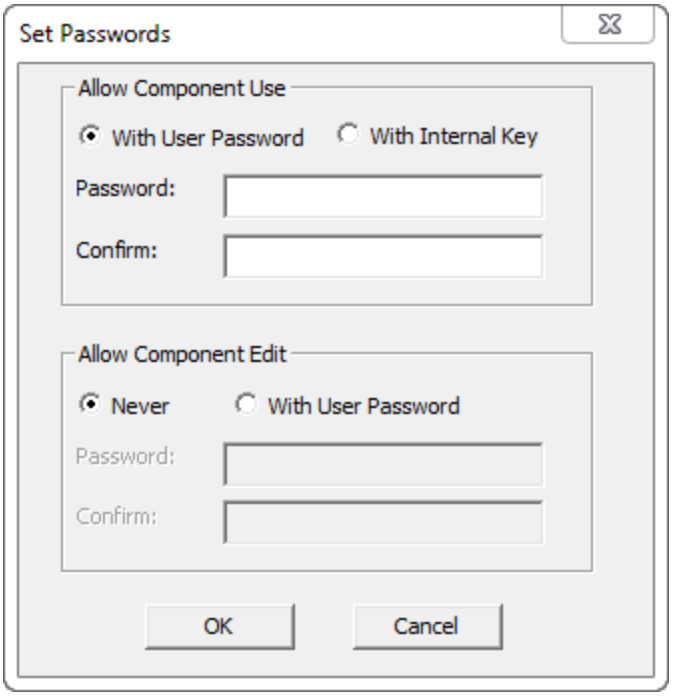
- It is not possible to edit the definition of an encrypted component within the Electronics Desktop.
- If the **Show All Contents** option is selected, the geometry and other contents will be shown when the component is used. Geometry export and links will operate as for general geometry.
- The **Hide Selected Contents** option can be used to further protect access to an encrypted component's details. When this option is selected, hidden contents will not appear in the Electronics Desktop user interface.
    - All geometry will be hidden, except for objects that the user specifies as visible during component creation.
    - Hidden geometry will not be visible in the model window or included in the history tree.
    - Geometry export and links will not be allowed.
    - Materials, boundaries, and other setup data will also be hidden, with limited exceptions such as excitation settings that must be accessed in order to control the simulation and post processing of the design.
    - For components with hidden contents, all geometry will be excluded from field calculations and from plots of fields and meshes. Plots in surrounding volumes **will extend to, and can include, the outer surfaces of the component**, but not the containing volume.
    - **Note**: Such plots may indirectly reveal component content by providing a view of the surfaces where the plots terminate. To prevent such exposure, include additional modeled objects that surround the hidden contents of the component and have material of the surrounding material environment (e.g. air, vacuum).
- When using the **Hide Selected Contents** option, the names of objects, materials, boundaries, and other setup data may appear in progress updates, messages, and other informational text. The **Replace Object and Material Names** option can be used to automatically convert object and material names to generic names in the exported component. Other sensitive names should be changed before exporting.
- When a project contains one or more encrypted 3D Components, the project file is encrypted in order to protect its contents. This encryption uses an internal key, so that you can open the project file without entering a password.

Note	Note that there are some additional considerations with respect to projects using encrypted components. The component itself will always be stored in encrypted form. When an HFSS or HFSS-IE design contains an encrypted component with hidden contents, it will also protect other project files containing data that could be used to extract component information. As of the R18 release, other design types, such as Maxwell or Q3D, do not support this additional security.

Checking the **Encrypt File** box enables the **Set Password** button, and selection buttons for whether the password is to **Show All Contents**, or to **Hide Selected Contents**. You can also specify a security message. If you provide a message, it is displayed at component insertion, and when the project containing the component is opened.



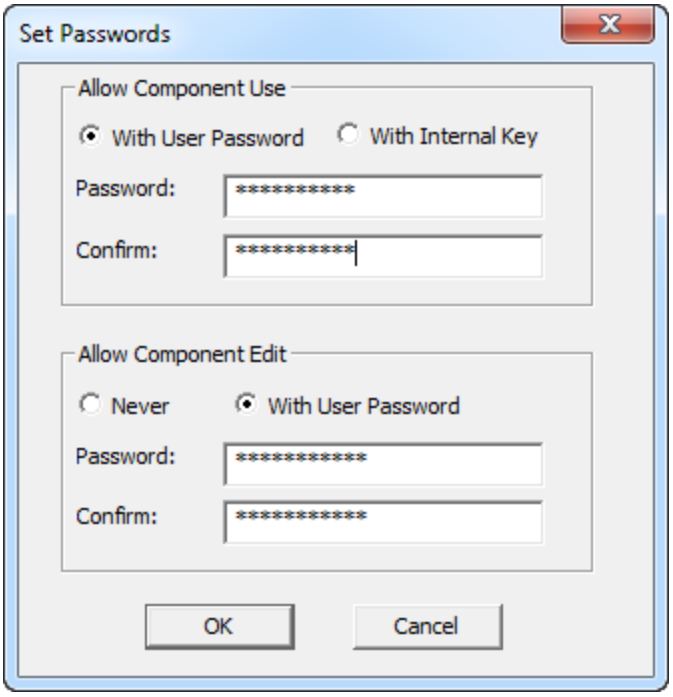
Clicking the **Set Password** button opens a dialog with fields for **Password**, and **Confirm**.This dialog also opens automatically when you check **Encrypt File**.



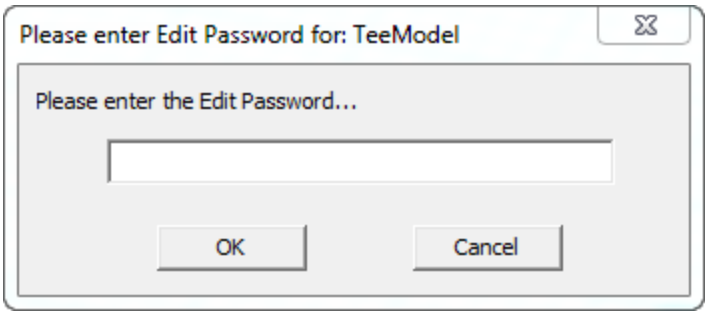
If you specify and OK the fields, the password is set. If you cancel, you will be prompted to provide a password before you save the 3D component.

Selecting **With Internal Key** disables the **Password** and **Confirm** fields. If you select **With Internal Key**, you don't have to specify the password when you use the component.

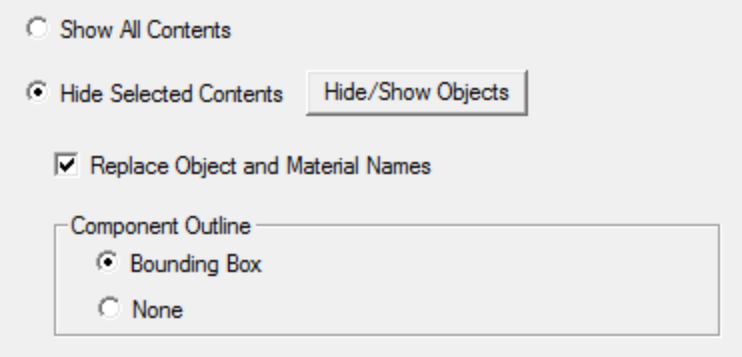
If you change **Allow Component Edit** to **With User Password**, you also specify a **Password** and confirmation. The password for Allow Component Edit does not have to be the same as the password for Allow Component Use. If either Confirm entry does not match the corresponding password, you will be prompted to correct the situation.



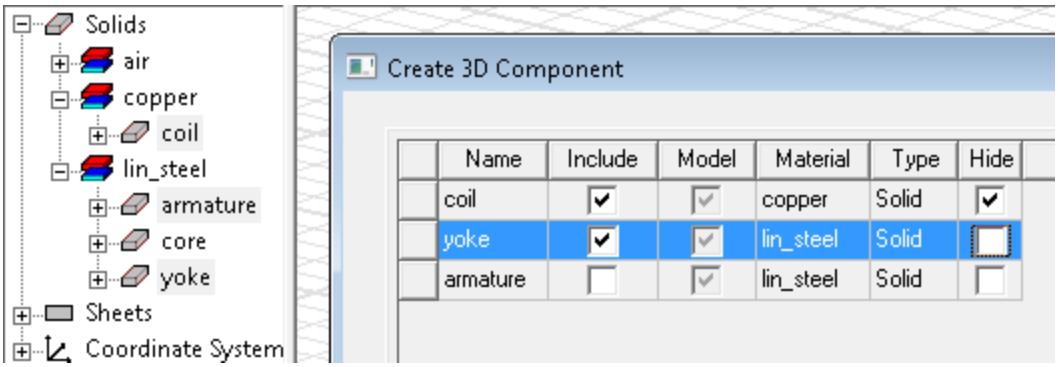
If you then attempt to edit the definition of an encrypted component for which editing is allowed, you will be prompted to enter the Password. You will have three tries to enter the correct password.



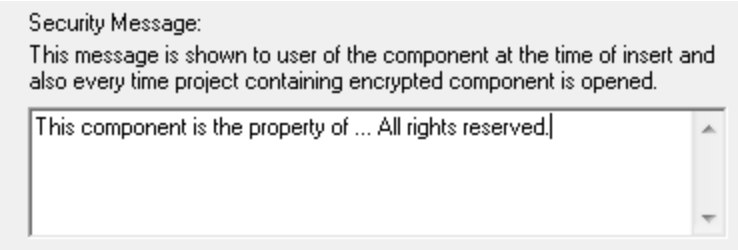
You have a choice regarding whether to **Show All Contents** or whether to **Hide Selected Contents**. If you select **Hide Selected Contents**, you then specify whether to display the component outline as a **Bounding Box** or **None**.



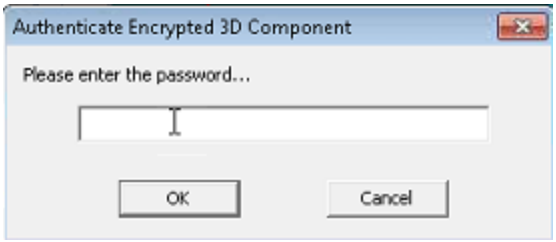
You can also control the visibility per model object by using the Hide check boxes in the Model tab.



You can specify a **Security Message** in the text field. The text you provide displays when you insert a component and when you open a project containing the component.



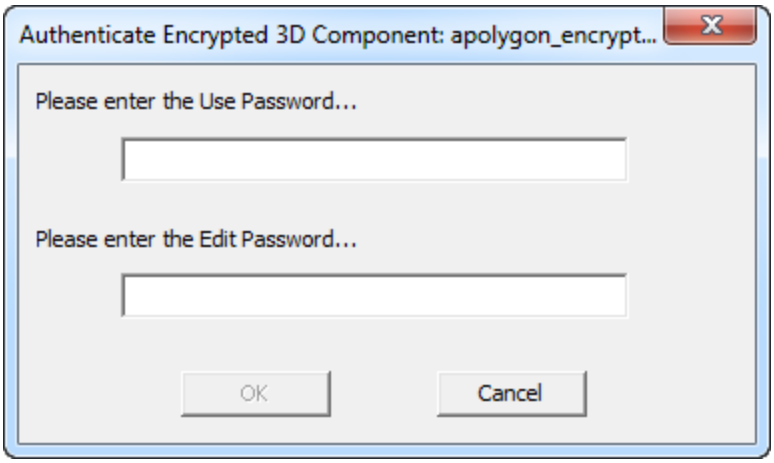
When you insert an encrypted component, you are presented with an Authentication dialog in which you enter a password. A user gets three attempts to enter the correct password.



After authentication, the component is inserted for use. If you have specified a security message, that is displayed.

If you choose to edit the definition for the inserted component, you will be prompted to enter the Edit password.

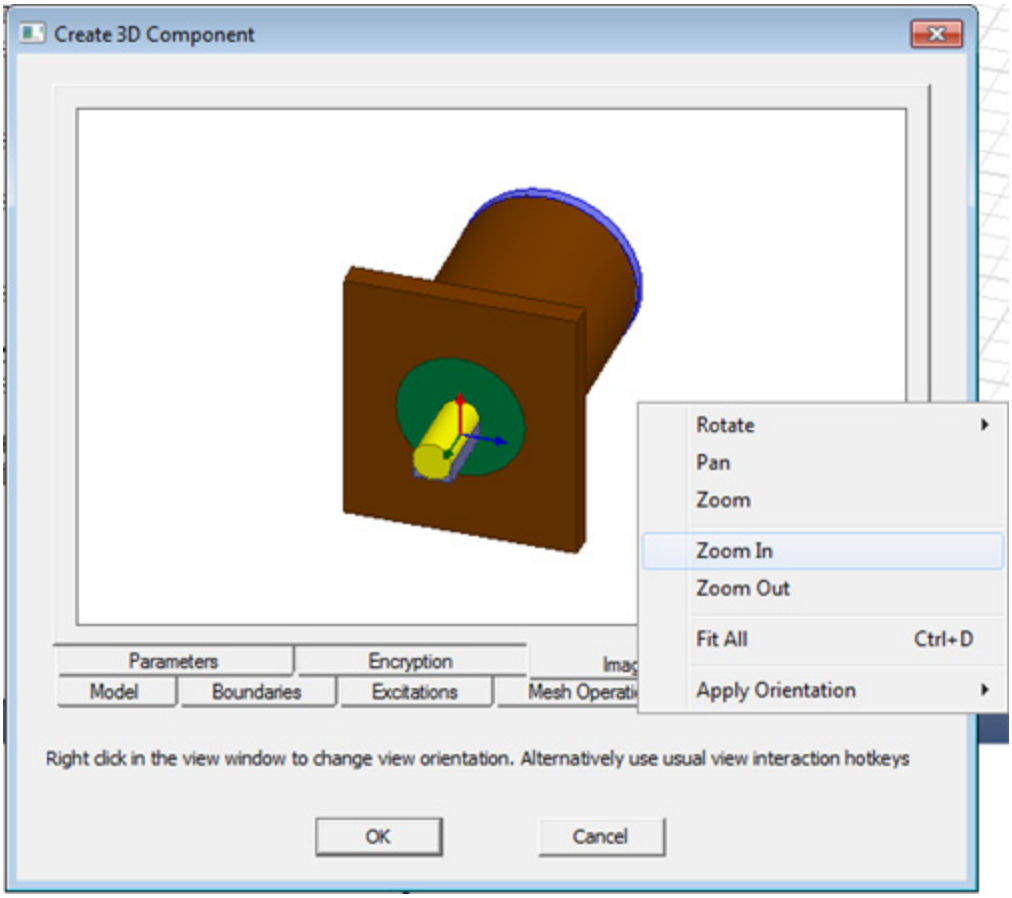
If you decide to open an encrypted but editable 3D Component file using **File>Open**, you are required to enter both the use password (unless encrypted with an internal key) , and the edit password.



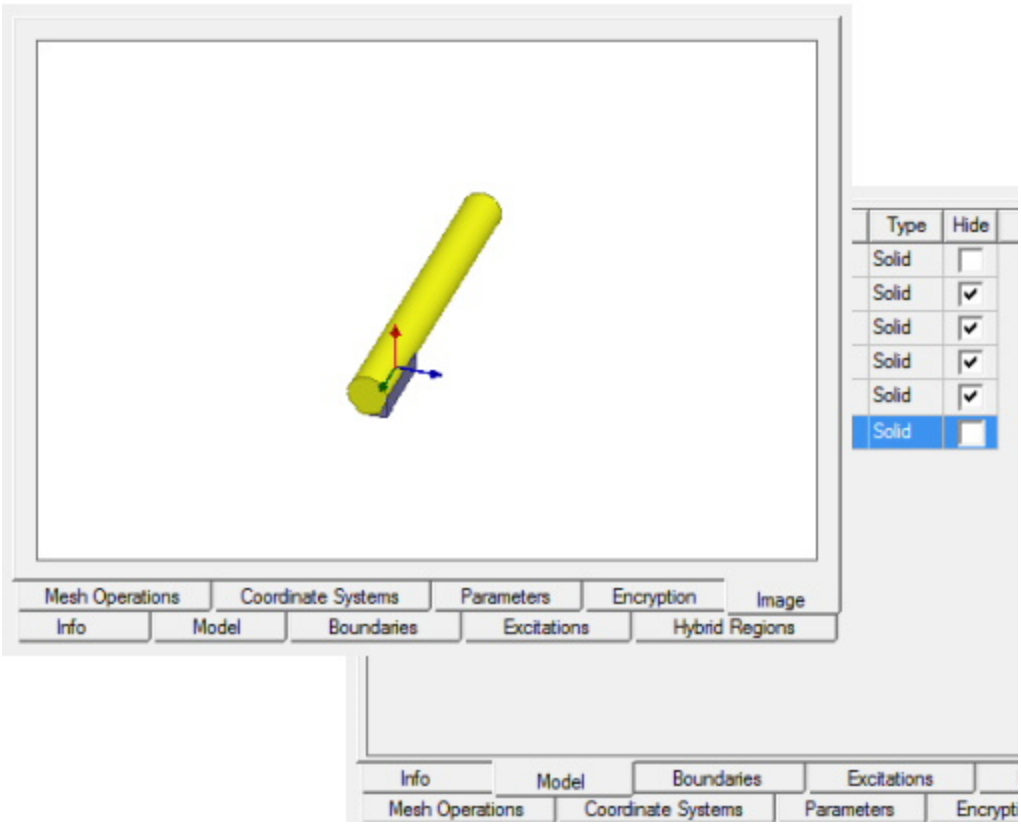
Create 3D Component: Image Tab

The **Image** tab shows the preview image for the component, based on the reference Coordinate System. The image also responds when you **Include** or **Exclude** objects from the **Model** tab.

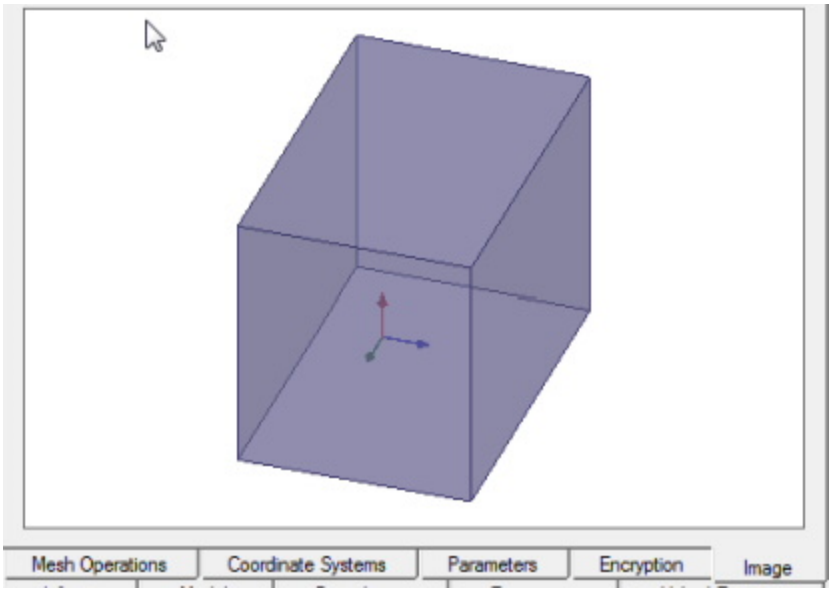
- You can right-click for a menu to change the view of the preview image.
- Changing the preview orientation does not affect the modeler window view.



If you use the Encryption tab and/or Model tab settings to hide/show the model or specified model objects, the Image tab displays accordingly.

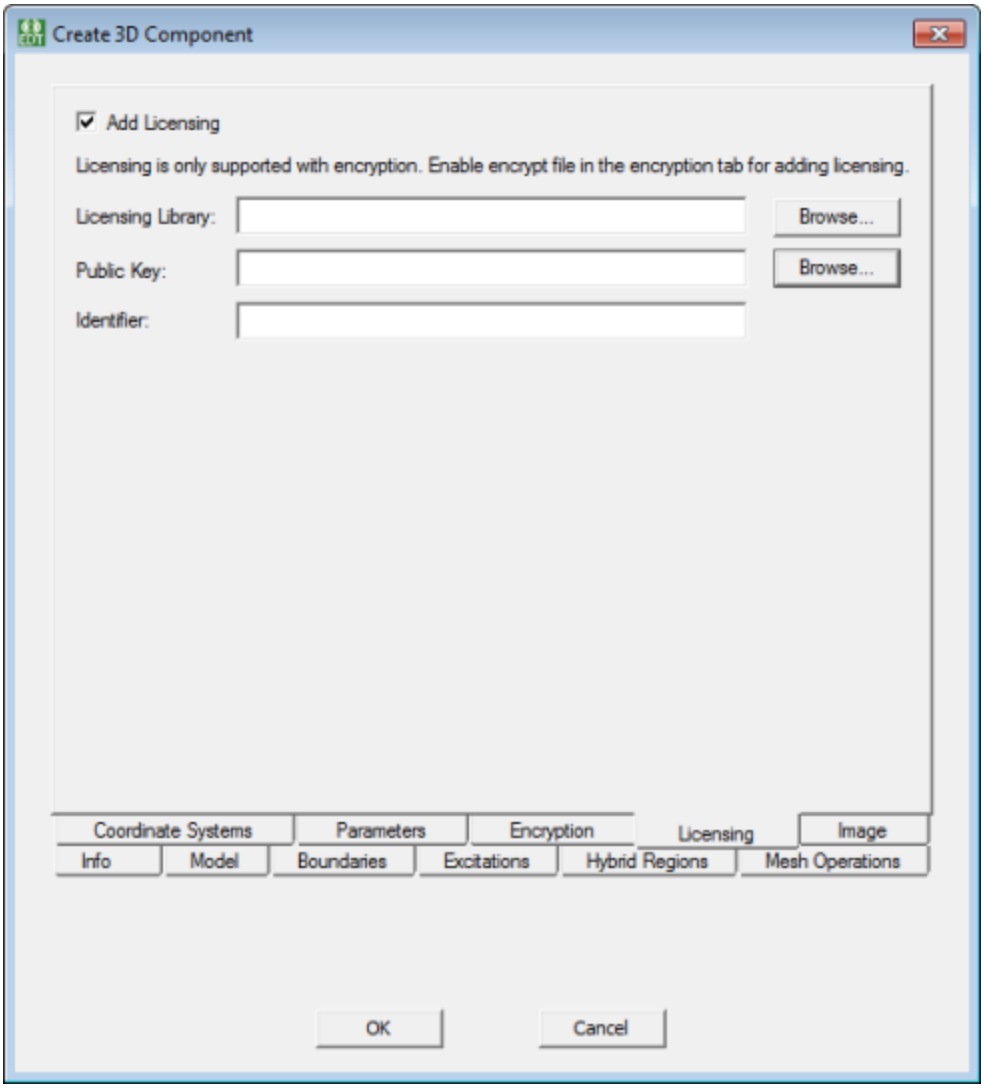


If you use the Encryption tab to display only an object outline, the Image tab displays accordingly.



Create 3D Component Licensing Tab

A 3D Component can be licensed using an external licensing library. This feature is for those who want to license and distribute their 3D Component models. On the **Licensing** tab, you specify a 3D Component Licensing dll, a public key and an optional component identifier. You can license a 3D Component only if it is also encrypted.

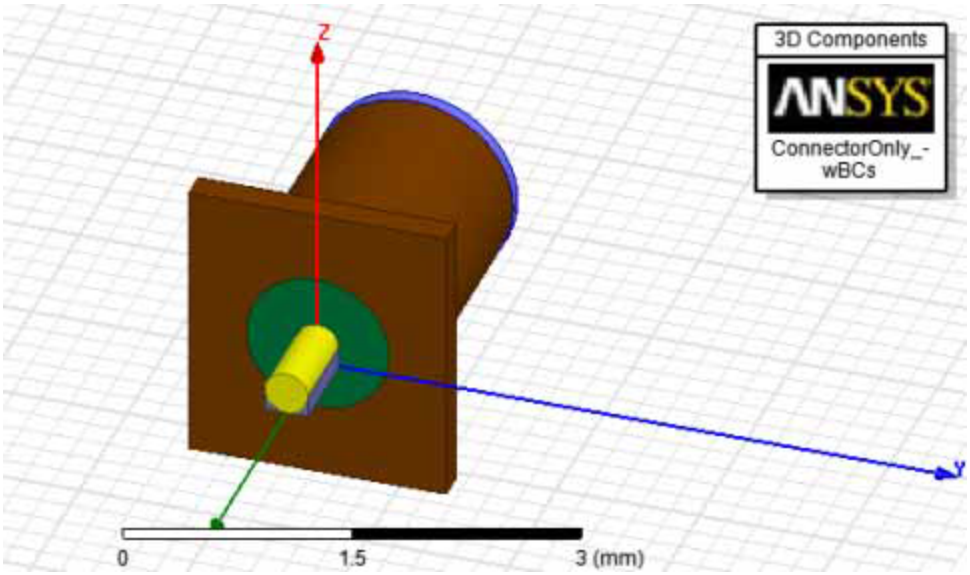


Create 3D Component: Info Tab

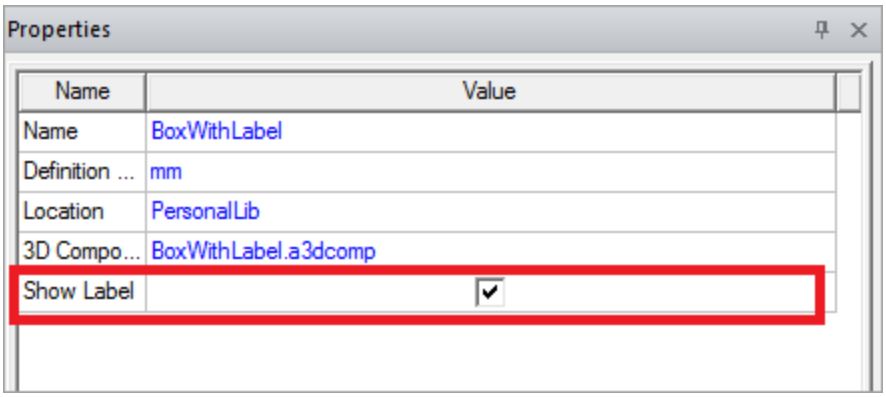
On the **Info** tab you can view and edit component information, as well as add notes. The *Name* in the first field is used when the component is inserted into a design. Other fields include *Owner, email, Company, Company URL, Model Number, Help URL version, Date,* and *Notes*.

You can also included a .bmp format image file to display in the upper right area of the 3D modeler whenever the component is used. The image file typically contains a company logo. Check the

Display image box to enable the **Image File** field, and click **Browse** to open a window to navigate your file system select the image.

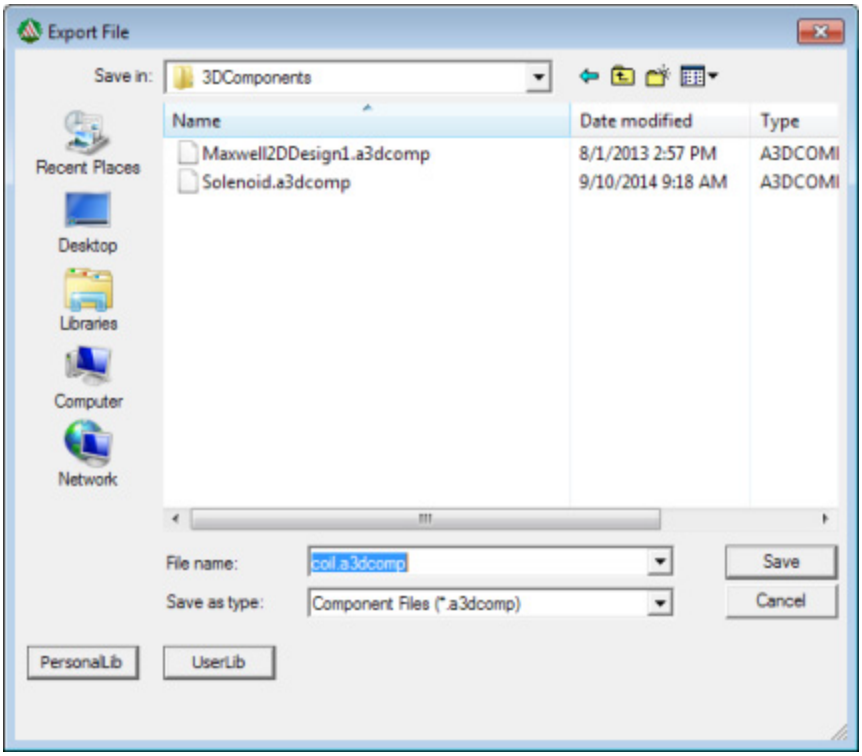


You can move the image in the modeling workspace by clicking the "3D Components" area of the box and dragging it. You can hide the image by editing the 3D component and clearing the **Display image...** check box, or by deselecting the Show Label check box in the Properties window:



Save 3D Component File

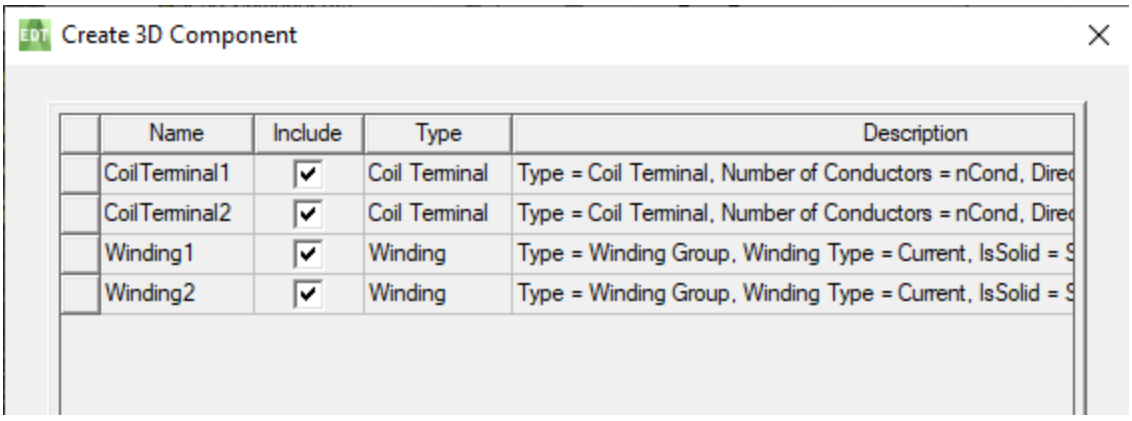
When you **OK** the **Component File** dialog box, an **Export File** dialog displays. By default the Save in field shows the model source directory. Click **PersonalLib** or **UserLib** to display a 3D Components directory.



The default File name is the Component name specified in the **Info tab**.

Maxwell 3D Component with Windings *(2D and 3D Eddy Current and Transient)*

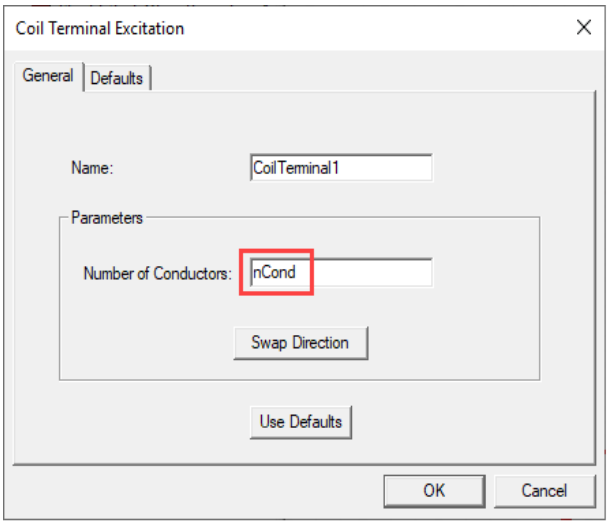
For Maxwell 2D and 3D Eddy current and Transient designs, both voltage and current windings can be included in 3D component definitions on the Excitations tab.

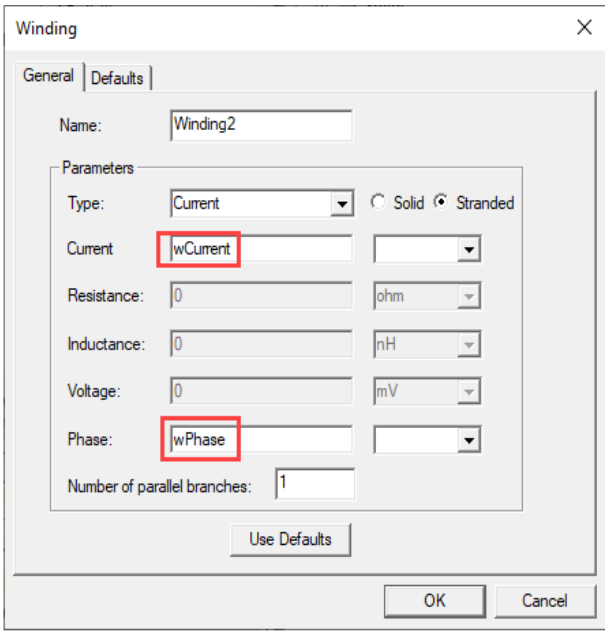


- Windings can only be included in a 3D component when all of its related coil terminals are included in the component as well.

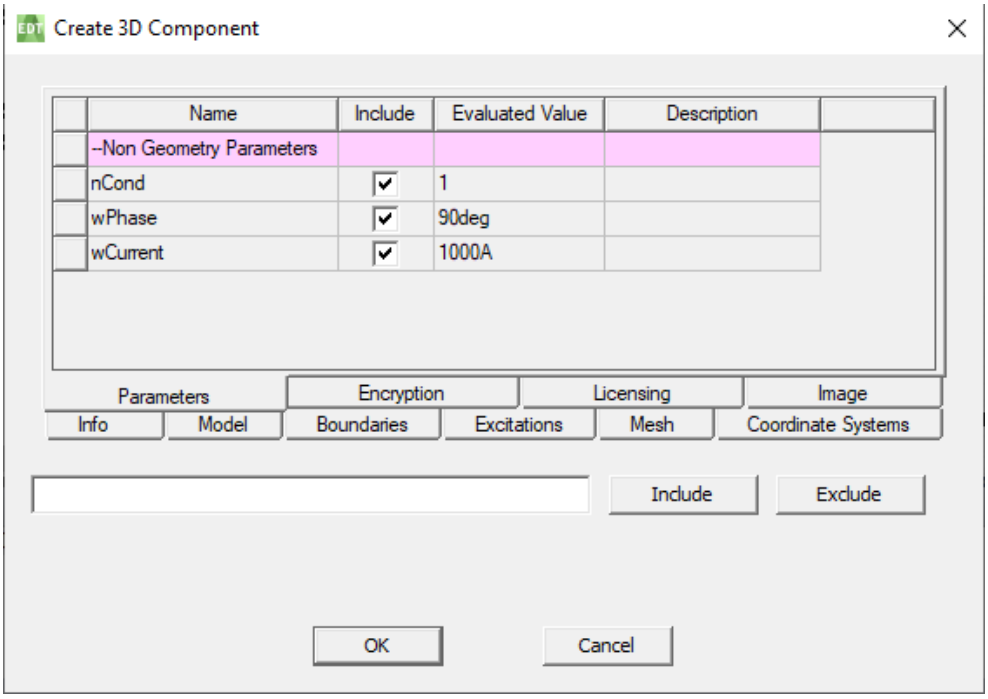
- After inserting a 3D component with windings into a design, only the names of the windings can be edited. Terminals cannot be added to, or removed from, these windings; nor can the windings and associated terminals be removed from the design's Excitations.
- Coil terminals that are assigned to 3D component windings cannot be reassigned to other windings.
- 3D component winding properties (non-geometry parameters) such as: type, resistance, inductance, etc., cannot be edited in a design that includes these 3D components.

  However, any of the winding properties *can* be exposed for editing by assigning design variables to these properties prior to creating the 3D component.

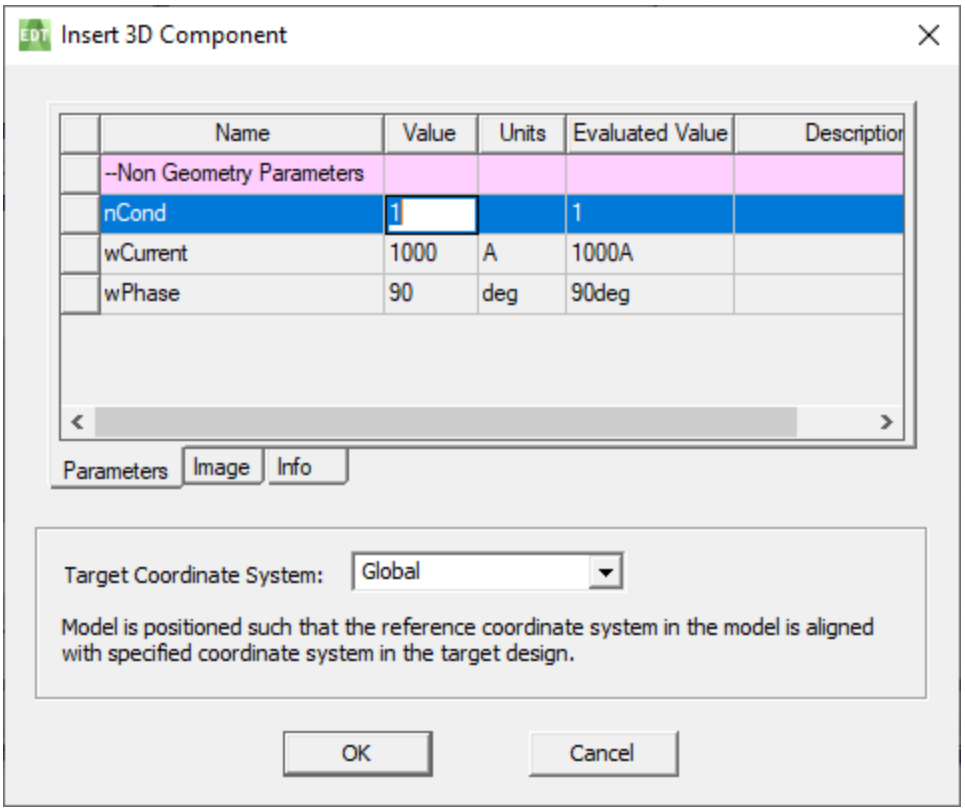




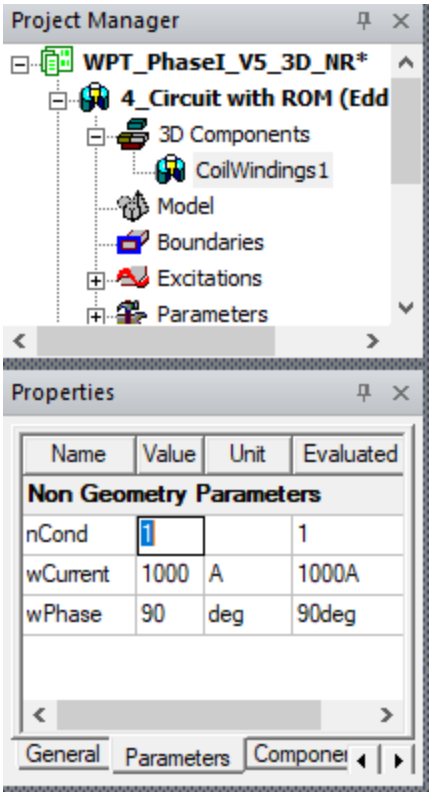
The non-geometry parameters in the example shown above can then be included when creating the 3D component.



When inserting the new 3D component in a design, parameter values can then be specified.



Parameter values can also be edited after the 3D component has been inserted in the design.



- Windings defined in a 3D component are available for use in Matrix setups, Reports, and Optimetrics.

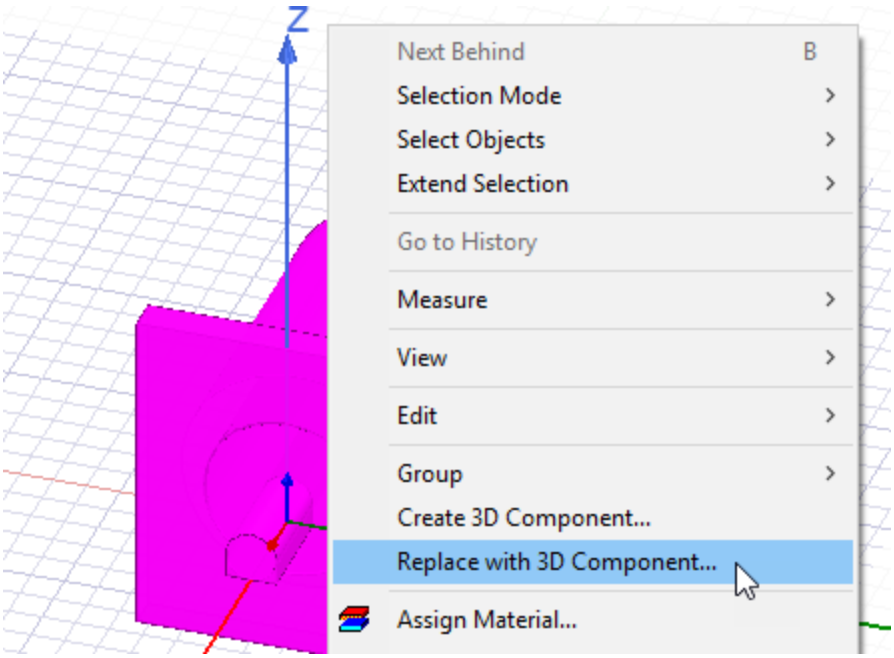
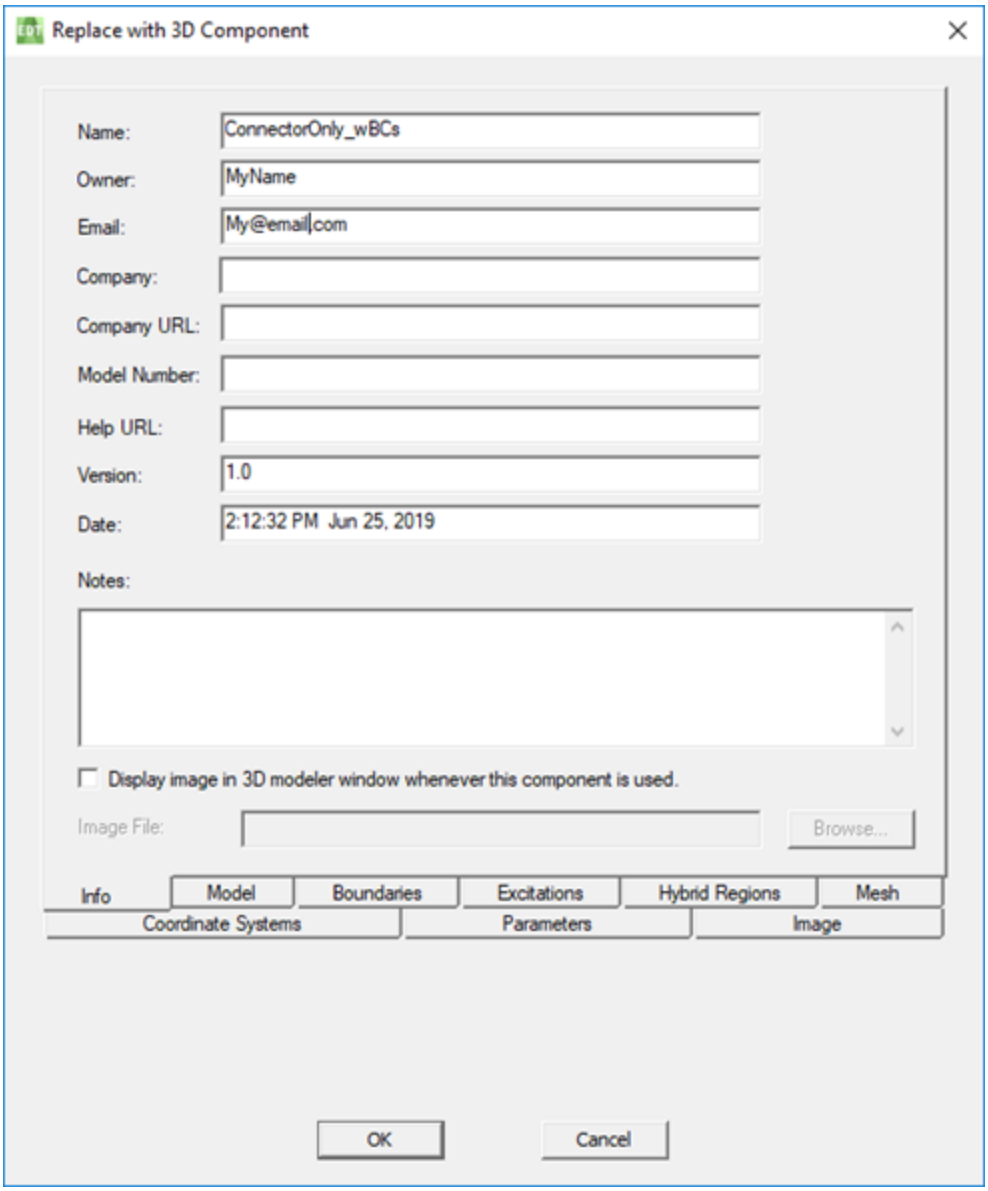
Replace Selection by 3D Component

To replace a selection in the 3D modeler window with a 3D component version of the selection, select an existing object or model, right-click, and select **Replace with 3D Component**. You can also click **Draw> 3D Component Library> Replace with 3D Component**. You cannot replace components from a design with an array setup. However, you create a 3D component from a unit cell and use that to create a Multi-Unit Cell array. When you replace a selection, object names are retained, port names are retained, component parameters map to existing design variables and report, field plot, and edit source are all preserved.



This opens the **Replace with 3D Component** dialog.



The tabs let you view the component features organized according to geometry, design data, and settings. The **Replace Selection with 3D Component** dialog box does not offer tabs for encryption or licensing, compared to Creating a 3D Component. You can use these tabs to change inclusion of objects, boundaries, ports, coordinate systems, or parameters for the 3D component. When you click **OK**, no *Save* dialog box is shown.

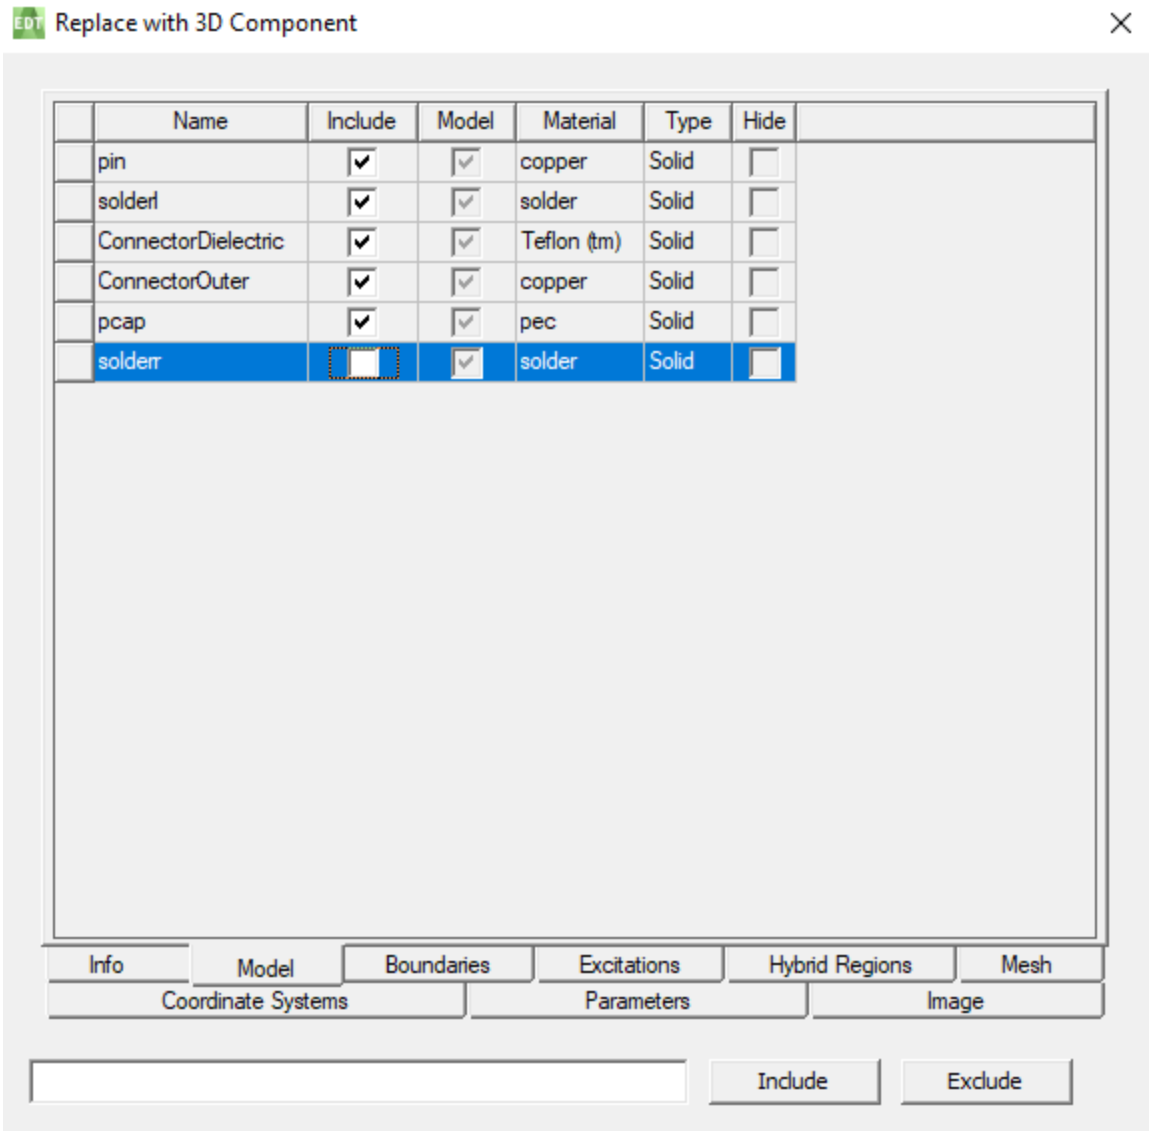
- Info tab
- Model tab
- Boundaries tab
- Excitations tab
- Mesh tab

- Coordinate Systems tab
- Parameters tab
- Image tab

When you click OK, no save dialog is shown. The 3D component is saved to a temporary location. Insertion of instances uses the temporary file, but works just as regular 3D component insertion. The Project tree shows the Component under 3D Components, the boundaries are no longer listed under the Boundaries icon. Excitations, Reports and Analysis Setups remain the same. History Tree no longer shows detailed model edits. You can **Undo** and **Redo**.

Include or Exclude Feature from Component

You can view the various tabs and select which features to include or exclude while replacing the selection with a component. You can use the check boxes in the **Include** column for this purpose. You can also type a feature *Name*in the text box and use the **Include** or **Exclude** button. The text field supports wildcard characters (* and ?), so you can toggle the inclusion state for multiple objects with similar names in a single operation.



An object's **Include** option under the *Model* tab impacts the inclusion state in other tabs. For example, if you exclude an object from the component creation, the design data, parameters, and coordinate systems corresponding to that object are also excluded.

Sorting Columns Using the Headers

The features listed for each tab include columns for the Name, check boxes for whether to include, and properties. You can click on the column headers to sort by Name, Model, or other feature listed for each tab. Click the column header to selects the column to sort. Click again to invert the column.

You can sort lists by using all columns except Include.

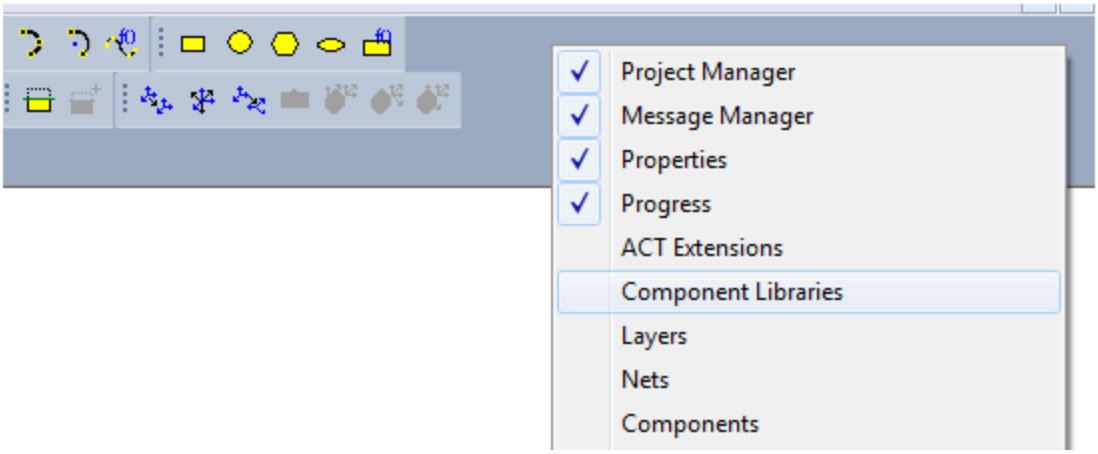
Design Data Notes:

- DC thickness on selected objects is always included in components. It is not listed in the **Boundaries** tab.
- The **Create 3D Component** dialog does not list design data without an assignment.
- The parent of any included boundary/excitation is included, as long as the parent does not require assignment.
- Design settings like material overrides are included.

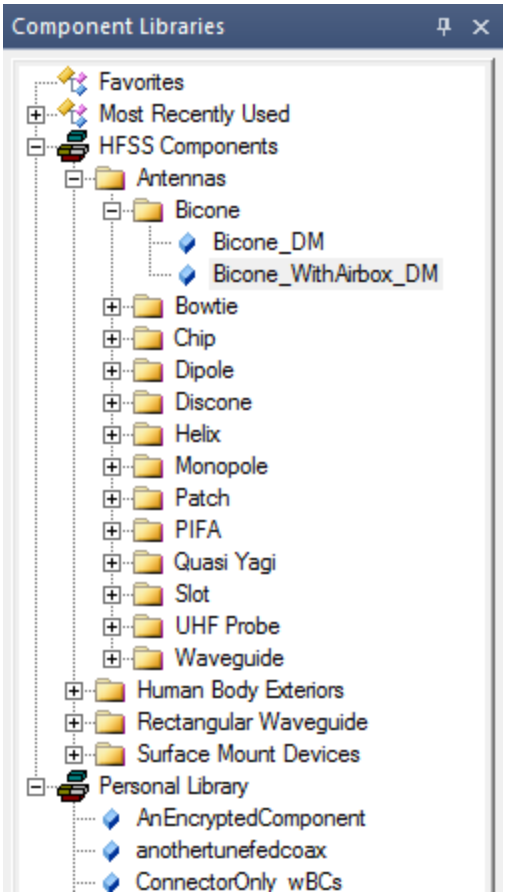
Once you have made the Include and Exclude settings, and have specified the Image and Info you click **OK** to Replace with 3D Component. When you click OK, the component is validated for everything that is included in the component. For example, you cannot include boundaries if the object on which the boundaries have been created is not included.

Using the Component Libraries Window

Once you save one or more components to a library, and create target coordinate systems in the design where you intend to place the component, you can right-click the 3D component icon in the Project tree or use the **Draw** > **3D Component Library** commands to browse your folders or libraries, or use the **View** > **Component Libraries** to display a **Component Libraries** window to navigate installed libraries. Visibility of the **Component Libraries** window is remembered for each design type so that if context switches between different design type, the window is shown or hidden based on setting for new design type.

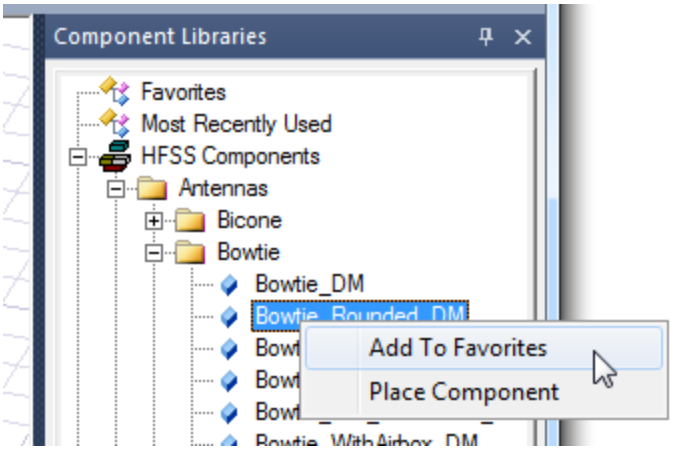


From the **Component Libraries** window, you can navigate the directory of installed components, as well as any in your Personal Library. The **Component Libraries** window lists all the 3D components available in syslib, UserLib and PersonalLib. It adds a folder corresponding to a library only if there are any components for active design under that library. There are also additional optional folders for managing Favorites and Most Recently Used components. **Component Libraries** window contents, including Most Recently Used and Favorites correspond to active design. When context is switched between different designs, Component Libraries window will be refreshed so that it is relevant to active design.



You can control whether to show the Favorites and Most Recently Used folders from the **Tools** > **Options** command dialog box, on the General > Component Libraries page.

Right-click a component to view the **Add to Favorites** command to include frequently used components to the Favorites folder. Once a model is included in the Favorites folder, you can also right clock to **Remove from Favorites**.



When you have added a component to a design, it also appears in the Most Recently Used folder. You can also right-click model there to view the **Add to Favorites** and **Place Component** commands.

You can select any component from the library, and drag and drop to insert it in the design. If you insert a component by the drag and drop method, the component is immediately inserted, skipping the **Insert Component** dialog box. The component is inserted with default component parameter values and is placed in current active coordinate system.

You can also select **Place Component** from the right-click menu or double-click any model in the component libraries to view the **Insert 3D Component Instance** dialog opened to the **Parameters** tab. Using the **Place Component** menu command allows you to review component parameter values, change target coordinate system, and so forth, using the **Insert Component** dialog box. You can also view the **Image** and **Info** tabs.

Component file organization on the disk

3D Component files are organized under three libraries, namely *syslib, UserLib,* and *PersonalLib*. 3D component files must be in a **3DComponents** folder under the appropriate library location. It is recommended that files are further organized by design type under the *3DComponents* folder. For example, component files for Maxwell should be organized under 3DComponents\Maxwell, as done for syslib. The 3D Component Libraries window and also Draw\3D Component Library\ menu look for components under a folder corresponding to the active design type, and it ignores component files under folders corresponding to another design type. For example, Maxwell will ignore component files under the HFSS subfolder. Any component files that are directly under *3DComponents* will be visible in all design types.

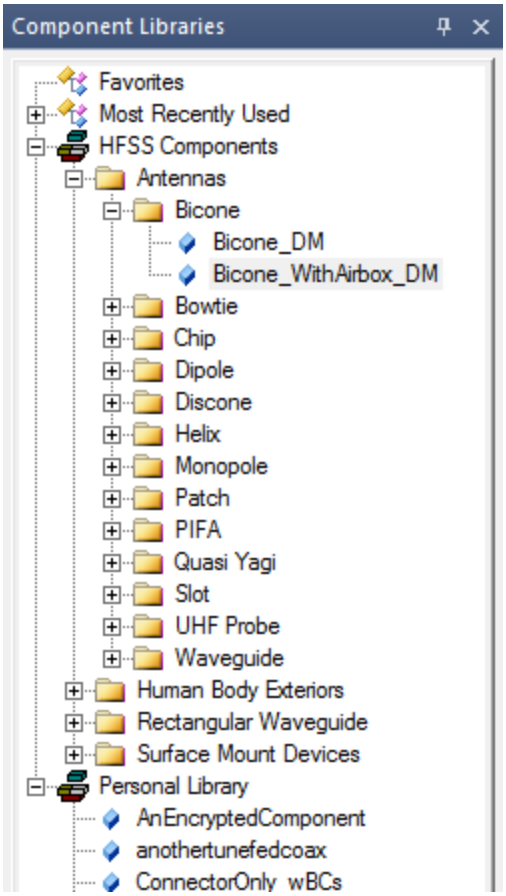
Inserting a 3D Component in a Design

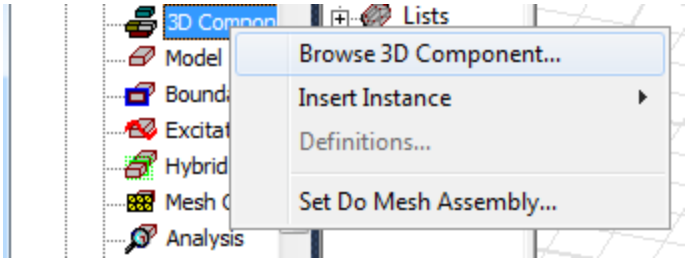
Once you save one or more components to a library, and create target coordinate systems in the design where you intend to place the component, you can either right click on the 3D component icon in the Project tree or use, or the **Draw>3D Component Library** command to browse your folders or libraries, or use the **View>Component Libraries** to display a Component Libraries window to navigate installed libraries.

From the Component Libraries window, you can navigate the directory of installed components, as well as any in your Personal Library. The Hierarchical tree display includes Favorites and Most Recently Used branches.

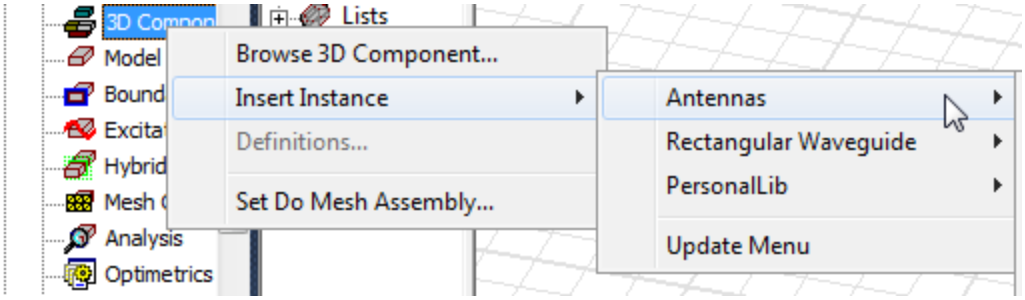


You can select any component from the library, and drag and drop to insert it in the design. Double-click on any model in the component libraries to view the **Insert 3D Component** Instance dialog opened to the **Parameters** tab. You can also view the **Image** and **Info** tabs, and select the target coordinate system.

Selecting **Browse 3D Components** lets you navigate directories via a browser window.

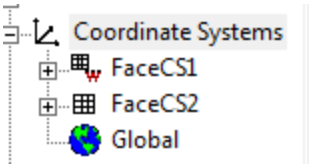


Selecting **Insert Instance** displays further menu selections for pre-defined components in other libraries such as the Antennas library and the Rectangular Waveguide library. If you have added components to PersonalLib or UserLib, these also appear after you refresh the menu.

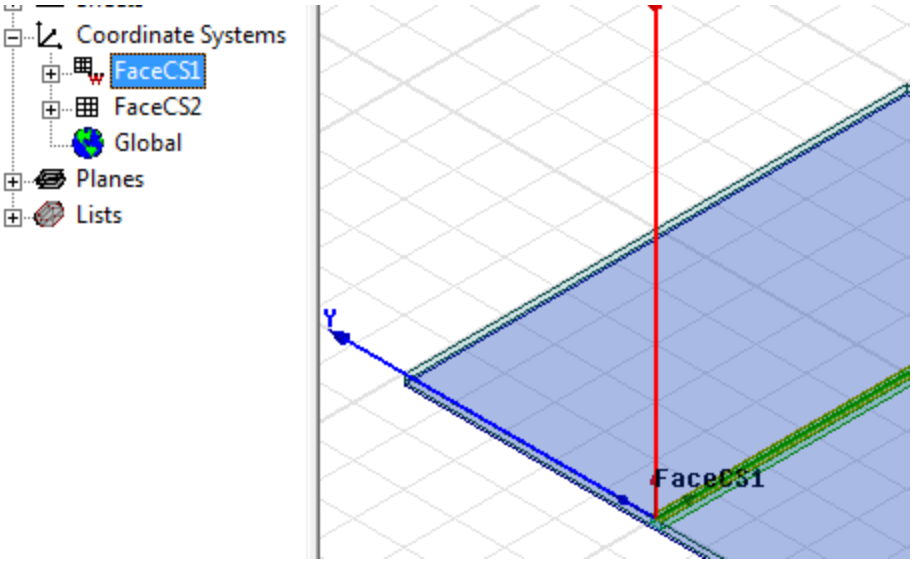


You can also click **Draw>3D Component Library** to access the **Browse** and **Insert Instance** menus to select a component to insert into a design.

Before inserting a component in a design, it can be helpful to create a target coordinate system to provide a location for the component. In the following 3D project example, the design includes two additional coordinate systems:

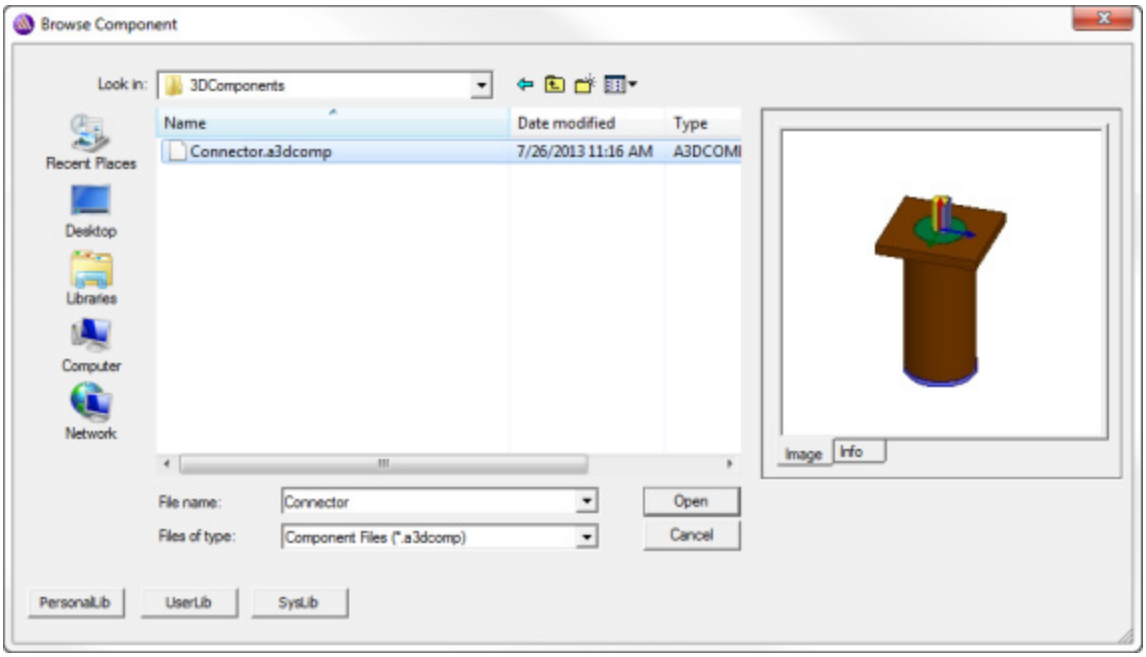


Selection of a coordinate system in the History tree displays a potential location for inserting a component.



To Insert a 3D Component from the Menus

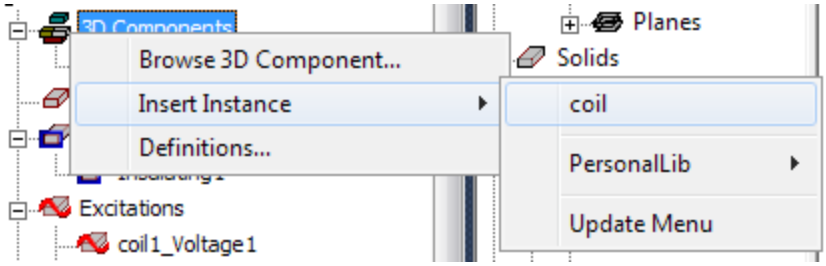
1. Right-click on the **3D Component** icon in the **Project tree** to open shortcut menu. You can select **Browse** to use a browser window navigate the file system to the component.



Selecting the *.a3dcomp file displays the component image and file name.

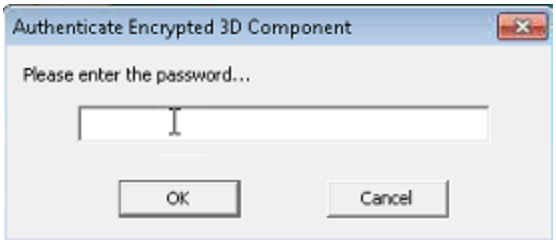
Note	3D components created in Maxwell 2D cannot be used in Maxwell 3D projects, and vice-versa. A message displays if you attempt to insert a component that is incompatible with the active design.

If you have previously inserted a component into a Project, the shortcut menu for the 3D Component displays that component so that you can easily insert another instance of the same component.



2. If you have used Browse, select a component and click the **Open** button. If you use the Insert Instance menu, select the component name.

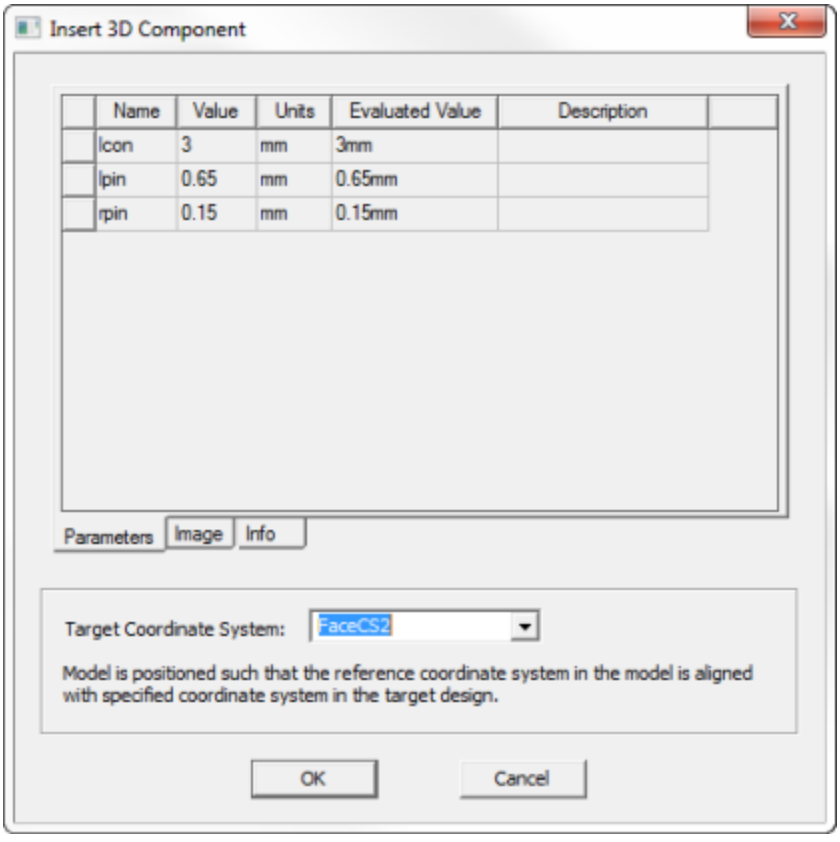
   If the component has been encrypted, you may be prompted to enter a password. If you insert another instance of the same component, you do not need to enter the password again for that component again.



You have three tries to enter the correct password. Upon successfully entering the password, the Insert 3D Component dialog opens with the Encryption tab displayed.

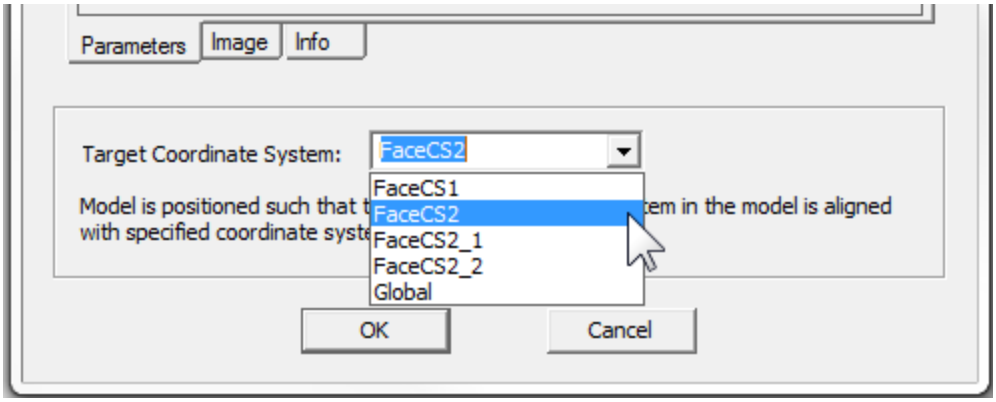
Note: There are some additional considerations with respect to projects using encrypted components. When a project contains encrypted components, the project file and other related files are also encrypted. Encrypted component contents may also be hidden from view in the design where the component is used. For more details, see Create 3D Component Encryption Tab.

You see the **Insert 3D Component** dialog opened on the Parameters tab.

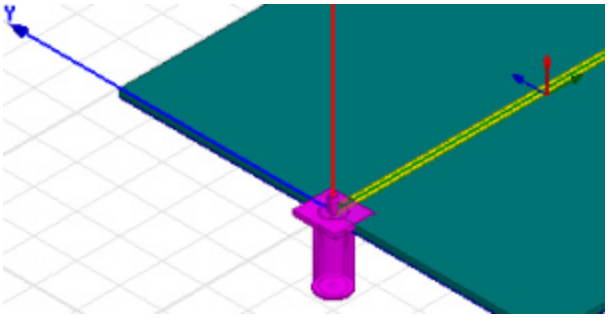


Tabs let you view the Parameters, Image, and Info. You can edit parameter values, and assign variables or expressions for parameters

3. Use the menu to select the Target Coordinate System if any have been defined in addition to the Global coordinate system. The target coordinate system that you select is highlighted in the modeler window.



4. When you click **OK** the component is placed at the coordinate system you selected.



5. If the component has a logo defined, the image is always displayed in the upper right of the modeler window.

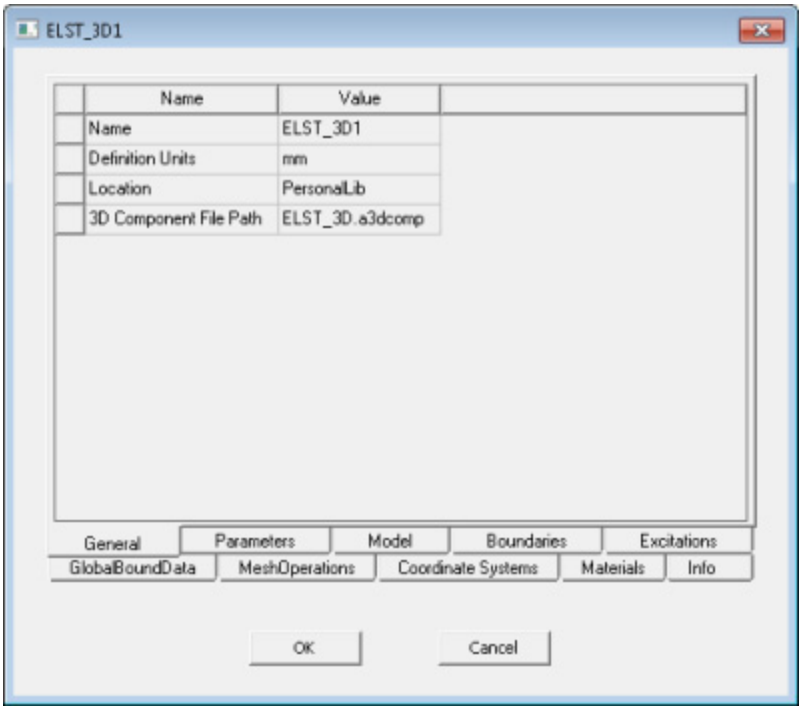
Viewing Properties of 3D Components

The Properties displayed for a selected 3D component depends on how you select that component. For a complete display of Properties, right click on the selected component (Project tree, History tree, or Modeler window) and click **Properties** on the shortcut menu, or click **Edit>Properties**.This displays a Properties window with tabs for all component properties.

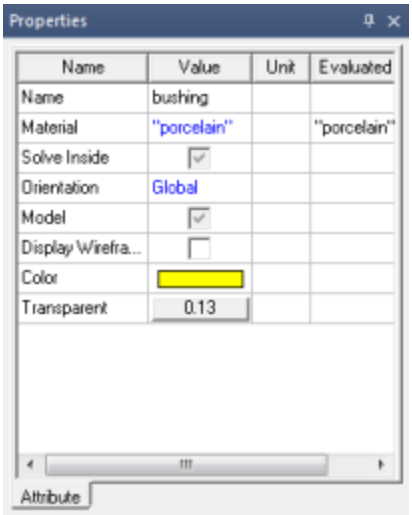


Selecting a 3D component in the Project tree displays docked properties with tabs for General, Materials and Component data.

If you select a component in the **Project** window, then right-click and select **Edit>Properties**, you can view the **Properties** window. If you choose the **Materials** tab, you can then select any listed material and the parts of the component made of that material are highlighted in the **Modeler** window.

Selecting a 3D component in the History tree displays docked properties with tabs for General and Parameters.

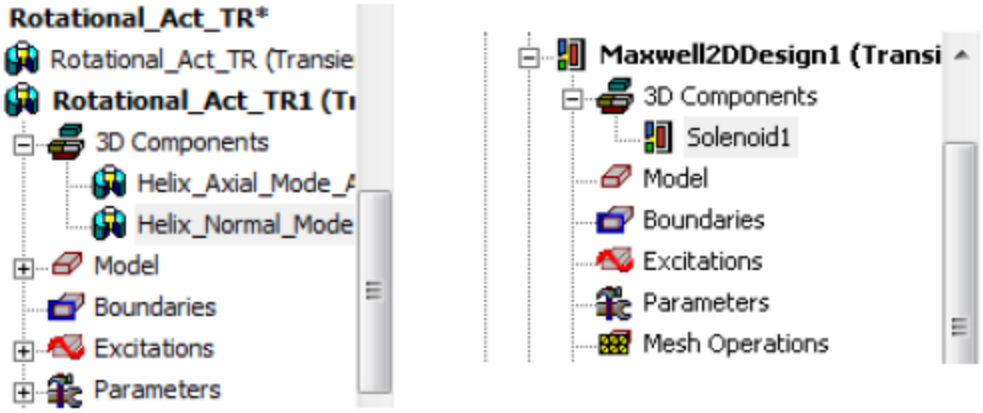
Selecting a 3D component in the Modeler window displays docked properties with a tab for Attributes.



Component materials do not appear in the Project Tree Definitions list. If you select the icon for an inserted component, the Properties window contains a Materials tab that shows the Materials defined for the selected component.

3D Components in the Project Manager Window

The **Project Manager** window organizes any components that you add to a design under the 3D Components icon in the **Project** tree.



Selecting these inserted components populates the Properties window which has tabs that display the instance attributes.

Excitations included in the 3D Components appear in the Project tree. This gives you the ability to edit Post Processing settings.

Boundaries defined inside the component do not appear in the project tree. However, boundary properties can be when you select the component in the Project tree and view the Component properties under the Component Data tab.

Also, you can use **Maxwell>Boundaries>Reprioritize** to set the priorities of all boundaries relative to non-component boundaries.

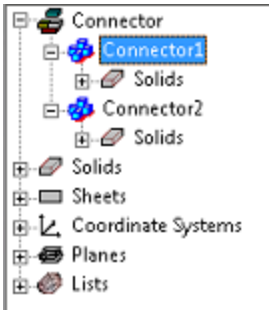
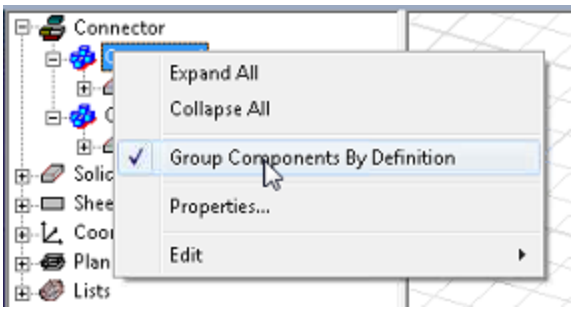
3D Components in the History Tree

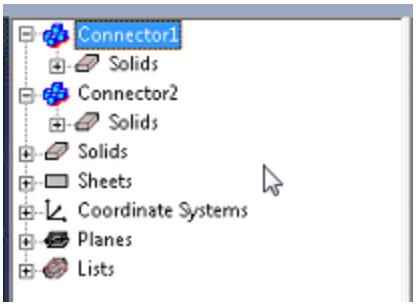
You can group all instances of a component by component definition in the History tree.



To disable this grouping, right click on an instance, and uncheck Group Components by Definition.

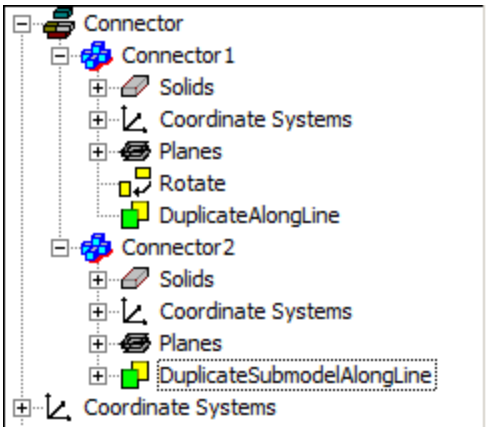


This causes the display to show numbered instances listed without the icon for the primary component.



Component Operations in the History Tree

- Component operations appear under that component folder toward the end.



- Component operations act on parts as well as CS.
- Boundaries and mesh operations are duplicated with duplicate and copy/paste operations, provided that you check the **Duplicate boundaries/mesh operations with geometry** option to do so (see Tools>Options/<design type options>).

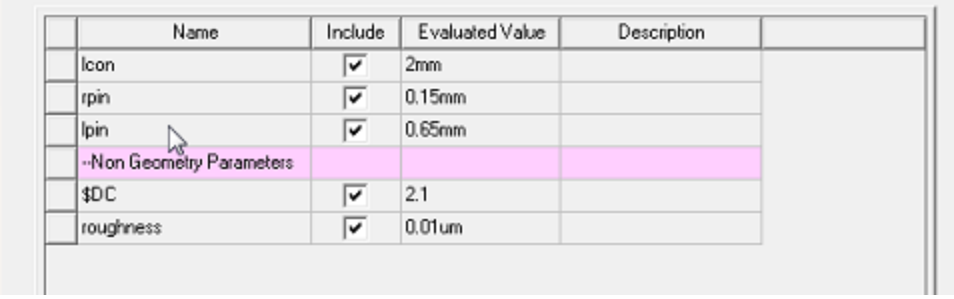
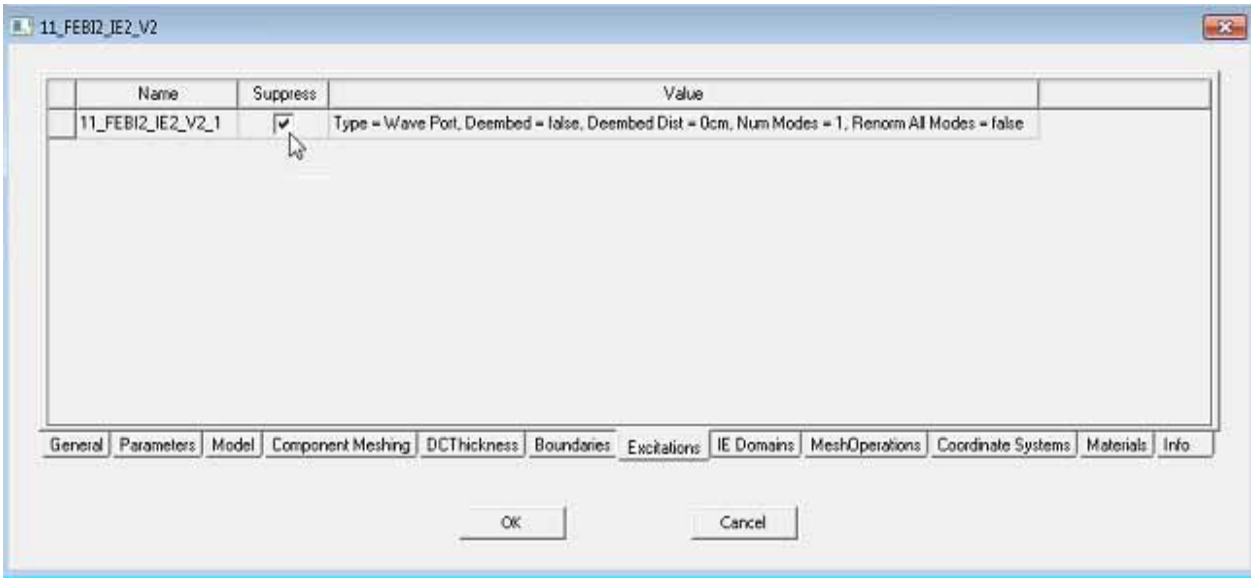
Editing 3D Component Properties

- Edit component parameters, if defined for that component. Editing the parameters of one component instance affects only that instance. If a component includes Non-Geometry Parameters, these are grouped separately on the Parameters tab.

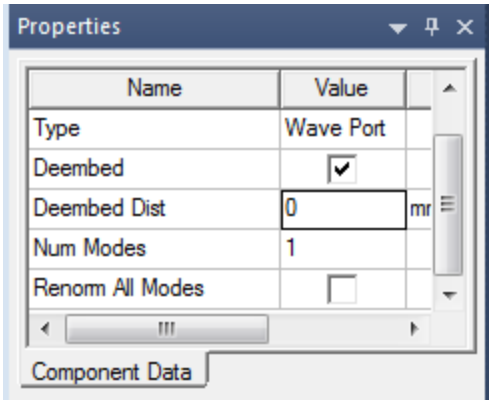


- Edit excitations by suppressing their use on the Excitations tab in the Properties window.

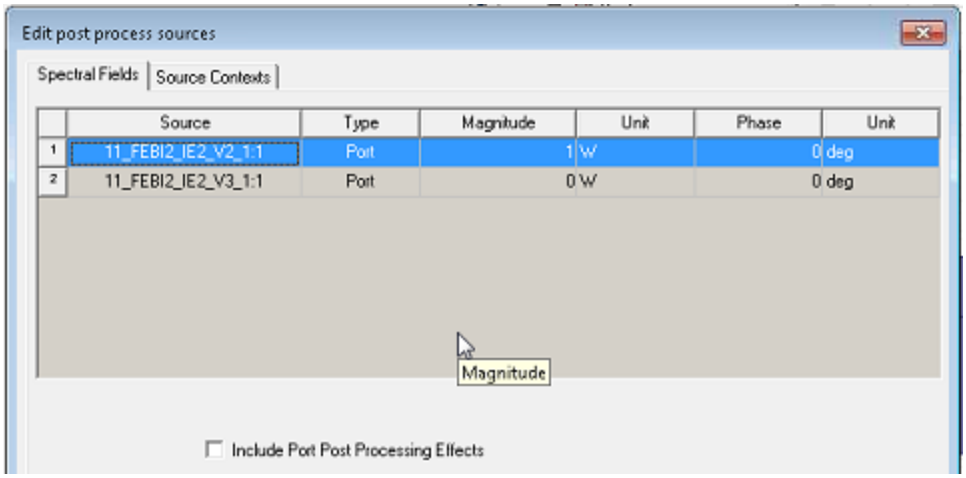


Checking Suppress in the Properties window removes the port on the selected instance from the Excitations list on the Project tree. Unchecking Suppress activates that port for the model and causes the port to appear in the Excitations list.

- Edit excitation Post Processing such as deembed distance, renormalization.



- Edit Sources for Post Processing



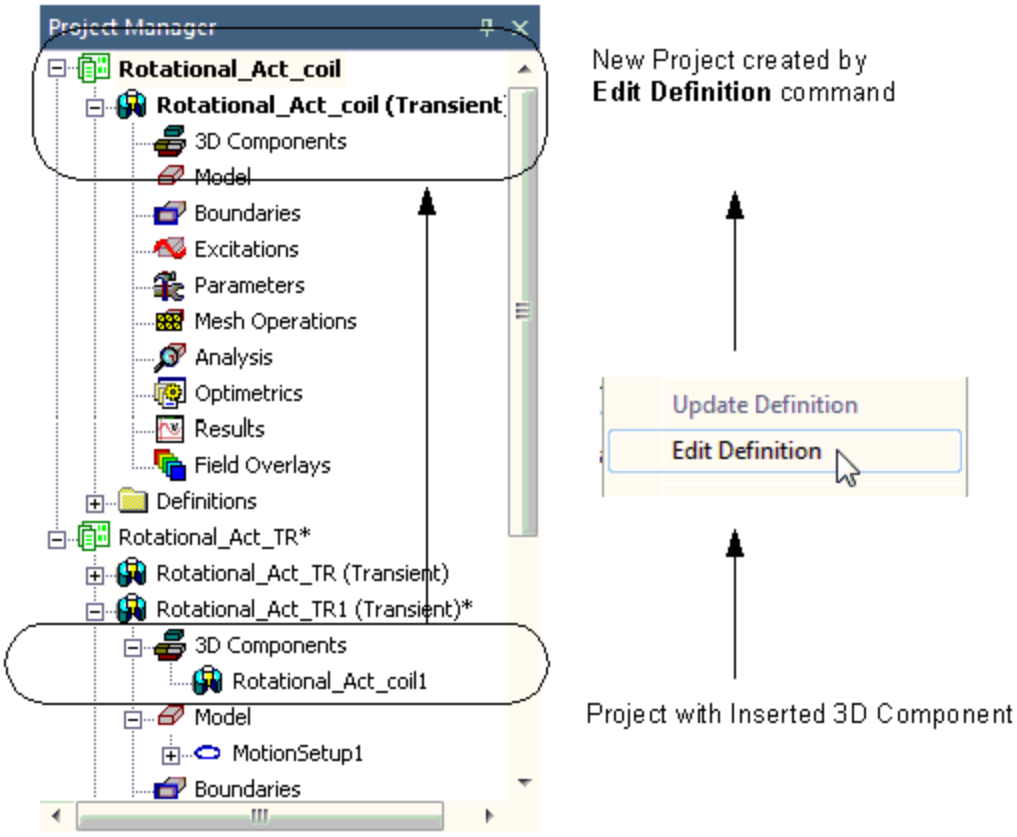
- Edit component attributes like component name, part names, material assignment, and model/non-model flags.
- Edit boundaries, excitation and mesh operations for the component on the corresponding tabs in the Properties window.
- Add additional boundaries/excitations on parts coming from component

  However, operations on individual parts of component are not allowed.
- Copy/Paste component
- Delete component
- Arrange component: Move, Rotate, and Mirror
- Duplicate component: Along Line, Around Axis, and Mirror
- Edit Attributes for Display Wire frame, Color, and Transparency.
- Use **Edit>Selection Mode>Submodels** to quickly select component

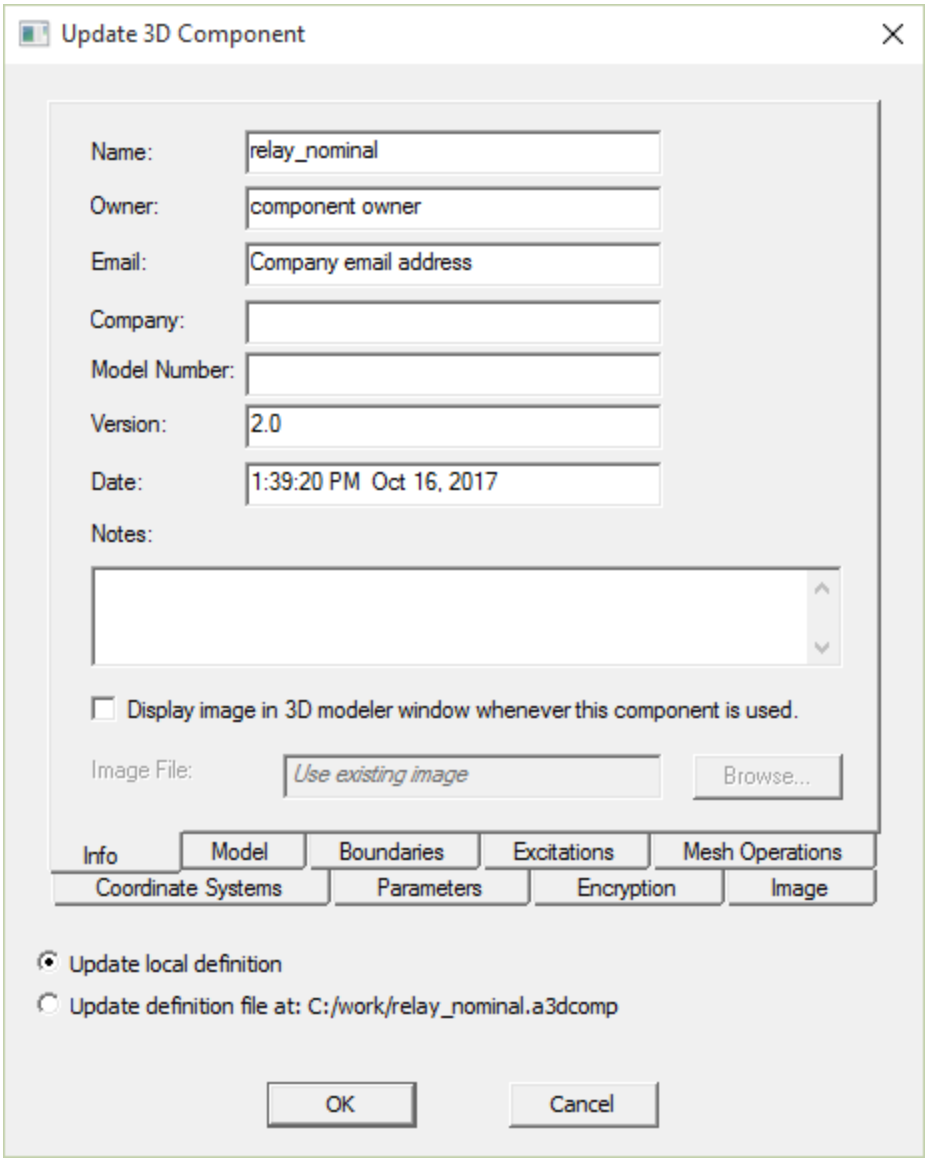
Editing a 3D Component Definition

The Edit Component definition feature allows you to create new version of component definition just by using previous 3D component file. This should also allow you to quickly create new version without having to go through all the creation steps. For 3D Components that are not encrypted you can edit the definition. Software will automatically create new project in the existing session. The Project will have one design of same type as original design from which edit definition was initiated. All 3D component data from the file will be read in ‘exploded’ form in that design. Component materials will be added at the project level, variables will be added at the project and design level, geometry will create detailed history for all objects in the component and design data will be added to respective folder in the project tree in the detailed form.

The **Edit Definition** command creates a new project named for the component. You can see the project in the **Project Manager** window.



You can then edit this new project. When you save the edited component, you see an **Update 3D Component** dialog including radio buttons for whether you want to save the edited component as a local instance, or to the original library.

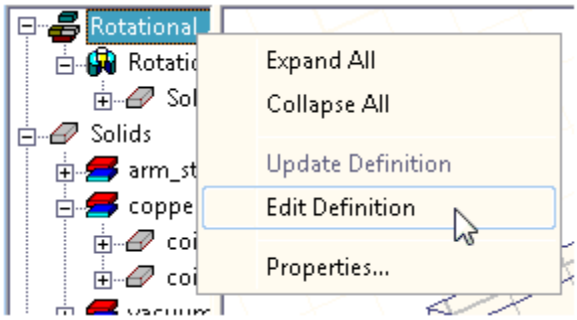


If you select **Update local definition**, any changes you make apply only to the local file. If you choose **Update definition file at: <*path*>** to save the component to the definition file in your library, you can Update 3D Component Definition for other component instances inserted in your designs.

To edit a 3D Component definition.

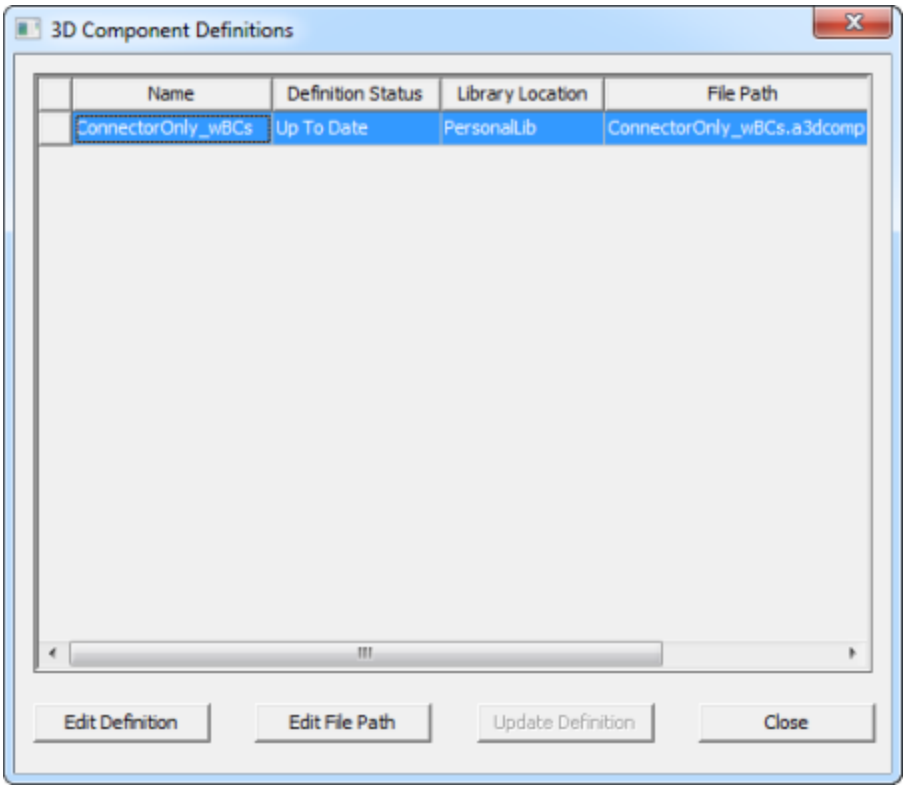
1. You can begin editing a 3D component definition from either the History tree or the Project tree.
   - To begin from the **History tree**, select the component,, and right-click to display the shortcut menu and click **Edit Definition**.

   For unencrypted components, this creates a new project in the **Project window** named for the component. For encrypted components, you must first supply the edit password.



- To begin from the **Project window**, select the 3D Components icon and right click to display the short cut menu. Then select **Definitions**.

This displays the **3D Component Definitions** window in which you can select the component and then click **Edit Definition**.

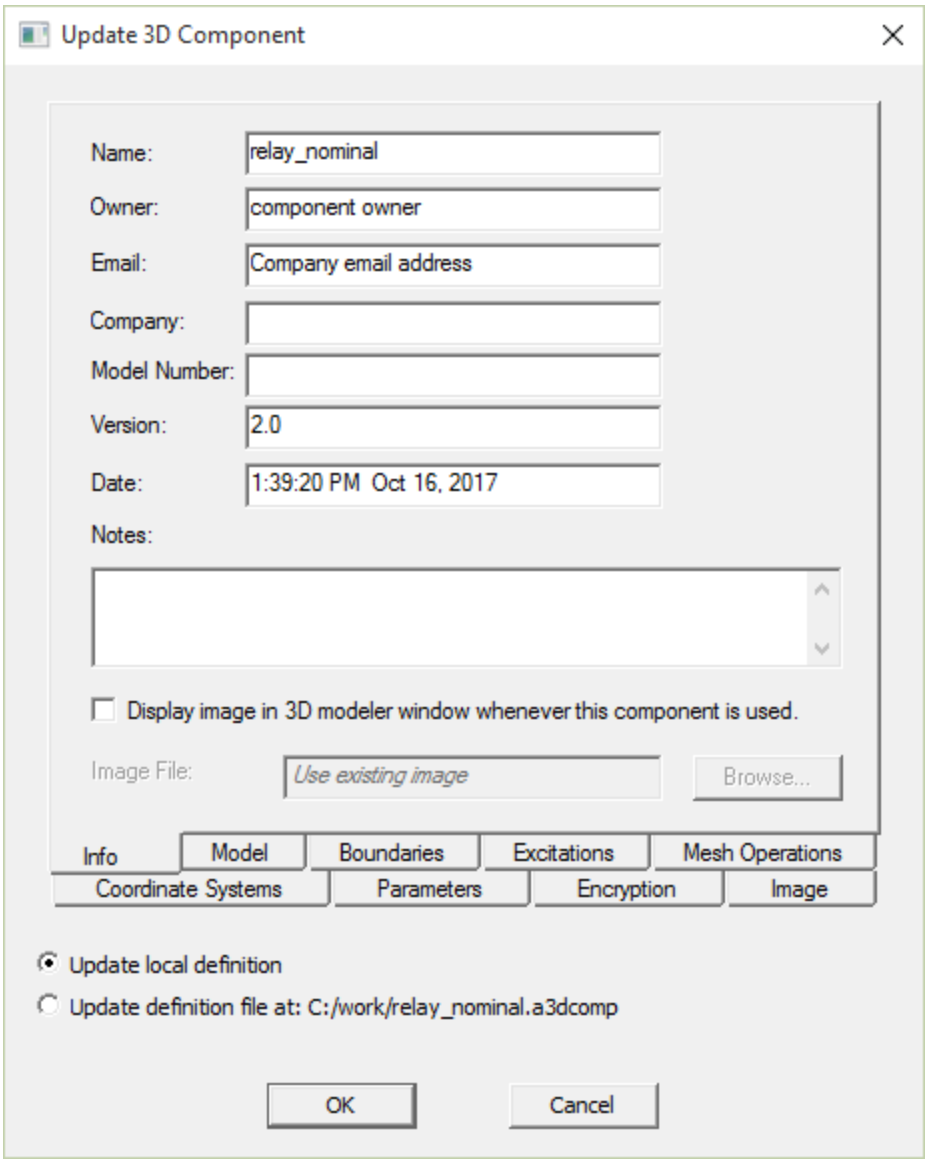


2. For 3D Components that are not encrypted, you can edit the definition. Software will automatically create a new project in the existing session. The Project will have one design of same type as the original design from which edit definition was initiated. You can now edit the design with component data as required without any restrictions. All the component details are available in their respective folders. Complete geometry history is available in

history tree. Material properties are added to the project definition folder. Boundaries, excitations, etc., go to their respective folders in the project tree and component parameters become project or design variables.

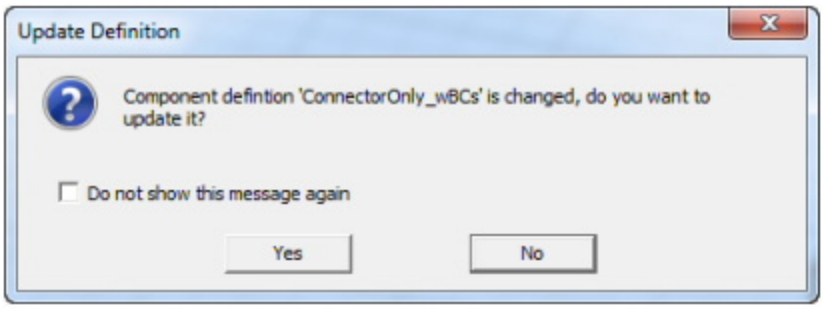
3. You can use **File>Save** to update the original component definition file. The **Update 3D Component** dialog will come after **File>Save**.

   The **Update 3D Component** dialog is populated with all entities - objects, boundaries, excitation etc. in the “component-edit” design. In addition, previous settings like reference coordinate system, component name, owner etc. from the **Info** tab, as well as encryption settings, are preserved. You can also select whether to **Update local definition** (for local editing) or **Update definition file at: <*path*>** to update the component library, which will affect other instances when updated.

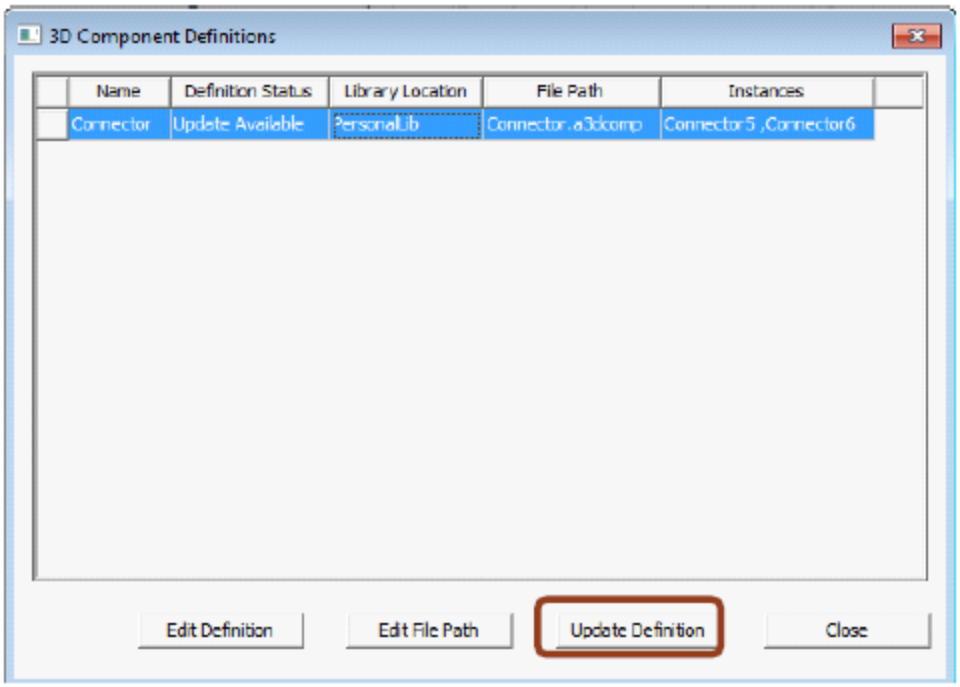


If you use **File/Save As** to save to a new component definition file, you also have the option to **Save As** Ansys Electronics Desktop file.

4. Once you have saved the updated component version, you can go back to the original design and update all the instances using that component. Note that update definition is not automatic even though component definition edit was triggered from that design. Instead when an assembly design becomes active, it prompts you to update the 3D component definition. You can then select to update the definition.



You can also open the 3D definitions window to select a component, and view the Definition Status column. If an update is available, you can select the component and click **Update Definition**.

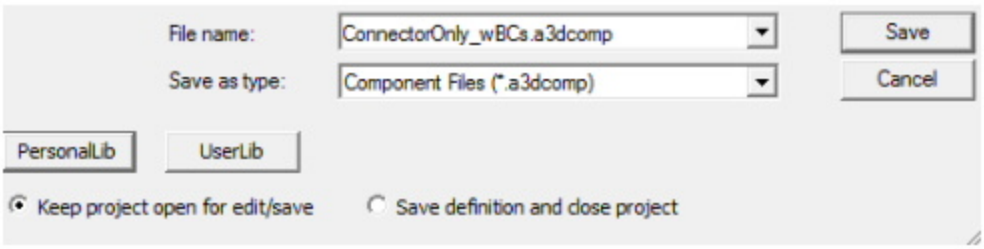


5. See Update 3D Component Definition

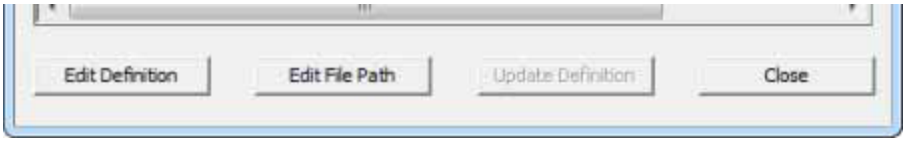
6. After editing is done, you also select the model and then use the **Create 3D Component** command.

   See Creating a 3D Component from an Existing Model.

   The component data is loaded from component definition file. The Info tab version automatically increments. Before saving, you have the option to **Keep project open for edit/save**, or **Save definition and close project**.

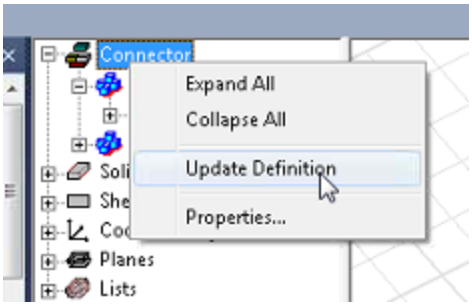


7. You can select **Edit File Path** to update the file path for component definition. This opens a browser window that lets you navigate your file system and select a file path to be used for the new component definition.

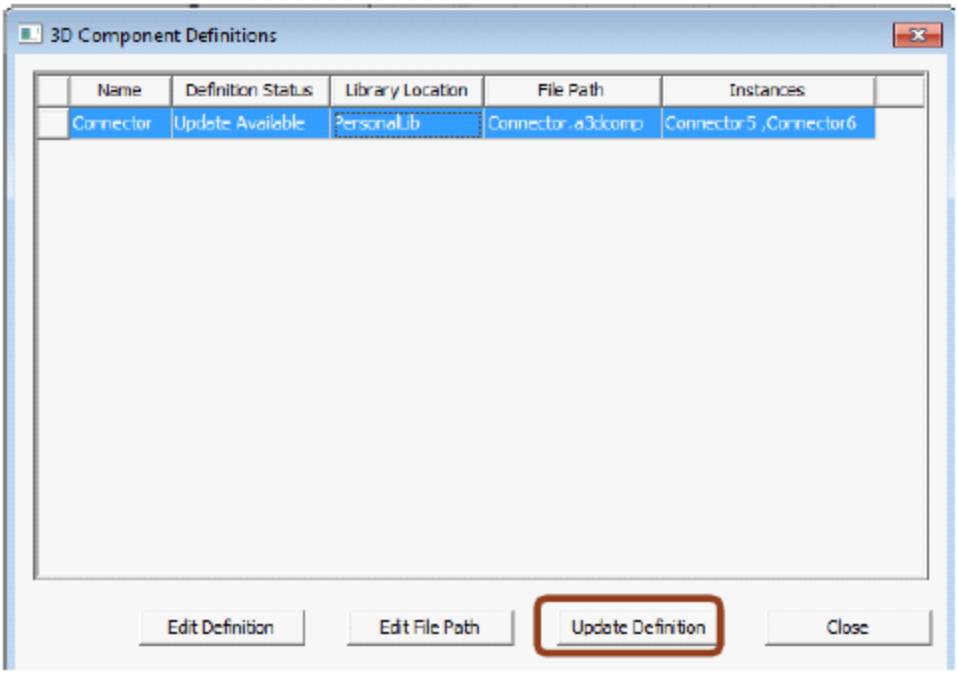


Updating 3D Component Definitions

If you create or obtain from a vendor a new version of a component, and then open a project that contained an earlier version of that component, you can right-click on the component in the History tree and select **Update Definition** to replace the older version of the component with the newer one This updates all the instances of the component using that definition. Update Definition is grayed out if a newer definition is unavailable.



You can also accomplish this by right-clicking on the 3D Component icon in the Project Tree and selecting Definitions from the shortcut menu. This displays a dialog listing available component definitions. The Definition status column lets you know if an undated definition is available.

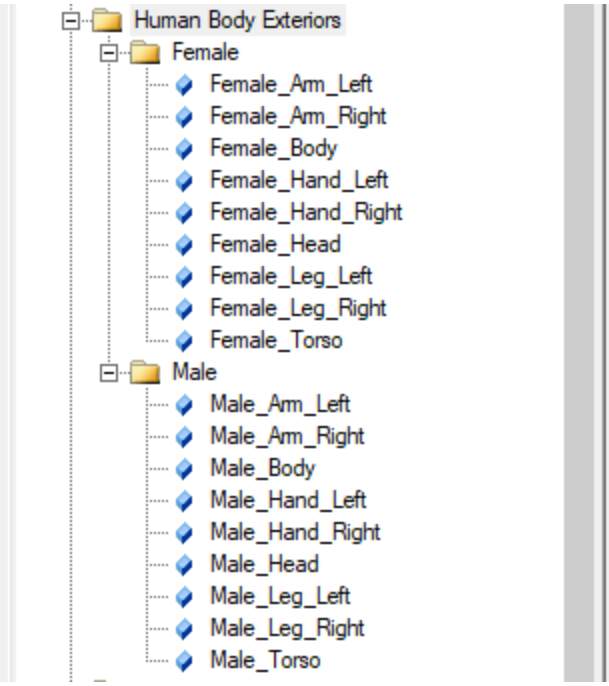


All instances and component operations in the design are updated

- Parameter values are preserved
- New parts are generated in all instances
- Deleted parts are deleted from all instances
- Edited parts are changed in all instances
- Design data, materials, coordinate systems can also be updated
- Undo is supported, command is scriptable
- Definitions dialog provides complete list of definitions in the design
- Definitions can be updated from the dialog

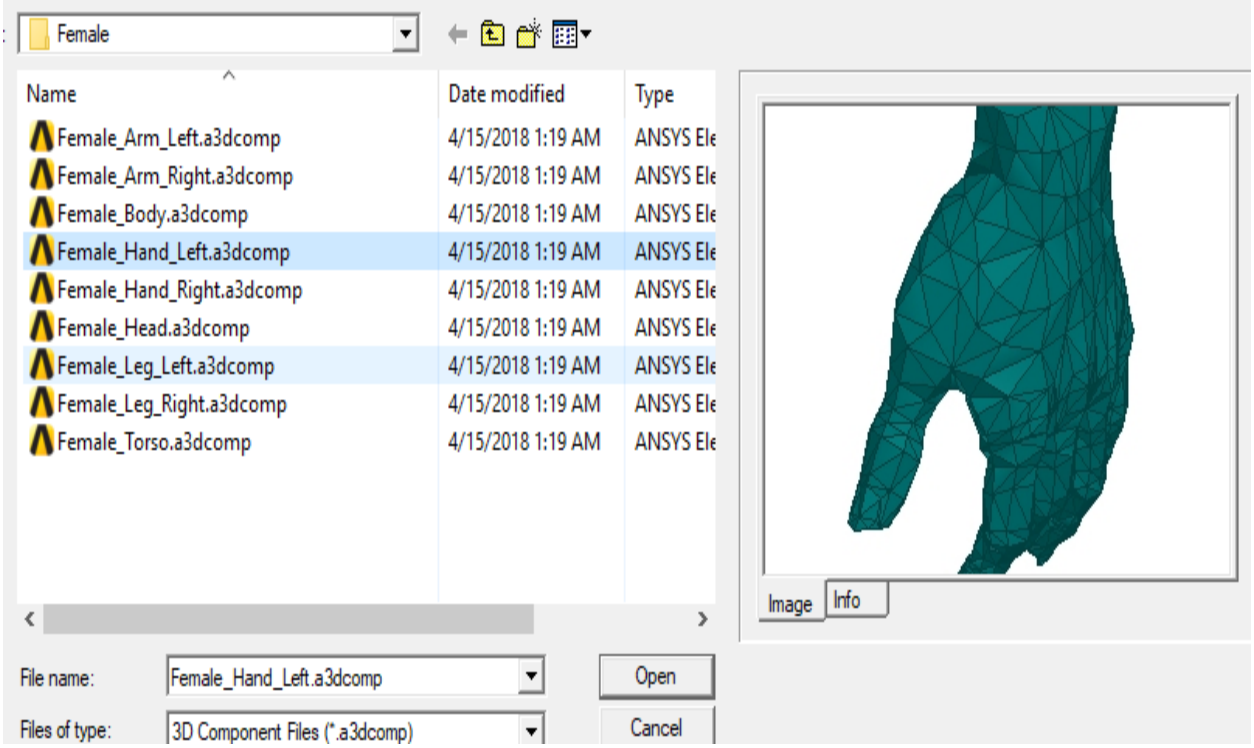
Human Body Exteriors

There are two ways to view the Human Body Exteriors in the 3D Component Libraries. If you have enabled **View** > **Component Libraries**, you can navigate to the different models in the tree. From the **Component Libraries** tree, you can drag and drop models to the **Modeler** window.

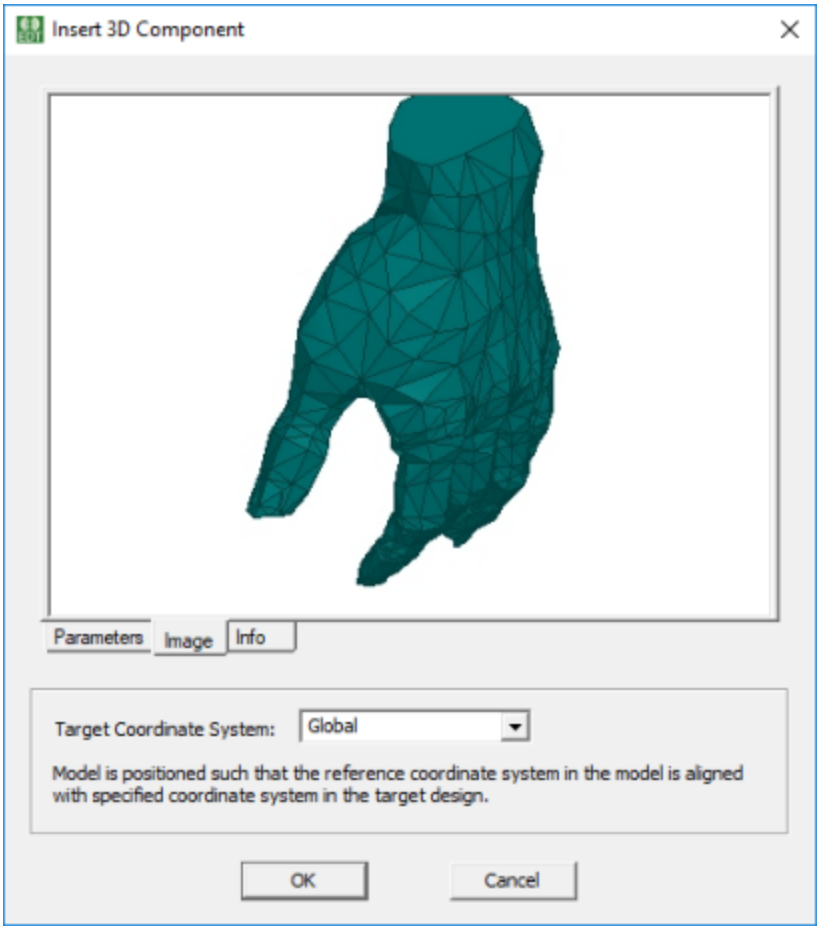


You can also access the **Human Body Exteriors** library using **Draw** > **3D Component Library** > **Browse...** to open the **Browse 3D Component** dialog. you then click **SysLib** to display the libraries included in your installation.

You can select from the Human Body Exterior models, and navigate the folders to select from available components. Once you have selected a Component file, you can view the Image and Info for that component.



You can click **Open** to display the **Insert 3D Component** dialog box. You can view the Image and Info tabs for that component. Human Body Exteriors do not have parameters.



You can also open the **Insert 3D Component** dialog by double-clicking on a model in the **Component Libraries** window. You can view the Image, and Info tabs for that component. See Inserting a Component into a Design.

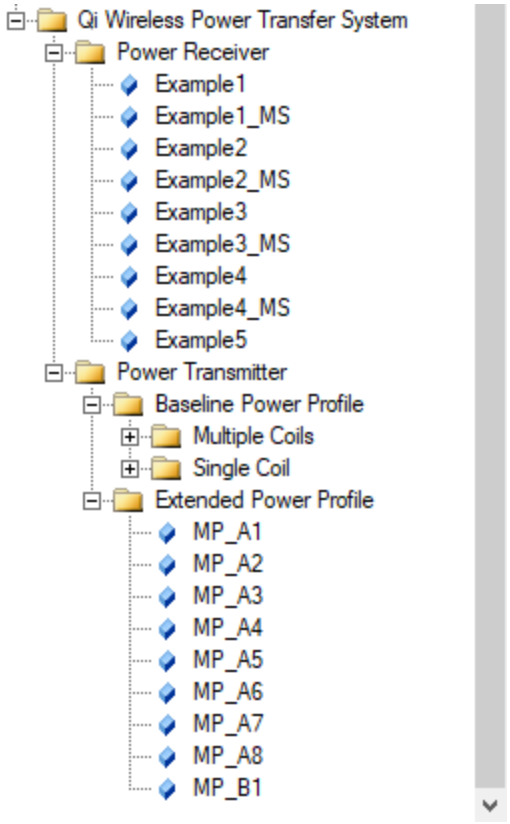
If you want to edit a 3D Component:

1. From Windows Explorer, copy and save the component design file to your PersonalLib or UserLib directory.
2. Do an update menu for 3D Components.
3. Open the component from the PersonalLib or UserLib directory and use edit mode for making modifications.

Qi Wireless Power Transfer System

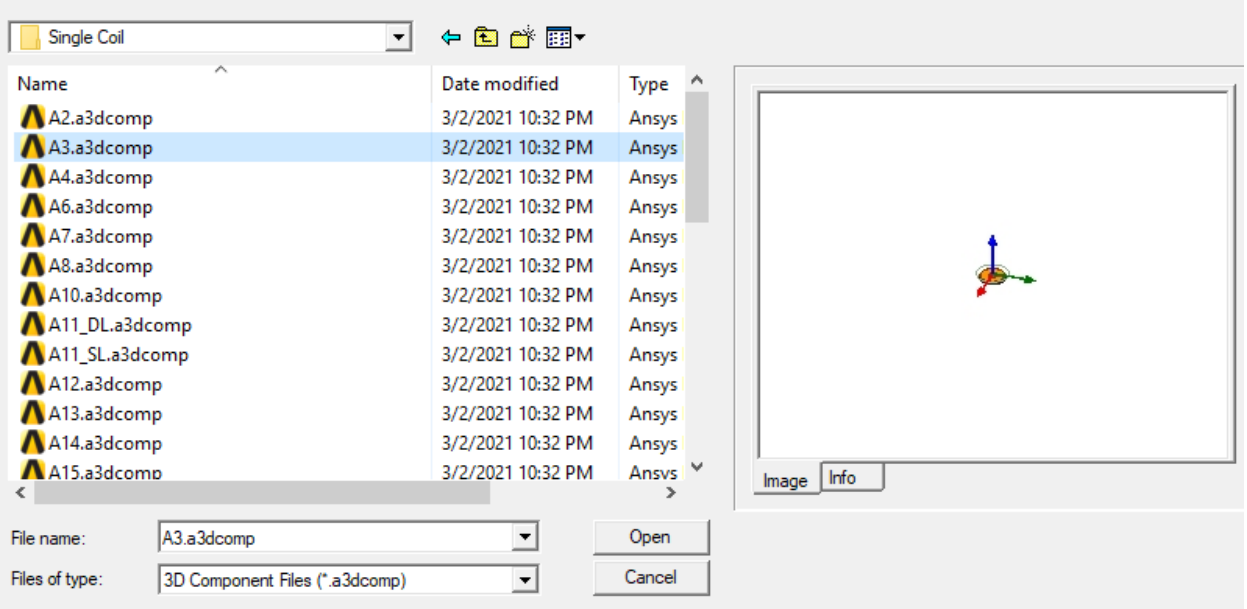
> **Note:** The Ansys models included in the Qi Wireless Power Transfer System 3D Component library are based on model specifications published by the *Wireless Power Consortium*.

There are two ways to view the Qi Wireless Power Transfer System components in the 3D Component Libraries. If you have enabled **View** > **Component Libraries**, you can navigate to the different models in the tree. From the **Component Libraries** tree, you can drag and drop models to the **Modeler** window.

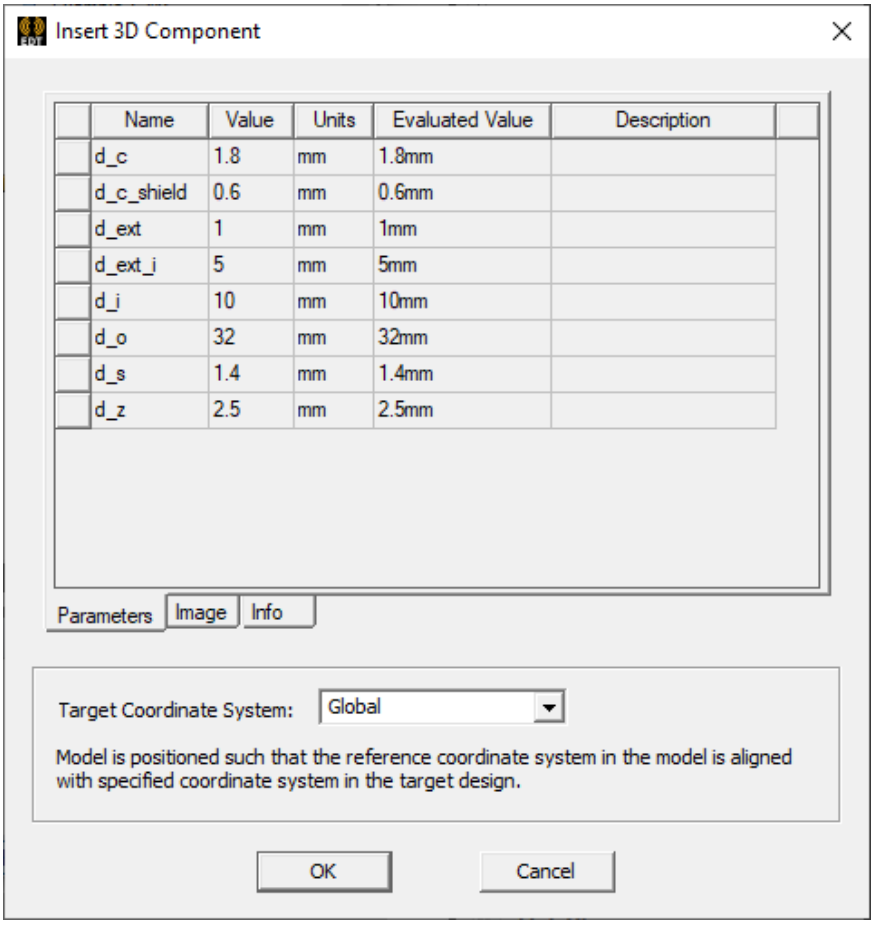


You can also access the **Qi Wireless Power Transfer System** library using **Draw** > **3D Component Library** > **Browse...** to open the **Browse 3D Component** dialog. You then click **SysLib** to display the libraries included in your installation.

You can select from the Qi Wireless Power Transfer System models, and navigate the folders to select from available components. Once you have selected a Component file, you can view the Image and Info for that component.



You can click **Open** to display the **Insert 3D Component** dialog box. You can view the Parameters, Image, and Info tabs for that component.



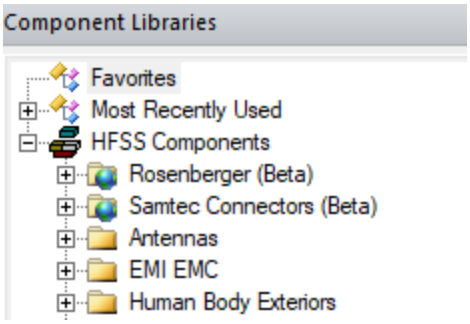
You can also open the **Insert 3D Component** dialog by double-clicking on a model in the **Component Libraries** window. (Refer to Inserting a Component into a Design.)

If you want to edit a 3D Component:

1. From Windows Explorer, copy and save the component design file to your **PersonalLib** or **UserLib** directory.
2. Open the component from the **PersonalLib** or **UserLib** directory and edit the component. (Refer to *Editing a 3D Component Definition*.)

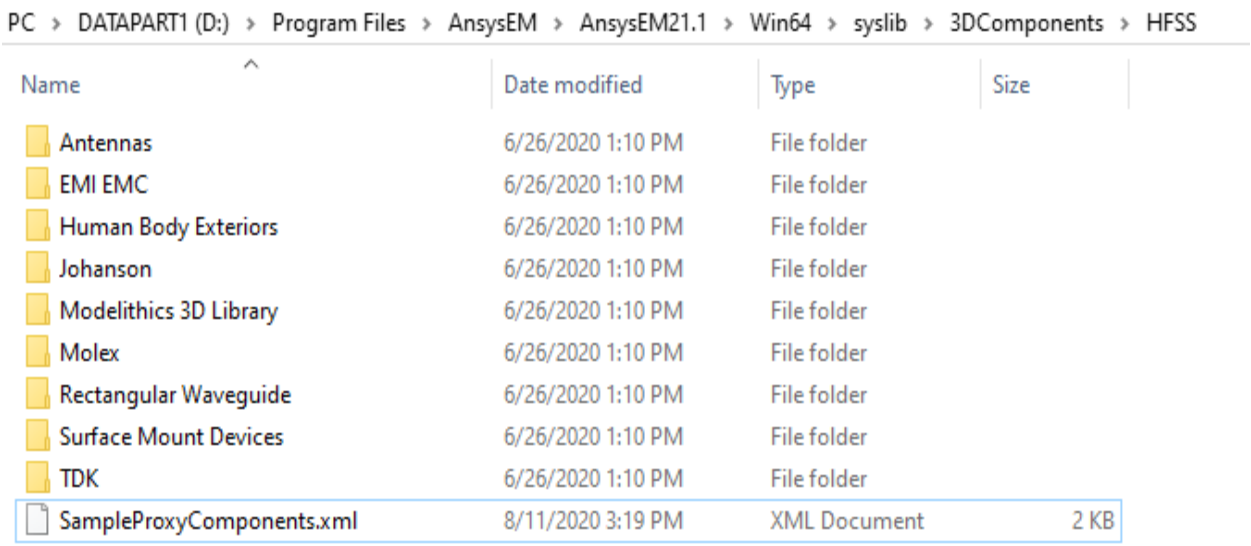
3D Component Agents: 3D Component Library

3D Component Agents is a feature that allows vendors to provide the information about 3D components that includes a link to their website for downloads. Such 3D Component Agents appear in the component browser along with other installed components, but shows them in a different color and with a globe icon or provide some other visual clue to indicate that these are different from components provided in the Ansys Electronics Desktop installation.



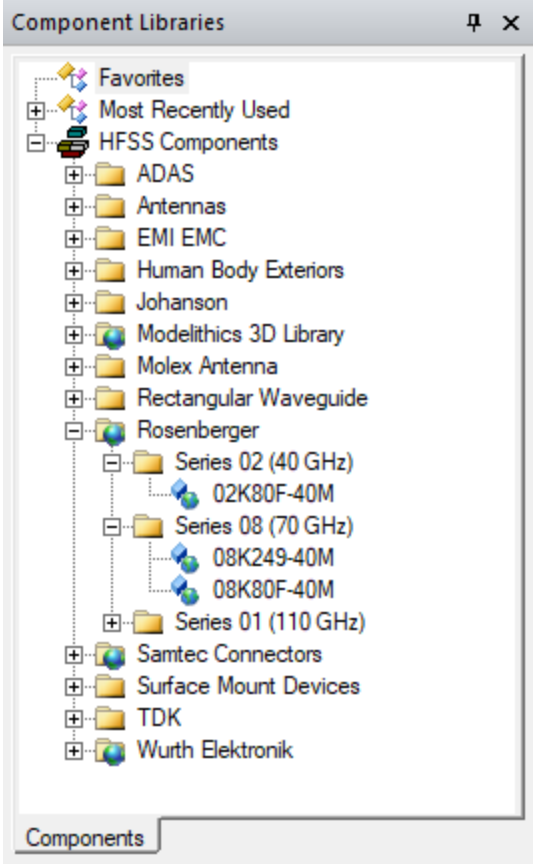
When you double click these 3D Component Agents, your default browser opens to a page with information about downloading the component. Dragging the proxy component into the editor window will do the same thing.

To view any 3D Component Agents, you must have a vendor-provided .xml file in the appropriate model directory:



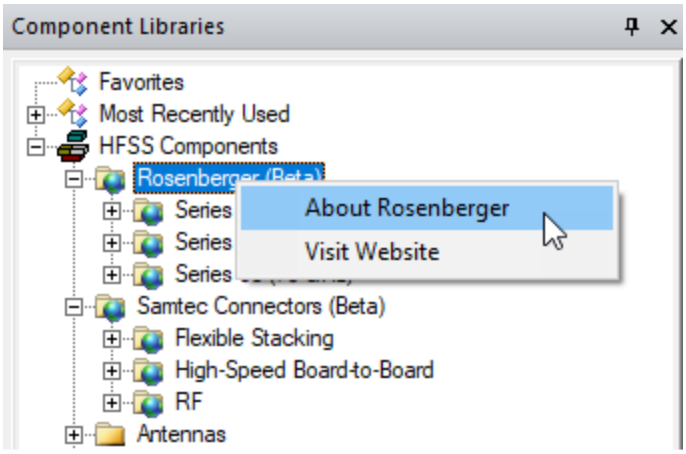
You can view 3D Component Agents in the 3D Component Library if you have enabled **View** > **Component Libraries**. You can see the **Component Libraries** window which will show available proxy libraries. Notice that folders for 3D Component Agents libraries have a small globe image overlaid on them, and the Agent components have a double icon (rectangle and circle) before the

name, rather than just a single blue rectangle.



Vendor Nodes of 3D Components Agent Libraries

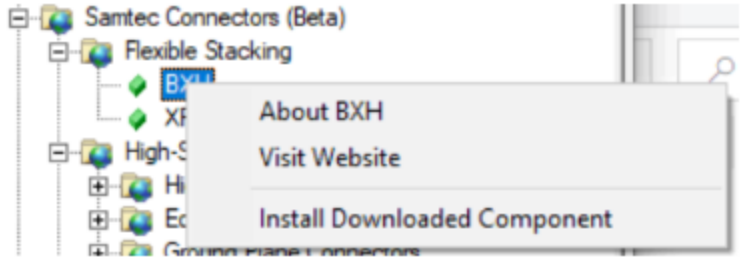
The vendors provide the name and other additional information such as part number, image, and so forth, for the 3D Components Agents, including the link to their website, and guidance for download, install, and organize them in a hierarchical folder structure just as the 3D components that are part of the installation libraries are organized. If you right click on the top node of a 3D Components Agent library, a menu lets you view information or visit their website.



- **About**: displays information about the whole group of components
- **Visit Website**: launch browser to website for whole group of components

3D Components Agent Node in Vendor Libraries

These nodes represent an individual proxy component.



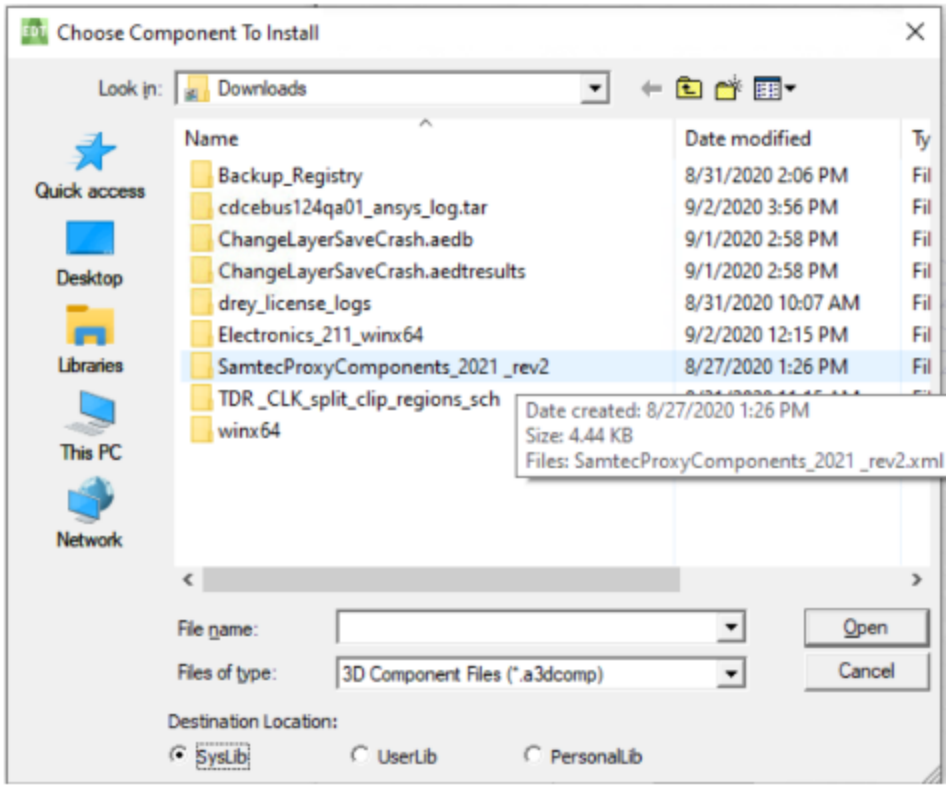
Right clicking on a component displays a menu with three items:

- **About**: displays information about the selected component
- **Visit Website**: launches browser to view information about the selected component, and possibly purchase/download the selected component.
- **Install Downloaded Component**: allows user to import the downloaded component into the component browser.

Installing Downloaded Components

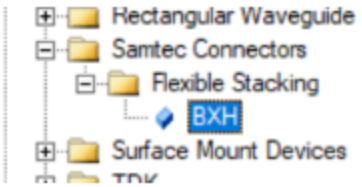
Once an agent has been purchased/downloaded, it needs to be installed into your component library. Right click on the Agent component node corresponding to the component you downloaded and choose **Install Downloaded Component**. Note: it is VERY important that you select the correct component node that corresponds to the component file that you downloaded or the component file may be installed as the wrong component.

When you click **Install Downloaded Component**, you will be shown a file browse dialog where you can choose the purchased/downloaded component file. See below.



You can also choose to import the component into your syslib, userlib, or personal directory.

Once the component file has been installed, it will now show up as a normal component that can be inserted into the design. See below.



You can drag and drop installed models from the **Component Libraries** window to the **Modeler** window.

Legacy Projects with 3D Components

Components created in earlier projects do not have the same degree of encapsulization and are not compatible with the current version of Maxwell.

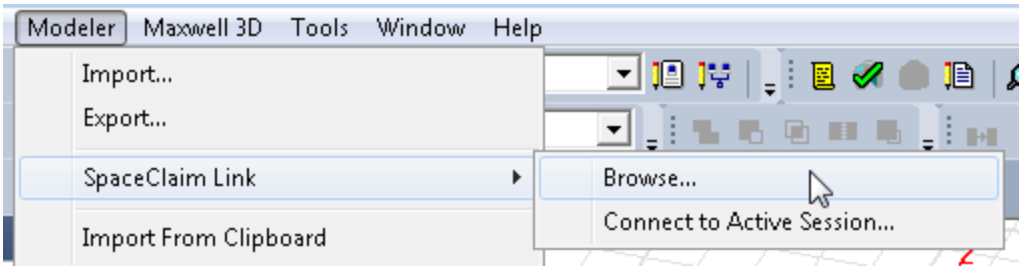
SpaceClaim Integration

Ansys Electronics Desktop can import geometry from a SpaceClaim document using the **SpaceClaim Link** feature. SpaceClaim Link can be used: if the SpaceClaim Direct Modeler (SCDM) is part of an Ansys installation that is of the same version as Ansys Electronics Desktop; or if a standalone installation of the SpaceClaim modeler exists on the same machine.

SpaceClaim Link is only available on Windows, and provides the following functionality:

Ansys Electronics Desktop can import geometry from the SpaceClaim modeler. To use **SpaceClaim Link** with Ansys Electronics Desktop, you must install the SpaceClaim modeler on the same Windows machine. SpaceClaim Link provides following functionality:

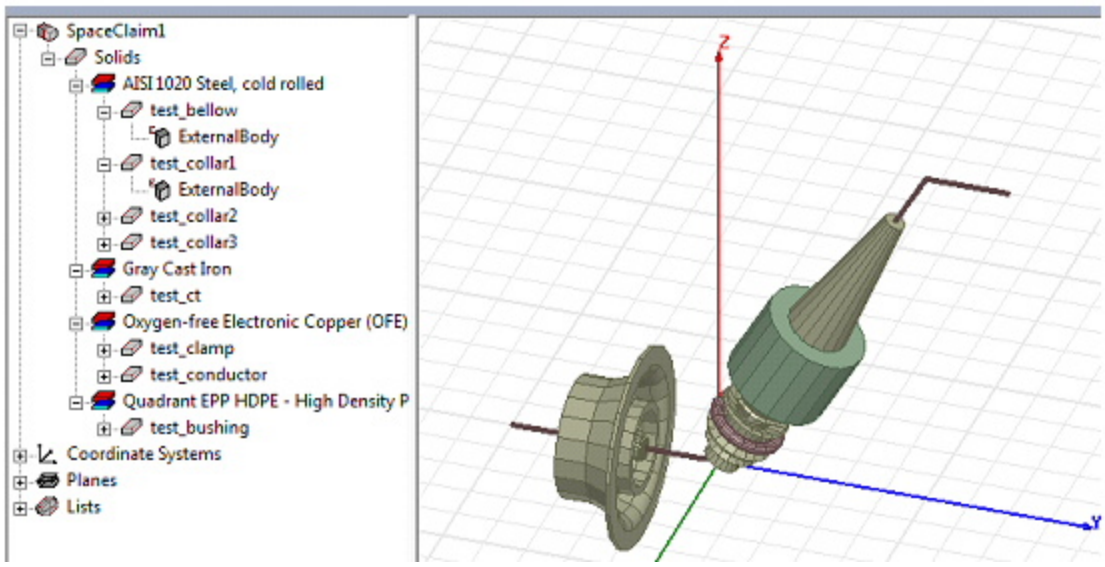
- Browse and select SpaceClaim documents to import geometry directly.
- Import geometry by connecting to a active SpaceClaim session.
- The SpaceClaim geometry is imported as a User Defined Model (UDM) along with geometry parameters with units, rendering attributes, and material assignments.
- For a SpaceClaim link for a UDM already in the design, you can launch a SpaceClaim session from AEDT and open the corresponding SpaceClaim document.
- A SpaceClaim document referenced by a SpaceClaim link UDM is included in project archive automatically.
- By option you can break a connection to SpaceClaim. In this case, all UDM parts are then converted to imported objects. This feature lets you use SpaceClaim just for its healing capacity.



Importing SpaceClaim geometry into Ansys Electronics Desktop

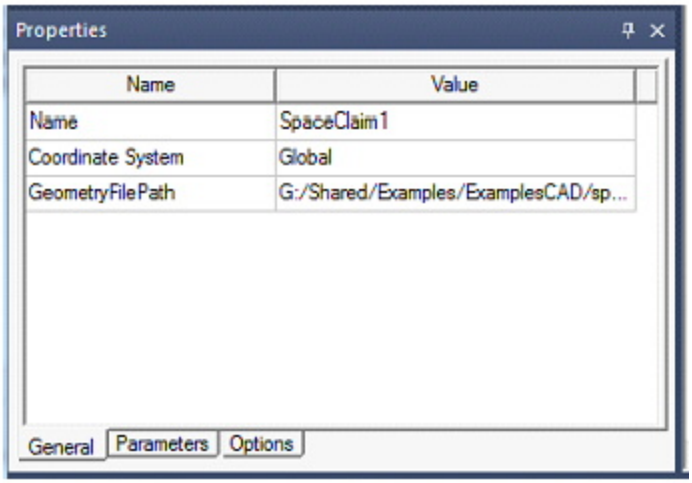
1. Click Modeler>SpaceClaim Link>Browse to open a file browse dialog.
2. Select a SpaceClaim .scdoc document file and import the geometry.

The imported geometry is shown in the History tree as a User Defined Model (UDM).

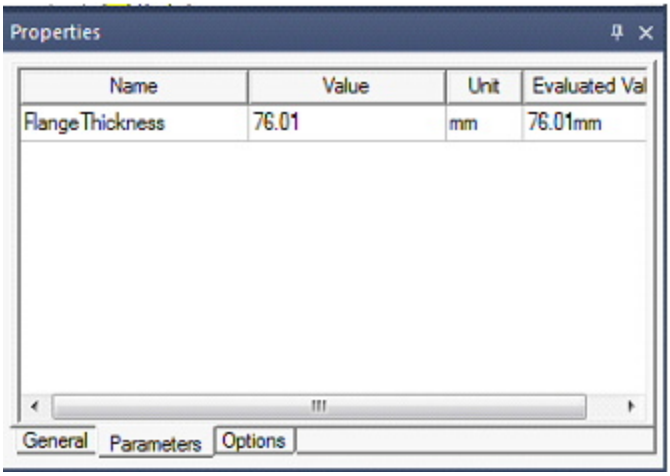


The Properties window of a SpaceClaim link UDM has 3 tabs.

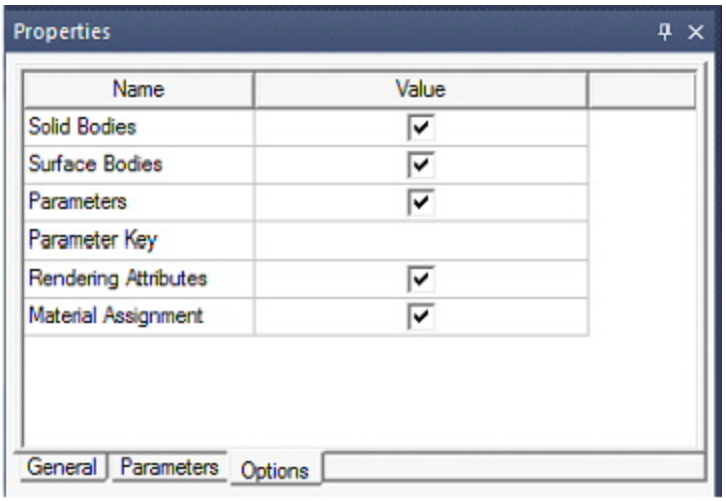
- The **General** tab shows general information such as SpaceClaim document path.



- The **Parameters** tab shows all parameters.



- The **Options** tab shows supported options.



Options Include:

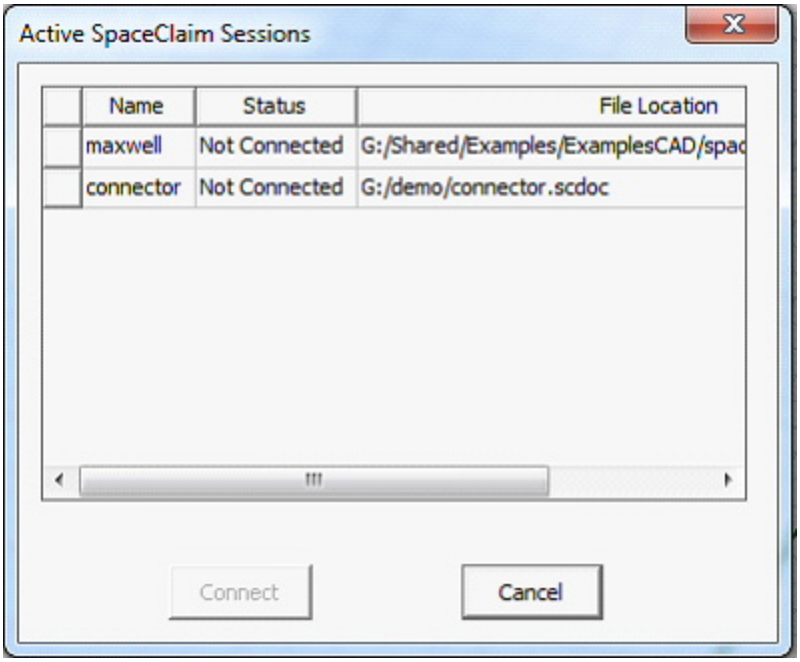
- **Import Solid Bodies**: Default is ON
- **Import Surface Bodies**: Default is ON
- **Impost Parameters**: Default is ON (It imports parameters).
- **Parameter Key**: A string that is used to filter out parameters. Default is no string - i.e. all SpaceClaim parameters will be imported.
- **Impost Rendering Attributes**: We import color of objects. By default the option is ON.
- **Import Material Assignments**: By default we import material assignment. Note that material properties are not imported. A material with exact name must already exist. Otherwise, validation issues a violation.

- **Import suppressed for physics objects**: By default, this is unchecked and objects suppressed for physics are not imported. If you check Import suppressed for physics objects option in the Property window for a SpaceClaim object, and you refresh the SpaceClaim link by "Send Params and Generate", suppressed objects are imported as non-model objects. Once imported, you can change them to model objects if desired.

Connecting to an Active SpaceClaim session:

If one or more SpaceClaim sessions are running on the machine, **SpaceClaim Link** can connect to them to import geometry directly.

When you click the **Connect to Active Session** menu item, Ansys Electronics Desktop opens a dialog showing all active SpaceClaim sessions, their document name and status.

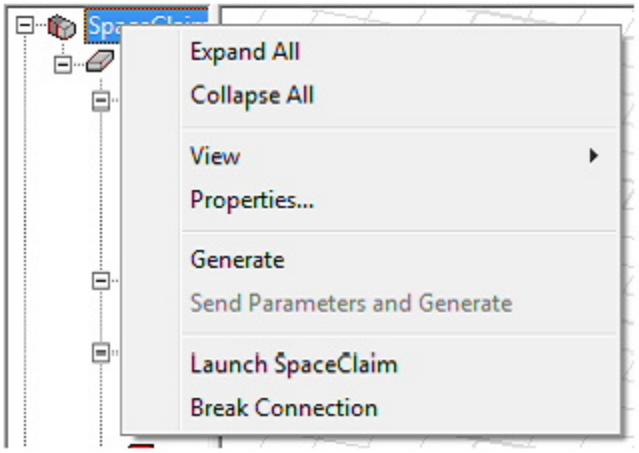


You can select a session with “Not Connected” status and press the **Connect** button to import geometry from that session. Once connected, that session is used to regenerate the corresponding SpaceClaim link UDM.

The dialog is empty if no sessions are running.

Launching a SpacClaim session from Ansys Electronics Desktop

The context menu of a SpaceClaim linked UDM shown in the History tree allows you to **Launch SpaceClaim** and to **Break Connection**.



When you select **Launch SpaceClaim**:

- If no SpaceClaim session is open, a new SpaceClaim session is opened, and the document corresponding to SpaceClaim link will be opened in it.
- If a SpaceClaim session is already open, the document will be opened in that session.

All refresh/regenerates of the linked SpaceClaim document use the session that is opened.

The session closes when Ansys Electronics Desktop closes.

Breaking Connection with SpaceClaim Link:

When you select the **Break Connection** command in the context menu of the SpaceClaim link UDM:

- Break Connection converts the UDM bodies to imported objects. The UDM will be removed.
- Any operation that you had performed on UDM bodies is preserved.
- Parameters of the UDM are lost. You lose the ability to create parametric variations with SpaceClaim parameters. Note that parameters for subsequent history operations on SpaceClaim parts will be retained.
- Attributes such as rendering attributes, materials, etc., are preserved.

Archive a Project containing SpaceClaim link

If you want to share a project with a SpaceClaim linked document with other users, you need to archive the project. Sharing the project file only is not sufficient because the SpaceClaim document is not included in the project.

- SpaceClaim documents corresponding to the link will be included in the project archive automatically.

- If any SpaceClaim document refers to other documents (e.g., an assembly document might refer to individual part documents), these indirectly referenced documents will also be included in the Ansys Electronics Desktop project archive.
- When an archive is unarchived, referenced SpaceClaim documents will be put in a “restored_files” subfolder in the project directory. All definition paths are updated to refer to the reference files in the “restored_files” folder.

Handling SpaceClaim document Save

When you launch a SpaceClaim session from Ansys Electronics Desktop or connect to a live session, whenever the project is saved, the SpaceClaim document corresponding to the SpaceClaim link UDM is automatically saved if any unsaved changes exist in that document.

If unsaved changes in SpaceClaim were not imported into Ansys Electronics Desktop before saving, they will be imported the next time that the SpaceClaim link UDM is regenerated.

You must ensure that the geometry in Ansys Electronics Desktop and that in SpaceClaim are in sync.

User Defined Model (UDM)

Model Analysis

For some models it may be beneficial to remove unnecessary small entities and to fix object misalignments to avoid potential mesh issues. Maxwell includes Model Analysis functions to help you evaluate models you have imported or created. Select **Modeler> Model Analysis** to see the menu options. Depending on the design and the current selection, some features may not be enabled. The menu includes the following commands.

- Analyze Objects
- Analyze Interobject Misalignment
- Analyze Surface Mesh
- Heal
- Show Analysis Dialog
- Align Faces

- Remove Faces
- Remove Edges

Note	Before running model analysis, you must remove all command history for the selected object by using the Purge History command. If you need to save the object history, save a separate copy.

1. After import, you typically perform validation check. This lets you focus on objects and object pairs that have errors and or warnings. The objects that fail should be analyzed by using the **Modeler>Model Analysis>Analyze Objects** menu item.
2. Select the objects and invoke **Modeler>Model Analysis>Analyze Objects**.

   This displays the **Analysis Options** dialog to allow you to specify settings for entity check level, and small feature detection.

   When you **OK** this dialog box, the initial analysis executes and the **Model Analysis** dialog is displayed.
3. Choose the objects that have "Invalid Entities Found" and **Perform>Heal Objects**.

   In most cases, the objects will be healed and the errors fixed.
4. If errors still persist, choose the edges and faces and click on **Delete**.

   This will replace the selected face/edge object by a tolerant edge/vertex respectively. In some cases the replacement of the face/edge by tolerant edge/vertex will fail.

When models pass the initial validity checks, mesh generation could still fail. The following errors can be present in models: (Refer to Detecting Errors.)

1. Non-manifold topology. These are non-manifold edges and vertices that are present in the model.

Note	One of the requirements for valid mesh generation is that the surface mesh must be ***manifold***, that is, a plot of all the surface triangles of a 3D solid object should not have any “holes.” Such a mesh is often referred to as a ***watertight*** mesh. If there is a hole and you were to fill the object with water, the water would leak out of that hole – the mesh would not be ***watertight***. Zero-area holes (often called cracks) will also “leak.” Having multiple triangles cover the same patch also results in a mesh that is not manifold. Refer to *Healing Models*, and the list of **Related Topics** below for information on detecting and correcting such errors.
2. Object pair intersection. This detects whether pairs of objects intersect.
3. Small feature detection – small edge length, small face area and sliver face detection.
4. Mis-aligned entities detection – detects pairs of faces from objects that can be aligned to remove object intersections. This improves the probability of mesh success.
5. Mesh failure error display. This is available for single object, object pairs and last simulation run (all objects in a model). Errors reported by the meshing module are reported to the user.

Errors of type 3 and 4 should be resolved before you invoke the meshing for the model.

By default, the **Heal** command is automatically applied to imported objects.

Analysis Options Dialog

To perform analysis on an object according to specified features and tolerance values:

1. Select the object you want to analyze and click **Modeler> Model Analysis>Analyze Objects.**

   This displays the **Analysis Options** dialog, with the **Analysis Options** tab selected. Selecting **Modeler>Model Analysis>Heal** also displays this dialog box. If, during **Modeler>Import...** you select **Heal Imported Objects** and **Manual** on the file browser dialog box, you also see this dialog.
2. If desired, check the **Perform Entity Check Errors** check box.

   This enables the **Check Level** menu. The setting can be **Basic**, **Strict**, or **Comprehensive**.
3. If desired, click the check boxes to enable and set the **Detect Feature** settings:
   - **Detect Holes**, and specify the Maximum Radius.
   - **Detect Chamfers**, and specify the Maximum Width.
   - **Detect Blends**, and specify the Maximum Radius.
4. If desired set the **Detect Small Entities** features and tolerance values.
   - **Small Edges**, length less than
   - **Small Faces**, area less than
   - **Sliver Faces**, which enables:
     - Object Bounding Box Scale Factor
     - Sliver Edge Width
5. Click the **Properties** tab to see a listing of the geometric properties of the selected object.
6. Clicking **OK** on this dialog displays the **Model Analysis** dialog which contains the results of the analysis.

Analyzing the Surface Mesh

To set the options to analyze the surface mesh:

1. Select an object of interest.

   This enables the Analyze Surface Mesh command in the menu.
2. Click **Modeler>Model Analysis>Analyze Surface Mesh**.

   The **Surface Mesh Analysis Options** dialog box appears. This dialog box allows you to set parameters to remove.
   - You can also open the **Surface Mesh Analysis Options** dialog box from the **Model Analysis** dialog box via the **Perform** pull-down menu on the **Objects** tab.
3. Select or clear the **Perform Object Pairs Analysis** check box. Selecting this option evaluates the mesh for all combinations of the selected objects.
4. Select or clear the **Ignore Objects Separated by greater than** check box, and enter a value in the text box. Selecting this option means that object pairs are disregarded from analysis if their separation is greater than the specified value.
5. Click **OK** to perform the analysis with the selected options.

   The **Model Analysis** dialog box appears, displaying the results of the analysis.

Objects Tab

All results relating to model analysis of specific objects are presented under the **Objects** tab. The **Objects** tab for the **Model Analysis** dialog lets you view the following information:

1. The results table contains the following information.
   - **Name** – column listing the objects in the current design.
   - **Last Analysis status** – column giving the analysis status of the listed objects. Objects can have the following status:
     - **Good** – the object contains no invalid geometry entities given the tolerance values specified in the **Analysis Options** dialog.
     - **Null Body** – the object is non-existent.
     - **Analysis not performed** – the object was not selected for analysis.
     - **Invalid entity errors** – these are api_check_entity() errors and non-manifold errors which must be fixed prior to meshing.
     - **Small entity errors** – small faces, sliver faces and small edges that are optionally detected based on the tolerance limits specified in the **Analysis Options** dialog.
2. Select any object name in the table which contains errors to display a set of radio buttons in the panel and a list of corresponding faces, edges and vertices.

Note	**Auto Zoom to Selection** – if this option is checked, the modeler automatically zooms to the item selected in the **Model Analysis** dialog box.

3. Select the face, edge or vertex entity from the list to view the error description in the **Description** field.
4. Select the **Delete** button if you want to remove a selected face or edge entity.
5. Select the **Perform** button to list the commands that you can execute on the selected objects in the Results table.
   - **Heal Objects -** repairs invalid geometry entities for the selected objects within the specified tolerance settings. The **Healing Analysis** dialog will appear.
   - **Analyze Objects** – evaluates the object status. Selecting this displays the Analysis Options dialog.
   - **Analyze Surface Mesh** – invokes a mesh for each selected object and reports analysis results under the **Surface Mesh (Single/Pairs)** tab. Selecting this option displays a dialog with radio buttons to select.
     - Perform Object Pairs Analysis - evaluates mesh for all combinations of the selected objects.
     - Ignore objects separated by greater than a specified value - object pairs are disregarded from analysis if their separation is greater than the specified value.
     - Click **OK** to perform the analysis with the selected options.
   - **Analyze Interobject Misalignment** – determines any misalignments between two selected objects in the results table. The results are reported under the **Objects Misalignment** tab.
   - **Display Healing Log** – checking this causes the **Model Analysis** dialog to display a healing log which includes information about operations performed on an object during the healing process.

Set Material Override

Objects Misalignment Tab

The table in this panel displays results of an **Interobject Misalignment** analysis. All misaligned face pairs corresponding to the analyzed objects are listed in the table.

- **Align Faces** – select a face pair in the table and click the **Align Faces** button to align selected faces.
- **Clear All Analysis Data** - this button removes all information from the tables.
- **Auto Zoom to Selection** – if this option is checked, the modeler automatically zooms to the item selected in the table.

After validation check is performed, the pairs of objects that intersect are chosen for analysis. Use the analysis results to find whether objects have faces that can be aligned.

Choose all the bodies that intersect with another body.

1. From the **Model Analysis** dialog choose perform/Analyze Interobject misalignment. Or you can run **Modeler>Model Analysis>Analyze Interobject Misalignment**.

   If the analysis finds object pairs that can be aligned, they will be displayed in the **Objects Misalignment** tab.
2. You can select individual or multiple rows and perform Align Faces. In some cases, face alignment will fail if the topology of the body changes by a large factor after alignment.
3. Identify individual bodies and body pairs that fail to mesh.
4. Perform Mesh analysis on individual objects and object pairs.
5. Review the reports and fix the errors.

Set Material Override

Surface Mesh (Single/Pairs) Tab

The panel displays the results of a surface mesh analysis.

1. You can display results for:
   - Individual Objects
   - Object Pairs

Note	**Auto Zoom to Selection** – if this option is checked, the modeler automatically zooms to the object or object pair selected.
2. The results table contains the following information:
   - Object - column listing object name or a pair of object names.
   - Last Analysis Status - column stating the meshing status of the object or object pair.
     - Mesh Success
     - Mesh Failure
   - Error Type - this column gives the category of error that caused the mesh failure.
   - Error Detail - provide specific geometry information regarding mesh error location.

   Display options include:

- **Display Mesh Analysis** log check box -checking this displays further details concerning each error to be listed.
- **Auto Zoom to Selection** – checking this causes the modeler to automatically zoom to objects or faces corresponding to the error.

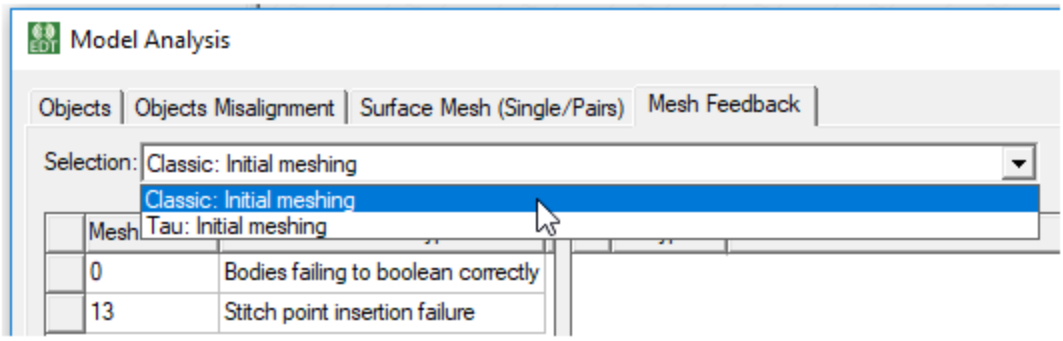
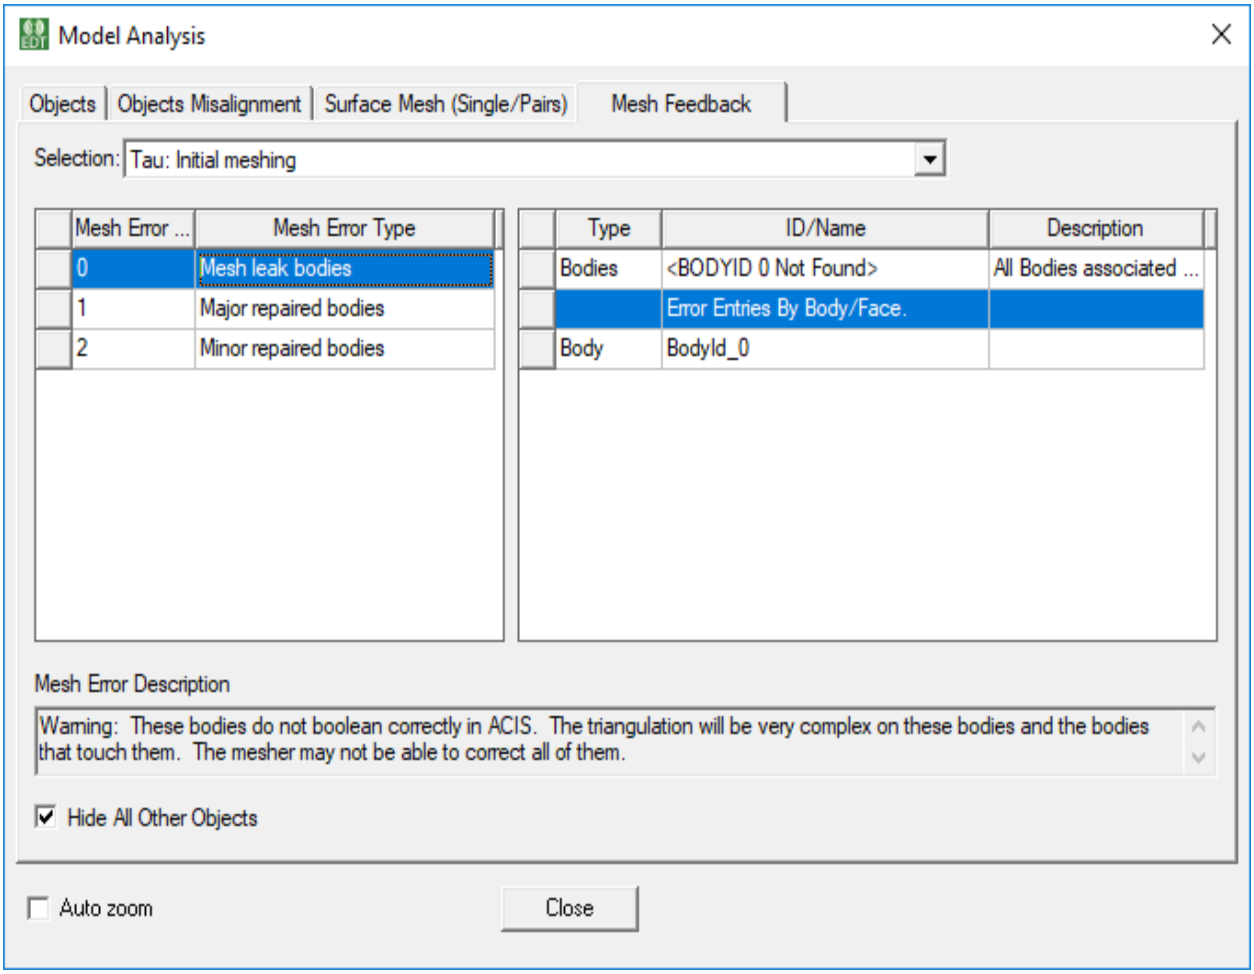
Mesh Feedback Tab

The tables in this panel lists all model errors as viewed by the mesher. If the project has solutions by different solvers, the **Selection** drop down lets yous select which to view.



The left side table has columns for Mesh Error Serial ID and Error Type.

- Mesh Error Serial ID - the 0 item is the body with which the subsequently listed entries are associated.
- Error Type - this column gives the category of error that caused the mesh failure, for example, Non-Manifold Edge, or Point Insertion Failure.



The display in the table on the right side of the **Model Analysis** dialog box depends on your selections from the left hand table. When you select a row in errors panel (the left panel as shown in above figure), all the faces are selected (second row in right panel) and if you enable **Auto Zoom**, the view fits to the errors:

- Type - whether the error applies to Bodies, Faces, or Triangles. If you select a particular error type, the columns for Type, ID/Name and Description are filled in.
- ID/Name -- the object name or object ID for the error type.
- Description -- the first three rows are for Bodies, Faces, and mesh Triangles. Subsequent rows, are of Error Entities By Body.Face.

The **Mesh Error Description** field describes error message describing the nature of the selected Mesh Error Serial ID, the implications, and provides a recommended response.

Display options include:

- **Display Mesh Analysis** log check box -checking this displays further details concerning each error to be listed.
- **Auto Zoom to Selection** – checking this causes the modeler to automatically zoom to objects or faces corresponding to the error.

Use of these selections let you more easily view and respond to the errors. If you enable **Auto Zoom**, any selection whether it is body(ies), face(s) or error triangle(s) or error segment(s) will fit to view. If all the faces are also selected (second row in right panel), then errors and selected entities will fit to view.

Focusing only on the errors when an error is selected in right panel, improves visualization of these meshing errors and provides you with precise information in order to take corrective action quickly.

Mesh Error Markers

As shown above the mesh errors are marked by red circles. The following table describes all such markers:

	Mesh errors
	Mesh warnings
	Mesher information
	Selected Faces

These markers are located at the center of errors or center of faces and their size correspond to the maximum side size of the entity, such as error triangles, error segments or faces. The size of these markers is clamped to a maximum and a minimum size. Additionally they have some transparency. The size and transparency of these markers cannot be changed by the user.

If many individual faces are selected in the right panel, each face is marked by a blue square. To find which blue square corresponds to which face in the right panel in the dialog box, click on the blue square. This action selects the corresponding face row in the right panel of the dialog box.

Face Selection

When the all faces row or individual face rows are selected, the Modeler selects the face(s). This enables the face related commands in the Modeler window. Also when you select faces this way, it makes the corresponding bodies of the selected faces visible, even when **Hide all other objects** is enabled. This provides some contextual information about the face location with respect to its body.

Multiple Selection of Mesh Errors

You can select multiple rows in the right pane of the **Mesh Feedback** tab. To view all the meshing errors, select all the rows and enable **Auto Zoom**. With **Auto Zoom** enabled, the view fits to all the errors, providing an overview of all the mesh errors. Also, when multiple errors are selected, right panel shows the merged information about all bodies, faces, error triangles etc. The **Mesh Error Description** text box shows description of all the errors.

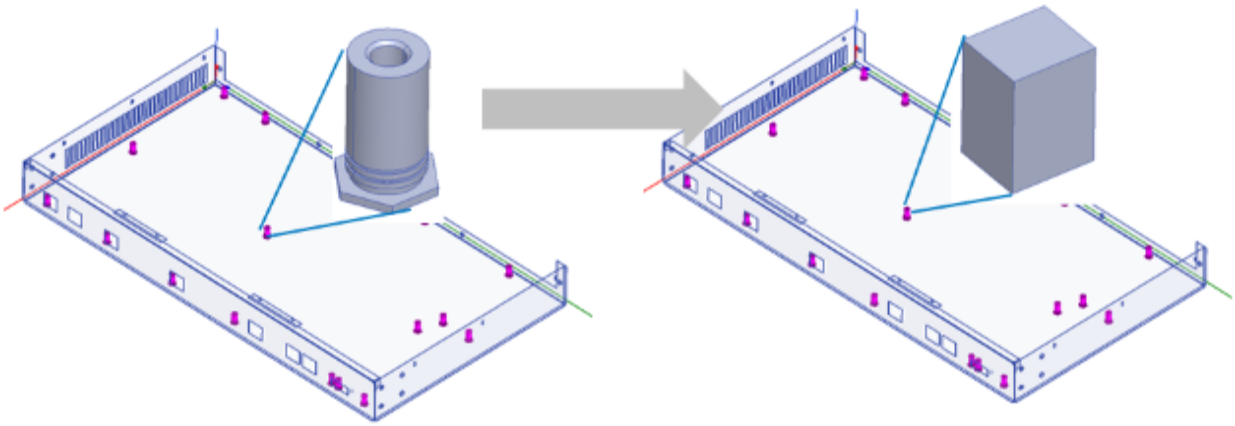
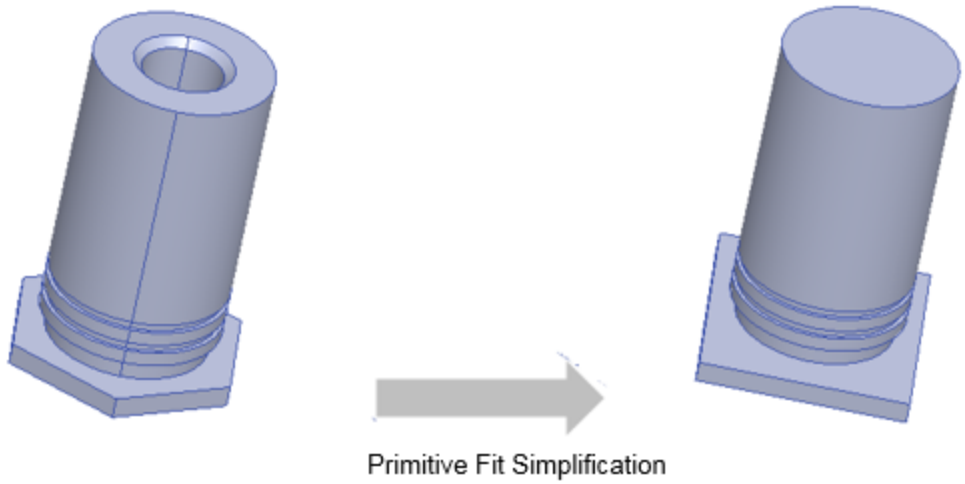
Modifying Objects
Drawing Objects

Simplify Command

Use the **Modeler>Model Preparation>Simplify** command to converts a complex MCAD object into simpler primitives which are easy to mesh and solve. The operation can be applied on any selected object and not just imported objects. You can specify the type of simplification as Bounding Box, Primitive Fit, or Polygon Fit.



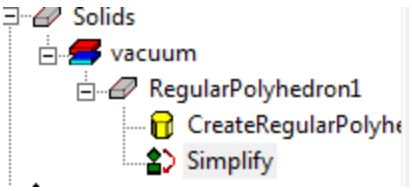
Bounding Box Simplification



Primitive Fit Simplification

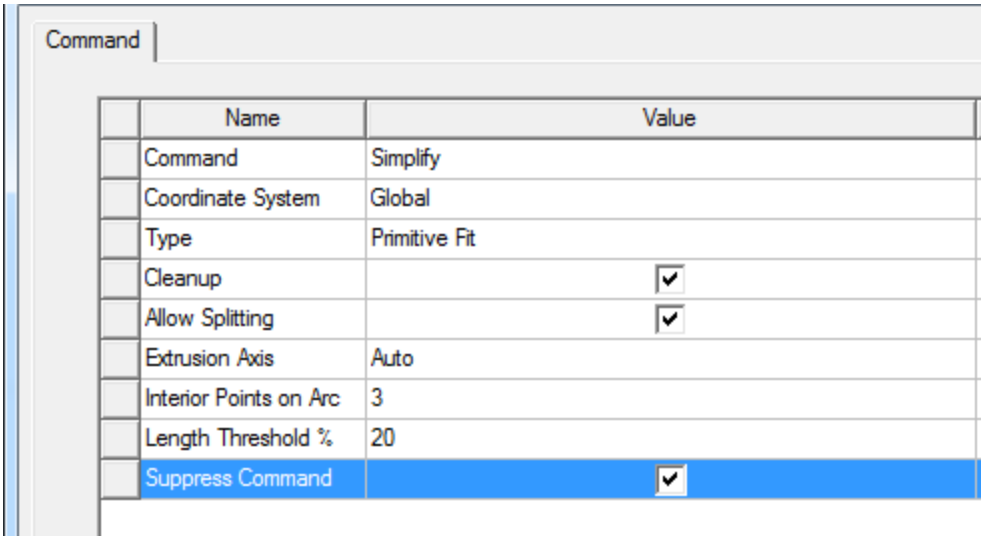
Polygon Fit Simplification

The History tree shows the **Simplify** command as being applied to the object.



Any parameters you specify in the dialog you can also edit in the Properties dialog for the History tree **Simplify** command to get a different simplification. The properties display in the docked properties includes only the parameters that are used by your currently selected **Simplify** command type. None of the parameters of simplify operation accept variables. If you right-click on Simplify for a project that was created for an earlier version, the menu displays and option to

Upgrade version. After an upgrade, the option not longer appears. The Properties dialog for the Simplify command allows you to suppress the command.



1. Select an object.

   This enables the Simplify command on the **Modeler>Model Preparation** submenu.

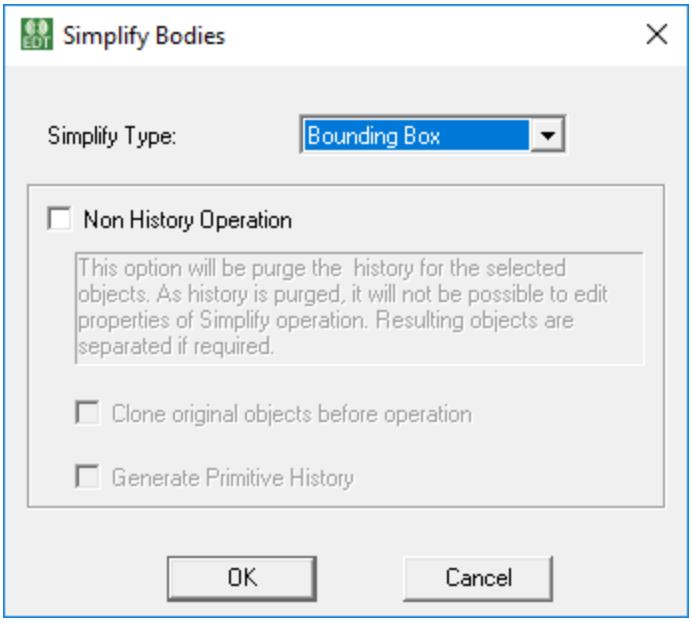
2. Click **Modeler>Model Preparation>Simplify**

   This opens the **Simplify Bodies** dialog box. A drop down menu lets you select the degree of simplification, from Bounding Box, Primitive Fit, or Polygon Fit.

   Bounding Box Simplify Type

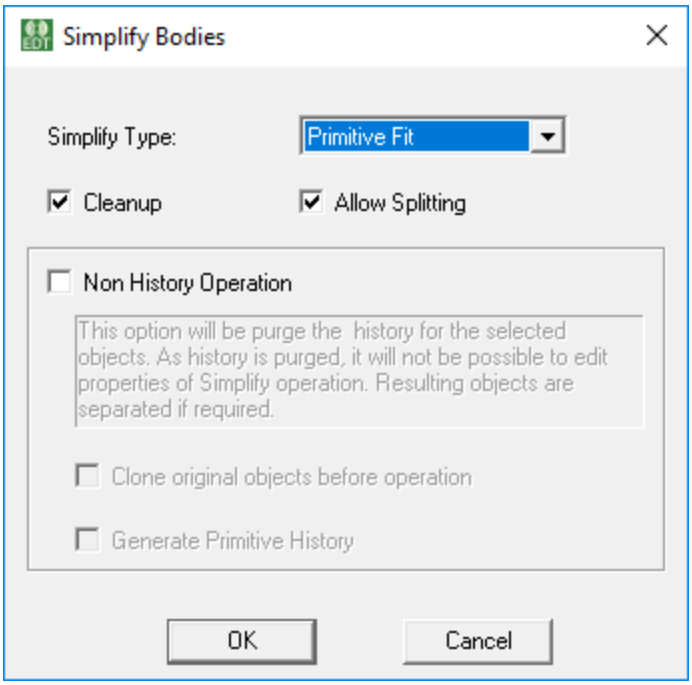
   If you select Bounding Box as the Simplify Type, there are no additional parameters. The object is replaced by its exact bounding box as computed in operation's coordinate system. You can change the operation CS to get a bounding box in an appropriate orientation.For

the **Non History Operation** options, see below.



Primitive Fit Simplification

For Primitive Fit simplification the object is replaced by a set of primitives shapes like Prism, Cylinder, Cone and so forth. This simplification type typically produces the simplest geometry with highest number of primitives. Primitive fit has the following options: Cleanup and Allow Splitting. For the **Non History Operation** options, see below.

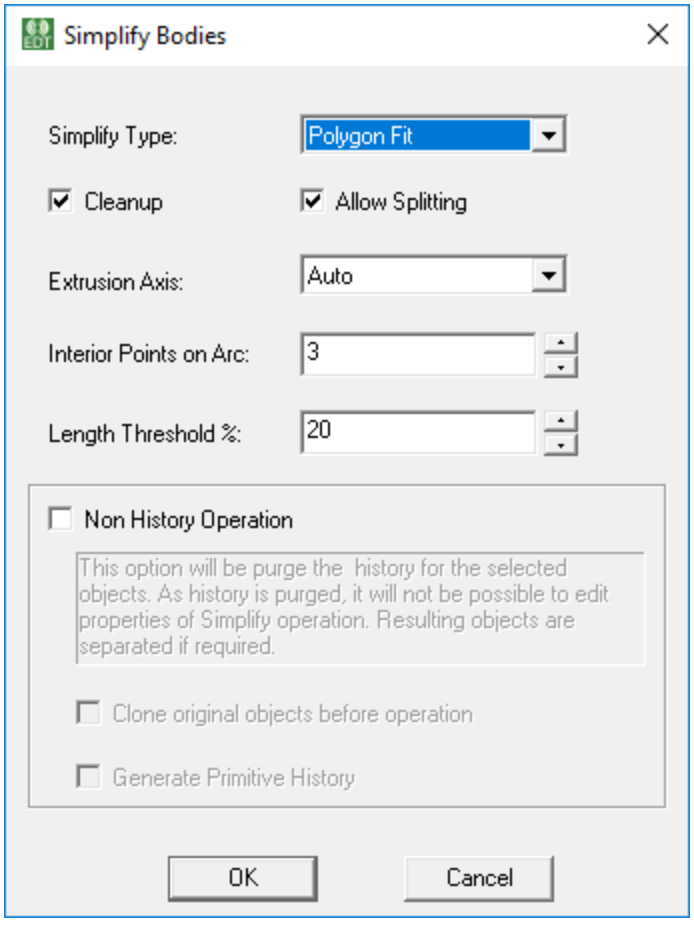


For Primitive Fit, the parameters are:

- Whether to Cleanup - This option allows you to clean the model before performing simplification. Cleanup include removing small features like rounds, fillets, chamfers in a solid body. It is recommended to set this option to get more simplified result.
- Whether to Allow Splitting - This option controls if object should be split during during simplification. If this option is selected, complex object will first split into multiple pieces and each piece will be further simplified. Setting this option will result in an object which will match more closely with original object. It is recommended to set this option.
- For the **Non History Operation** options, see below.

Polygon Fit Simplification

For Polygon Fit simplification, the object is replaced by set of polygon swept along normal and other primitives like box and cylinder. This simplification type typically produces geometry closest to original object with highest number of primitives. If you select Polygon Fit as the Simplify Type, the parameters are Clean Up, Allow Splitting, Extrusion Axis, Interior Points on Arc, and Length Threshold. For the **Non History Operation** options, see below.

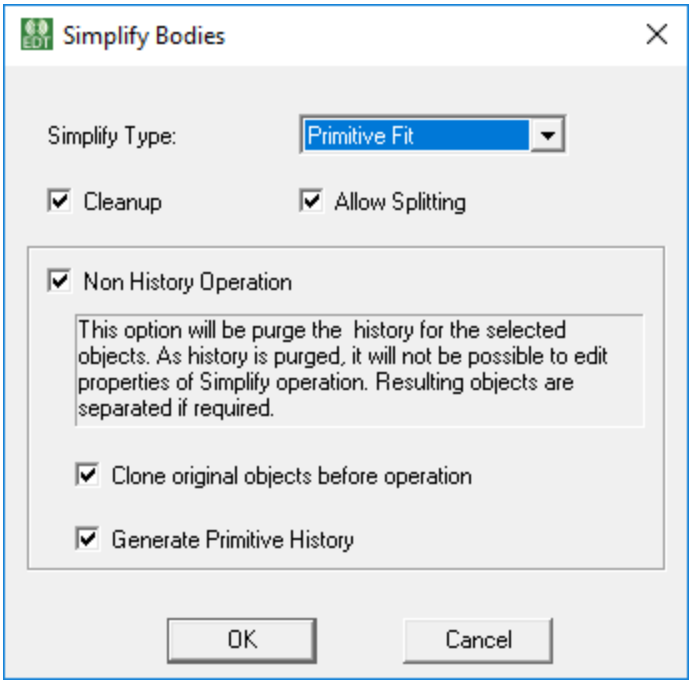


For Polygon Fit, you specify parameters for

- Whether to Cleanup - This option allows you to clean the model before performing simplification. Cleanup include removing small features like rounds, fillets, chamfers in a solid body. It is recommended to set this option to get more simplified result.
- Whether to Allow Splitting - This option controls if object should be split during during simplification. If this option is selected, complex object will first split into multiple pieces and each piece will be further simplified. Setting this option will result in an object which will match more closely with original object. It is recommended to set this option.
- Extrusion Axis, whether Auto selected, or X, Y, or Z. - This option specified a normal plane in which polygon profile is looked for. The default is Auto which allows an algorithm to determine best possible plane for polygon profile. You can specify a axis to help the algorithm, particularly when there is a draft or chamfer in the extrusion direction. The polygon profile is then swept in the extrusion direction.
- Interior Points on Arc - This specifies number of interior points created when a curve on the polygon profile is represented by line segments. The range is 1 to 100 with default being 3. Total number of points used to represent a curve is 5 when number of interior points is 3. This number specifies the maximum number of interior points to add. The number of points added could be less if the Length Threshold is already met.
- Length Threshold % - This specifies the length of edge as percentage of maximum length of an edge in the profile. It is specified as percentage of maximum edge length. If length of edge is more than the specified threshold, more interior points are added until the number of “Interior Points on Arc” is met.
- For the **Non History Operation** options, see below.

Non History Operation Options

The Non History Operation options are available for all Simplify Types.



With this option selected, the input body is simplified into multiple primitives (or polygon shapes) and a new part is created for each simplified shape. This option also purges the history of original part and it is not possible Edit Properties of the Simplify operation. You can choose to clone original object before simplification to retain history of original part. You can also choose to generate a primitive history.

Simplify result with separate bodies option

Use of Coordinate System

By default, the current working CS is used as the Simplify operation CS, but you can also change operation CS through the **Simplify** command property window or Property dialog.

Related Topics

Healing

Heal

The **Heal** command provides a way to correct geometric violations and to remove specific kinds of small features. When models are imported, two types of errors can occur – geometry errors and topology errors. Geometry errors are errors in definition of the underlying geometry while topology errors are errors in how the underlying components like faces, edges and vertices are connected. Ansys recommends that these be fixed before you invoke mesh generation.

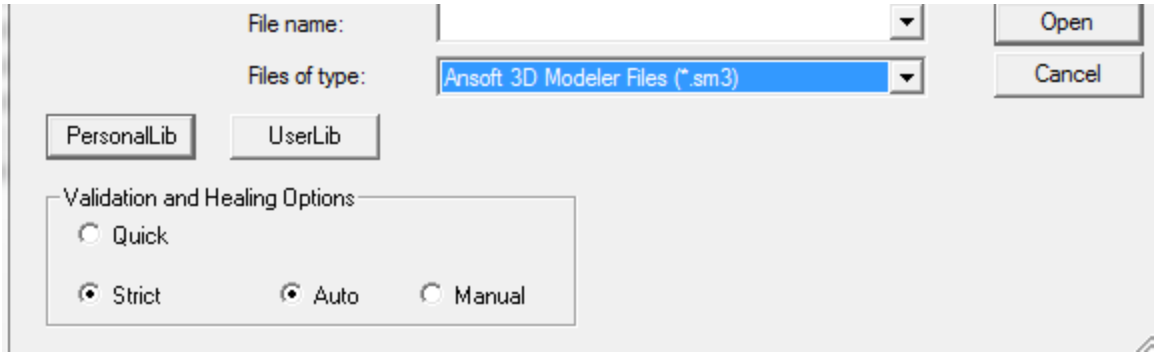
Imported objects which have only one operation on the history tree, can be healed. (Use the Purge History command to remove unwanted history operations before using **Heal**.)

Note	If you need to save the object history, save a separate copy for that purpose before you heal the object.

Healing can be invoked in different ways.

- The menu command **Modeler>Model Preparation>Heal** command applies to a selected object.
- Some formats permit healing during **Modeler>Import**. These are: 3D Modeler file (*.sm3), SAT file (*.sat), STEP file (*.step,*. stp), IGES file (*.iges, *.igs), ProE files (*.prt, *.asm), CATIA (*.model, *.CATpart), and Parasolid file (*.x_t, and *.x_b).

Selecting any of these formats enables a check box at the bottom of this window, "**Validation and Healing Options**."



See this table for details. The **Quick** option allows you to switch off healing to speed up the import process.

- The **Model Analysis** dialog that appears after running **Modeler>Model Analysis>Analyze Objects**, or **Modeler>Model Analysis>Show Analysis** dialog includes a **Perform** action menu with **Heal Objects** as a selection.

Any of these approaches leads to the same heal process.

Basic Steps in the Heal Process

There are several steps that are performed on selected objects.

1. Entity check, according to the **Analysis Options** settings.
2. Basic healing. This is done for all selected objects. Basic healing consists of fixing surface normals in the object and updating the orientation (to avoid having an object with negative volume).
3. Advanced healing. This is auto-heal. This is invoked on objects that require healing, that is, bodies that have errors, including have non-manifold errors.
4. Feature Removal. If you choose in the **Healing Options** to remove small holes, chamfers, blends, small edges, small faces and/or sliver faces, the actions are performed on all selected objects. There is no guarantee that small feature removal will be successful. (Also see Modifying the Model Resolution for defeaturing through the Auto Simplify and Model Resolution settings there.)

The above actions are performed on the selected objects. If you choose objects for healing which have not been analyzed, analysis is performed to determine its state (that is, whether it has invalid entities, small entities, and so forth). Invalid objects have all the above steps performed. Advanced healing is not performed on objects that do not require it.

While working on analyzing complex bodies, it is sometimes useful to examine faces, edges and vertices. In particular it is useful to find the connected faces for a face or edge or vertex, connected edges for a face/edge/vertex and connected vertices for a face/edge/vertex. The additional selection modes are available under **Edit->Selection Mode** and **Edit->Extend Selection**.

Technical Notes: Detecting and Addressing Model Problems to Improve Meshing

Technical Notes: *Mixed Dimensionality*.

Healing Stage One: Validation Check

After import an object, you should perform a validation check. This lets you focus on objects and object pairs that prevent the mesh from being invoked. The objects that fail api_check_entity() should be analyzed via the **Analyze Objects** menu item.

1. Select the objects, and click **Modeler >Model Analysis >Analyze Objects**.
   The **Analysis Options** dialog box appears, allowing you to perform small feature detections. Once you have completed this, click **OK**. The **Model Analysis** dialog box appears.
2. In the **Model Analysis** dialog box, select the objects marked with "Invalid Entities Found", and click **Perform>Heal Objects**. The **Healing Options** dialog box appears, allowing you to remove parameters. Click **OK**. The **Model Analysis** dialog box reappears.

Note	In most cases, the objects are healed, and the errors are fixed.

3. If errors persist, select the edges and faces still containing errors, and click **Delete**.
   This replaces each selected face/edge object by a tolerant edge/vertex, respectively. In some cases, the replacement of the face/edge by tolerant edge/vertex fails.

When models pass the initial validity checks, mesh generation could still fail. The following errors can be present in models: (See Detecting Errors.)

1. Non-manifold topology. These are non-manifold edges and vertices that are present in the model.
2. Object pair intersection. This detects whether pairs of objects intersect.
3. Small feature detection – small edge length, small face area and sliver face detection.
4. Mis-aligned entities detection – detects pairs of faces from objects that can be aligned to remove object intersections. This improves the probability of mesh success.
5. Mesh failure error display. This is available for single object, object pairs and last simulation run (all objects in a model). Errors reported by the meshing module are reported to the user.

Errors of type 3 and 4 must be resolved before the mesh can be invoked on the model.

By default, the **Heal** command is automatically applied to imported objects.

Analysis Phase (Healing Stage 4)

Healing Non-manifold Objects

Healing Options

Set Material Override

Technical Notes*: Healing and Meshing*

Technical Notes: *Detecting and Addressing Model Problems to Improve Meshing*

Healing Stage Two: Fix Intersections Between Objects

The second stage in healing is to fix intersections between objects. After validation check is performed, the pairs of objects that intersect are chosen for analysis. Use the analysis results to find whether objects have faces that can be aligned.

Choose all the bodies that intersect with another body.

1. From the **Objects** tab of the **Model Analysis** dialog box, click **Perform>Analyze Interobject Misalignment**.
   - Alternatively, you can click **Modeler>Model Analysis>Analyze Interobject Misalignment**.

   If the analysis finds object pairs that can be aligned, they are displayed on the **Objects Misalignment** tab.
2. You can select individual or multiple rows, and align the faces. In some cases, face alignment fails if the topology of the body changes by a large factor after alignment.
3. Identify individual bodies and body pairs that fail to mesh.
4. Perform a mesh analysis on individual objects and object pairs.
5. Review the reports and fix the errors.

Related Topics

Analysis Phase (Healing Stage 4)

Healing Non-manifold Objects

Healing Options

Set Material Override

Technical Notes*: Healing and Meshing*

Technical Notes: *Detecting and Addressing Model Problems to Improve Meshing*

Healing Stage Three: Fix Object Pair Intersections

The next stage of healing is to fix object-pair intersections. The healing process in stage two might fix some of these errors (by alignment).

1. If these errors are still present, you must remove them either by using the **Remove Faces** command (**Modeler>Model Analysis>Remove Faces**) or by performing a Boolean subtraction.
2. Overlap between objects is too large to be fixed by healing or by face alignment. Boolean intersect shows the common portion between the bodies. In this case, use a subtract operation to remove overlaps.

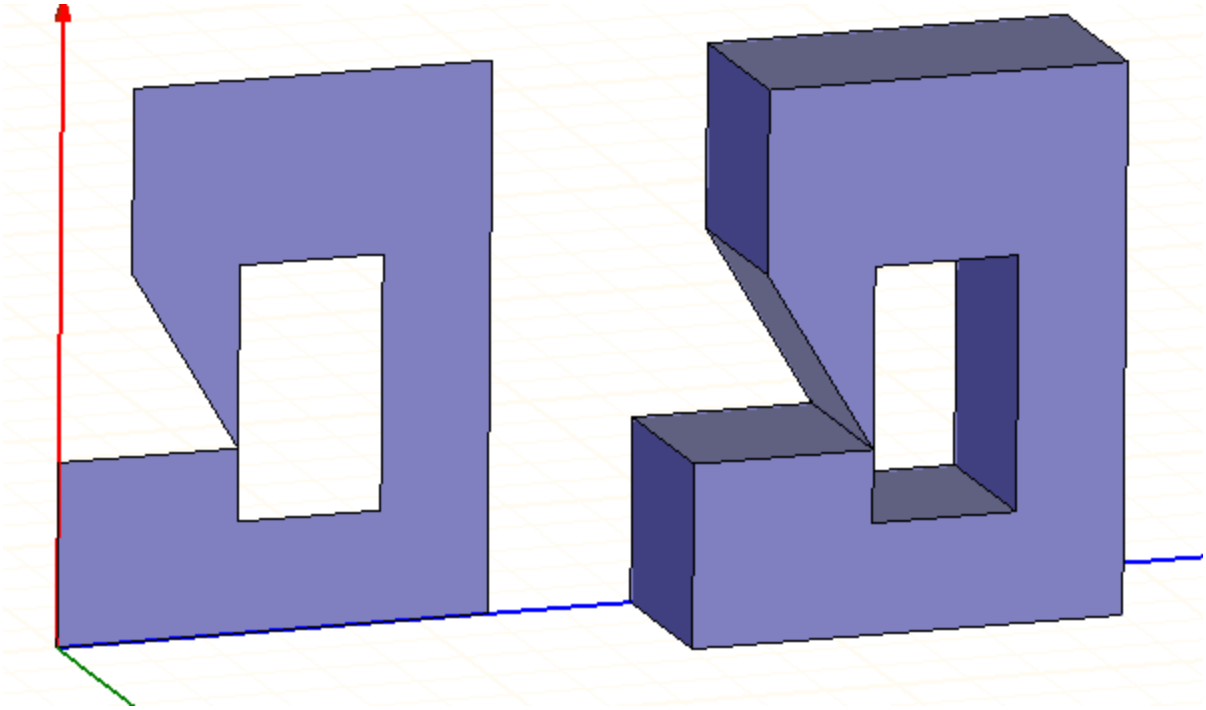
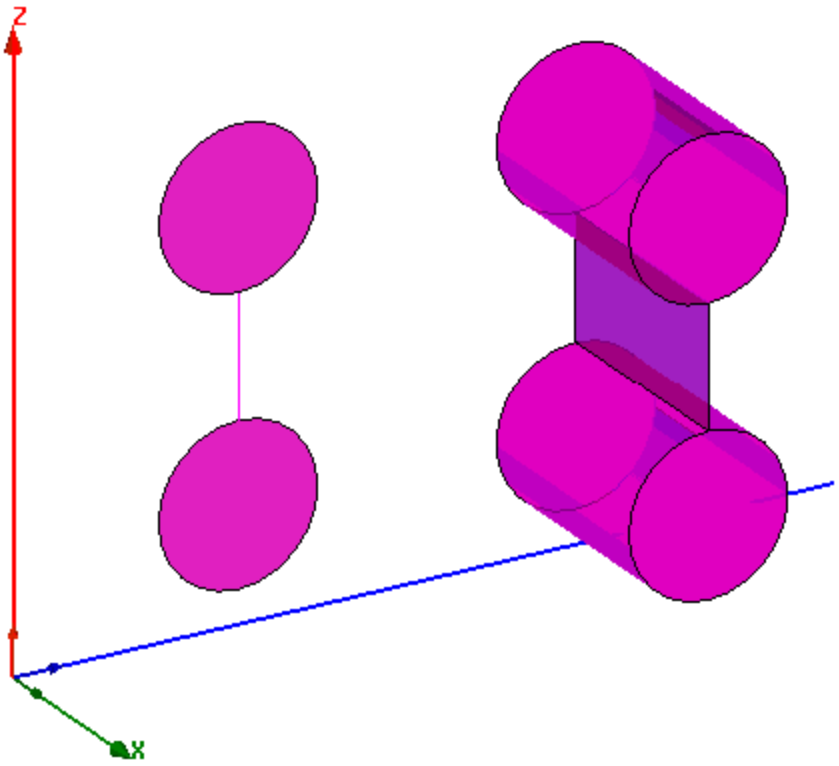
Healing Non-Manifold Objects

Non-manifold objects, in simple terms, are non-physical objects or objects that cannot be manufactured. For example, objects that intersect themselves (like the symbol for infinity in 2d)

are clearly non-manifold. In addition objects that touch themselves may be non-manifold such as when a 2D object touches itself at a vertex, or a 3D object touches itself at a point or edge. These cases are shown in the following figure.



Another type of non-manifold object has mixed dimensionality. For example, a pair of 2D objects connected by a 1D line segment, or a pair of 3D objects connected by a 2D sheet object. These cases are illustrated below.



The criteria for manufacturability is a simple manifestation of a complex mathematical concept that must be adhered to in the solid modeling system. When creating geometry, either directly, or through boolean operations, you should always consider whether or not the resulting operation will result in an object that could not be manufactured. If this is the case, then the object will cause an error in the modeler or in the meshing system.

To heal non-manifold objects:

1. Identify an edge that is non-manifold.
2. Select the connected faces.

   You can use Face selection.
3. Create a face coordinate system on the planar face.
4. Create a small box to cover the non-manifold edge.
5. Either do a union or a subtraction to remove the faces that contain the non-manifold edge.

   The non-manifold edge is now removed. You may also remove or add a small portion of the model.
6. Repeat the above steps for all the non-manifold edges.

Setting the Healing Options

The **Healing Options** let you control how healing proceeds with respect to a variety of features and issues.

1. Click **Modeler>Model Healing>Heal** to open the **Healing Options** dialog box. You can also open the **Healing Options** dialog from the **Model Analysis** dialog via the **Objects** tab drop down menu.

   The **Healing Options** dialog contains three tabs:
   - **Healing Options**
   - **Feature Removal Options**
   - **Properties**, which lists the geometric properties of the currently selected object.
2. Select the **Healing Options** tab on the **Healing Options** dialog to specify the following:
   - **Heal Type** as: **Auto Heal** (default), **Manual Heal**, or **No Heal**.

   Selecting **Manual Heal** enables the **Manual Heal Options**:
   - **Perform Tolerant Stitching** check box.

   This enables a field for the **Stitch Tolerance** value, and a check box to **Stop After First Error**.

   - **Perform Geometry Simplification**

   This enables fields for **Simplification Tolerance** and **Maximum Generated Radius** values.

   You can also select radio buttons to **Simplify Curves**, **Surfaces**, or **Both**.

- **Tighten Gaps** settings.

  A check box to select **Perform Tighten Gaps**

  A field to specify **Tighten Gaps Within** a given value in mm.

3. Select the **Feature Removal Options** tab to specify the following:

   Here you can specify the following **Feature Removal Options**.
   - **Remove Holes** check box and **Maximum Radius** value.
   - **Remove Chamfers** check box and **Maximum Width** value.
   - **Remove Blends** check box and **Maximum Radius** value.

   You can specify the following **Remove Small Entity Options**:
   - **Small Edges, Length Less Than**, less than a specified value.
   - **Small Faces Area e Less Than**, less than a specified area.
   - **Sliver Face Width Less Than**, less than either:
     - **Object Bounding box Scale Factor**, less than a specified scale factor
     - **Sliver Edge Width**, less than a specified value.

Note	Sliver faces have a maximum distance among the long edges that is smaller than the specified tolerance and have at least one short edge and at most three long edges. A short edge has a length less than the specified tolerance. A long edge has a length greater than the specified tolerance. You can give the tolerance as a absolute value or a factor of the bounding box containing the face.

   You can **Control Object Properties Change** according to the following settings:
   - **Allowable Change in Surface Area** check box, and percent value.
   - **Allowable Change in Volume** check box, and percent value.
4. Select the **Properties** tab to view the geometric properties of the currently selected object.
5. Click **OK** to apply the specified Healing options and to open the Analysis dialog.

Stitch Sheets

Use the **Modeler>Model Healing>Stitch Sheets** command to stitch selected sheets.

1. Select two or more sheet objects.

   This enables the Stitch Sheets command on the **Modeler>Model Healing** submenu.
2. Click **Modeler>Model Healing>Stitch Sheets**

   This displays a Stitch dialog with a Maximum Stitch Tolerance field. The default value (auto) comes from the **Healing** dialog **Options** tab with Manual Healing selected. You may edit the value in the Stitch dialog or in the Healing Options.
3. Click OK.

   This closes the dialog and attempts to perform stitching on the selected sheets. If the sheets are separated beyond the stitch tolerance, stitching is not performed and a warning is issued.

Healing

Removing Selected Faces

Use the **Modeler>Model Preparation>Remove Faces** command to remove the selected faces. You can also use the Model ribbon **Remove Faces** icon when you have made an appropriate face selection.

If you find object-pair intersections that healing does not fix, or that can be fixed (by alignment), you can correct the problem by one of the following methods.

1. Use the **Remove Faces** command (**Modeler>Model Healing>Remove Faces**) or by performing Boolean subtract.
2. If overlap between objects is too large to be fixed by healing or by face alignment. Boolean intersect shows the common portion between the bodies. In this case, use a subtract operation to remove overlaps.

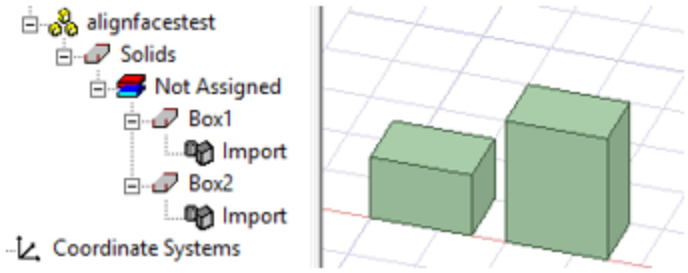
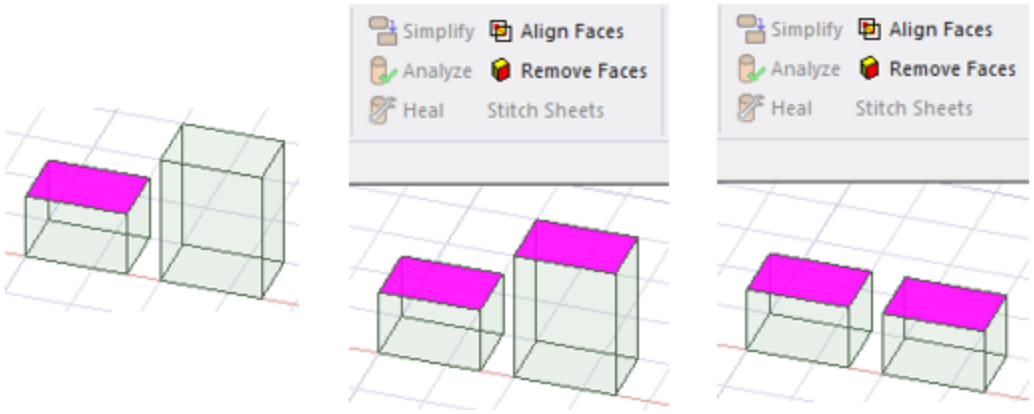
Aligning Selected Faces

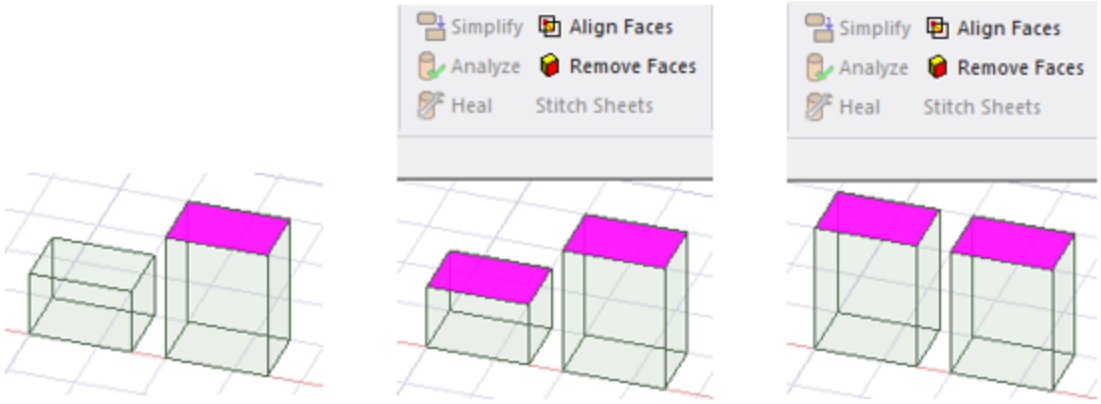
Use the **Modeler>Model Preparation>Align Faces** command to align the adjacent selected faces of imported objects which have only one operation in their **History** tree. This command is **Undo**-able.



The **Model** ribbon also includes an **Align Faces** icon, which is enabled when you make appropriate face selection. The first selected face defines the plane of alignment for subsequent selection, that is, tool faces to blank faces.



Selecting faces in a different order changes the alignment.



The selected faces can touch.

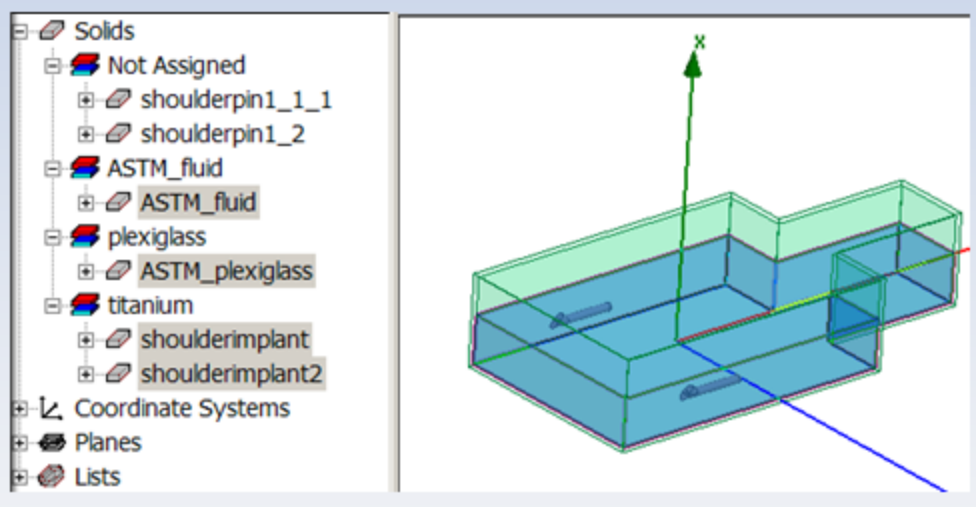
Performing Explicit Subtractions

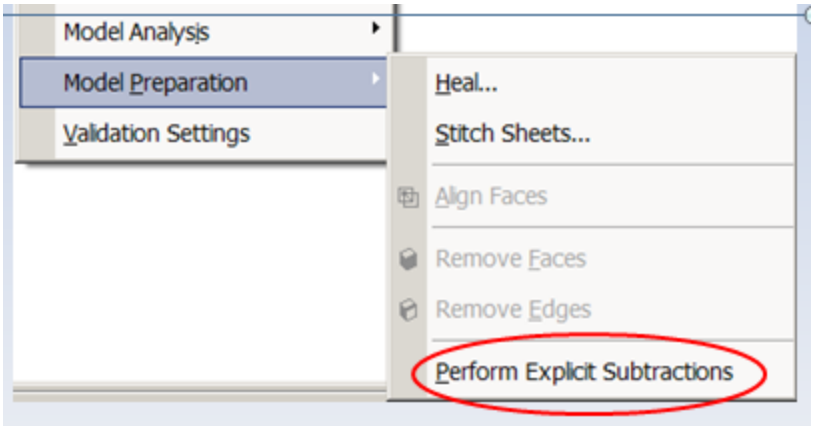
Use the **Modeler>Model Preparation>Perform Explicit Subtractions** command to subtract selected **History** tree objects that are fully contained by other parts.

1. Select two or more history objects.

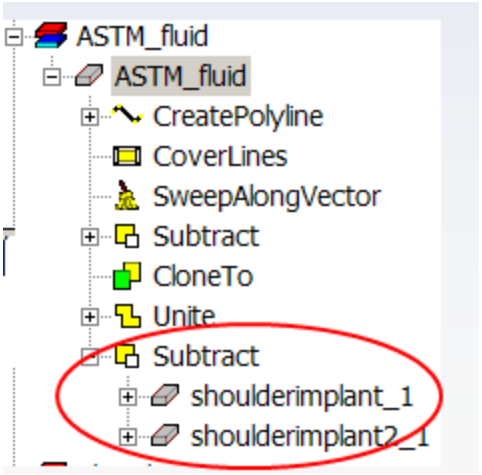
   This enables the Stitch Sheets command on the **Modeler>Model Preparation>Perform Explicit Subtractions** submenu. For example, consider the following model.



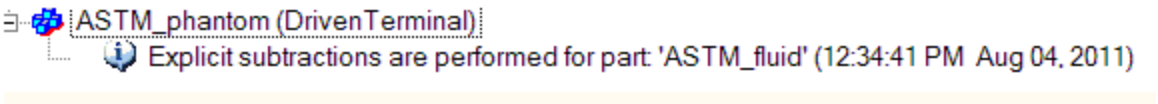
2. **Perform Explicit Subtraction** can be performed.



The results appear in the History tree as shown:



The Message window also reports this action.



If no parts are fully contained by other parts, a message explains that no explicit subtraction is needed.

Modifying Objects

You can quickly modify the position, dimensions, and other characteristics of objects created in the **Modeler** window.

What do you want to do?

- Assign color to an object
- Assign transparency to an object
- Assigning a Cross Section and Dimension to a Polyline
- Copy and paste objects
- Delete objects
- Delete Last Operation
- Cutting Objects
- Move objects
- Rotate objects
- Change the Orientation of an object

- Mirror objects about a plane
- Offset an object (move every face of an object)
- Duplicate objects
- Scale the size of objects
- Sweeping objects
- Cover lines
- Cover faces
- Uncover faces
- Detach faces
- Detach edges
- Create a new object by taking a cross-section of a 3D object
- Connect objects
- Move faces
- Move Edges
- Unite objects
- Subtract objects
- Create objects from intersections
- Create an object from a face
- Create an object from an edge
- Split objects
- Separate objects
- Convert polyline segments.
- Round the edge of an object (Fillet)
- Flatten the edge of an object (Chamfer)
- Wrap Sheet Command
- Imprint Projection Commands
- Imprinting an Object
- View and Edit Commands on History Tree Objects
- Purge History
- Generate History

Assigning Color to Objects

1. Select the object to which you want to assign a color.

Note	If the **Properties** window not visible on the desktop, click **View>Properties Window**.

2. In the **Properties** window on the desktop, click the **Attribute** tab.
3. Click **Edit** in the **Color** row.

   The **Color** palette appears.
4. Select a color from the **Color** palette, and then click **OK**.

The color is assigned to the selected object.

5. Click OK to close the **Properties** dialog box.

Related Topics

Setting the Default Color of Objects

Setting the Default Color of Objects

1. Click **Tools>Options>Modeler Options**.
2. Click the **Display** tab.
3. Select **Object** from the **Default color** pull-down list.
4. Click the color button beside the **Default color** pull-down list.
   The **Color** palette appears.
5. Select a color from the **Color** palette, and then click **OK**.
   Any objects you draw after this point are assigned the default color you selected.

Setting the Default Color of Object Outlines

1. Click **Tools>Options>Modeler Options**.
2. Click the **Display** tab.
3. Select **Object Wire** from the **Default color** pull-down list.
4. Click the color button beside the **Default color** pull-down list.
   The **Color** palette appears.
5. Select a color from the **Color** palette, and then click **OK**.
   The outlines of any objects you draw after this point are assigned the default color you selected.

Assigning Transparency to an Object

1. Select the object to which you want to assign a transparency.

Note	If the **Properties** window not visible on the desktop, click **View>Properties Window** or use **Edit>Properties**.

2. In the **Properties** dialog box, click the **Attribute** tab.
3. Click the value in the **Transparency** row.
   The **Set Transparency** window appears.
4. Move the slider to the right to increase the transparency of the object. Move the slider to the left to decrease the transparency of the object.
5. Click **OK**.

Related Topics

Setting the Default Transparency of Objects

Setting the Default Transparency of Objects

1. Click **Tools**>**Options**>**Modeler Options**.
2. Click the **Display** tab.
3. Move the **Default transparency** slider to the right to increase the transparency of objects.

   Move the slider to the left to decrease the transparency of objects.

   Any objects you draw after this point are assigned the default transparency you selected.

Copying and Pasting Objects

To copy objects and paste them in the same design or another design, use the **Edit>Copy** and **Edit>Paste** commands. For data link purposes, where you want to include the material assignments as well as the geometry, you can use the Import from Clipboard command.

1. Select the objects you want to copy.
2. Click **Edit**>**Copy**  .

   The objects are copied to the Clipboard, a temporary storage area. The selected items are not deleted.
3. Select the design into which you want to paste the objects. It can be the same design from which you copied the items.
4. Click in the **Modeler** window.
5. Select the working coordinate system. Objects are pasted relative to the current working coordinate system.
6. Click **Edit**>**Paste**  .

The objects appear in the targeted Modeler window and in the new History tree. The pasted objects become the current active selection. If you undo the paste, the active selection goes back to the previous selection. If you redo, the pasted objects become the current active selection.

Items on the Clipboard can be pasted repeatedly. The items currently stored on the Clipboard are replaced by the next items that are cut or copied.

Related Topics

Duplicating Boundaries and Excitations with Geometry

Copying an Image to the Clipboard

Use this command to copy a 3D view of the design, field plots, or 2D reports to the Clipboard and paste it into another document, such as Word or PowerPoint.

To copy an image to the Clipboard:

1. Make the window of the image you wish to copy active.

   This enables the **Edit>Copy Image** command in the menu bar.
2. Click **Edit>Copy Image**, or right click on the active window to display the shortcut menu and select **Copy Image**.

   The report is copied to the Clipboard as an image.
3. Select and open the application into which you want to paste the objects, and paste the image.

Deleting Objects

1. Select the objects to delete.
2. Click **Edit**>**Delete**  .
   - Alternatively, press **Delete**.

   The objects are deleted.

Note	To maintain valid boundaries, excitations, or other parameters that were associated with the deleted object, reassign them to other objects.

Related Topics

Deleting Start Points and Endpoints

Deleting Start Points and Endpoints

If you select a polyline in the history tree, the **Delete Start Point** and **Delete End Point** commands may be enabled. These permit you to delete portions of the line.

1. In the history tree, locate the polyline that contains the segment you want to delete. Expand this part of the history tree.
2. In the history tree, select the polyline you want to edit.

   The segment is highlighted.
3. On the **Edit** menu or the shortcut menu, click either **Delete Start Point to remove the leading segments or Delete End Point to remove the following segments.**

   The designated segment is removed, and the line changes.

Deleting Last Operation

This undoes the last operation, including removing that operation from the history, and updating the context for the **Undo** and **Redo** commands.

Related Topics

Undoing Commands
Redoing Commands

Cutting Objects

1. Select the objects to cut.
2. Click **Edit**>**Cut**.

The objects are copied to the Clipboard and deleted from the design.

Moving Objects

1. Select the objects to move.
2. Click **Edit**>**Arrange**>**Move**  .
3. Select an arbitrary anchor point in one of the following ways:
   - Click the point.
   - Enter the point's coordinates in the **X**,**Y**, and **Z** boxes.
4. Select a target point in one of the following ways:
   - Click the point.
   - Type the coordinates of a point relative to the anchor point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   All selected objects move the distance determined by the offset between the anchor point and the target point.

Rotating Objects

Rotate objects about the x-, y-, or z-axis using the **Edit>Arrange>Rotate** command.

To rotate objects about an axis:

1. Select the objects to rotate.
2. Click **Edit**>**Arrange**>**Rotate**  .

   The **Rotate** dialog box appears.

3. Select the axis about which to rotate the objects: **X**, **Y**, or **Z**.
4. Type the angle to rotate the objects in the **Angle** box.

   A positive angle causes the object to be rotated in the counter-clockwise direction. A negative angle causes the object to be rotated in the clockwise direction.
5. Click **OK**.

   The selected objects are rotated about the axis.

To rotate *andcopy* objects, use the **Edit>Duplicate>Around Axis** command.

Changing the Orientation of an Object

Each object has an **Orientation** property that specifies the coordinate system it uses is Global, or a user defined orientation relative to the Global coordinate.

This property is useful in dealing with anisotropic materials. The properties of anisotropic materials are specified relative to the objects orientation. Changing the orientation of an object provides a way for objects made of the same material to be orientated differently.

To change an object's orientation.

1. Define the coordinate systems you want to have available.
2. Open the properties window for the object.
3. Click on the Orientation property, and select from the Drop down list. If no Orientations other than Global have been defined, none appear on the list.
4. Click **OK** to close the dialog and apply the changes.

Assigning Material Property Types

Setting Coordinate Systems

Creating a Relative Coordinate System

Mirroring Objects

Mirror an object about a plane using the **Edit>Arrange>Mirror** command. The plane is selected by defining a point on the plane and a normal point. This command allows you to move an object and change its orientation.

Note	The distance between the point on the mirror plane and the point along the normal does not matter — only the vector direction matters.

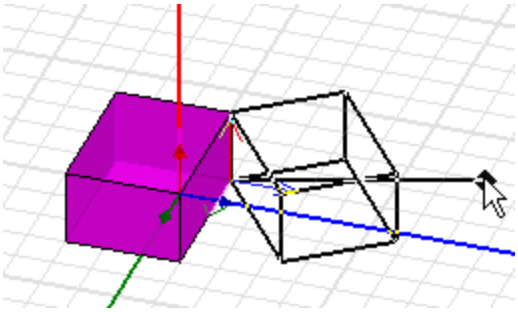
To mirror an object about a plane:

1. Select the object you want to mirror. You can select multiple objects.

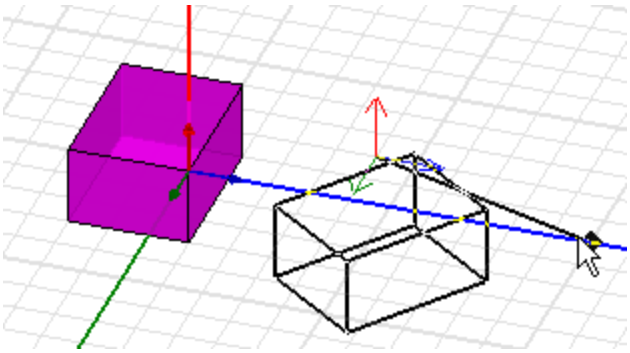
1. Click **Edit**>**Arrange**>**Mirror**  .
2. Select a point on the plane on which you want to mirror the object.

You can do this by clicking a point, or typing coordinates in the X, Y, and Z boxes in the status bar.

If you select a point on the object, the mirroring is relative to that point on the object. In the following example, the first point clicked after selecting **Edit>Arrange>Mirror** was on the right-rear bottom corner of the selected object. So the axis of rotation as you move the cursor is that corner. As you move the cursor, it drags a diamond-shape on a vector extending from the initial point. The distance along the vector does not matter. Moving the mouse rotates an outline of the object to new orientations. Clicking the mouse moves the object to location indicated by the outline.



In this second example, the initial point is at a distance from the original object, designated by the triad from which the handle for rotation extends to the dragging cursor.



3. Select a normal point in one of the following ways:
   - Click the point.
   - Type the coordinates of a point relative to the first point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point. As you type in the values, the outline moves to the coordinates. Press the Enter key to complete the command.

Note	For 2D designs, movement is restricted to the XY or RZ plane.

   The selected object is moved to the plane you specified and oriented relative to the normal point you specify.

To mirror *and copy* objects about a plane, use the **Edit>Duplicate>Mirror** command.

Related Topics

Duplicating and Mirroring Objects

Offsetting Objects

Move every face of a 3D object in a direction normal to its surface using the **Edit>Arrange>Offset** command. The faces are moved a specified distance normal to their original planes. This command enables you to move every face of a solid object without having to individually select and move each face. Use the **Surfaces>Move Faces>Along Normal** command if you want to move just one or more faces of an object.

To offset every face of an object:

1. Select the object you want to offset.
2. Click **Edit>Arrange>Offset**.

   The **Offset** dialog box appears.
3. Type the distance you want to move the object faces from their origins, and then select a unit from the pull-down list.
4. Click **OK**.

   The selected object's faces are moved the distance you specified.

Duplicating Objects

You can duplicate objects within a design using the **Edit>Duplicate** commands. Duplicates are dependent upon the parameters of their *parent* object at the time they were created, that is, they share the parent object's history at the time of creation. The command hierarchy in the history tree shows the duplication command, illustrating which commands affect all duplicates (those performed before the duplication) and which commands do not affect the duplicates (those performed after the duplication). For example, if you modify the radius of a parent object's hole, the change is applied to the holes of the object's duplicates because they share the radius specification history, but if you move the faces of the parent object, its duplicates are not affected because this operation took place after the duplicates were created.

Operations performed on duplicates are independent. For example, if you duplicate a cylinder twice, creating a row of three, and then split the second cylinder, the first and third cylinders are not affected by the split.

When creating duplicates, the parent object is duplicated along a line or around an axis the number of times you specify. You can also create a single duplicate that mirrors the parent object about a plane.

Choose from the following commands:

Edit>Duplicate>Along Line	Duplicates the parent object along a straight line.

Edit>Duplicate>Around Axis	Duplicates the parent object around an axis.
Edit>Duplicate>Mirror	Duplicates a mirror image of the parent object about a plane.

To copy objects to another design, use the **Edit>Copy** and **Edit>Paste** commands.

Note	There is currently no method for dissolving the parent/duplicate relationship once a duplicate has been created.

Duplicating Objects Along a Line

You can duplicate an object along a straight line using the **Edit>Duplicate>Along Line** command. The line along which the object is duplicated can be vertical, horizontal, or lie at an angle.

1. Select the object you want to duplicate.
2. Click **Edit**>**Duplicate>Along Line**  ..
3. Specify the vector along which the object is to be duplicated:
   a. Select an arbitrary anchor point in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

   Any point in the drawing region can be selected; however, selecting an anchor point on the object's edge or within the object makes it easier to select the duplication line.

   b. Select a second point in one of the following ways:
      - Click the point.
      - Type the coordinates of a point relative to the anchor point in the **dX**, **dY**, and **dZ** boxes.

   This point defines the direction and distance from the anchor point to duplicate the object.

   The **Duplicate along line** dialog box appears.
4. Type the total number of objects, including the original, in the **Total number** box.
5. By option check the **Attach to Original Object** check box. If this is checked, no ports or boundary conditions are duplicated for the child.
6. Click **OK**.

   The duplicates are placed along the vector you specified.

Duplicating Objects Around an Axis

To duplicate an object around the x-, y-, or z-axis, use the **Edit>Duplicate>Around Axis** command.

1. Select the object you want to duplicate.
2. Click **Edit>Duplicate>Around Axis**  .

   The **Duplicate Around Axis** dialog box appears.
3. Select the axis around which you want to duplicate the object: **X**, **Y**, or **Z**.
4. Type the angle between duplicates in the **Angle** box.

   A positive angle causes the object to be pasted in the counter-clockwise direction.

   A negative angle causes the object to be pasted in the clockwise direction.
5. Type the total number of objects, including the original, in the **Total number** box.
6. By option check the **Attach to Original Object** check box. If this is checked, no ports or boundary conditions are duplicated for the child.
7. Click **OK**.

   The object is duplicated around the axis at the angle you specified.

Duplicating and Mirroring Objects

To duplicate and mirror an object about a plane, use the **Edit>Duplicate>Mirror** command. The plane is selected by defining a point on the plane and a normal point. This command allows you to duplicate an object and specify the duplicate's position.

This command is similar to **Edit>Arrange>Mirror**, except that this command duplicates an object, rather than moves it.

1. Select the object you want to mirror.
2. Click **Edit>Duplicate>Mirror**  .
3. Select a point on the plane on which you want to mirror the object.

   A line drawn from this point to the mirror plane will be perpendicular to the plane. The distance between the point on mirror plane and point along the normal does not matter; only the vector direction matters
4. Select a normal point on the plane in one of the following ways:
   - Click the point.
   - Type the coordinates of a point relative to the first point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

Note	For 2D designs, movement is restricted to the XY or RZ plane.

   A duplicate of the object appears on the plane you specified, oriented according to the normal point you specified.

Related Topics

Mirroring Objects

Scaling Objects

Scale an object's dimensions in one or more directions using the **Edit>Scale** command.

The scale of an object is determined by the distance of each of its vertices from the origin of the model coordinate system. When an object is scaled, the distance of each vertex from the origin is multiplied by the scaling factor, causing the object to be resized and/or moved.

For example, if you specify a scaling factor of 2 in the x direction, each vertex in the model is moved so that the distance to its origin is doubled. A vertex located at the origin cannot not move. You can alter an object's proportions by scaling it in one direction.

To scale an object's dimensions in one or more directions:

1. If necessary, set a different working coordinate system to achieve the desired scaling.
2. Select the object to scale.
3. Click **Edit>Scale**.

   The **Scale** dialog box appears.
4. Type the scale factor for each axis.
5. Click **OK**.

   The object is scaled about the working coordinate system's origin.

Related Topics

Modifying Object Attributes using the Properties Window

Sweeping Objects

You can sweep a 2D object around an axis, along a vector, or along a path to create a 3D solid object. Objects that can be swept include circles, arcs, rectangles, trapezoids, polylines, or any 2D object created in the **3D Modeler** window. The 2D object need not be orthogonal to the sweep path.

You can also thicken sheets to make a 3D object.

You can also sweep open 1D objects, such as polylines. This results in open 2D sheet objects.

You can also sweep one or more faces of a 3D object to create a new object. See Sweep Faces Along Normal.

Thicken Sheet

Sweeping Around an Axis

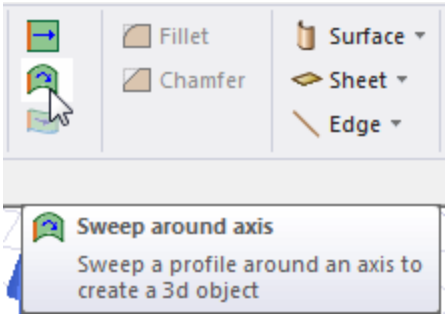
Sweep a 1D or 2D object around the x-, y-, or z-axis using the **Draw>Sweep>Around Axis** command. Sweeping circles around an axis is a convenient way to create an open coil loop.

Before using this command, keep the following guidelines in mind:

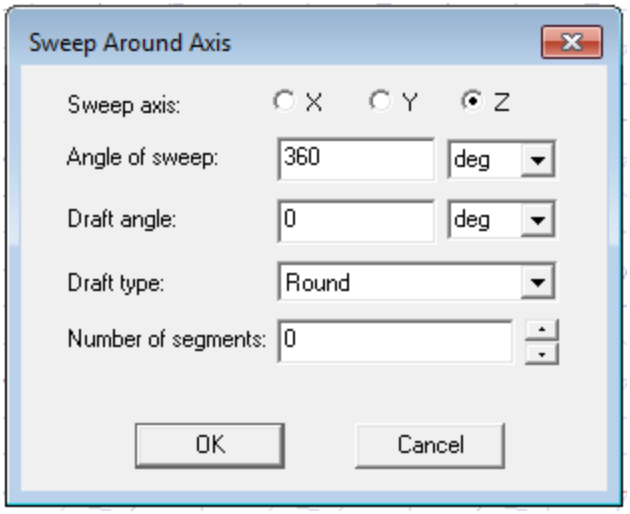
- The object and the axis you are sweeping around must lie in the same plane. For example, if you are sweeping an object around the z-axis, the object must lie in a plane that includes the z-axis, such as xz or yz.
- The normal of the object's plane faces must be perpendicular to the axis around which you are sweeping.
- The object may not cross the axis around which it is being swept.

To sweep an object around an axis:

1. Select the object you want to sweep.
2. From the menu bar, click **Draw> Sweep> Around Axis** or, in the **Draw** ribbon tab, click **Sweep around axis**:



The **Sweep Around Axis** dialog box appears.



3. Select **X**, **Y**, or **Z** as the **Sweep axis**.
4. Type an angle in the **Angle of sweep** text box, and select the unit of measurement. The value must be between **-360** and **360** degrees.
5. Type an angle into the **Draft angle** text box and select the desired unit of measure.

   This is the angle to which you want a 2D object's profile, or shape, expanded (positive angle) or contracted (negative angle) as it is swept. Among other purposes, drafts make it easy to remove molded or cast parts from their molds.

   For 1D objects, the draft angle progressively alters the sweep radius but does not alter the length of the object as it is swept. For example, a 10 mm straight line swept around a parallel axis with a nonzero draft angle would produce a spiral surface with a fixed width of 10 mm. When the sweep angle is *positive*, a positive draft angle produces a spiral surface with a *decreasing* radius (that is, the distance from the generated surface to the sweep axis decrease along the sweep angle. A negative angle produces a spiral surface with an *increasing* radius along the sweep angle. When the sweep angle is *negative*, the spiral behavior is the opposite of that just described.
6. Select one of the following **Draft type** options from the drop-down menu. The draft type instructs the modeler whether to maintain the original object shape and how to transition between adjacent faces. This setting affects the results when sweeping 2D objects into 3D solids or when sweeping lines and curves into 3D sheets.
   - **Extended**
   - **Round**
   - **Natural**

   For a complete description of the behavior of each of these three options, see the Draft Types page.
7. Type the number of segments in the **Number of segments** text box.

Note	The default number of segments is zero, which creates a true path. A positive value results in a segmented sweep, while a negative value results in an error. If the sweep angle is 360 degrees, the number of segments is equal to the value specified. If the sweep angle is less than 360 degrees, half segments appear at the ends. Projects and scripts from previous software versions are treated as if the number of segments were zero.

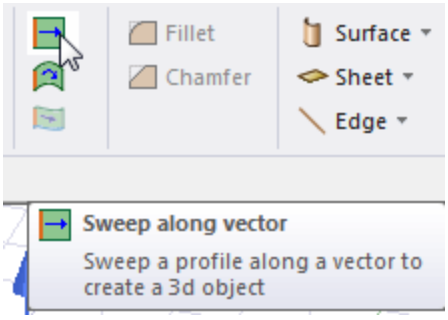
8. Click **OK**.

   The object is swept around the axis. The new object has the properties of the original object.

Sweeping Along a Vector

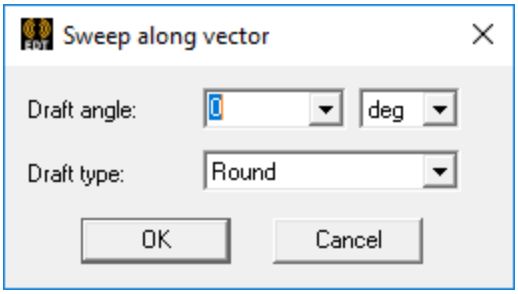
Sweep a 1D or 2D object along a vector using the **Draw>Sweep>Along Vector** command.

1. Select the object you want to sweep.
2. From the menu bar, click **Draw> Sweep> Along Vector** or, in the **Draw** ribbon tab, click **Sweep along vector**:



3. Draw the vector you want to sweep the object along:
    a. Select the start point by clicking the point or typing its coordinates in the **X**, **Y**, and **Z** boxes.
    b. Select the endpoint in one of the following ways:
        - Click the point.
        - Type the coordinates of a point relative to the start point in the **dX**, **dY**, and **dZ** boxes, where **d** is the relative distance from the previously selected point.

    The **Sweep along vector** dialog box appears.



4. Type an angle into the **Draft angle** text box and select the desired unit of measure.

    This is the angle to which you want a 2D object's profile, or shape, expanded (positive angle) or contracted (negative angle) as it is swept. Among other purposes, drafts make it easy to remove molded or cast parts from their molds.

    For 1D objects, the draft angle alters the sweep direction but does not alter the length of the object as it is swept. For example, a 10 mm straight line swept with a 5-degree draft angle does not produce a trapezoidal 2D object. It produces a rectangle with a constant 10 mm width but tilted 5 degrees relative to the specified sweep vector.

5. Select one of the following **Draft type** options from the drop-down menu. The draft type instructs the modeler whether to maintain the original object shape and how to transition between adjacent faces. This setting affects the results when sweeping 2D objects into 3D solids or when sweeping lines and curves into 3D sheets.
   - **Extended**
   - **Round**
   - **Natural**

   For a complete description of the behavior of each of these three options, see the Draft Types page.
6. Click **OK**.

   The object is swept along the vector. The new object has the name and color of the original profile. The **Properties** dialog box appears, enabling you to modify the object's properties.

Sweeping Along a Path

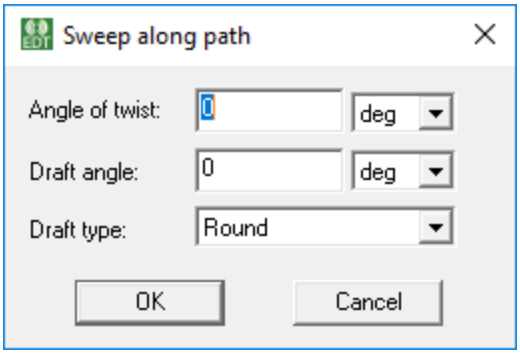
Sweep a 1D or 2D object along a path that is defined by an open or closed polyline using the **Draw>Sweep>Along Path** command.

Note	If the path curve is tangential to the sweep profile, then the sweep will fail.

To sweep an object along a path:

1. Create the polyline you want to use as a path.
2. Select the object you want to sweep, and then select the new polyline.
3. From the menu bar, click **Draw> Sweep> Along Path** or, in the **Draw** ribbon tab, click **Along a path**:

   The **Sweep along path** dialog box appears.



4. Type an angle in the **Angle of twist** text box and choose the desired unit of measure.

   This is the angle the profile will rotate about the sweep path vector as it is swept through the complete path.
5. Type an angle into the **Draft angle** text box and select the desired unit of measure.

   This is the angle to which you want the object's profile, or shape, expanded (positive angle) or contracted (negative angle) as it is swept. Among other purposes, drafts make it easy to remove molded or cast parts from their molds.

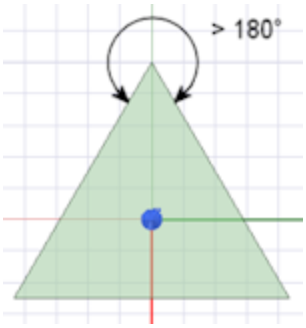
   For 1D objects, the draft angle alters the sweep direction but does not alter the length of the object as it is swept. For example, a 10 mm straight line swept with a 5-degree draft angle does not produce a trapezoidal 2D object. It produces a rectangle with a constant 10 mm width but tilted 5 degrees relative to the specified sweep path.
6. Select one of the following **Draft type** options from the drop-down menu. The draft type instructs the modeler whether to maintain the original object shape and how to transition between adjacent faces. This setting affects the results when sweeping 2D objects into 3D solids or when sweeping lines and curves into 3D sheets.
   - **Extended**
   - **Round**
   - **Natural**

   For a complete description of the behavior of each of these three options, see the Draft Types page.
7. Click **OK**.

   The object is swept along the path. The polyline object used as the path is deleted. The new object has the properties of the original object. The **Properties** dialog box appears, enabling you to modify the object's properties.

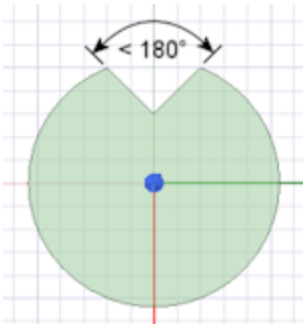
Draft Type Options

In many cases, the **Draft type** setting may have little to no effect on the resultant geometry of a swept object unless a *positive, non-zero draft angle* is specified. Consider a *sharp corner* feature. For the purpose of this discussion let's define a sharp corner as any protruding feature where the *external* angle between the adjacent faces is greater than 180-degrees:



When this type of feature is expanding, the corner can gradually become rounded. However, if the same corner is contracting, the radius is already zero at the start of the sweep and cannot contract or decrease further. Therefore, no rounding occurs in the latter case.

Now, consider a *groove* in the perimeter of a 2D object to be swept. Let's define a groove as any indented feature, where the *external* angle between the adjacent faces is less than 180-degrees:



A groove will grow in size as the object is swept with a *negative* draft angle specified. In this case, progressive rounding of the corners is possible.

You may need to experiment with the three draft type options to determine what the effect will be for nontrivial object shapes. The behavior of each option can differ according to the shape of the 2D object, the draft angle, and whether it is swept along a vector, a path, or about an axis.

The following three **Draft type** options are available:

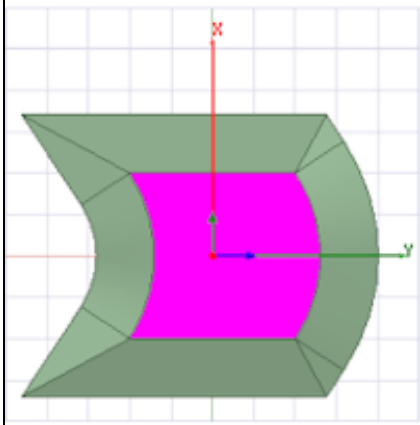
- **Natural:** This draft type generally maintains the shape of the original object as it is swept along the specified direction. That is, all sharp corners remain sharp, producing sharp edges in the sweep direction. There are exceptions to this general behavior. Rounding of certain corners may occur if required to accommodate sides with complex shapes (for example, a complex side might be split into a combination of planar, cylindrical, helical, or conic-section faces).
- **Extended:** This option maintains the shape of the original object as it is swept along the specified direction. Sharp corners of the original object remain sharp corners along the entire swept direction. However, the side faces may be split into three separate tangential faces, as needed and as described in the preceding bullet.

- **Round:** This option rounds all sharp corners of the original object as it is swept along the specified direction.

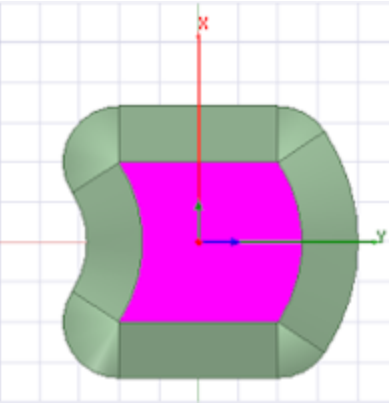
Examples

The images below compare the results of sweeping an object using each of the available **Draft type** options. The first six images are of an object swept with a positive draft angle defined. The final three images are of a different object swept with a negative draft angle defined. For all examples, the original 2D object is highlighted in magenta.

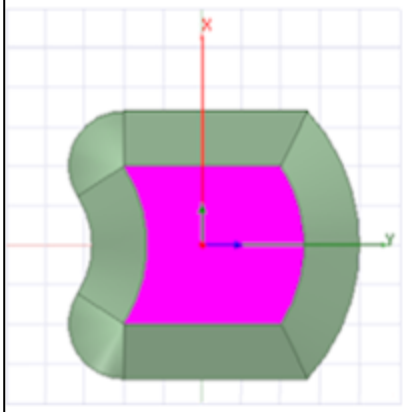
Sweep Along Vector (Positive Draft Angle):



1a: Extended

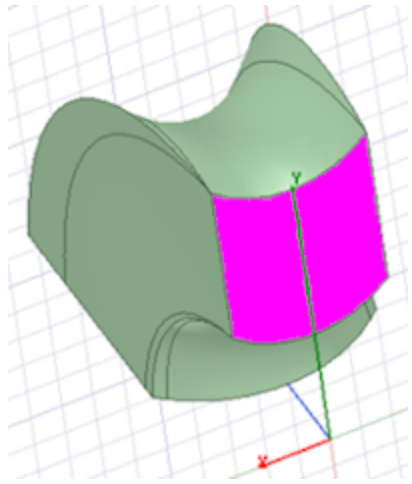


1b: Round

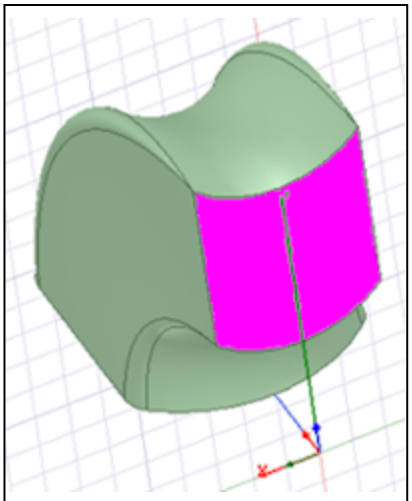


1c: Natural

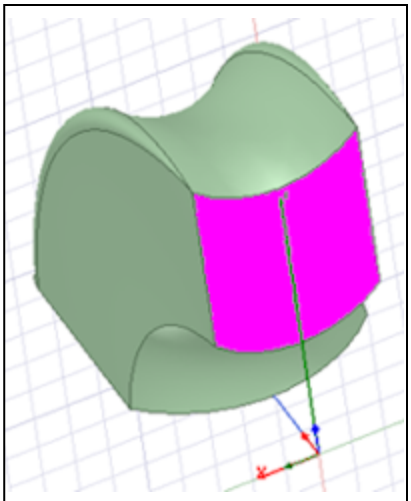
2. **Sweep About Axis** (Positive Draft Angle):



2a: Extended

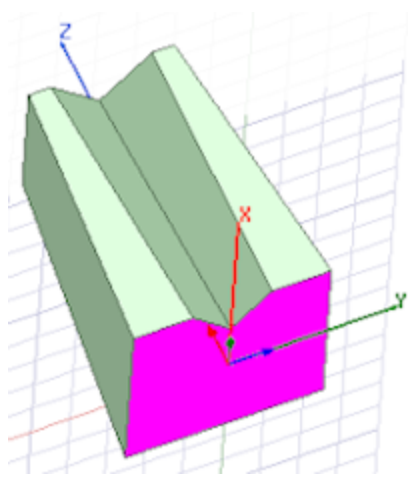


2b: Round

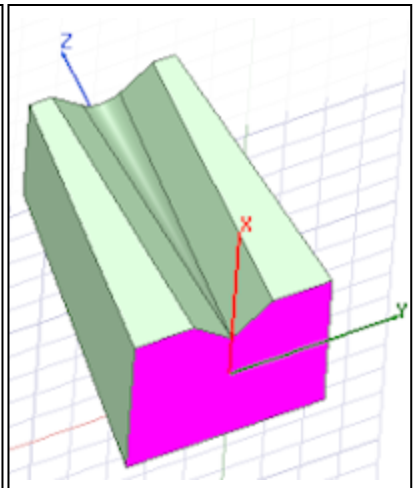


2c: Natural

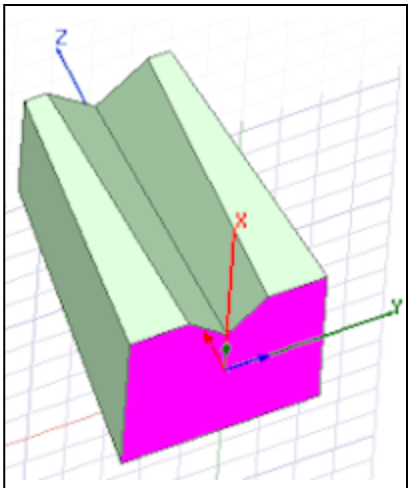
3. **Sweep Along Vector** (Negative Draft Angle):



3a: Extended



3b: Round



3c: Natural

Observations:

- **Extended Option:** Notice how two of the four sides of example **1a** have been divided into three faces each (the sides generated by sweeping curved edges). However, the other two sides (those generated from straight edges) have not been divided.
  For example **2a**, all four sides have been divided into three faces each. Even the straight sides generate a complex surface due to the combination of a positive draft angle and a circular sweep path.
  For example **3a** (negative draft angle), no face is split and no edge is rounded.
- **Round Option:** In both examples **1b** and **-b**, all corners of the original 2D object have been progressively rounded (with the radius increasing from zero at the plane of the original object to a maximum radius at the end of the sweep).
  For example **3b** (negative draft angle), only the corner of the groove has been rounded. The indented feature is the only one increasing is size along the sweep direction.
- **Natural Option:** In both examples **1c** and **2c**, the corners adjacent to the convex curved face remain sharp. However, the corners adjacent to the concave curved face are progressively rounded in both cases (with the radius increasing from zero at the plane of the original object to a maximum radius at the end of the sweep).
  For example **3c** (negative draft angle), no face is split and no edge is rounded.

Sweeping Faces Along Normal

To create a new object by sweeping select 3D object's face a specified distance in a direction normal to its original plane, use the **Modeler>Surface>Sweep Faces Along Normal** command. Note that the adjoining faces will not be sheared or bent.

This command is useful for extruding faces, resizing holes, and removing rounded corners.

To sweep selected object faces in a normal direction:

1. Click **Select Faces** on the shortcut menu.
2. Select the faces of the object you want to sweep.
3. Click **Modeler>Surface>Sweep FacesAlong Normal**.
4. The **Sweep FacesAlong Normal** dialog box appears.
5. Type the distance you want to sweep the object face from its origin.
6. Click **OK**.

   The face is swept the distance you specified to create a new object.

Related Topics

Moving Faces Along the Normal

Thicken Sheet

To thicken a sheet object to make a 3D object:

1. Select the sheet.
2. Click **Modeler>Surface>Thicken Sheet**.

   The **Thicken Sheet** dialog appears.
3. Specify the thickness by typing in the field.
4. Specify the units by selecting from the drop down menu.
5. If you want to thicken both sides, use the check box.
6. Click **OK**.

   The dialog closes and the sheet is changed into a 3D object of the desired thickness.

Wrap Sheet Command

You can use **Modeler>Surface>Wrap Sheet** command to wrap a sheet object around a suitable 3D object. The sheet object does not have to be in contact with the 3D object. It should have smaller dimensions than the 3D object.

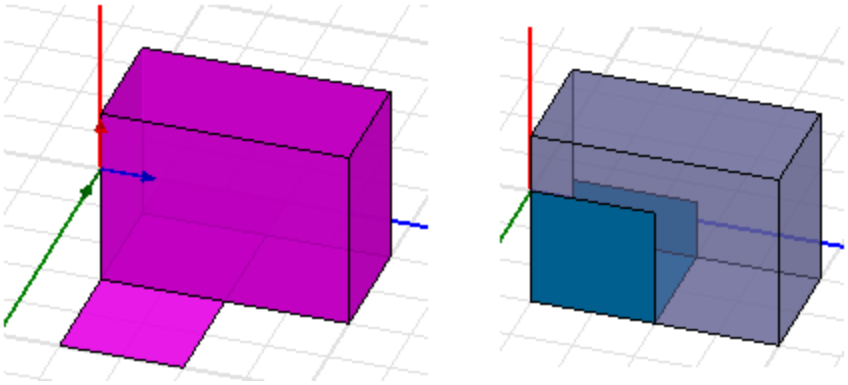
When the sheet to be wrapped and the target body do not touch, the wrap sheet command chooses among several different methods for bringing them into contact.

- If an edge from the sheet body and the target body are close enough and at a small angle (10 degrees), the edges are brought into alignment before the wrap.
- If a vertex from the sheet body and an edge on the target body are close enough, the vertex is moved to the target edge.
- If the previous criteria are not matched, a vertex from the sheet body is moved to the closest face of the target body.

If both the sheet to be wrapped and the target face are both planar and have the same or opposite normal, the closest vertex from the sheet body is moved to the target face. No movement to or alignment of edges is performed.

If the sheet body has multiple lumps, a single rectangle is fitted around all of the lumps. The rectangle is moved to the target surface using the above procedure.

If the sheet object does not overlap the corners of the 3D object, the wrap is straightforward, as shown in the figure.

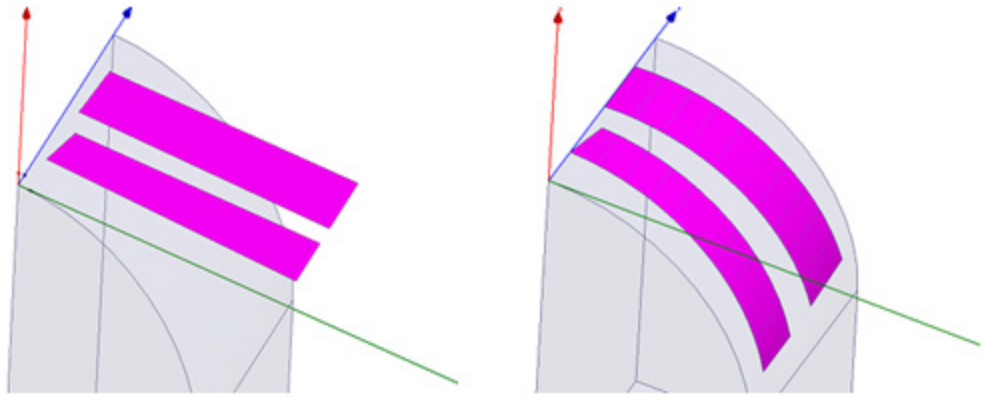


If you delete the 3D object, the wrapped sheet retains the form it took when wrapped.

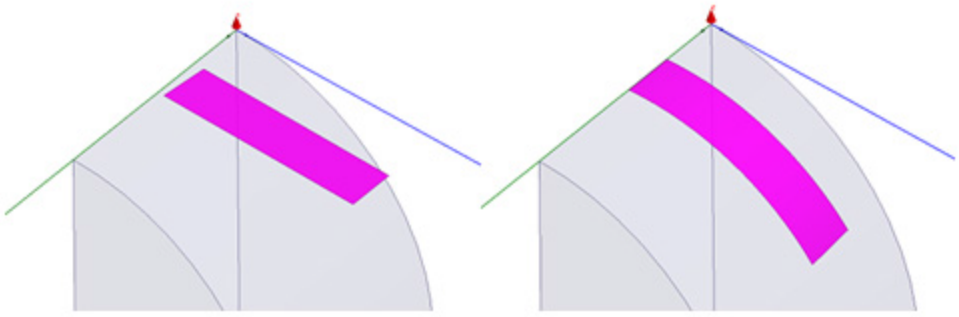
A sheet object that overlaps corners may not wrap in straightforward fashion, depending on both the angle(s) involved, and the sheet object. While it is possible, it is not recommended.

Examples:

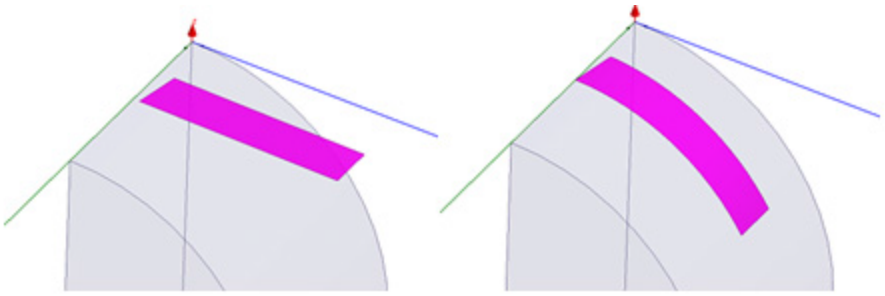
The following figure illustrates wrapping on a target surface with the snap to an edge. The surface will snap to an edge if close relative to length of edge. If the angle between the edge is less than 10 degrees, the edge to be wrapped will be aligned to the target body. In the example on the left, the lower sheet has an edge angle more than 10 degrees. The vertex will be snapped to the edge. The top sheet in the picture has an edge angle of less than 10 degrees. The vertex is snapped to the target edge and the sheet edge is aligned to the target. To avoid snapping to an edge or edge alignment the wrap sheet can be put into contact with the target surface. In that case the sheet will vertex will not be moved to target edge unless it is within modeling tolerances.



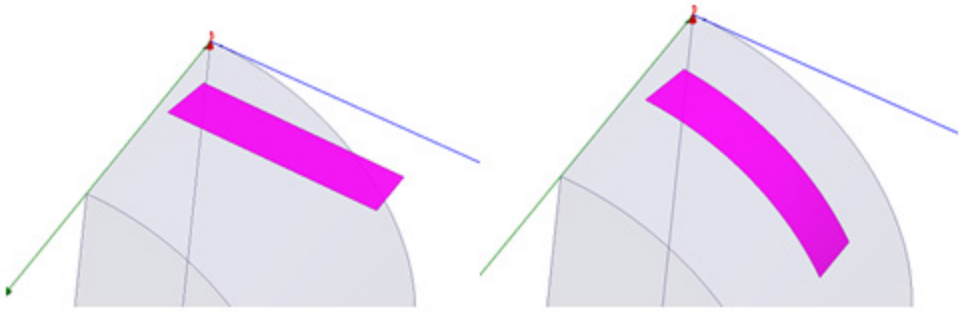
The following figure shows the situation when you move the edge to the edge before wrapping.



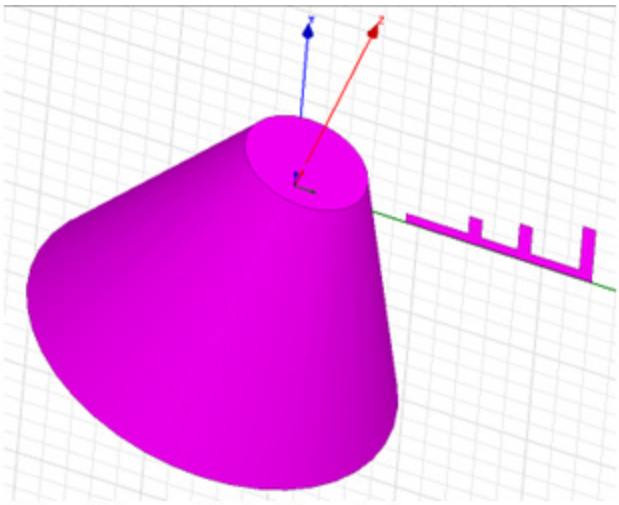
The following figure shows the situation when you move a vertex to an edge before wrapping.



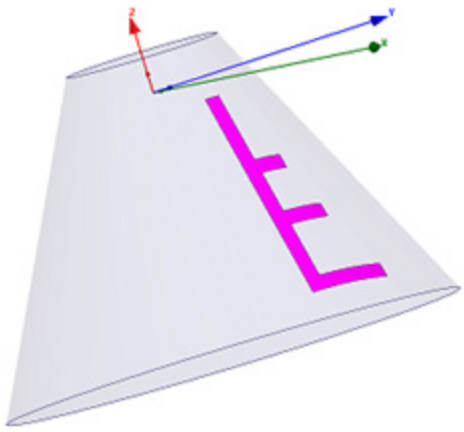
The following figure shows the situation where you move a vertex to a face before wrapping.



The figure below illustrates wrapping sheet onto cone. The sheet does not have line contact.

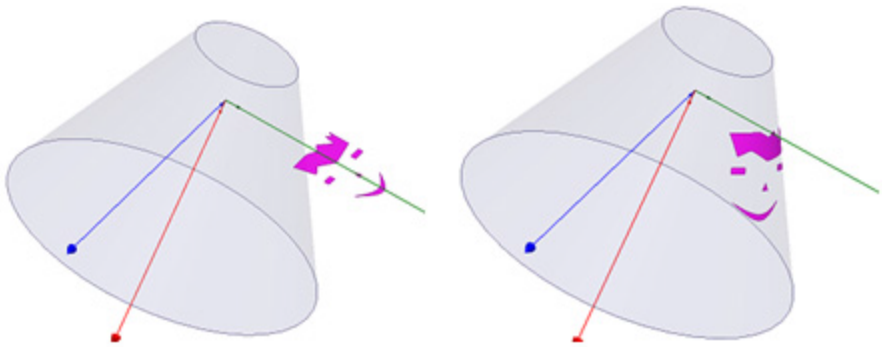


Picture 1: Use case 1 before Wrap sheet

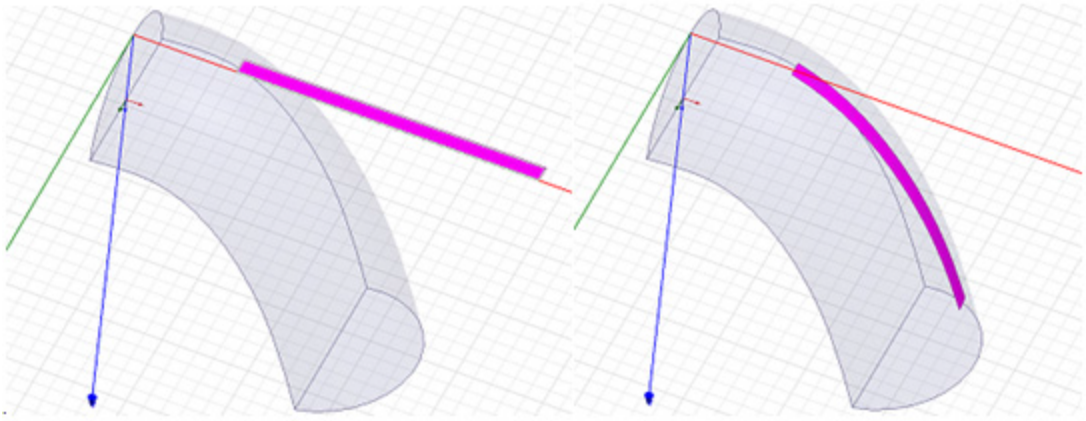


Picture 2: Use case 1 after Wrap sheet.

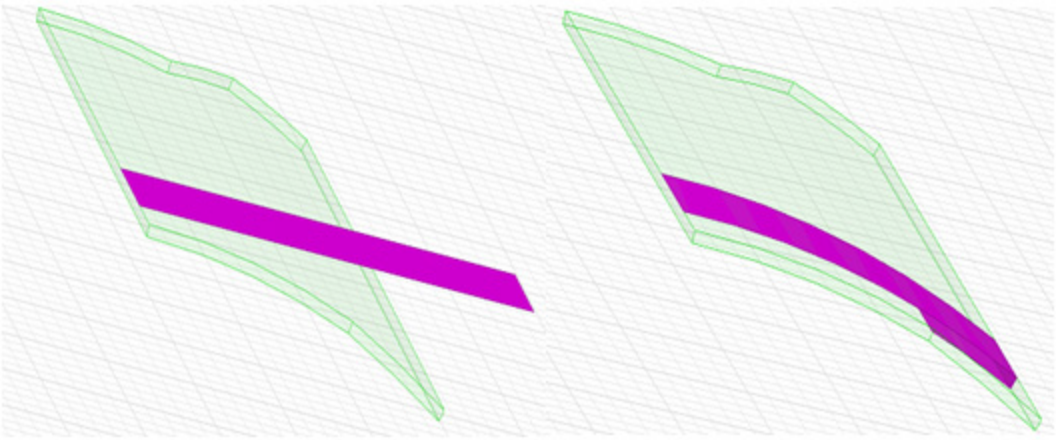
The following figure shows the situation when you move a multilump sheet to touch the target body.



The next figure illustrates wrapping to a non-developable surface. The area of sheet changed from 0.7000mm^2 before wrap to 0.6986 mm^2 after.



The following figure illustrates wrapping on a target surface which has tolerant edges. The tolerant edge is at the beginning of the wrap. The tolerant edge is not evident visually.



Limitations/Error Conditions:

- Wrapping on non-developable surfaces creates distortion in lengths.
- Wrapping is not allowed across curved boundaries between faces.
- Working with tolerant edges will work only if the gaps can be tightened sufficiently for the operation.
- Wrapping on the pole of a surface (such as sphere or cone) is not supported. A warning is given: WrapSheet: Wrapping sheet contacted pole of target surface. Recommend moving sheet and splitting out pole from target surface.
- The choice of method for how the sheet body is moved to touch the target face is not directly selectable by the user. If the sheet to be wrapped and target body touch, then the sheet body is only rotated at point of contact.

To wrap a sheet object:

1. Create a sheet close to an appropriate 3D object.
2. Select both objects.
3. Click **Modeler>Surface>Wrap Sheet.**

   The sheet object wraps around the 3D object. You can select the wrapped sheet object and the 3D object separately, and assign properties separately.

   If the object cannot wrap, the Message window contains a warning and description.

   You can wrap multiple sheets on the same 3D object.

   If you delete the 3D object, the wrapped sheet retains the form it took when wrapped.

You can use the **Tools>Options>Modeler** Options to automatically perform a **Modeler>Boolean>Imprint** command after performing a **Wrap.**

Modeler Options: Operation Tab

Covering Lines

To cover a closed 1D polyline object with a face, use the **Modeler>Surface>Cover Lines** command. The polyline object becomes a 2D sheet object.

To convert a polyline object to a sheet object:

1. Select the closed polyline object you want to cover.
2. Click **Modeler>Surface>Cover Lines**.

   The object is now covered. It is now a 2D sheet object that can be swept to form a 3D solid object.

Note	If you want the modeler to automatically cover all closed polyline objects you draw, including circles, ellipses, rectangles, and regular polygons, select the **Automatically cover closed polylines** option in the **Modeler Options** dialog box. A closed polyline object can also be created by using boolean unite operations on two or more polylines.

Covering Faces

To cover object faces, the faces must be united into a 3D sheet object. To cover the face of a 2D or 3D object, use the **Modeler>Surface>Cover Faces** command.

Covering the face of an open 2D sheet object that had previously been uncovered results in a 3D solid object. For example, for a box, when you select and uncover a face, the solid box becomes a sheet with five faces. When you then select that sheet body box and use the **Cover Faces** command, the box becomes a solid again with six faces.

To cover the faces of objects:

1. Select the faces of the objects you want to cover.
2. Click **Modeler>Surface>Cover Faces**.

   The object faces are now covered.

Uncovering Faces

Uncover a surface of a 3D object using the **Modeler>Surface>Uncover Faces** command. Uncovering the surface of a 3D solid object results in an open 2D sheet object.

To uncover the face of a 3D object:

1. Switch to face selection mode: Click **Edit>Selection Mode>Faces**.
2. Select a face of the object you want to uncover.
3. Click **Modeler>Surface>Uncover Faces**.

   The selected face is uncovered, leaving an open face on the object.

Note	You can uncover one face of a 3D object at a time. If you select multiple faces, only the first face will be uncovered.

Detaching Faces

The **Modeler>Surface>Detach Faces** command enables you to remove the face of a 3D object, resulting in two separate objects.

To detach the face of an object:

1. Switch to face selection mode: Click **Edit>Selection Mode>Faces**.
2. Select the face of the object you want to detach. You can select multiple faces to detach.
3. Click **Modeler>Surface>Detach Faces**.

   The selected face is now detached, resulting in two 2D sheet objects.

Detaching Edges

The **Modeler>Edge>Detach Edges** command enables you to remove an edge of a wire object, resulting in two separate wire objects.

To detach an edge of an object:

1. Switch to edge selection mode: Click **Edit>Selection Mode>Edges**.
2. Select the edge of the object you want to detach. You can select multiple edges to detach.
3. Click **Modeler>Edge>Detach Edges**.

   The selected edge is now detached, resulting in multiple wire objects.

Note	Only edges from wire bodies can be used in a detach edge operation.

Creating a Cross-Section

You can take a cross-section of a 3D object to create a new 2D object. This is done using the **Modeler>Surface>Section** command.

Use this command to create cross-sections of 3D objects on the xy, yz, or xz plane. The cross-sections are created as 2D closed polyline objects.

To create a cross-section of an object:

1. Make sure the working coordinate system you want to use for the cross-sectioning plane is set.
2. Select the object from which you want to create a cross-section.
3. Click **Modeler>Surface>Section**.
4. Select the section plane you plan to use to divide the object: **XY**, **YZ**, or **ZX**.
5. Click **OK**.

   A closed polyline object is created from the object that was sliced by the selected plane. The original, sectioned object is unmodified.

Setting the Working Coordinate System

Connecting Objects

Use the **Modeler>Surface>Connect** command to perform the following operations:

- Connect two or more 1D polyline objects. Maxwell will modify the first polyline you select to be a 2D sheet object that connects to the second and any subsequently selected polylines. The second and subsequent polylines selected are deleted.
- Connect two or more 2D sheet objects. Maxwell will modify the first 2D object you select to be a 3D solid object that connects to the second and any subsequently selected objects. The second and subsequent objects selected are deleted.

To connect objects:

1. Select the objects you want to connect.
2. Click **Modeler>Surface>Connect**.

   A new object is created that connects the objects you selected. The first object you selected was modified to create the new object and all subsequently selected objects were deleted.

Moving Faces

You can move the faces of a 3D object in a normal direction using the **Modeler>Surface>Move Faces** commands. Moving object faces enables you to resize, reshape, or relocate an object.

Moving Faces Along the Normal

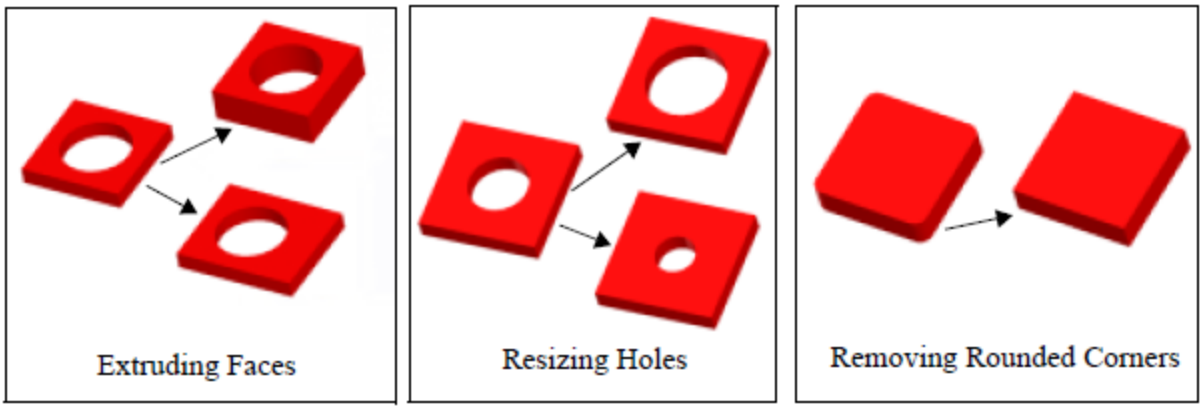
To move a 3D object's face a specified distance in a direction normal to its original plane, use the **Modeler>Surface>Move Faces>Along Normal** command. The faces that adjoin the original face are extended or shortened along their own planes to meet the new face. Note that the adjoining faces will not be sheared or bent.

This command is useful for extruding faces, resizing holes, and removing rounded corners, as shown below.

To move an object face in a normal direction:

1. Click **Select Faces** on the shortcut menu.
2. Select the face of the object you want to move.
3. Click **Modeler>Surface>Move Faces**>**Along Normal**.
4. The **Move facesalong normal** dialog box appears.
5. Type the distance you want to move the object face from its origin.
6. Click **OK**.

   The face is moved the distance you specified.



To move every face of an object normal to its surface, use the **Edit>Arrange>Offset** command.

Moving Edges Along the Normal

Moving Faces Along a Vector

To move the faces of a 3D object a specified distance along a vector use the **Modeler>Surface>Move Faces>Along Vector** command. Each selected face is moved along the vector, normal to its original plane. The faces that adjoin the original face are extended or shortened along their own planes to meet the new face. Note that the adjoining faces will not be sheared or bent.

This command is useful for relocating holes in an object, as shown below.

To move an object face along a vector:

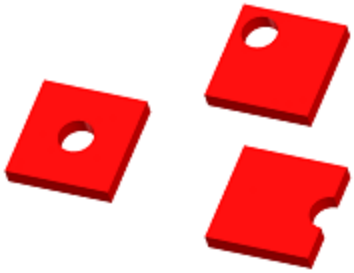
1. Click **Select Faces** on the shortcut menu.
2. Select the face of the object you want to move.
3. Click **Modeler>Surface>Move Faces**>**Along Vector.**
4. Specify the vector along which the face is to be moved:
   a. Select an arbitrary anchor point in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

   Any point in the drawing region can be selected; however, selecting an anchor point on the object's edge or within the object makes it easier to select the vector.

   b. Select a second point in one of the following ways:
      - Click the point.
      - Type the coordinates of a point relative to the anchor point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   This point defines the direction and distance from the anchor point to move the face.

   The face is moved along the vector you specified.



To move every face of an object normal to its surface, use the **Edit>Arrange>Offset** command.

Moving Edges Along Normal

To move a 2D object's edge a specified distance in a direction normal to its original plane, use the **Modeler>Edge>Move Edge** command. The edge is extended or shortened along its own plane. Note that the adjoining faces will not be sheared or bent. The edge can be on a rectangle, an ellipse, a circle, a regular polygon, or an equation based surface.

This command is useful for extending or shrinking faces and resizing holes.

To move an object edge in a normal direction:

1. Click **Select Edge** on the shortcut menu.
2. Select the edge of the object you want to move.
3. Click **Modeler>Edge>Move Edge**.
   The **Move FacesAlong Normal** dialog box appears.
4. Type the distance you want to move the object face from its origin.
5. Click **OK**.
   The edge of the object is moved based on the value you specified.

Uniting Objects

To join two or more objects into one object, use the **Modeler>Boolean>Unite** command. The new object has the name, color, boundary, and material assignment of the first object selected. The objects are united at the point of intersection.

You can unite objects that do not touch.

To unite two or more objects:

1. Select the objects you want to join.
2. Click **Modeler>Boolean>Unite**  ..
   The objects are united.

Note	By default, the objects being joined to the first object selected are *not* preserved for later use. If you want to keep a copy of the objects being joined to the first object selected, do one of the following: • Copy the objects, and then paste them back into the design after uniting them. • Select **Clone before unite** in the **Modeler Options** dialog box. This option instructs the modeler to always keep a copy of the original objects being joined.

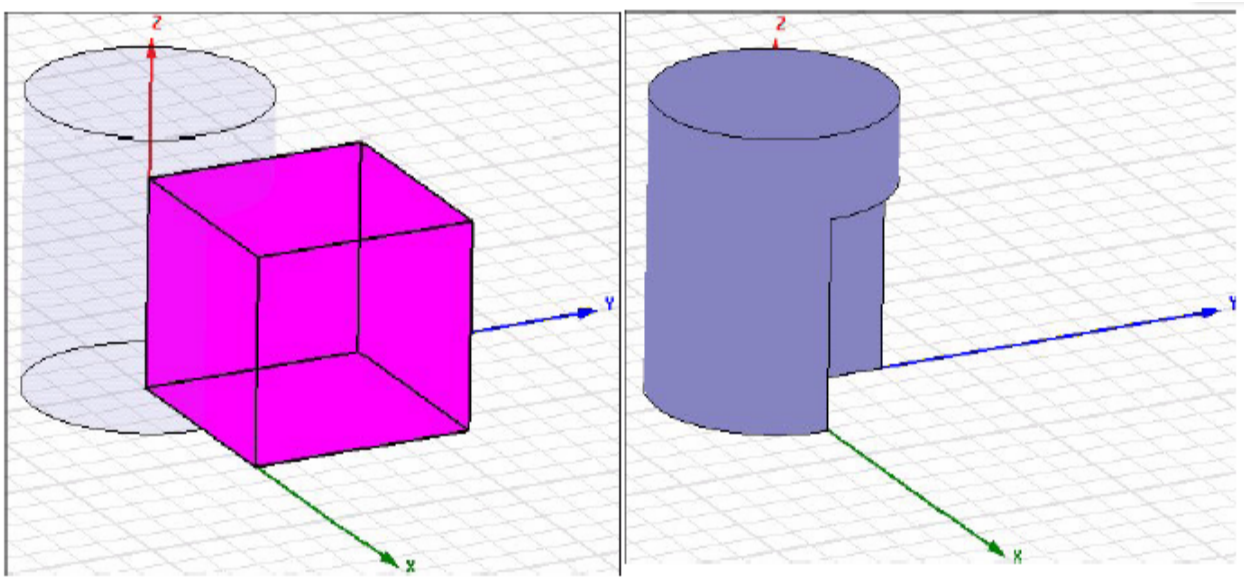
Subtracting Objects

1. Select the object from which you want to subtract other objects.
2. Hold down the **Ctrl** key and select the objects you want to subtract.
3. Click **Modeler**>**Boolean**>**Subtract**  .

   The **Subtract** dialog box appears.

   Objects listed in the **Tool Parts** list are subtracted from the object or objects listed in the **Blank Parts** list.
4. Optionally, select an object name in either list, and use the left and right arrow buttons to move the object name to the opposite list.
   - Alternatively, type the name of object you want to subtract in the empty box below the **Tool Parts** list, and then type the name of the object from which you want to subtract it in the empty box below the **Blank Parts** list.
5. Optionally, select **Clone tool objects before subtract**. This instructs Maxwell to always keep a copy of the original objects being subtracted.
6. Click **OK**.

   The new object retains the name, color, and material of the first object selected.



An intersecting box and cylinder.

A box subtracted from a cylinder.
The cylinder was selected first.

Note	By default, the objects being subtracted from the first object selected are *not* preserved for later use. If you want to keep a copy of the objects being subtracted from the first object selected, do one of the following: • Copy the objects, and then paste them back into the design after subtracting them. • Select **Clone before subtract** in the **Modeler Options** dialog box. This option instructs Maxwell to always keep a copy of the original objects being subtracted.

Creating New Objects By Intersecting Objects

To create a new object from the intersection of two or more objects, use the **Modeler>Boolean>Intersect** command.

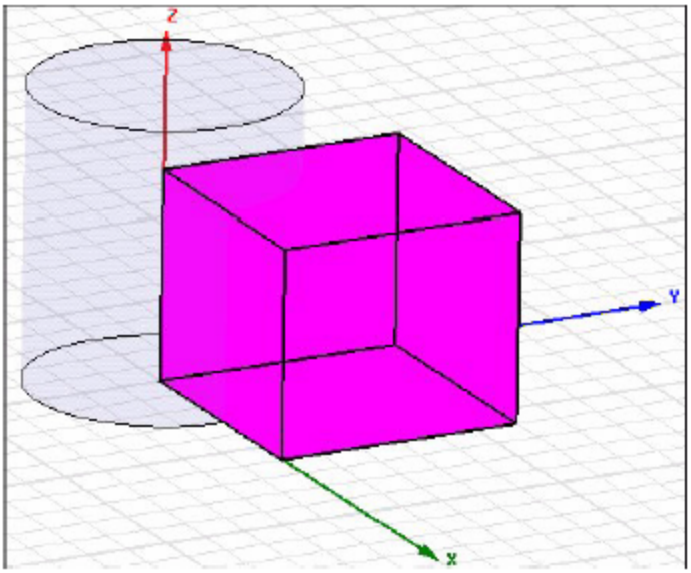
To create an object from an intersection:

1. Select the objects from which you want to take the intersection.

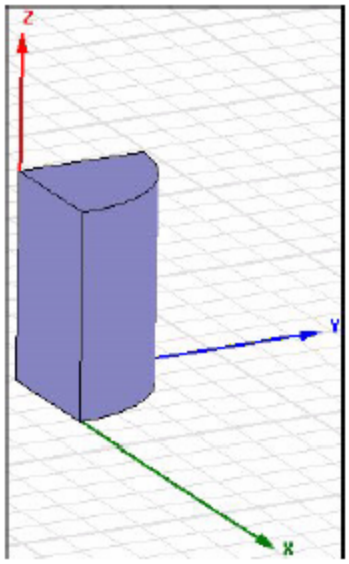
Warning	If the objects you selected do not overlap, the result is a null object, and all objects vanish.

2. Click **Modeler**>**Boolean**>**Intersect**  .

   The original objects vanish, leaving only the new object that was formed from their intersection.



An intersecting box and cylinder.



Object formed from the intersection of the box and cylinder.

Note	By default, the original intersecting objects are *not* preserved for later use. If you want to keep a copy of the objects that intersect the first object selected, do one of the following: • Copy the objects, and then paste them back into the design after creating the new object from the intersection. • Select **Clone before intersect** in the **Modeler Options** dialog box. This option instructs the modeler to always keep a copy of the original objects that intersect the first object selected.

Creating an Object from a Face

The **Modeler>Surface>Create Object From Face** command copies a selected face, resulting in a new 2D sheet object.

To create a new object from a face:

1. Right-click in the modeler window, and select **Select Faces** on the shortcut menu.
2. Select the object face you want to copy. If you select multiple faces, each becomes a new object.
3. Click **Modeler**>**Surface>Create Object From Face**.

   The face is copied, resulting in a new 2D sheet object.

Hint	This command is useful for assigning a boundary to the intersection of two faces. To do this, first select the faces, and then create an object from them using the procedure

	above. Next, make sure the **Clone before intersect** option is clear in the **Modeler Options** window, and then use the **Modeler>Boolean>Intersect** command to modify the object so that it includes only the intersection of the two faces. Then assign the boundary to the new object.

Related Topics

Assigning a Cross Section and Dimension to a Polyline

Creating an Object from an Edge

Creating an Object from an Edge

The **Modeler>Edge>Create Object From Edge** command copies a selected edge, resulting in a new 2D sheet object.

To create a new object from an edge:

1. Right-click in the modeler window, and select **Select Edges** on the shortcut menu.
2. Select the object edge you want to copy. If you select multiple edges, each becomes a new object.
3. Click **Modeler>Edge**>**Create Object From Edge**.

The edge is copied. The resulting object appears in the history tree as a line object.

Assigning a Cross Section and Dimension to a Polyline

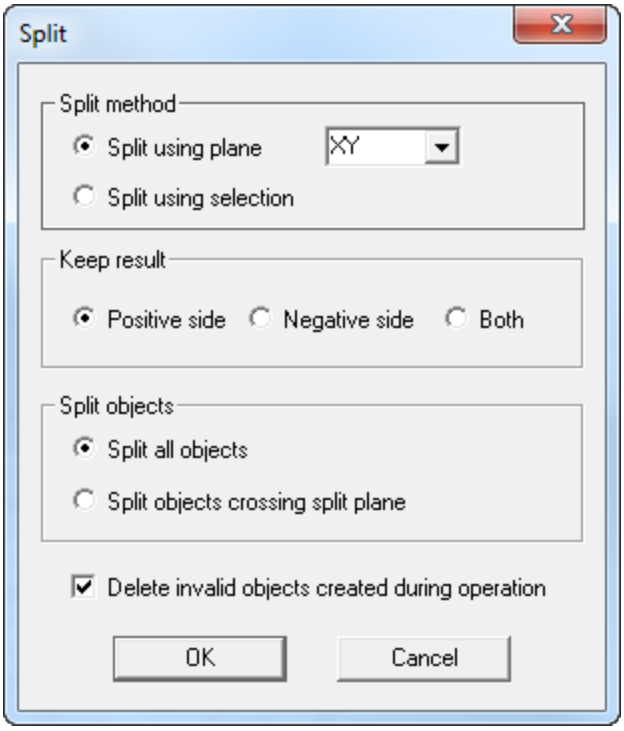
Creating an Object from a Face

Splitting Objects

To delete parts of an object that lie on the xy, yz, or xz plane, use the **Modeler>Boolean>Split** command.

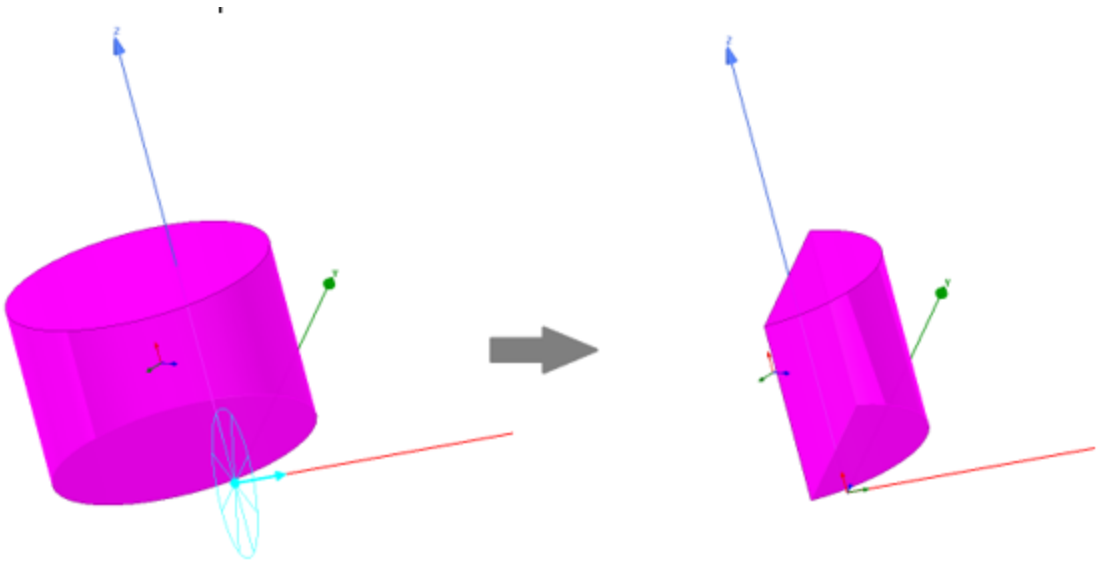
1. Select the object you want to split. You can select more than one.
2. Click **Modeler>Boolean>Split**  .

   The **Split** dialog box appears.

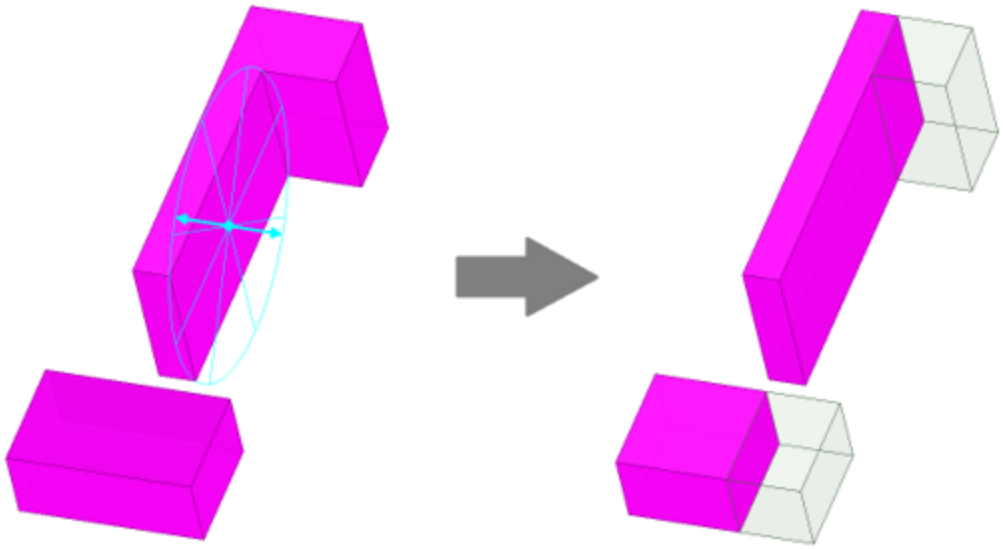


3. Select **Split using plane**, and then select **XY**, **YZ**, or **XZ** as the **Split plane** or click **Split using selection** and select a planar face or arc edge.
4. Select one of the following **Keep result** options to specify which object fragments you want to keep:
    - **Positive side**- keep objects on the positive side of the selected plane.
    - **Negative side** - keep objects on the negative side of the selected plane.
    - **Both** - all pieces on both sides of the plane.

    The split plane is shown with a blue wheel with spokes as seen in the picture below left. A blue arrow, in case to the right, indicates which side of the split plane is to be kept. Once the proper selections have been made press OK. In this example the positive side of YZ (green and blue axes) plane results was kept. The picture on the left is before the split. The picture on the right is the result for the split command.



If you select **Split using selection** you can choose a planar face or edge arc to define the split plane. You can only select one entity. Face or edge to define plane need not belong to one of objects selected for split operation - it could be any face or edge from the model. You can position, scale, or view the model as needed to make the selection easier. The following example shows the operation with keep result for both sides. (Notice the arrow is in both directions for the split plane graphics.) The picture on the left is before the split. The picture on the right is the result for the split command.



5. Select one of the following **Split objects** options:
   - **Split entire selection** –Select this option if you do not want to preserve objects that are not crossing the split plane and still part of the selection.

- **Split all objects crossing split plane** – This option allows you to identify selected objects that do not cross the split plane and ignore them for the operation. For a multiple selection, only those objects that cross the split plane are split; others are kept intact. By design, splits in existing designs from previous versions are not changed.

6. If you choose split entire selection, it could create invalid objects if the split plane does not cut any of the selected objects. You can use the option **Delete invalid objects created during operation** to delete these invalid objects.
7. Click **OK**.

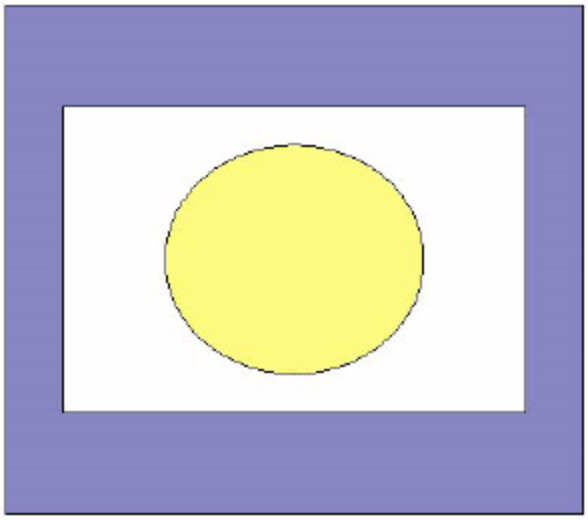
   The objects are divided as specified.

Separating Bodies

To separate an object with multiple lumps into individual bodies:

1. Select the object you want to separate.
2. Click **Modeler>Boolean>Separate Bodies**.

   The object is separated.



This figure shows two separate bodies, each with one lump, that were created from one object.

Converting Polyline Segments

A polyline is a single object that includes any combination of straight line, arc line, or spline segments. You can convert a polyline segment from one type to another. The following conversions are supported:

- Straight line segments to arc line or spline segments.
- Arc line segments to straight line or spline segments.

- Spline segments to straight line segments.

To convert polyline segments:

1. In the history tree, locate the polyline that contains the segment you want to convert. Expand this part of the history tree.
2. In the history tree, right-click the polyline segment operation you want to change, and then click **Properties**.
   The Properties dialog appears.
3. In the **Properties** dialog box, click in the **Value** box of the **Segment Type** row.
4. Select the desired polyline segment type from the pull-down list.
   The polyline segment you selected is changed to the new type.

Note	Converting an arc line or spline segment to a straight line segment results in two straight line segments; one segment is created between the start point and midpoint, and one segment is created between the midpoint and endpoint.

5. By default, curved surfaces are treated as smooth (True) surfaces. If segmented surfaces are desired, enter an integer number in the **Number of Segments** parameter.
6. Click **OK** to dismiss the properties panel and implement the changes.
   If the changes are not what was expected, undo the change using the **Edit>Undo** command or press **CTRL-Z**.

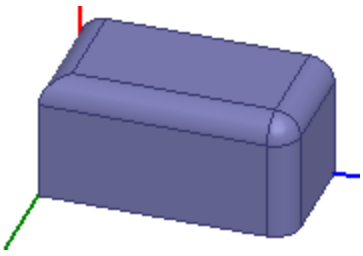
Surface Approximation

Rounding the Edge of an Object (Fillet Command)

Note	The Fillet command may only be applied to edges of 3D solid objects. Therefore, the command is only available when working on a 3D Project.

The fillet command rounds the object at the original edges and vertices. This means that the edges and vertices are going to be replaced by new rounded surfaces, so that the original faces of the object reconnect in a smooth manner.



Vertices are only going to be replaced by new rounded surfaces if all the edges connecting to the original vertex are selected; otherwise, the vertex is preserved but moved (if necessary). The edges are replaced by quarter-cylindrical surfaces, of which the radius can be customized (see the **Fillet Radius** property). Vertices are replaced by more complicated new faces. You can control the setback distance.

The fillet command is disabled if an edge is not selected.

To switch to edge selection mode:

- Right-click the desktop, and select **Selection Mode>Edges** from the shortcut menu.

To round an object's edge:

1. Select the edge you want to change.

   The edge is highlighted, and the **Fillet** command is enabled.
2. Click **Modeler>Fillet**, or click the **Fillet** icon on the **Draw** ribbon.

   The **Fillet Properties** dialog box appears.
3. Enter a value for the **Fillet Radius** in the text field and select units from the drop down menu. The default is millimeters.
4. Enter a value for the **Setback distance**.

   The setback distance controls the shape of the vertex. It is the distance of the cross curve from the vertex at the end of the edge. If it is less than the fillet radius it has no effect. You will get an error if it is greater than the length of the edge.

Note	The setback feature works only on corners where three or more edges meet and only if all edges meeting at the vertex are selected.

5. Click **OK** to apply the change to the edge.

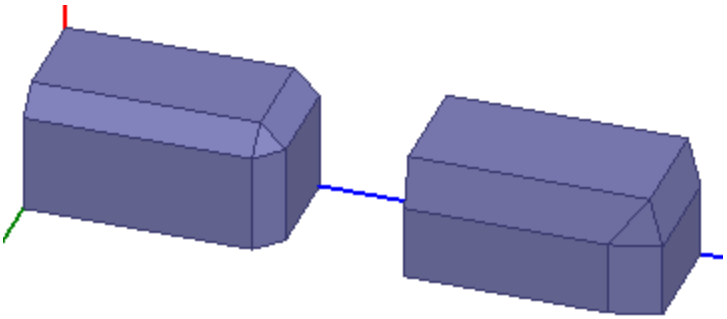
   The dialog closes and the object is rounded by the radius value relative to the edge you selected.

Flattening the Edge of an Object (Chamfer Command)

Note	The Chamfer command may only be applied to edges of 3D solid objects. Therefore, the command is only available when working on a 3D Project.

The chamfer command flattens the edges and vertices of the object. This means that the edges and vertices are replaced by new flat surfaces, so that the original faces of the object reconnect through the newly introduced flat surfaces. Vertices are replaced by new flat surfaces only if all the edges connecting to the original vertex are selected; otherwise, the vertex is preserved but moved (if necessary).

Chamfers can be symmetric, or asymmetric.



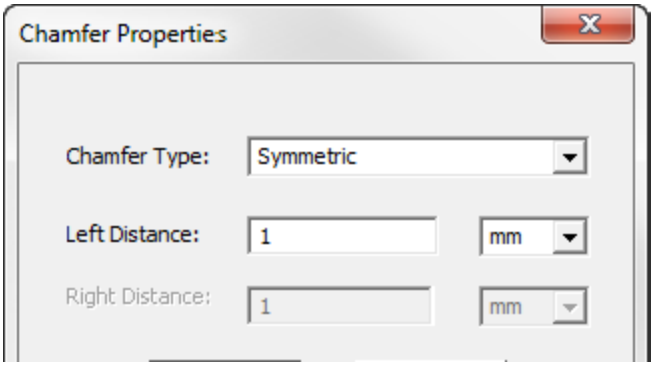
The chamfer command is disabled if an edge is not selected.

To switch to edge selection mode:

- Right-click the desktop, and select **Selection Mode>Edges** from the shortcut menu.

To flatten an object's edge.

1. Select the edge you want to change.
   The edge is highlighted, and the **Chamfer** command is enabled.
2. Click **Modeler>Chamfer** or click the **Chamfer**icon on the **Draw** ribbon.
   The **Chamfer Properties** dialog box appears.

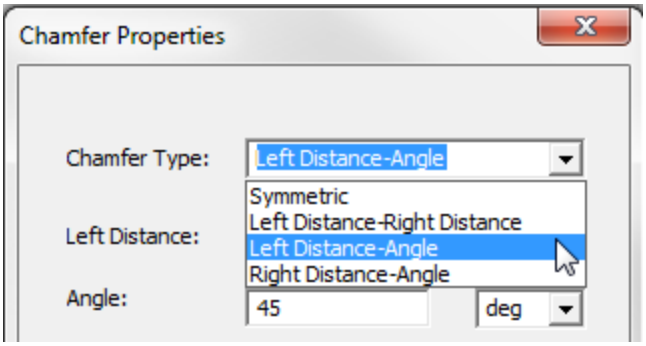


3. Type a value in the **Left Distance** text box, and select the units from the pull-down list.
4. Click **OK** to apply the change to the edge.
   The **Chamfer Properties** dialog box closes, and the object is flattened by the radius value relative to the edge you selected.

To flatten an object's edge for an asymmetric chamfer:

1. Select one or more edges and click **Modeler>Chamfer** to open the **Chamfer Properties** dialog.

2. Use the Chamfer type drop down menu to select the type:



You control an asymmetric chamfer by selecting a type that defines the chamfer asymmetry as Left-Distance Right Distance, as Left Distance-Angle, or as Right Distance Angle. Notice that red directional arrows on the selected edges provide the direction against which left distance and right distance are determined.

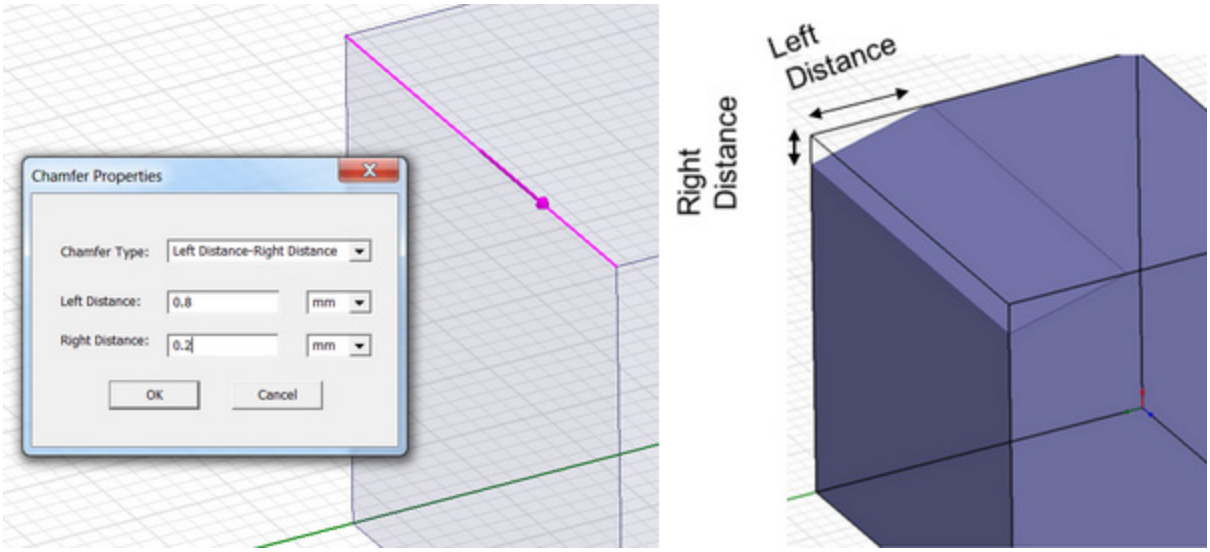


Figure 8-2 Left Distance-RightDistance

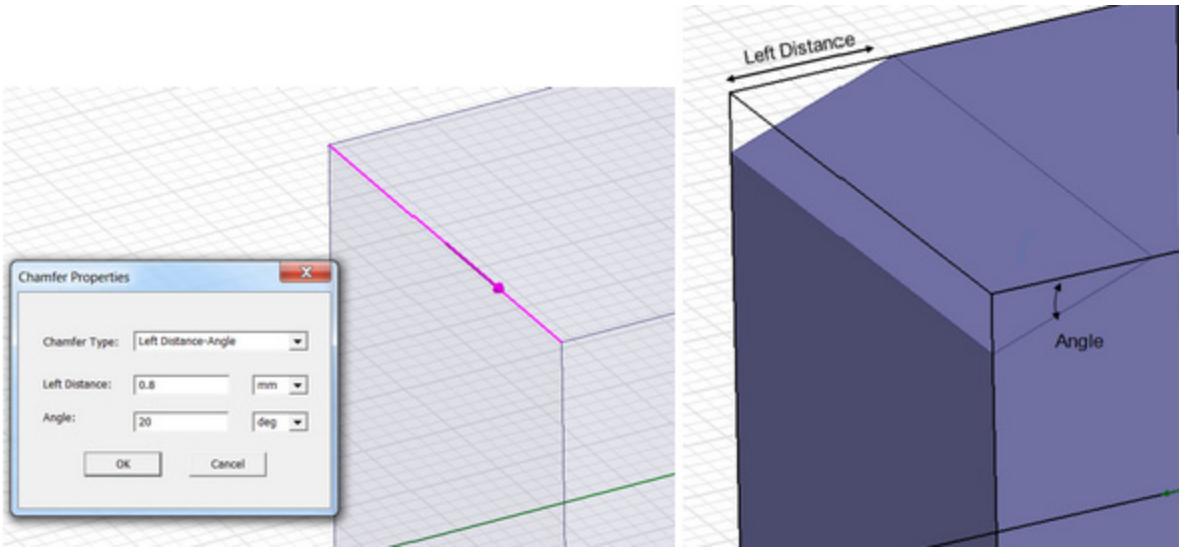

Figure 8-3 Left Distance Angle

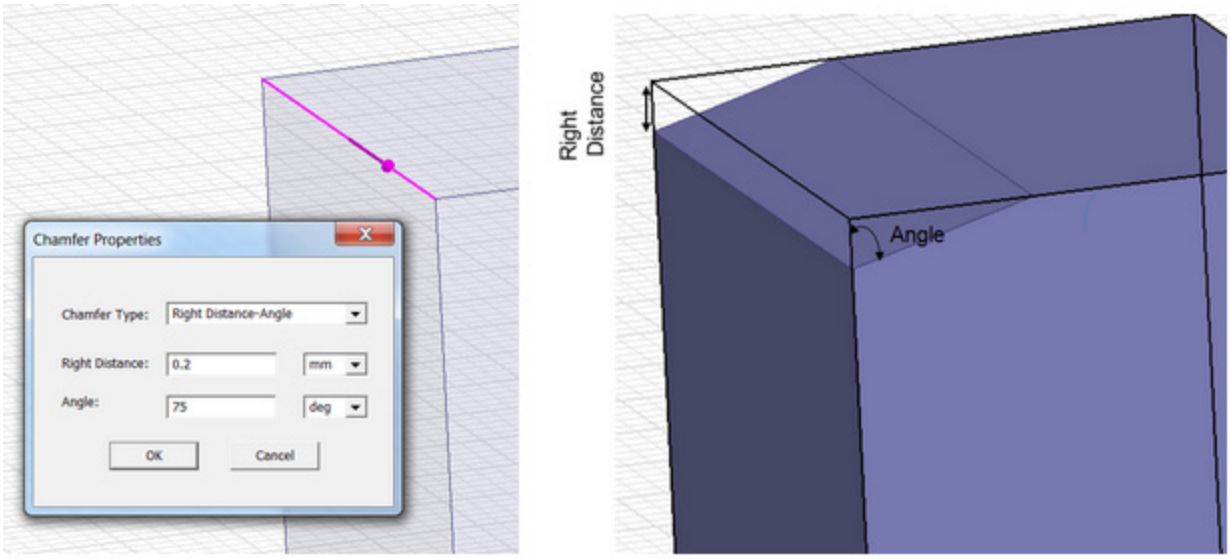

Figure 8-4 Right Distance-Angle

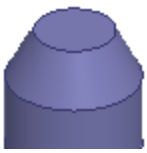
Only symmetric and left distance-right distance chamfers are supported for edges formed by a curved surface.

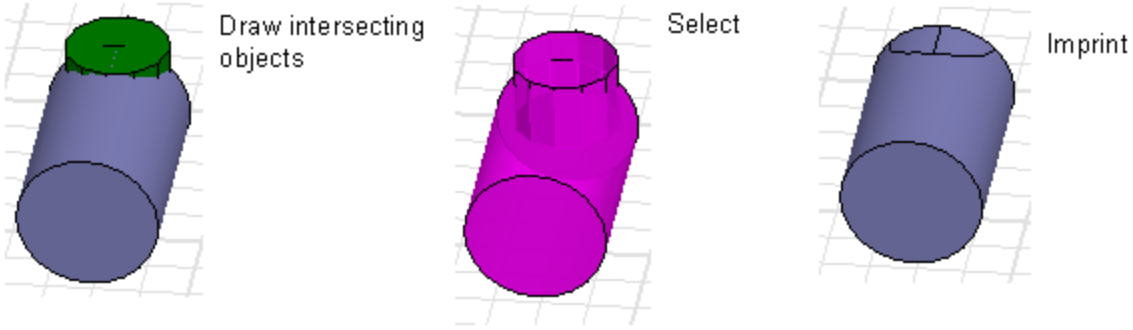


Angle-distance chamfers are not supported in such cases and do not appear on the Chamfer Type drop down menu.

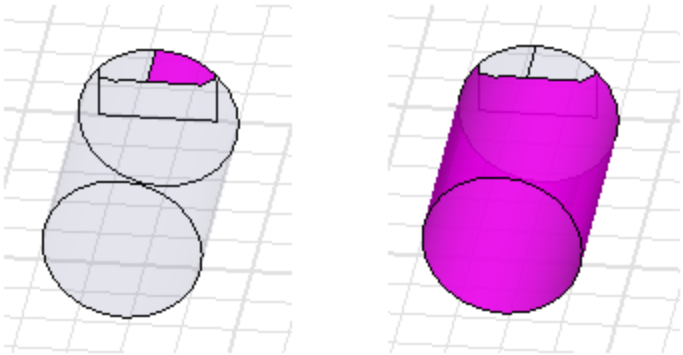
3. Click **OK** to apply the chamfer to the selected edges.

Imprinting an Object

The **Boolean>Imprint** command lets you imprint the geometry of one object upon another. For example, you could draw a polyhedron intersecting a cylinder, and then imprint the intersecting lines on the cylinder.



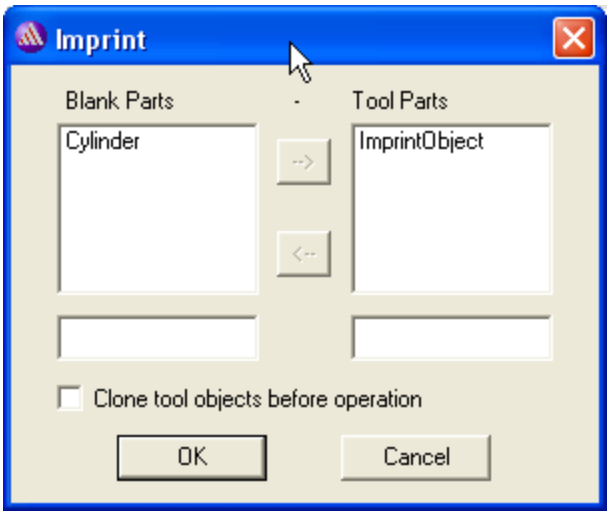
You can select the faces of the imprinted surface separately and assign properties as needed.



To imprint one object with another:

1. Select the intersecting objects.
2. Click **Modeler>Boolean>Imprint...**

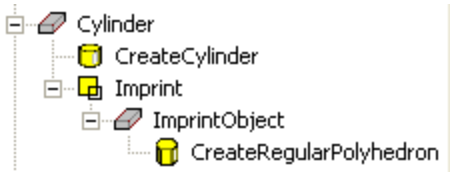
   This displays the Imprint dialog in which you designate which objects are the Blank Parts, and which the Tool Parts. If necessary, you can select the objects in lists, and use the arrow keys to move them. If desired, you can clone the tool objects before the imprint operation.



3. Click **OK**.

   This closes the dialog and performs the boolean imprinting.

After you perform the imprinting, the History tree retains the Imprint Object command and the create command for the imprinted object



If you select the Imprint command in the History tree, you can suppress the command via the Properties window. If you select the Create <*object*> icon for the object, you can edit the properties of that object. The changes applied to the object carry over to the imprinting.

Related Topics

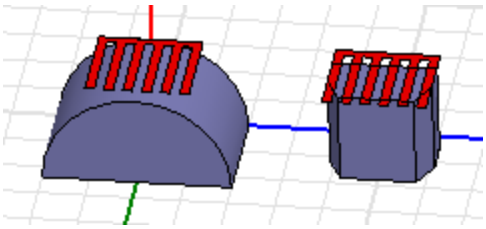
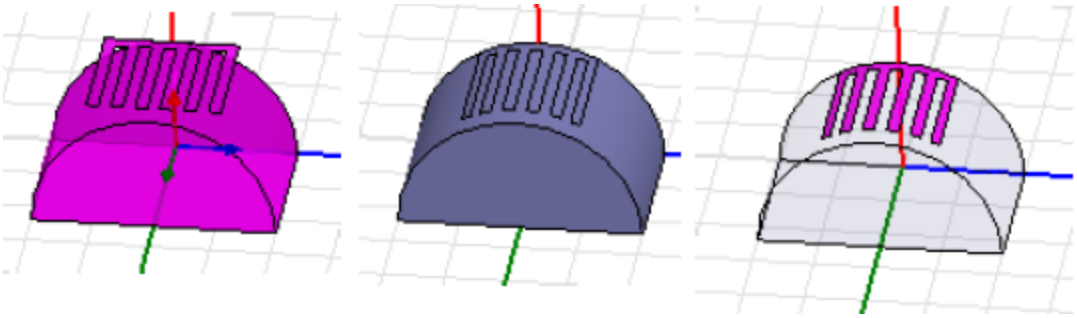
Imprint Projection Commands

Imprint Projection commands

The **Boolean>Imprint Projection** commands lets you project the form of one object to another surface. The receiving surface can be curved or faceted.



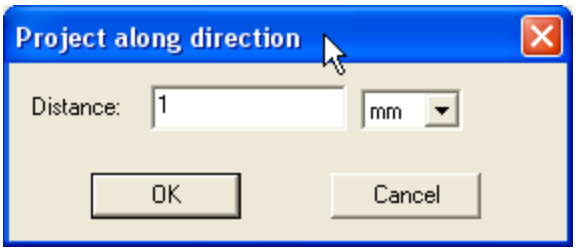
If the surface is curved, the dimensions of the projection will be affected.You can select the faces of the imprinted object separately, and edit properties as needed.



If projected shape extends beyond the face of the receiving object, the shape wraps.

1. Select the intersecting objects.
2. Click **Modeler>Boolean>Imprint Projection>Along Normal** or **Modeler>Boolean>Imprint Projection>Along Direction...**

   If you select **Along Normal**, the projection occurs along the normal. If you select Along Direction, you need to specify two points that describe the direction. Once you have defined a line by clicking two points, you see a dialog for specifying the distance for the projection.



3. Specify a distance and select units from the drop down menu and click OK.

   This closes the dialog and performs the boolean imprinting.

After you perform the imprinting, the History tree shows the Imprint Object command and the create command for the imprinted object

If you select the Imprint Projection command in the History tree, you can suppress the command via the Properties window. If you select the Create <object> icon for the object, you can edit the properties of that object. The changes applied to the object carry over to the imprinting.

Purging the History

Each object is a sequence of modeler-based operations. The history for each object is shown under its name in the model tree. You can use the Purge History command to remove the history of operations while not affecting the geometry itself. This is useful when you want to perform healing operations on the object. If there is an object for which you want to keep the history, you should make a copy of the object for that purpose before purging.

To purge the history:

1. Select the object.
2. Select **Modeler>Purge History**.

The history for the model is purged, and the context for the **Undo** and **Redo** commands is updated.

Generating History to Reproduce Portions of a Model

If a polyline object (line, spline, or arc), circle, or ellipse is imported or history was previously purged, you can click on the polyline object and select **Generate History** to reproduce the individual line segments used to create the polyline in the model history tree.

To reproduce the line segments in the model history tree:

1. Select the polyline object.
2. Click **Modeler>Generate History**.

Draw Polyline

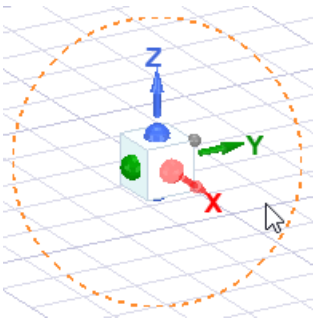
Modifying the 3D Model View

You can modify the view of contents in the **Modeler** window without changing their actual dimensions or positions within the coordinate system. You vary the viewing direction and the relative location of the "camera" (that is, the viewpoint) relative to the model geometry. The tools allow you to zoom, pan, or rotate the model viewpoint, and to quickly switch to pre-defined or user-defined viewpoints. Additionally, you can choose different object visualization options, show/hide objects, and customize the window background.

What do you want to do?

- Change the model view with Alt+double-click on areas in the modeler window.
- Set the View Options
- Rotate the view.
- Pan the view.
- Spin the view.
- Zoom in or out.
- Viewing 3D User Interface Options
- Fit contents in the view window.
- Show or Hideobjects.
- Render objects as wireframes, flat-shaded, or smooth-shaded solids.
- Set the Enhanced Display of Material Color and Transparency
- Modify the view orientation.
- Modify the lighting.
- Set the projection view.
- Set the background color.
- Modify the appearance of the coordinate system axes.
- Modify the appearance of the grid.
- Set the Surface Visualization
- Setting a symmetry multiplier
- Use Clip Planes

In addition to various menu bar and shortcut menu commands, you can manipulate the 3D model view using the Orientation Gadget:



Finally, you can also access many of the Modify View features via the **View Ribbon**. The following image has hot links for each area.

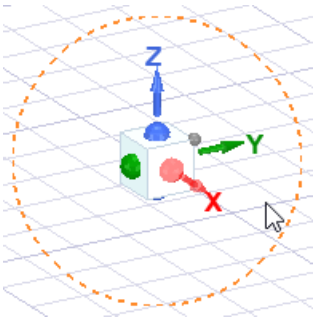
Using the Orientation Gadget

The *Orientation Gadget* is a tool for quickly manipulating the 3D model viewpoint graphically, rather than by navigating command menus. The gadget is enabled by default and appears near the lower left corner of the Modeler window's display area:



The orange dashed circle appears only when the cursor is near the gadget, and its purpose is discussed later in this topic.

There is a colored dot at the center of each face of the cube and red (x), green (y), and blue (z) miniaxes indicating the global axis positive directions. Additionally, there is a smaller gray dot at the corner where the +X, +Y, and +Z faces meet.

The following list summarizes the results of clicking different parts of the gadget (and optionally dragging the mouse while clicking). The descriptions are based on the behavior when the *Global* coordinate system is active:

- **Click the large dot at the center of any of the six cube faces:**

  This action rotates the viewpoint to place the side of the model that the clicked face represents towards you, parallel with the screen. For example, if you click the dot on the -Y face, the -Y side of the model faces you. Therefore, you would be looking in the +Y direction, which is the *Left* view.

> **Note:** If the current viewing direction corresponds to one of the global axes (±X, ±Y, or ±Z), clicking the axis label or dot at the center of the orientation gadget (on the face that is towards you) reverses the model viewpoint. So, you can switch from front-to-back, right-to-left, top-to-bottom, or the inverses of these viewpoint changes with a single click of the mouse. This behavior holds true even for relative coordinate systems, as long as the current viewing direction corresponds to a global axis.

- **Click on one of the miniaxes:**

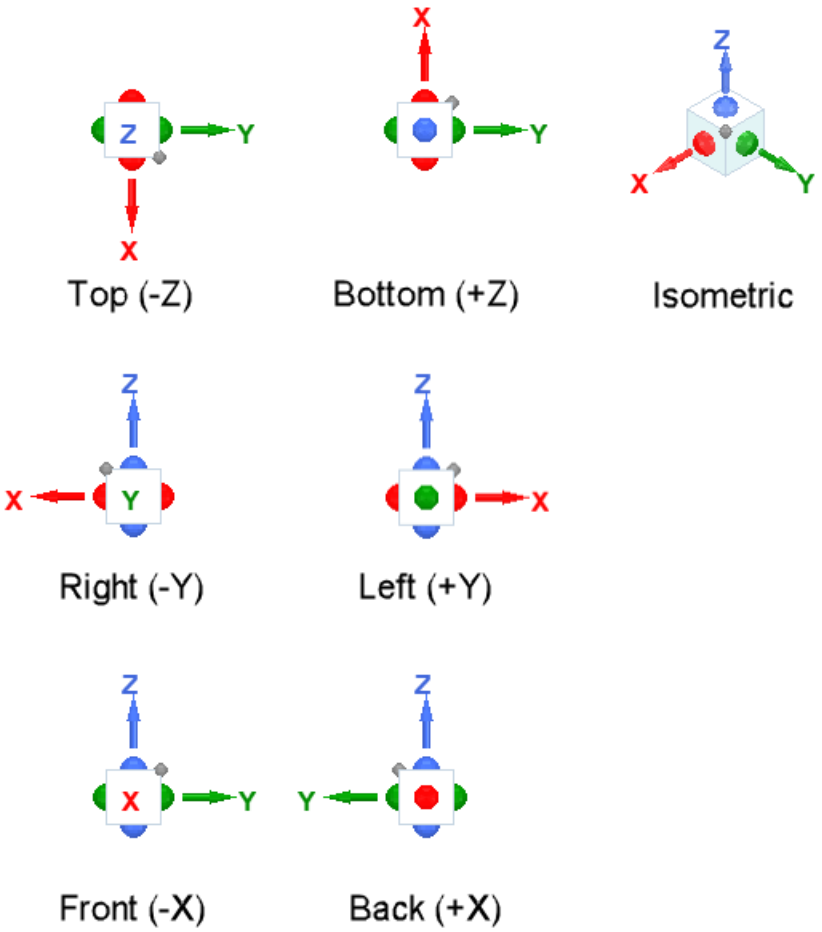
  This action is equivalent to clicking the dot at the center of the same positive cube face. The axis orientation becomes perpendicular to the screen and towards you. Therefore, the resulting three views are looking at the +X (front), +Y (right), or +Z (top) side of the model.
- **Click the small gray dot at the cube's +X, +Y, +Z corner:**

  This action produces the standard *Isometric* model viewpoint.
- **Click on or very close to the cube and drag the mouse:**

  This action freely rotates the model viewpoint. The rotation center depends on the **Default Rotation About** option selected in the *3D UI Options* dialog box. The behavior is equivalent to clicking and dragging in the display area using the middle button / wheel but is performed with the left mouse button.
- **Click on the orange dashed circle and drag the mouse:**

  This action rotates the model view about an axis normal to the screen. That is, the model view rotation is constrained to the plane of the screen regardless of the current viewing direction. The line weight of the dashed orange circle becomes heavier when the cursor is touching it, indicating a correct clicking point for constrained rotation.

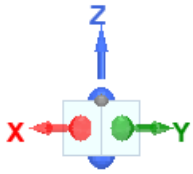
The appearance of the Orientation Gadget for each of the standard views is as shown in the following image:



Note:

The cube orientation, colored dots, and miniaxes of the Orientation Gadget always correspond to the Global coordinate system. However, the result of clicking on a dot or axis is a viewpoint that conforms to any currently active coordinate system. See the example that follows.

Example: Assume that you have defined a relative coordinate system in which the Ux axis is rotated counter-clockwise 45° from the Global X axis, in the Global XY plane, and that this relative coordinate system is active. If you click on the X miniaxis of the Orientation Gadget, the model viewpoint will place the Ux axis perpendicular to the screen. The appearance of the gadget after clicking would be as shown below:

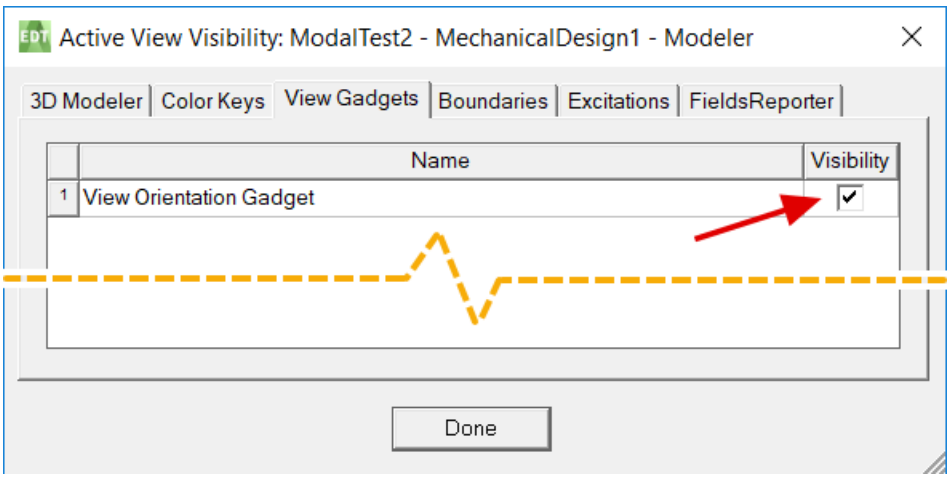


For the same relative coordinate system example, clicking the Z axis of the Orientation Gadget will produce the following result:

Controlling Visibility of the Orientation Gadget

You can enable or disable the Orientation Gadget from the, as follows:

1. Access the *Active View Visibility* dialog box using one of the following two methods:
   - From the menu bar, click **View> Visibility> Active View Visibility**.
   - On the **View, Draw,** or **Model** ribbon tab, click **Hide/Show overlaid visualization in the active view"**.
2. Select the **View Gadgets** tab.
3. Select or clear the checkbox in the **Visibility** column to the right of **View Orientation Gadget** to control the gadget visibility.



4. Click **Done** to close the dialog box.

Change the Model View with Alt-Double Click Areas

Viewing 3D User Interface Options

Use the **View>Options** command to open the **3D UI Options** dialog box. This lets you set defaults for the following view options:

- **Stereo mode(Default is disabled)**

  This mode is designed for stereo shutter glasses. It should remain disabled when not in use as it causes blurring of the screen. This mode requires special graphics hardware and drivers for OpenGL page flipping. If you hardware does not support this mode, you will receive an error.
- **Drag Optimization(Default is disabled)**
- **Show Ansoft logo in prints** (Default is disabled)
- **Default Color Key height** - the maximum number of values displayed (Default is 16)
- Under **When there is a selection**, you may set the following:
  - **Selection always visible** (Default is enabled)
  - **Set transparency of selected objects** (Default is enabled with value set at 0.1)
  - **Set transparency of non-selected objects** (Default is enabled with value set at 0.9)
- Under **Default Rotation About**, you may select one of the following:
  - **Screen Center (Default)**
  - **Current Axis**
  - **Model Center**
  - **Cursor**

Rotating the View

You can rotate the view relative to the Model Center, the Screen Center, or the Current Axis.

When you select one of these as the View>Options default, the **View>Rotate** selection menu changes to show that the Alt-Drag combination attaches to your selection.

To rotate the model center from the menus or icons:

1. Click **View**>**Interaction>Rotate Model Center** or click the **Rotate** icon on the **View** ribbon.
2. Drag the mouse in the direction you want to rotate the view.

   The view rotates until you release the mouse button.
3. To exit **Rotate** mode, click **View>Interaction>Rotate Model Center** again, or click the icon again or press **ESC**.

Hint	Alternatively, rotate the view using one of the following methods: • Hold down the **ALT** key as you drag the mouse. • Right-click in the view window, and then click **View>Rotate** on the shortcut menu.

To rotate the view around the current axis:

1. Click **View**>**Interaction>Rotate Current Axis**.
   - Alternatively, click **View>Interaction>Spin**.
2. Drag the mouse left or right at the speed you want to spin the view.

   The view spins continually in the direction and at the speed you dragged the mouse.
3. To stop spinning the view, click in the view window.
4. To end **Spin** mode, click **Spin** again on the **View>Interaction** menu or press **ESC**.

To rotate the view around the screen center:

1. Click **View>Interaction>Rotate Screen Center** or click the rotate around screen **Center** icon on the Model ribbon.
2. Drag the mouse up and down at the speed you want to rotate the view.
3. To end **Rotate** mode, click **View>Interaction>Rotate Screen Center**, or click the icon again or press **ESC**.

Related Topics

Pan the view

Panning the View

To move (pan) the view:

1. Click **View**>**Pan**  .
2. Drag the mouse in the direction you want to pan the view.

   The view will pan until you release the mouse button.

3. To exit **Pan** mode, click **Pan** on the **View** menu again or press **ESC**.

Hint	Alternatively, pan the view using one of the following methods: • Hold down the **SHIFT** key as you drag the mouse. • Right-click in the view window, and then click **View>Pan** on the shortcut menu.

Spinning the View

1. Click **View>Spin**.
2. Click-and-drag the mouse in the direction and at the speed you want to spin the view.
   The view spins continually in the direction and at the speed you dragged the mouse.
3. To stop spinning the view, click in the view window.
4. To end **Spin** mode, click **View>Spin** again, or press **Esc**.

Hint	Alternatively, right-click in the view window, and then click **View>Spin** on the shortcut menu.

Zooming In and Out

You can magnify (zoom in) or shrink (zoom out) the contents in the view window using hot keys, or mouse drag zoom mode, use **Zoom In** and **Zoom Out** commands for 5% increments, and use **Zoom Previous** to undo recent commands, as described below. You can also Zoom out on a Rectangular Area, Zoom in or Out Using a Mousewheel, or Zoom to Selected Excitation.

> **Note:** Some international keyboards may not support the following hotkeys. If the Shift key is required for a character, such as the plus sign (+), the hotkey may not function.

To zoom in using hotkeys:

- Press the plus sign (**+**) or equals sign (**=**) key
- Press **Ctrl++**

  The view zooms in 5 percent.

To zoom out using hotkeys:

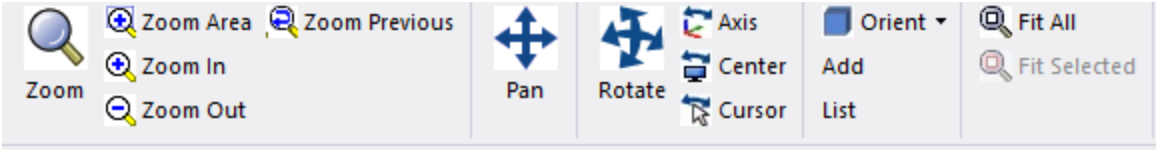
- Press the minus sign (**-**) key
- Press **Ctrl+-**

  The view zooms out 5 percent.

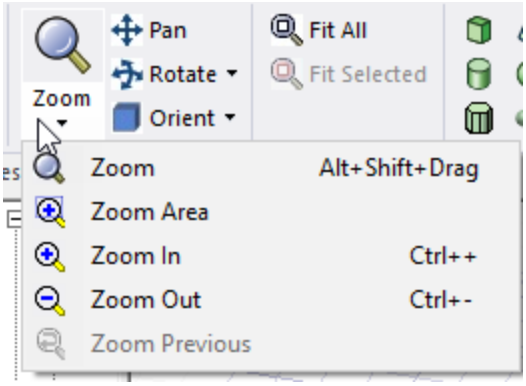
To zoom by dragging the mouse.

1. Click **View** > **Interaction** > **Zoom**, click **View** > **Zoom** on the shortcut menu, or click the **Zoom** icon on the **View, Draw,** or **Model** ribbon tabs.

   View ribbon tab with **Zoom**.



Draw or **Model** ribbon tabs with Zoom icon, and drop-down menu for Zoom:



2. To zoom in, drag the mouse toward the top of the view window. The objects in view expand as you drag.

   To zoom out, drag the mouse toward the bottom of the view window. The objects in view decrease in size as you drag.

   When zooming on a view of model objects the absolute size of the model does not change.

   When zooming on a 2D report, axis labels and ticks will adjust automatically during the zoom operation and will rescale to their final value after the zoom operation is complete.
3. To end **Zoom** mode, click **View** > **Interaction** > **Zoom** again, or click the Zoom icon, or press **Esc**.

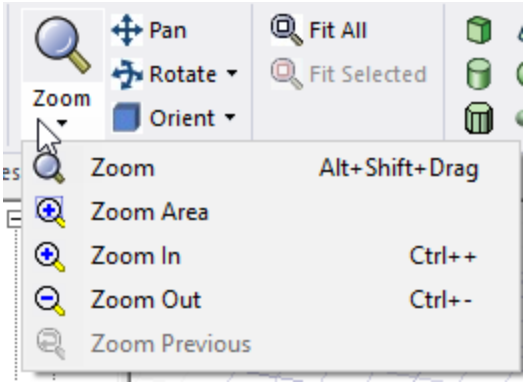
Zoom In and Zoom Out Commands

To use **Zoom In**, **Zoom Out** to zoom in or out in 5% increments:

1. Click **View** > **Interaction** > **Zoom**, click **View** > **Zoom In** or **Zoom Out** on the shortcut menu, or click the **Zoom** icon on the **View, Draw,** or **Model** ribbon tabs.

   View ribbon tab with **Zoom In** and **Zoom Out**.

Draw or **Model** ribbon tabs with **Zoom** icon, and drop-down menu for **Zoom In** and **Zoom Out**:



2. Click **Zoom In** or **Zoom Out** for a 5% increment zoom in or out respectively.

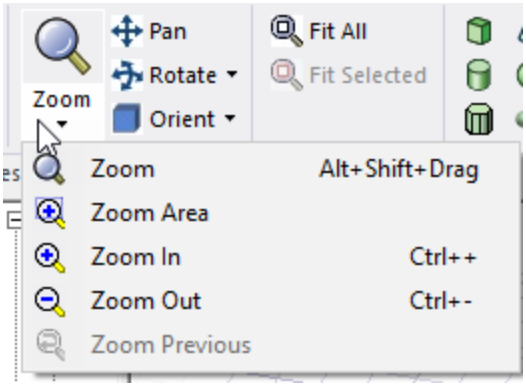
   To zoom out, drag the mouse toward the bottom of the view window. The objects in view decrease in size as you drag.

   When zooming on a view of model objects the absolute size of the model does not change.

   When zooming on a 2D report, axis labels and ticks will adjust automatically during the zoom operation and will rescale to their final value after the zoom operation is complete.
3. To end **Zoom** mode, click **View** > **Interaction** > **Zoom** again, or click the **Zoom** icon, or press **Esc**.

Zoom Previous Command

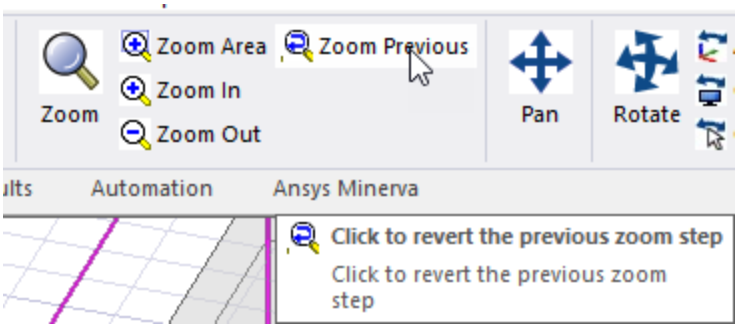
The **Zoom Previous** command is not enabled until at least one **Zoom** command has been used.



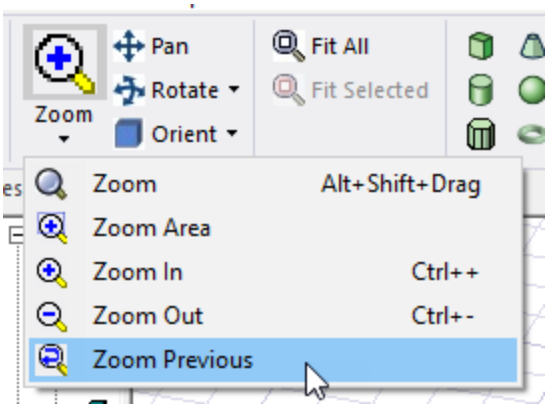
It operates on any existing sequence of **Zoom** commands. That is, it undoes the last previous **Zoom** command, and then, another exists, the one before that. To use **Zoom Previous**.

1. Click **View** > **Interaction** > **Zoom Previous**, click **View** > **Zoom Previous** or Zoom Out on the shortcut menu, or click the **Zoom** icon on the **View, Draw,** or **Model** ribbon tabs.

   View ribbon tab with .



Draw or **Model** ribbon tabs with **Zoom** icon, and drop-down menu for **Zoom Previous** :



2. Zoom Previous undoes the last executed Zoom command, and then, if others exist, can be used to undo them in reversed order of execution.

   When zooming on a view of model objects the absolute size of the model does not change.

   When zooming on a 2D report, axis labels and ticks will adjust automatically during the zoom operation and will rescale to their final value after the zoom operation is complete.
3. To end **Zoom** mode, click **View** > **Interaction** > **Zoom** again, or click the **Zoom** icon, or press **Esc**.

Tip:

Alternatively, zoom in or out using one of the following methods:

- Hold down the **Alt**+**Shift** keys as you click and drag the mouse.
- Right-click in the Modeler window and then click **View** > **Zoom** on the shortcut menu.

Note:

If Zooming is slow, especially for complex models, for some graphics cards, you can improve performance by setting **NVIDIA Control Panel** > **3D Settings** > **Manage 3D Settings** > **Global Settings** > **Global Presets: Workstation App - Dynamic Streaming**

For more information about graphics card see the section *Open GL* under *Installation Prerequisites* in the *Ansys EM Installation Guide*.

Zooming In or Out on a Rectangular Area

To magnify or shrink a specific rectangular area in the view window:

1. Click **View**>**Zoom In**  or **View>Zoom Out**  .
   - Alternatively, right-click in the view window, and then click **View>ZoomIn** or **View>Zoom Out** on the shortcut menu.
2. Use the mouse to draw a rectangle (or square) by selecting two diagonally opposite corners.

   This is the area of magnification to be increased or decreased.

   The rectangular area is magnified or decreases in size.

   When zooming on a view of model objects, the absolute size of the model does not change.

   When zooming on a 2D report, axis labels and ticks will adjust after the zoom operation is complete.
3. To end **Zoom** mode, click **Zoom In** or **Zoom Out** on the **View** menu again, or press **Esc**.

Related Topics

Zooming In and Out
Fitting Objects in the View Window

Zooming In or Out using a Mousewheel

By clicking in the Modeler window you can use the mousewheel to zoom in and out of the 3D Modeler window. The cursor location becomes the center relative to the zoom, rolling the wheel

forward increases the zoom, and rolling the wheel backwards decreases the zoom. If the window includes a ruler display, this adjusts as you scroll in and out.

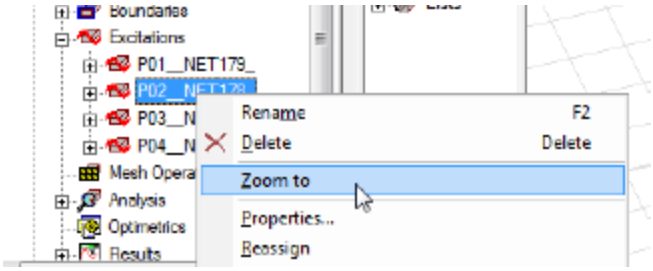
> **Note:**
>
> If Zooming is slow, especially for complex models, for some graphics cards, you can improve performance by setting **NVIDIA Control Panel** > **3D Settings** > **Manage 3D Settings Global Settings** > **Global Presets: Workstation App - Dynamic Streaming**
>
> For more information about graphics card see the section **Open GL** under **Installation Prerequisites** in the **Ansys EM Installation Guide**.

Zoom to Selected Excitation

Zoom to is an option that can enlarge the view of an excitation. This can be very useful if you want to inspect any problem areas.

You can use the **Zoom to** option as follows.

1. Select the port under **Excitations** in the project tree to highlight it in the geometry.
2. Right-click to generate the shortcut menu as shown below.



3. Select the option **Zoom to**.

   Notice that the option instantly increases magnification of the surface excited with the wave port as shown in the Figure below.

Fitting Objects in the View Window

What do you want to do?

- Fit all objects or traces in a view window.
- Fit selected objects in a view window.

Fitting All Objects in a View Window

To fit all the views: click **View>Fit All>All Views**.

All view windows displaying the active design change to include all model objects.

To fit only the active view: click **View>Fit All>Active View**.

The view in the active **Modeler** window changes to include all model objects.

Hint	Alternatively, fit all objects in the *active* view window using one of the following methods: • Press **CTRL+D**. • Right-click in the view window, and then click **View>Fit All** on the shortcut menu.

When **Fit All** is used in a **Report** view, the window is automatically rescaled to fit all traces in the window and the axis label and ticks are rescaled.

Related Topics

Fitting a Selection in a View Window

Fitting Selected Objects in a View Window

To fit one or more selected objects, 3D Components, or User Defined Models in the Modeler window or to fit traces selected in the Reporter:

1. When you are working on a model view, select the objects, 3D Components, or User Defined Models you want to fit in the view. When you are working on a report, select the traces you want to fit.
   - To fit the selection in the active view window: **Click View>Fit Selection>Active View**.
   - To fit the selection in every open view window of the active design: **Click View>Fit Selection>All Views.**

Hint	Alternatively, fit the selection in the active view window by clicking **View>Fit Selection** on the shortcut menu.

To fit one or more objects or components selected in the History tree:

1. Select the objects or components of interest, and right click to display the menu.
2. Select **View>Fit in Active View** or **Fit in All Views**:

   The view adjusts to fit the select objects.

Related Topics

Fitting All Objects in a View Window

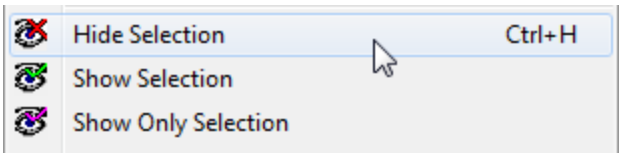
Showing Only Selected Objects in All or Active Views

Hiding Objects from View

To hide selected objects.

1. Select the object you want to hide from view. This enables the menu commands and the **View**, **Draw**, and **Model** ribbon tabs icons for hiding objects.
2. Click **View>Visibility>Hide Selection** and one of the following commands:
   - **All Views** to hide the selected object in every open view window.
   - **Active View** to hide the selected object in the active view window. You can also use CTRL-H to hide a selected object.

   You can also right-click in the modeler window for a short-cut menu and use the **View** commands for **Hide Selection**, or **Show Only Selection**.



You can also use the **Hide** selected objects icons on the **View**, **Draw**, and **Model** ribbon tabs to hide selected objects in all views or the active view.

The objects you selected are hidden.

If there are many objects, you may find it easier to hide objects using the **Active View Visibility**dialog box. You can also chose to show only selected objects in all or active views, effectively hiding all unselected objects.

Note	Hiding boundaries also turns off a check for boundary overlaps during boundary assignment. In the case of very large models with many boundaries, hiding boundaries can prevent delays during boundary assignment. Full model validation will subsequently check for boundary overlaps.

Object visibility is saved with the project.

Related Topics

Showing Objects

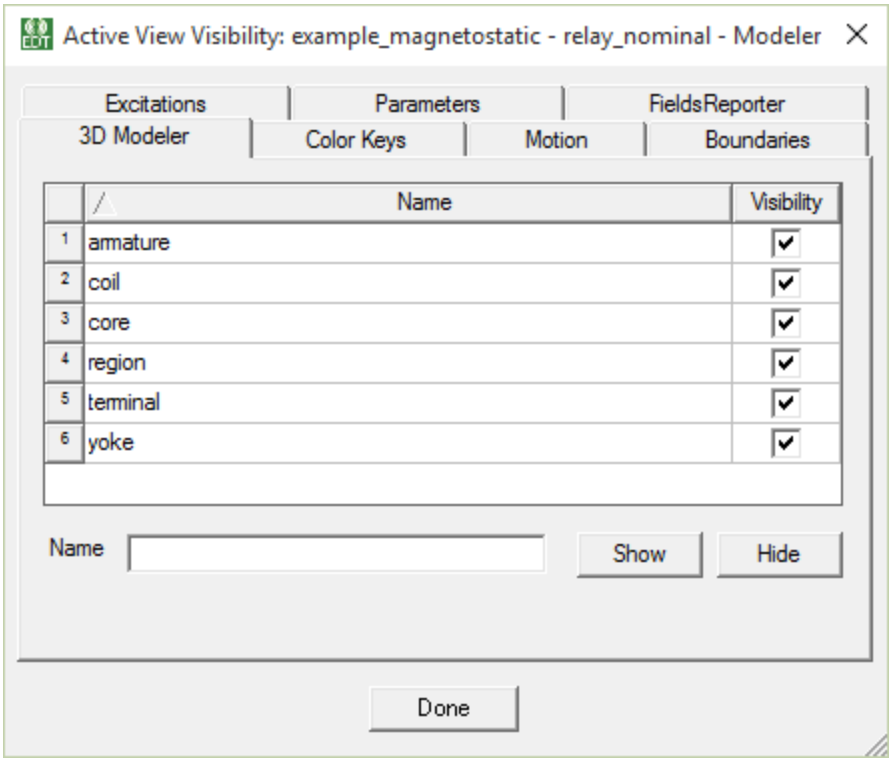
Showing Only Selected Objects in All or Active Views

Active View Visibility

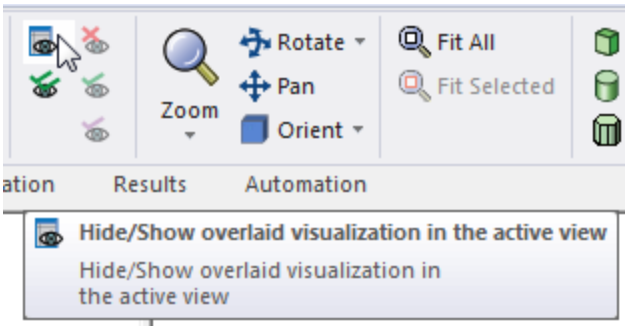
Showing Objects

You can show or hide objects in several ways, using the **Active View Visibility** dialog for individual objects, or **Visibility** menu selections for All Objects, Only Selection, Model Objects, Non-model Objects, Primitive Shapes, or Non-primitive shapes.

The **Active View Visibility** dialog contains tabs for 3D Modeler, Color Keys, Array Setup, Boundaries, Excitations, and Fields Reporter. Select the tab for the objects you want to show or hide, and check or uncheck **Visibility**.



You can access the dialog from the **View>Visibility>Active View Visibility...** menu item or by clicking the **Hide/Show** visualization icon on the ribbon **View**, **Draw**, and **Model** tabs.



The **Visibility** menus are available on the **View** menu and as short-cut menus in the modeler window and in the history tree when you select the Model icon

To show *one or more objects* that are currently hidden:

1. Click **View>Visibility>Active View Visibility** , or click the ribbon visibility icon  .
   The **Active View Visibility**dialog box appears.
2. Select the tab for the objects you want to show or hide. The dialog contains tabs for:
   - 3D Modeler Objects
   - ColorKeys

- MotionSetup Indicators
- Boundary Indicators
- Excitations Indicators
- Parameter Indicators
- FieldsReporter

3. Under the tab you need, select the **Visibility** option for the objects you want to show in the active view window.
   - For designs with large numbers of objects, you can resize the dialog for easier selection.
   - By default, objects are listed in alphabetical order. You can invert the order by clicking the Name bar above the Name fields. A triangle in the bar indicates the direction of the listing.
   - You can also use the **Name** field to type in an object name and apply the visibility via the **Show** and **Hide** buttons.

   The objects you select and designate as Visible (by selecting the property or using Show) reappear.

To show *all objects* that are currently hidden:

1. Click **View>Visibility>Show All** and one of the following commands:
   - **All Views** to show all objects in every open view window
   - **Active Views** to show all objects in the active view window.

   The selected objects reappear.

To show *selected objects* that are currently hidden:

1. Select the object. Hidden items are selected once the node corresponding to them is clicked in the history tree.
2. Click **View**>**Show Selection** and one of the following.
   - **All Views** to show selected objects in every open view window
   - **Active Views** to show selected objects in the active view window.

   You can also use the ribbon **View** tab icons to **Show selected objects in active views** or open the **Active View Visibility** dialog..

To show one or more *3D components* that are currently hidden:

1. In the history tree, select one or more 3D components. This activates the **View**, **Draw**, and **Model** tab **Hide/Show** icons in the ribbon and the **View>Visibility** menu selections.
2. You can right click to display the shortcut menu and select **View>Visibility>Show All**.

Object visibility is saved with the project.

Showing Only Selected Objects in All or Active Views

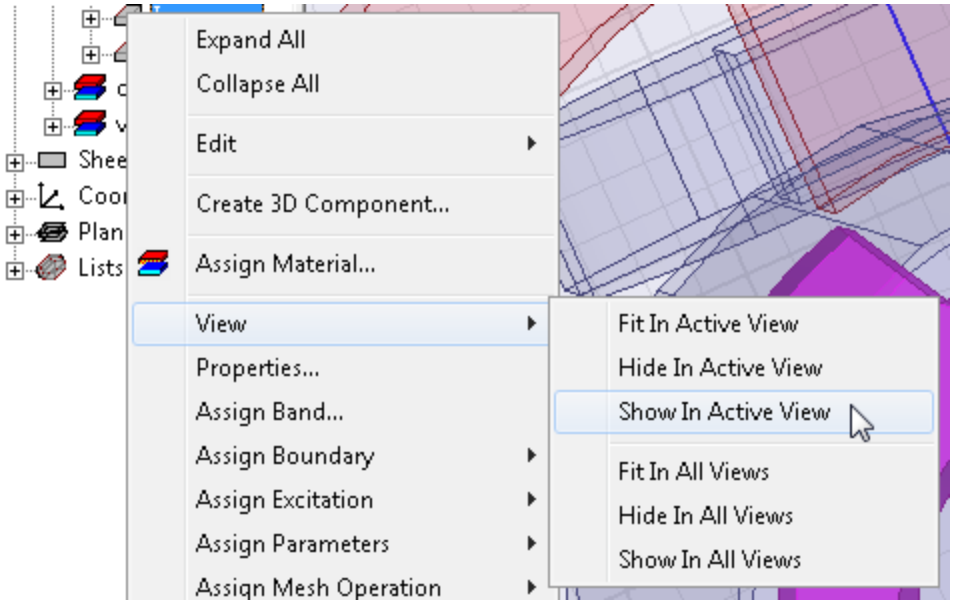
Active View Visibility

Showing Only Selected Objects in All or Active Views

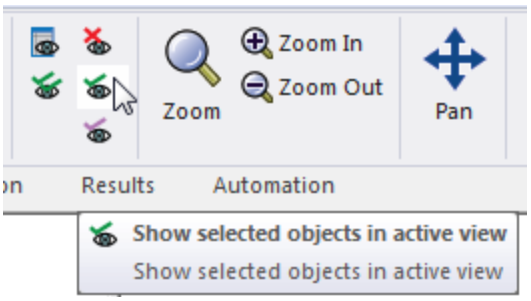
To show only *selected objects*:

1. Select the object from the Project tree or history tree. Hidden items are selected once the node corresponding to them is clicked in the history tree.
2. Click **View>Visibility>Show Selection** and one of the following.
   - **All Views** to show selected objects in every open view window
   - **Active Views** to show selected objects in the active view window.

   You can also right click, and use the shortcut menu:
3. You can right click to display the shortcut menu and select **View>Show in Active View** or **Show in All Views.**



You can also use the ribbon View, Draw, and Model tab **Show selected objects in all views** and **Show selected objects in active views** icons.



The selected objects reappear.

Active View Visibility Dialog

If there are many objects, it may be easier to show or hide objects using the ***Active View Visibility*** dialog

1. Click **View**>**Visibility>Active View Visibility**, or click the **Hide/Show** icon on the **View**, **Draw**, or **Model** ribbon tabs.

   The **Active View Visibility** dialog box appears.
2. Select the tab for the objects you want to show or hide. The dialog contains tabs for 3D Modeler objects, Color Key objects, Boundaries, Excitations, and Fields Reporter objects.
   - For designs with large numbers of objects, you can resize the dialog for easier selection.
   - By default, objects are listed in alphabetical order. You can invert the order by clicking the Name bar above the Name fields. A triangle in the bar indicates the direction of the listing.
   - You can also use the **Name** field to type in an object name and apply the visibility via the **Show** and **Hide** buttons.
3. Under the tab, clear the **Visibility** option for the objects you want to hide in the active view window.

   The objects you designate are hidden.

Note	Hiding boundaries also turns off a check for boundary overlaps during boundary assignment. In the case of very large models with many boundaries, hiding boundaries can prevent delays during boundary assignment. Full model validation will subsequently check for boundary overlaps.

Object visibility is saved with the project.

Showing Only Selected Objects in All or Active Views

Hiding Objects

Rendering Objects as Wire Frames or Solids

To render (display) *all* objects in the view window as wireframe outlines or smooth-shaded solids:

1. Click **View**>**Render**.
2. On the **Render** menu, click one of the following:
   - **Wire Frame**. The objects in the view window are displayed as skeletal structures, enabling you to see all sides of the objects at one time.

     You can also use the **F6** key or the shade icon  to toggle the display to wireframe.
   - **Smooth Shaded**. The objects in the view window are displayed as shaded objects with smooth edges.

You can also use the **F7** key or the shade icon  to toggle the display to smooth shaded.

To render *a single* object in the view window as a *wireframe outline*:

1. Select the object you want to render as a wireframe:
2. In the Properties dialog box, under the **Attribute** tab, select the check box for the **Display Wireframe** property.

Hint	You can also press **F6** (Wire Frame) and **F7** (Smooth Shaded) to toggle between these two views.

Setting the Default Rendering Mode

Setting the Curved Surface Visualization

Setting the Default Rendering Mode

To set a default rendering mode for all objects created in the active design and in future designs:

1. Click **Tools>Options>General Options** to open the **Options** dialog displaying a hierarchical list of options.
2. Click the + next to **3D Modeler** to expand the list.
3. Click the + next to **Display**, and select the **Rendering** option to display the various rendering options .
4. Select one of the following from the **Default view render mode** pull-down list.
   - **WireFrame**. The objects in the view window are displayed as skeletal structures, enabling you to see all sides of the objects at one time.
   - **SmoothShade**. The objects in the view window are displayed as shaded objects with smooth edges.
4. Click **OK**.

The rendering mode is applied to all new objects you create.

Related Topics

3D Modeler Options: Display

Setting the Enhanced Display of Material Color and Transparency

You can specify the use of material color and transparency display by using the **View>Render>Enhanced Display** command. Any changes reset the default.

To set the Enhanced Display for the active modeler window:

1. Click **View>Render>Enhanced Display** or press F8.

Enhanced Display overrides a part's color and transparency properties with material settings for all the parts visible in the active view. By default it is off (unchecked on the **View>Render** menu) and the part's attribute color and transparent values are applied.

It is possible for the view to be **Enhanced Display** mode, yet some of the parts in model could have **Use Material Appearance** unchecked. In this case you can edit color or transparent values or **Use Material Appearance** in the Property window but they are applied to active view visualization.

Sheet objects in the 3D modeler do not have a material assignment, but they could have a boundary assignment with material assigned to the boundary. In this case sheet object visualization resembles solid object visualization where material appearance from the assignment is used.

Rendering Objects as Wireframes or Solids

Setting the Curved Surface Visualization

Maxwell allows you to specify the faceting for rendering true curves by using the **View>Render>Curved Object Visualization** command. There are two options for control--Maximum surface deviation and Maximum normal deviation. This resembles the Mesh surface approximation settings. Reduce either or both of the allowed deviations to improve the image quality. Improved image quality comes at the cost of increased CPU consumption. Changes apply to the current model until they are changed again. Any changes reset the default.

Legacy projects with non default settings are approximately converted to new settings with warning. Overall faceting time may be around 20% more but number of triangles should reduce.

The default gives satisfactory results (i.e. cpu/memory consumption vs. graphical display) for various model complexities.

When you change Curved Object Visualization settings and apply them to a design, those settings are saved with design unless you change it again. That means when you open the design again, it will apply saved visualization settings and NOT the default settings. Because this affects the CPU and memory required to open the project, typically, you should not save a project with other than the default settings.

To set the Curved Object Visualization settings for the active modeler window:

1. Click **View>Render>Curved Object Visualization**.

   This command displays the **Curved Object Visualization** dialog for the active modeler window. The dialog contains areas for setting the Maximum Deviation, and the Maximum Normal deviation.

2. Set the Maximum Deviation by first selecting from the radio buttons for **Ignore**, set as **Relative Deviation** or set as **Absolute Deviation**. Selecting the later two radio buttons enables the value field.

   When set as **Relative Deviation**, the actual surface deviation depends on the model size. For example, sphere with a radius of 10 has same number of facets as a sphere with a radius of 1. This means that CPU cost does not increase based on the model dimension.

When set as **Absolute Deviation**, the maximum surface deviation for both the spheres will be approximately same since a bigger sphere has more facets than a smaller one. This means that the most CPU cost applies to the larger objects.

3. If you selected the radio buttons for Relative or Absolute Deviation for Maximum Deviation, enter a value in the field.
4. To change the **Maximum Normal Deviation**, enter a value in the text field. Units are degrees.

Note	Wire bodies cannot be rendered with a Maximum Normal Deviation value less than 1 degree. When using a setting less than 1 degree all wire bodies will be rendered with a setting of 1 degree and all closed bodies will be rendered with the dialog box setting.

5. The **Save As Default** button lets you Save any values you change to the drop down menus for the fields.
6. The **Restore Default**s button lets you return to the original values. Any values you provided through **Save As Default** remain on the drop down menus for the fields for surface and normal deviations
7. Click **Apply** to apply the current values to the active modeler window, and **Close** or **Cancel** to close the dialog without changing settings.

Rendering Objects as Wireframes or Solids

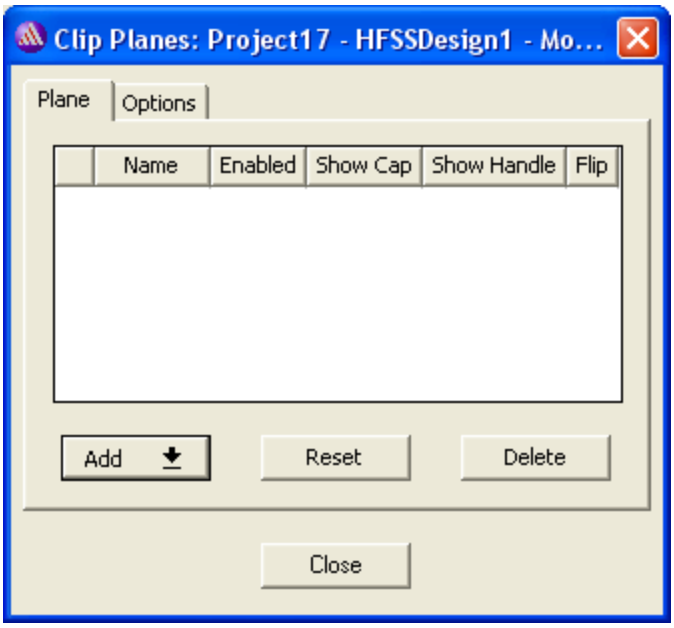
Using Clip Planes

The **View>Clip Plane** command lets you define a clip plane that you can use to interactively make any desired cut-away view of a model. If you use **Edit>Copy Image** or **Modeler>Export>***image format* with the clip plane active, the image shows the clipped plane. When parts of the model are hidden by a clip plane, model selection works as though only the visible parts are present.

To add a clip plane:

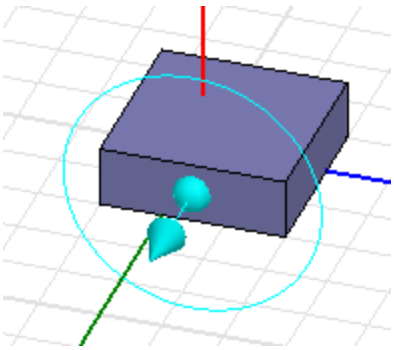
1. Click **View>Clip Plane**...

   This displays the **Clip Plane** dialog with the Plane tab selected.

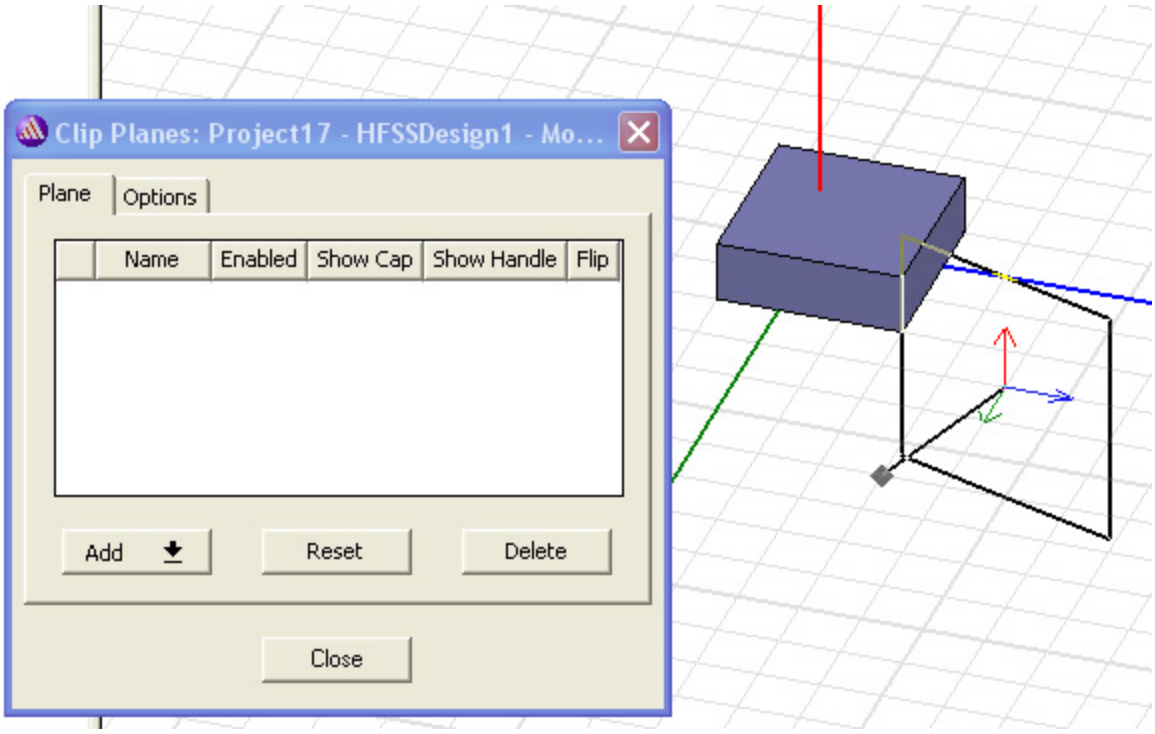


2. The **Add** button contains a drop down menu with choices for **Specify center, normal**, and **Use selection**. Of you want to use selection, you must first select a face or a cut plane.

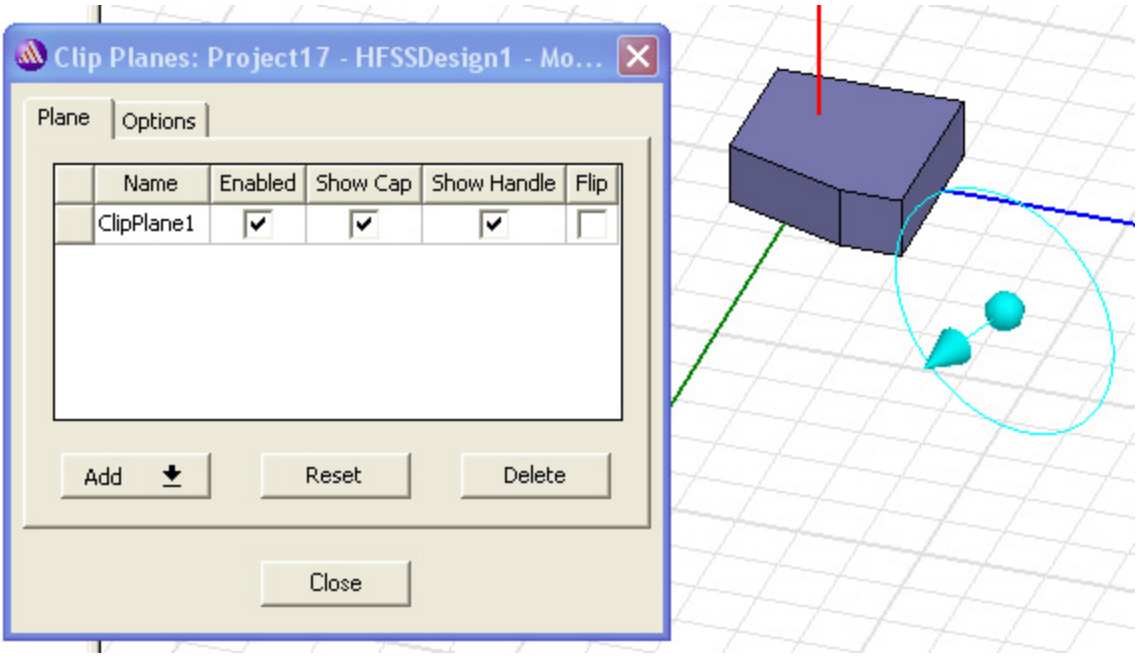
- If you first select a face or cut plane, and then click **Add>Use Selection**, the clip plane is added on that face.



a. If you select **Add>Specify center, normal**, this launches a Measure dialog and enters a mode for you click to first define the start location, shown as a triad. When you move the cursor, a rectangle represents the clip plane, and a vector the current direction.

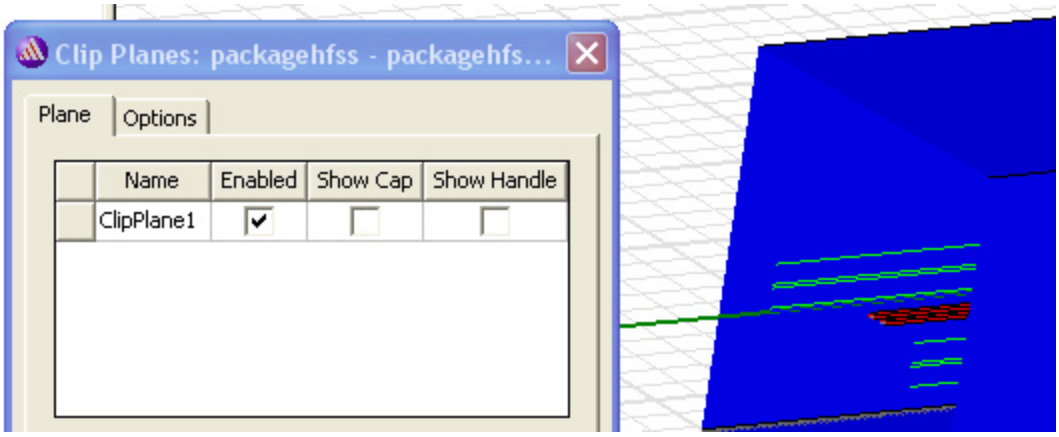


b. Click again to set the reference position.

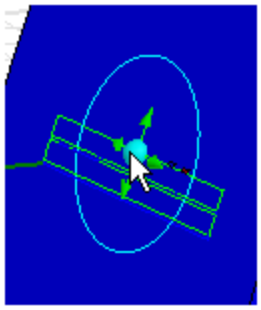


After the second click, the clip plane is active. The handle is visible as a circle with a sphere at the center, and an arrow pointing the normal for the plane. The **Clip Planes** dialog shows the clip plane name, that it is enabled, shows the cap (which is the plane

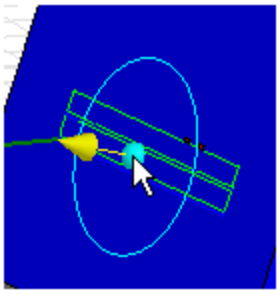
surface), and shows the handle.The Flip selection lets you reverse the direction of the clip plane. If you uncheck **Show cap** and/or **Show Handle**, they disappear from the display.



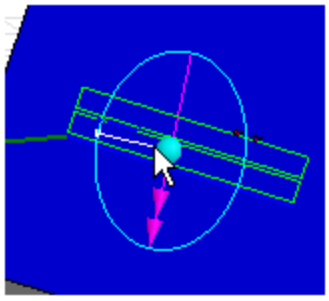
3. With Show Handle enabled, you can use the handle to manipulate the location and orientation of the clip plane. The handle changes appearance and function relative to the position of the cursor. Dragging the cursor makes use of the current function.



Move Handle independently of clip plane. This lets you move the handle away from the model.



Move Handle while dragging clip plane



Rotate clip plane by dragging the cursor. The white line is parallel to the clip plane rotation. The double arrow line is the axis.

Move the cursor around the center of the handle to change the axis.

4. The **Options** tab for the **Clip Planes** dialog contains four options.
   - Force opaque for the unclipped portion.
   - Disable clip plane when drawing a new clip plane.
   - Plane handle color

     The button shows the current color. Click the button to display a color selection dialog box. Select a default or custom color and click **OK**.
   - Plane handle radius.

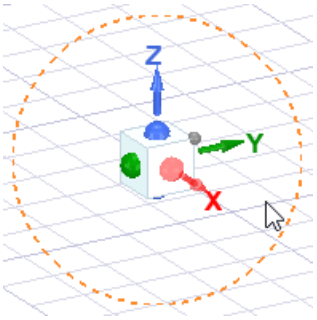
This slider lets you resize the radius of the handle to the most convenient size. The radius resizes dynamically. When you close and reopen the modeler window, the last selected size persists.

You can save your choices as new defaults.

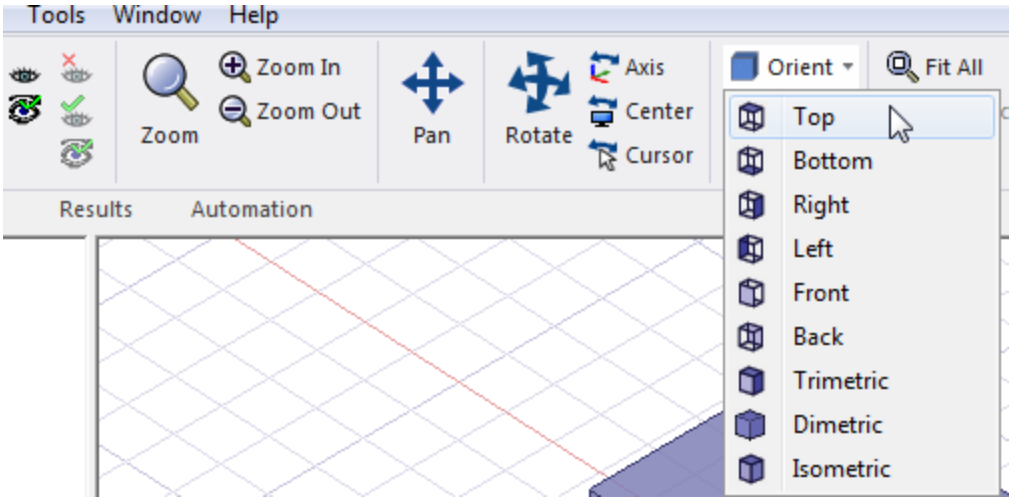
Modifying the View Orientation

There are several places you can access commands to change the orientation of the view in the *Modeler* window (that is, the viewing direction):

- Use the Orientation Gadget:



- Select the **Orient** drop-down Menu on the **View** ribbon tab and choose one of the predefined model orientations:



- Right-click in the Modeler window and, from the shortcut menu that appears, point to **View**> **Apply Orientation**, and select the desired viewing direction from the submenu. The choices include those shown in the preceding image plus any custom views you have defined (see next bullet).
- From the menu bar, click **View**> **Modify Attributes**> **Orientation List**.

A dialog box with orientation settings appears. It includes a table with the names of nine basic orientations (Top, Bottom, Right, Left, Front, Back, Trimetric, Dimetric, and Isometric), any additional orientations that you have added, and a section for managing orientations (adding/removing orientations or setting the default view). The table includes columns that show the viewing angles relative to the global axes and the equivalent vector components. These vector components are listed based on the global coordinate system and any applicable local coordinate systems.

1. Click **View>Modify Attributes>Orientation List**.

   The **Update View Orientation** dialog box appears. It includes a table of names of nine basic orientations (Top, Bottom, Right, Left, Front, Back, Trimetric, Dimetric, Isometric), any additional orientations that you have added, and a section for adding new orientations. The table includes columns that show the input angles, and the equivalent vector components.
2. Select a default orientation to the view, or create and apply a new orientation.
3. Click **Apply to View** for the selected view to appear in the view window.

   You can use the **Reset View Orientation** button to restore the view to the original angle.
4. Click **Make Default** if you want the selected viewing direction to be the initial viewing direction when a **Modeler** window is opened, either in the current project or future projects. Clicking the **Orient** button on the ribbon will apply default orientation.
5. Click **Close** to dismiss the dialog box.

   The orientation you set is saved with the design. New orientations assigned to other designs after this point do not affect this orientation.

Related Topics

Applying a Default View Orientation

Applying a New Orientation

Removing an Orientation

Using the Orientation Gadget

Applying a Default View Orientation

To apply a default viewing direction to the active view window:

1. Click **View>Modify Attributes>Orientation List**.

   The **Update View Orientation** dialog box appears.
2. Click one of the orientation names listed in the orientation list.
   - To view the associated vector components for the orientation you selected, select **Input vector components** under **Add Orientation to List**.

   The Vx, Vy, and Vz components are displayed in the boxes on the left.

   - To view the associated input angles for the orientation you selected, select **Input angles** under **Add Orientation to List**.

The psi, phi, and theta components of the selected orientation are listed in the boxes on the left.

3. Click **Apply to View**.

   The selected orientation is applied to the active view window.

   You can use the **Reset View Orientation** button to restore the view to the original angle.
4. Click **Close**.

Applying a New Orientation

Removing an Orientation

Applying a New View Orientation

To create and apply a new viewing direction to the active view window:

1. Click **View**>**Modify Attributes>Orientation**.

   The **Update View Orientation** dialog box appears.
2. To create a viewing direction that is based on a default viewing direction, click the existing orientation name in the viewing directions list.

   To create a viewing direction based on the current view in the **Modeler** window, click **Get Current View Direction**.
   - To modify the selected orientation's vector components, select **Input vector components** under **Add Orientation to List**, and then modify the values in the **Vx**, **Vy**, or **Vz** text boxes, and the Up vector boxes for Ux, Uy, and Uz.
   - To modify the selected orientation's input angles, select **Input angles** under **Add Orientation to List**, and then modify the values in the psi, theta, and phi text boxes.
3. Type a name for the new orientation in the **Name** box.
4. Click **Add/Edit**.

   The new orientation is added to the list of viewing directions.
5. Click **Make Default** if you want the new viewing direction to be the initial viewing direction when a **Modeler** window is opened in the current project or future projects.
6. Click **Close**.

Modifying the Lighting

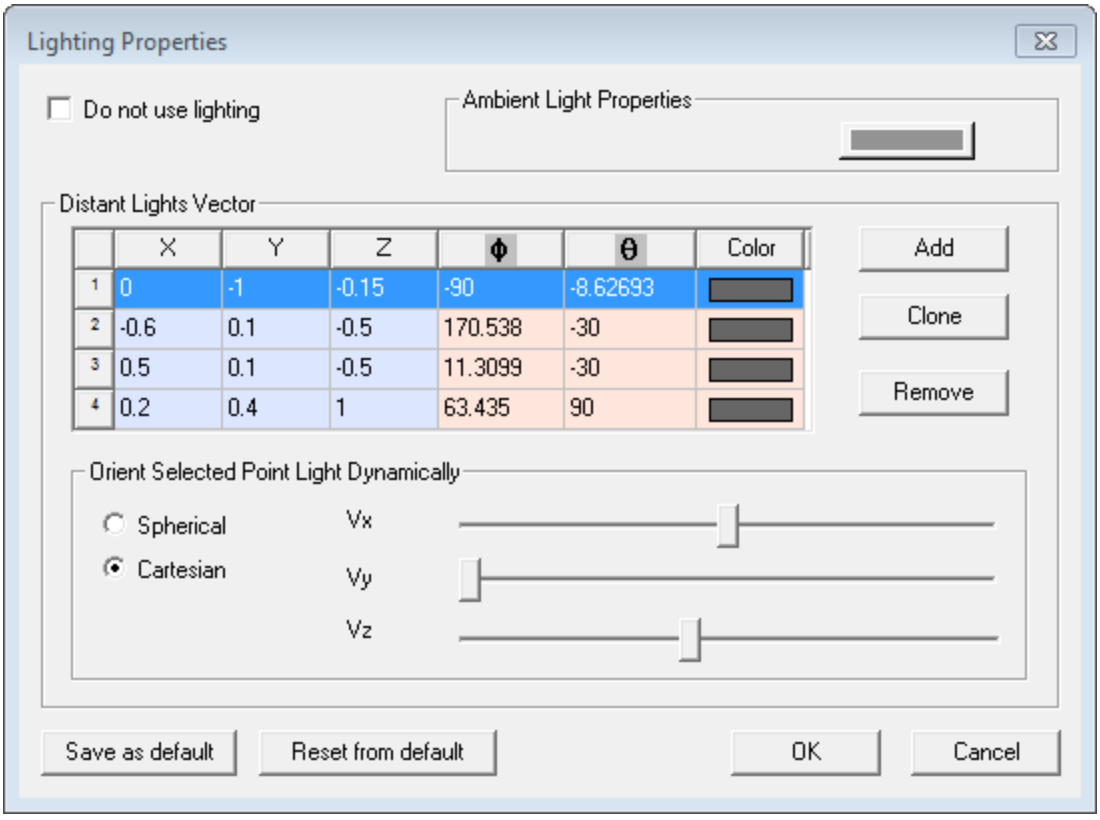
You have the option to emit the following types of light on a design:

- *Ambient* lighting surrounds the model evenly with light. All objects are lit evenly in every direction by a color of light that you specify.
- *Distant* lighting directs a ray of light at the model in a direction you specify. By default, two distant light vectors are in effect for every new view window.

To modify the lighting:

1. Click **View** > **Modify Attributes** > **Lighting** or, on the **View** tab of the ribbon, click on **Modify Attributes** and select **Lighting** from the drop-down menu.

   The **Lighting Properties** dialog box appears.



2. To turn off ambient and distant lighting, select **Do Not Use Lighting**.
3. To surround the model with light, click the **Ambient Light Properties** color button and then select a color for the surrounding light from the *Color* palette.
4. To modify the distant light on a model, do one of the following:
    - Add a new distant light by clicking **Add**.
    - Copy an existing distant light that you intend to modify by first selecting it in the **Distant Light Vectors** table and then clicking **Clone**.
    - Select a default distant light to modify by selecting it in the **Distant Light Vectors** table.
5. For the selected distant light vector, specify the vector direction:
    a. To modify the direction by specifying Cartesian coordinates, do one of the following:
        - Enter the new Cartesian coordinates in the **X**, **Y**, and **Z** boxes.
        - Use the **Vx**, **Vy**, and **Vz** sliders to specify the Cartesian coordinates dynamically.
    b. To modify the direction by specifying the spherical coordinates, do one of the following:
        - Enter the new spherical coordinates in the Φ (phi) and θ (theta) boxes.
        - Use the Φ and θ sliders to specify the spherical coordinates dynamically.

6. To revert to the default ambient and distant light settings, click **Reset**.
7. Click **Save As Default** if you want the new lighting settings to be the defaults for all **3D Modeler** windows, either in the current project or future projects.
8. Click **OK** to dismiss the dialog box.

   The lighting settings are saved with the design.

Note	New lighting applied to other designs after this point, including new default settings, do not affect these lighting settings.

Setting the Projection View

To modify the projection of model objects (the camera angle) in the view window:

1. Click **View>Modify Attributes>Projection**.

   The **Select Projection Type** window appears.
2. Select **Perspective** to change the camera angle of the view.
   - Move the slider to the right to increase the proximity, or widen, the view. Move the slider to the left to decrease the proximity, or flatten, the view.

   Objects that are closer appear larger relative to objects that are farther away.
3. Select **Orthographic** to view the model without distortion.

   The slider is disabled because a distortion scale is no longer applicable.
4. Click **Reset** to return the model to its original view.
5. Click **Close** to accept the projection setting and dismiss the window.

   The **Select Projection Type** window closes. The last view you specified in the projection window remains visible in the view window.

The projection view you set is saved with the design.

Note	New projection views assigned to other designs after this point do not affect this projection setting.

Setting the Background Color

To set the color of the background in the view window:

1. Click **View**>**Modify Attributes>Background color**.

   The **Select Background Color** window appears.
2. To assign a solid background color, do the following:
   a. Select **Plain Background**.
   b. Modify the background color in one of the following ways:
      - Click the **Background Color** button, and then select a color from the **Color** palette.
      - Click **OK**.
      - Use the RGB sliders under **Change View Color Dynamically** to specify the color's red, green, and blue values.

3. To assign a background color that gradually changes from one color to another, do the following:
   a. Select **Gradient Background**.
   b. Specify the background color at the top and bottom of the view window in one of the following ways:
      - Under **Select Background Type**, click the **Top Color** button, and select a color from the **Color** palette. Click **OK**. Then click the **BottomColor** button, and select a color from the **Color** palette. Then click **OK**.
      - Under **Change View Color Dynamically**, click **Top Color** or **Bottom Color**, and use the RGB sliders to specify the color's red, green, and blue values.
4. Click **Reset** to revert to the default background colors.
5. Click **Save As Default** if you want the new background color to be the background color for all **Modeler** windows in either the current project or future project.
6. Click **OK**.

The background color you set is saved with the design.

Note	New background color settings assigned to other designs after this point, including new default settings, do not affect this design.

Modifying the Coordinate System Axes View

What do you want to do?

- Show or hide the coordinate system axes.
- Show the coordinate system axes for selected objects.
- Enlarge or shrink the size of the coordinate system axes.
- Show or hide the triad axes.

Showing or Hiding the Axes

1. Click **View**>**Coordinate System**, then click one of the following:
   - **Hide** to hide the x-, y-, and z-axes in the active view window.
   - **Show** to display the x-, y-, and z-axes in the active view window.

Show the Axes for Selected Objects

1. Click **Tools**>**Options**>**Modeler Options**.
   This displays the Modeler Options dialog.
2. Select the **Display** tab.
3. Select **Show orientation of selected objects**.
4. Click **OK** to close the dialog.

Enlarging or Shrinking the Axes

1. Click **View>Coordinate System**, then click one of the following:
   - **Large** to display the x-, y-, and z-axes as extending to the edges of the active view window.
   - **Small** to display the x-, y-, and z-axes in a smaller size in relative to the edges of the active view window.

Showing or Hiding the Triad Axes

The triad is a secondary depiction of the coordinate system that appears at the lower right of the Modeler window. It shows the orientation of the currently selected working coordinate system. It can be shown or hidden separately from the selected coordinate system.

To show the triad:

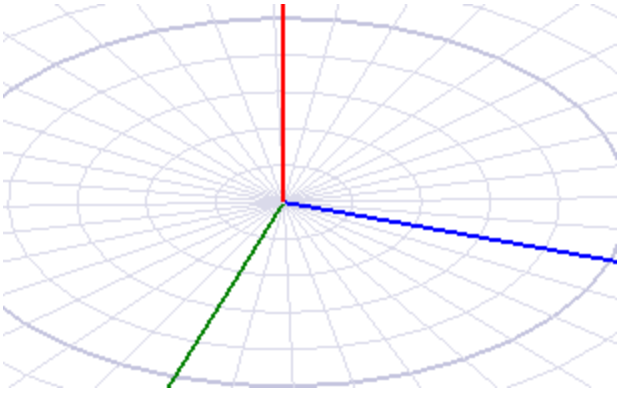
1. Click **View>Coordinate System>Triad**, then click one of the following:
   - **Hide** to hide the triad x-, y-, and z-axes at the lower right of the active view window.
   - **Show** to display the triad x-, y-, and z-axes in the lower right active view window.
   - **Auto** to generally hide the triad axes.

Choosing Grid Settings

The grid displayed in the **Modeler** window is a drawing aid that helps to visualize the location of objects.

For Cartesian grids, the location of points on the grid are defined by intersections of planes that are perpendicular to and along the x-, y-, and z-axes. The division (the distance between neighboring parallel planes perpendicular to the same axis) can be set.

For polar grids, the location of points on the grid are defined by intersections of planes that are perpendicular to the local radius and angle coordinates. The division (the distance between neighboring parallel planes perpendicular to the same radius and angle) can be set.



Grid spacing is set according to the current project's drawing units.

You can control the following aspects of the grid:

- Type (rectangular or circular)
- Style (dots or lines)
- Grid Extent
- Density
- Spacing
- Visibility
- Snap settings
- Grid plane

Setting the Grid Type

1. Click **View**>**Grid Settings**.

   The **Grid Spacing** window appears.
2. Select a **Grid type** for the active view window: **Cartesian** for a rectangular grid or **Polar** for a circular grid.

   The grid in the active view window is centered at the origin of the working coordinate system.

   - For Cartesian grids, define a coordinate by specifying its relative distance from the previously selected point in the **dX**, **dY**, and **dZ** text boxes.
   - For polar grids, define a coordinate by specifying its radius from the origin in the **R** text box and its angle from the x-axis in the **Theta** text box or its relative distance from the previously selected point in the **dR** and **dTheta** text boxes.

Setting the Grid Style

1. Click **View**>**Grid Settings**.

   The **Grid Spacing** window appears.

2. Select one of the following **Grid styles** for the active view window:

Dot	Displays each grid point as a dot.
Line	Displays lines between grid points.

3. To show a minimal grid around existing objects, check **Auto adjust grid extents**. To display a grid as a plane, uncheck **Auto adjust grid extents**.
4. Click **OK**.

Setting the Grid Density and Spacing

1. Click **View>Grid Settings**.

   The **Grid Spacing** window appears.
2. If you want to change the density of the grid in the active view window as you zoom in or out on objects, do the following:
   a. Select **Auto adjust density to**.
   b. Specify a distance between grid points by typing a value in the **pixels** box.

      The default is set to 30 pixels, which is generally the best setting for displaying objects.

   The distance between grid points will increase and decrease proportionately as you zoom in and out in the active view window.
3. If you do not want the grid density to change when you zoom in or out, but instead want to specify a constant grid spacing, do the following:
   a. Clear the **Auto adjust density to** option.
   b. Specify the grid's spacing in the active design's units.

      If you selected a Cartesian grid type, type the values of **dX**, **dY**, and **dZ**. These values represent the difference between one grid point and the next in the x, y, and z directions, respectively.

      If you selected a polar grid type, type the values for **dR** and **dTheta**. **dR** represents the difference between each radius. **dTheta** is the difference between angles.
4. Click **OK**.

Setting the Grid's Visibility

To hide the grid, click the Draw ribbon's Grid icon:  . Click it again to show the grid.

Alternatively:

1. Click **View**>**Grid Settings**.

   The **Grid Spacing** window appears.

2. To set Grid visibility:
    - Select **Show** to make the grid always visible in the active 3D Modeler window.
    - Select **Hide** to make the grid always invisible in the active 3D Modeler window.
    - Select **Auto** so the grid appears only while you are drawing an object in the 3D Modeler window.
3. Click **OK**.

Choosing Grid Settings

Selecting Items in the Modeler Window

To modify or learn more about an item's properties, you must first select it. All commands you choose while an item is selected are performed on or in reference to the selected item.

What selection mode do you want to use?

- Select Objects.
- Select Faces.
- Select Edges.
- Select Vertices.
- Select Multi (a mode for selecting objects, faces, edges or vertices)
- Coordinates in the drawing space.
- Select By Area
- Select by Variable
- Selecting Objects by Name
- Select by History Tree Folder
- Selecting the Face or Object Behind

Selecting Objects

By default, the modeler is in *object selection mode*. Click an object in the view window or an object name in the history tree to select it. All other objects become relatively transparent.

When the mouse hovers over an object in the view window, the object is highlighted. This indicates that it will be selected when you click it. Selected objects become the color specified under the **Display** tab of the **Modeler Options** dialog box.

Tooltips, as you hover the cursor over an entity, indicate the type/ID of entity (object name in the case of objects, Face_id in the case of faces, and so on). This feature helps you distinguish between face-of-sheet-object pick versus sheet-object pick.

If the modeler is not currently in object selection mode, you can switch to it using one of the following methods:

- Press the shortcut key **O**.
- Right-click in the view window, and then click **Select Objects**.
- Click **Edit>Selection Mode>Objects**.
- Select **Object** from the **Select:** pull-down list on the **Model** ribbon.

Selecting Several Objects

1. If you are selecting objects in the Modeler window make sure that the modeler is in object selection mode by pressing the shortcut key **O**. You can always select objects in the History tree.
2. Select multiple objects in one of the following ways:
    - Hold down **Ctrl,** and click the objects in the view window that you want to select.
    - Hold down **Ctrl**, and click the object names in the history tree that you want to select.

- In the History tree, select a range of objects by first clicking one object to select it, and then Shift-click to extend the selection of visible items.
- In the History tree, under Lists, select AllObjects. This is an automatically created list that lets you selects all objects.
- Click **Edit>Select All** to select all objects that were drawn in the active view window, including objects that are not currently visible.
- Click **Edit>Select All Visible** (or press **Ctrl**+**A**) to select all objects that are visible in the active view window.
- Right click on a History tree icon for Model, Group, object, category such as Solid or Sheet, or material to perform context-sensitive selection. See Select Objects in the History Tree.

Selected objects become the color that is specified for selected objects under the **Display** tab of the **Modeler Options** dialog box. Use **Tools>Options>Modeler Options** to display the dialog and set the default color. By default, the selected objects are opaque and all other objects become relatively transparent.The settings for the relative opacity and transparency of selected and non-selected objects also appear in the **3D UI Options** dialog box. Use **View>Options** to display the **3D UI Options** dialog.

To deselect all objects, do one of the following:

- Click **Edit>Deselect All**.
- Press **Ctrl+Shift+A**.

Select By Area

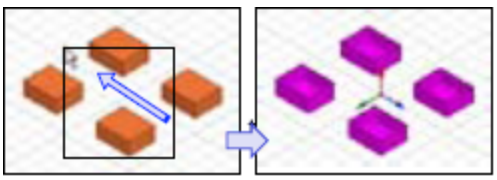
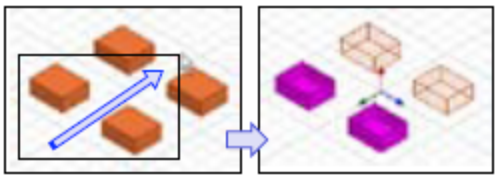
You can select items by area in the Modeler window by clicking and rubber-band dragging around objects. Rubber-band selection works differently depending on the drag direction.

- From right to left: Selects all the items that are wholly or partly enclosed within the rubber band.



- From left to right: Selects all the items wholly enclosed within the rubber band.

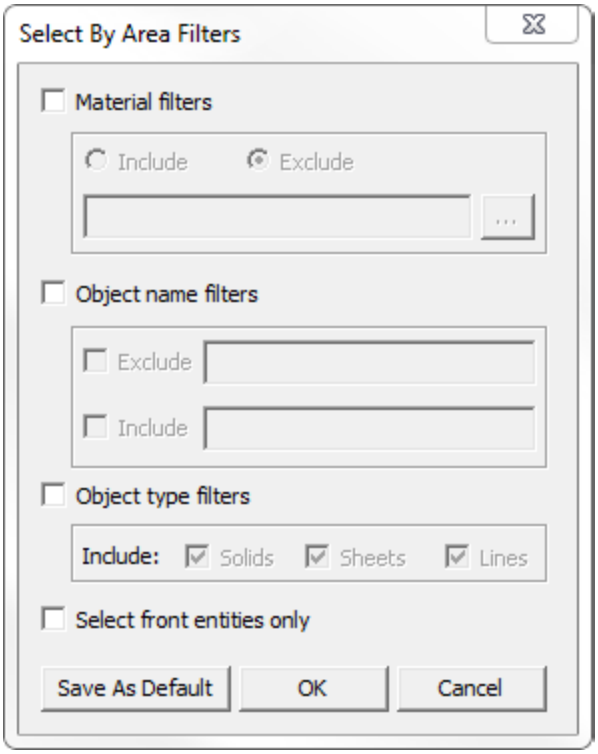


Select By Area works with Selection mode for Objects, Faces, Edges, and Vertices, but not for Select Multi. By default, only items with external surfaces are selected.

However you can control which objects to include or exclude from area selection based on material, object names, or object types.

To do this:

1. Click **Edit>Select By Area Filter** to display this dialog:



2. Check **Material filters** to enable the **Include** and **Exclude** radio buttons. Use the text field to specify filters by name, or use the ellipsis [...] button to display the Materials manager for selections.
3. Check **Object name filters** to enable the **Exclude** and **Include** check boxes, and text fields in which you can specify object names.
4. Check **Object type filters** to enable the check boxes for including **Solids**, **Sheets**, and/or **Lines**.

5. Check **Select front entities only** to select only objects that are in front.
6. If you click **Save As Default**, the settings persist for the project until you change the settings and **Save as Default** again.
7. Click **OK** to close the dialog.

Now, when you left-click and drag around an area, those objects which meet the filter criteria are highlighted in the Modeler window, and those objects are shown as selected in the History tree.

Working with the History Tree

Setting the Default Color and Transparency of Selected Objects

To set the color of objects when they are selected:

1. Click **Tools>Options>Modeler Options**.
   The **Modeler Options** dialog box appears.
2. Click the **Display** tab.
3. Click **Select** on the **Default color** pull-down list.
4. Click the color button beside the **Default color** pull-down list.
   The **Color** palette appears.
5. Select a color from the **Color** palette, and then click **OK**.
   Any objects you select after this point will temporarily become the default color you selected.

By default, Maxwell shows selected objects as nearly opaque and shows non-selected objects as nearly transparent. This features helps you distinguish between selected and non-selected objects.

To set the transparency of selected and non-selected objects:

1. Click **View>Options**.

   The **3D UI Options** dialog appears. The **When there is a selection** region contains check boxes for setting the transparency for selected and non-selected objects.
2. Click the check box for the value you want to change.

   This enables the value field. The default transparency for selected objects is 0.1, which makes them almost opaque. The default transparency for non-selected objects is 0.9, which makes them highly transparent.
3. Enter a new value, and click **OK** to apply the new transparency values.

Setting the Default Color of Highlighted Objects

1. Click **Tools**>**Options>Modeler Options**.

   The **Modeler Options** dialog box appears.
2. Click the **Display** tab.
3. Click **Highlight** on the **Default color** pull-down list.
4. Click the color button beside the **Default color** pull-down list.

   The **Color** palette appears.
5. Select a color from the **Color** palette, and then click **OKto return to the Modeler Options** dialog box.
6. Click **OK**.

   Outlines of all object you hover over temporarily become the default color you specified above.

Creating an Object List

Create an object list when you want to define a list of objects. Creating an object list is a convenient way to identify and select a group of objects for a field plot or calculation. Objects in a list can still be treated as separate objects. The same object can be included in several different lists.

To create an object list:

1. If you are selecting in the Modeler window, make sure that the modeler is in object selection mode by pressing the shortcut key **O**. This is not necessary for selecting in the History tree.
2. Select the objects you want to include in the list.
3. Click **Modeler>List>Create>Object List**.

   The object list is created with the default name Objectlist*n*. It is listed in the history tree under **Lists**. Selecting an object list displays the properties of that list in the Properties window. One of the properties is a list of objects contained in the list.

   To rename the Object list, edit the Name property in the **Properties** window for the list. Object lists are sorted in alphanumeric order.

The object list is treated as one volume when you are plotting and performing fields calculations. It is listed in the **Geometry** window of the Fields Calculator when you select **Volume**.

There is an automatically created list called AllObjects. Selecting it selects all objects. If a list contains mixed types of geometry, for example, volume and sheet objects, the volume calculation only uses the geometry of the highest dimension in plots or integral, and so forth.

Example: To plot the E-field on a surface formed by the intersection of the xy-plane and several objects, first define a list of these objects. Then, when plotting fields, select the object list name from the **Geometry** window of the Fields Calculator. Fields are plotted only at the intersection of the plane and the objects in the list.

Reassigning Objects to Another Object List

Using or Viewing List Objects

Reassigning Objects to Another Object List

You can assign objects after you have created object lists. Creating an object list is a convenient way to identify and select a group of objects for a field plot or calculation. Objects in a list can still be treated as separate objects. The same object can be included in several different lists.

To reassign objects to an existing object list:

1. If you are selecting in the Modeler window, make sure that the modeler is in object selection mode by pressing the shortcut key **O**. This is not necessary for selecting in the History tree.
2. Select the objects you want to reassign.
3. Click **Modeler>List>Reassign**

   A dialog with the existing object lists is displayed. (They appear in the history tree under **Lists**.) One of the Properties in for the List shows the objects contained in the list.
4. Select the list to which you want to assign the select object and click **OK**.

   The object is reassigned to the selected list, replacing previous list members. The Objects Property in for the List shows the objects contained in the list.

The object list will be treated as one volume when you are plotting and performing fields calculations. It will be listed in the **Geometry** window of the Fields Calculator, when you select **Volume**.

Creating an Object List

Using or Viewing List Objects

Using or Viewing List Objects

To view the objects included in an Object list:

1. In the model tree, expand the **Lists** tree.
2. Right-click the list you want to select, and click **Select Assignment**.

   The objects that are included in that list are highlighted in the modeler, and the properties appear in the desktop.

To view the properties of the object list (including a list of the objects included):

1. In the model history tree, expand the **Lists** tree.
2. Under **Lists**, right-click the list object you want to view, and click **Properties**.
   The **Properties** window appears for that object list. The objects included are listed in the **Objects** row.
3. Click **OK** or **Cancel** to close the **Properties** window.

To use an object from a list in another operation:

1. In the model tree, expand the **Lists** tree.
2. Right-click the list you want to select, and click **Select Assignment**.

   The objects that are included in that list are highlighted in the modeler, and the properties appear in the desktop.
3. Select any other objects you want to use in the operation.
4. Complete the operation.

For example, you could select an object list and another object, and then specify one of the boolean commands (such as unite or subtract).

Selecting Faces

If the modeler is in face selection mode, click an object face in the view window to select it. To select multiple faces, hold the **Ctrl** key as you click the faces. You also have the option to create face lists, which define a list of object faces, or you can make face selections from a Face ID list in the By Face dialog.

Switch to face selection mode using one of the following methods:

- Click **Edit>Selection Mode>Faces**.
- Select **Face** from the **Select** pull-down list on the **Model** ribbon.
- Right-click in the view window, and then click **Select Faces**. (Not available when working on a 2D Design)
- Press the shortcut key **F**. (Not available when working on a 2D Design)

You can also select faces in the Select Multi mode.

When the mouse hovers over a face in the view window, that face is highlighted, which indicates that it will be selected when you click. Selected faces become the color specified under the **Display** tab of the **Modeler Options** dialog box. All other objects and faces become relatively transparent.

To select faces touching the current selection:

- Click **Edit>Extend Selection>Select Connected Faces**.

To select faces that touch each other:

- Click **Edit>Extend Selection>Select Face Chain**. This option allows faces that are part of a "protrusion" to be selected.

You can also use the **By Face** dialog to select from a list of faces associated with an object:

1. To use the dialog box, no objects should be selected to start.
2. Click **Edit**>**Selection Mode**>**Faces** or on the Model ribbon, Select Face from the drop-down menu; then click the Select by Name  icon.

   This displays the **Select Face** dialog. This contains a list of the available objects.
3. Select an object in the Object Name list.

   The Face ID list is then populated with the faces in that object.
4. Selecting a face ID from the list highlights the face in the 3D window. Use Ctrl-click to select additional faces, or shift-click to select a range of faces.

2. Click **Edit>Select Objects>By Name**,

   

   or on the **Model** ribbon, select **Face** from the **Select:** drop-down menu, then click **Select by Name**

   The **Select Face** dialog box appears.
3. In the **Object name** list, click the name of the object with the face you want to select.

   The object's faces are listed in the **Face ID** column.
4. Click the face you want to select in the **Face ID** column. You can select more than one.

   The face is selected in the view window.
5. Click **OK**.

Related Topics

Selecting Faces
Creating a Face List

Selecting Faces by Plane

To select a face that is aligned with a global plane, use one of the following two methods.

1. Make sure that the modeler is in face selection mode by pressing the shortcut key **F**.
2. In the History Tree, expand the **Planes** icon. Left-click on a plane (Global:XY, Global:YZ, or Global:XZ) to display the selected global plane.
3. On the **Edit** menu, point to **Extend Selection**, and then click **Faces on Plane**.

   The selected faces are highlighted.

Alternative method:

1. In the History Tree, expand the **Planes** icon.
2. Right-click on a plane (Global:XY, Global:YZ, or Global:XZ) to select the global plane and display a pull-down menu.
3. On the pull-down menu, click **Faces on Plane**.

The selected faces are highlighted.

Select Multi (a mode for selecting objects, faces, edges or vertices)

Creating a Face List

Create a face list when you want to define a list of object faces. Creating a face list is a convenient way to identify and select a specific set of surfaces for a field plot or calculation. The same face can be included in several different lists.

To create a face list:

1. Make sure that the modeler is in face selection mode by pressing the shortcut key **F**.
2. Select the object faces you want to include in the face list.
3. Click **Modeler>List>Create>Face List**.

The face list is created. It is listed in the history tree under **Lists**. The default name is Facelist*n.* The lists appear in alphanumeric order. To change the name of a face list (for example, to a name describing the listed faces as ports or boundaries), select the list in the History Tree and **Edit Properties**. Editing the Name property changes the name. If necessary, the list order in the History tree changes for the new name.

The face list is treated as one selection of surfaces when you are plotting and performing fields calculations. The face list will be listed in the **Geometry** window of the Fields Calculator when you select **Surface**.

Selecting Edges

If the modeler is in edge selection mode, simply click an object's edge in the view window to select it. To select multiple edges, hold the **CTRL** key as you click the edges.

When the mouse hovers over an edge in the view window, that edge is highlighted, indicating it is click-able. Selected edges become the color specified under the **Display** tab of the **Modeler Options** dialog box. All other objects become relatively transparent.

Switch to edge selection mode using one of the following methods:

- Click **Edit>Selection Mode>Edges**.
- Select **Edge** from the pull-down list on the **Model** ribbon.
- Right-click in the modeler window, and then click **Selection Mode>Edges**.
- Press the shortcut key **E**.

Edit>Extend Selection offers additional edge selections such as:

- **Select Edge Chain** selects the edges that touch the selected edge.
- **Select Connected Faces** selects faces touching to the current selection.
- **Select Connected Edges** selects the edges that touch the current selection.
- **Select Connected Vertices** selects the vertices of the selected edge or edges.

Face Selection

Selecting Vertices

If the modeler is in vertex selection mode, simply click an object's vertex in the view window to select it. To select multiple vertices, hold the **Ctrl** key as you click the vertices.

When the mouse hovers over a vertex in the view window, that vertex is highlighted, which indicates that it will be selected when you click. Selected vertices become the color specified under the **Display** tab of the **Modeler Options** dialog box. All other objects become relatively transparent.

Switch to vertex selection mode using one of the following methods:

- Click **Edit>Selection Mode>Vertices**.
- Select **Vertex** from the **Select:** pull-down list on the **Model** ribbon.
- Press the shortcut key **V**.

Selecting a vertex enables the following selections on the **Edit>Extend Selection** menu and the model view window **Extend Selection** context menu:

- **Select Connected Faces** selects faces touching to the current selection.
- **Select Connected Edges** selects the edges that touch the current selection.
- **Select Connected Vertices** selects the vertices of edges that touch the current selection.

Select Multi (a mode for selecting objects, faces, edges or vertices)

Selecting Multi (a Mode for Selecting Objects, Faces, Vertices or Edges)

The Select Multi mode permits you to select objects, faces, vertices, or edges, depending on where you click. This very useful in conjunction with Measure Mode, for measuring the distances between different entities. Enter Select Multi mode by one of the following methods:

- Press the shortcut key **M**.
- Right-click in the view window, and then click **Selection Mode>Select Multi**.
- On the **Edit** menu, point to **Selection Mode**, and then click **Multi**.
- Select **Multi** from the **Select:** pull-down list on the **Model** ribbon.

With Multi mode active:

- To select a vertex, click near a vertex, within 10 pixel radius.
- To select an edge, click near an edge (and 10 pixels away from vertex).
- To select an object, click little farther from edge, between 10 and 20 pixels.
- To select a face, click anywhere else on the interior of face.

Tooltips, as you hover the cursor over an entity, indicate the type/ID of entity (object name in the case of objects, Face_id in the case of faces, and so on). This feature helps you distinguish between face-of-sheet-object pick versus sheet-object pick.

By holding down the Ctrl key, you can make multiple selections.

Controlling the Selection in Multi Mode

Controlling the Selection in Multi Mode

You can control the behavior of this mode by clicking **Edit>Selection Mode>Select Multi Mode Settings**. This displays a dialog with check boxes for Object, Face, Edge, and Vertex. Unchecking a box cancels the selection behavior for that category.

You can also control the behavior of this mode on the **Model** ribbon tab by selecting the desired mode from the **Select:** drop-down list.

Related Topics

Selecting All Faces of an Object

Selecting Groups and Submodels

With group selection mode, the parent group of selected object is selected. Selecting group highlights all children under the group in the Modeler window. If you click an object that has not been assigned to a group, nothing is selected.To select multiple groups, hold the **CTRL** key as you click the groups.

To set the selection mode to Group:

- From the menu bar, click **Edit**>**Selection Mode**>**Groups**
- Press the "**G**" key to enter group selection mode.
- From the 3D Modeler window context menu, select **Selection Mode>Group**

If your design contains submodels, you can set the selection mode to Submodel.

- From the menu bar, click **Edit**>**Selection Mode**>**Submodel**
- Press the "**U**" key to enter Group selection mode.
- From the 3D Modeler window context menu, select **Selection Mode>Submodel**

Related Topics

Selecting the Face or Object Behind

Select Multi (a mode for selecting objects, faces, edges or vertices)

Clearing a Selection

To clear an object, face, edge, or vertex selection, do one of the following:

- Click the view window at a location where no objects exist.
- To clear an object selection, click a point away from the object name in the history tree.
- Click **Edit>Deselect All**.
- Press **Ctrl+Shift+A**.

  The items are no longer selected.

Selecting the Face, Edge, Vertex, or Object Behind

To select the face, edge, vertex, or object behind another selected face, edge, vertex, or object, do one of the following:

- Click **Edit>Next Behind**.
- Right-click in the view window and click **Next Behind**.

  When there are multiple faces behind, the one selected is relatively close to where you right-click.
- Press the shortcut key **B**.

  When there are multiple faces behind, the one selected is relatively close to the cursor.
- Press **Ctrl+B**.

  This option is useful when you are trying to select a face, edge, vertex, or object that is in the interior of a model, or when you do not want to change the model view to select an item.

Related Topics

Selecting Objects and Surfaces that Lie Inside Other Objects

Selecting the Edges of the Problem Region

If you have excluded the background object from your model, do not assign boundary conditions or sources to it.

Selecting Objects and Surfaces That Lie Inside Other Objects

To select objects and surfaces that lie inside other objects (such as an object that lies within an air box, a conductive shield, or the background object), do one of the following:

- Make the objects on the outside of the model invisible using the **View>Visibility** commands. This is useful when you want to select objects using the mouse. Since the mouse cannot select invisible objects, you can select the interior surfaces or objects by clicking on them.
- Use the **Edit>Select Objects>By Name** command to select objects or surfaces inside the model.
- Use the **Next Behind** command on the shortcut menu. This selects the object that lies behind the one you initially selected. This command does nothing if no objects have previously been selected.

Related Topics

Selecting the Face or Object Behind

Using the Mouse to Select Objects

To select objects or surfaces, do one of the following:

- Click the object directly.
- Right-click an object or surface, and use one of the **Select** commands on the shortcut menu.
  The following commands appear on the shortcut menu:
  - **Select Objects**
  - **Select Faces**
  - **Next Behind**: Use this command to select the object or face that lies behind the currently selected object or face. This command chooses objects or faces depending on the graphical pick mode. **Next Behind** does nothing if no object has previously been selected or if the object you select has nothing behind it. You can also use the keyboard shortcut **B**.
  - **All Object Faces**
  - **Faces on Plane**

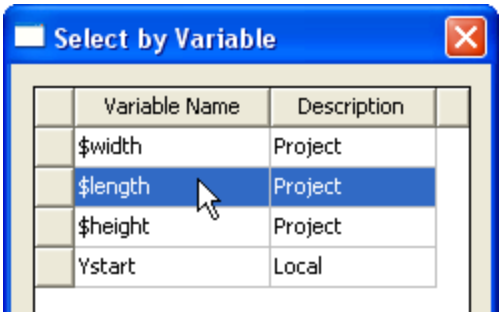
The snap mode defines how items are selected by the mouse. By default, **Grid** and **Vertex** snaps are enabled.

Selecting Objects by Variable

You can select an object based on a variable that affects it. If your design includes variables, you do so as follows:

1. Click **Edit>Select Objects>By Variable**.

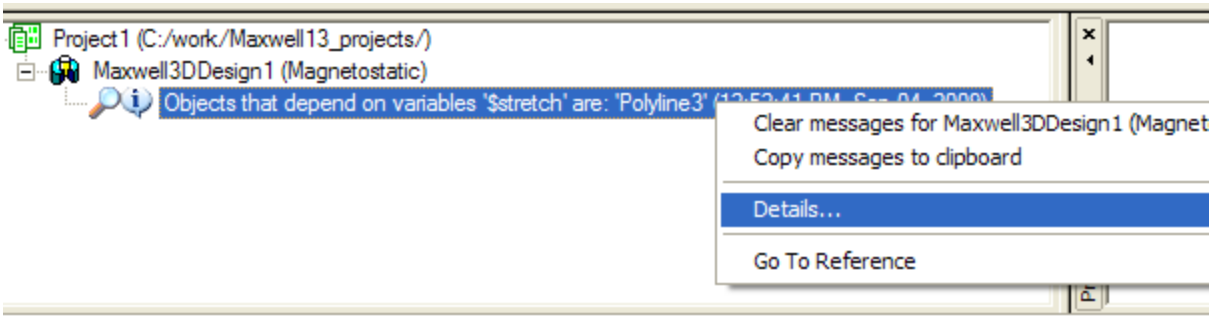
   This displays the Select by Variable dialog, which lists the variables in your design. Both columns are sortable by clicking the header. You can resize and move the dialog box. When you next open it, it uses that size and location.



2. Select the variable of interest, and click **OK**.

   The dialog closes, and the object affected by the variable is highlighted in the Modeler window.

   The Message window contains a reference that you can select and use to go to the affected object.



If you execute the command again, without clearing the current selection(s), the additional object can be highlighted. You can resize and move the dialog box. When you next open it, it uses that size and location.

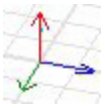
Assigning Coordinates to New Objects

When you insert and draw new 3D, 2D, or 1D objects in the geometry model, you need to define coordinate systems and locations of points, distances between objects, and other geometry items.

- Setting the Reference Point
- Defining Cartesian Coordinates
- Defining Cylindrical Coordinates
- Defining Spherical Coordinates
- Defining Relative Coordinates
- Defining Absolute Coordinates

Setting the Reference Point

When you draw objects, the cursor's location is always relative to a reference point. The reference point is displayed with a mini xyz-axis:



To change the reference point:

1. Select the drawing command to use.

   The Measure Data dialog opens. As you move the cursor over the modeler window, the top line in the measure dialog shows the coordinates of the current reference point.
2. Move the cursor to the desired reference point and press **Ctrl+Click** or right click and select **Set Reference Point** from the short cut menu.

   This moves the reference point marker to the new location. The **Measure Data** dialog updates. The coordinates boxes in the Status bar change to accept relative distance

information. If you choose, rather than setting the reference point with the cursor, you can press Tab to activate a text cursor in the status bar fields, and enter coordinates directly.

Defining Cartesian Coordinates

When drawing an object, define a point using Cartesian coordinates by typing its distance from the origin in the **X**, **Y**, and **Z** boxes, respectively. When defining a second point, specify its distance from the previously defined point in the x, y, and z directions in the **dX**, **dY**, and **dZ** boxes, respectively.

1. Select the desired drawing command.
2. Select **Cartesian** from the pull-down list on the status bar.
3. Type the point's x-, y-, and z-coordinates in the **X**, **Y**, and **Z** text boxes.

Hint	Press **Tab** to move from one coordinate text box to the next. Press **Shift+Tab** to move to the previous coordinate text box.

   - Alternatively, click the point in the view window.
4. When drawing objects other than polylines, the second point you select is relative to the first point. Type the second point's distance from the previously selected point in the **dX**, **dY**, and **dZ** boxes.

Related Topics

Selecting Cylindrical Coordinates
Selecting Spherical Coordinates

Defining Cylindrical Coordinates

To define a point using cylindrical coordinates, specify the point's radius, measured from the origin, in the **R** box, the angle from the x-axis in the **Theta** box, and the distance from the origin in the z direction in the **Z** box. When defining a second point, specify its distance from the previously defined point in the in **dR**, **dTheta**, and **dZ** boxes.

1. After clicking the desired drawing command, select **Cylindrical** from the pull-down list on the status bar.
2. Type the point's r-, theta-, and z-coordinates in the **R**, **Theta**, and **Z** boxes.

Hint	Press **Tab** to move from one coordinate box to the next. Press **Shift+Tab** to move

	to the previous coordinate box.

- Alternatively, click the point in the view window.

3. When drawing objects other than polylines and helices, the second point you select is relative to the first point. Type the second point's distance from the previously selected point in the **dR**, **dTheta**, and **dZ** boxes.

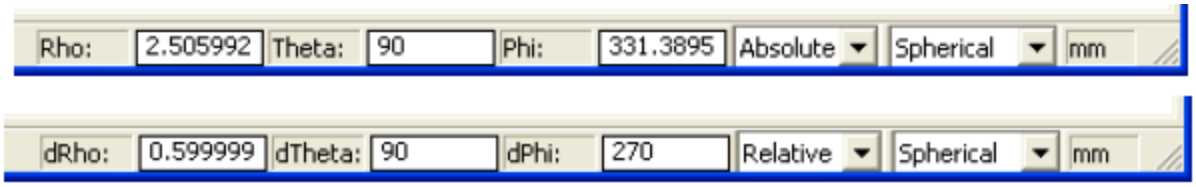
Related Topics

Selecting Cartesian Coordinates

Selecting Spherical Coordinates

Defining Spherical Coordinates

To define a point in spherical coordinates, specify the point's radius, measured from the origin, in the **R** box, the angle from the z-axis in the **Theta** box, and the angle rotated counter-clockwise (CCW) from the x-axis in the **Phi** box. When defining a second point, specify its distance from the previously-defined point in the in **dR**, **dTheta**, and **dPhi** boxes.



Note	Even though you are inputting spherical coordinates, all data is internally stored in Cartesian coordinates.

To define a point in spherical coordinates:

1. After clicking the desired drawing command, select **Spherical** from the pull-down list on the status bar.
2. Type the point's r-, theta-, and phi-coordinates in the **R**, **Theta**, and **Phi** boxes.

Hint	Press **Tab** to move from one coordinate box to the next. Press **Shift+Tab** to move to the previous coordinate box.

- Alternatively, click the point in the view window.

3. When drawing objects other than polylines and helices, the second point you select is relative to the first point. Type the second point's distance from the previously selected point in the **dR**, **dTheta**, and **dPhi** boxes.

Related Topics

Selecting Cartesian Coordinates

Selecting Cylindrical Coordinates

Using Absolute Coordinates

When entering a point's coordinates, you can specify them in *absolute* or *relative* coordinates. Absolute coordinates are relative to the working coordinate system's origin (0, 0, 0). This is the default setting for the first point you select after clicking a drawing command. Relative coordinates are relative to the reference point, or the previously selected point, represented by a small coordinate system on the user interface.

To enter a point's absolute coordinates:

1. Click the desired drawing command.
2. Select **Absolute** from the **Absolute/Relative** pull-down list on the status bar.
3. Specify the point's coordinates in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the appropriate boxes on the status bar.

Note	When drawing objects other than polylines and helices, by default, the second point you select is relative to the first point; **Relative** is automatically selected in the **Absolute/Relative** pull-down list in the status bar. Be sure to select **Absolute** from the **Absolute/Relative** pull-down list in the status bar if you want the second point to be relative to the working coordinate system.

Related Topics

Selecting Relative Coordinates

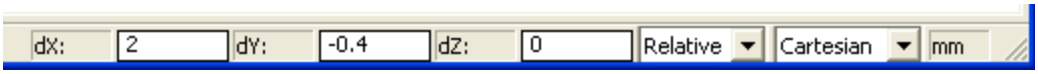
Using Relative Coordinates

When entering a point's coordinates, you can specify them in *absolute* or *relative* coordinates. Relative coordinates are relative to the reference point, or the previously selected point. Absolute coordinates are relative to the working coordinate system's origin (0, 0, 0).

To enter a point's relative coordinates:

1. Click the desired drawing command.
2. Select **Relative** from the **Absolute/Relative** pull-down list on the status bar.

   When you are in relative mode, the text boxes for a coordinate show an “d” before the coordinate description, to indicate “distance from” the working reference. For example:



3. Specify the point's coordinates in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the appropriate boxes in the status bar.

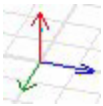
Selecting Absolute Coordinates

Choosing the Movement Mode

When drawing objects, the cursor's location is always relative to a reference point. The reference point is displayed with a mini xyz-axis:



To change the reference point, move the cursor to the desired point and press **Ctrl+Enter**.

You can move the cursor to one of the following points:

- In the same plane as the reference point (in-plane movement mode).
- Perpendicular to the reference point (out-of-plane movement mode).
- If an object is present to snap to a point in 3D space (3D movement mode).
- Along the x-axis
- Along the y-axis
- Along the z-axis

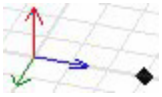
Changes you make to the movement mode persist until you change them again.

Moving the Cursor In Plane

To move the cursor to a point *on the same plane* as the reference point:

1. Click the desired drawing command.
2. Do one of the following:
   - Click **Modeler** > **Movement Mode**>**In Plane**.
   - In the model view window, right-click and select **Movement Mode**>**In Plane**.

   The next point you select will be on the same plane as the reference point.



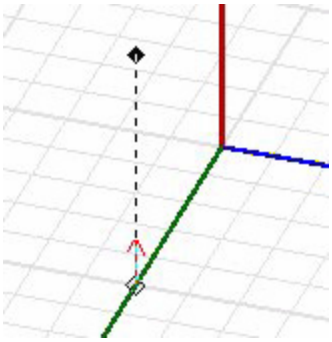
The cursor's location, displayed with a black diamond that indicates it has snapped to the grid, is on the same plane as the reference point.

Moving the Cursor Out of Plane

To move the cursor to a point on a line that is *perpendicular* to the drawing plane and that intersects the reference point:

1. After clicking the desired drawing command.
2. Do one of the following:
   - click **Modeler>Movement Mode>Out of Plane**.
   - In the model view window, right-click and select **Movement Mode**>**Out of Plane**.

   A dashed line is displayed between the reference point and the cursor's location, which is now on a line that is perpendicular to the drawing plane and that intersects the reference point.

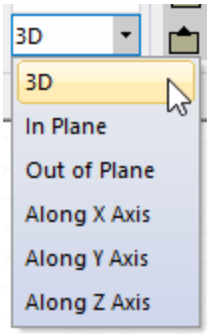


The cursor's location, displayed with a black diamond that indicates it has snapped to a grid, is on a line that is perpendicular to the drawing plane and that intersects the reference point.

Moving the Cursor in 3D Space

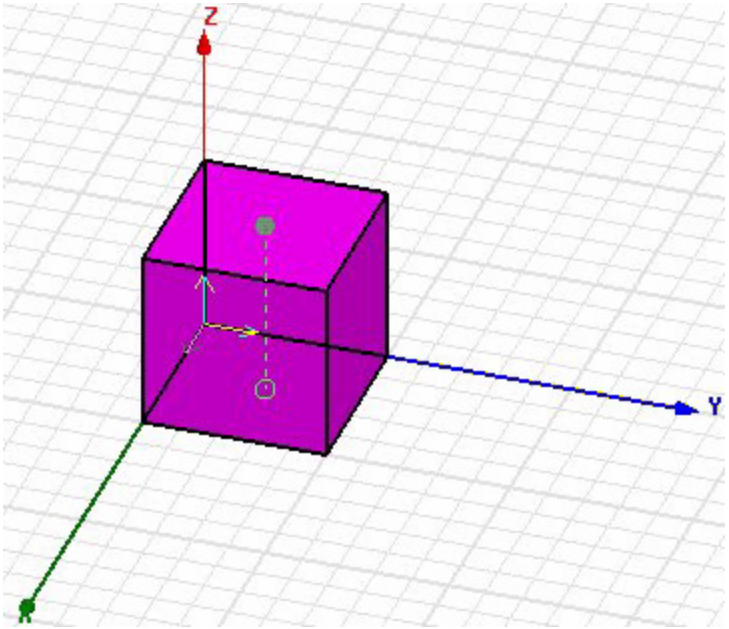
To move the cursor to a point in 3D space relative to the reference point:

1. Click the desired drawing command.
2. Do one of the following:
   - Click **Modeler>Movement Mode>3D**.
   - Click **3D** in the movement mode pull-down list on the **Draw** ribbon.



If one of an object's snapping centers is within snapping range, the cursor snaps to the nearest point in 3D space occupied by the object.

If any of the objects has a snapping center not within snapping range, the 3D movement mode is identical to the in-plane movement mode.



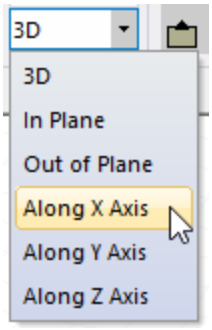
The cursor's location, displayed by a circle that indicates it has snapped to a face center, is (0.5, 0.5, 1.0), a point in 3D space.

Moving the Cursor Along the X-Axis

To move the cursor to a point away from the reference point in the x direction:

1. Click the desired drawing command.
2. Do one of the following:
   - Click **Modeler>Movement Mode>Along X Axis**.
   - Press and hold down the shortcut key **X**.

- Select **Along X Axis** from the **Movement mode** pull-down list on the **Draw** ribbon.

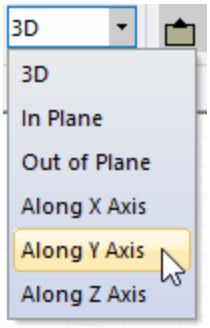


The next point you select will be on the same plane as the reference point in the positive or negative x direction.

Moving the Cursor Along the Y-Axis

To move the cursor to a point away from the reference point in the y direction:

1. Click the desired drawing command.
2. Do one of the following:
   - Click **Modeler>Movement Mode>Along Y Axis**.
   - Press and hold down the shortcut key **Y**.
   - Select **Along Y Axis** from the **Movement mode** pull-down list on the **Draw**ribbon.



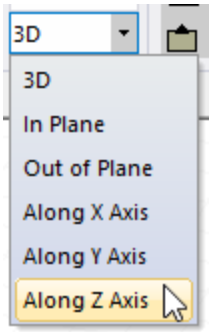
The next point you select will be on the same plane as the reference point in the positive or negative y direction.

Moving the Cursor Along the Z-Axis

To move the cursor to a point away from the reference point in the z direction:

1. Click the desired drawing command.
2. Do one of the following:

- Click **Modeler>Movement Mode>Along Z Axis**.
- Hold the shortcut key **Z**.
- Select **Along Z Axis** from the **Movement mode** pull-down list on the **Draw** ribbon.



The next point you select will be on the same plane as the reference point in the positive or negative z direction.

Choosing Snap Settings

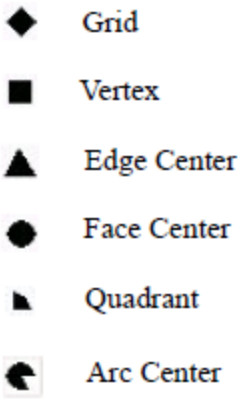
By default, the selection point and graphical objects are set to "snap to", or adhere to, a point on the grid when the cursor hovers over it. The coordinates of this point are used, rather than the exact location of the mouse. The cursor changes to the shape of the snap mode when it is being snapped.

To change the snap settings for the active design, you can use either the **Modeler** menu or the Draw ribbon Snap icons :

1. Click **Modeler>Snap Mode** or click the Draw ribbon **Snap** icons.

   If you select the menu command, the **Snap Mode** dialog box appears.
2. Specify the snap mode settings you want.
   - If you want the cursor to snap to a point on the grid, select **Grid** .
   - To snap to a vertex, select **Vertex**.
   - To snap to the center point of an edge, select **Edge Center** . The center point may be on a 1D, 2D, or 3D object edge.
   - To snap to the center of an object face, select **Face Center**.
   - To snap to the nearest quarter point on an edge, select **Quadrant**.
   - To snap to the center of an arc, select **Arc Center**.

     When the cursor snaps to a point, it changes to one of the following snap mode shapes:



Note	By default, the mouse is set to snap to the grid, a vertex, an edge center, a face center, and the nearest quadrant. To modify the default snap settings for the active design and all new designs, modify the selections on the **Snap** panel under the **3D Modeler** options.

Snap Setting Guidelines

Snap Setting Guidelines

For each object (3D, 2D, or 1D), you can define snapping points. Then, when moving in the Modeler window, if the cursor approaches a snap point (gets closer in terms of screen coordinates, not 3D coordinates), the snap point is highlighted. If you then click it, it becomes selected, even if that point is out of the plane you are working in (for example, even if the point has 3D coordinates when you are working in a 2D plane).

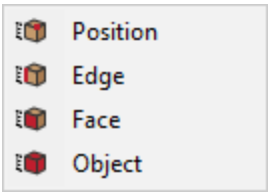
In general, select at least one of the snap options in the **Snap Mode** dialog box. If none of these options are selected, the software is in "free mode" and selects whatever point you click, regardless of its coordinates. This can cause problems when you are trying to create closed objects. Although the point you select may appear to be the vertex point of an open object, you may not have actually clicked the exact coordinates of the point.

Measure Modes for Objects

The Measure modes lets you measure the position, length, area, and volume of objects. With two faces selected, with two edges selected, or with an edge and a face selected, the Measure Mode displays the angle and distance between them. The Measure Position mode dynamically measures the distance between a reference point and the cursor location. You can Pause dynamic tracking in order to copy text information from the **Measure Data** dialog box, and then Resume dynamic updating.

1. To access the Measure mode, either:
   - Select **Modeler>Measure**.
   - Right-click and select **Measure** from the short-cut menu.

   After you select **Measure**, a cascading menu appears for **Position**, **Edge**, **Face** and **Object**. You can also select using the equivalent Draw ribbon icons:



2. Select **Position** to obtain location and distance formation between a specified reference point and the cursor location.

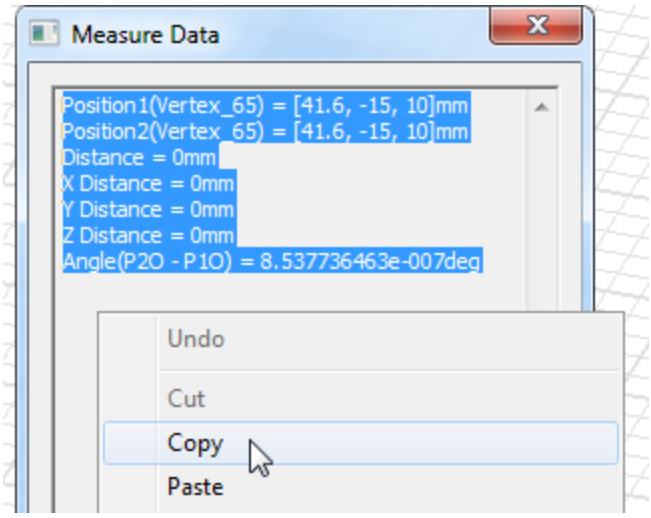
   The **Measure Information** dialog box appears.

   With **Measure>Position** selected, the information displayed includes:
   - The location of the reference point. (Position1)
   - The current cursor location. (Position2)
   - The distance between the Reference and Current location.
   - The X distance.
   - The Y distance.
   - The Z distance.
   - The angle between the current reference point and the current cursor location.

Note	As you move the cursor, the Measure Information dialog displays the current cursor location and measurement information from the reference. Clicking on a new vertex updates the reference to the new location.

   To pause the dynamic tracking, either right-click and select **Pause**, or press P.

   While paused, you can move the cursor without changing the Measure Data. You can also cut and paste.



Press P or right-click and select **Resume** to resume cursor tracking.

With **Measure>Edge**, **Face**, or **Object** selected, the information displayed for each selected object is the name and:

- The area and volume of a 3D object.
- The area of a face.
- The length of a polyline (in edge selection mode, you can still see this if you select the polyline in the History tree)
- The length of an edge
- The location of a vertex.

For more information on cursor and reference point behavior in this mode, see Measuring Position and Distance

3. To use **Measure>Edge**, **Face**, or **Object** to measure the distance and angle between two selected items:
   - Select two points. Click the first and Ctrl-click to select the second.

     The **Measure Information** dialog displays the coordinates of each point, the distance between the points and the angle between Origin-P1, Origin-P2 line.
   - Select two faces, the **Measure Information** dialog displays the angle/distance between them.
   - The function is similar when you select two edges and when you select an edge and a face.
   - You can also measure distance between vertex/face, vertex/edge. In these cases, use the Select Multi mode.
4. To exit the Measure mode, click **Close** on the Measure Information dialog.

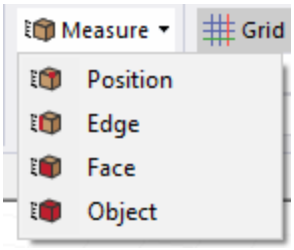
Choosing Movement Mode (3D, in plane, X, Y, or Z)
Select Multi (a mode for selecting objects, faces, edges or vertices)

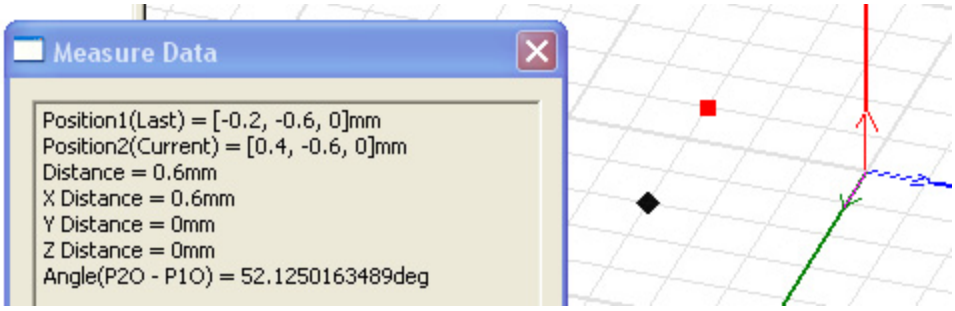
Measuring Position and Distance

To measure the distance between any cursor location relative to a designated reference point:

- Select **Modeler>Measure>Position** or use the equivalent icon on the **Draw** ribbon:

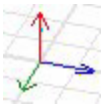


This enables the Measure Position mode and opens the **Measure Data** dialog box. The dialog lists the coordinates of the current reference point (Position1)and the cursor location (Position2). If you click, it shows the last position as a red square, and the current position as a black cursor. It also lists the distance between those points, the X, Y, and Z distances, and the angle between them. You can Pause dynamic tracking in order to copy text information from the **Measure Data** dialog box, and then Resume dynamic updating.



The shortcut menu displays the Hints item. When Hints are on (the default), a text display in the lower right of the 3D Modeler window, explaining how to set the reference point, and ways to control the movement mode.

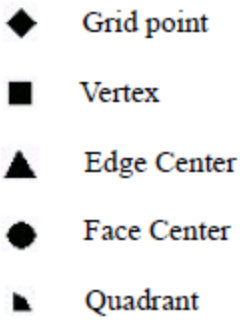
- The reference point is displayed as a mini x-y-z-axis:



Use Ctrl-Click to set the reference point at a new location.

- The cursor leads a diamond-shape selection marker that snaps from grid point to grid point. The **Measure Data** dialog also provides a text identification of the current grid points. If you drag the cursor off design objects, by default, it moves in the xy-plane. You can restrict movement to in a specific plane, out of plane, or z,x, or y. Besides the context menu for movement, you can also use the X, Y, and Z keys to restrict movement. See *Choosing a Movement Mode.* for further details.

  If you drag the selection marker over an object, it follows the 3D surfaces of the object, dropping a dashed reference line to a point on the current plane. The cursor changes shape to provide information about the object at the corresponding coordinate:

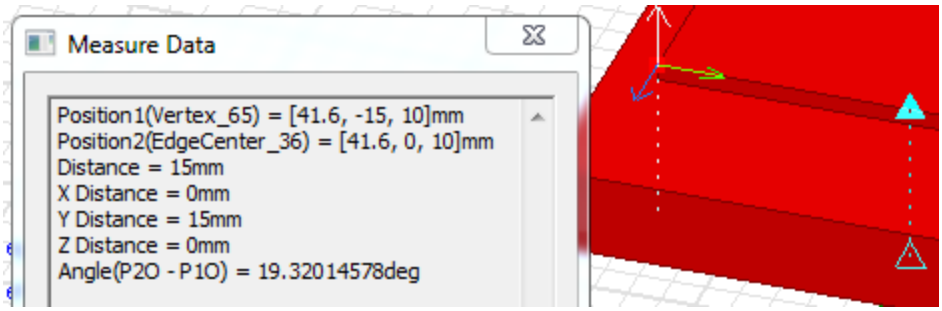


To measure the distance between two points:

1. Select **Modeler>Measure>Position** to enter Measure Position mode.
2. Ctrl-click to set the reference point.

   The reference point display moves to the selected point. This becomes the coordinate for Position1 in the Measure Data dialog box.
3. Drag the cursor to the second point.

   The value of the Position2 dynamically changes as you drag the cursor. You do not need to click. The values shown include:
   - Distance.
   - X distance
   - Y Distance.
   - Z Distance.
4. You can click P or right-click and select **Pause** from the shortcut menu to stop dynamic tracking. You can then copy text from the **Measure Data** dialog.



5. To resume dynamic tracking, either press P or right click and select Resume.
6. To close the dialog box and exit **Measure** mode, click the **Close** button. You can also use the ESC key to exit Measure mode.

Choosing Movement Mode (3D, in plane, X, Y, or Z)

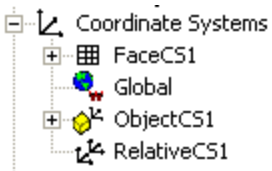
Select Multi (a mode for selecting objects, faces, edges or vertices)

Setting Coordinate Systems

The modeler has three types of coordinate systems that enable you to easily orient new objects:

- A *global* coordinate system.
- A *relative* coordinate system.
- A *face* coordinate system.
- An *object* coordinate system.

Every coordinate system (CS) has an x-axis that lies at a right angle to a y-axis, and a z-axis that is perpendicular to the xy plane. The origin (0,0,0) of every CS is located at the intersection of the x-, y-, and z-axes.The default Global coordinate system and any additional coordinate systems that you create for a project appear in the History tree of the modeler window.



- The *globalcoordinate system* (CS) is the fixed, default CS for each new project. It cannot be edited or deleted.
- A *relativeCS* is user-defined. Its origin and orientation can be set relative to an existing CS. Relative CSs enable you to easily draw objects that are located relative to other objects. If you modify a relative CS, all objects drawn on that CS will be affected and change position accordingly. You can define a relative CS to be *offset* and/or *rotated* from an existing CS. This feature provides a way for objects made of the same anisotropic materials to have different orientations.

  When you set a new relative coordinate system, you specify whether to express the coordinates as Absolute or Relative Coordinates. Absolute uses the specified values in terms of the global coordinate system. Relative interprets the values as differences from the current working CS.

  You have choices for expressing the coordinates as Cartesian, Cylindrical, or Spherical. These are evaluated as cartesian for the coordinate system properties.
- A *faceCS* is also user-defined. Its origin is specified on a planar object face. Face CSs enable you to easily draw objects that are located relative to an object's face.
- An *Object CS* is user-defined as attached to a specific object.

Switch between global, relative, object, and face CSs by changing the *workingCS*. Simply click the CS you want to use in the history tree. The working CS is indicated by a red *W* that appears at the lower-left corner of the CS name in the history tree. The **Properties** dialog box lists the CS associated with an object as the Orientation. By default, this is Global, but if you have created the object under a different coordinate system, that will be the orientation. You can click on the current orientation to see a drop down list of other orientation that you can assign for an object.

User-defined CSs are saved with the active project. When you open a project, it uses the CS designated as working CS when you last saved.

Setting the Working Coordinate System

The working coordinate system is the current CS with which objects being drawn are associated. The working CS can be the global CS or a user-defined relative CS or face CS. Select the working CS by clicking its name in the history tree, or do the following:

1. Click **Modeler>Coordinate System>Set Working CS**.

   The **Select Coordinate System** dialog box appears.

2. Click a CS in the list.
3. Click **Select**.

   A red ***W*** appears at the lower-left corner of the CS name in the history tree, indicating that it is the working CS.

   Objects that you draw from now on are drawn in and associated with the CS you selected.

Related Topics

Setting Coordinate Systems

Creating a Relative Coordinate System

When creating a relative CS, you have the following options:

- You can create an offset relative CS, that is, a relative CS whose origin lies a specified distance from another CS's origin. By moving a CS's origin, you can enter coordinates relative to an existing object, without having to add or subtract the existing object's coordinates.
- You can create a rotated relative CS, that is, a relative CS whose axes are rotated away from another CS's axes. By rotating the axes of a CS, you can easily add an object that is turned at an angle relative to another object.
- You can also create a relative CS that is both offset and rotated.

Creating an Offset Relative CS

To create a relative CS with an origin that lies a specified distance from another CS's origin:

1. In the history tree, click the CS upon which you want to base the new relative CS, making it the working CS.
2. Click **Modeler>Coordinate System>Create>Relative CS>Offset**.
3. On the **Relative CS** menu, click **Offset**  .
4. Select the origin in one of the following ways:
   - Click the point.
   - At the lower right of the modeler window, use the drop down menu to select the system for expressing coordinates (Cartesian, Cylindrical, or Spherical), select either relative or absolute coordinates, then select the units, and type the CS origin coordinates in boxes.

   To select a point that does not lie in the current plane, use the **Movement Mode** commands on the shortcut menu.

   The new relative CS is created. Its origin has moved from the previous working CS, but its axes remain the same. It is listed in the history tree under **Coordinate Systems**. It automatically becomes the working CS; objects that you draw hereafter will be based on the coordinates of this relative CS. Default planes are created on its xy, yz, and xz planes.

Related Topics

Creating a Relative Coordinate System
Creating an Offset and Rotated Relative CS

Creating a Rotated Relative CS

To create a new relative CS with its axes rotated away from another CS's axes:

1. In the history tree, select the CS upon which you want to base the new relative CS, making it the working CS.
2. Click **Modeler>Coordinate System>Create>Relative CS**>**Rotated**  .
3. Specify the x-axis by selecting a point in one of the following ways:
   - Click the point.
   - At the lower right of the modeler window, use the drop down menu to select the system for expressing coordinates (Cartesian, Cylindrical, or Spherical), select either relative or absolute coordinates, then select the units, and type the CS origin coordinates in boxes.

   To select a point that does not lie in the current plane, use the **Movement Mode** commands on the shortcut menu.
4. Specify the xy plane by selecting any point on it in one of the following ways:
   - Click the point.
   - Type the coordinates of a point that is relative to the previously selected point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   You do not need to specify the z-axis. It is automatically calculated so that the axes form a right-handed Cartesian coordinate system.

   The new relative CS is created. It has the same origin as the previous working CS, but its axes are rotated. It is listed in the history tree under **Coordinate Systems**. It automatically becomes the working CS; objects that you draw hereafter are based on the coordinates of this relative CS. Default planes are created on its xy, yz, and xz planes.

Related Topics

Creating a Relative Coordinate System
Creating an Offset and Rotated Relative CS

Creating an Offset and Rotated Relative CS

To create a new relative CS that is both offset and rotated from an existing CS:

1. In the history tree, select the CS upon which you want to base the new relative CS, making it the working CS.
2. Point to **Modeler>Coordinate System>Create>Relative CS**.

3. On the **Relative CS** menu, click **Both**  .
4. Select the origin in one of the following ways:
   - Click the point.
   - At the lower right of the modeler window, use the drop down menu to select the system for expressing coordinates (Cartesian, Cylindrical, or Spherical), select either relative or absolute coordinates, then select the units, and type the CS origin coordinates in boxes.

   To select a point that does not lie in the current plane, use the **Movement Mode** commands on the shortcut menu.
5. Specify the x-axis by selecting a point on the axis in one of the following ways:
   - Click the point.
   - Type the coordinates of a point that is relative to the origin in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.
6. Specify the xy plane by selecting any point on it in one of the following ways:
   - Click the point.
   - Type the coordinates of a point that is relative to the previously selected point in the **dX**, **dY**, and **dZ** boxes.

   You do not need to specify the z-axis. It is automatically calculated so that it is at a right angle to the y-axis.

   The new relative CS is created. It is listed in the history tree under **Coordinate Systems**. It automatically becomes the working CS; objects that you draw hereafter are based on the coordinates of this relative CS. Default planes are created on its xy, yz, and xz planes.

Related Topics

Creating a Relative Coordinate System

Creating a Face Coordinate System

1. Select the object face upon which you want to create the face CS.
2. Click **Modeler>Coordinate System>Create>Face CS**  .
3. Select the origin in one of the following ways:
   - Click the point on the face.
   - Type the point's coordinates in the **X**, **Y**, and **Z** boxes.
4. Specify the x-axis by selecting a point on the object face in one of the following ways:
   - Click the point.
   - Type the coordinates of a point that is relative to the previously selected point in the **dX**, **dY**, and **dZ** boxes, where **d** is the distance from the previously selected point.

   You do not need to specify the y- or z-axes. The modeler assumes that the z-axis is normal to the object face and the y-axis is automatically calculated to be at a right angle to the z-axis.

The new face CS is listed in the history tree under **Coordinate Systems**. It automatically becomes the working CS; objects that you draw hereafter are referenced to the coordinates of this face CS. Default planes are created on its xy, yz, and xz planes.

Only operations listed in the history tree *before* the face CS's creation affect the face CS, and in turn, affect objects dependent upon that face CS. A face CS, or objects created on it, are *not* affected by operations that occur after it is created.

For example, suppose you create a box, then a face CS on a face of the box, and then a cylinder on the face CS. If you then edit the box's dimensions in the **Properties** dialog box, the cylinder moves accordingly. But if you rotate the box using the **Edit>Arrange>Rotate** command, the box moves, but the cylinder does not because the operation occurs later in the history tree.

Related Topics

Automatically Creating Face Coordinate Systems

Setting the Working Coordinate System

Modifying Coordinate Systems

Setting Coordinate Systems

Automatically Creating Face Coordinate Systems

You can instruct Maxwell to automatically create a new face CS every time you draw on an object's face.

1. Click **Tools>Options>Modeler Options**.

   The **Modeler Options** dialog box appears.
2. In the **Operation** tab, select **Automatically switch to face coordinate system**.
3. Click **OK**.

Now, when you select a face, and then click any drawing command, a new face CS is created. The modeler automatically sets the new face CS as the working CS. The object you draw is oriented according to the new face CS.

Note	The modeler does not automatically create a new face CS if a face CS has already been assigned to the selected face.

Related Topics

Creating a Face Coordinate System

Creating an Object Coordinate System

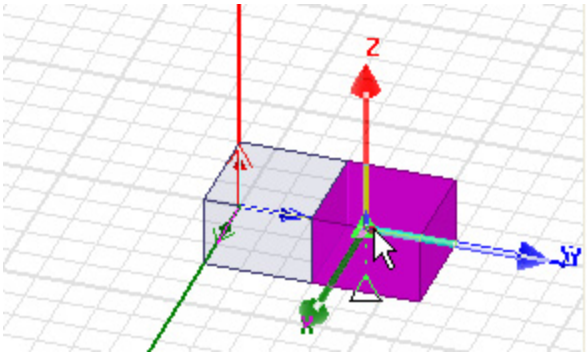
You can create coordinate systems based on any object of solid, sheet, or wire type. The **Modeler>Coordinate System>Create>Object CS** command is enabled when you select an

object. An Object CS can be Offset, Rotated or both. Executing one of the Object CS commands changes the cursor to the selection marker mode.

As you drag the selection marker over an object, it follows the 3D surfaces of the object, dropping a dashed reference line to a point on the current plane. The cursor changes shape to provide information about the object at the corresponding coordinate:

- Grid point
- Vertex
- Edge Center
- Face Center
- Quadrant

For example, in this case, the cursor shows Edge Center triangles as valid selection points for an **Modeler>Coordinate Systems>Create Object CS>Offset** command.



Only operations listed in the history tree *before* the Object CS's creation will affect the Object CS, and in turn, affect objects dependent upon that Object CS. An Object CS, or objects created on it, is *not* affected by operations that occur after it is created. Also see the Move CS to End command.

For example, suppose you create a box, then an Object CS on a face of the box, and then a cylinder on the Object CS. If you then edit the box's dimensions in the **Properties** dialog box, the cylinder will move accordingly. But if you rotate the box using the **Edit>Arrange>Rotate** command, the box will move, but the cylinder will not move because the operation occurs later in the history tree.

Creating an Object CS that is both Rotated and Offset
Expressing Cartesian, Cylindrical, or Spherical Coordinates

Creating a Rotated Object CS

To create a Rotated Object coordinate system (CS):

1. Select the working CS.
2. Select the object, and click **Modeler>Coordinate System>Create>Object>Rotated**
   - The origin is taken as {0,0,0}. You can edit this later through the Properties window.
   - The GUI is in multi select mode where you define the direction by picking any of vertex, straight edge, planar face or conical face.
     - If you select vertex, direction from origin to vertex defines the axis.
     - If you select a straight edge, the edge direction defines the axis.
     - If you select a planar face, face normal defines the axis.
     - If you select a conical face, the face axis defines the CS axis.
   - The selected vertex, edge or face must be on the selected object.
3. You are prompted to first select X axis. A preview of X axis is shown for valid selections.
4. You are later prompted to select to define the XY plane. Another direction (edge or face selection) or point (i.e. vertex selection) helps to define the plane.
   - During 2nd XY plane selection, a CS preview shows as the cursor hovers over valid selections. The preview includes the three CS axes and the XY plane.

   - In 2D modeler, you are prompted to select only X axis. The Y axis is defined based on 2D modeler type. This resembles **Relative CS** behavior. Face picking is not available in 2D modeler as it defines the direction out of plane.

Creating a Face Coordinate System

Move CS to End

Creating an Offset Object CS

Creating a Rotated Object CS

Creating an Object CS that is both Rotated and Offset

Expressing Cartesian, Cylindrical, or Spherical Coordinates

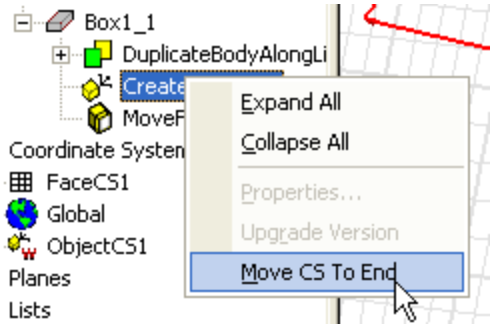
Move CS to End Command for History Tree

Only operations listed in the history tree *before* the Object CS's creation will affect the Object CS, and in turn, affect objects dependent upon that Object CS. An Object CS, or objects created on it, is *not* affected by operations that occur after it is created. It is sometimes useful to have the coordinate system affected after any other operations that might have edited, moved or rotated the object.

If you have at least one History operation after a Face or Object CS in the History tree, selecting a Face or Object CS enables the **Move CS to End** command in the **Modeler>Coordinate System** cascade menu and the History Tree shortcut menu.



Executing the command moves the selected CreateObject CS to the end position in the History tree and updates associated items (other CS, object history, any dependent parts etc.).

Creating an Object CS that is both Rotated and Offset

Modifying Coordinate Systems

Keep in mind that when you edit a CS, the following are also affected:

- All objects drawn in the CS.
- All CSs that were defined relative to that CS.
- All objects drawn on a CS that was defined relative to that CS.

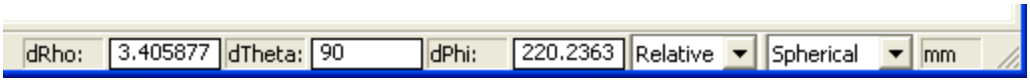
There are two ways to modify a coordinate system: you can select the coordinate system in the history tree in the modeler window, and open its properties dialog box. This approach does not also allow you to change whether the coordinate system is Absolute or Relative, or to change how you express the coordinates (as Cartesian, Cylindrical, or Spherical).

If you want to also modify the whether the coordinate system is Absolute or Relative, and to change how your express the coordinate, do the following:

1. Click **Modeler>Coordinate System>Edit**.

   The **Select Coordinate System** dialog box appears.
2. Click the CS you want to modify.
3. Click **Select**.

This selects that coordinate system and enables the editable fields at the lower right of the Modeler window. After you click the cursor in the first field, you can type in values, and tab to the next fields.



4. You can select Absolute or Relative as the Coordinate system If you selected a relative CS, follow the directions for creating a relative CS.

   If you selected a face CS, follow the directions for creating a face CS.
5. You select the coordinate system from the drop down menus as Cartesian, Cylindrical, or Spherical.
6. Select the units from the drop down menu.

   The value you give here is translated to Cartesian coordinates in the Properties for the Coordinate system.

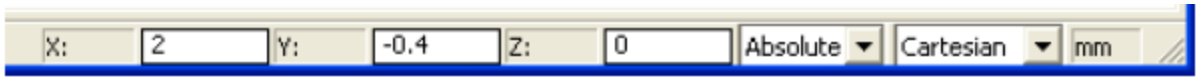
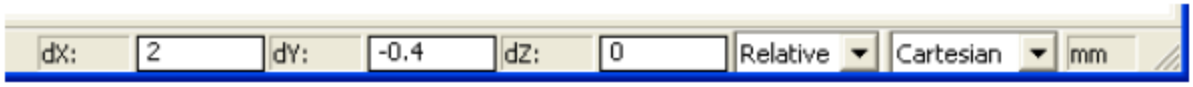
Expressing Cartesian, Cylindrical, or Spherical Coordinates

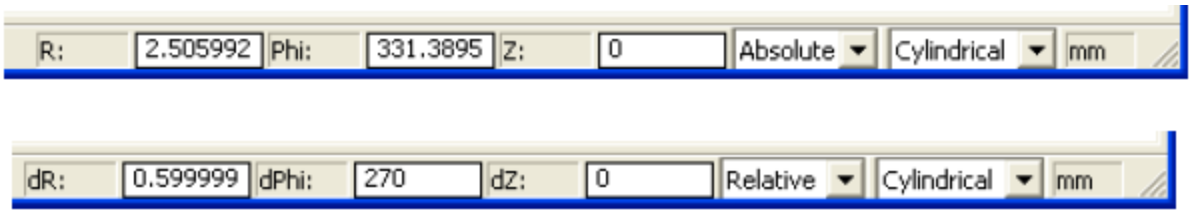
You have choices for expressing the coordinates for as Cartesian, Cylindrical, or Spherical. In each case, you also specify whether to enter the coordinates as Absolute or Relative to the working coordinate system. Click the cursor in the first text field to begin entering values or variables. Tab to the next fields, and Enter when your are done. After you enter values or variables in the text fields, they are evaluated as Cartesian for the Properties window for that coordinate system.

- **Cartesian**, that is the point's distance from the origin in the x, y, and z directions in the **X**, **Y**, and **Z** text boxes.





- **Cylindrical**, that is, the point's radius, measured from the origin, in the **R** text box, the angle from the x-axis in the **Theta** text box, and the distance from the origin in the z direction in the **Z** text box.



- **Spherical**, that is, in the point's radius, measured from the origin, in the **Rho** text box, the angle from the x-axis in the **Theta** text box, and the angle from the origin in the z direction in the **Phi** text box.

Deleting Coordinate Systems

1. Click the name of the CS you want to delete in the history tree.
2. Click **Edit>Delete**  .
   - Alternatively, press **Delete**.

   The CS is deleted and all objects drawn on it are deleted. Further, any CS that depended on the deleted CS is deleted and any objects that were drawn in the dependent CS are also be deleted.

Setting the Drawing Plane

The **Drawing plane** pull-down list is available on the **Draw** ribbon.

To set the drawing plane, do one of the following:

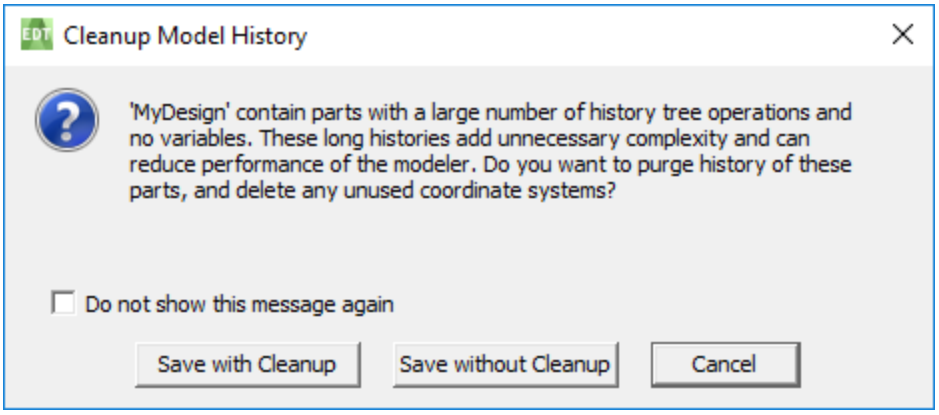
- Select **XY** from the **Drawing plane** pull-down list on the **Model** ribbon.
- Click **Modeler>Grid Plane**, and then select a grid plane: **XY**, **YZ**, or **XZ**.

Cleaning Up Model History

Ansys Electronics Desktop can clean up history tree operations in order to improve performance.

When saving your project, you will be prompted to clean up your model's history if some parts meet two conditions:

- No variables assigned to the part
- A history greater than a specified number of actions



The number of actions that triggers this prompt can be set in 3D Modeler Operations Options.

When promoted, you can choose **Do not show this message again** to hide the prompt for the active project.

To clean up the model history manually:

- Select **Modeler** > **Cleanup Model History**.

After the model has been cleaned up, you can view cleaned up parts in the **Messages** window:

3D Modeler Options: Operation Options

9 - Maxwell User Defined Primitives

User Defined Primitives (UDPs) are compiled libraries of commonly used geometric models in electromechanical energy devices and power systems that can be added to the desktop interface and shared between users with common modeling needs. UDPs allow you to add customized geometric models to the Maxwell Desktop.

- In Maxwell, many commonly used UDPs have been defined, especially for RMxprt UDPs. For more information, see RMxprt UDPs and Helix UDPs.
- You can also define your own UDPs by writing source code and then generating .dll files for UDPs. For more information, see Source Code Files.

Launching a UDP from Maxwell Desktop

In the Maxwell desktop, click **Draw>User Defined Primitive** to choose a UDP. For example, a band UDP is launched as follows:

1. Click **Draw>User Defined Primitive>RMxprt>Band**, as shown in the following figure**.**

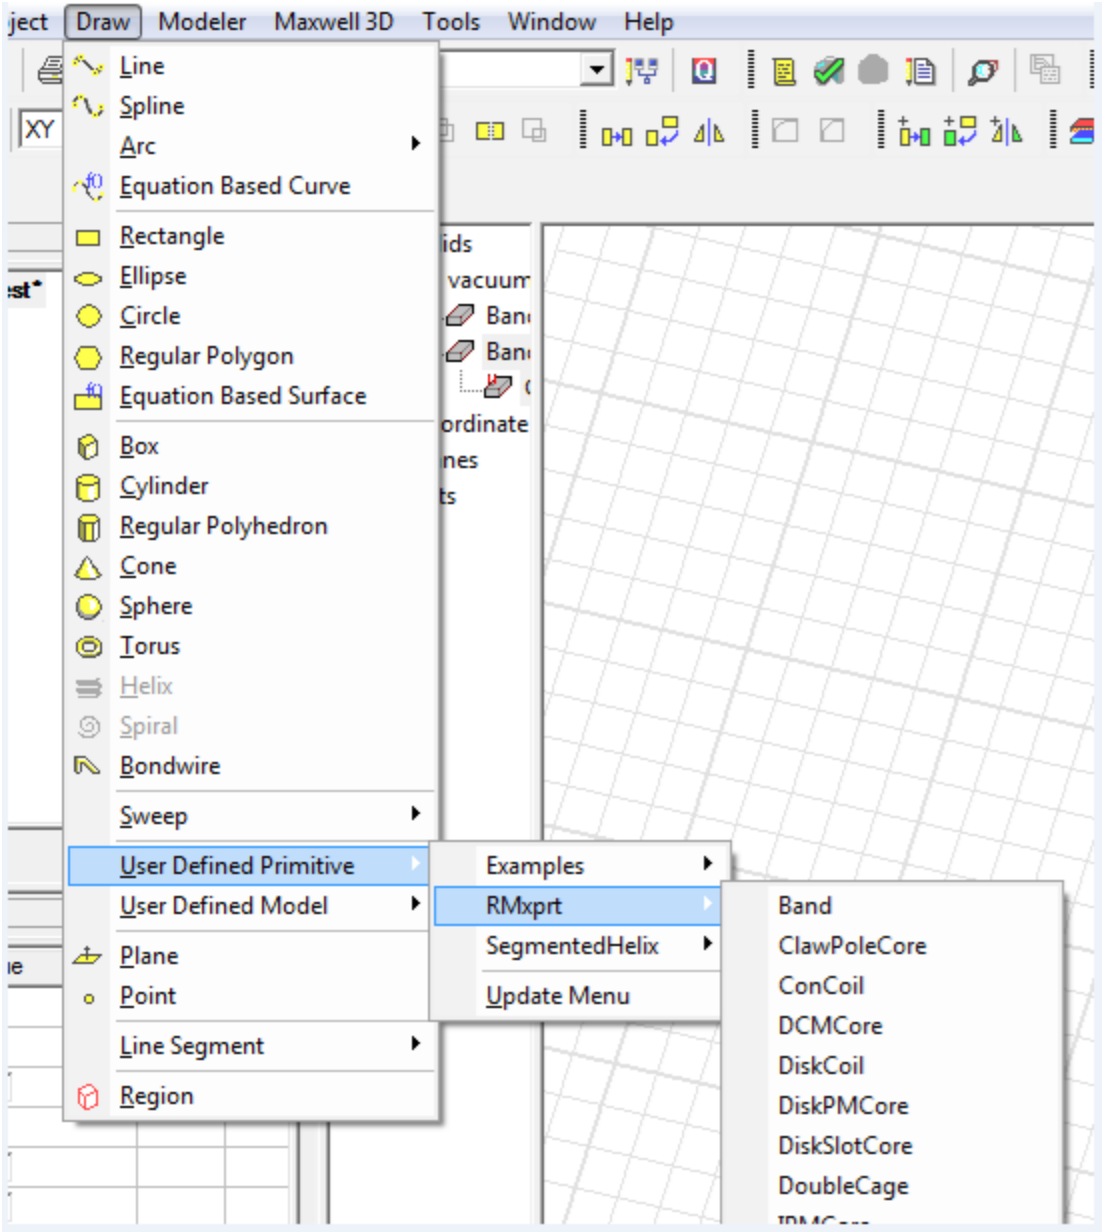

Figure 9-1 Create a band

A **User Defined Primitive Operation** dialog opens.

On the **Parameters** tab, you can view and edit the parameters. An **Info** tab contains information about the user defined primitive, its purpose, the company/author who created it, the date created and the version number.

2. Assign the values in the **Parameters** tab, and then click **OK** to finish setting parameters.

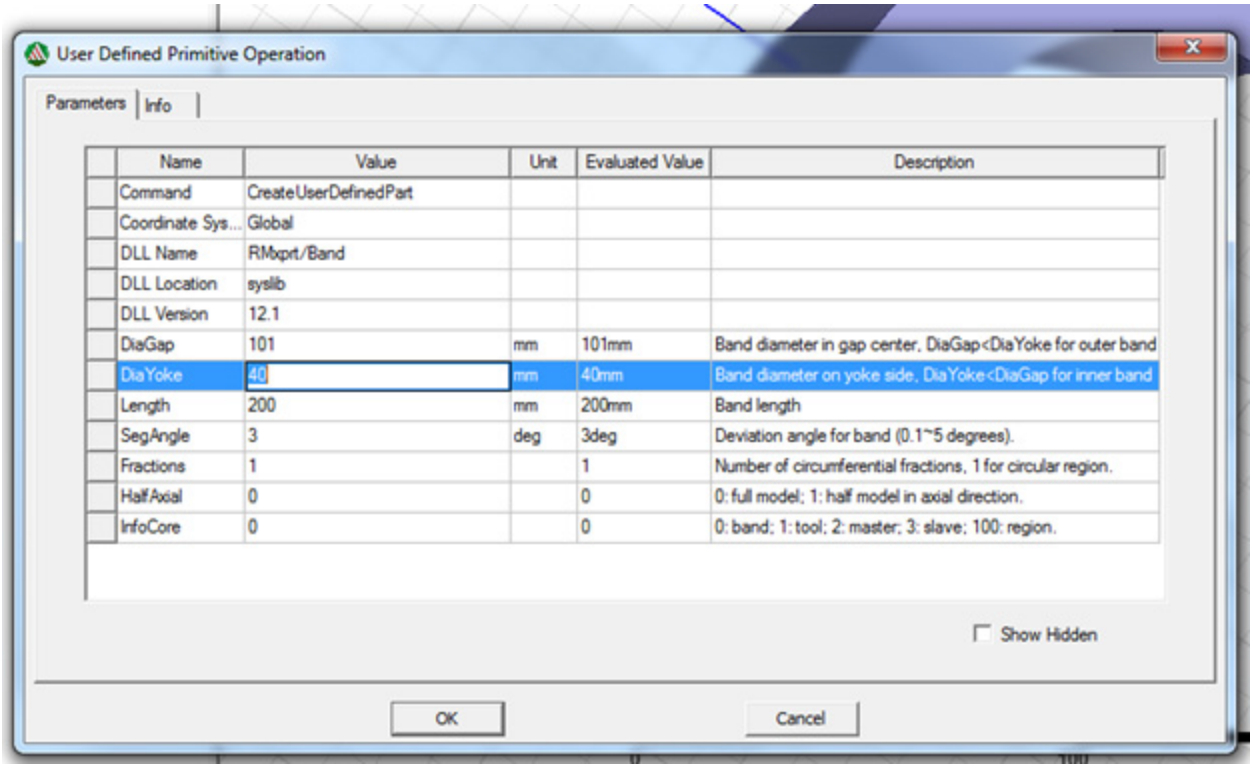

Figure 9-2 Assign parameters values

A UDP model appears in the coordinate system window.

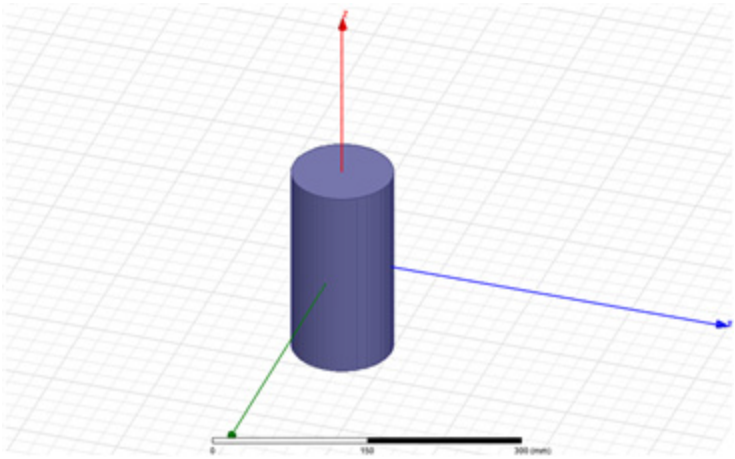

Figure 9-3 A band UDP is created

RMxprt UDPs

RMxprt UDPs are 2D and 3D geometries created for finite element analysis of electrical machines.

RMxprt UDPs consist of the following types:

- UDPs for Band and Regions
- UDPs for Slot Cores and Coils
- UDPs for Pole Cores and Coils
- UDPs for Other Cores and Coils
- UDPs for Press Plates, Fingers, and Stems

UDPs for Bands and Regions

RMxprt includes two types of UDPs for defining bands and regions:

- Band UDP
- Core regions

Band UDP

The Band UDP is used to create:

- A region to include all moving objects, which is called a “band”
- An outer region to include all moving and static objects
- A region used as a subtract tool to derive a partial model
- Independent and dependent boundaries

Property	Description
DiaGap	Band diameter in gap center, DiaGap < DiaYoke for outer band
DiaYoke	Band diameter on yoke side, DiaYoke < DiaGap for inner band
Length	Band Length
SegAngle	Angle per segment of band (0.1 ~ 5 degrees)
Fractions	Number of circumferential fractions, 1 for circular region
HalfAxial	0: full model; 1: half model in axial direction.
InfoCore	0: band; 1: tool; 2: independent; 3: dependent; 100: region

These parameters are used in the following 2D inner band and 2D outer band examples:

Figure 9-4 Inner band

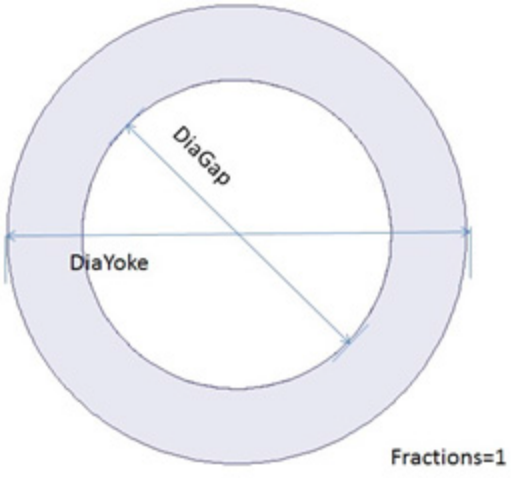

Figure 9-5 Outer band

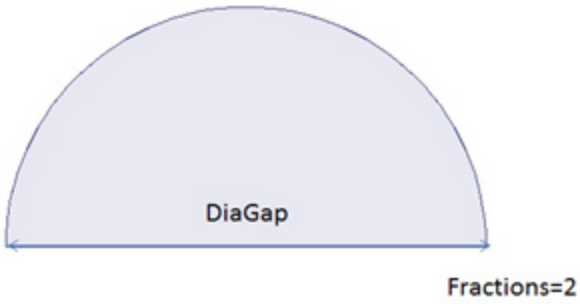

Figure 9-6 Inner band half

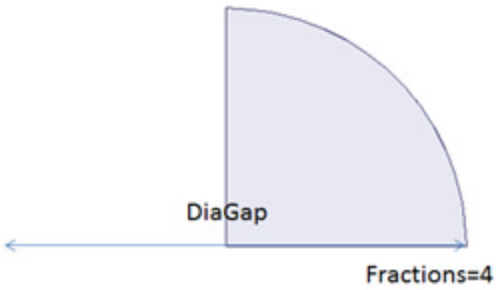

Figure 9-7 Inner band semi

Parameters such as **SegAngle**, **Length** and **HalfAxial** are shown in the following 3D figures:

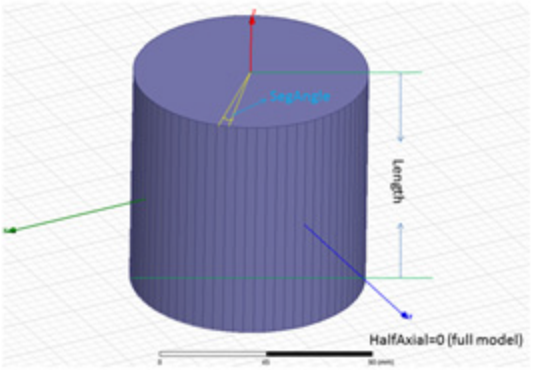

Figure 9-8 Inner band (full model)

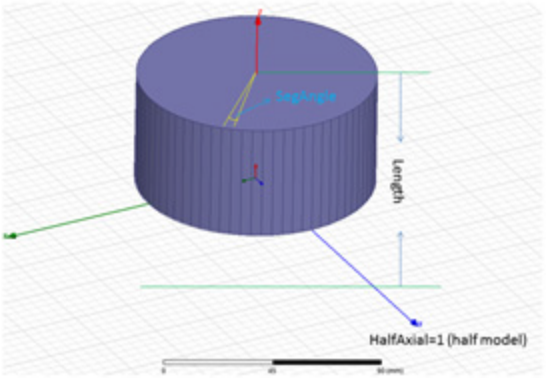

Figure 9-9 Inner band (half model)

Creating a Band

Maxwell provides you with a .dll file to define the parameters of a band.

1. Click **Draw>User Defined Primitive>RMxprt>Band**.
   The **User Defined Primitive Operation** dialog box appears.

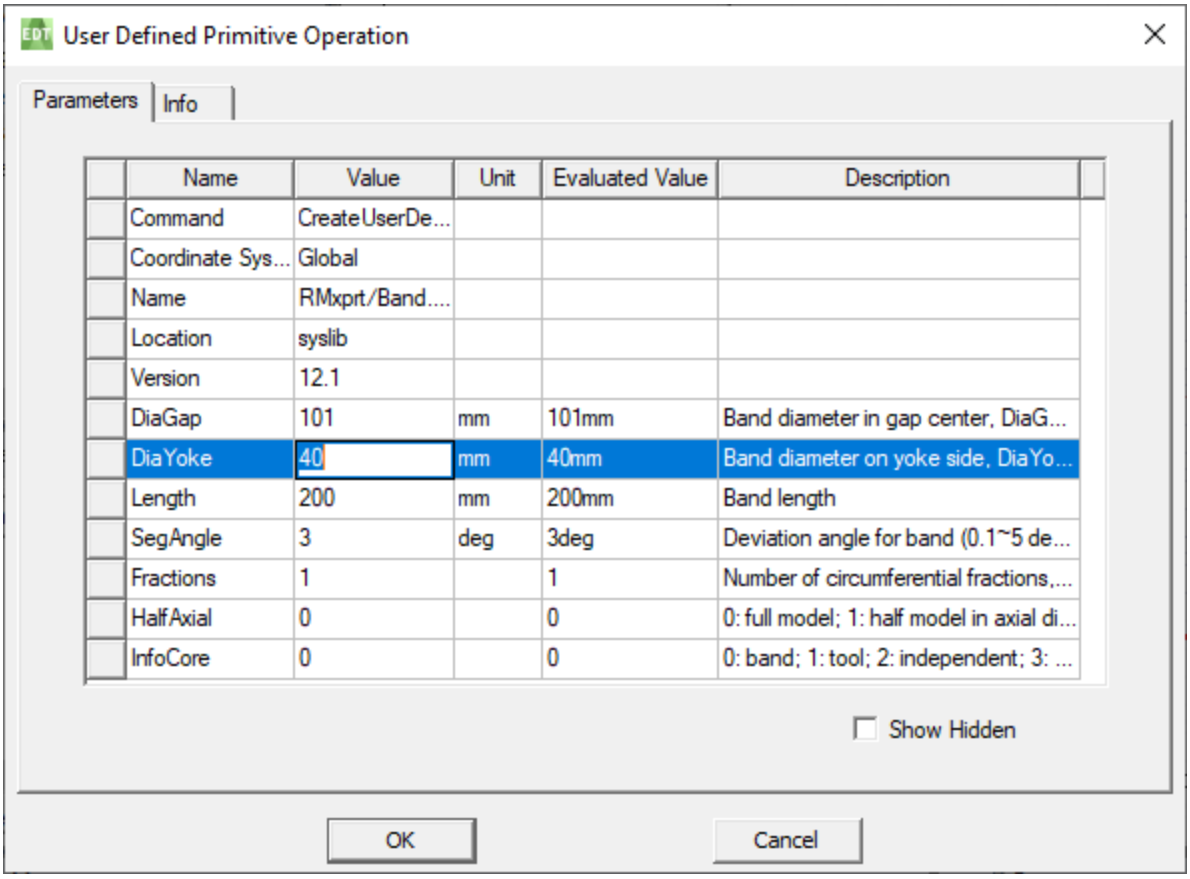

Figure 9-10 Change values of parameters when creating a UDP

The **Parameters** tab permits you to see and edit the parameters. An **Info** tab contains information about the user defined primitive, its purpose, the company/author who created it, the date created and the version number.

2. Specify the values for the parameters.
3. Click **OK**.

Creating an Outer Region

An outer region can be assigned by setting the **InfoCore** property to 100 either when creating the band or after creating it. The method for assigning during band creation is discussed in Creating a Band. The method for assigning after the band is created is as follows:

1. For assigning an outer region after the band is created, click **CreateUserDefinedPart** in the history tree under the specific band, as shown in Figure 9-11 . You can change the **InfoCore** property to **100** under **Command** tab.

2. For an outer region, set **DiaGap** < **DiaYoke**. For a shaft, set **DiaGap** > **DiaYoke**.

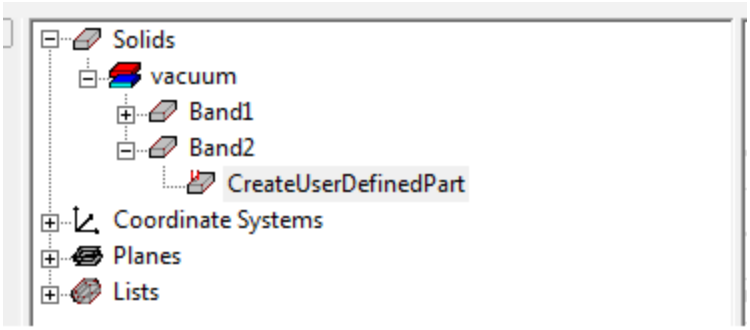

Figure 9-11 CreateUserDefinedPart in the history tree

Creating a Tool

When you are defining parameters, the **InfoCore** property can be assigned to **1**, which means the band is used as a tool. This property can be assigned either when creating the band or after creating it. The method for assigning during band creation is discussed in Creating a Band. For assigning after the band is created, click **CreateUserDefinedPart** in the history tree under the specific band, as shown in Figure 9-11 . You can then change the **InfoCore** property to **1** under **Command** tab.

Note	To be assigned as a tool, the band must be an outer band, which means the band's DiaGap value must be less than DiaYoke value.

A tool is mainly used for subtraction in the model.

For example, if a half model of NonSalientPoleCore UDP is needed, a tool is necessary to be used to subtract half of NonSalientPoleCore.

First, create a tool.

1. Click **Draw>User Defined Primitive>RMxprt>Band**.
2. Change **DiaGap** and **DiaYoke** values to set the **DiaGap** value to be less than the **DiaYoke** value.
3. Set **InfoCore** value to 1 and change the **Color** of the tool to another one in order to

distinguish the tool from the NonSalientPoleCore, which is created later.

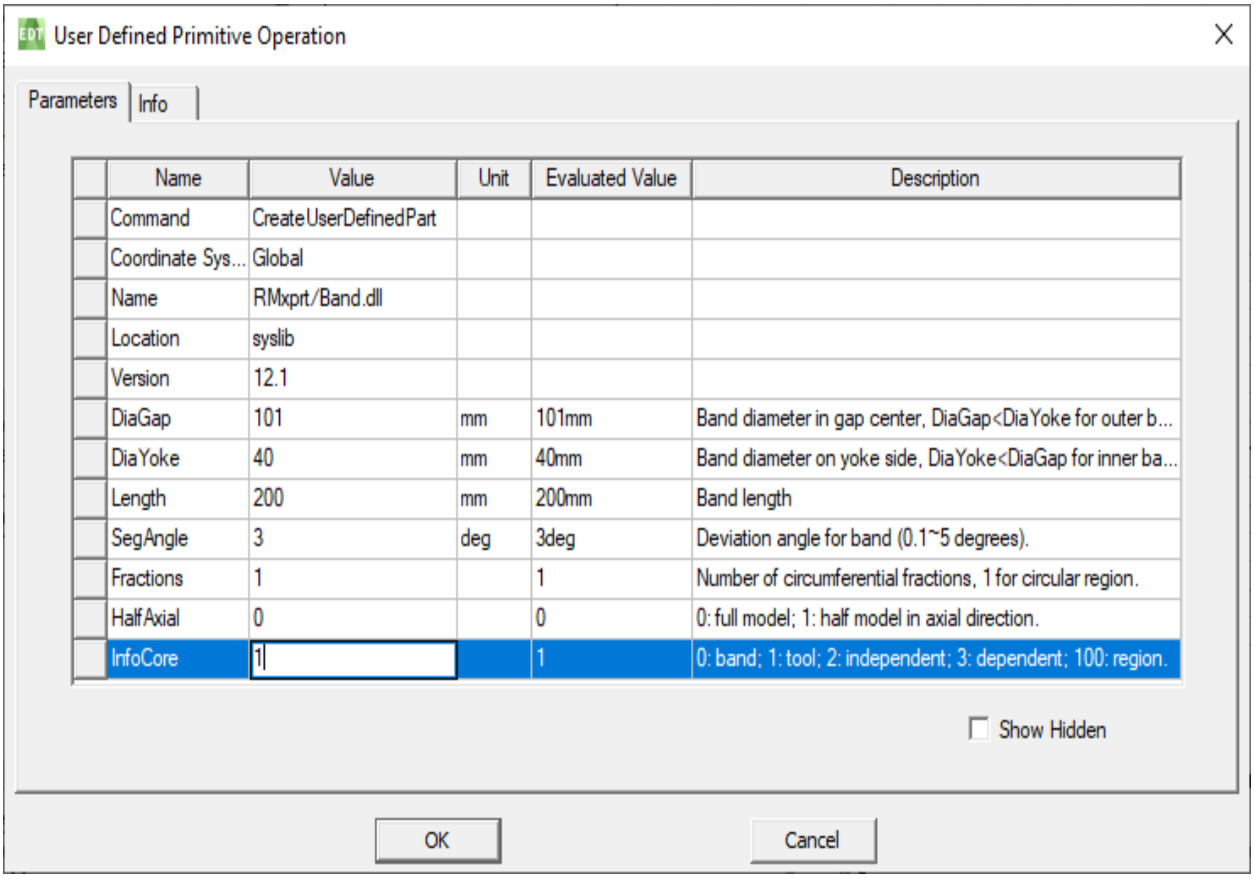

Figure 9-12 Set the values of parameters to create a tool

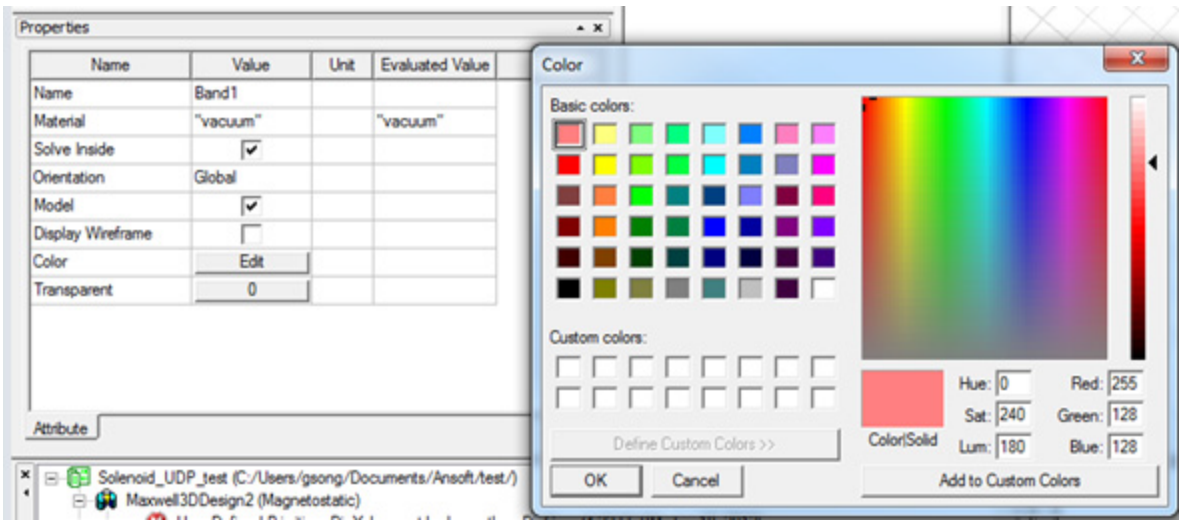

Figure 9-13 Change the color of the tool

Then, create a non-salient pole core.

1. Click **Draw>User Defined Primitive>RMxprt>NonSalientPoleCore**.
2. Click **OK** to finish setting the parameter.

The coordinate system window looks similar to the following figure:

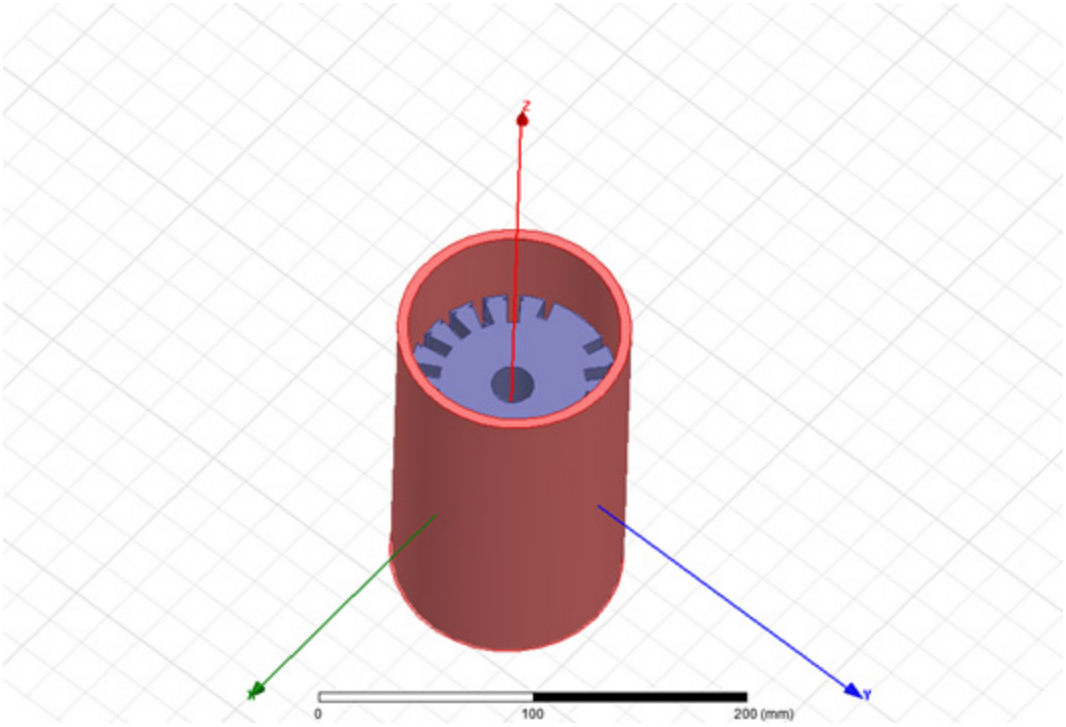

Figure 9-14 Non-Salient Pole Core (gray) with a tool

Change the **Fractions** of the tool to 2.

1. Click **CreateUserDefinedPart** in the history tree under the tool (named Band1 in the figure).
2. Change the value of **Fractions** to 2.

3. Click **OK** to finish setting the parameter.

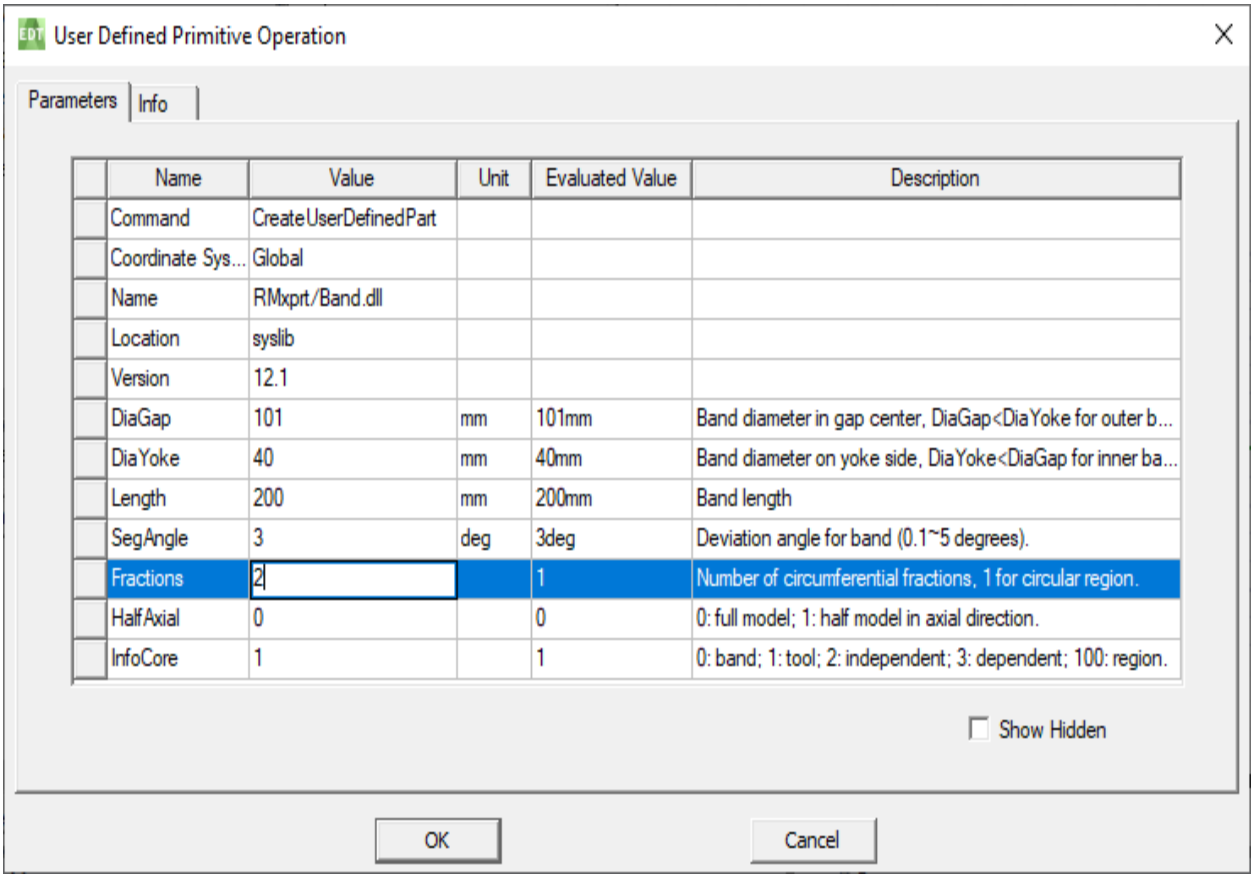

Figure 9-15 Change the value of Fractions of Non-Salient Pole Core (gray)

The last step is to subtract the non-salient pole core using the tool.

1. Choose NonSalientPoleCore1 and Band1 (tool) simultaneously by pressing **Ctrl** on the keyboard.

2. Click **Modeler>Boolean>Subtract** to do the subtraction.

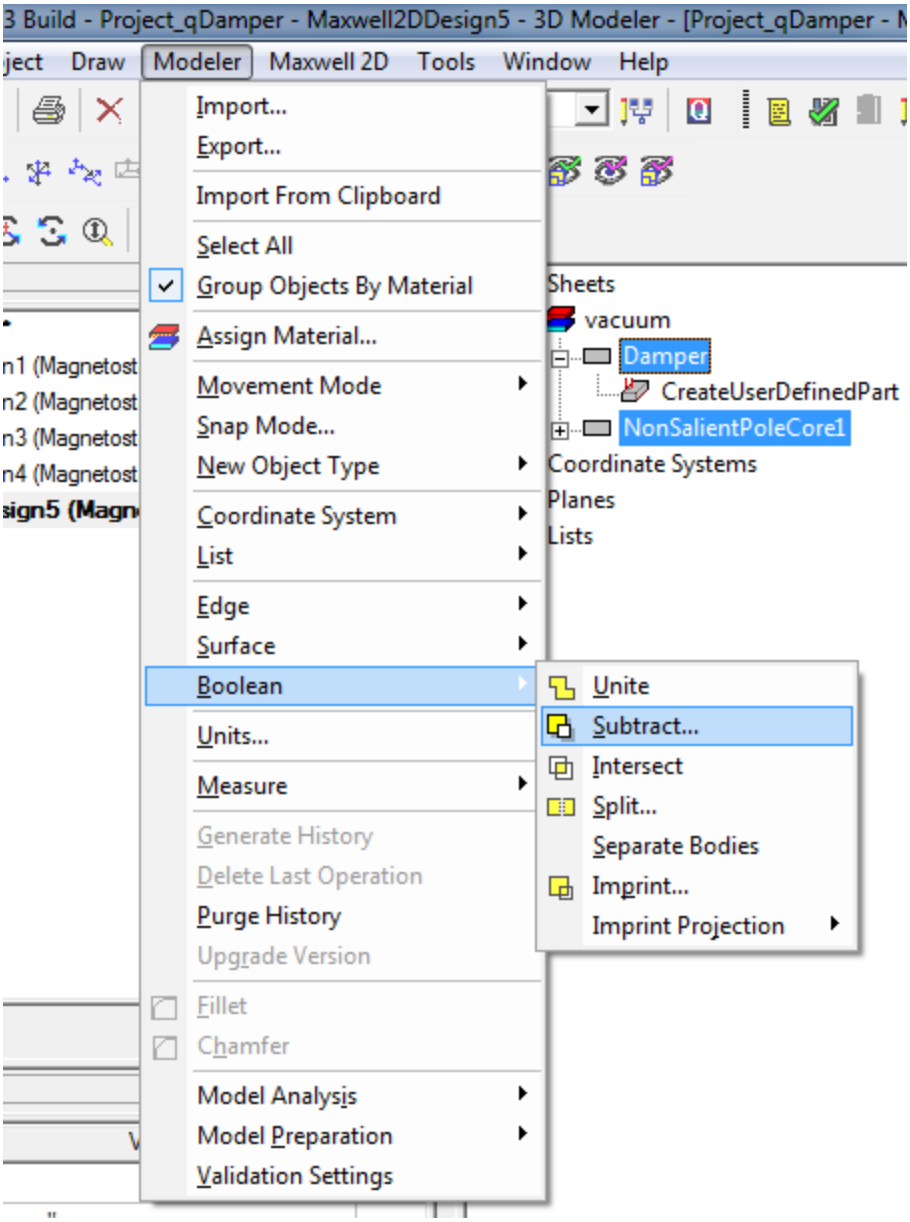

Figure 9-16 Subtraction of two objects

A Subtract window appears.

3. Choose NonSalientPoleCore1 as the **Blank Parts** and Band1 as the **Tool Parts**.
4. Click **OK** to finish subtraction.

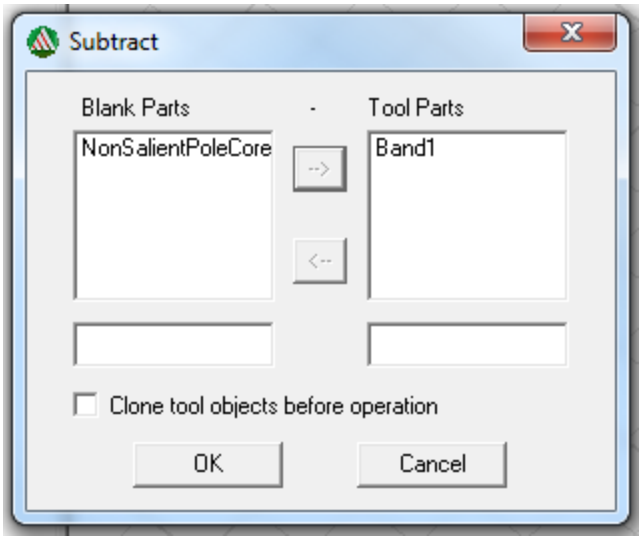

Figure 9-17 Set Blank Parts and Tool Parts

The final Non-Salient Pole Core is shown in the coordinate system window in the following figure:

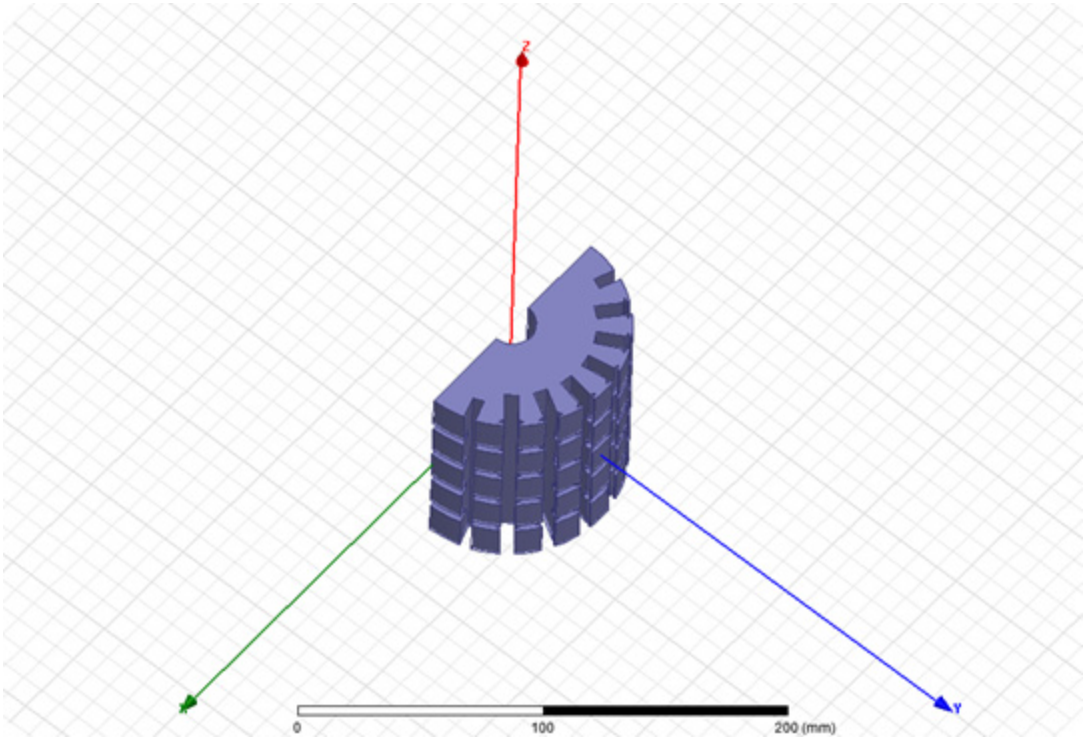

Figure 9-18 A non-salient pole core after subtraction

Creating 3D Independent and Dependent Boundaries

There are two ways to create 3D independent and dependent boundaries:

- Creating a new band and changing the entire band to an independent or dependent boundary
- Selecting one of the planar faces of an existing band in the coordinate window and assigning the face to an independent or dependent boundary

The process of changing an entire band to an independent or dependent boundary is similar to creating a tool. When creating a new band or after creation of a band, you can assign the **InfoCore** property to 2 (for independent) or 3 (for dependent). After clicking **OK**, the band is changed to a face.

The process of assigning independent and dependent boundaries on an existing face follows:

1. Click **CreateUserDefinedPart** in the history tree under the band for which you are assigning boundaries. Set the **Fractions** property of the band to an integer larger than 1 to make the band have a planar face.
2. Click **Edit>Selection Mode>Faces** or right-click anywhere in the coordinate window to choose **Selection Mode>Faces**.
3. Select a planar face of the band by right-clicking the face. Then select **Assign Boundary>Matching>Independent**(or **Assign Boundary>Matching>Dependent** after the Independent boundary has been set up). When assigning an independent boundary, an **Independent Boundary** window appears. Otherwise a **Dependent Boundary** window appears.
4. Build up a tiny coordinate system of the face by setting the U vector and V vector to indicate the direction of the face. The U vector needs to be set using an arrow on the coordinate, and then the V vector is set automatically on the face (you can choose **Reverse Direction** of default V vector). Note that the U vectors and V vectors of a related independent and

dependent must have the same orientation.

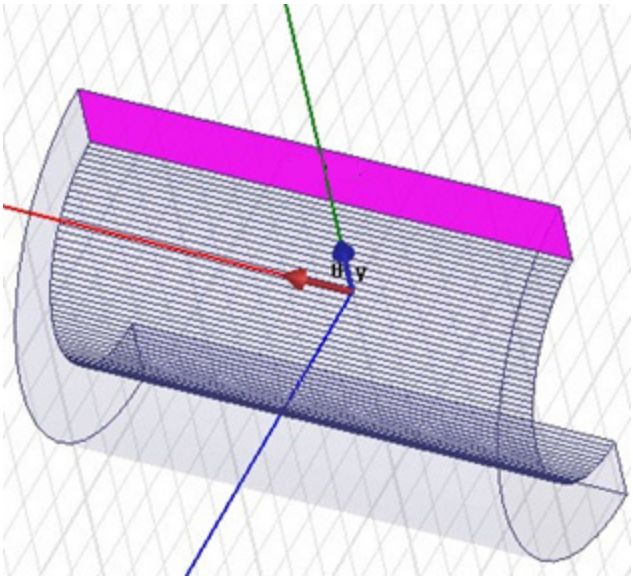

Figure 9-19 Set up U vector and V vector

5. When creating a dependent boundary, you also need to set its independent boundary and its magnetic field strength (either Hm or –Hm).
6. Click **OK** to finish independent or dependent boundary creation.

Creating Core Regions

Most core UDPs, which are covered in UDPs for Slot Cores and Coils, UDPs for Pole Cores and Coils, and UDPs for Other Cores and Coils, can be changed to core regions. The ways to change them into regions are similar. This section gives a general introduction of how to change those core UDPs into core regions.

Inner and outer cores are defined as follows:

- An inner core is a core for which the **DiaGap** value is greater than the **DiaYoke** value.
- An outer core is a core for which the **DiaGap** value is less than the **DiaYoke** value.

Creating an Inner Core Region

Because the properties and parameters of an inner core region should be the same as the corresponding inner core, an inner core region is usually created by replicating an inner core and changing the new object's **InfoCore** property to **100**. The detailed steps are as follows:

1. Select the inner core in the history tree. Then right-click to choose **Edit>Copy**.

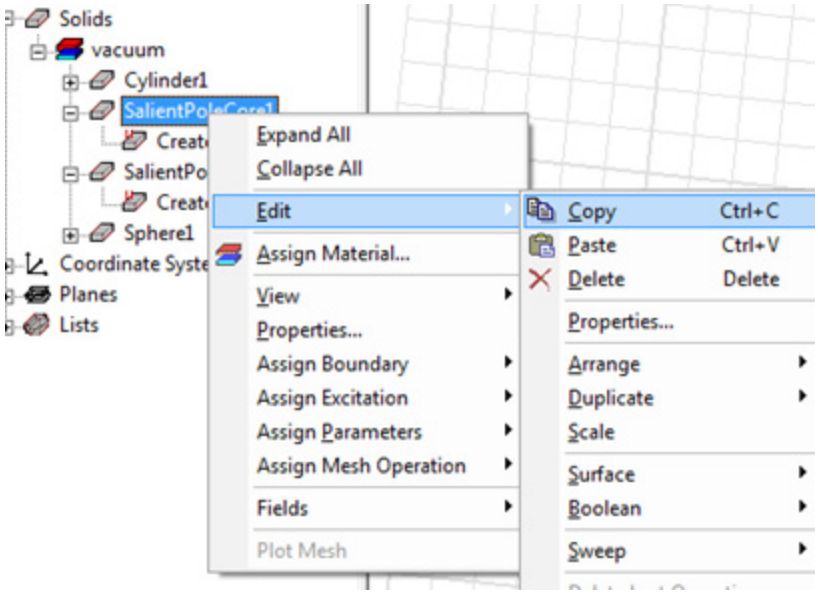

Figure 9-20 Copy a SalientPoleCore

2. Right-click the same object in the history tree to choose **Edit>Paste**. This process is shown in the following figure:

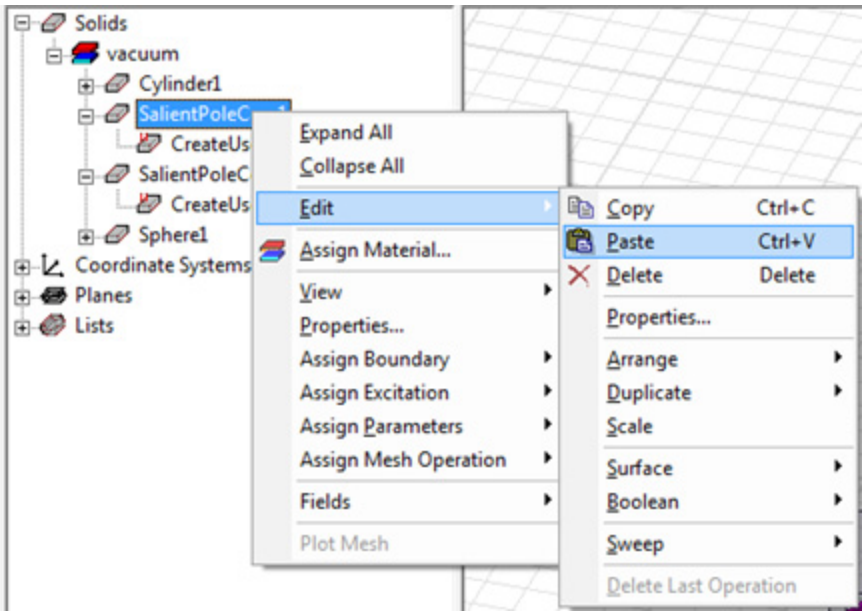

Figure 9-21 Paste a SalientPoleCore

3. Click **CreateUserDefinedPart**, and set **InfoCore** property to **100** in the pop-up window.

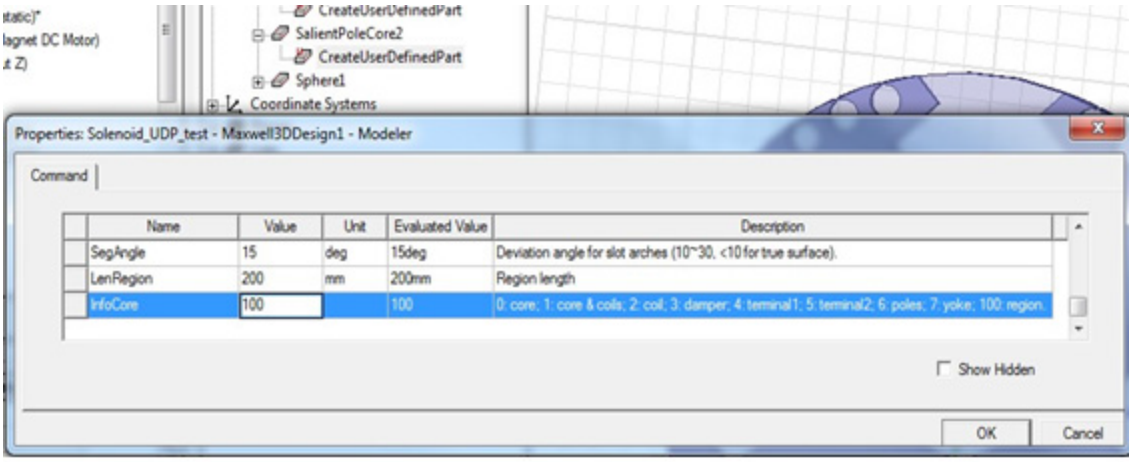

Figure 9-22 Change the value of InfoCore of SalientPoleCore

4. Click **OK.**

Creating an Outer Core Region

Because the properties and parameters of an outer core region should be the same as the corresponding outer core, an outer core region is usually created by replicating an outer core and changing the new object's **InfoCore** property to **100**. The detailed steps are as follows:

1. Select the outer core in the history tree. Then right-click to choose **Edit>Copy**.

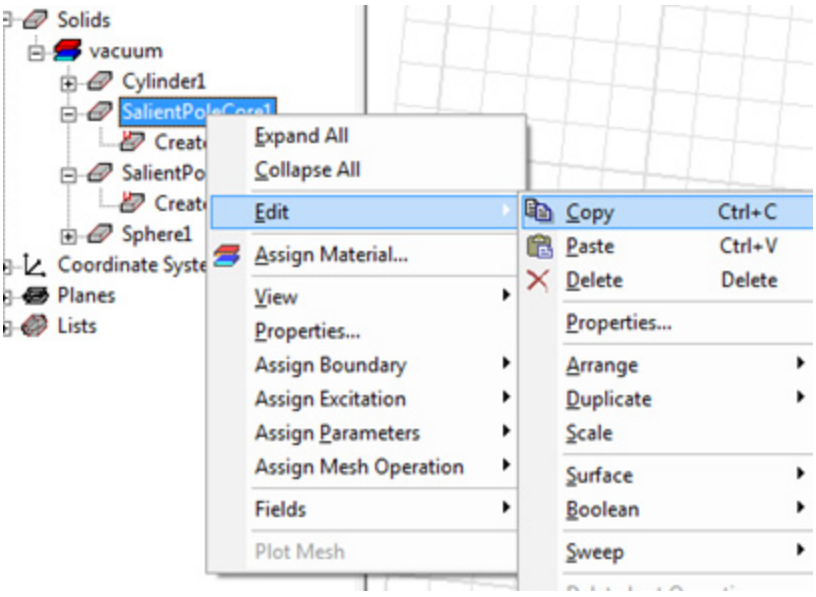

Figure 9-23 Copy a SalientPoleCore

2. Right-click the same object in the history tree to choose **Edit>Paste**. This process is shown in the following figure:

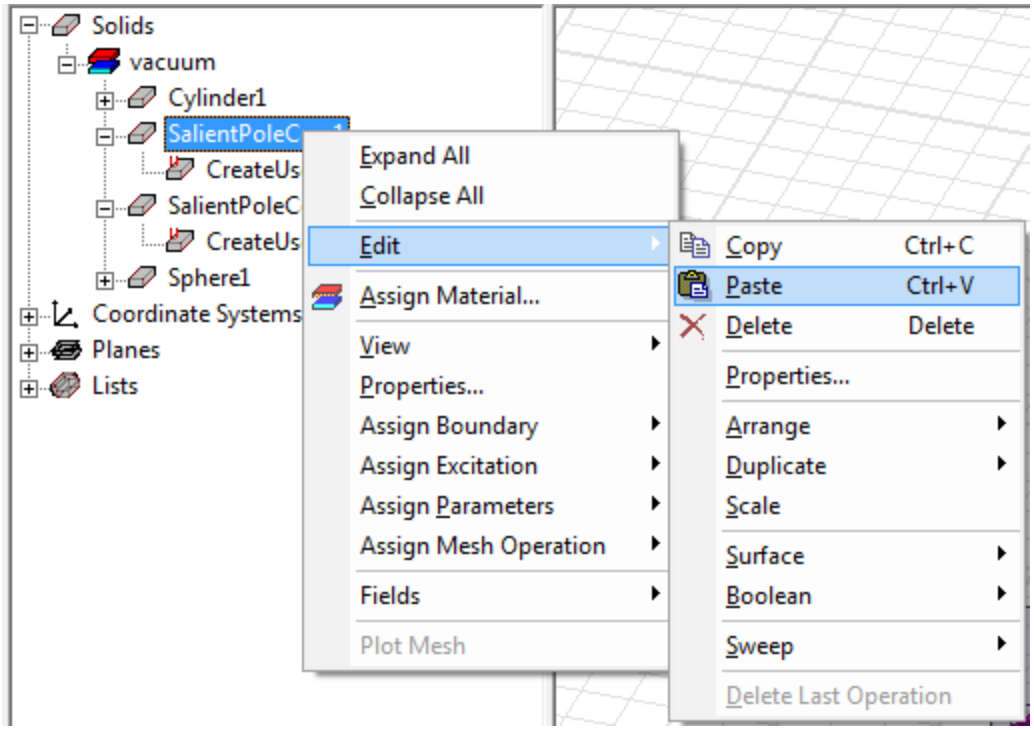

Figure 9-24 Paste a SalientPoleCore

3. Click **CreateUserDefinedPart**, and set **InfoCore** property to **100** in the pop-up window.

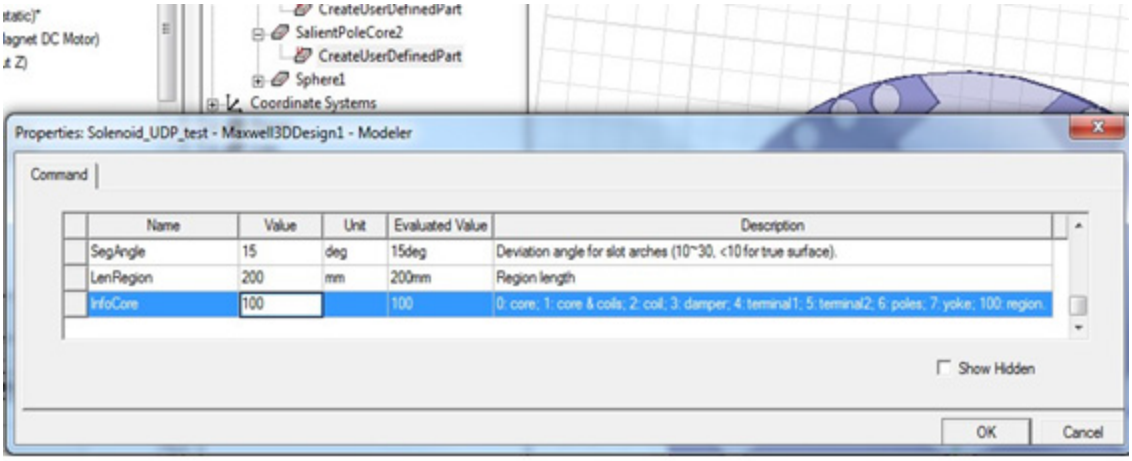

Figure 9-25 Change the value of InfoCore of SalientPoleCore

4. Click **OK.**

UDPs for Slot Cores and Coils

UDPs for defining slot cores and coils include:

- SlotCore UDP
- VentSlotCore UDP
- RacetrackSlotCore UDP
- NonSalientPoleCore UDP
- LapCoil UDP
- ConCoil UDP
- WaveCoil UDP
- SquirrelCage UDP
- DoubleCage UDP
- CupCoil UDP

SlotCore UDP

The SlotCore UDP is used to create a stator or rotor core with a distributed AC winding, or a DC commutating winding, or a squirrel-cage winding for the following machine types:

- Single-phase or multi-phase induction machines
- Wound-field or PM synchronous machines
- Brush-commutating machines, such as wound-field or PM DC machines, as well as universal motors
- Brushless DC machines, and others

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 6.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.

Property	Description
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom; 4&5: V bottom.
HalfSlot	0 for symmetric slot; 1 for half slot.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: Core; 100: region.

These parameters are used in the following 2D SlotCore example:

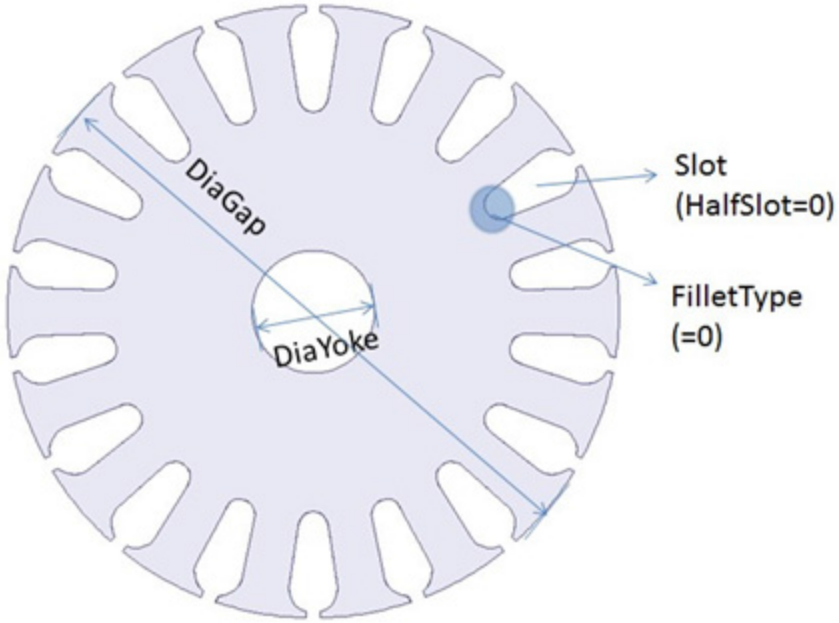

Figure 9-26 Diameters of SlotCore when HalfSlot is 0

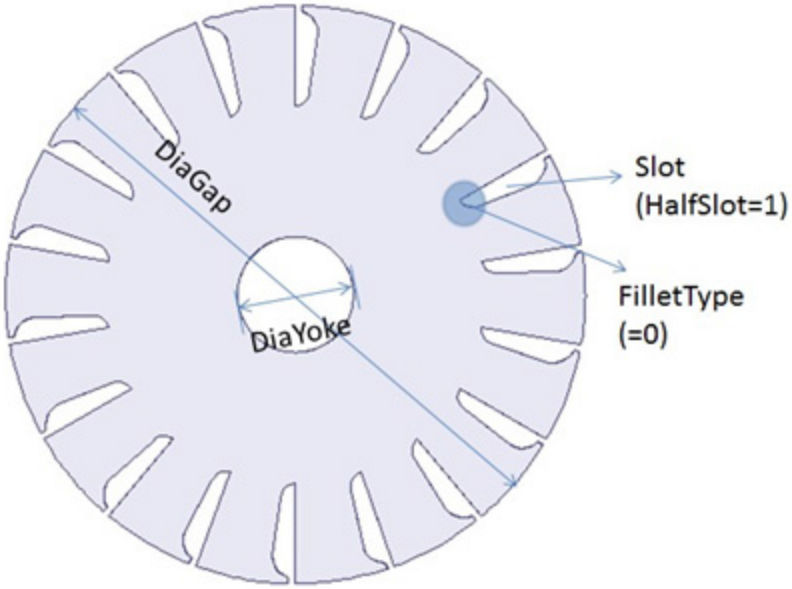

Figure 9-27 Diameters of SlotCore when HalfSlot is 1

3D figures of a slot core are shown in the following examples:

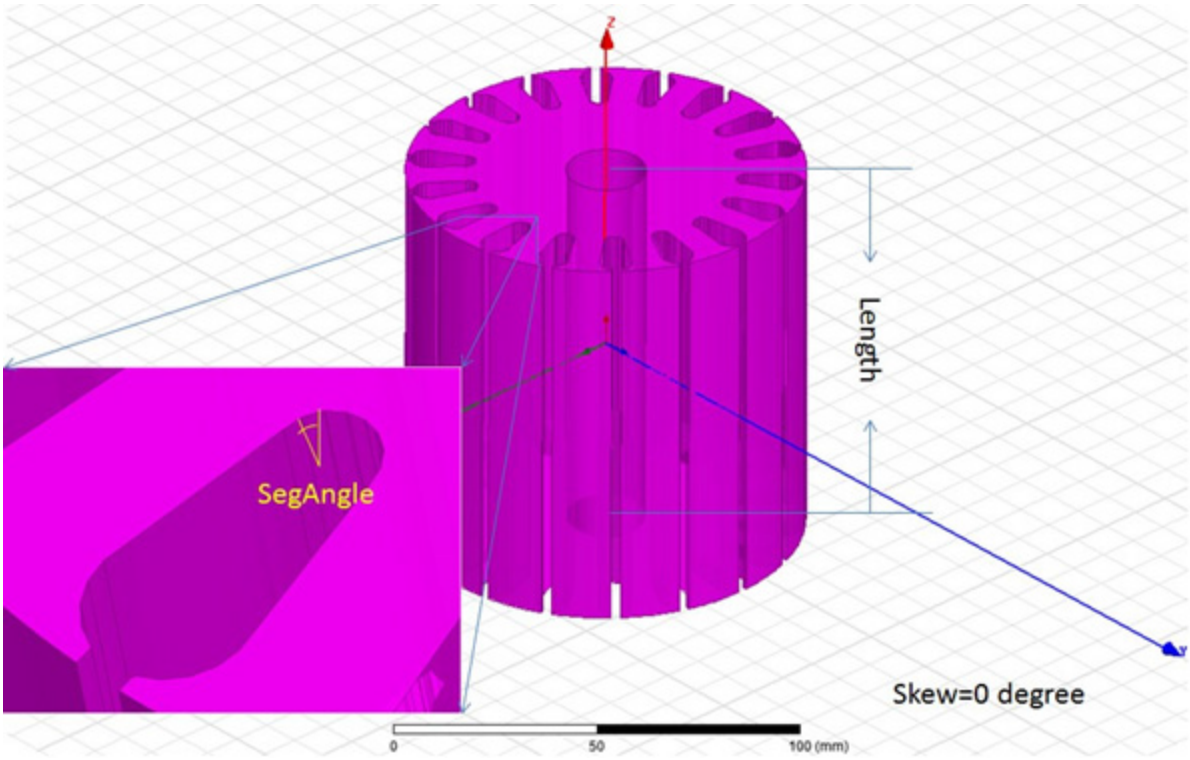

Figure 9-28 SegAngle and Length of SlotCore

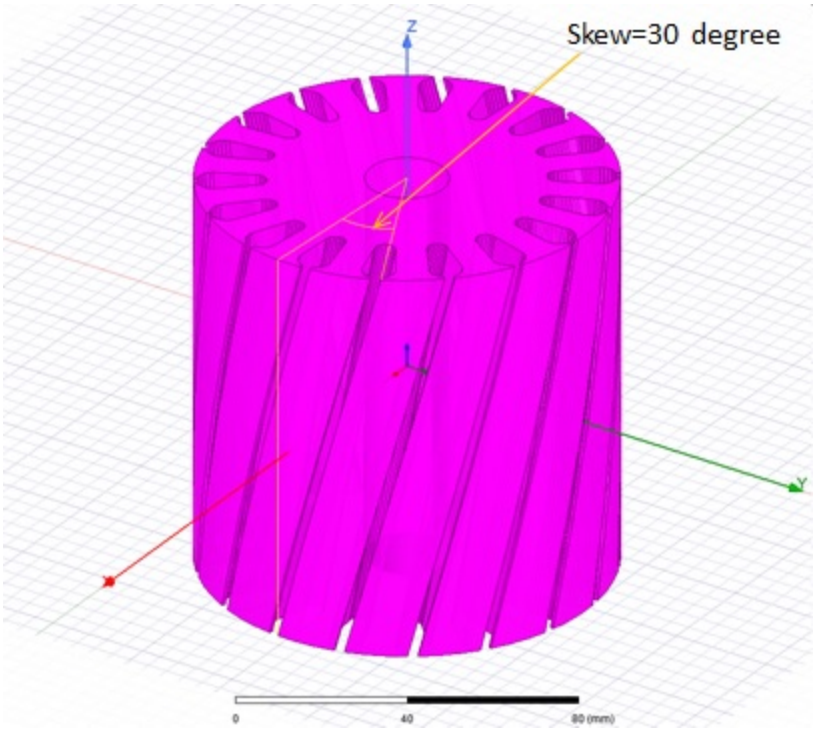

Figure 9-29 Skew of SlotCore

Six common slot types and their related parameters are shown in the following figures:

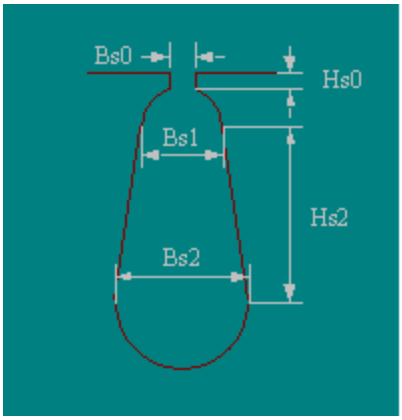

Figure 9-30 Slot Type 1

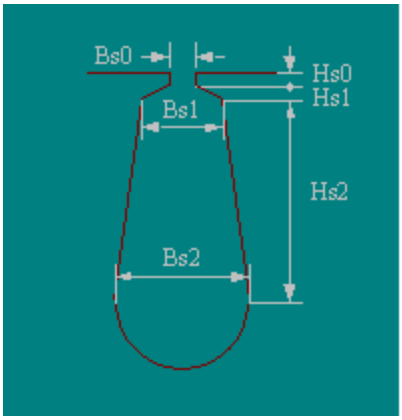

Figure 9-31 Slot Type 2

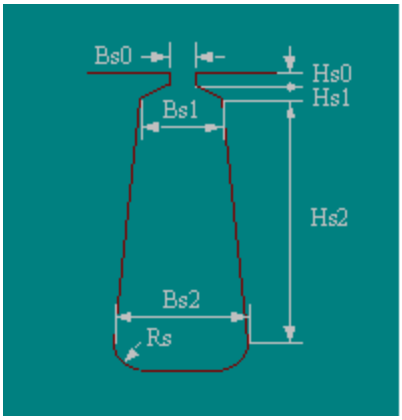

Figure 9-32 Slot Type 3

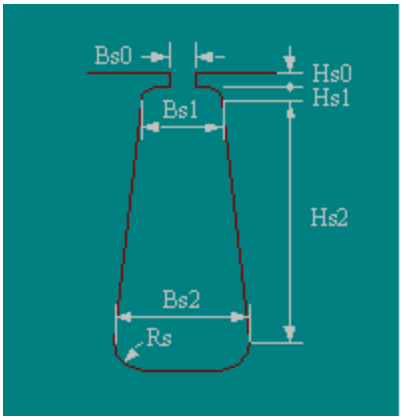

Figure 9-33 Slot Type 4

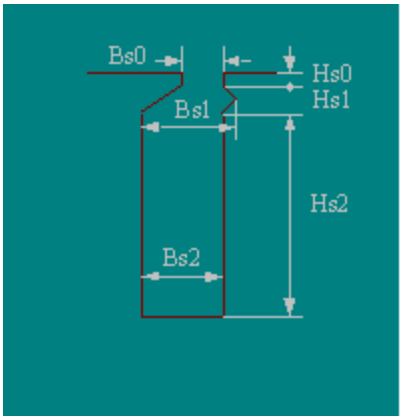

Figure 9-34 Slot Type 5

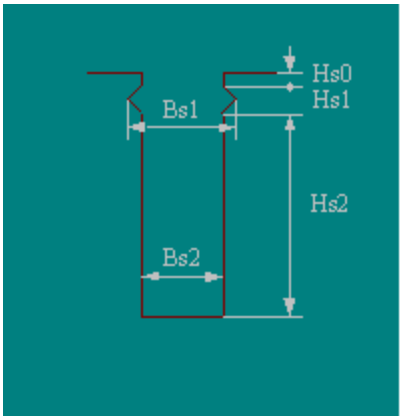

Figure 9-35 Slot Type 6

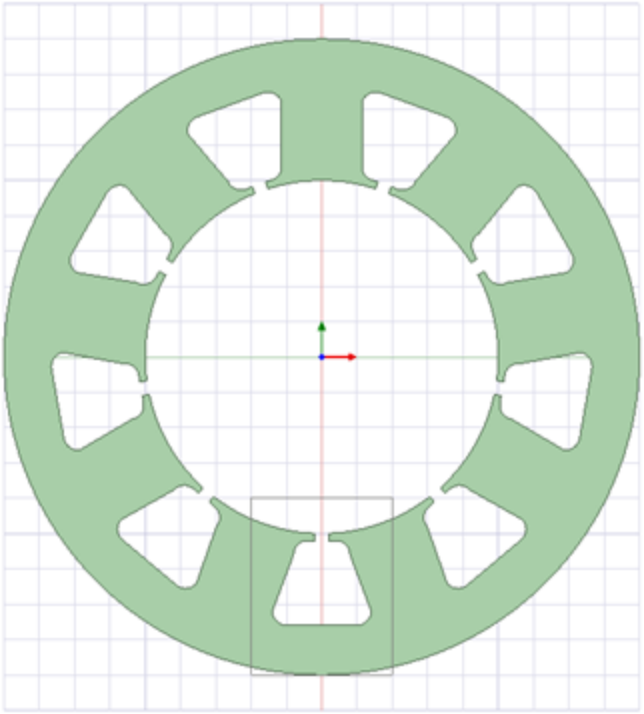
Slot cores or coils with a **SlotType** parameter can choose one of these slots.

Creating an Inner or Outer Slot Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

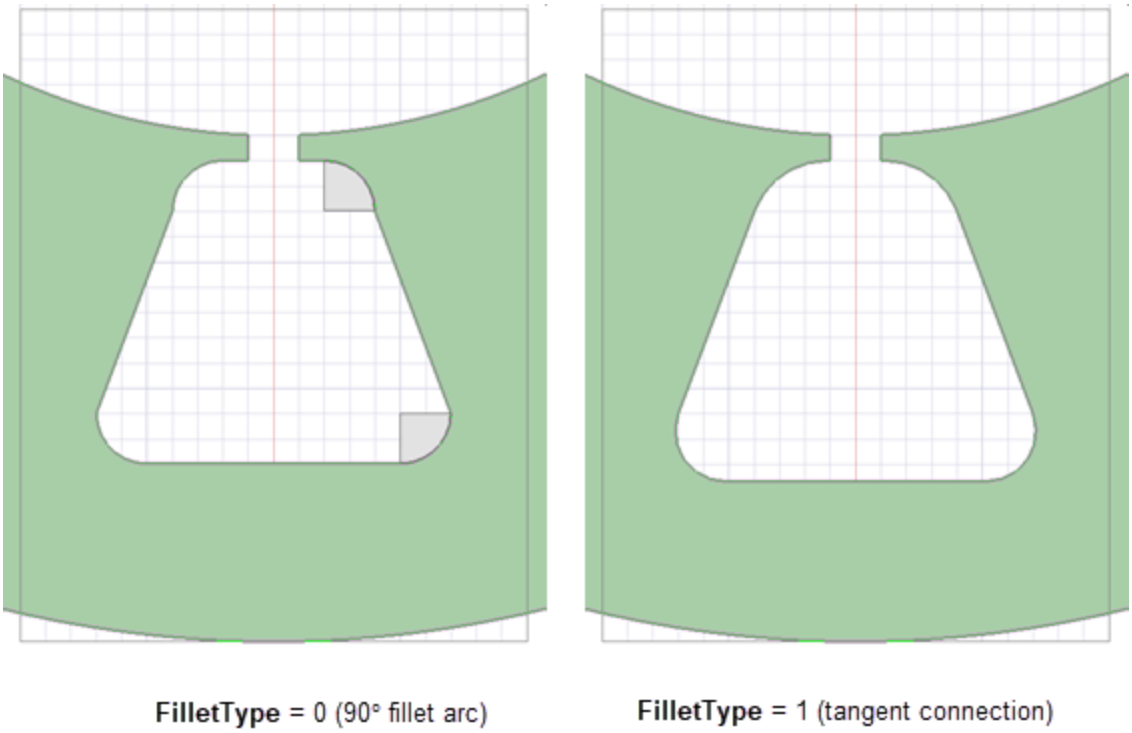
Set the **InfoCore** value to 0.

Slots with Different Fillet and Bottom Types



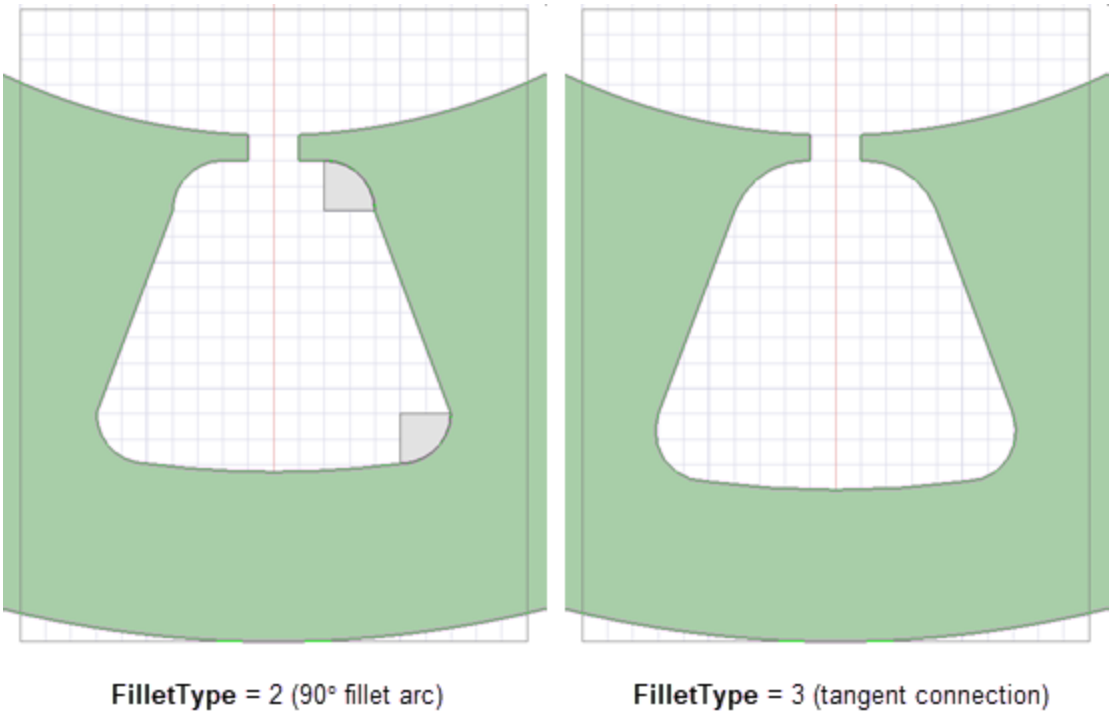
Slot core with Type-4 slots

Various values of **FilletType** are used for different fillet and bottom types. **FilletType** values 0 and 1 are for half-circle slot bottom for **SlotType** = 1 and 2, or for flat slot bottom for **SlotType** = 3 and 4, as shown below.



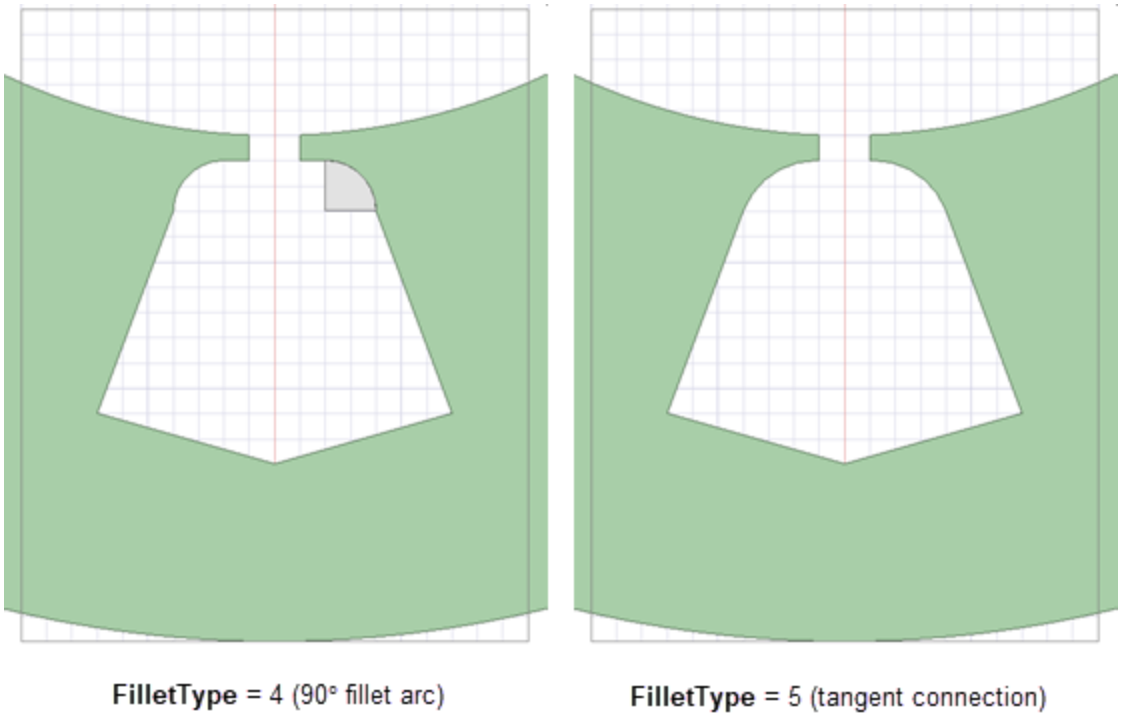
Slot Type 4 with flat bottom

FilletType values 2 and 3 are for outer-core arc slot bottom for **SlotType** = 3 and 4 only, as shown below.



Slot Type 4 with arc bottom

FilletType values 4 and 5 are for V-shape slot bottom for **SlotType** = 3 and 4 only, as shown below.



Slot Type 4 with V-shape bottom (Rs is V-shape height)

VentSlotCore UDP

The VentSlotCore UDP can create the same core that the SlotCore UDP does. However, the VentSlotCore UDP can create cores with radial vents and axial holes. If you want to create a slotted core without radial vents or axial holes, use the SlotCore UDP to have less data input.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 6.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Wedge height.

Property	Description
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom.
HalfSlot	0 for symmetric slot; 1 for half slot.
VentHoles	Number of axial vent holes per row.
HoleDiaIn	Diameter of inner vent holes.
HoleDiaOut	Diameter of outer vent holes.
HoleLocIn	Diameter of inner vent hole center layout circle.
HoleLocOut	Diameter of outer vent hole center layout circle.
VentDucts	Number of radial vent ducts.
DuctWidth	Axial width of radial vent ducts.
DuctPitch	Center-to-center distance between two adjacent ducts.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: Core; 100: region.

These parameters are used in the following inner VentSlotCore example:

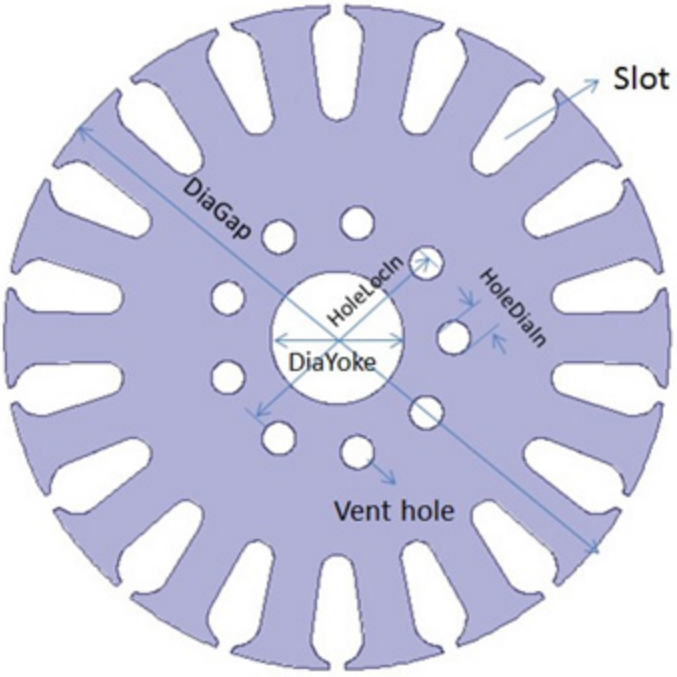


Figure 9-36 Parameters on cross-section of VentSlotCore

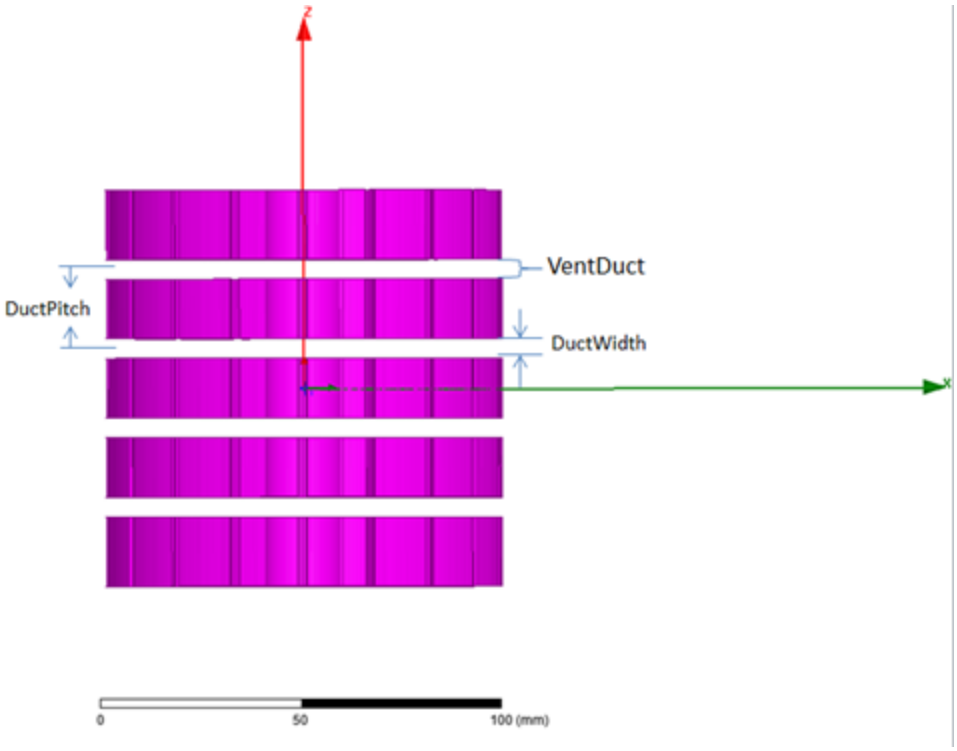

Figure 9-37 Parameters on axial direction of VentSlotCore

Note	For parameters such as **Skew**, **FilletType**, **SegAngle**, **HalfSlot** and parameters related to slots, refer to SlotCore UDP parameters.

Creating an Inner or Outer Vent Slot Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores. You can set the values when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

RacetrackSlotCore UDP

The RacetrackSlotCore UDP is used to create a stator core with a single-phase concentric AC winding for single-phase induction machines. The stator may have up to three different slot sizes.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 6.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom.
Poles	Number of poles.
WidYoke	Racetrack width for 2/4-pole cores.
MidSlots	Number of middle-size slots for 2/4-pole cores.

Property	Description
MidHs2	Middle-size slot body height for 2/4-pole cores.
MidBs2	Middle-size slot body bottom width for 2/4-pole cores.
SmlSlots	Number of small-size slots for 2/4-pole cores.
SmlHs2	Small-size slot body height for 2/4 pole cores.
SmlBs2	Small-size slot body bottom width for 2/4-pole cores.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: Core; 100: region.

These parameters are used in the following outer Racetrack SlotCore example:

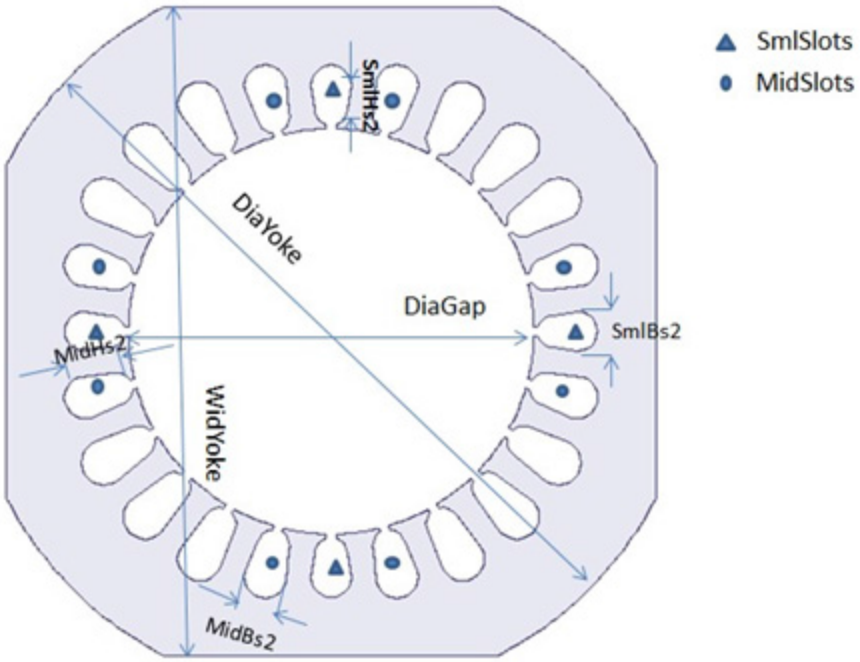

Figure 9-38 Parameters on cross-section of RacetrackSlotCore

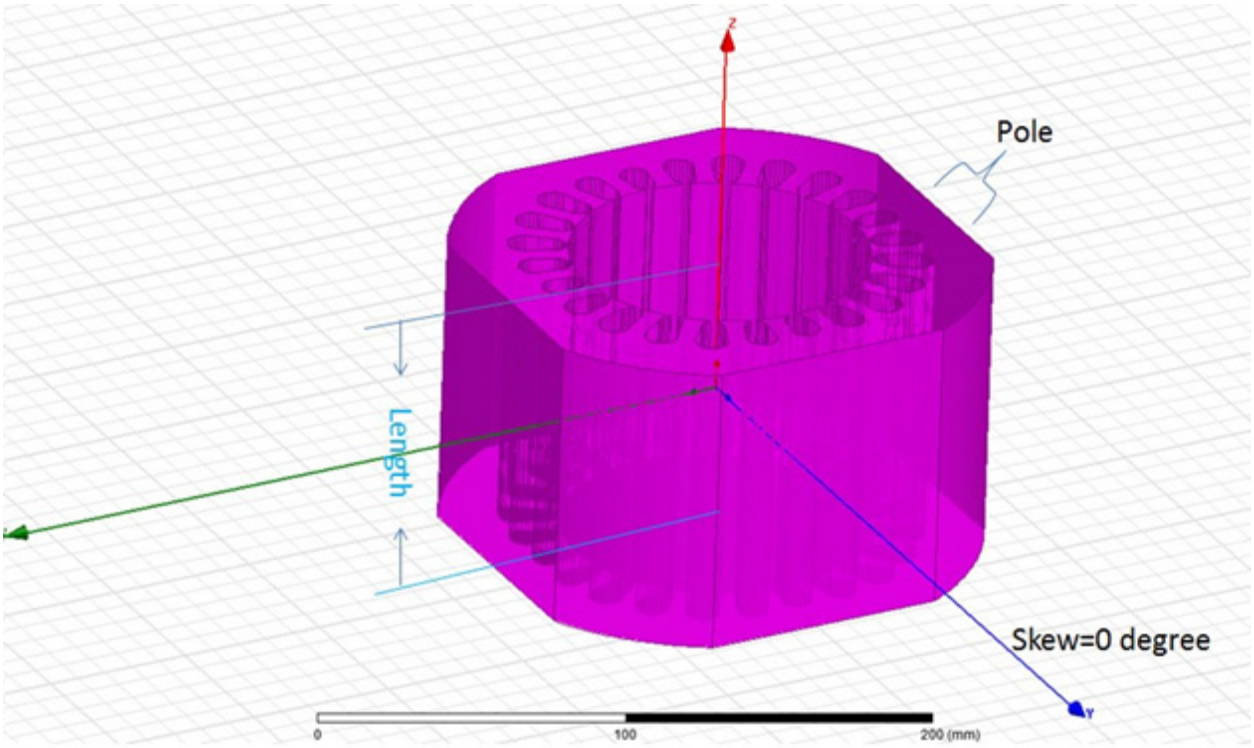

Figure 9-39 Parameters on axial direction of RacetrackSlotCore

Note	For parameters such as **Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

Creating an Outer Racetrack Slot Core

Generally, Racetrack Slot Cores are used as outer cores. Set the value of **DiaYoke** and **DiaGap** as **DiaGap**<**DiaYoke** for outer cores. You can set the values when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

NonSalientPoleCore UDP

The NonSalientPoleCore UDP is used to create non-salient rotor cores for non-salient rotor synchronous machines. This core type may include surface tangential vent ducts, axial vent ducts, as well as a damper.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner

	cores.
Length	Core length.
Skew	Skew angle in core length range.
IndexingSlots	Number of indexing slots for slot pitch calculation.
ActualSlots	Number of actual slots: ActualSlots <= IndexingSlots.
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom.
Poles	Number of poles.
TangentDucts	Number of surface tangential vent ducts.
TDuctWidth	Axial width of surface tangential vent ducts (or damper rings).
TDuctDepth	Radial depth of surface tangential vent ducts (or damper rings).
TDuctPitch	Pitch of surface tangential vent ducts (or damper bar extension).
AxialDucts	Number of axial vent ducts per pole.
ADuctWidth	Width of axial vent ducts in main tooth.
ADuctDepth	Depth of axial vent ducts in main tooth.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: Core; 100: region.

These parameters are used in the following inner Non-Salient SlotCore example:

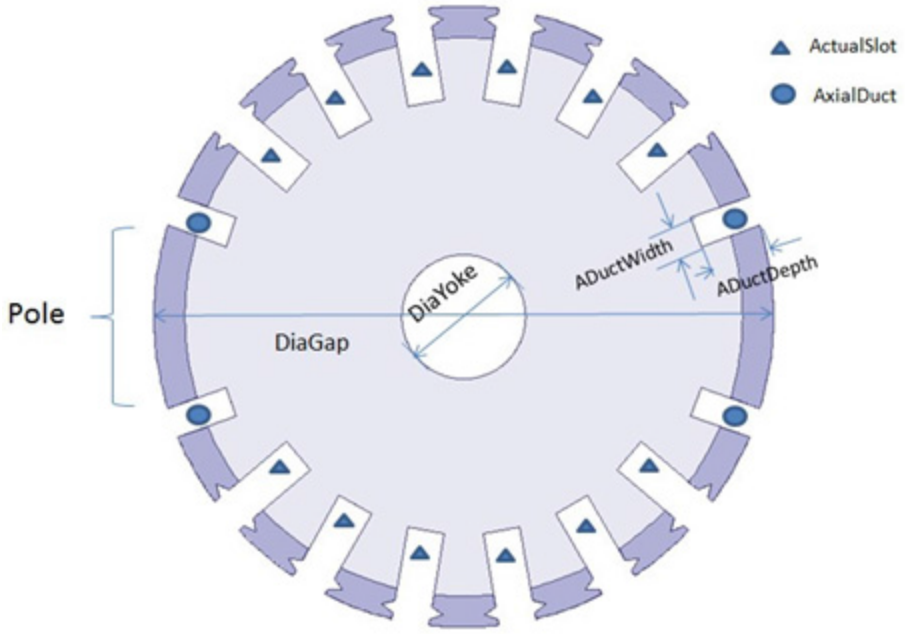

Figure 9-40 Parameters on cross-section of NonSalientPoleCore

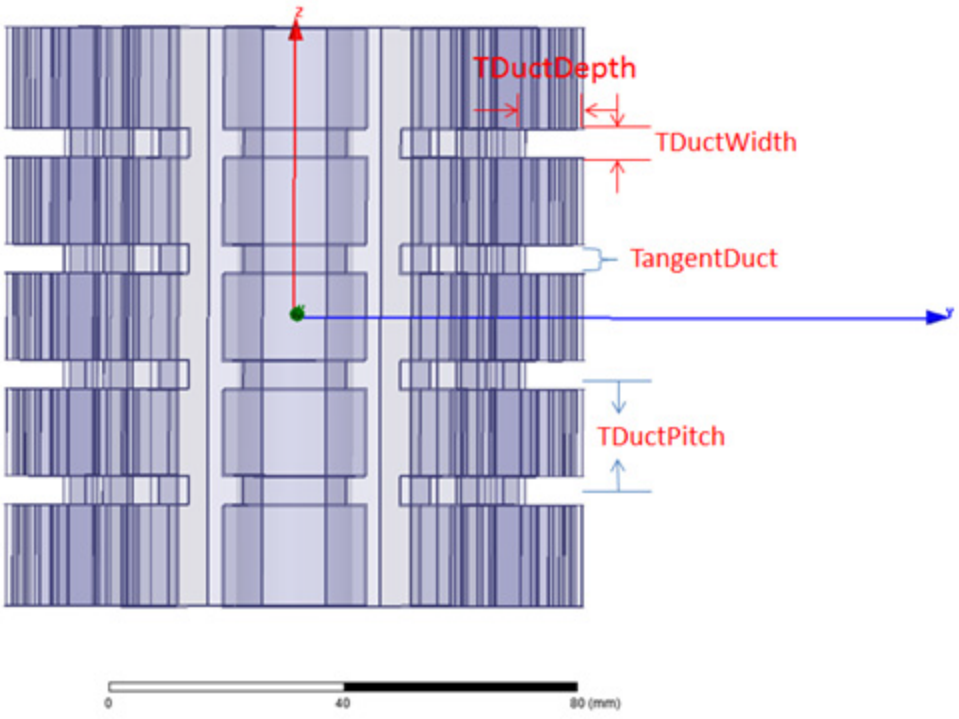

Figure 9-41 Parameters on axial direction of NonSalientPoleCore

Note	For parameters such as **Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

Creating an Inner Non-Salient Pole Core

Generally, Non-Salient Pole Cores are used as inner cores. Set the value of **DiaYoke** and **DiaGap** as **DiaGap**>**DiaYoke** for inner cores. You can set the values when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

Creating a Non-Salient Pole Core with a Q-Axis Damper

In general, this process is realized by a subtraction of two objects. Several steps are needed to finish the procedure.

1. Click **Project>Insert Maxwell 2D Design** to create a Maxwell2D Design in a project.

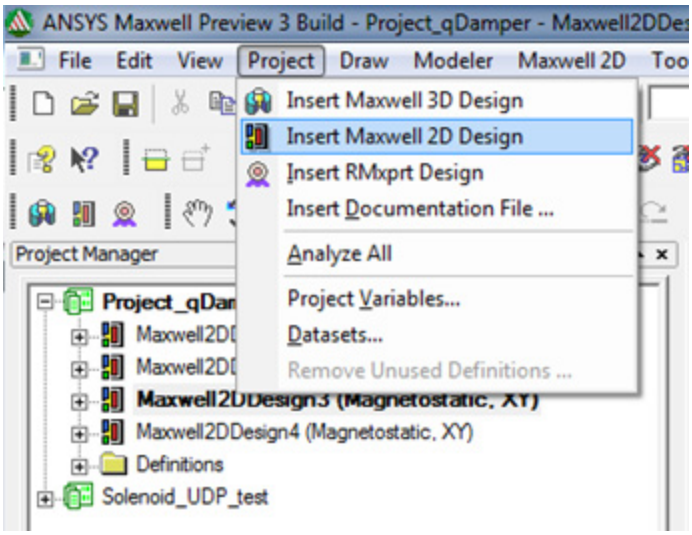

Figure 9-42 Insert a 2D design to create a Non-Salient Pole Core

2. Click **Draw>User Defined Primitive>RMxprt>NonSalientPoleCore** to draw a Non-Salient Pole Core UDP. In order to show it in a 2D dimension, set the **Length** to 0. Also set

AxialDucts to 0 for subtraction, as shown in the following figure.

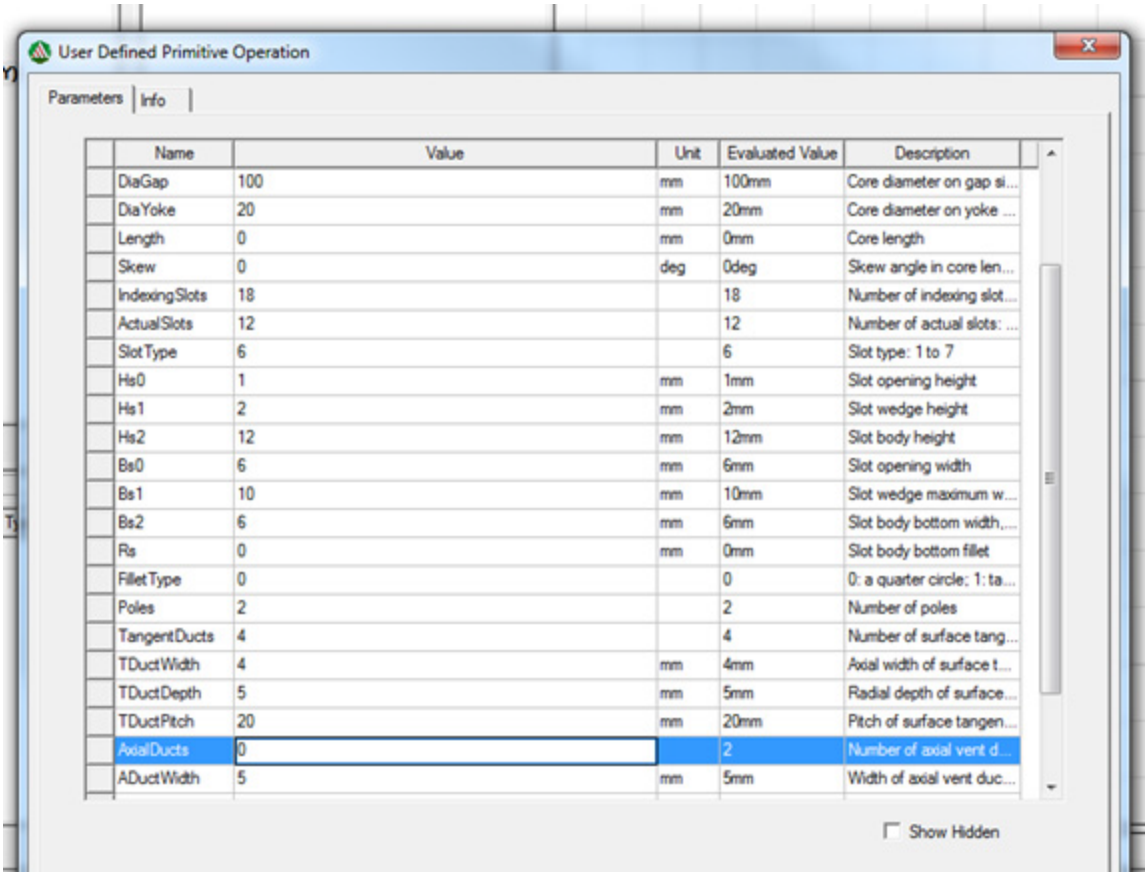

Figure 9-43 Parameter settings of NonSalientPoleCore

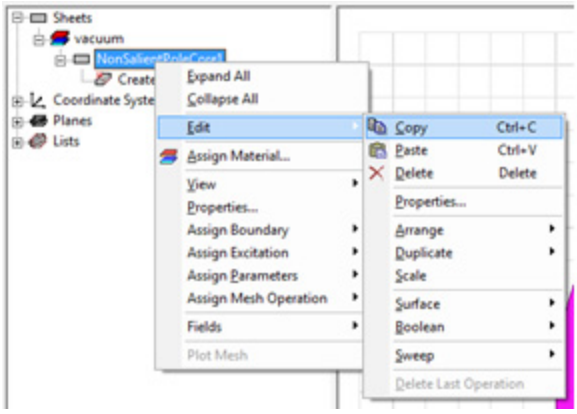
3. Create a damper. Make a copy of the NonSalientPoleCore, and then paste it and rename it to damper.



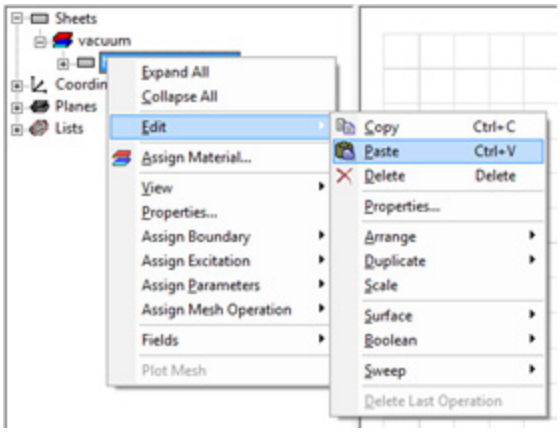


Figure 9-44 Make a copy of NonSalientPoleCore and paste it

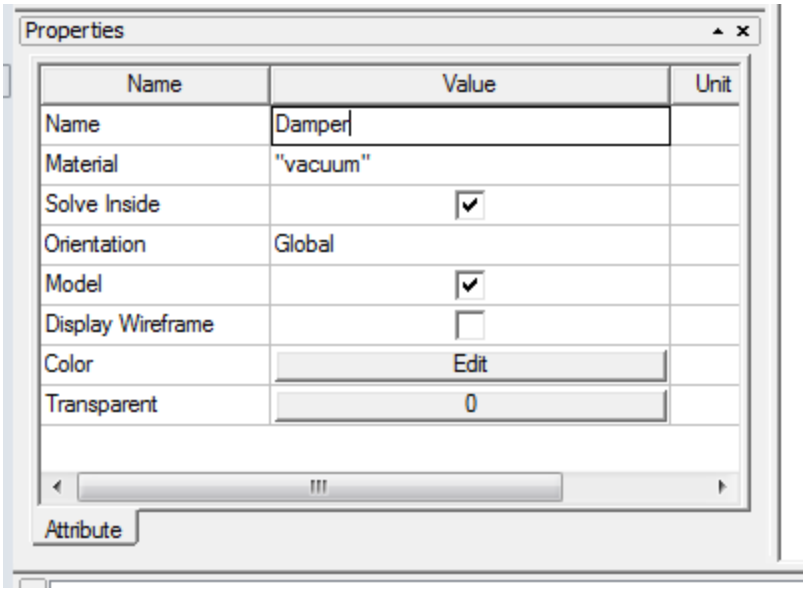

Figure 9-45 Rename the new NonSalientPoleCore to “Damper”

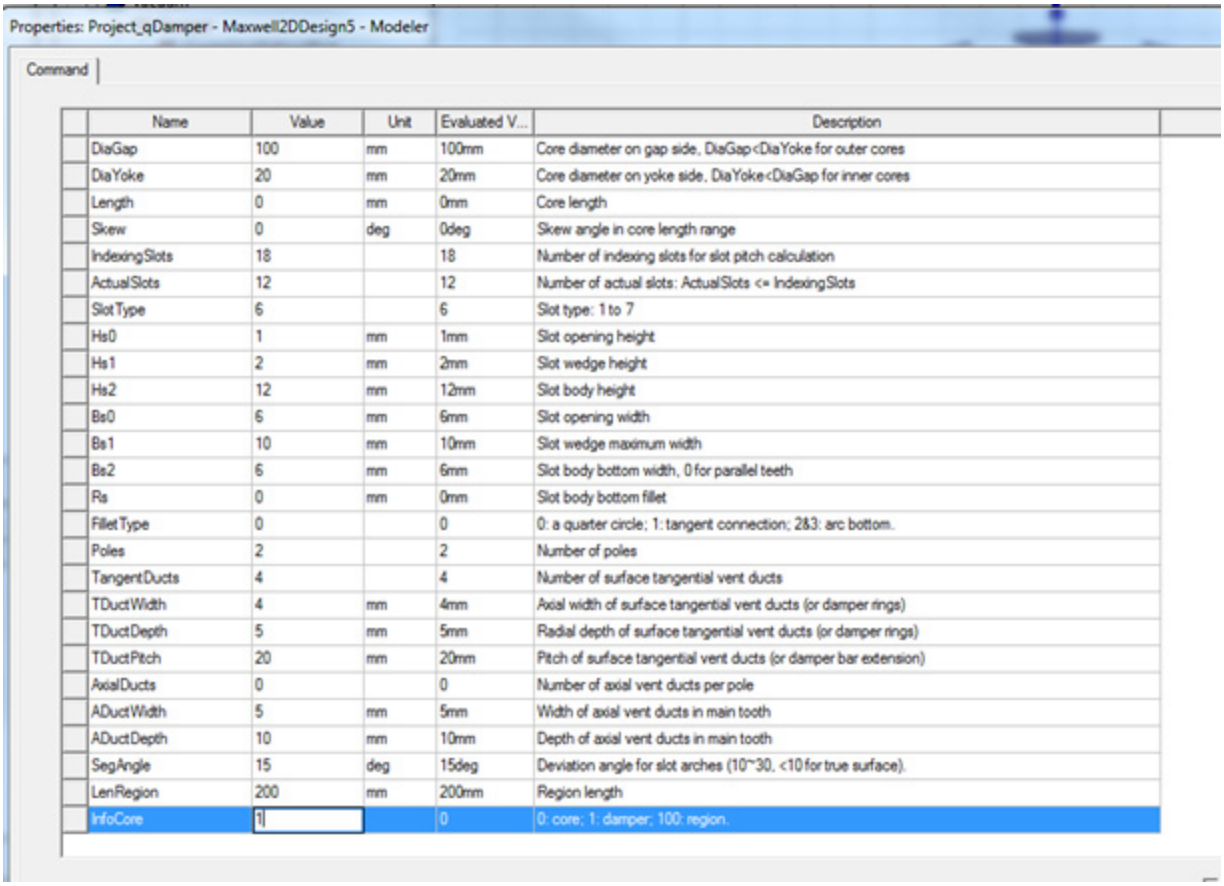
4. Change the **InfoCore** value to **1** to make a damper. Also change the **Color** of the damper to distinguish it from the NonSalientPoleCore.



Name	Value	Unit	Evaluated V...	Description
DiaGap	100	mm	100mm	Core diameter on gap side, DiaGap<DiaYoke for outer cores
DiaYoke	20	mm	20mm	Core diameter on yoke side, DiaYoke<DiaGap for inner cores
Length	0	mm	0mm	Core length
Skew	0	deg	0deg	Skew angle in core length range
IndexingSlots	18		18	Number of indexing slots for slot pitch calculation
ActualSlots	12		12	Number of actual slots: ActualSlots <= IndexingSlots
SlotType	6		6	Slot type: 1 to 7
Hs0	1	mm	1mm	Slot opening height
Hs1	2	mm	2mm	Slot wedge height
Hs2	12	mm	12mm	Slot body height
Bs0	6	mm	6mm	Slot opening width
Bs1	10	mm	10mm	Slot wedge maximum width
Bs2	6	mm	6mm	Slot body bottom width, 0 for parallel teeth
Rs	0	mm	0mm	Slot body bottom fillet
FilletType	0		0	0: a quarter circle; 1: tangent connection; 2&3: arc bottom.
Poles	2		2	Number of poles
TangentDucts	4		4	Number of surface tangential vent ducts
TDuctWidth	4	mm	4mm	Axial width of surface tangential vent ducts (or damper rings)
TDuctDepth	5	mm	5mm	Radial depth of surface tangential vent ducts (or damper rings)
TDuctPitch	20	mm	20mm	Pitch of surface tangential vent ducts (or damper bar extension)
AxialDucts	0		0	Number of axial vent ducts per pole
ADuctWidth	5	mm	5mm	Width of axial vent ducts in main tooth
ADuctDepth	10	mm	10mm	Depth of axial vent ducts in main tooth
SegAngle	15	deg	15deg	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	200	mm	200mm	Region length
InfoCore	1		0	0: core; 1: damper; 100: region.

Figure 9-46 Change the InfoCore value to make it a damper

The objects appear as follows in the coordinate system window.

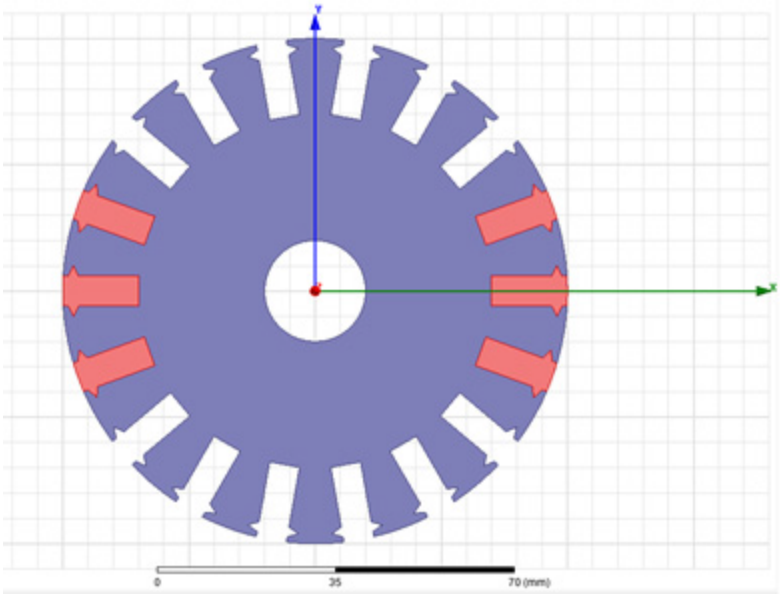


Figure 9-47 Non-Salient Pole Core (gray) with a damper (red)

5. You can also change the damper's **SlotType** and slot parameters if necessary. For instance, **SlotType** is reset to **1** and slot parameters are reassigned as in the following

figure.

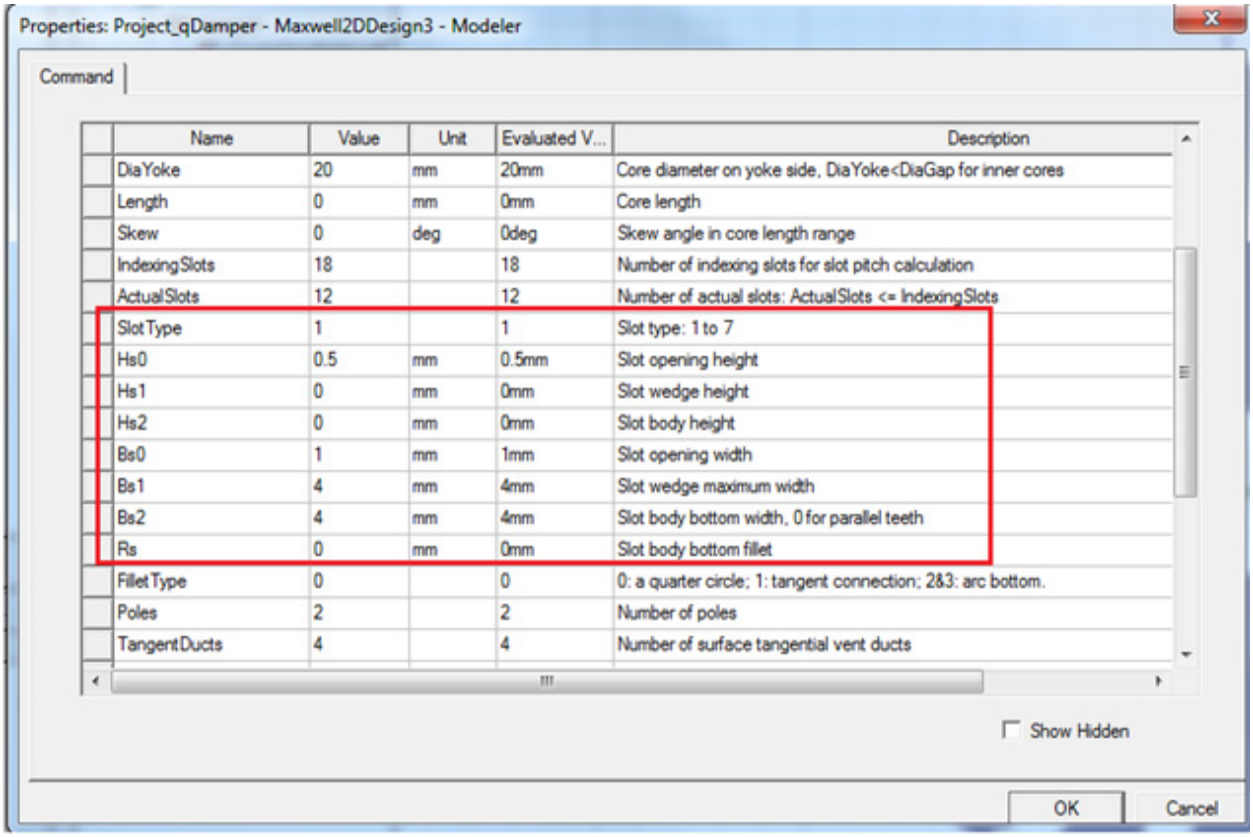

Figure 9-48 Change the slot-related parameters of the damper

After you modify the parameters, the objects in the coordinate system window appear as in the following example:

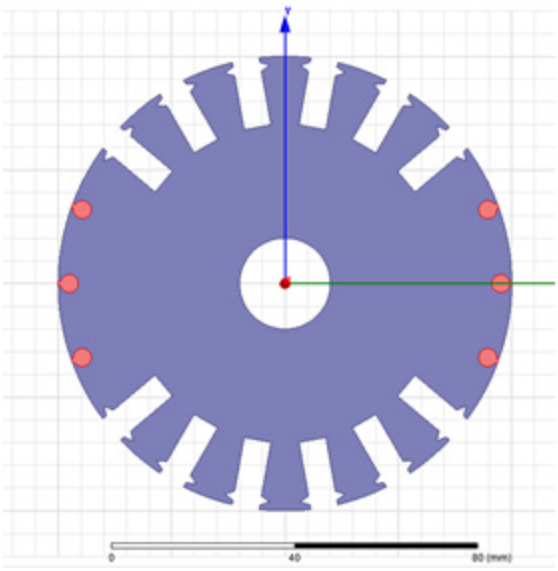

Figure 9-49 Results after changing the slot-related parameters of the damper

6. Select both objects (Damper and NonSalientPoleCore) in the history tree simultaneously by pressing **Ctrl** on the keyboard. Click **Modeler>Boolen>Subtract**. A Subtract window

appears.

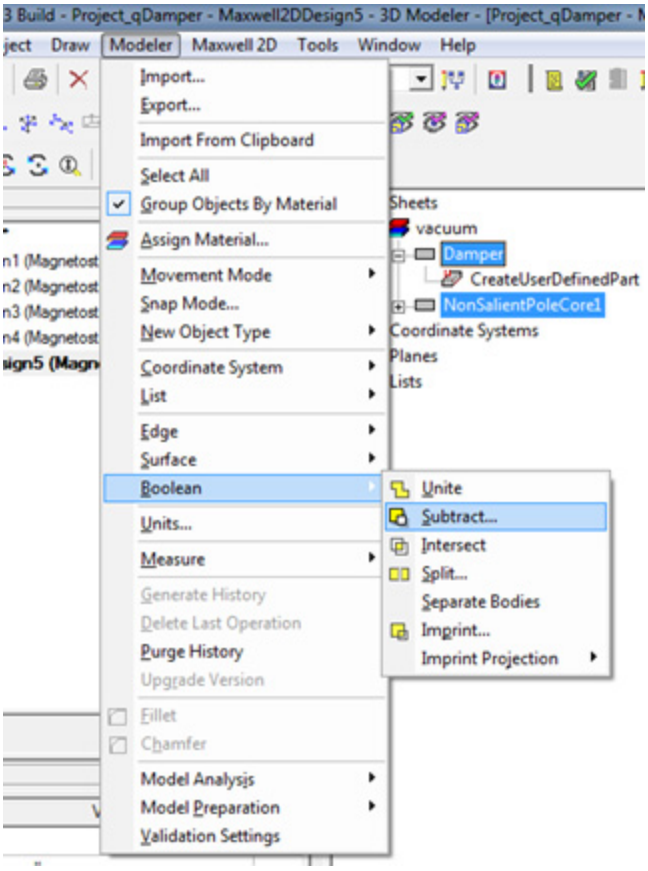

Figure 9-50 Subtraction of two objects

7. Move NonSalientPoleCore to **Blank Parts** and Damper to **Tool Parts**,and check the **Clone tool objects before operation** box. Click **OK** to finish subtraction.

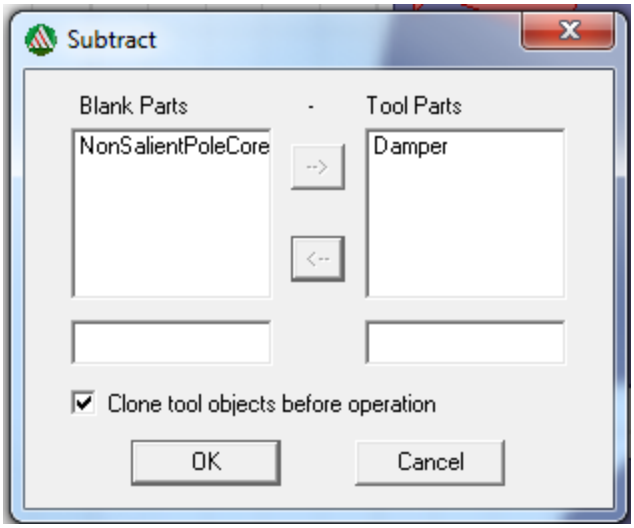

Figure 9-51 Set Blank Parts and Tool Parts

8. The final history tree and coordinate system window are shown in the following example:

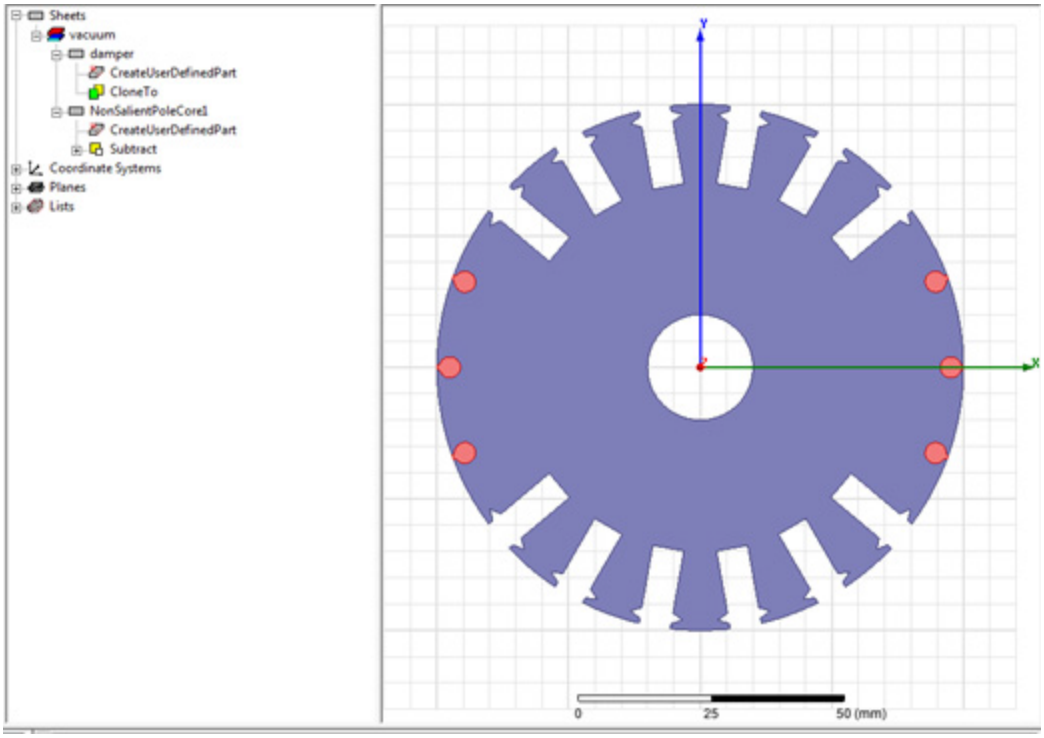

Figure 9-52 Objects after subtraction

Creating a Non-Salient Pole Core with a Uniform-Distributed Damper

This process relies on subtraction of two objects and is very similar to Creating a Non-Salient Pole Core with a Q-Axis Damper. The major difference is that you create a squirrel cage instead of copying a NonSalientPoleCore to create a damper.

1. Click **Project>Insert Maxwell 2D Design** to create a Maxwell2D Design in a project.
2. Click **Draw>User Defined Primitive>RMxprt>NonSalientPoleCore** to draw a Non-Salient Pole Core UDP. To show it in a 2D dimension, set the **Length** to 0. Also set **AxialDucts** to 0 for subtraction, as shown in Figure 9-53 .
3. Click **Draw>User Defined Primitive>RMxprt>SquirrelCage** to draw a squirrel cage UDP. Set the **Length** to 0, change its **Color** to a different one, and rename it to “Damper.” Then objects in the coordinate system window appear as in the following figure:

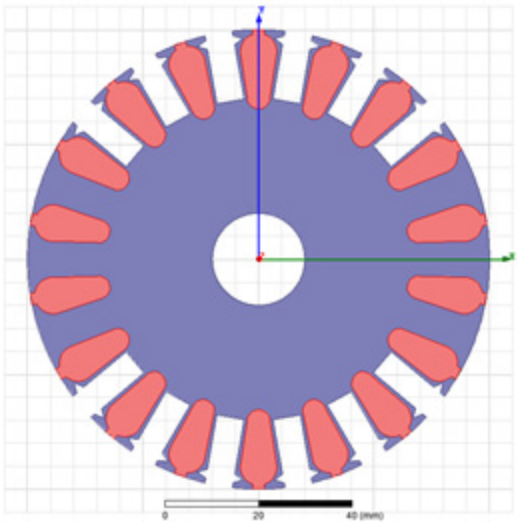

Figure 9-53 Non-Salient Pole Core with a damper (red)

4. You can also change the damper’s **SlotType** and slot parameters if necessary. For instance, **SlotType** is reset to **1** and slot parameters are reassigned as in the following

figure.

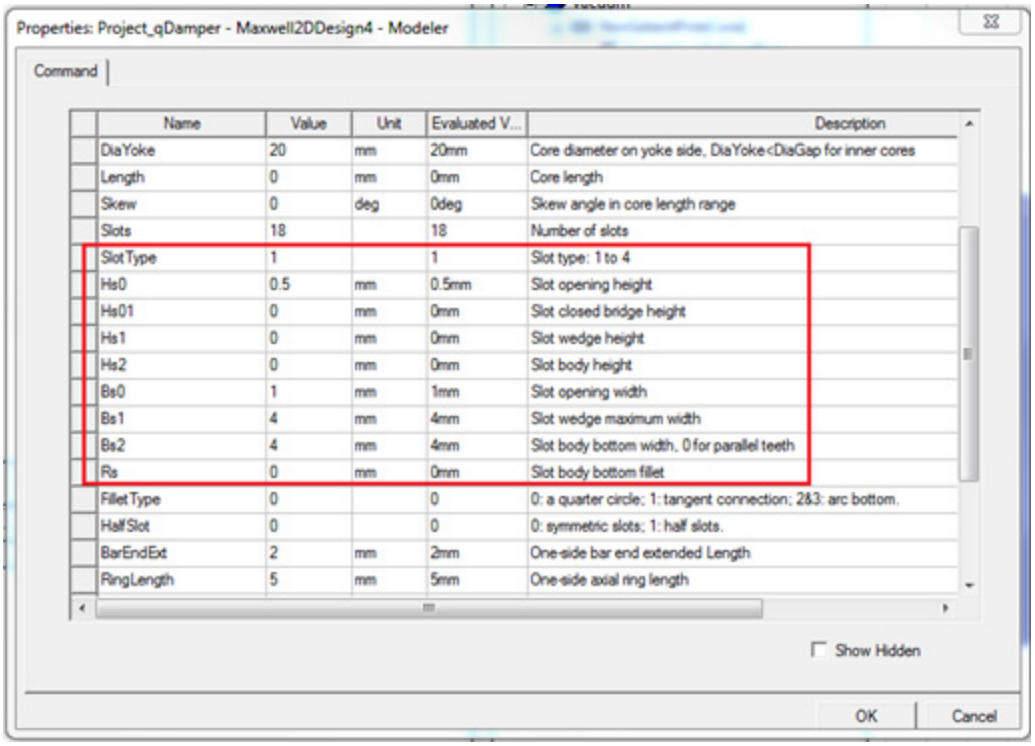

Figure 9-54 Change the slot-related parameters of the damper

5. After you modify the parameters, the objects in the coordinate system window appear as in the following figure:

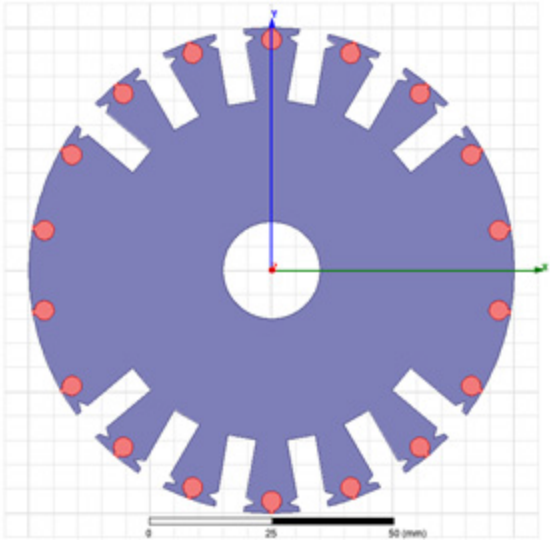

Figure 9-55 Results after changing the slot-related parameters of the damper

6. Select both objects (Damper and NonSalientPoleCore) in the history tree simultaneously by pressing **Ctrl** on the keyboard. Click **Modeler>Boolean>Subtract**. A Subtract window appears.
7. Move NonSalientPoleCore to **Blank Parts** and Damper to **Tool Parts**, and check the **Clone tool objects before operation** box. Click **OK** to finish subtraction.
8. The final history tree and coordinate system window are shown in the following figure:

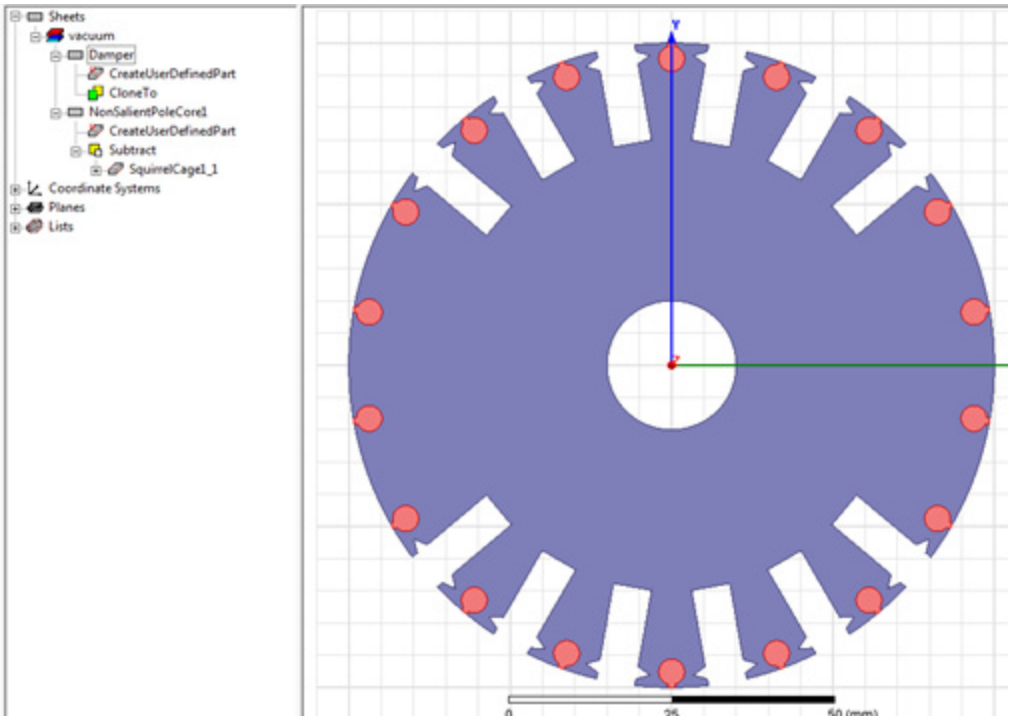

Figure 9-56 Non-Salient Pole Core with a uniform-distributed damper

LapCoil UDP

The LapCoil UDP is used to create a coil for lap-type distributed AC windings or lap-type DC commutating windings in a slotted core created by the SlotCore or VentSlotCore UDP. This UDP can also create a coil cross-section used as a terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.

Property	Description
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom; 4&5: V bottom.
Layers	Number of winding layers.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side end extended length.
SpanExt	Axial length of end span; 0 for no span.
BendAngle	Bending angle viewed in the rz plane.
SegAngle	Deviation angle for slot arches (5~15, <5 for true surface).
LenRegion	Region length.
InfoCoil	0: winding; 1: coil; 2 terminal1; 3: terminal2; 4:insulation; 100: region.

A single coil is much easier to be described with a slot core as reference. In the following two figures, coils are in gray and slot cores are orange. The lap coil's **InfoCoil** property is set to **1** to use a single coil to show parameters of lap coil.

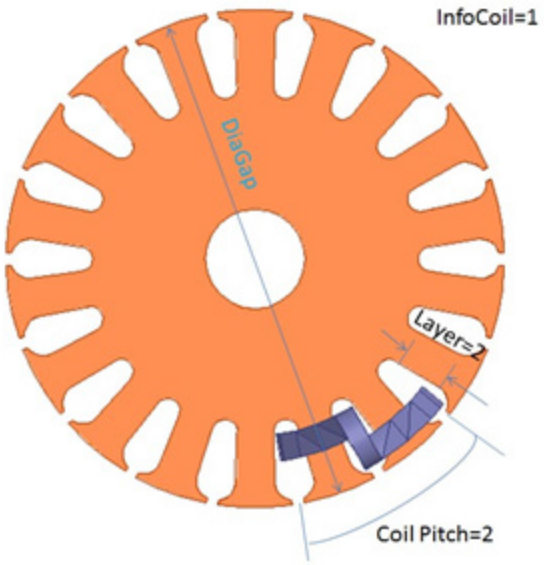

Figure 9-57 Single Lap Coil with Coil Pitch set to 2

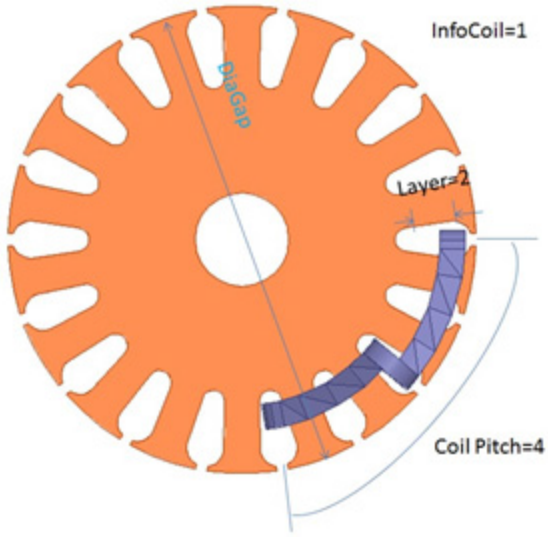

Figure 9-58 Single Lap Coil with Coil Pitch set to 4

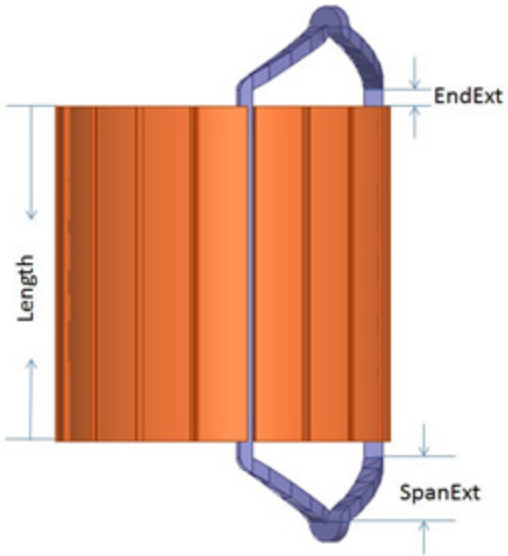

Figure 9-59 Axial Single Lap Coil with Coil Pitch set to 4

Figure 9-60

Figure 9-61 Below is an axial view of an outer core winding with bended end coil. The lap coil's InfoCoil property is set to 0.

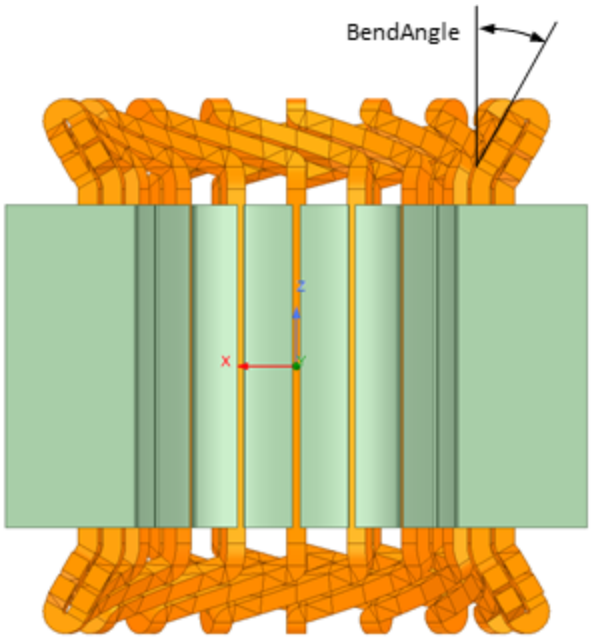

Figure 9-62

Creating a Whole Lap Winding

A whole lap winding is created by default or by manually setting the property of **InfoCoil** to 0. You can assign the value of this property either when creating the lap coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example of a whole lap winding with an orange slot core is shown in the following figure:

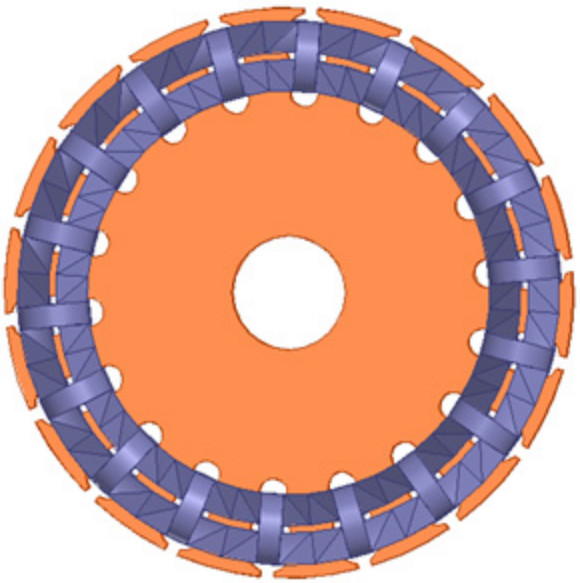

Figure 9-63 Whole Lap Winding

Creating a Single Lap Coil and its Terminals

1. Create a single lap coil by manually setting the property of **InfoCoil** to 1. Figure 9-57 ,Figure 9-58 , and Figure 9-59 show the single lap coil from different angles.
2. For the terminals of the lap coil, set the property of **InfoCoil** to 2 or 3 (terminal1 or terminal2). Figure 9-64 shows terminal1 in the coordinate system.

You can assign the value of this property either when creating the lap coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

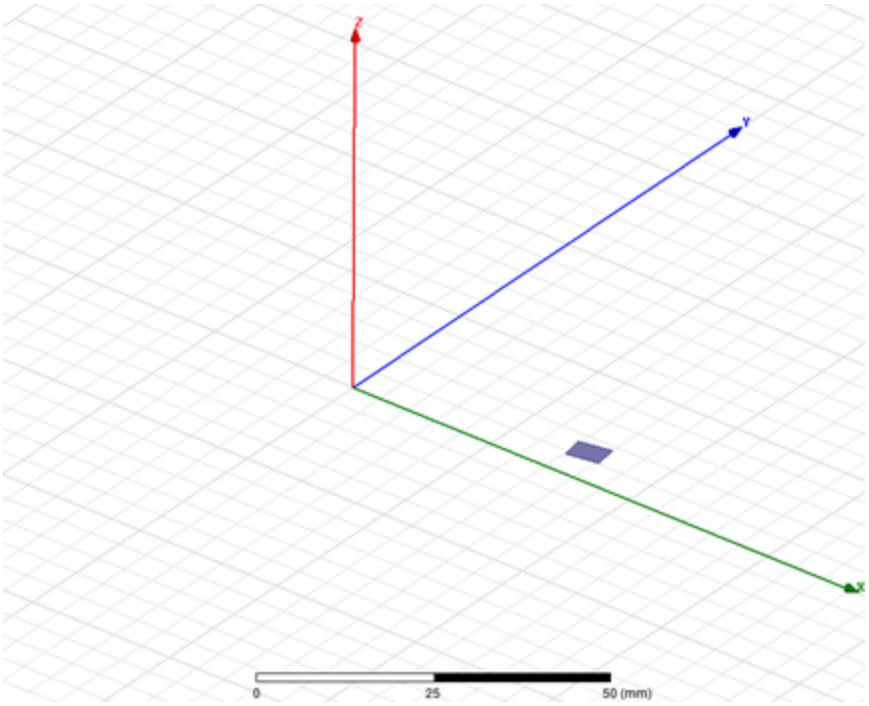

Figure 9-64 Terminal 1 of LapCoil

Creating a 3D Open Insulation

A 3D open insulation is created by manually setting the property of **InfoCoil** to 4. In the history tree, the object changes from a solid to a sheet.

You can assign the value of this property either when creating the lap coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

A 3D open insulation is shown in Figure 9-65 . Note that it is a sheet instead of a solid: it is empty if you observe it carefully.

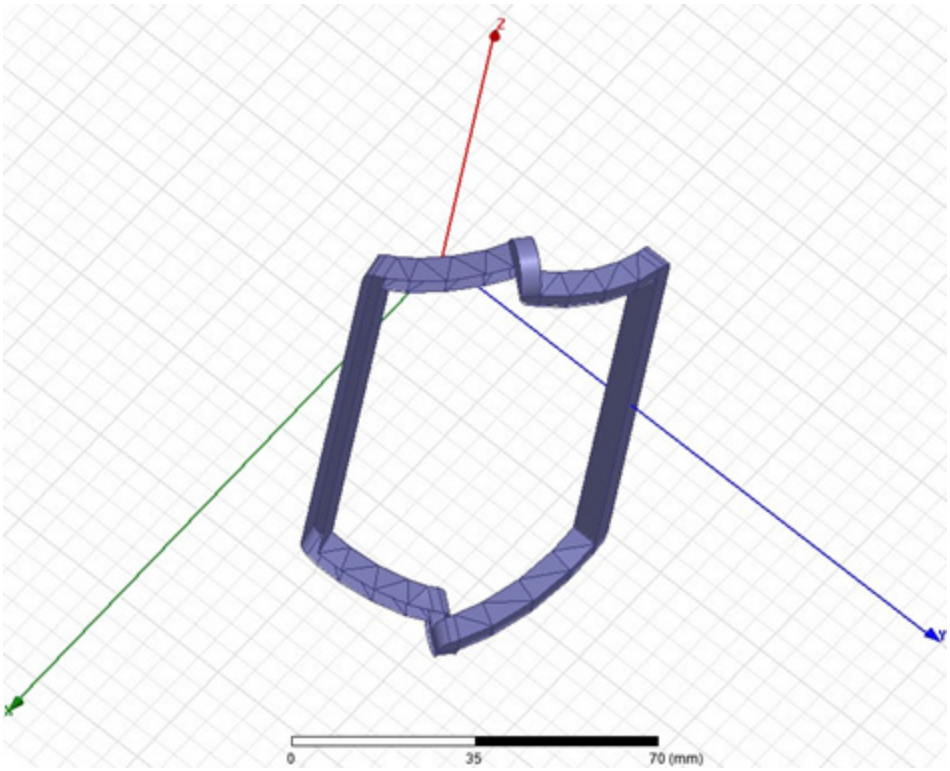

Figure 9-65 3D open insulation of LapCoil

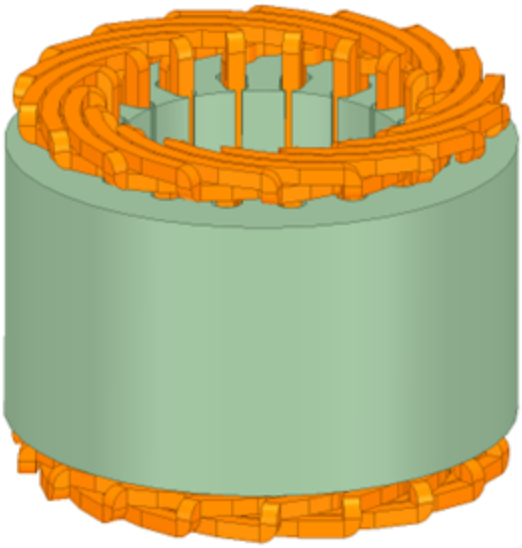
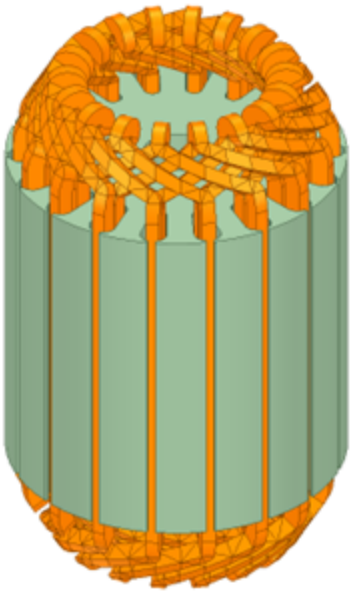
Creating a Bended Coil

The following figures show an outer core lap winding with a 90° bended end coil (**BendAngle** = 90°), and an inner-core lap winding with a 30° bended end coil (**BendAngle** = 30°).



Outer-core lap winding with 90° bended end coil.

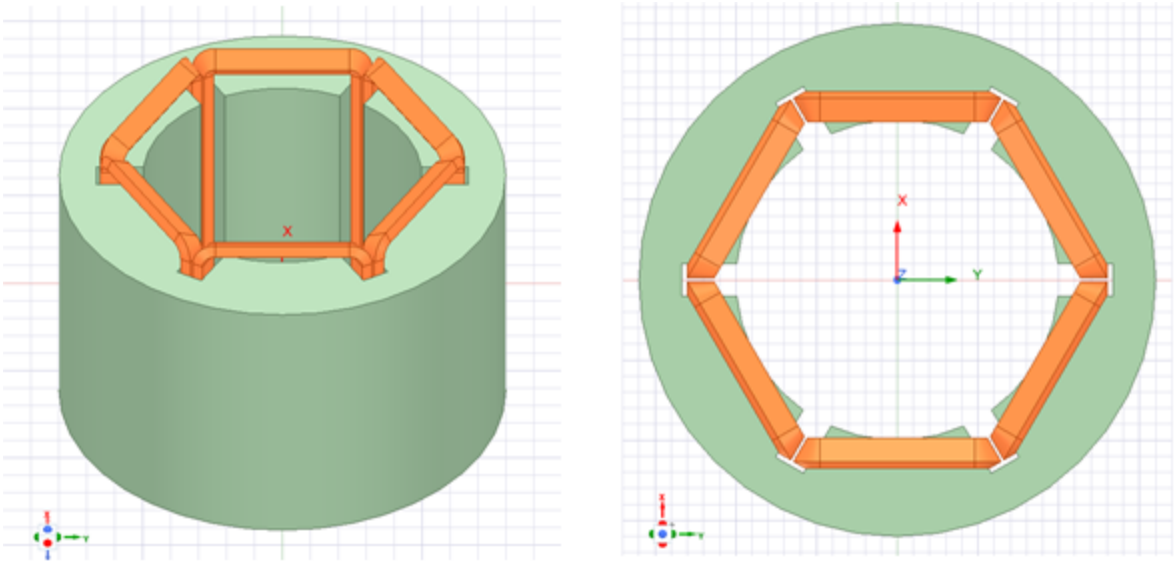


Inner-core lap winding with 30° bended end coil.

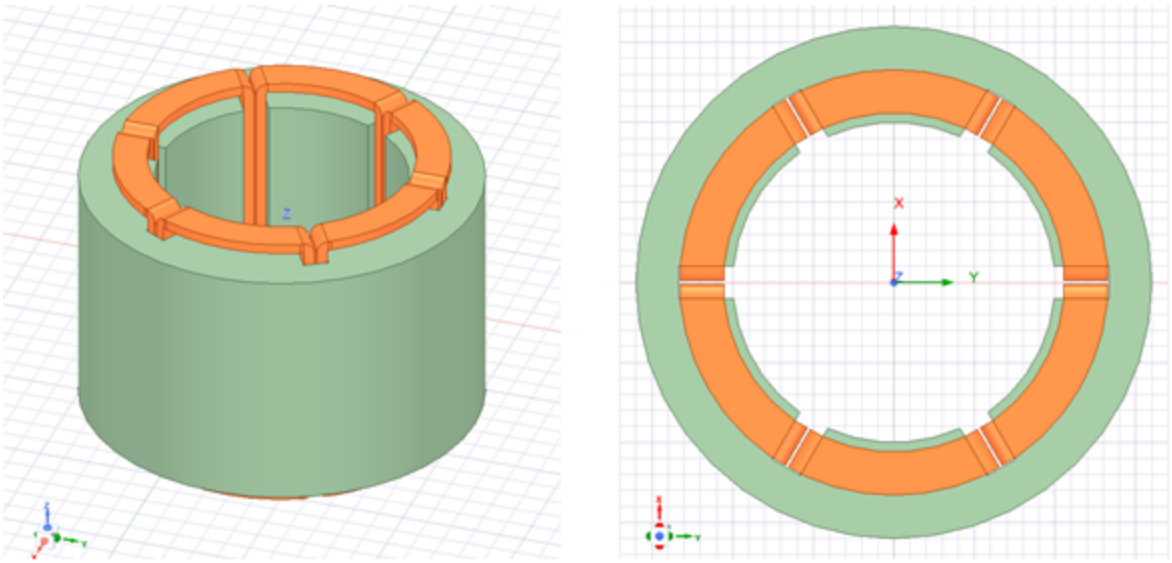
Creating a Tooth Coil

A Tooth Coil – a coil directly wound on a tooth – is a special lap coil with abs(**CoilPitch**) = 1. Examples of a tooth-coil winding with sloped straight end coil (**CoilPitch** = 1), and with flat arced end coil (**CoilPitch** = -1), are shown below. For an outer core with few slots, the straight end coil

might cover the inner bore when CoilPitch = 1. In such a case, the conductor height inside slots should be reduced to ensure that the end coil will not overlap with the inner core which might be longer than the outer core. However, if you create a tooth coil with a flat arced end coil, you do not need to reduce the conductor height inside slots.



Tooth-coil winding with sloped straight end coil (**CoilPitch** = 1).



Tooth-coil winding with flat arced end coil (**CoilPitch** = -1).

ConCoil UDP

The ConCoil UDP is used to create a coil for concentric distributed AC windings or concentric DC field windings in a slotted core created by the SlotCore, VentSlotCore, RacetrackSlotCore, or NonSalientPoleCore UDP. This UDP can also create a coil cross-section used as a terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection.
LayerLoc	0: whole; 1: middle; 2: top; 3: bottom.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side end extended length.
LayerExt	Span layer extension in the axial direction.
LayerDiff	Span layer difference in the radial direction.
AltEnd	0: same end layers; 1: alternate end layers.
LenRegion	Region length.
InfoCoil	0: coil; 1 terminal1; 2: terminal2; 100: region.

The following four 2D figures show the parameter **LayerLoc** with different values. Slot cores are used as references to help better understand concoils.

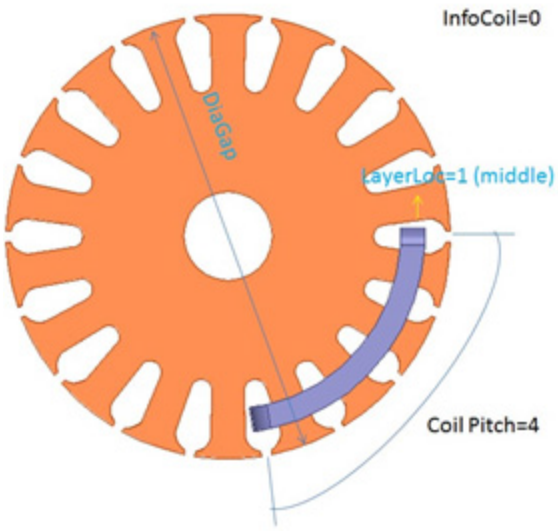


Figure 9-66 LayerLoc set to 1

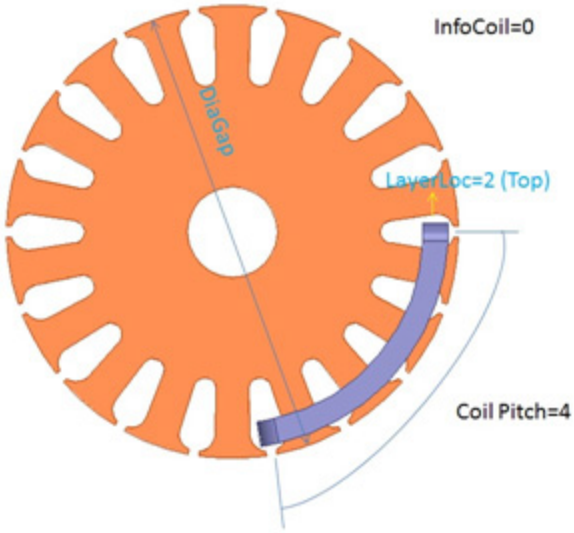

Figure 9-67 LayerLoc set to 2

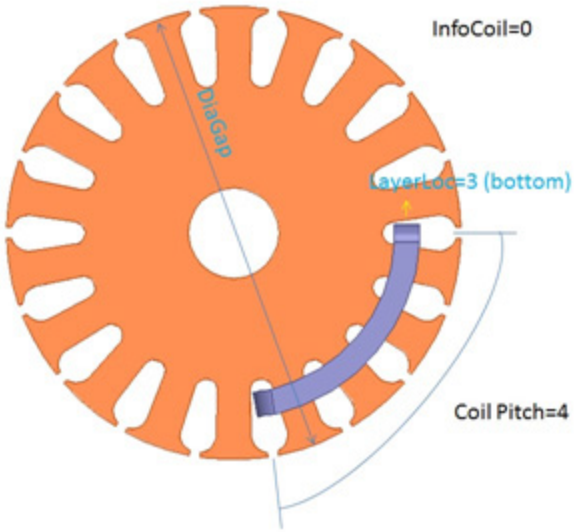

Figure 9-68 LayerLoc set to 3

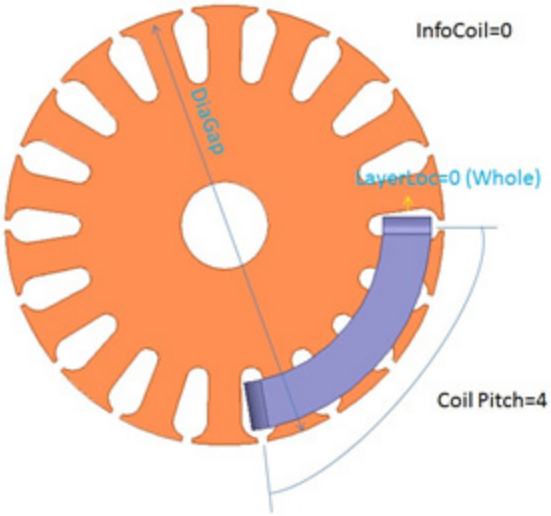

Figure 9-69 LayerLoc set to 0

The following four 3D figures illustrate parameters of ConCoil such as **LayerExt**, **LayerDiff** and **AltEnd**.

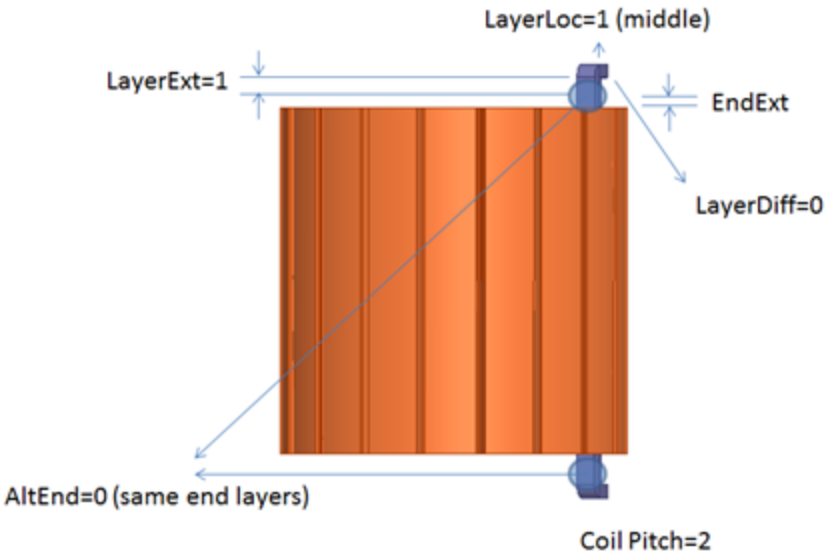

Figure 9-70 Reference 3D ConCoil

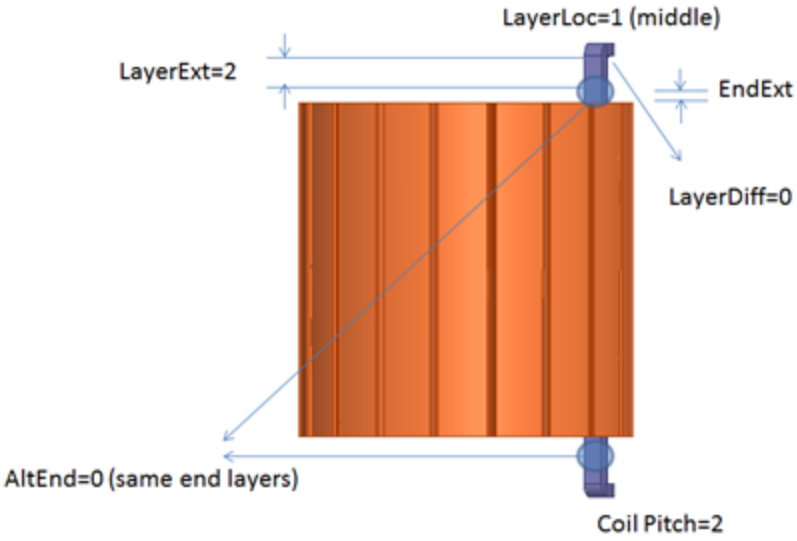

Figure 9-71 3D ConCoil with a different LayerExt than shown in Figure 9-70 .

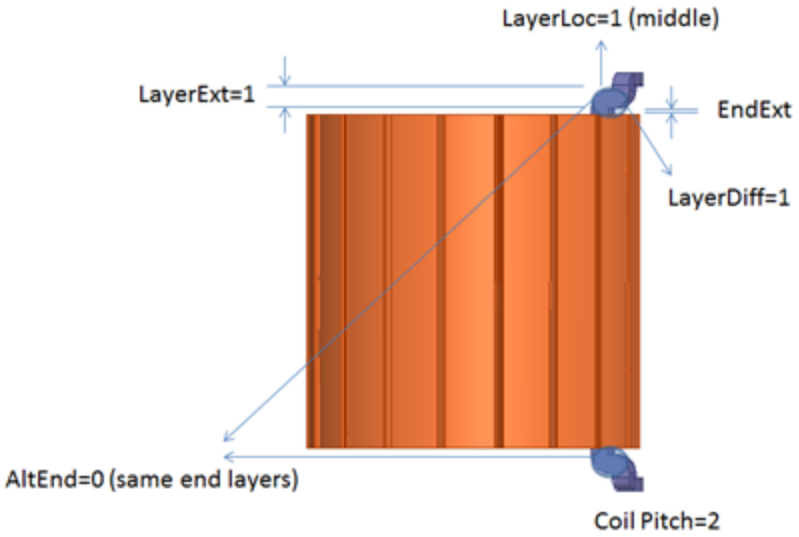

Figure 9-72 3D ConCoil with a different LayerDiff than shown in Figure 9-70 .

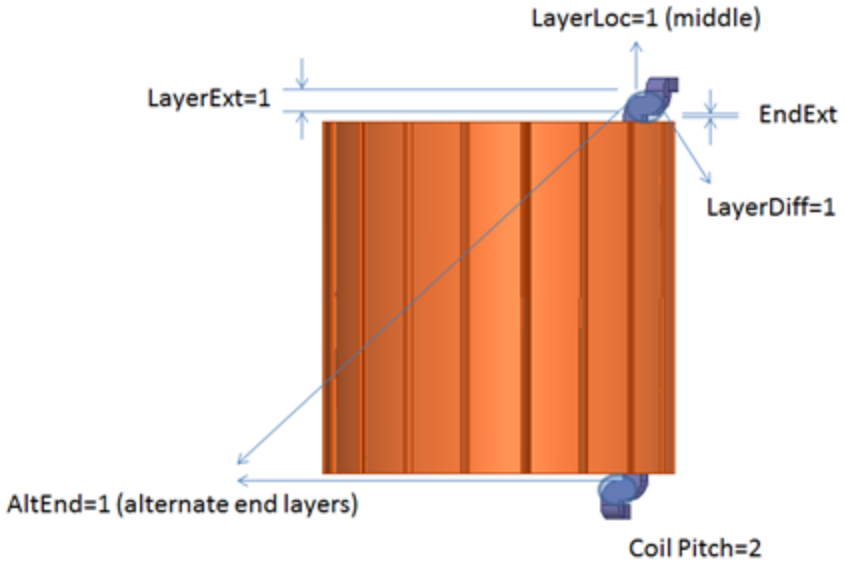

Figure 9-73 3D ConCoil with a different AltEnd than shown in Figure 9-72 .

Note	For parameters such as **Skew**, **FilletType** and parameters related to slots, refer to SlotCore UDP parameters.

Creating a Single Concentric Coil and its Terminals

You create a single concentric coil by manually setting the property of **InfoCoil** to 0.Figure 9-66 through Figure 9-70 show the single concentric coil.

For the terminals of a concentric coil, set the property of **InfoCoil** to 1 or 2 (terminal1 or terminal2). Figure 9-72 shows terminal 1 of a concentric coil.

You can assign the value of this property either when creating a concentric coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

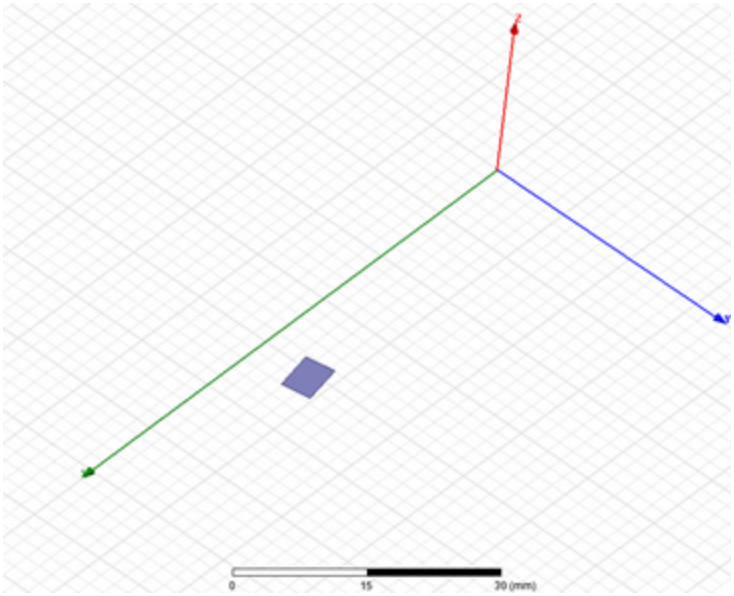

Figure 9-74 Terminal 1 of ConCoil

WaveCoil UDP

The WaveCoil UDP is used to create a wave-type coil in a slotted core created by the SlotCore or VentSlotCore UDP.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.

Property	Description
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection.
Layers	Number of winding layers.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side end extended length.
SpanExt	Axial length of end span; 0 for no span.
SegAngle	Deviation angle for slot arches (5~15, <5 for true surface).
PolePitch	Pole pair pitch measured in slots.
LenRegion	Region length.
InfoCoil	0: winding; 1: one coil; 100: region.

The following three figures illustrate these parameters of wave coil.

Note	• A slot core (orange) is used as reference to better present the parameters and position of the wave coil. • Most parameters in a wave coil are similar or exactly the same as those in a lap coil except **PolePitch**. Figure 9-75 shows the definition of the parameter **PolePitch**. Figure 9-76 presents a winding wave coil that can be compared with a single wave coil in Figure 9-75 . Further, Figure 9-77 gives an overview of parameters in axial direction. • For parameters such as **Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

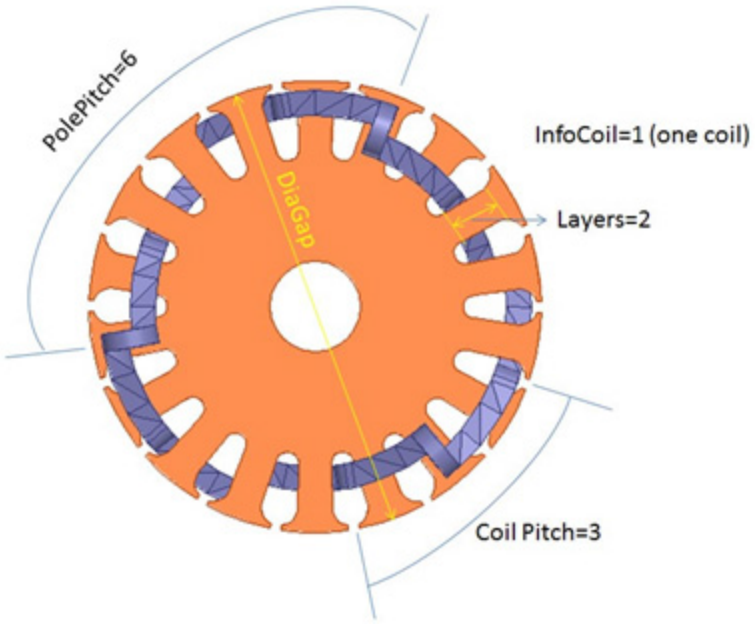

Figure 9-75 One Wave Coil

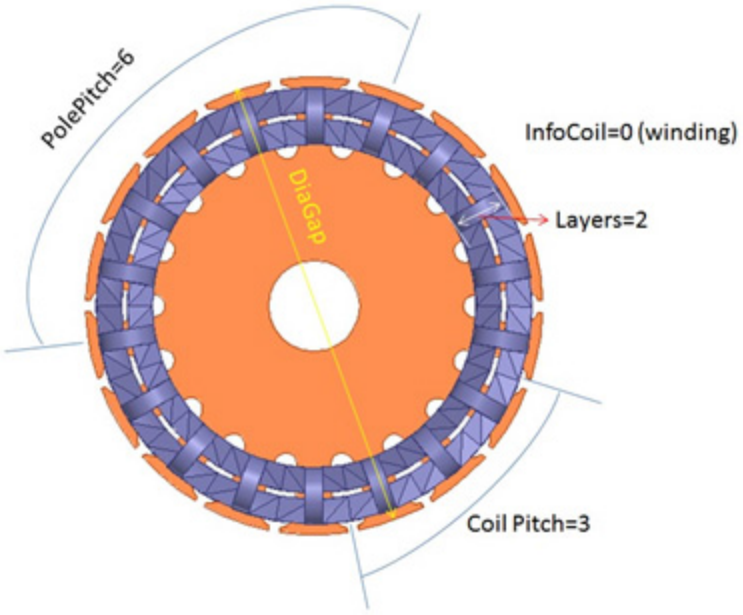

Figure 9-76 A Whole Winding Wave Coil

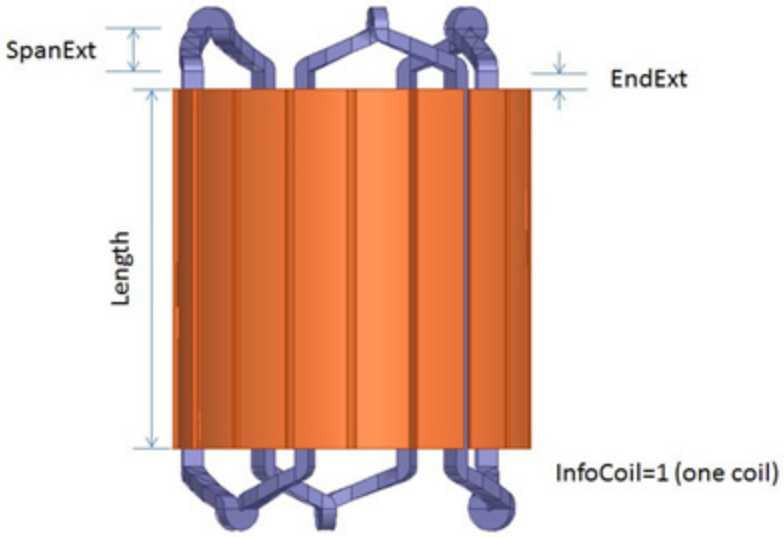

Figure 9-77 Parameters of Wave Coil in axial direction

Creating a Whole Wave Winding

You can create a whole wave winding by manually setting the property of **InfoCoil** to 0.

You can assign the value of this property either when creating a wave coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example is shown in Figure 9-76 .

Creating a Single Wave Coil

In Maxwell, wave coil is set to a single wave coil by default when being created (**InfoCoil** is equal to 1).

You can assign the value of this property either when creating a wave coil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples are shown in Figure 9-75 and Figure 9-77 .

SquirrelCage UDP

The SquirrelCage UDP is used to create a squirrel-cage winding in a core created by the SlotCore or VentSlotCore UDP for single-phase or multi-phase induction machines..

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.

Property	Description
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection.
HalfSlot	0: symmetric slots; 1: half slots.
BarEndExt	One-side bar end extended Length.
RingLength	One-side axial ring length.
RingHeight	Radial ring height.
RingDiaGap	Ring diameter on gap side.
CastRotor	0: insert-bar; 1: cast-rotor.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCoil	0: bars & rings; 1: bars; 2: rings; 100: region.

These parameters are used in the following figures:

Note	
	1. **RingDiaGap** is set to 95 mm whereas **DiaGap** is 100 mm to distinguish these two parameters in the following figures. 2. In the following 3D figure, a slot core is drawn to show the **BarEndExt** and **Length** of Squirrel Cage. 3. For parameters such as **Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

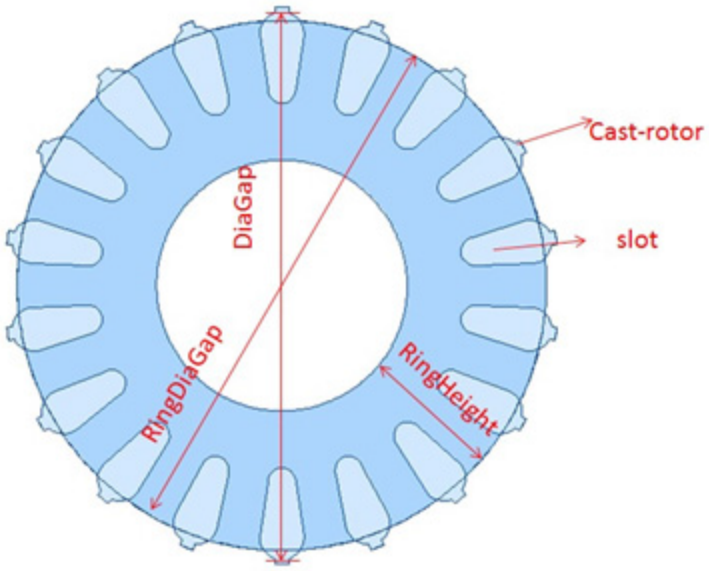

Figure 9-78 Parameters of squirrel cage on cross-section

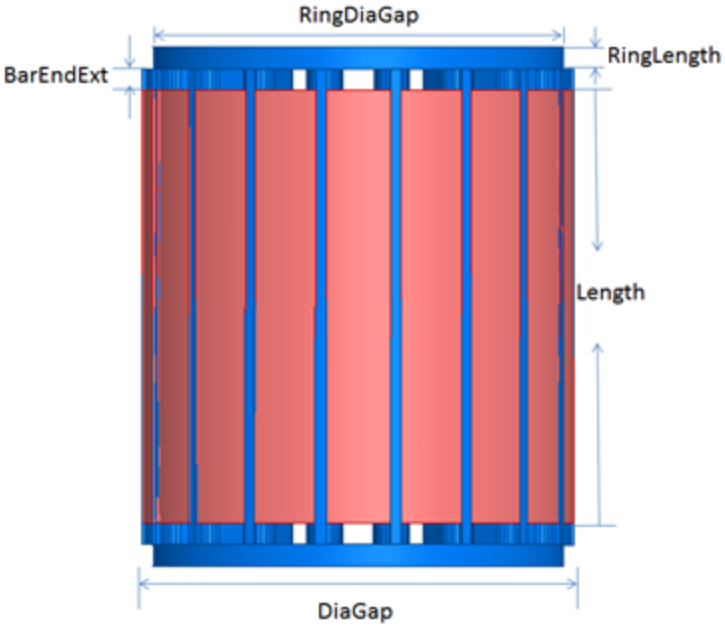

Figure 9-79 Parameters of squirrel cage on axial direction

Creating a Whole Squirrel-Cage Winding

A whole squirrel cage winding is set by default when being created (**InfoCoil** is equal to 0). An example is shown in Figure 9-79 as a blue object.

You can assign the value of this property either when creating a squirrel cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating Bars Only (Squirrel Cage)

You can create bars of a squirrel cage by manually setting the property of **InfoCoil** to 1. Figure 9-80 shows bars of a squirrel cage.

You can assign the value of this property either when creating a squirrel cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

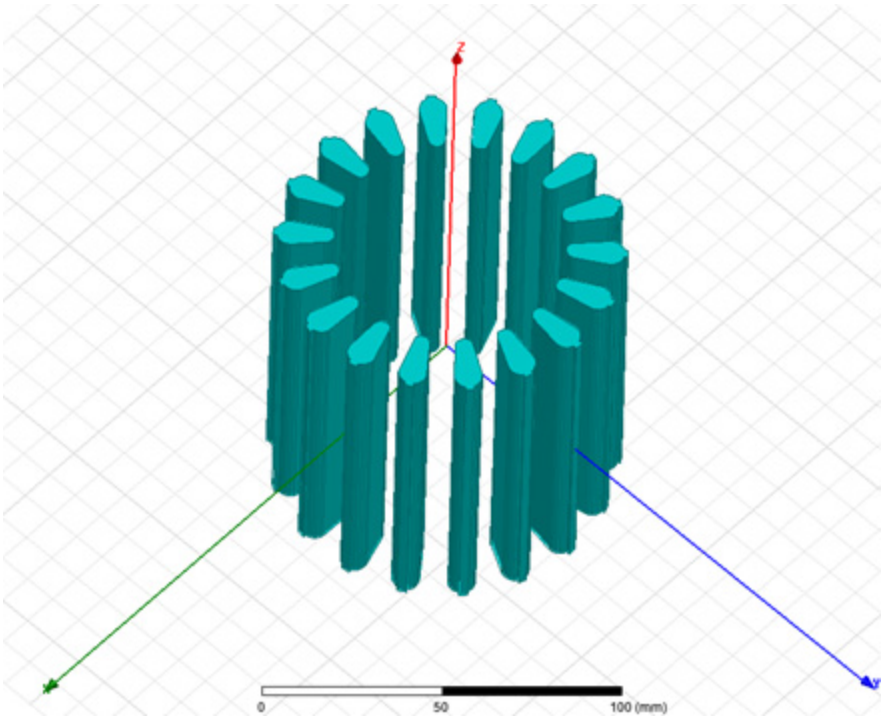

Figure 9-80 Bars of squirrel cage

Creating Two Rings Only

You can create two rings of a squirrel cage by manually setting the property of **InfoCoil** to 2. Figure 9-81 shows rings of a squirrel cage.

You can assign the value of this property either when creating a squirrel cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

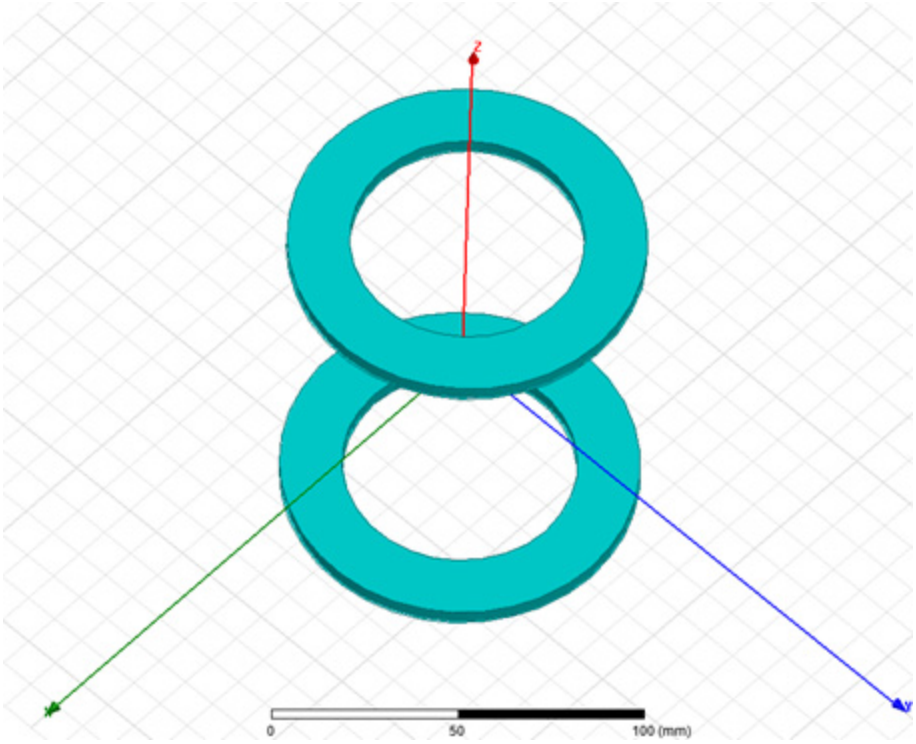

Figure 9-81 Rings of squirrel cage

DoubleCage UDP

The DoubleCage UDP is used to create a double squirrel-cage winding in a slotted core created by the SlotCore UDP or VentSlotCore UDP for induction machines with a double squirrel-cage rotor. The created double squirrel-cage winding can also be used as a subtract tool to derive a core with top and bottom slots.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.

Property	Description
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection.
HalfSlot	0: symmetric slots; 1: half slots.
BarEndExt	One-side bar end extended Length.
RingLength	One-side axial ring length.
RingHeight	Radial ring height.
RingDiaGap	Ring diameter on gap side.
DoubleCage	0: normal squirrel cage; 1: double squirrel cage.
BSlotType	Bottom slot type: 1 to 4.
BHs0	Slot opening height.
BHs1	Slot wedge height.
BHs2	Slot body height.
BBs0	Slot opening width.
BBs1	Slot wedge maximum width.
BBs2	Slot body bottom width, 0 for parallel teeth.
BRs	Slot body bottom fillet.
CastRotor	0: insert-bar; 1: cast-rotor.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCoil	0: bars & rings; 1: bars; 2: rings; 100: region.

The main difference between double cage and squirrel cage is that a double cage has double slots instead of single slots. The following 2D figure shows the bottom slot, which is connected to the normal slot. The parameters for a bottom slot are similar to those of a normal slot. Other parameters are exactly the same as a squirrel cage.

Note	For parameters such as **Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

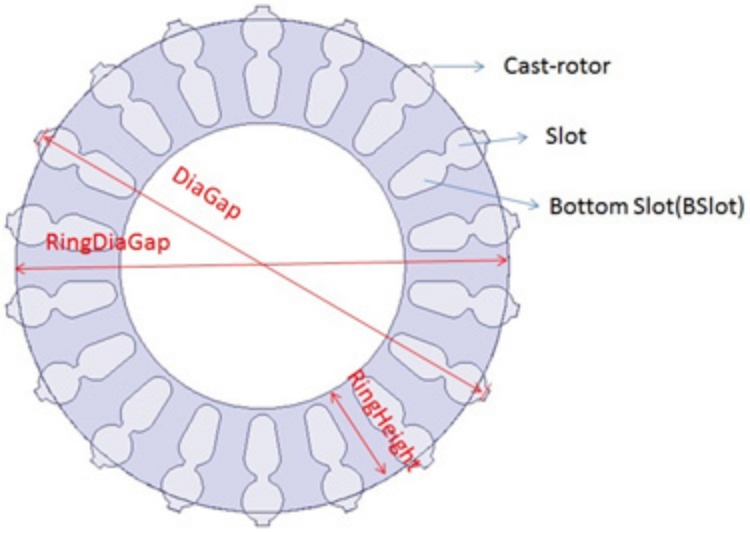

Figure 9-82 Parameters of double cage on cross-section

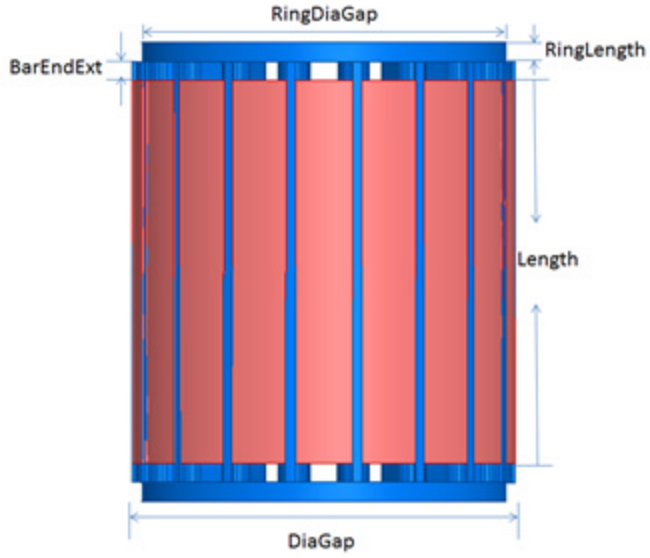

Figure 9-83 Parameters of double cage on axial direction

Creating a Whole Double-Cage Winding

A whole double-cage winding is set by default when being created (**InfoCoil** is equal to 0). An example is shown in Figure 9-83 as a blue object.

You can assign the value of this property either when creating a squirrel cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating Bars Only (Double Cage)

You can create bars of a double cage by manually setting the property of **InfoCoil** to 1. Figure 9-84 shows bars of a double cage.

You can assign the value of this property either when creating a double cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

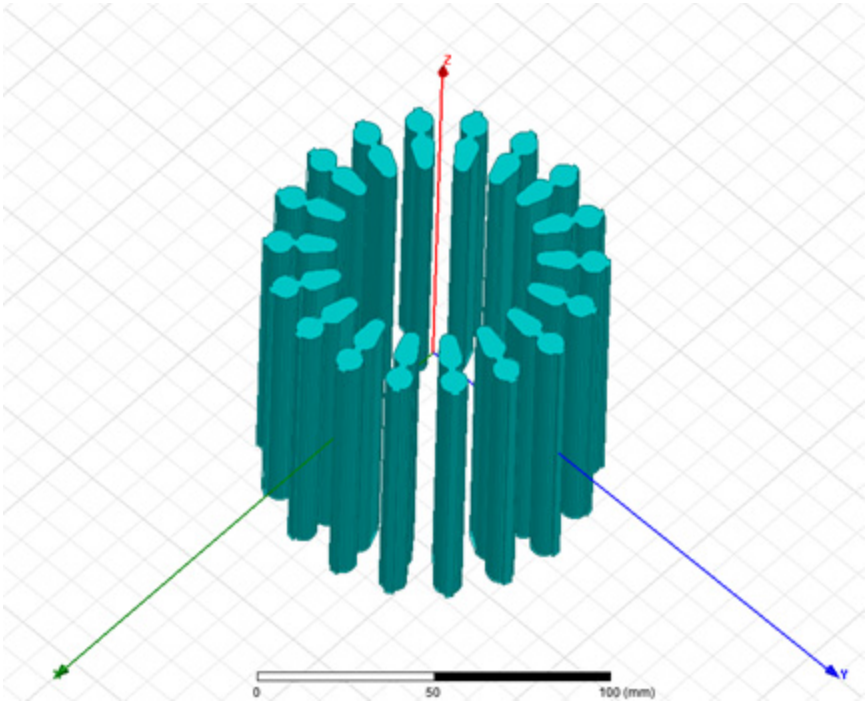

Figure 9-84 Bars of double cage

Creating Two Rings Only (Double Cage)

You can create two rings of a double cage manually by setting the property of **InfoCoil** to 2. The following figure shows rings of a double cage.

You can assign the value of this property either when creating a double cage or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

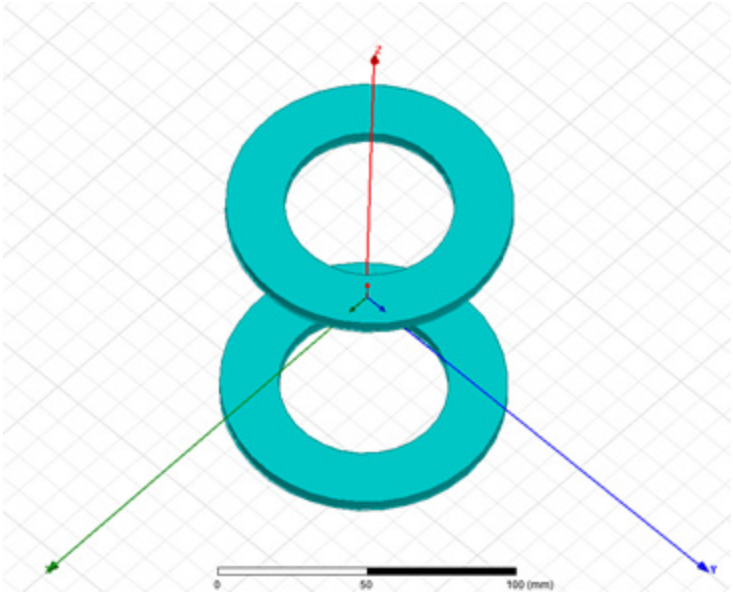

Figure 9-85 Rings of double cage

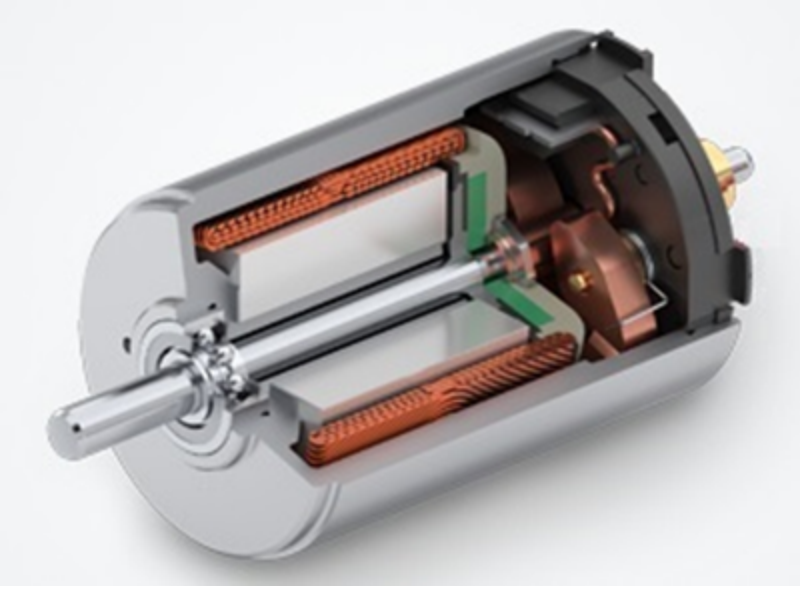
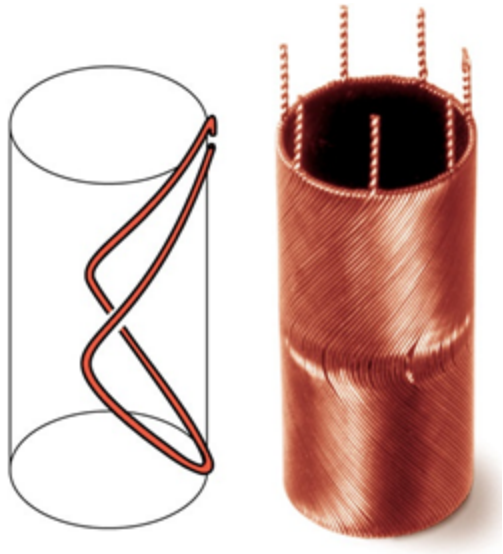
CupCoil UDP

The CupCoil UDP is used to create a coil for distributed slotless AC windings or coreless DC commutating windings in the air-gap between outer and inner cores. This UDP can also create a coil cross-section, which can be used as a terminal for current assignment.

Property	Description
DiaOuter	Coil outer diameter
DiaInner	Coil inner diameter
Length	Length of coil straight part
Coils	Number of total coils in a circle
CoilType	1: lap; 2: wave
CoilPitch	Coil pitch in degrees
LenTotal	Tip-to-tip length of a coil, 0 for 2D
LenRegion	Region length
InfoCoil	0: coils; 1: coil; 2 terminal1; 3: terminal2; 100: region

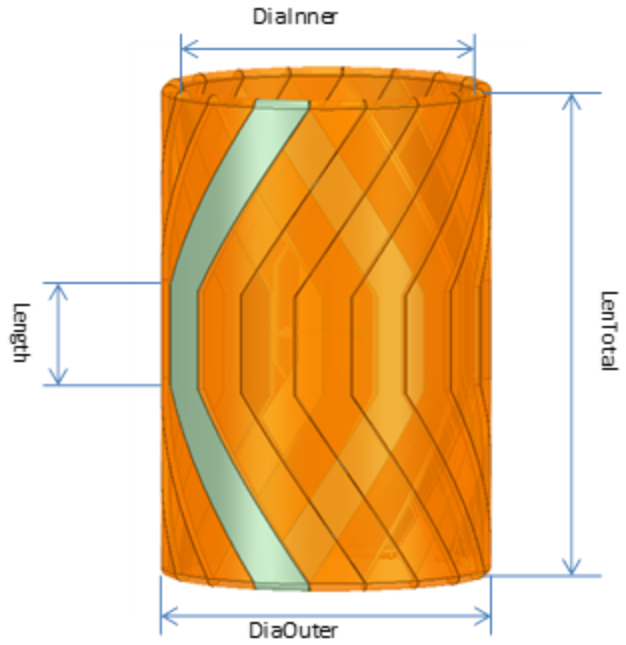


Coreless DC motor



Coreless DC Winding

The following figure shows some of the parameters described in the table above. To avoid too small a mesh size, wire turns are not created one-by-one as solid conductors. Instead, all adjacent wires carrying the same current are grouped as a strand coil with one or more turns.

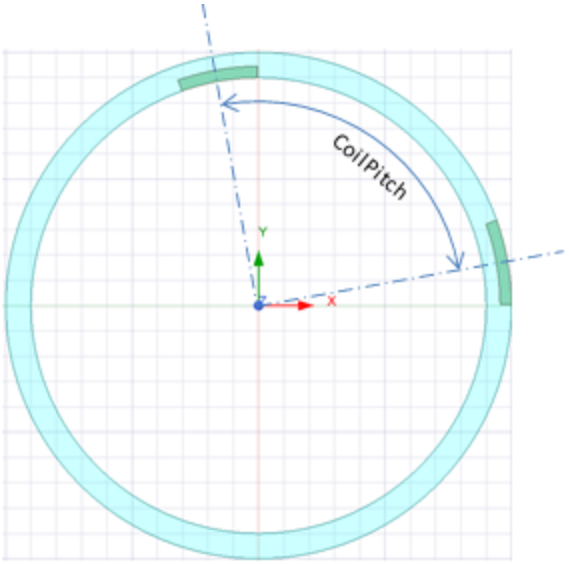


A coreless lap-type DC winding created by CupCoil UDP

Creating a Coil and its Terminals (CupCoil)

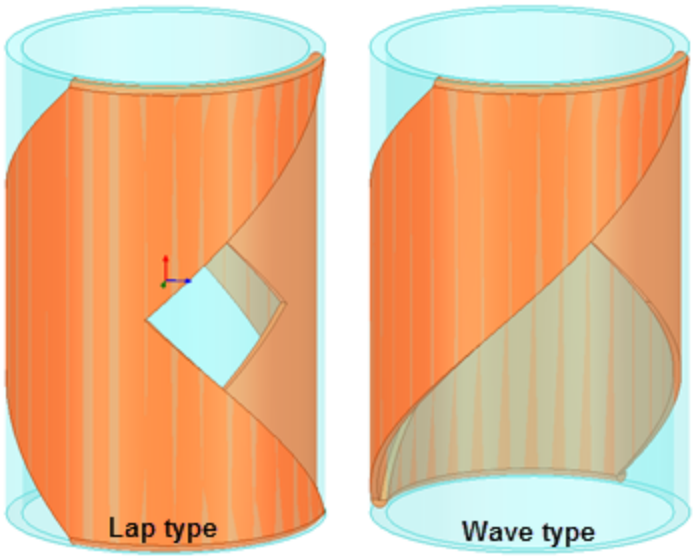
When **InfoCoil** = 0, the created object includes all coils which are united together. To separate them you can use **Modeler>Boolean>Separate Bodies** menu command. When **InfoCoil** = 1, the created object includes only one coil, as shown by the coil in green color in the figure. You can use menu command **Edit>Duplicate>Around Axis** to duplicate it.

When **InfoCoil** = 2, you can create a terminal for coil assignment. You can create a return terminal for a coil in 2D by setting **InfoCoil** = 3. The following figure shows both “go” and “return” terminals, and shows the definition of the **CoilPitch** parameter (90 degrees in this example).



“go” and “return” terminals for a CupCoil with a given CoilPitch

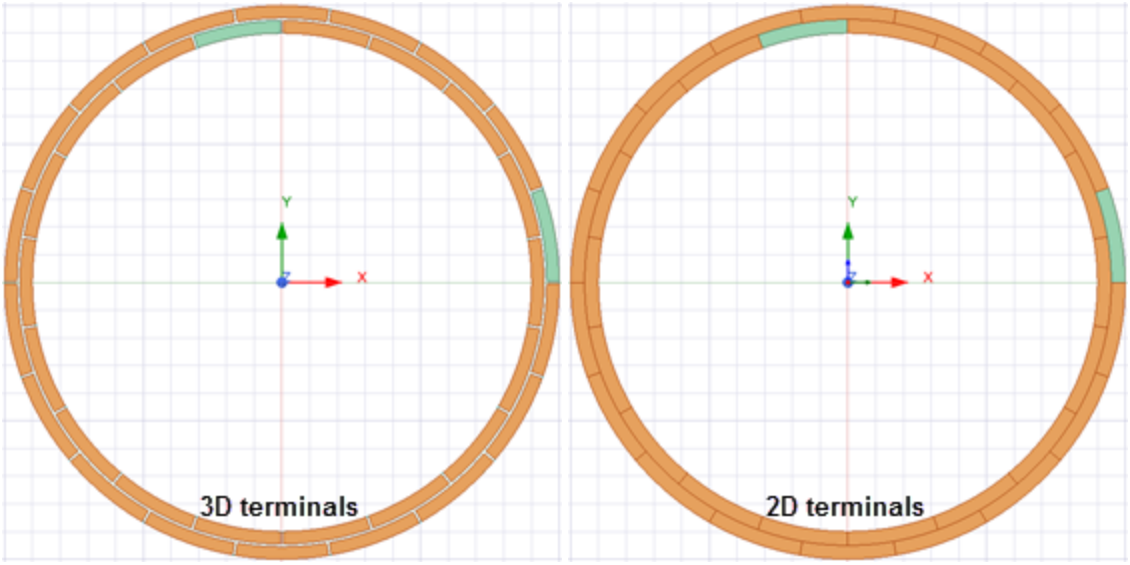
When **CoilType** = 1 , the created coil is a lap-type. When **CoilType** = 2, the created coil is a wave-type. For a wave-type coil, the bottom span will be skewed in the same direction as the top span, and therefore, the bottom tip will shift from the top tip by one pole pitch. The pole pitch will be 180°, 90°, 60°, …, for 2, 4, 6, …, poles, respectively. The input value of **CoilPitch** will be adjusted to the closest value of possible pole pitches. The following figure compares a wave-type coil with a lap-type coil.



Wave-type coil compared with a lap-type coil

You can set **LenTotal** = 0 to create coils or terminals in 2D, or directly use **InfoCoil** = 2 and **InfoCoil** = 3 with **LenTotal** > 0 to draw 3D terminals for 2D coils. The difference between 2D

terminals and 3D terminals is that: there will be a gap between any two adjacent 3D coil terminals, but there will be no gap between 2D terminals to improve mesh quality, as compared in the figure below.



2D terminals compared with 3D terminals

A user needs to input an average CoilPitch when we try to create coil terminals for 2D FEA model. For a wave-type coil, since the bottom span is continuously skewed without changing the skew direction from the top span, the average coil pitch is the same as the real CoilPitch. For a lap-type coil, the average coil pitch can be derived from:

PitchAve = (Length x CoilPitch + (LenCore – Length) x (CoilPitch + PitchMin) / 2) / LenCore

where **LenCore** is the length of the inner and outer cores which carry magnetic field, and

PitchMin = (LenTotal – 2 x RadTip – LenCore) / (LenTotal – 2 x RadTip – Length) x CoilPitch

which must be limited within (0, CoilPitch). In the equation above, **RadTip** is the radius of top and bottom coil tips, which is obtained from:

RadTip = (DiaOuter – DiaInner) / 4

The skew angle for multi-slice 2D FEA model can be obtained from:

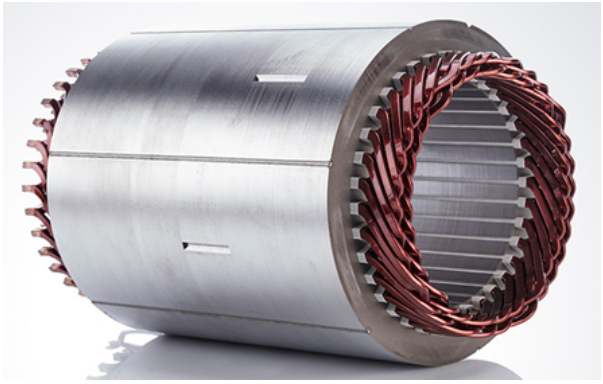
AngSkew = (PitchAve – PitchMin) x 2

which is applicable for both lap-type and wave-type coils.

HairpinCoil UDP

The HairpinCoil UDP is used to create a hairpin-type coil. Hairpin coils are used to make a hairpin winding in a slotted core. All hairpin coils belonging to the same phase are welded in series to perform a hairpin winding.

Hairpin Coil



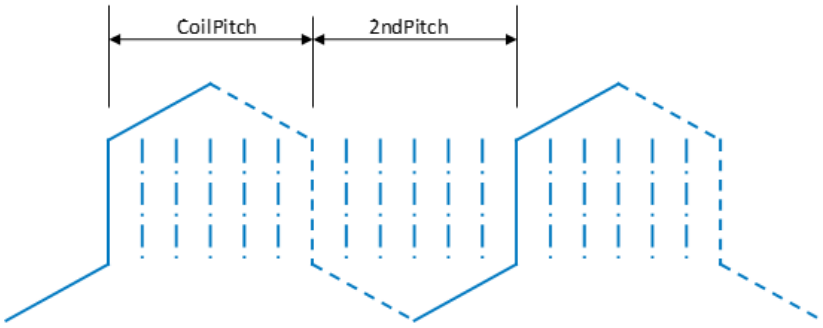
Stator with Hairpin Winding

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length, 0 for 2D.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom; 4&5: V bottom
Layers	Number of total coil layers in a slot, should be an even number.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side end extended length.
SpanExt	Axial length of end span; 0 for no span.
SegAngle	Deviation angle for slot arches (5~15, <5 for true surface).
2ndPitch	The second coil pitch, the pitch between two conductor sides to be welded
2ndSpanExt	Pole pair pitch measured in slots.

Property	Description
WireWidth	Wire width in slot width direction.
WireThick	Wire thickness in slot depth direction.
WireRad	Wire fillet radius, used to calculate equivalent wire size based on wire area.
LayerSetGap	Gap between two layer-sets, one layer-set is two layers of one coil.
LayerSetIdx	Layer-set index for the location of the coil to be drawn.
LayerGap	Gap between two layers in a layer set.
WindingType	1: whole-coiled (2 coil sets per pole pair); 2: half-coiled (1 coil set per pole pair).
CoilSetIdx	0: create 1st coil set; 1: create the 2nd coil set (for whole-coiled winding only).
LenRegion	Region length, to limit lead length for open coils.
InfoCoil	0: winding; 1: one coil; 100: region.

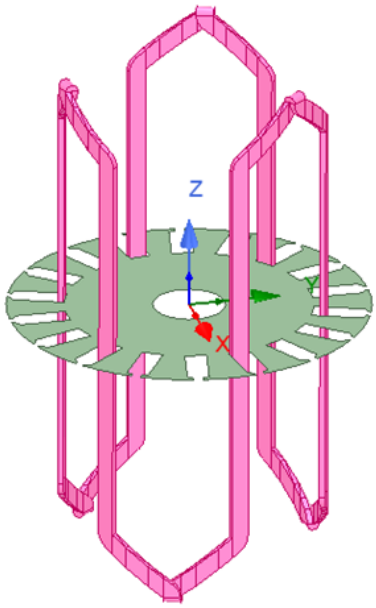
NOTE:

- Parameter **Layers** defines the total number of layers, or total number of conductors per slot. The value must be an even number. Two layers related to one coil are referred as one layer-set.
- Parameter **2ndPitch** which defines the second coil pitch (shown below) is the pitch between two coil sides to be welded.



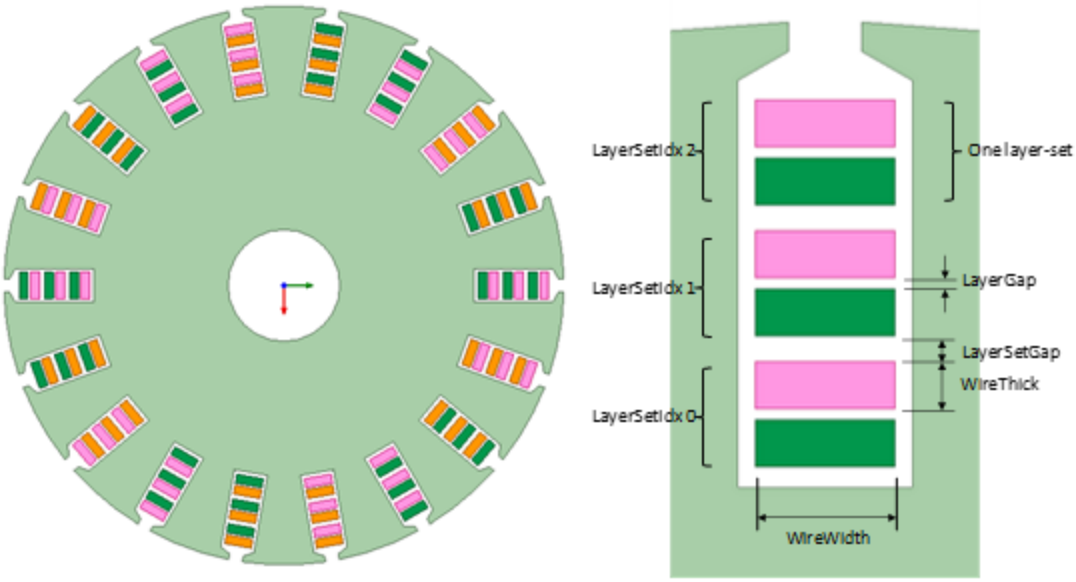
Parameters for CoilPitch and 2ndPitch

For an integer-slot winding, **Slots** value is a multiple of **2ndPitch** plus **CoilPitch** values. In such a case, the last coil in a coil chain will close the first coil, resulting in a closed coil chain, as shownbelow.



Closed hairpin-coil chain with 2ndPitch = 3 in an 18-slot core lamination

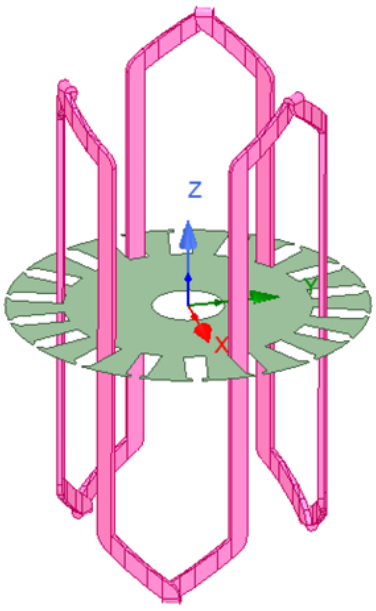
- In order to obtain good mesh quality, the UDP will not create wire with wire fillet radius, as shown above, but the effect of wire fillet radius on the wire area will be considered using a scaling factor for both **WireWidth** and **WireThick**. The scaling factor k = (WireArea / WireWidth / WidthThick) ^ 0.5, where WireArea is the wire cross-section area considering wire fillet.
- The UDP will get the maximum available rectangular space inside a slot via an optimization process for wire arrangement. The minimum gap between a wire and a rectangle side will be default as 0.3mm, considered as the thickness of a slot liner insulation. The gap between two layers in one layer-set is the same for all layer-sets. The value is automatically derived from the height of the rectangular space minus total wire thickness and total layer-set gap.
- **WindingType** and **CoilSetIdx** are used for fractional-slot windings only. You do not need to input these values for integer-slot windings. For a fractional-slot winding, the last coil in a coil chain will not close the first coil, and the coil chain will continue to include all coils belong to the same coil set. Finally, the UDP will create an opened coil set. Two lead wires will extend the opened coil set to touch one region end. For whole-coiled windings, since the two coil sets may have different coil arrangement, we need to create two coil sets separately. Parameter **CoilSetIdx** indicates which coil set is being created. The coil arrangement is based on three-phase windings.



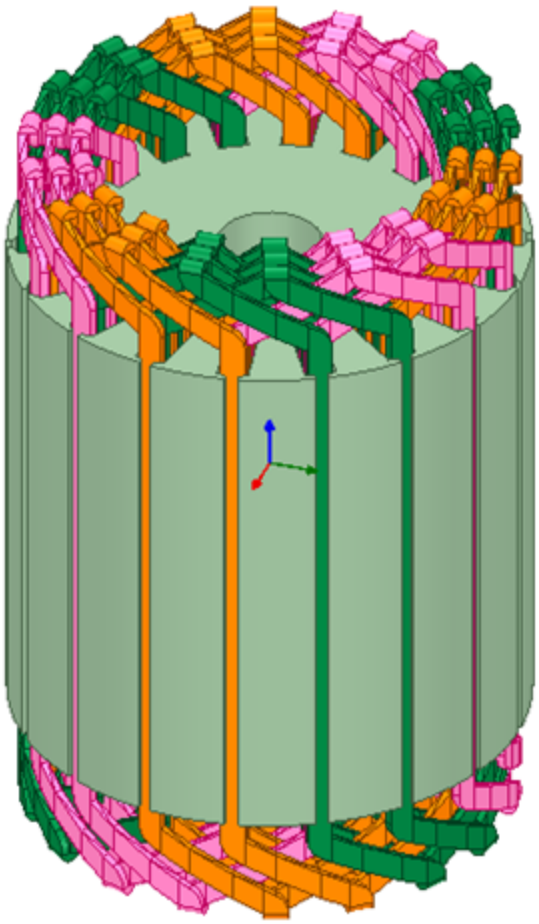
- For other parameters, please refer to *LapCoil UDP*.

Creating Closed Three-Phase Hairpin Windings (HairpinCoil)

1. In Maxwell 3D, launch HairpinCoil UDP with default setting, that is **Slots**=18, **Layers**=6, **CoilPitch**=3, **2ndPitch**=3, **LayerSetIdx**=0, and **InfoCoil**=1. Since the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 3 (an integer number), the UDP will create a closed-coil chain, or a coil loop, located at slot bottom, as shown below (excluding the core lamination).



2. Make a copy of the coil loop, and change **LayerSetIdx** to 1, this copied coil loop is changed to locate at the slot center.
3. Make a copy of the coil loop again, and change **LayerSetIdx** to 2, this copied coil loop is changed to locate at the slot top.
4. Duplicate all these three coil loops with the following parameters in **Duplicate/Around Axis** command: **Angle** = 20deg, **Total Number** = 6, and change colors for different phases, then you will get the final three-phase windings, as shown below.



Closed three-phase hairpin windings

Creating One Phase Half-Coiled Windings (HairpinCoil)

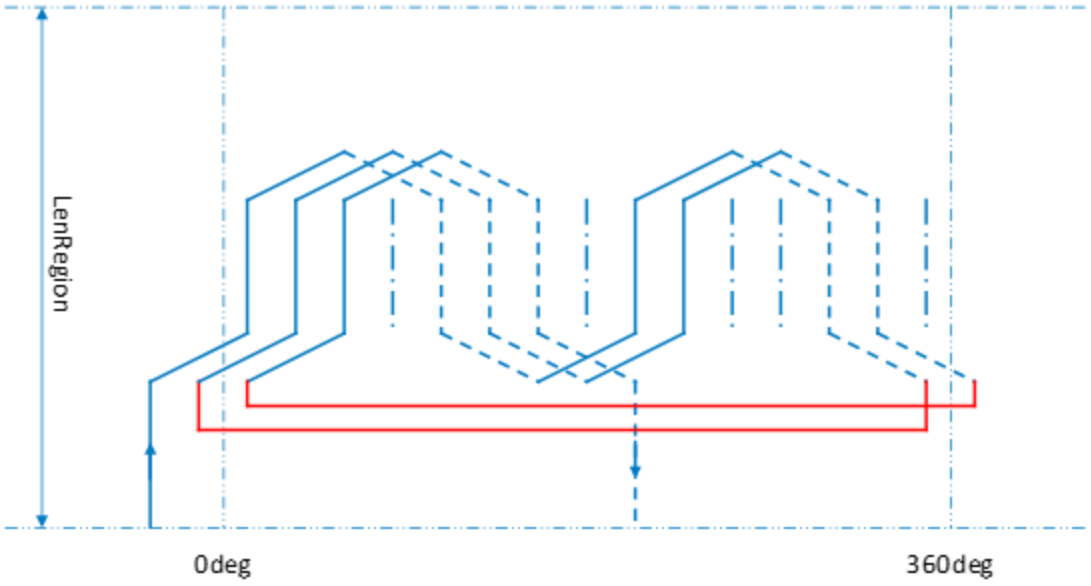
Set **Slots**=15, **Layers**=2, **CoilPitch**=4, **2ndPitch**=4, **LayerSetIdx**=0, and **InfoCoil**=1. Since the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 15/8 (not an integer number), the UDP will create an opened coil set. In this UDP, we will support a fractional-slot winding that satisfies:

(2ndPitch + CoilPitch) x PolePairs = Slots ± 1

For this example, the number of pole pairs is 2, and the winding arrangement, for top coil side only, will be:

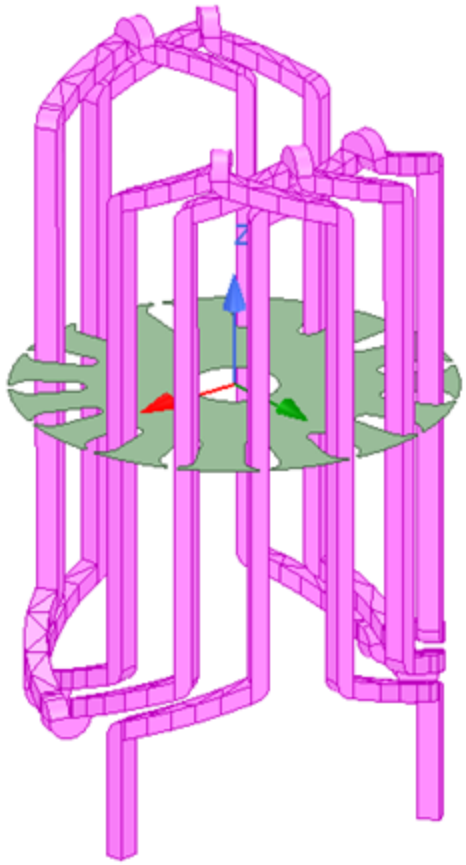
AAABBCCCAABBBCC

For this half-coiled winding, all hairpin coils labeled with “A” are included in one opened coil set, which has already contained all phase A coils, as shown below, where red lines indicate the short-circuit connection without using physical wires.



Flat expanded view of phase-A hairpin winding containing only one opened coil set

The created 3D opened winding is shown below.



3D view of phase-A hairpin winding containing only one opened coil set

Creating One Phase Whole-Coiled Windings (HairpinCoil)

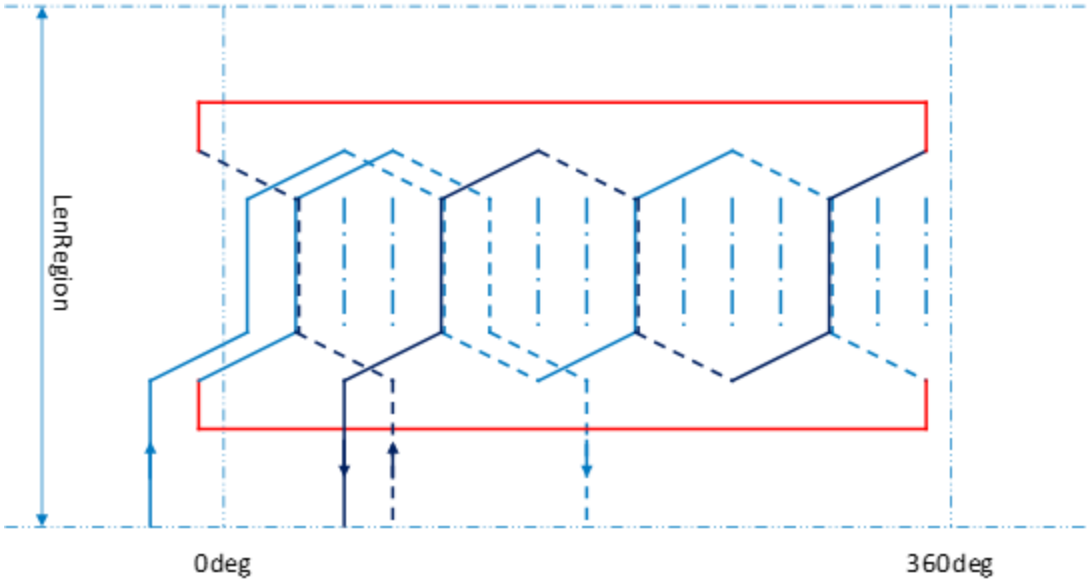
Set **Slots**=15, **Layers**=2, **CoilPitch**=4, **2ndPitch**=4, **LayerSetIdx**=0, **WindingType** = 1, **CoilSetIdx** = 0, and **InfoCoil**=1. Since the ratio of **Slots** to (**2ndPitch** + **CoilPitch**) is 15/8 (not an integer number), the UDP will create an opened coil chain. This fractional-slot winding satisfies:

(2ndPitch + CoilPitch) x PolePairs = Slots ± 1

where the number of pole pairs is 2. The winding arrangement, for top coil side only, is:

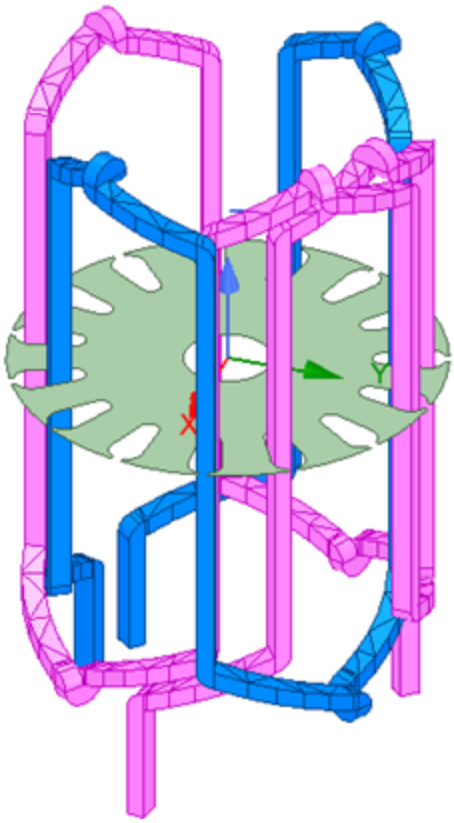
AAZBXCCYAZBBXCY

With the above parameter setting, this UDP will create an opened coil set including all coils related to all “A” coils of the above winding arrangement. Copy the coil set, and change **CoilSetIdx** to 1. The coil set is modified to include all coils related to all “X” coils of the winding arrangement. The phase-A winding is made up of these two coil sets, as shown below, where red lines indicate the short-circuit connection without using physical wires.



Flat expanded view of phase-A hairpin winding containing two opened coil sets (all coils with light blue color relate to “A” coils, and all coils with dark blue color relate to “X” coils, in the winding arrangement)

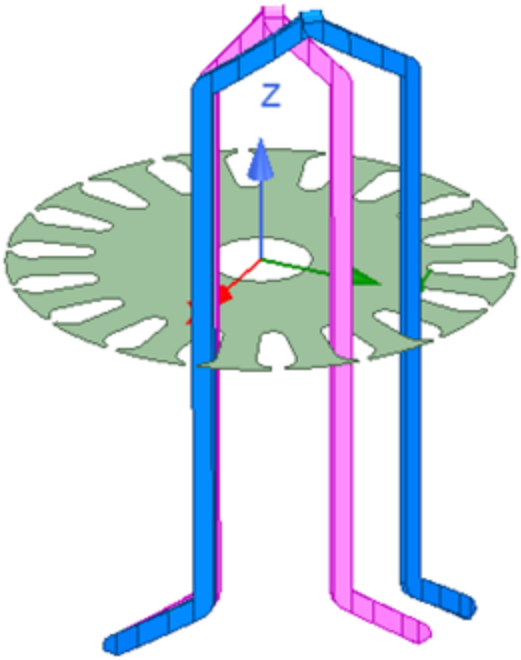
The created 3D opened winding is shown below.



3D view of phase-A hairpin winding containing two opened coil sets

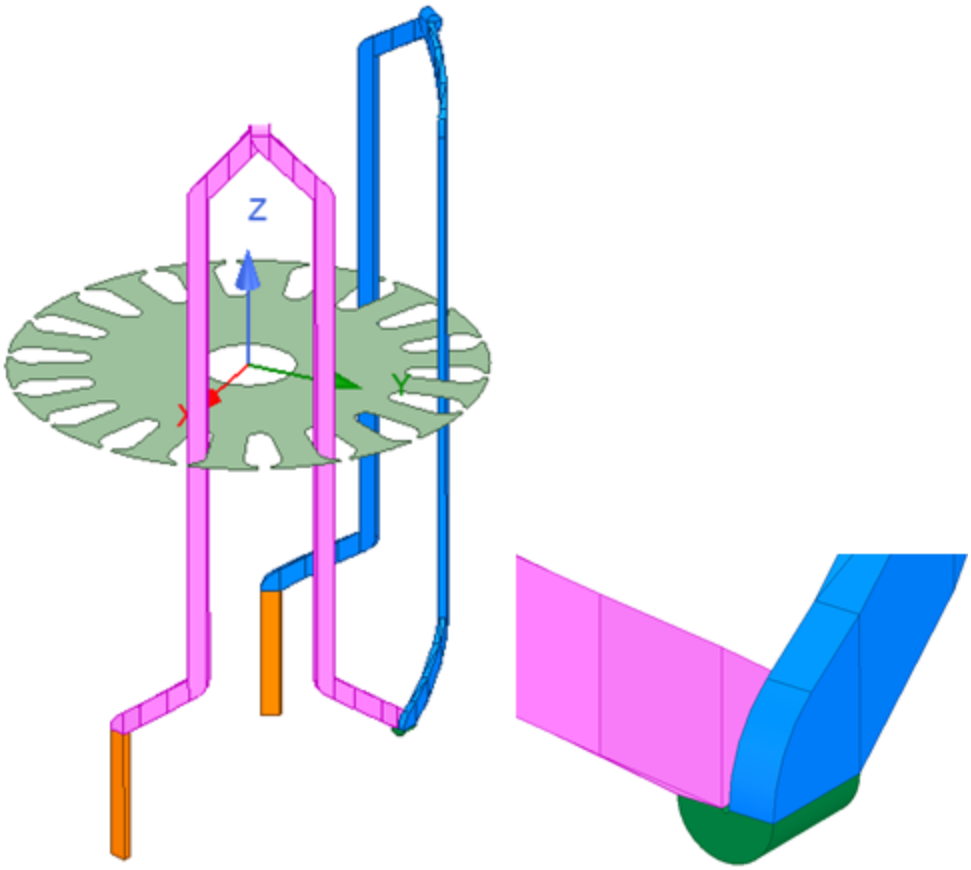
Creating Two Hairpin Coils Connected with End-Tip and Leads

1. Set **Slots**=18, **Layers**=6, **CoilPitch**=2, **2ndPitch**=3, **LayerSetIdx**=0, and **InfoCoil**=4. These parameter settings will create a single hairpin coil located at the slot bottom, as shown by the pink-color coil in the figure below.



Two hairpin coils with different coil pitch at different slot locations

2. Make a copy of the coil, and change **CoilPitch** to 3, and **LayerSetIdx** to 1. The copied coil is modified to be located at the slot center, as shown by the blue-color coil in the above figure.
3. Rotate the blue-color coil by 100deg, or 5 slot-angle, the bottom leg-span of the blue-color coil will align with the top leg-span of the pink-color coil, as shown in the figure below.



Two hairpin coils at different slot locations connected with end-tip and leads

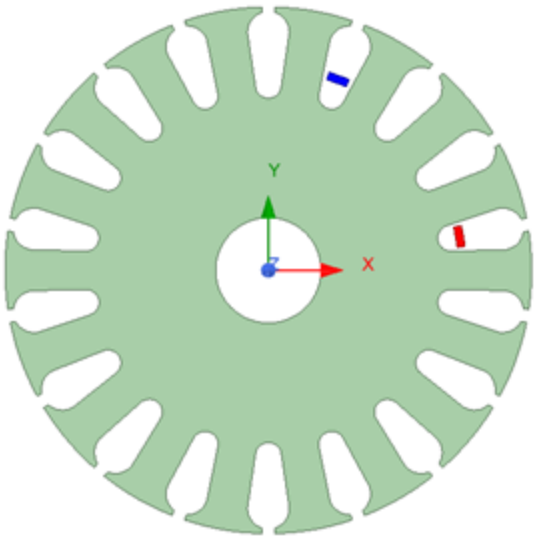
4. Make a copy of the blue-color coil, and change **LayerSetIdx** to 0.5 (for end-tip between layer-set index of 0 and 1) and **InfoCoil** to 4. The copied coil is modified to an end tip, as shown by the green-color object in the above figure.
5. Make a copy of the pink-color coil and change **InfoCoil** to 6, the copied coil is modified to a going lead; and make a copy of the blue-color coil and change **InfoCoil** to 7. The copied coil is modified to a returning lead, as shown by the golden-color objects in the figure.

The two hairpin coils, two leads, and one end-tip can thus be united to become a single connected coil set.

Note: In order for the end-tip and leads to be able to perfectly connect two hairpin coils, the parameter value of **2ndSpanExt** for all components must be the same to keep the same axial span length. If you see a message such as: “HairpinCoil - 2ndSpanExt is modified from xxx to xxx”, you need to increase the value of **2ndSpanExt** for all components to be at least the maximum modified value of all components.

Creating a Terminal for a Hairpin Coil

A terminal is a 2D cross section of a 3D coil that can be used to assign current or voltage excitations. You can create a *going* terminal by setting **InfoCoil** to 2; or you can create a *returning* terminal by setting **InfoCoil** to 3. In a connected 3D coil set, you need to create only one terminal, but you need to create both *going* and *returning* terminals for each hairpin coil for a 2D model. *Going* and *returning* terminals are shown below.



***Going* terminal (red) and *returning* terminal (blue) inside two slots**

UDPs for Pole Cores and Coils

UDPs defined for pole cores and coils include:

- SalientPoleCore UDP
- DCMCore UDP
- ShadedPoleCore UDP
- UnivMCore UDP
- SRMCore UDP
- SynRMCore UDP
- ClawPoleCore UDP

SalientPoleCore UDP

The SalientPoleCore UDP is used to create a salient-pole core, a field winding, and a damper for salient-pole synchronous machines. It can also create a coil cross-section used as a terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of slots.
SlotType	Slot Type: 1 to 4.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: a tangent connection; 2&3: arc bottom; 4&5: V bottom.
SlotPitch	Slot pitch in mechanical degrees, refer to offset point.
CenterPitch	Center slot pitch in mechanical degrees, refer to offset point.
Poles	Number of poles.
PoleType	Pole type: 1 or 2 (not valid for inner cores)
WidthShoe	Pole shoe width.
HeightShoe	Pole shoe height at pole center
FilletShoe	Pole shoe tip fillet radius.
WidthBody	Pole body width.
HeightBody	Pole body height.
AirGap2	Second air gap length.
Offset	Pole arc offset.
Off2_x	The second pole arc offset perpendicular to the pole-center line.

Property	Description
Off2_y	The second pole arc offset parallel with the pole-center line.
Bp1/Rp1	Bp1: for pole type 1; or Rp1: shoe fillet radius for pole type 2.
Bp2/Rp2	Bp2: for pole type 1; or Rp2: shoe fillet radius for pole type 2.
CoilEndExt	One-side coil end extended length.
EndRingType	0: whole press board; 1: pole press board; 2: pole ring; 3: whole ring.
BarEndExt	One-side damper bar end extended Length; for types 2 & 3 only.
RingLength	One-side axial ring length, or conductor press board thickness.
RingHeight	Radial ring height, for types 2 & 3 only.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: core; 1: core & coils; 2: coil; 3: damper; 4: terminal1; 5: terminal2; 6:poles; 7: yoke; 100: region.

These parameters are used in the following figures. In figures with both gray and red objects, the gray objects are used as references.

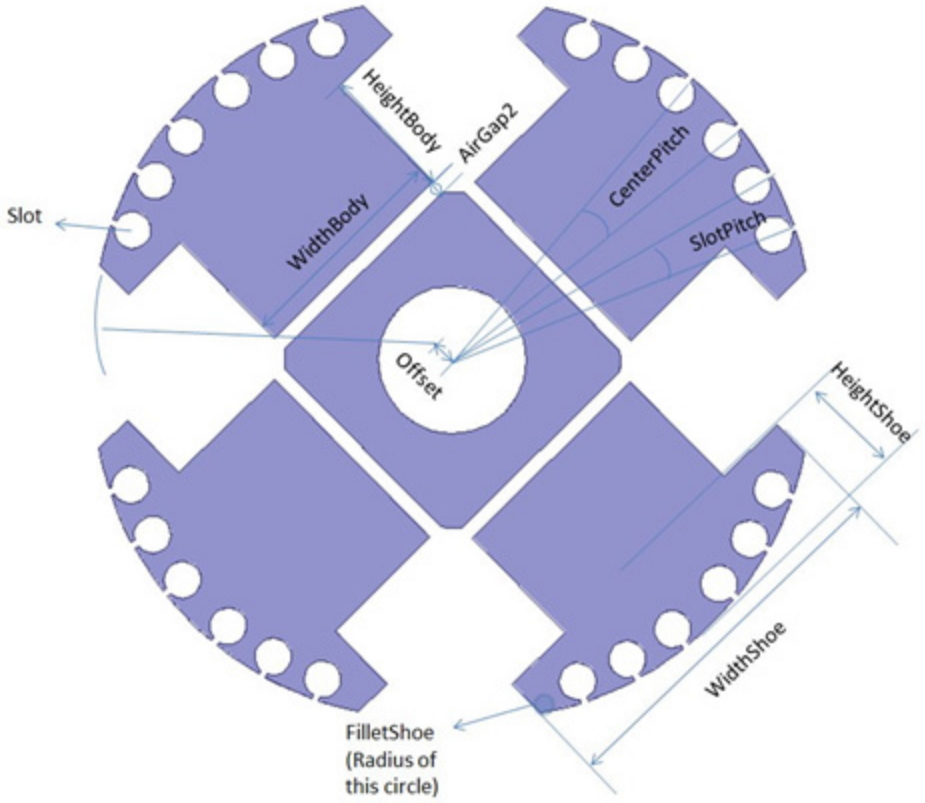

Figure 9-86 Salient Pole Core (InfoCore set to 0)

Figure 9-87 This UDP supports 2 pole types for outer cores, as shown below;

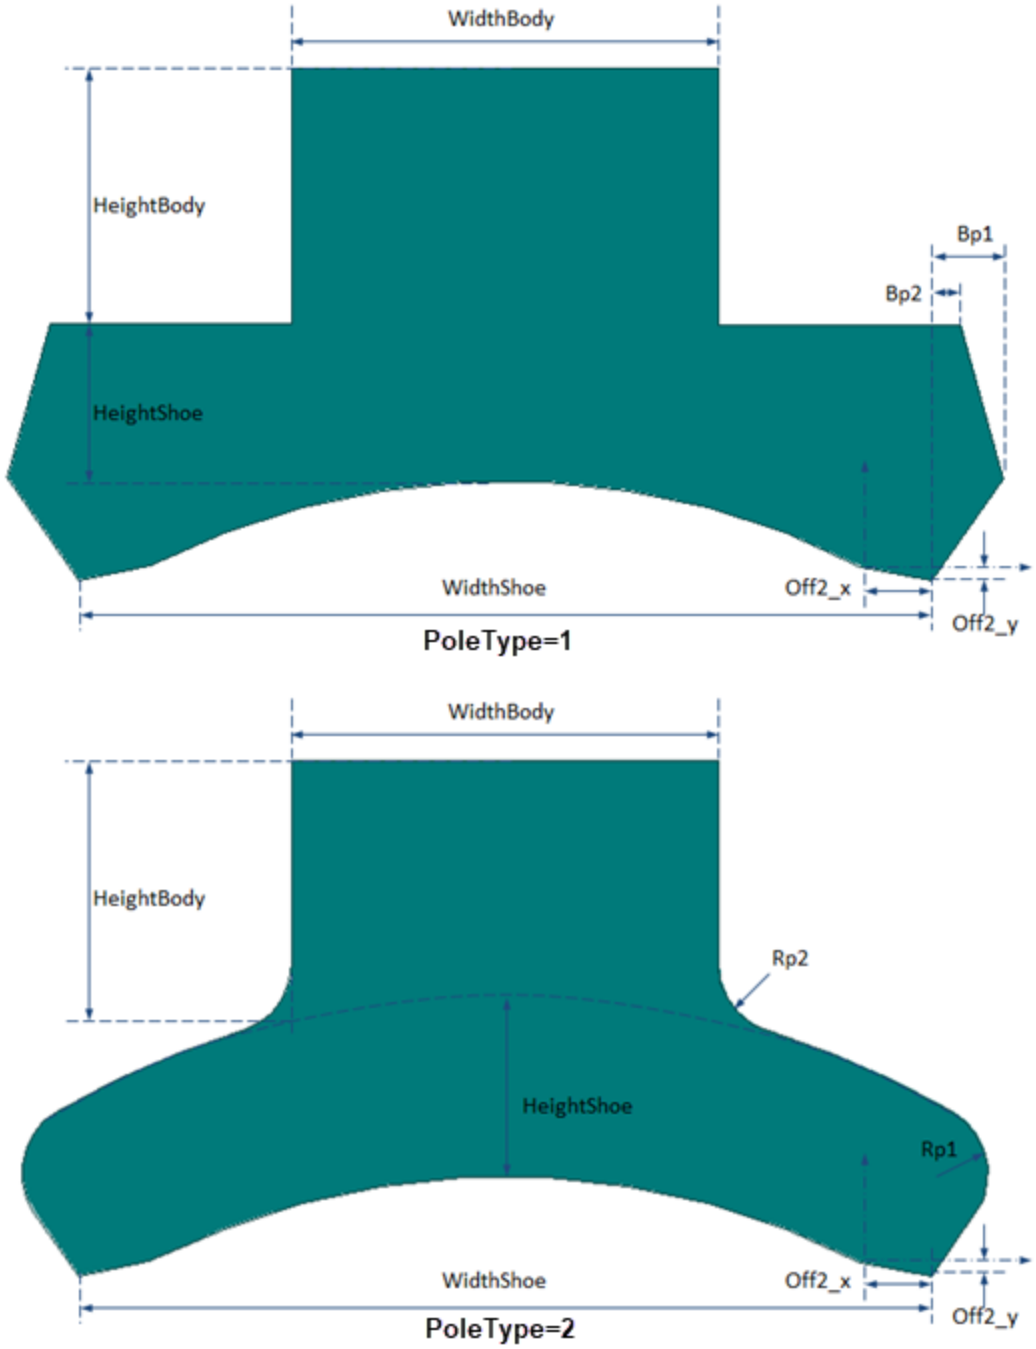

Figure 9-88

Two pole types available for outer cores

Figure 9-89 but supports only one pole type for inner cores.

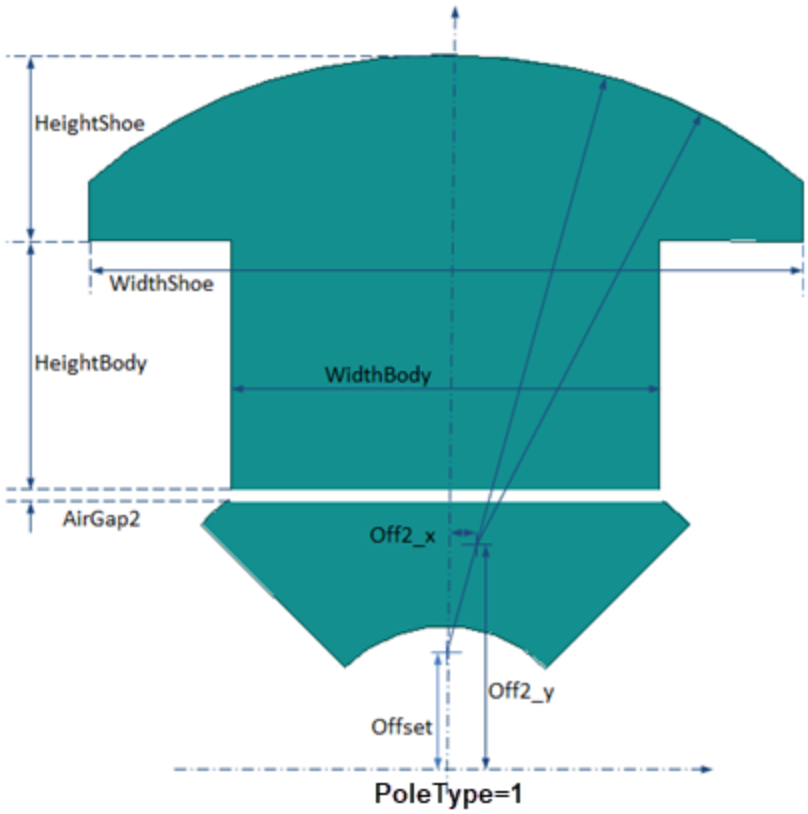

Figure 9-90

Only one pole type available for inner cores

Figure 9-91 Axial parameters for coils and dampers are shown in the following figures.

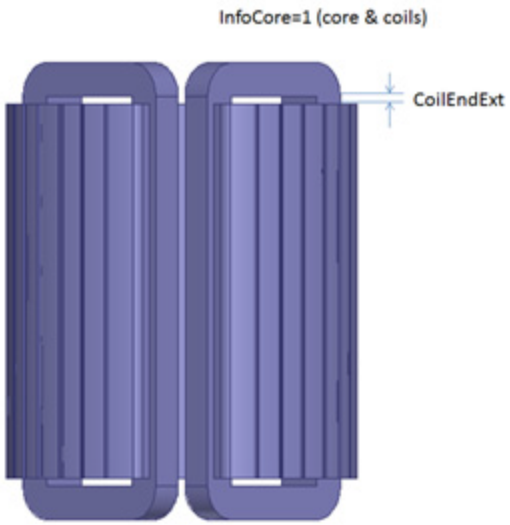

Figure 9-92 3D Salient Pole Core and coils (InfoCore set to 1)

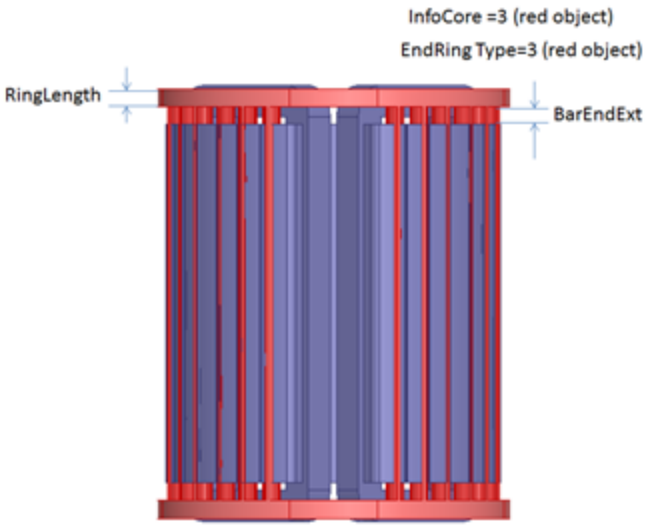

Figure 9-93 SalientPoleCore damper (InfoCore set to 3)

Creating an Inner or Outer Salient Pole Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores.

An example of an inner salient pole core is shown in Figure 9-86 . For an outer salient pole core, see Figure 9-94 .

You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

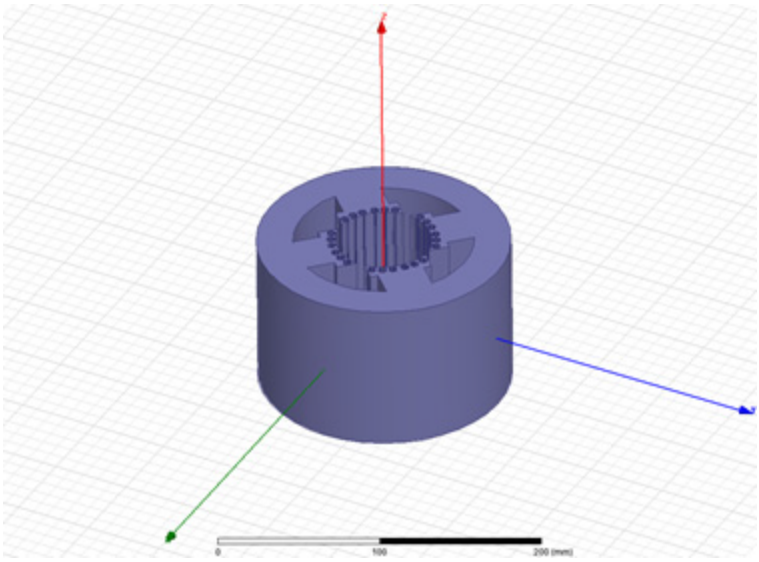

Figure 9-94 Outer salient pole core

Creating a Coil and its Terminals (Salient Pole)

You can create a coil of a salient pole core by manually setting the property of **InfoCoil** to 2. An example is shown below.

Its terminals are created manually by setting the property of **InfoCoil** to 4 or 5 (Terminal1 or Terminal2). The red sheet in the figure shows terminal 1 of the coil.

You can assign values for these properties either when creating a salient pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

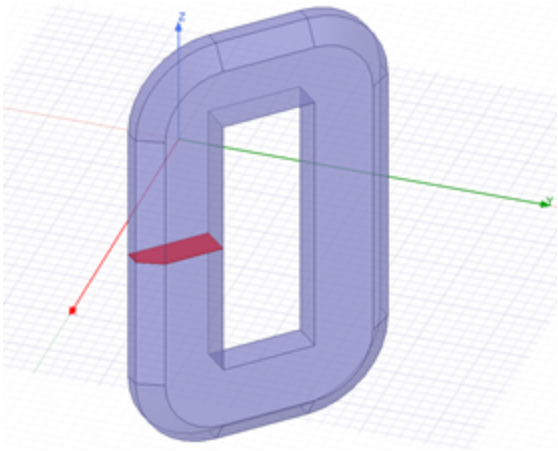

Figure 9-95 Salient pole core coil and its terminal

Creating a Damper (Salient Pole)

You can create a damper of a salient pole core by manually setting the property of **InfoCoil** to 3. An example is shown in Figure 9-93 as a red object.

Figure 9-96 ,Figure 9-97 , Figure 9-98 , and Figure 9-99 illustrate the shapes of the damper (InfoCore set to 3) with different EndRingType values. Gray objects are used as references.

You can assign the value of these properties either when creating a salient pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

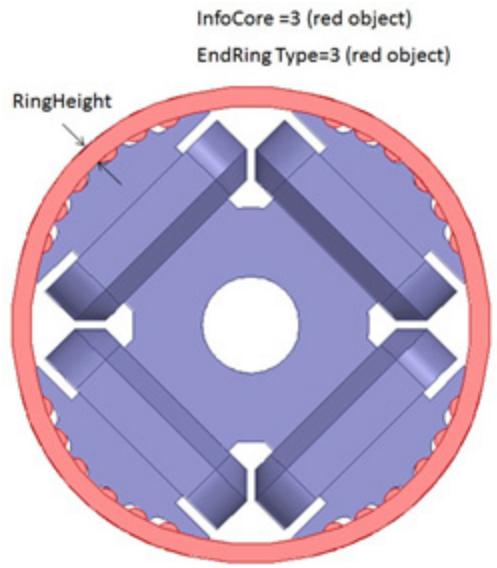

Figure 9-96 Damper with EndRing Type set to 3

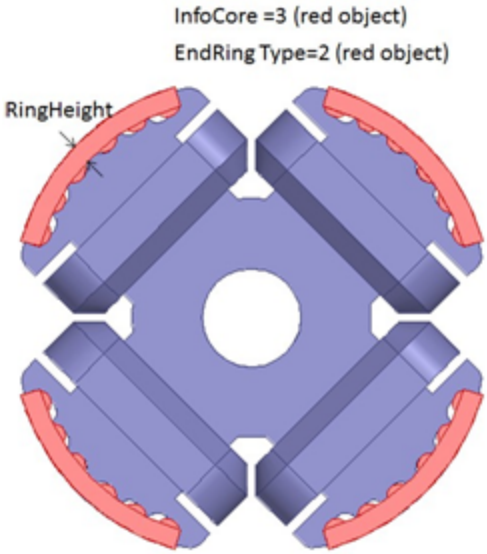

Figure 9-97 Damper with EndRing Type set to 2

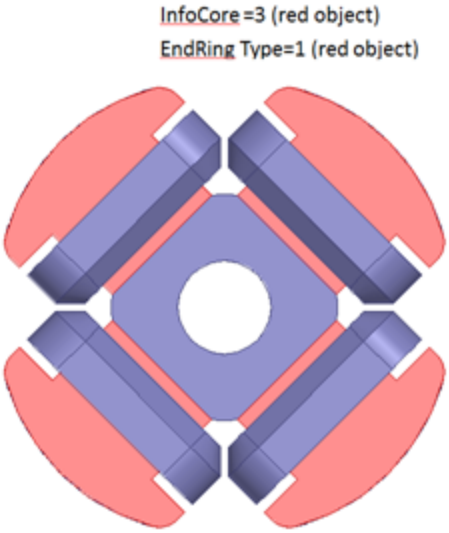

Figure 9-98 Damper with EndRing Type set to 1

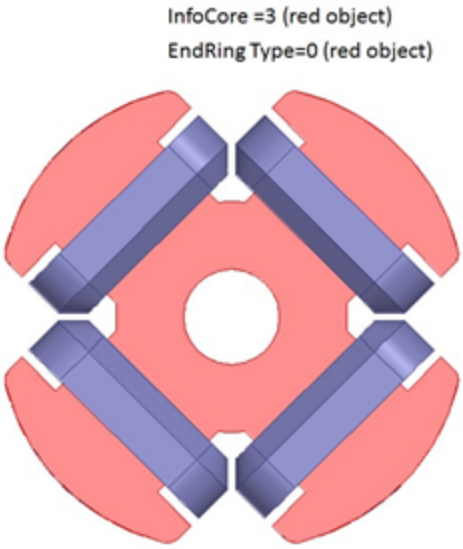

Figure 9-99 Damper with EndRing Type set to 0

Creating Poles or the Yoke

You can create poles or the yoke of SalientPoleCore UDP through assigning the **InfoCore** parameter to 6 or 7, respectively.

You can assign the value of this property either when creating a Salient Pole Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples of poles and the yoke are shown in Figure 9-100 and Figure 9-101 , respectively.

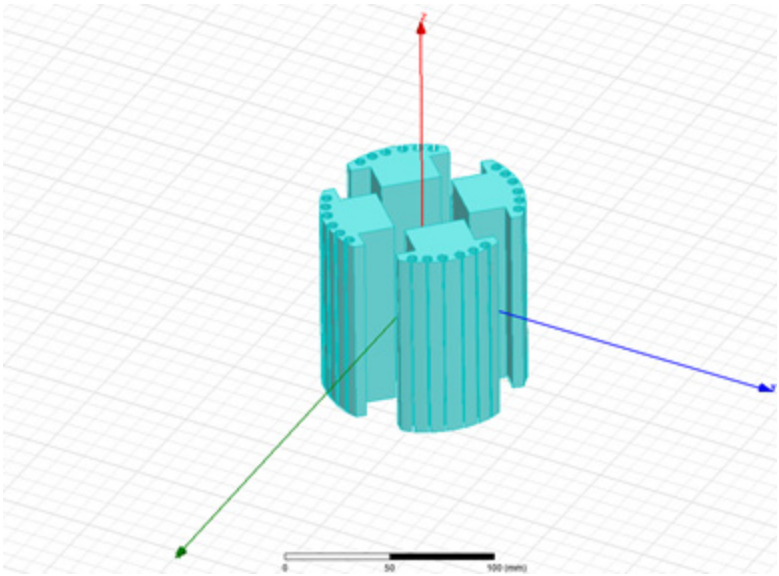

Figure 9-100 Poles of salient pole core

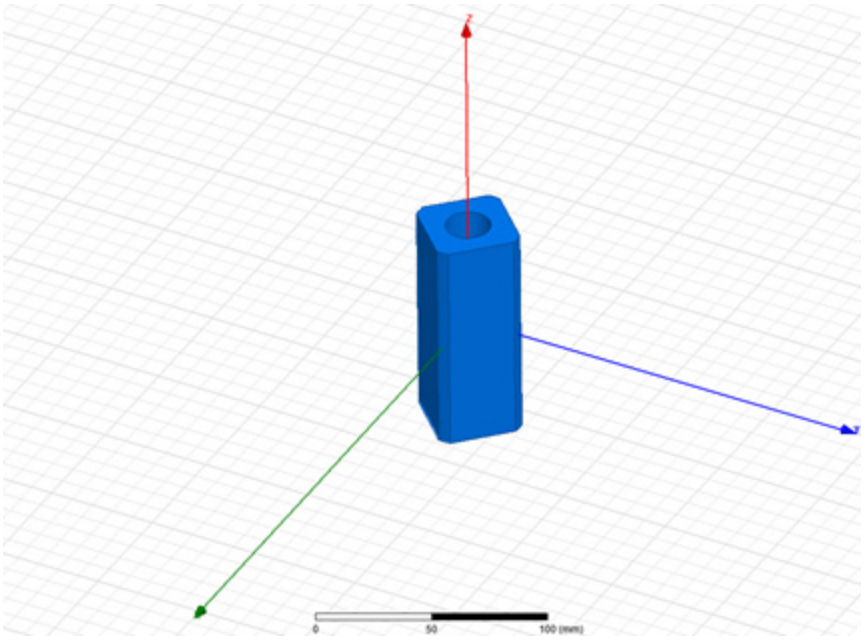

Figure 9-101 Yoke of salient pole core

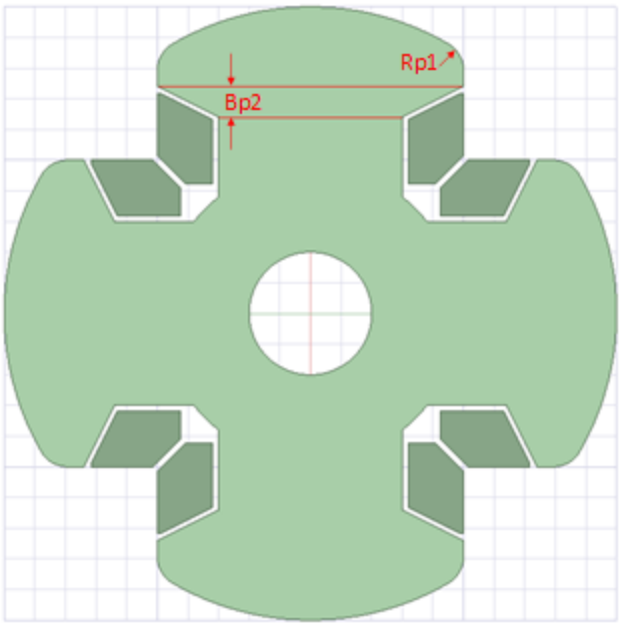
Creating Inner Poles with Shoe Slope

For inner-core type-1 pole, parameters **Rp1/Bp1** and **Rp2/Bp2** stand for shoe-tip fillet radius and shoe-slope height, respectively, as shown below, where all coils are included.



Parameters **Rp1** and **Bp2** for inner core type 1 pole

DCMCore UDP

The DCMCore UDP is used to create a stator core with or without a compensating winding, a shunt and/or a series field winding, and a commutating pole with a commutating winding for DC machines. It can also create coil terminals for all windings for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores.
Length	Core length.
Skew	Skew angle in core length range.
FrameWidth	Overall width of a racetrack frame.
FrameThick	Frame thickness.
FrameLength	Frame length.
Poles	Number of poles.
PoleType	Pole type: 1 to 2.
Dmax	Diameter of shoe tip with maximum air gap length.
Bp0	Pole arc width with uniform air gap; 0 for eccentric air gap.
Bp1	Total pole width (the width between shoe tips).
Bp2/Rp0	Bp2 (max shoe width for pole type 1), or Rp0 (shoe fillet radius for pole type

Property	Description
	2).
Bp3/Rp1	Bp3 (min shoe width for pole type 1), or Rp1 (pole fillet radius for pole type 2).
Hp	Pole body height.
Bm	Pole body width.
FieldWndgs	Number of field windings, 2 for both series and shunt windings.
EndExt	Coil one-side end extended length.
SlotsPerPole	Compensating slots per pole distributed under pole arc surface.
Bc0	Opening width of compensating slots.
Hc0	Opening height of compensating slots.
Bc2	Width of compensating slots.
Hc2	Height of compensating slots.
CmpEndExt	One-side end extended length of compensating coils.
ComPoleWidth	Width of the commutating poles.
ComPoleHeight	Height of the commutating poles.
ComPoleLength	Length of the commutating poles.
ComShoeWidth	Shoe width of the commutating poles.
ComShoeHeight	Shoe height of the commutating poles.
ComShoeLength	Shoe length of the commutating poles.
ComGap2	Air gap length between commutating poles and the frame.
CmtEndExt	One-side end extended length of commutating coils.
LenRegion	Region length.
InfoCore	0: core & coils; 1: poles; 2: frame; 3: com poles; 4: shunt coil; 5: series coil; 6: com coil; 100: region.
Info Term	0: whole coil; 1: terminal1; 2: terminal2.

The DC Machine core is complex compared with other UDPs. When creating a DCM core in a Maxwell 3D design, it looks at first like the following figure in the coordinate system window.

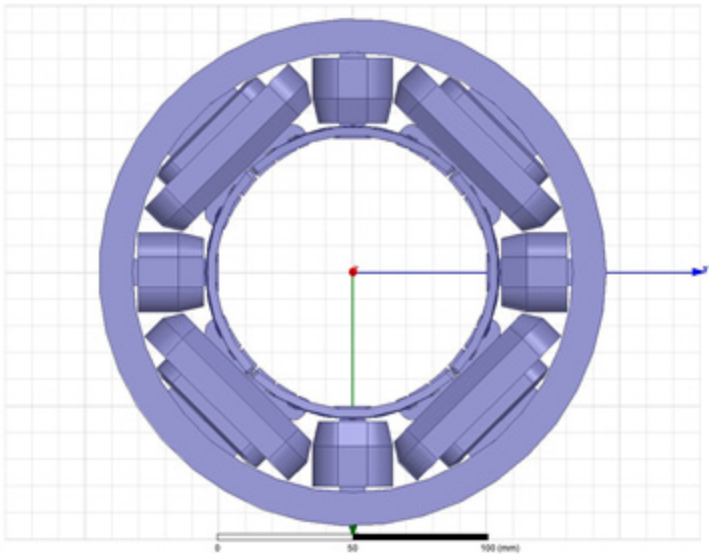


Figure 9-102 Initial DCM Core

In order to better describe the parameters in this UDP, a slot core was added inside the DCM core and their lengths were set to be 0. Also the **DiaGap** of slot core was changed to 92 to show the air gap between two UDPs. The model now looks like the following example:

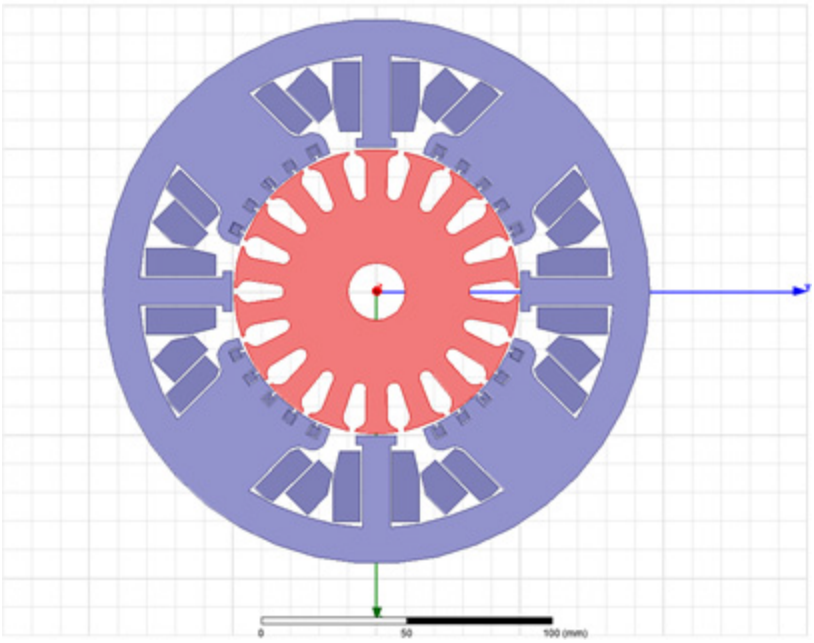

Figure 9-103 DCM Core Sheet (gray) with Slot Core Sheet (red)

The following figures show two different overviews of the gray, transparent DCM core and the referencing red slot core from different angles.

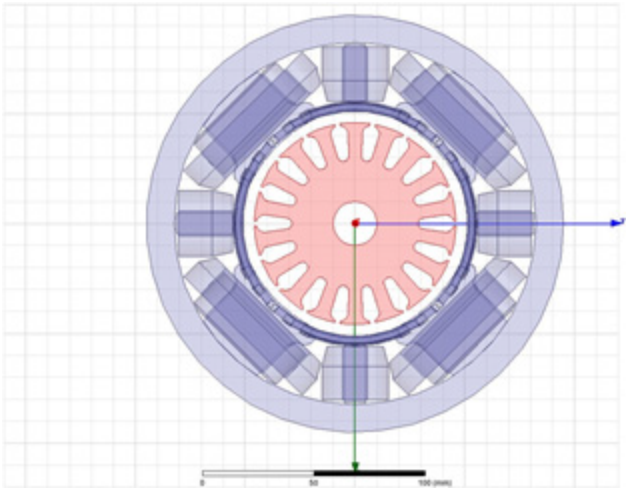

Figure 9-104 Transparent DCM core (gray) with Slot Core from different angles

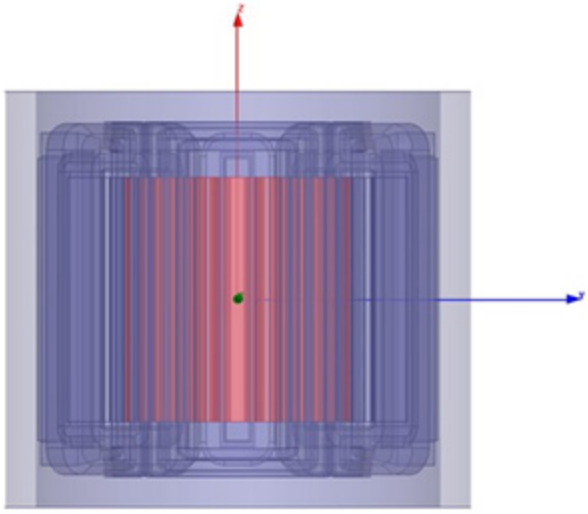

Figure 9-105 Transparent DCM core (gray) with Slot Core from different angles

The following figures show the parameters of a DCM core.

Note	1. A slot core in red is drawn as reference. 2. Because the structure of a DCM core is complicated and there are many parameters, figures are drawn using different **InfoCore** values of DCM core UDP to clearly describe parameters. 3. Figure 9-106 and Figure 9-107 show parameters of two different pole types in the DCM core UDP. In these two figures, **Bp0** is not 0, whereas in Figure 9-108 **Bp0**

	is 0, which means the air gap is eccentric. 4. **Dmax**, by definition, is the diameter of shoe tip with maximum air gap length, which means **Dmax**=Drout+2*Gmax. “Drout” means the outer diameter of the rotor (which means **DiaGap** of slot core in this example and is shown in Figure 9-108), and “Gmax” is the maximum air gap between poles and rotor, which is shown in Figure 9-106 and Figure 9-107 . 5. Correspondingly, there is **Dmin** (which is called **DiaGap** in DCM UDP and Figure 9-108) and **Gmin**. Their relationship is **Dmin**=Drout+2*Gmin. They are also shown inFigure 9-106 , Figure 9-107 , and Figure 9-108 . 6. The value of **ComGap2** in Figure 9-108 is 0, whereas it is positive in Figure 9-109 . In order to make the value of **ComGap2** larger than 0, make sure to reserve enough space for **ComGap2**. This can be done by reducing the value of **ComPoleHeight** or **ComShoeHeight** or both.

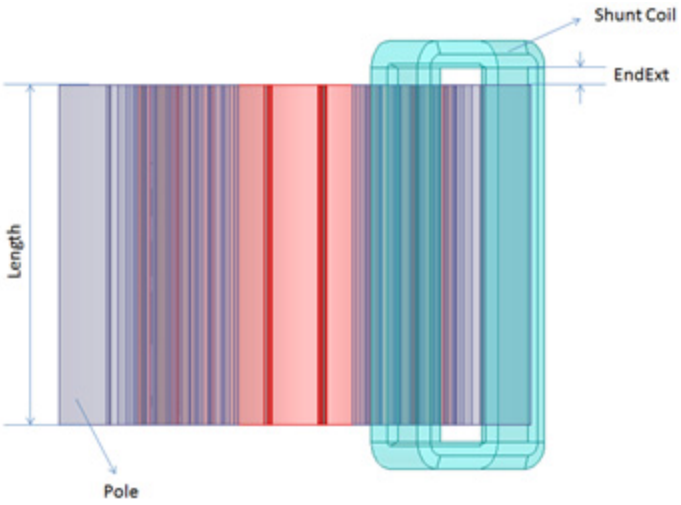

Figure 9-111 Axial parameters of poles and field windings

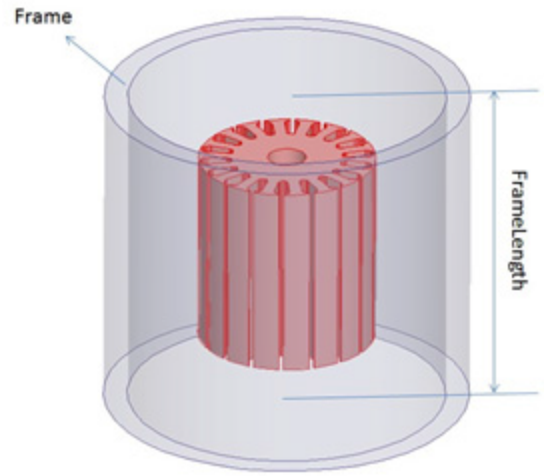

Figure 9-112 Length of frame

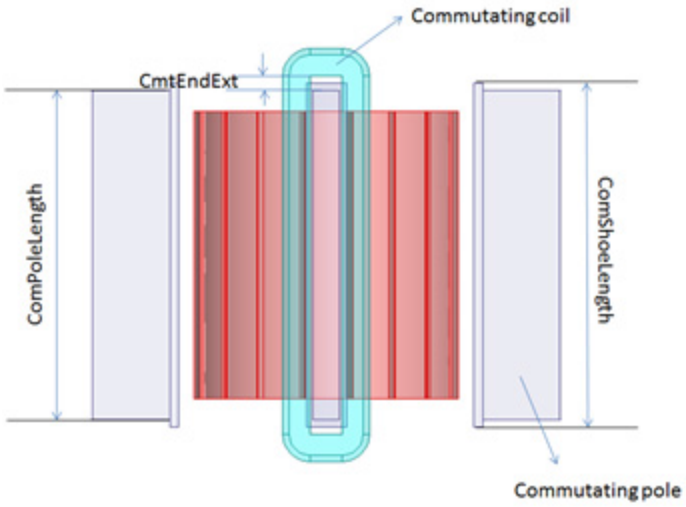

Figure 9-113 Axial parameters of commutating poles and commutating coils

Creating an Outer DC Machine Core and All Coils

This core is used only as outer core, which means the value of **DiaYoke** is larger than that of **DiaGap**. Also,set both **InfoCore** and **Info Term** values to be 0. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example of an outer DC machine core is shown in the following figure:

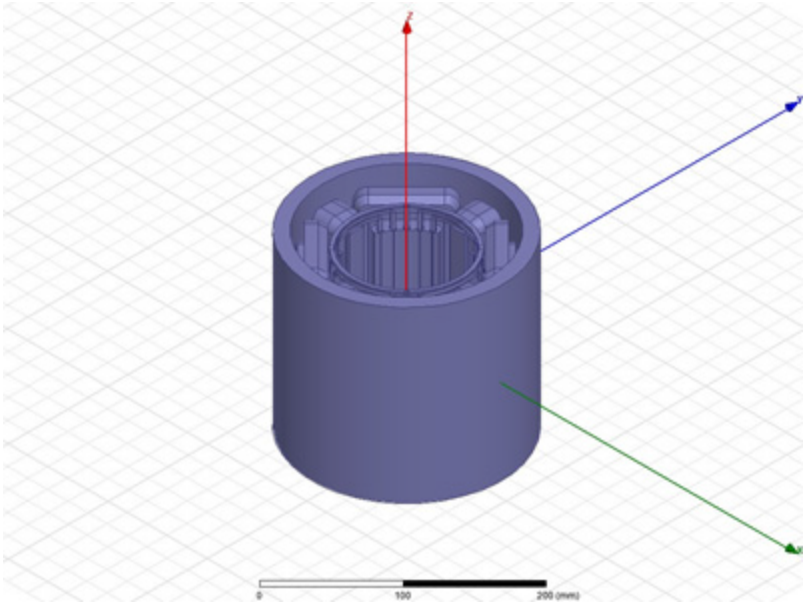

Figure 9-114 Outer DC Machine core and all coils

Creating Main Poles, Frame and Commutating Poles Separately

You can create the main poles of a DC Machine core by manually setting the property of **InfoCore** to 1 and **Info Term** to 0. The result is shown as the gray object in Figure 9-110 and Figure 9-111 .

You can create the frame of a DC Machine core by manually setting the property of **InfoCore** to 2 and **Info Term** to 0. The result is shown as the gray object in Figure 9-112 .

You can create the commutating poles of a DC Machine core by manually setting the property of **InfoCore** to 3 and **Info Term** to 0. The result is shown as the gray object in Figure 9-113 .

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating a Shunt Coil and its Terminals

You can create a shunt coil of a DC Machine core by manually setting the property of **InfoCore** to 4 and **Info Term** to 0. The result is shown as a blue object in Figure 9-111 .

You can also create its terminals by setting the property of **InfoCore** to 4 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating a Series Coil and its Terminals

You can create a series coil of a DC Machine core by manually setting the property of **InfoCore** to 5 and **Info Term** to 0. An example is shown in the following figure.

You can also create its terminals by setting the property of **InfoCore** to 5 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

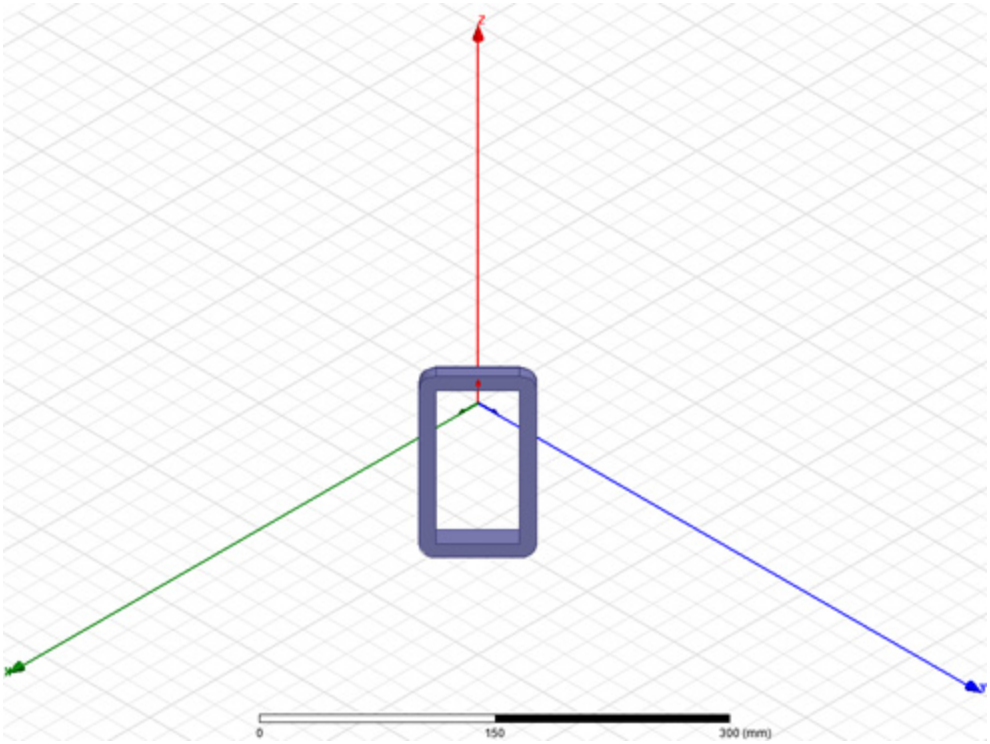

Figure 9-115 A series coil of DCM Core

Creating a Commutating Coil and its Terminals

You can create a commutating coil of a DC Machine core by manually setting the property of **InfoCore** to 6 and **Info Term** to 0. The result is shown as a blue object in Figure 9-113 .

You can also create its terminals by setting the property of **InfoCore** to 6 and **Info Term** to 1 or 2 (for terminal1 and terminal2, respectively).

You can assign the values of these properties either when creating a DC Machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

ShadedPoleCore2 UDP

The ShadedPoleCore2 UDP is used to create the stator core for shaded-pole induction motors.

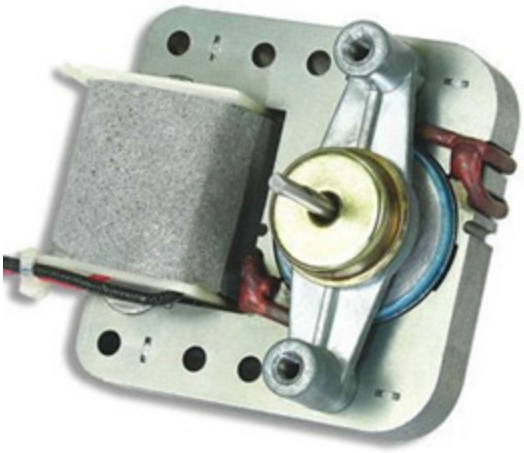

Figure 9-116 Shaded pole induction motor example 1

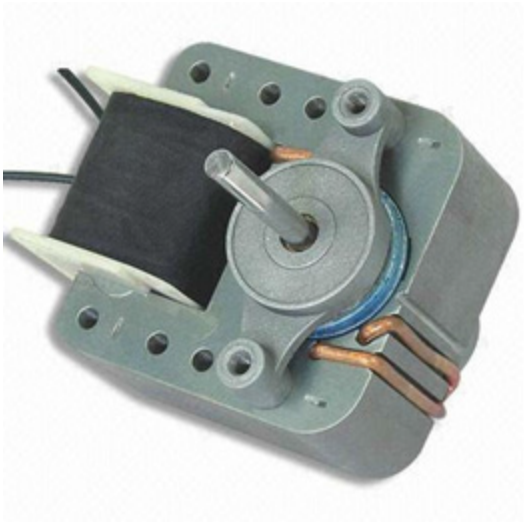

Figure 9-117 Shaded pole induction motor example 2

Property	Description
DiaGap	Core diameter on gap side, or inner diameter.
HighCore	Core height in d-axis direction.

Property	Description
WidthCore	Core width in q-axis direction.
WidthPole	WidthPole = DiaGap + 2 * (pole bridge thickness).
Length	Core length in the axial direction.
WidthYoke1	Width of the winding-core yoke.
WidthYoke2	Width of the parallel yokes.
Slots	Number of slots per pole (1 or 2).
Hs0	Slot opening height.
Bs0	Slot opening width.
Bs1	Slot diameter.
DiaCond	Diameter of the short-circuit solid conductor.
AngleOff	Angle offset in mechanical degrees from the first slot to d-axis.
SlotPitch	Slot pitch in mechanical degrees for two slots.
Dist1	Outer-slot center-to-center distance when Slots = 2.
DiaS2	Additional outer-slot diameter.
Dist2	Additional outer-slot distance.
InfoEnd	0: Separated end connectors; 1: Jointed end connectors.
GapDelta	Maximum gap - minimum gap.
AngleBegin	Begin angle of maximum gap in mechanical degrees.
AngleEnd	End angle of maximum gap in mechanical degrees.
RadFillet	Radius of outer-corner fillet.
RadDelta	Step depth in outer-corner fillet.
DiaHole	Diameter of holes for shaft bearing covers.
SpanHole	Hole span in d-axis direction.
LenRegion	Region length.
InfoCore	0: Core; 1: All; 2: Coil; 3: Cond1; 4: Cond2; 5: Hole filler; 100: Region.
InfoTerm	0: Whole coil; 1: Terminal1; 2: Terminal2.

These parameters are used in the following figures.

Note	• The number of parameters is large in this UDP, so different colors are used to indicate different parameters in the stator bore (area of the circle of **DiaGap**). Each parameter is shown with an arc/line and text in the same color. • For parameters such as **Length** and parameters related to slots, refer to SlotCore UDP parameters.

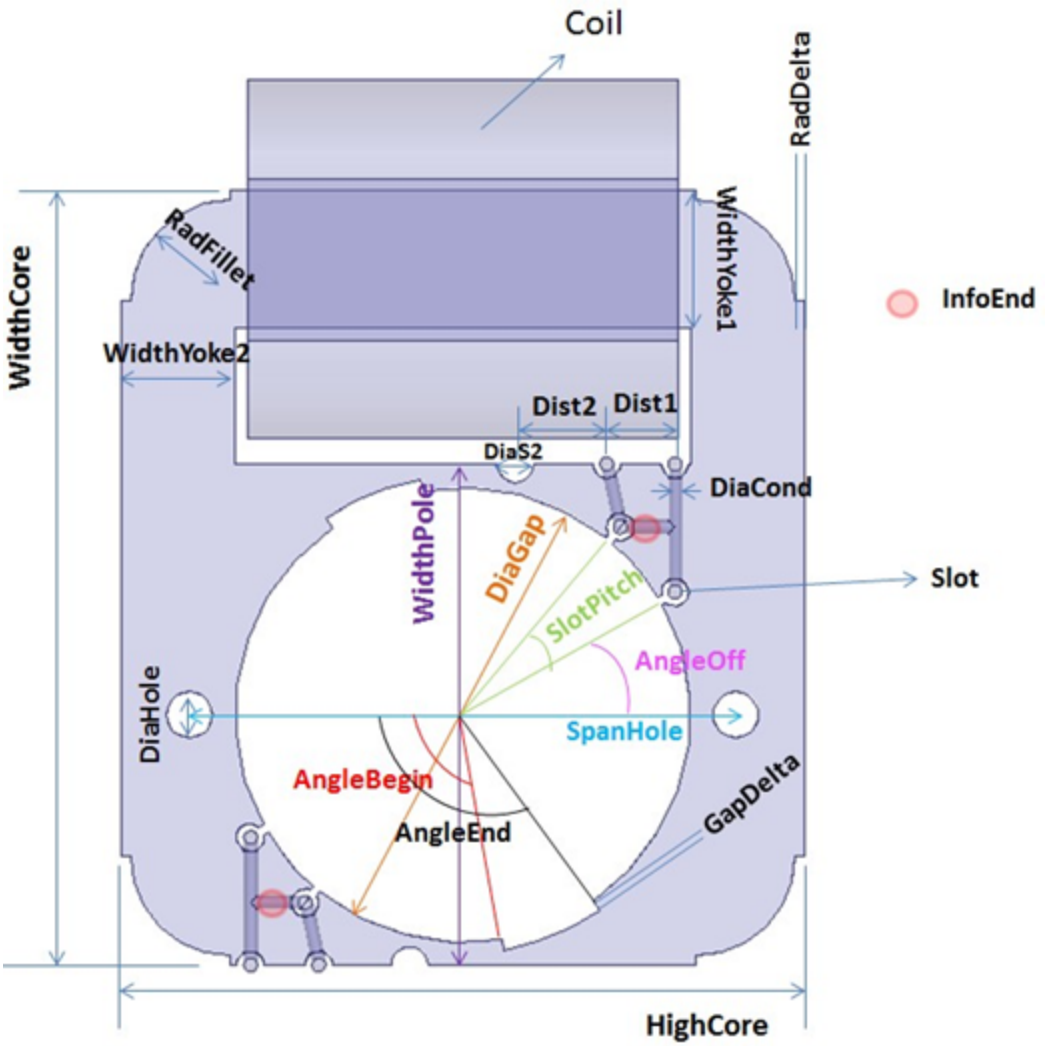

Figure 9-118 Parameters of ShadedPoleCore2 (InfoCore set to 1, Info Term set to 0)

Creating an Outer Shaded Pole Core

This core is used only as an outer core. There is no **DiaYoke** parameter in this UDP, so to create an outer shaded pole core,set both **InfoCore** and **Info Term** values to be 0. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example of the core for a ShadedPoleCore2 is shown in the following figure.

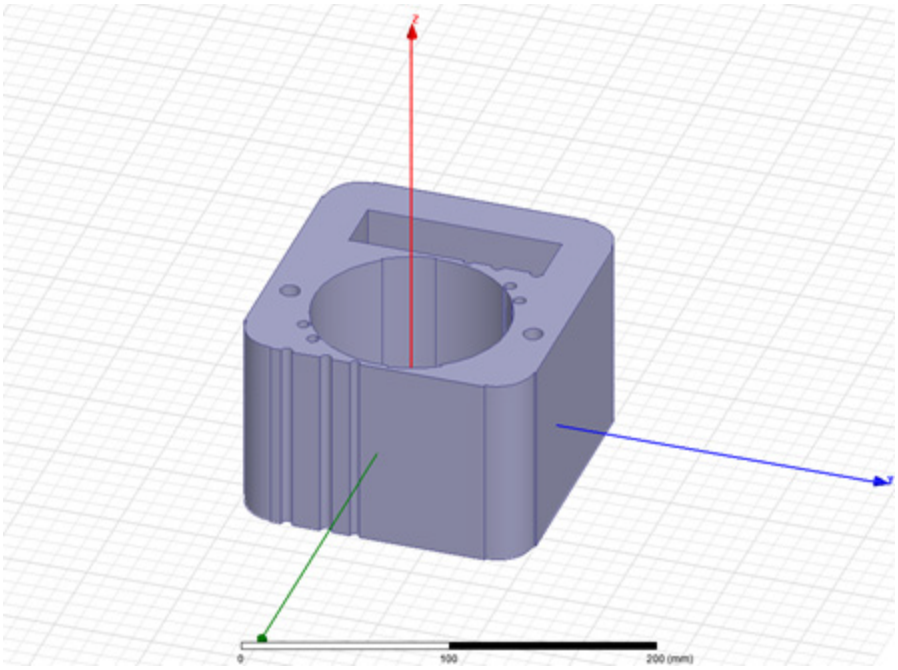

Figure 9-119 Core of ShadedPoleCore2

Creating a Coil and its Terminals (Shaded Pole Core)

A coil of a shaded pole core is created by manually setting the property of **InfoCore** to 2 and **Info Term** to 0. An example of the coil for a ShadedPoleCore2 UDP is shown in Figure 9-120 .

You can create its terminals by setting the property of **InfoCore** to 2 and **Info Term** to 1 or 2 (for terminal1 and terminal2 respectively). Figure 9-121 gives an example of a terminal.

You can assign the values of these properties either when creating a shaded-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

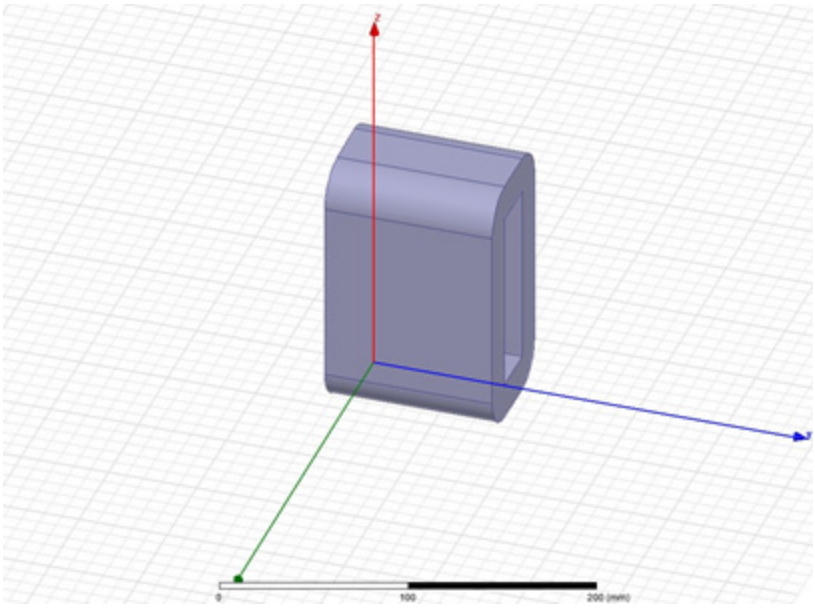

Figure 9-120 A coil of a ShadedPole Core

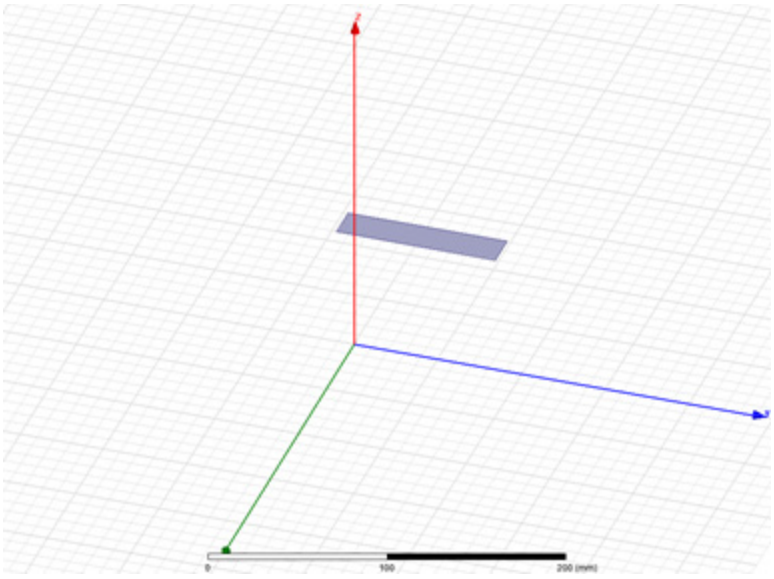

Figure 9-121 A terminal of a coil for a ShadedPole Core

Creating a Jointed or a Separated Shaded Conductor and Its Terminals

You can create a jointed conductor by manually setting the parameter **InfoCore** to 3 and **Info Term** to 0. At the same time, set **InfoEnd** to 1 to make the conductor connected. An example of a jointed conductor is shown in the following figure.

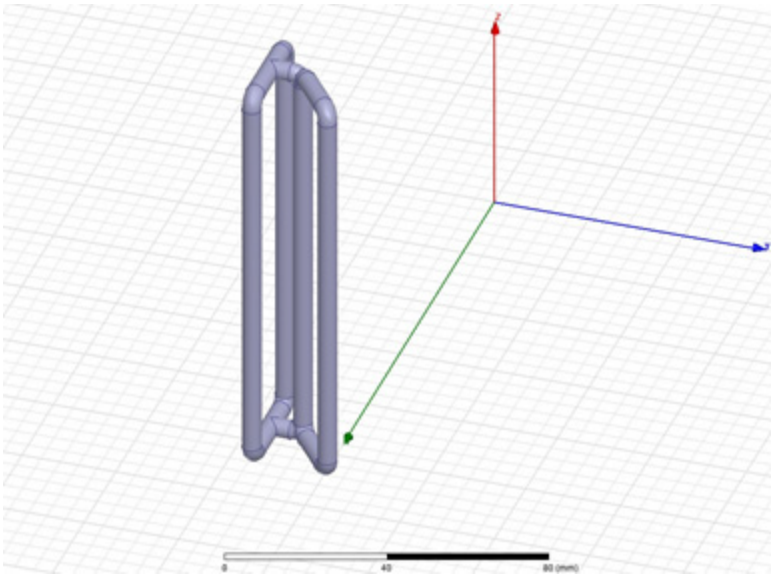

Figure 9-122 A jointed shaded conductor for a ShadedPole Core

You create a separated conductor by changing **InfoEnd** to 0. Set **InfoCore** to 3 or 4 to create conductor 1 or 2, respectively. **Info Term** remains 0. The following figure provides an example of the separated conductor.

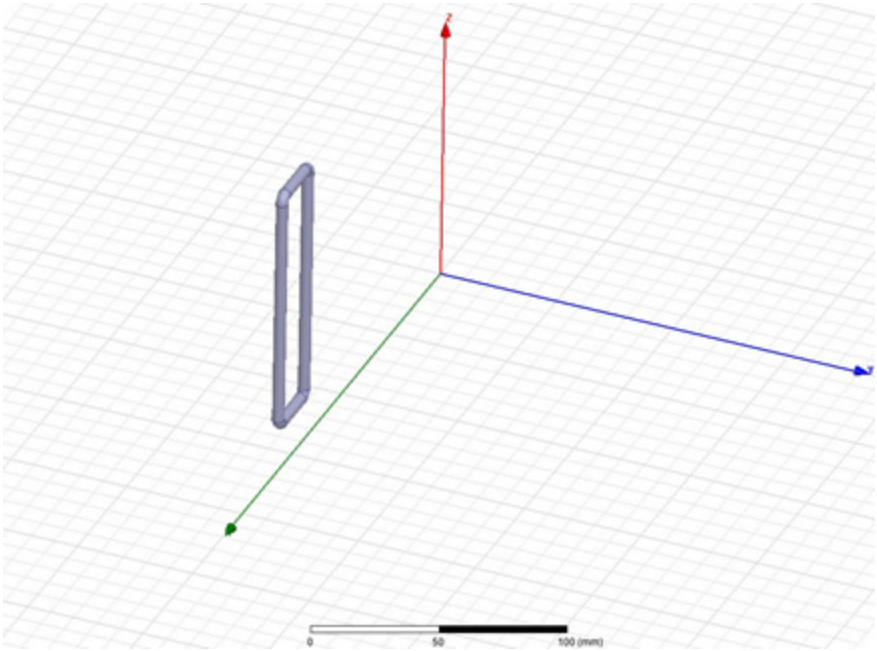

Figure 9-123 A separated shaded conductor for a ShadedPole Core

You create terminals of a conductor by changing the **Info Term** to 1 or 2 for terminal1 or terminal2, respectively. At the same time, **InfoCore** should be 3 or 4. Figure 9-124 shows the results of setting the parameters.

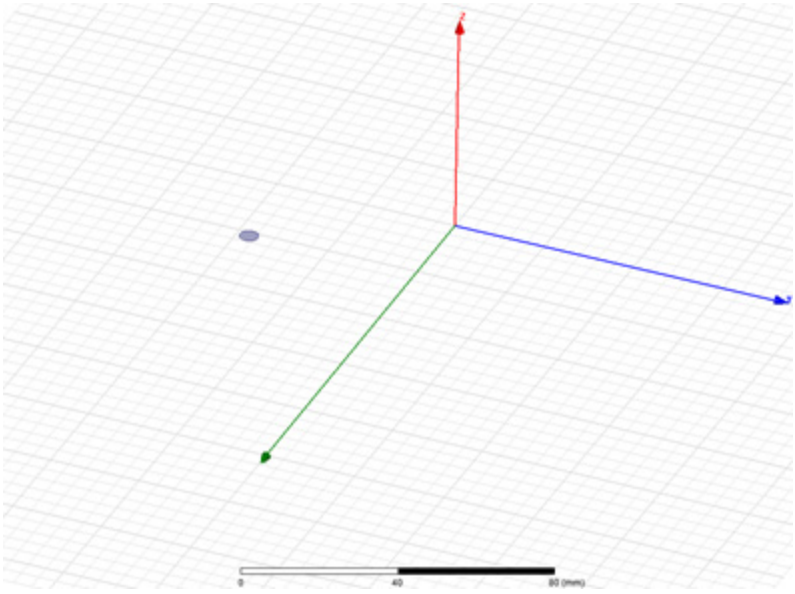

Figure 9-124 A terminal of conductor for a ShadedPole Core

Creating a Core with Poly Holes

Normally a Shaded Pole Core UDP has only one pair of holes. In order to create a poly-hole Pole Core UDP, you need to use subtraction and move commands. Detailed steps are as follows.

1. Create a core as described in Creating an Outer Shaded-Pole Core.

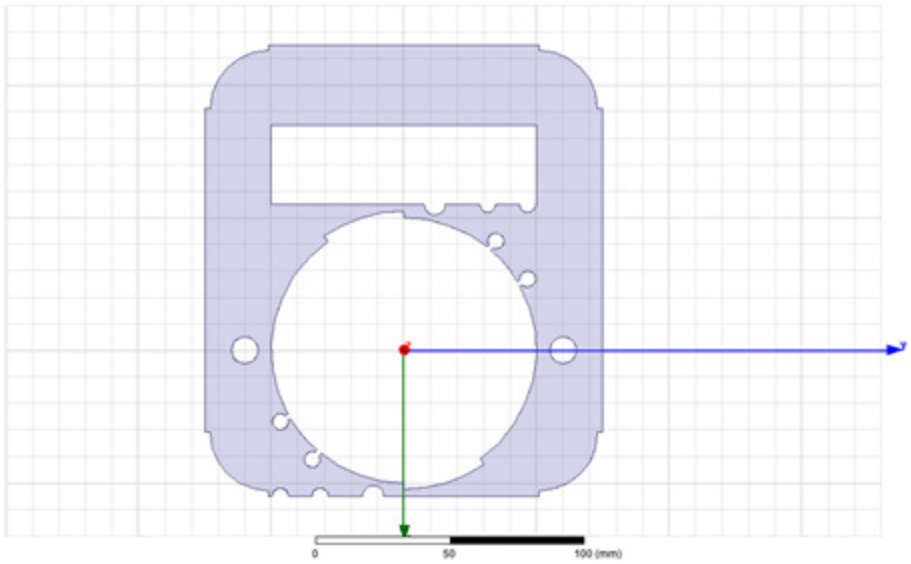

Figure 9-125 Original ShadedPoleCore

2. Make a copy of the current core.
3. Select the desired inner core in the history tree, and right-click to choose **Edit>Copy**.

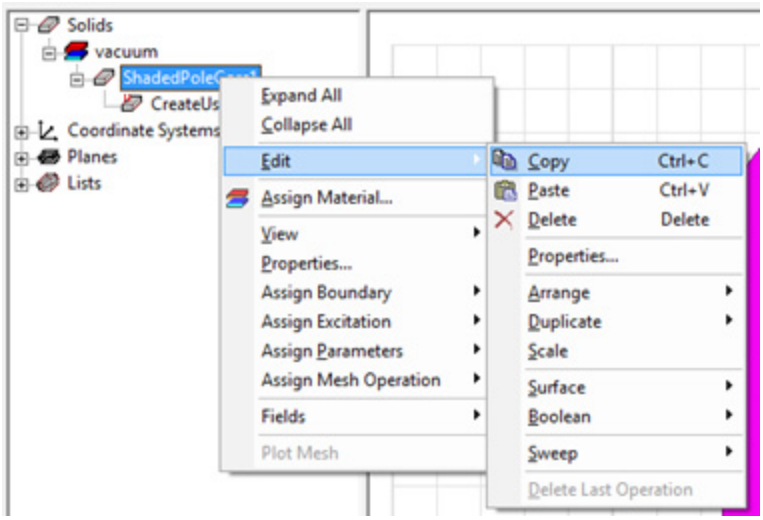

Figure 9-126 Copy ShadedPoleCore

4. Then right-click the same object in the history tree to choose **Edit>Paste**. This process is shown in the following figure:

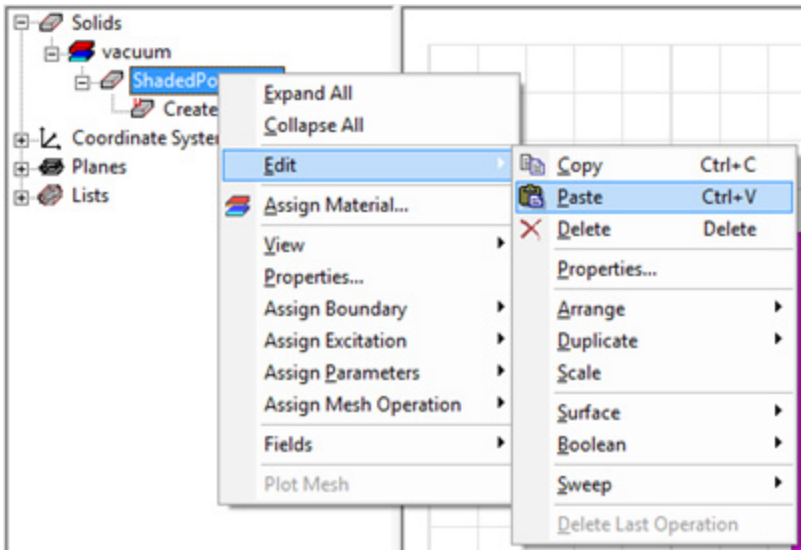

Figure 9-127 Paste ShadedPoleCore

5. Change the new object to a Hole filler.

   Click on **CreateUserDefinedPart** of ShadedPoleCore2 objectand set **InfoCore** property to **5** in the pop-up window. The objects in the coordinate system window are shown in the following figure:

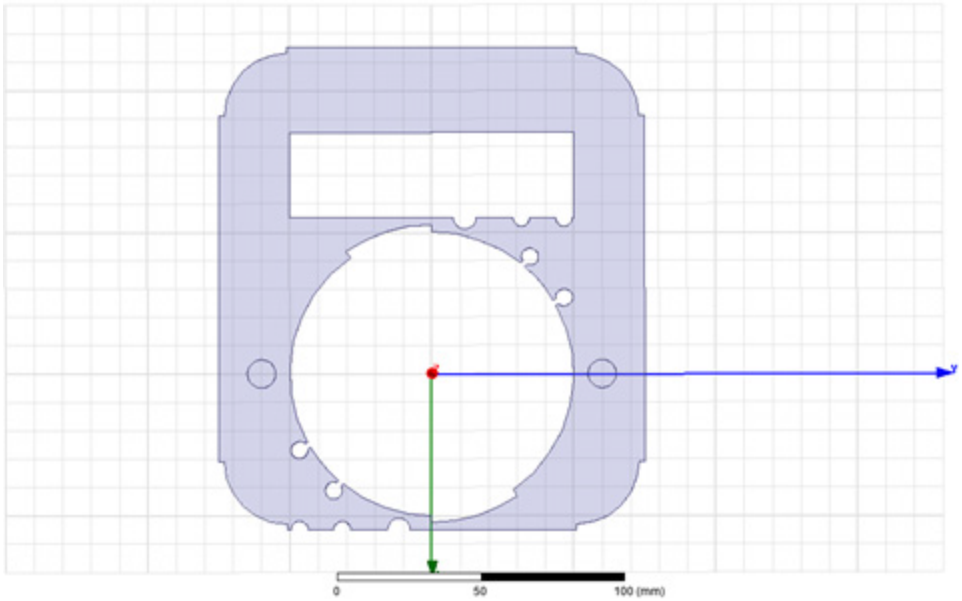

Figure 9-128 Change the InfoCore of the second ShadedPoleCore

6. Move the hole filler to another position for subtraction.
7. Select the hole filler (ShadedPoleCore2) in the history tree.
8. Click **Edit**>**Arrange**>**Move** from the menu. The modeler switches to move mode and prompts you for a reference point in the status bar.

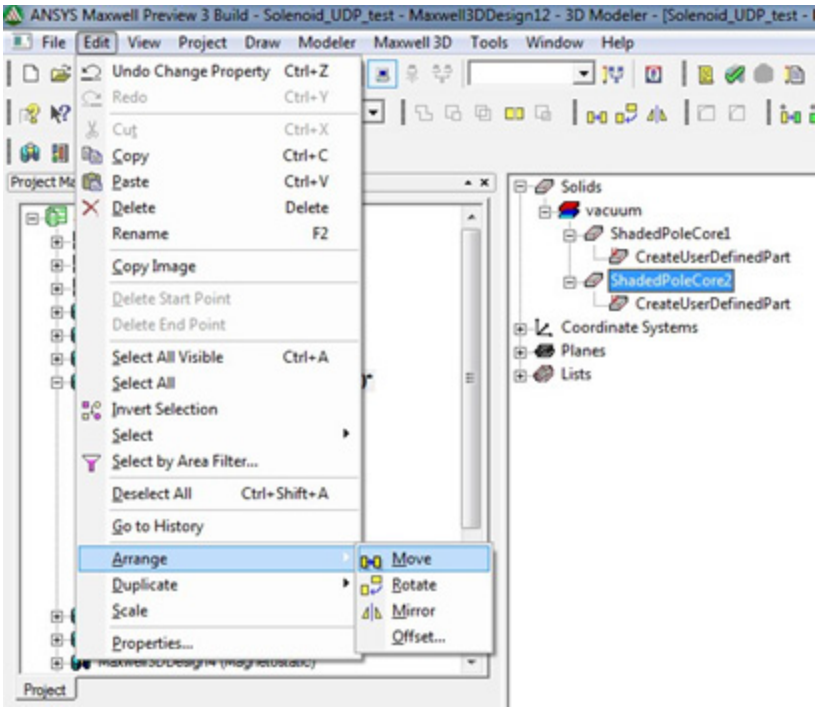

Figure 9-129 Move the position of the hole filler

9. Enter a reference point by clicking at the origin. Another option is to enter **(0, 0, 0)** in the keyboard entry area of the status bar, and press **Enter**.
10. Enter a target point along the Z-axis by clicking the mouse along the axis. Another option is to enter **(30, 0, 0)** in the keyboard entry area, and press **Enter**, which is shown in the

following figure.

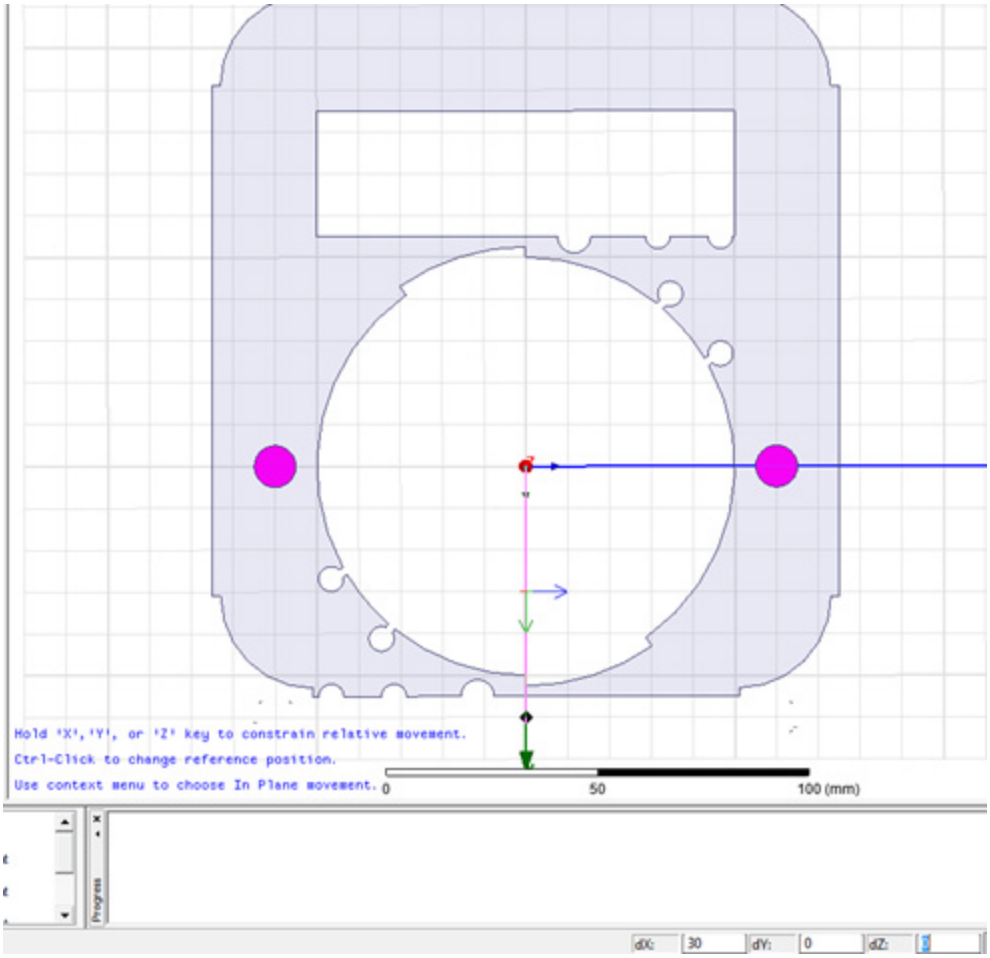

Figure 9-130 Enter a target position

11. Choose the core (ShadedPoleCore1) and the hole filler (ShadedPoleCore2) to make a subtraction.
12. Select both the core and hole filler by pressing **Ctrl** on the keyboard.

13. Click **Modeler**>**Boolean**>**Subtract** to subtract the two selected objects.

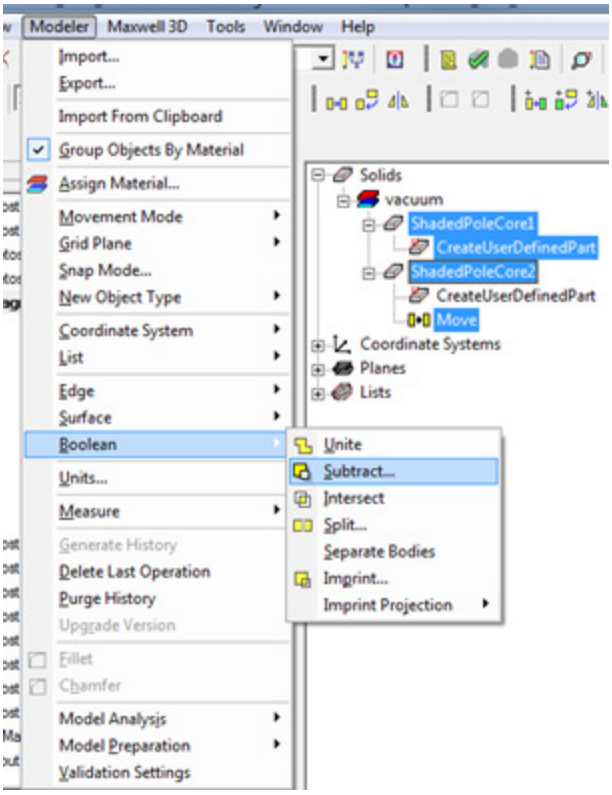

Figure 9-131 Choose Subtract operation from Boolean operation

14. In the **Subtract** window, put core (ShadedPoleCore1) in the **Blank Parts** and hole filler (ShadedPoleCore2) in **Tool Parts**.

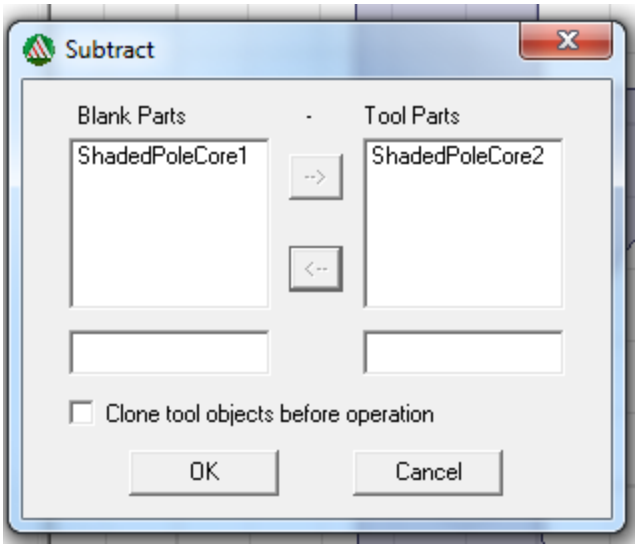

Figure 9-132 Select the Blank Parts and Tool Parts

15. Click **OK** to finish subtraction. The core look likes the following figure:

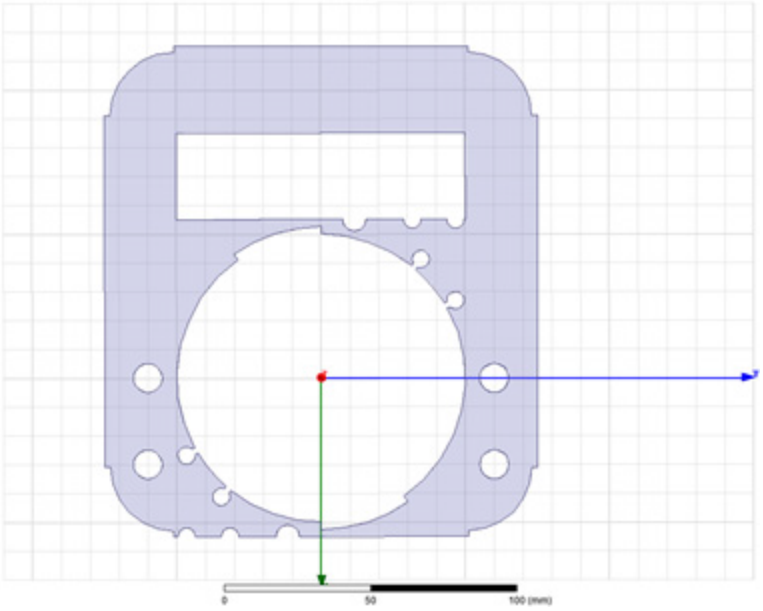

Figure 9-133 Finish subtraction

Another option is to copy and paste multiple cores, change them to hole fillers and move them to different positions to create a core with more than 2 pairs of holes. The following figure shows a sample hole:

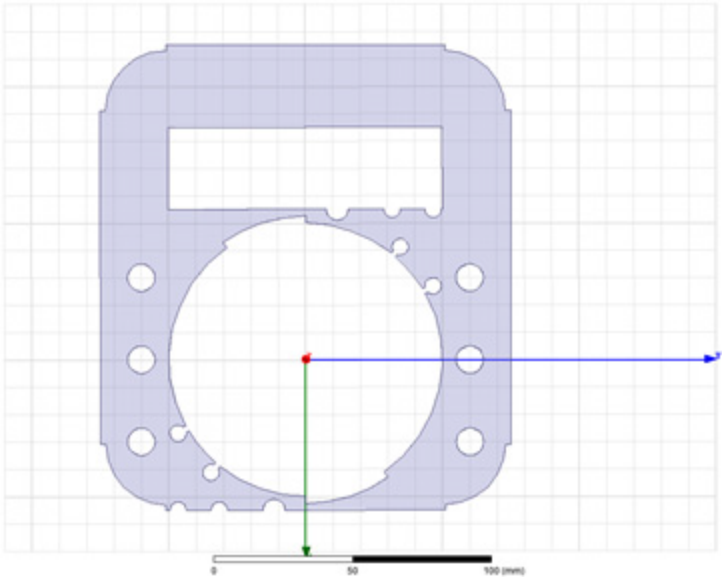

Figure 9-134 ShadedPoleCore with multiple poles

UnivMCore UDP

The UnivMCore UDP is used to create the stator core and the field winding of a universal motor. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, or inner diameter.
DiaYoke	Core diameter on yoke side, or outer diameter.
Length	Core length.
Skew	Skew angle in core length range.
Poles	Number of poles.
PoleType	Pole type: 1 to 2.
WidthCore	Overall width of a racetrack core.
Embrace	Pole embrace (the ratio of pole arc to pole pitch).
Offset	Pole arc offset.
WidthPole	Minimum width at pole root.
Ty	Yoke thickness.
Ts	Shoe-tip thickness.
R1	Radius of the screw holes in pole center.
R2	Radius of the side fillet arc at pole root.
R3	Radius of the side fillet arc center layout circle.
R4	Radius of the shoe connecting arc, 0 for auto-design.
R5	Inner radius of the screw holes in between two poles.
R6	Outer radius of the screw holes in between two poles.
EndExt	Coil one-side end extended length.
LenRegion	Region length.
InfoCore	0: core; 1: coils; 2: one coil; 3: terminal1; 4: terminal2; 100: region.

These parameters are used in the following figures:

Note	• In figures with both gray and red objects, gray objects are used as references. • Universal motor core is used as outer core, which means the value of DiaYoke is larger than that of DiaGap. • Although R4 is drawn in Figure 9-135 , it is not easy to be understood. It is the radius of a circle which is externally tangential to the circle of radius R2 and internally tangential to the circle of diameter of Ts on the same side of a pole. R4

	and the two circles that it is tangential to are marked in red. When the value of R4 is 0, the length of it is automatically designed.

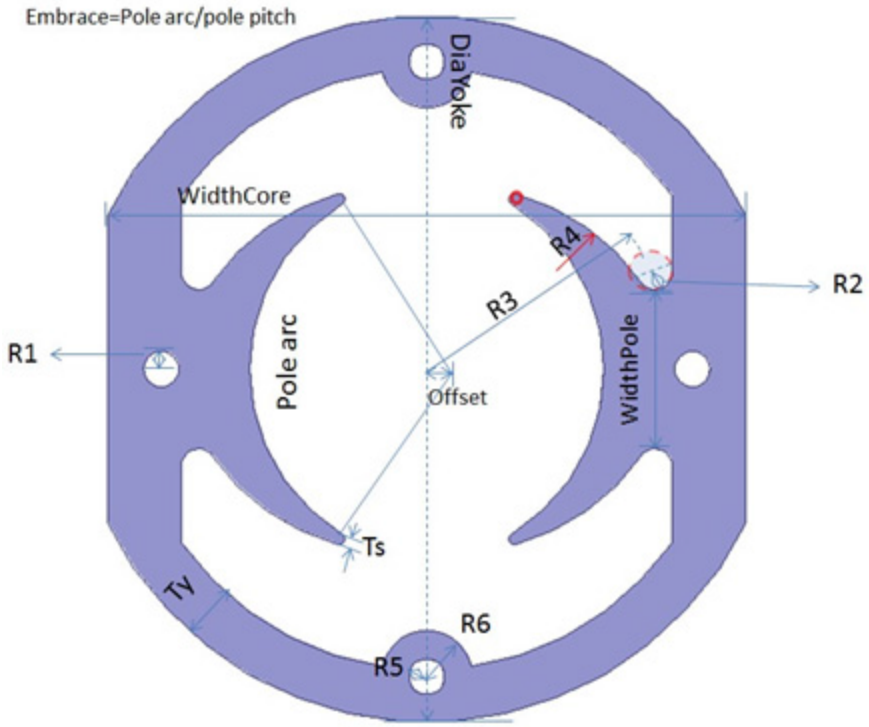

Figure 9-135 Parameters in UnivM Core

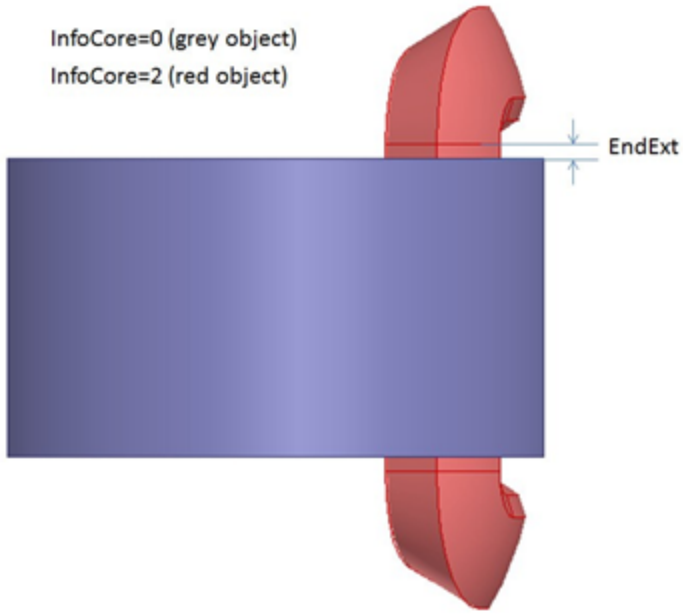

Figure 9-136 Two UnivM Core with different InfoCore value

Creating an Outer Universal Motor Core

This core is used only as an outer core. You can set the value of **DiaYoke** and **DiaGap** as **DiaYoke**>**DiaGap** to create an outer universal motor core. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

The following figure shows the results.

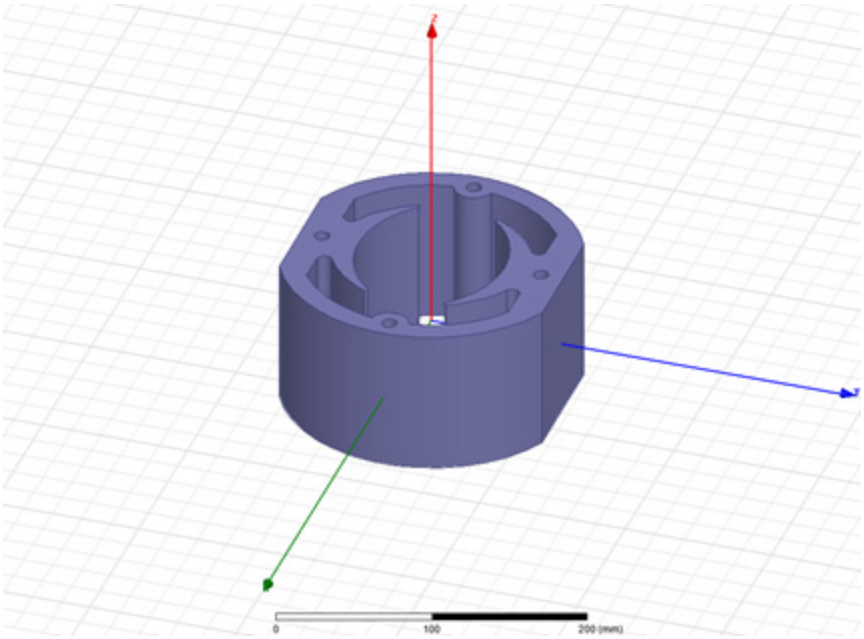

Figure 9-137 Outer universal-motor core

Creating All Coils (UnivMCore)

You can create all coils of a universal-motor core manually by setting the property of **InfoCoil** to 1.

You can assign the value of this property either when creating a universal-motor core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

The following figure gives an example of all coils for this UDP.

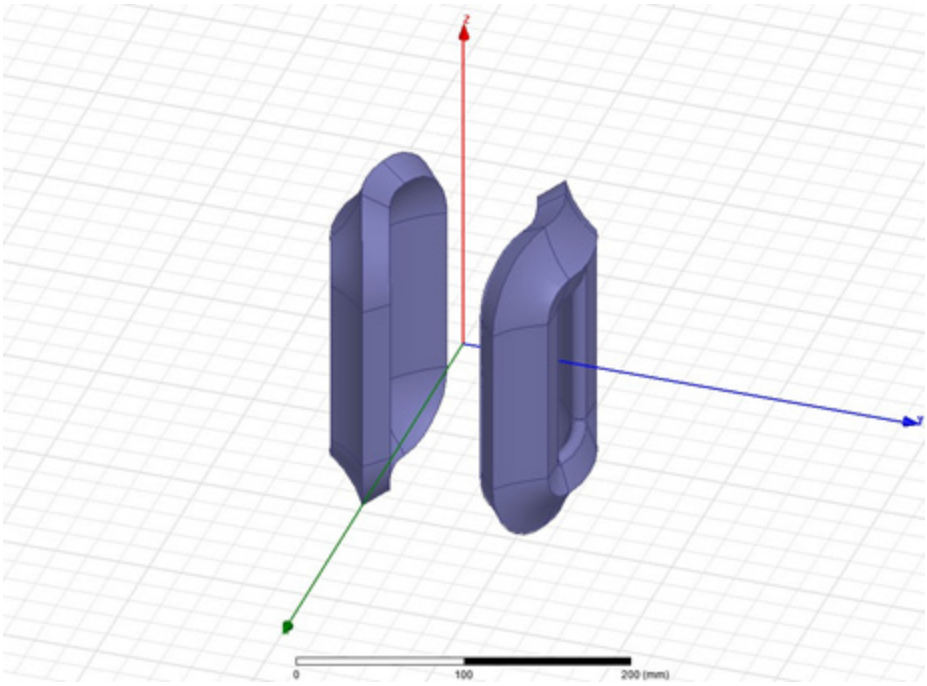

Figure 9-138 Coils of Universal-Motor Core

Creating a Coil and its Terminal (UnivMCore)

You can create a coil of a universal-motor core manually by setting the property of **InfoCoil** to 2, shown in Figure 9-136 as a red object.

You can create its terminals by setting the property of **InfoCoil** to 3 or 4 (for terminal1 and terminal2 respectively).Figure 9-139 shows what a terminal looks like.

You can assign the value of this property either when creating a universal-motor core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

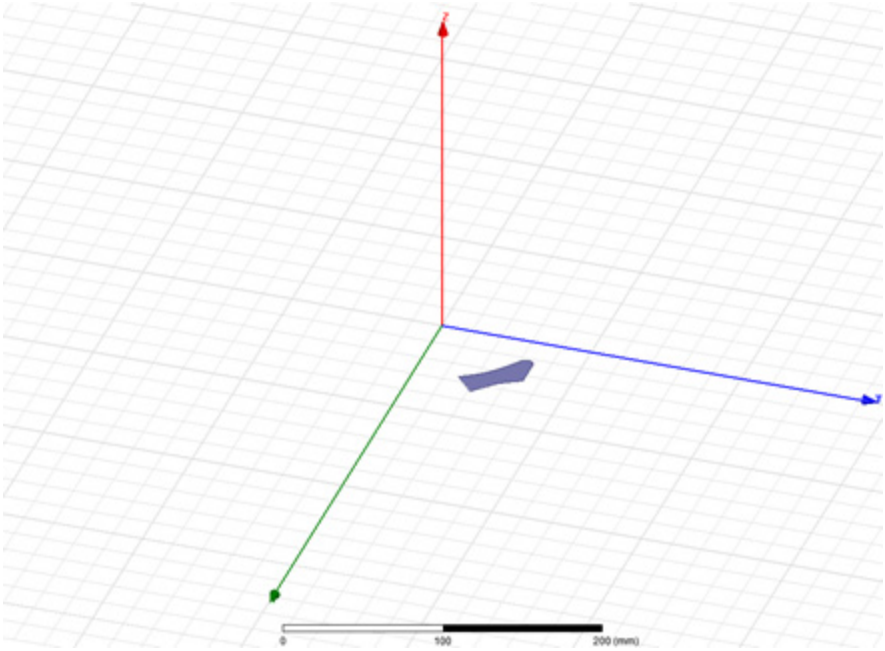

Figure 9-139 A terminal of a coil of Universal-Motor Core

SRMCore UDP

The SRMCore UDP is used to create the stator core, a stator winding, and the rotor core for switched reluctance motors. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke<DiaGap for inner cores.
Length	Core length.
Poles	Number of poles.
ThkYoke	Yoke thickness.
Embrace	Pole embrace (the ratio of pole arc to pole pitch).
Delta	One side pole-edge angle, 0 for parallel pole edges.
RFillet	RFillet > 0 for SRM cores with fillet corner; RFillet < 0, its absolute value defines the height of the V-shape slot bottom.
EndExt	Coil one-side end extended length.
LenRegion	Region length.
InfoCore	0: core; 1: core & coils; 2: coil; 3: terminal1; 4: terminal2; 100: region.

These parameters are used in the following figures.

Figure 9-142 shows the parameter **EndExt**, which is a parameter of a coil. The **InfoCore** value of **EndExt** is 1 (core & coils) to better describe the parameter.

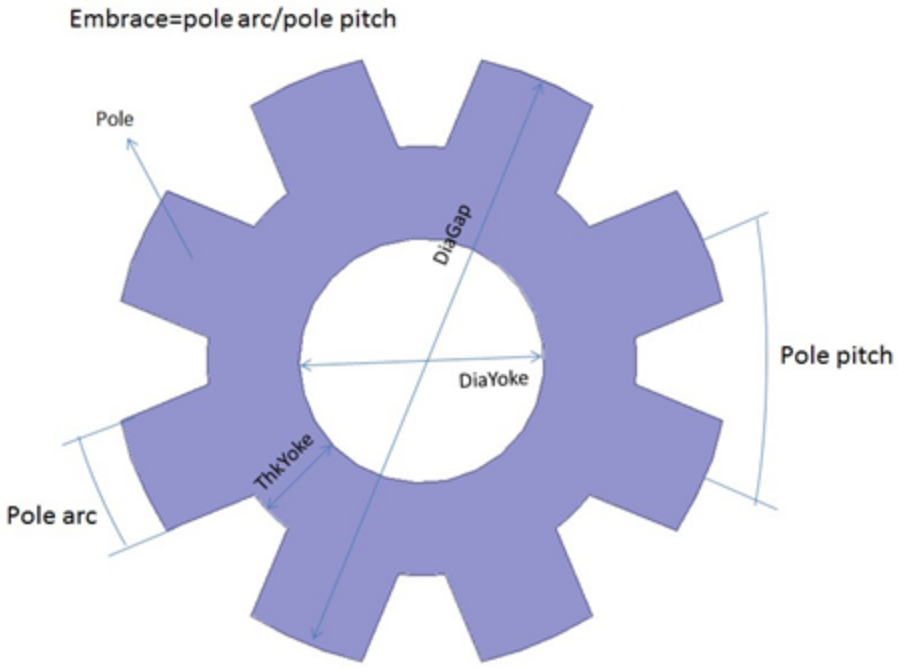

Figure 9-140 Inner core of SRM Core (InfoCore set to 0)

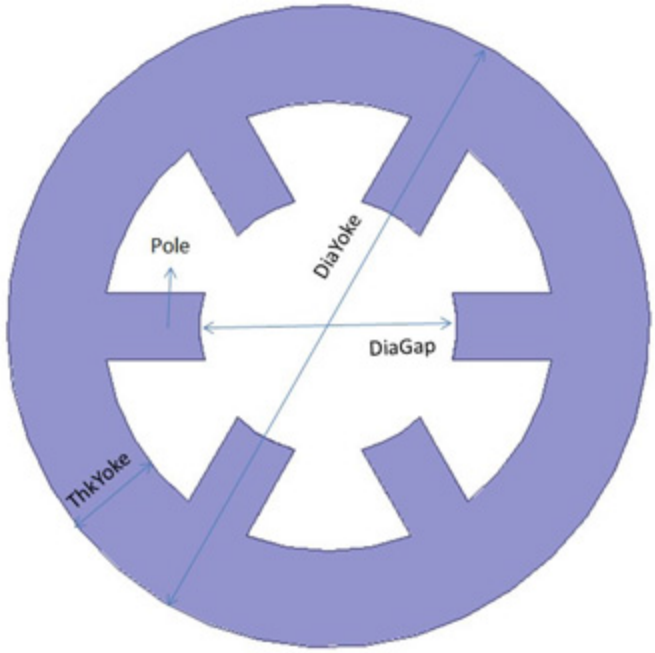

Figure 9-141 Outer core of SRM Core (InfoCore set to 0)

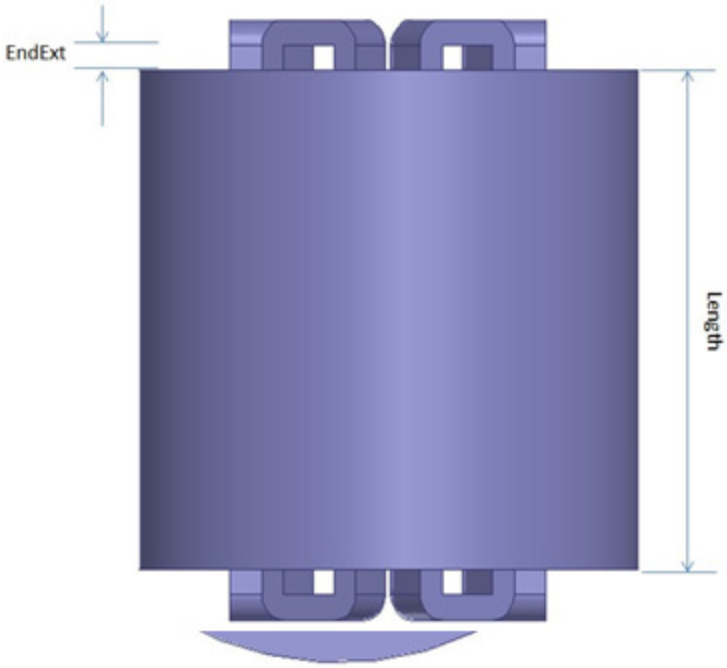

Figure 9-142 Core & coils of SRM Core (InfoCore set to 1)

Creating an Inner or Outer Core for Switched Reluctance Machines

You can set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

Examples of inner SRM core are shown in Figure 9-140 and Figure 9-143 . For outer core, refer to Figure 9-141 and Figure 9-144 .

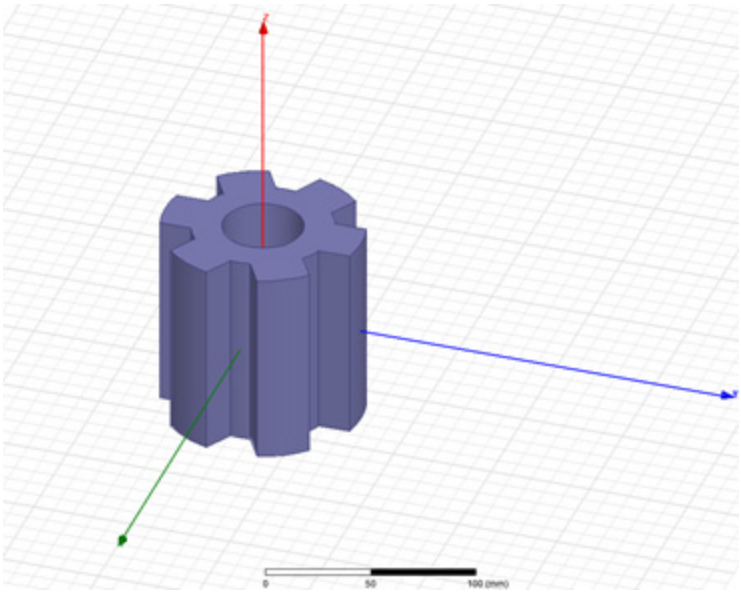

Figure 9-143 3D inner core of SRM Core (InfoCore set to 0)

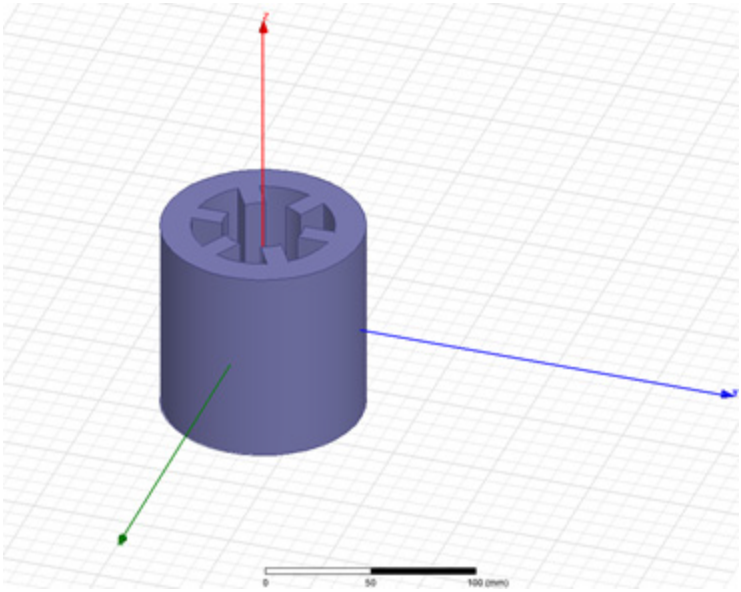

Figure 9-144 3D outer core of SRM Core (InfoCore set to 0)

Creating Core and All Coils (SRMCore)

You can create a core and all coils of an SRM Core manually by setting the value of **InfoCoil** to 1.

You can assign the value of this property either when creating an SRM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Core and all coils can be created only when the core is an outer core (value of **DiaYoke** > **DiaGap**).

Examples of this core are shown in Figure 9-142 and Figure 9-145 .

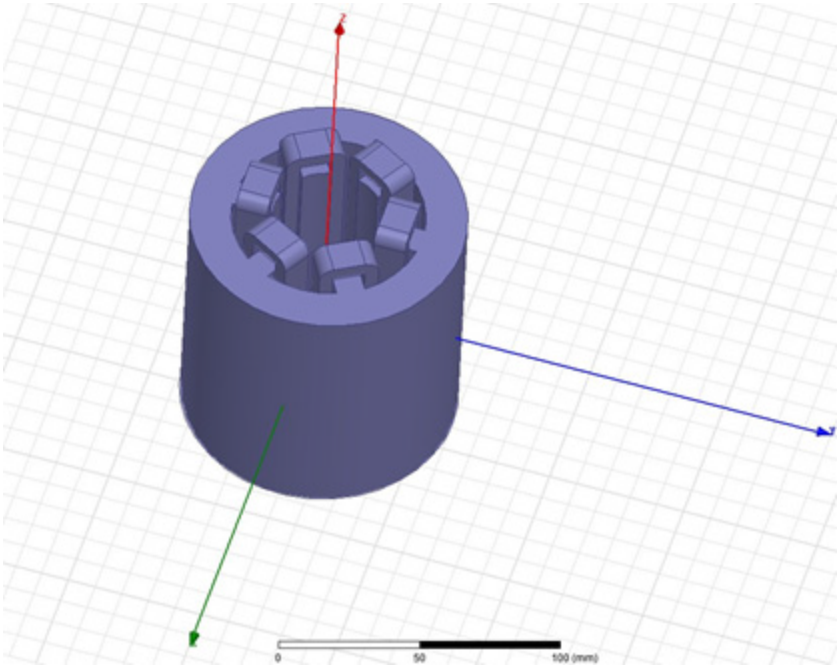

Figure 9-145 3D core and coils of SRM Core (InfoCore set to 1)

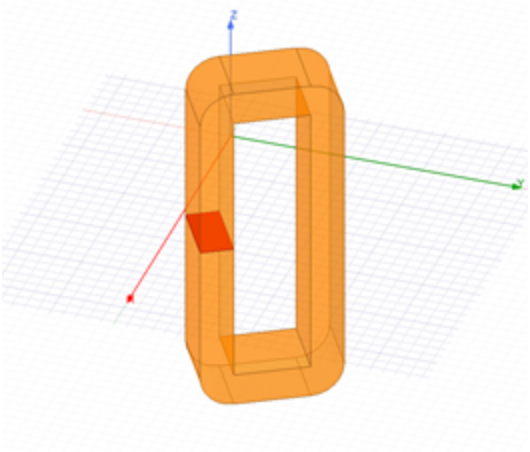
Creating a Coil and its Terminal (SRMCore)

You can create a coil of an SRM core manually by setting the value of **InfoCoil** to 2. An example is shown below.

You can create a terminal manually by setting the property of **InfoCoil** to 3 or 4, for terminal1 or terminal2 respectively. An example is shown by the red sheel in the figure.

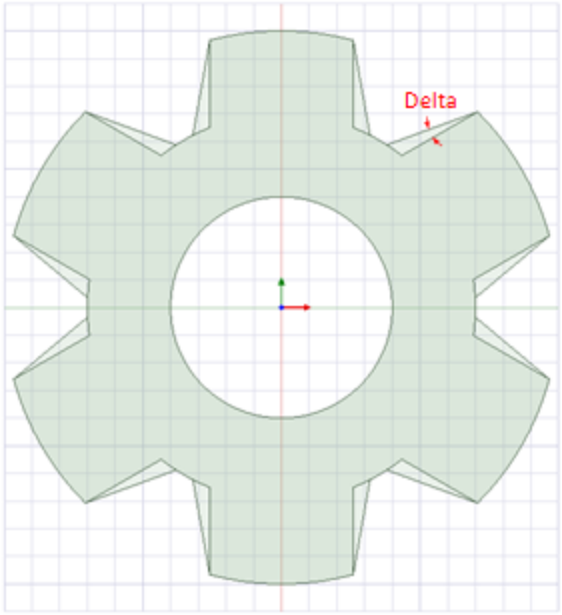
You can assign the value of this property either when creating an SRM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.



Single coil and its terminal created by SRMCore

Creating Core with Unparallel Pole Edges (SRMCore)

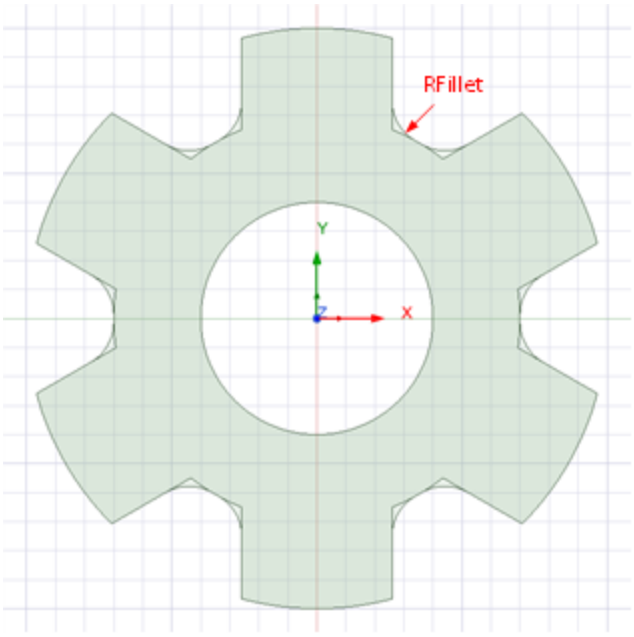
Parameter **Delta** is introduced to define one side pole-edge angle, as shown below. When **Delta** = 0, the two pole-edge sides are parallel.



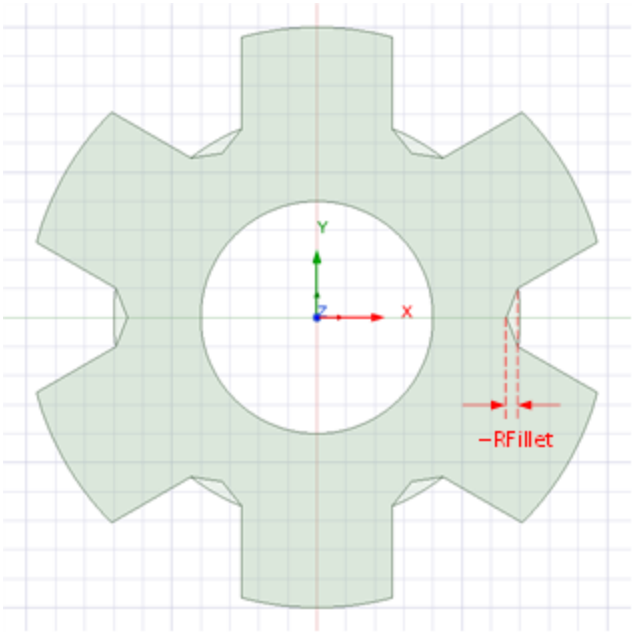
Parameter **Delta** for unparallel pole edges

SRM Core with Slot Corner Fillet and V-Shaft Bottom

Parameter **RFillet** is introduced to define corner fillet radius. **RFillet** > 0 for SRM cores with fillet corner as shown below.



When parameter **RFillet** < 0, its absolute value defines the height of the V-shape slot bottom as shown below.



SynRMCore UDP

The SynRMCore UDP is used to create the rotor core for synchronous reluctance machines.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles
PoleType	1: ALA; 2: arc; 3: hyperbolic; 4: hyperbolic line.
Barriers	Barriers per Pole, for PoleType 2 & 3 only.
H	Bridge thickness, for PoleType 2 & 3 only.
W	Rib width, for PoleType 2 & 3 only.
R	Barrier fillet radius, for PoleType 2 & 3 only.
R0	Radius of the bottom barrier arch, for PoleType 2 only.
Rb	Barrier bottom minimum radius.
Y0	Yoke bottom thickness.
B0	Barrier bottom thickness, for PoleType of 2 & 3 only.
LenRegion	Region length.
InfoCore	0: core; 1: one barrier; 100: region.

The SynRM UDP supports four pole types:

- **Type 1** – axially laminated core
- **Type 2** – barriers with concentric arcs and lines
- **Type 3** – barriers with hyperbolic curves
- **Type 4** – barriers with hyperbolic polylines

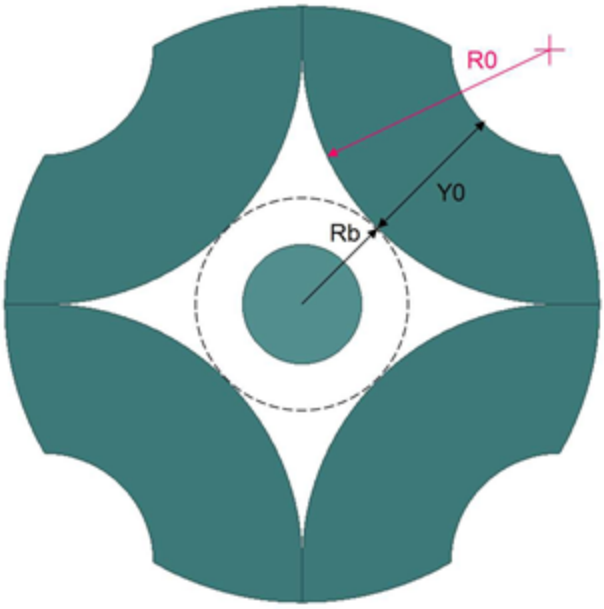
Type 1

Type 2

Type 3

Type 4

Parameters for SynRM core with PoleType = 1



In the figure, *R0* is a derived parameter, as given below:

$$R0 = Rb\sin\theta/(1 - \sin\theta)$$

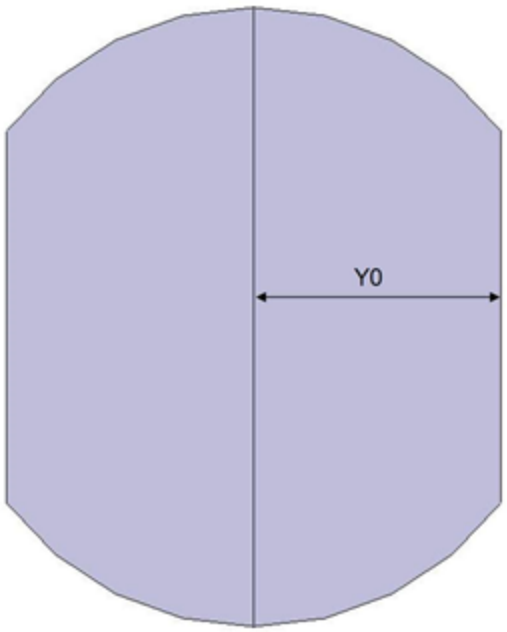
where $\theta = \pi/p$, and p, the number of poles, should be ≥ 4.

The center point (x, y) of the *R0* circle is:

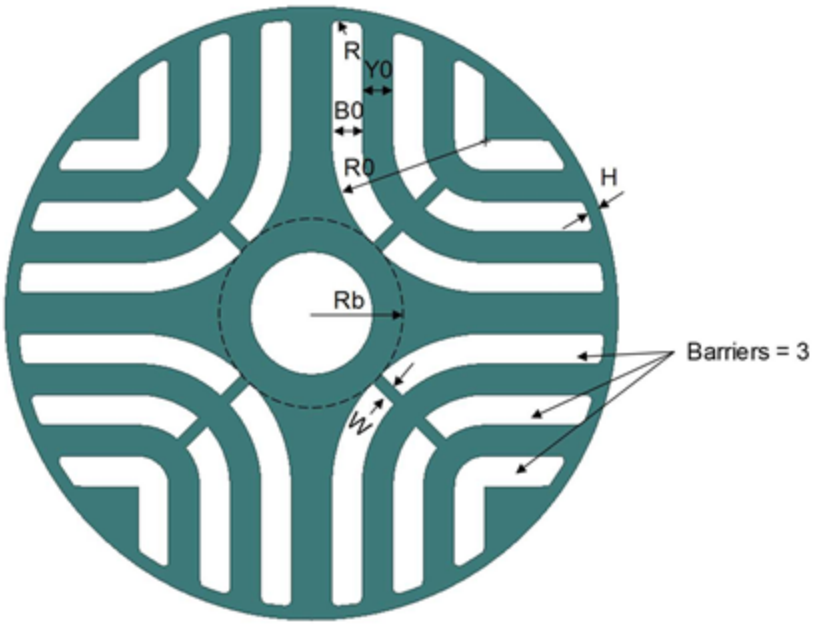
$$x = (Rb + R0)\cos\theta$$

$$y = (Rb + R0)\sin\theta$$

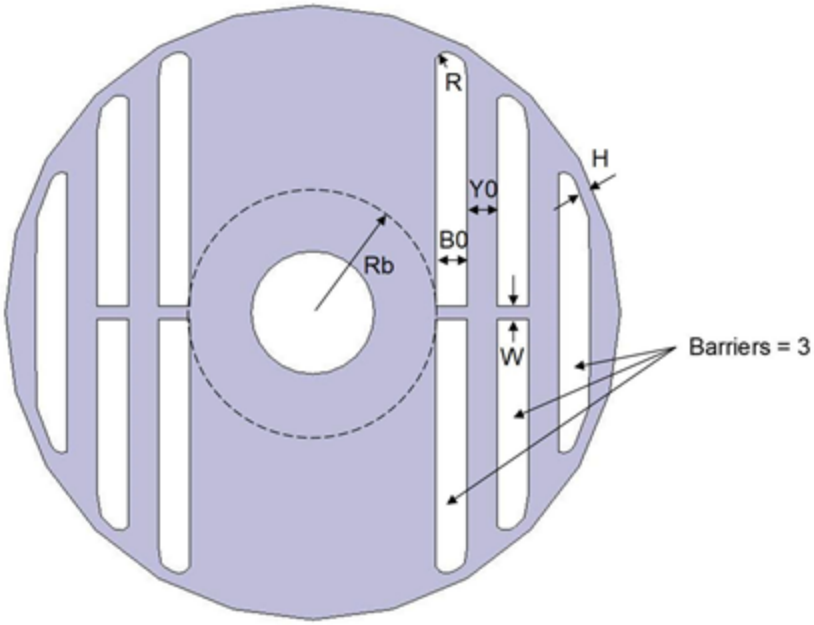
Below is a two-pole SynRM core with PoleType = 1.



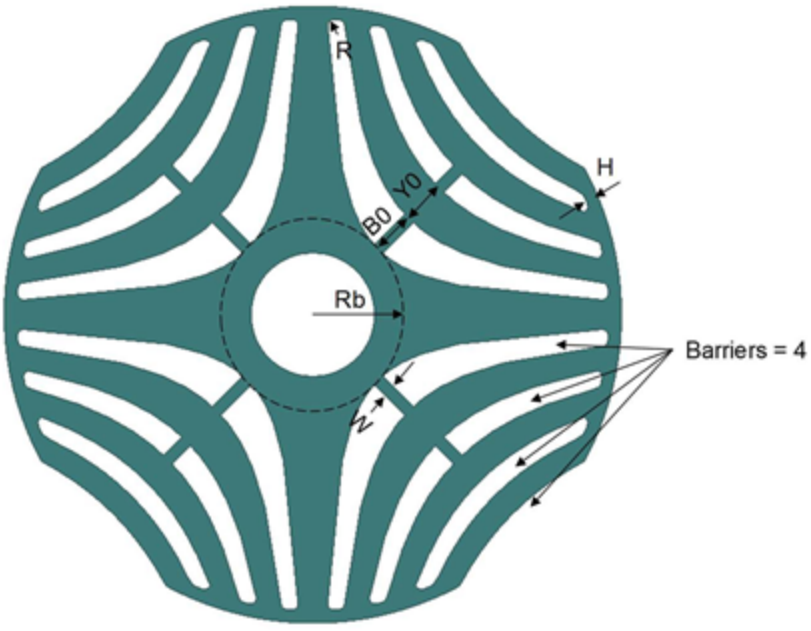
Parameters for SynRM core with PoleType = 2



Below is a two-pole SynRM core with PoleType = 2



Parameters for SynRM core with PoleType = 3



The main edges of barriers for Type 3 are hyperbolic curves defined by

$$r^2 \sin(pp \bullet \theta) = R_m^2$$

$$x = r \bullet \cos\theta$$

$$y = r \bullet \sin \theta$$

where *pp* is the number of pole pairs, $\pi/pp > \theta > 0$, and R_m is the minimum radius of a hyperbolic line. For different R_m values, you will get different hyperbolic curves.

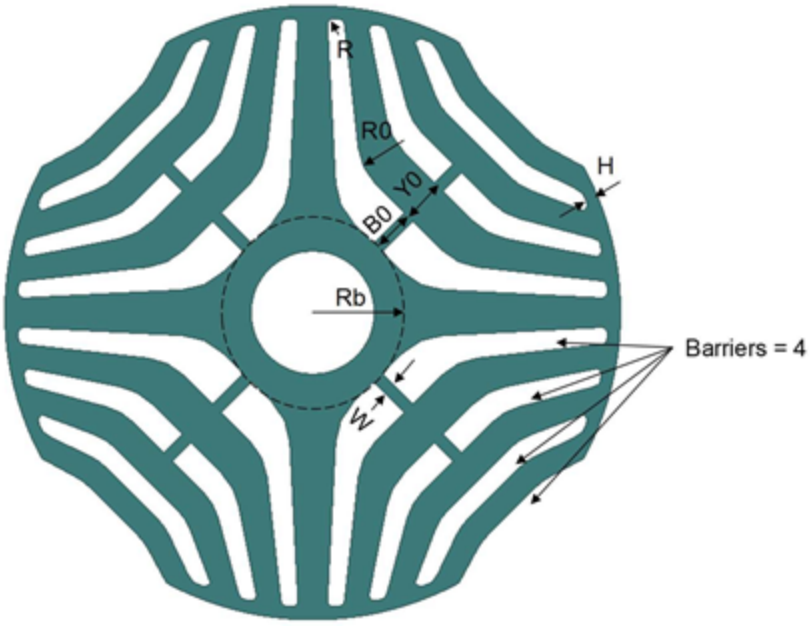
The first barrier is created based on the following two hyperbolic curves:

- for the bottom hyperbolic curve, *Rm2* = *Rb*
- for the top hyperbolic curve, *Rm1* = *Rb* +*B0*

The second and all other barriers are created based on a constant minimum barrier width and minimum tooth width at maximum limit radius which is derived from outer radius minus the value of bridge thickness parameter H.

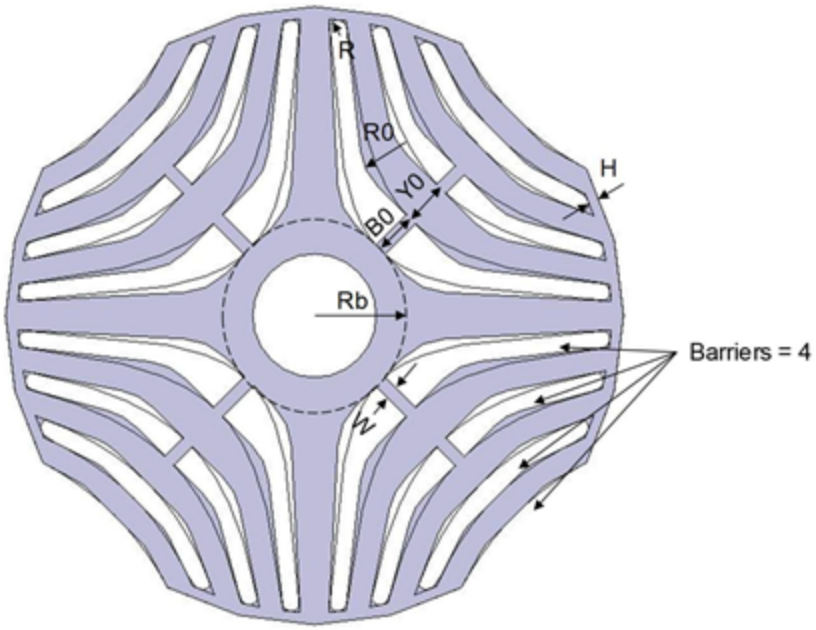
The minimum barrier width and minimum tooth width can be derived from *B0* and *Y0*, respectively. If the top and bottom hyperbolic curves are defined by *Rm1* and *Rm2*, respectively, and let *r* to be the maximum limit radius, you can obtain two points (*x1*, *y1*) and (*x2*, *y2*) at the maximum limit circle intersected with the top and bottom hyperbolic curves, respectively, based on the above hyperbolic curve equation. Please note that the distance between these two intersection points is not the minimum width because the connection line is not perpendicular to the center hyperbolic curve. The angle between the connection line and normal line is the angle between the *r* line and the tangent line which can be computed from *dy*/*dx* and *θ* of the center hyperbolic curve at the maximum limit radius.

Parameters for SynRM core with PoleType = 4



The main edges of barriers for Type 4 are hyperbolic polylines. A hyperbolic polyline is derived from a hyperbolic curve. It consists of one bottom line (tangent to the bottom points of the hyperbolic curve), two side lines (tangent to the point on the hyperbolic curve at the maximum limit radius), and fillet arcs defined *R0*. The value of fillet radius *R0* is the same for all hyperbolic

polylines. All parameters for hyperbolic curves to derive hyperbolic polylines are defined in the same way as those for pole Type 3. The following figure shows how barriers of Type 4 are derived from those of Type 3.



Note: Two-pole SynRM cores for Types 3 and 4 will be the same as those of Type 2.

Creating an Inner Core for a Synchronous Reluctance Machine

You can set the value of **DiaYoke** and **DiaGap** as **DiaYoke<DiaGap** to create inner cores. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

Figure 9-146 gives an example of an inner core for SynRM.

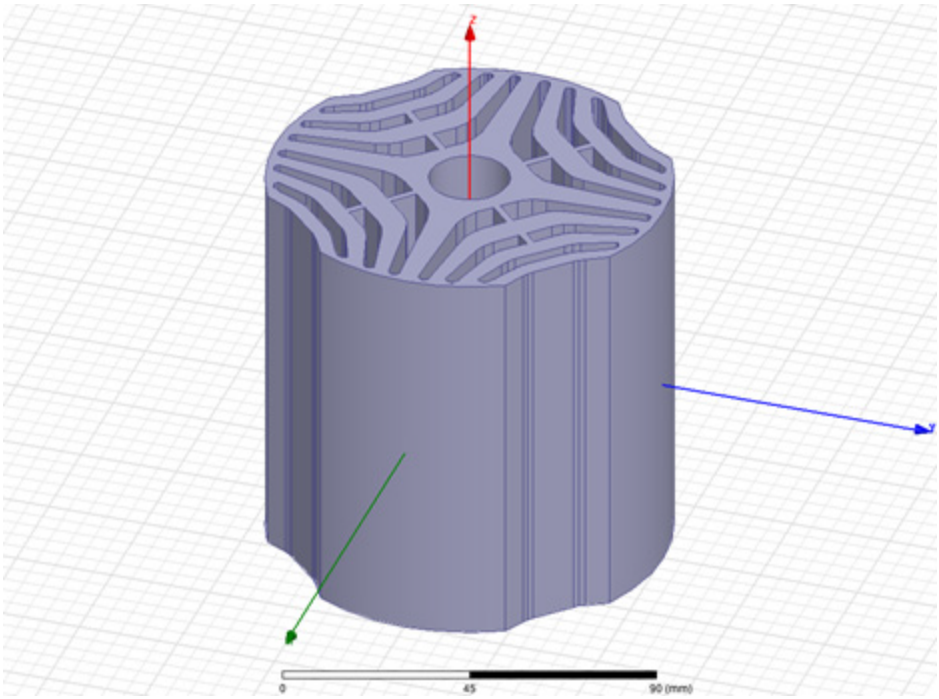


Figure 9-146 3D SynRM Core

Creating a SynRMCore with Different Barriers

You can create a SynRMCore with different barriers through several steps, as follows.

1. Create a SynRMCore as shown in Creating an Inner Core for a Synchronous Reluctance Machine.

2. Change the value of Barriers to 1. The result is shown in the following figure.

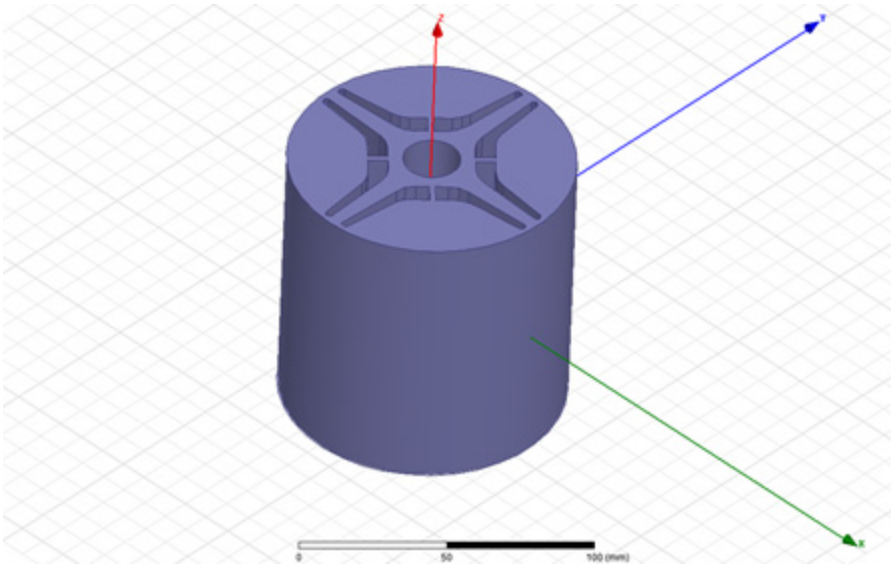

Figure 9-147 A SynRMCore with one barrier

3. Change the value of **DiaGap** to be larger and make the value of **Y0** smaller to make enough space for other barriers. You can modify these values by clicking on **CreateUserDefinedPart** in the history tree under the SynRMCore, as shown in the following figure.

   As an example, the values of **DiaGap** and **Y0** are changed to 130 and 5, respectively.

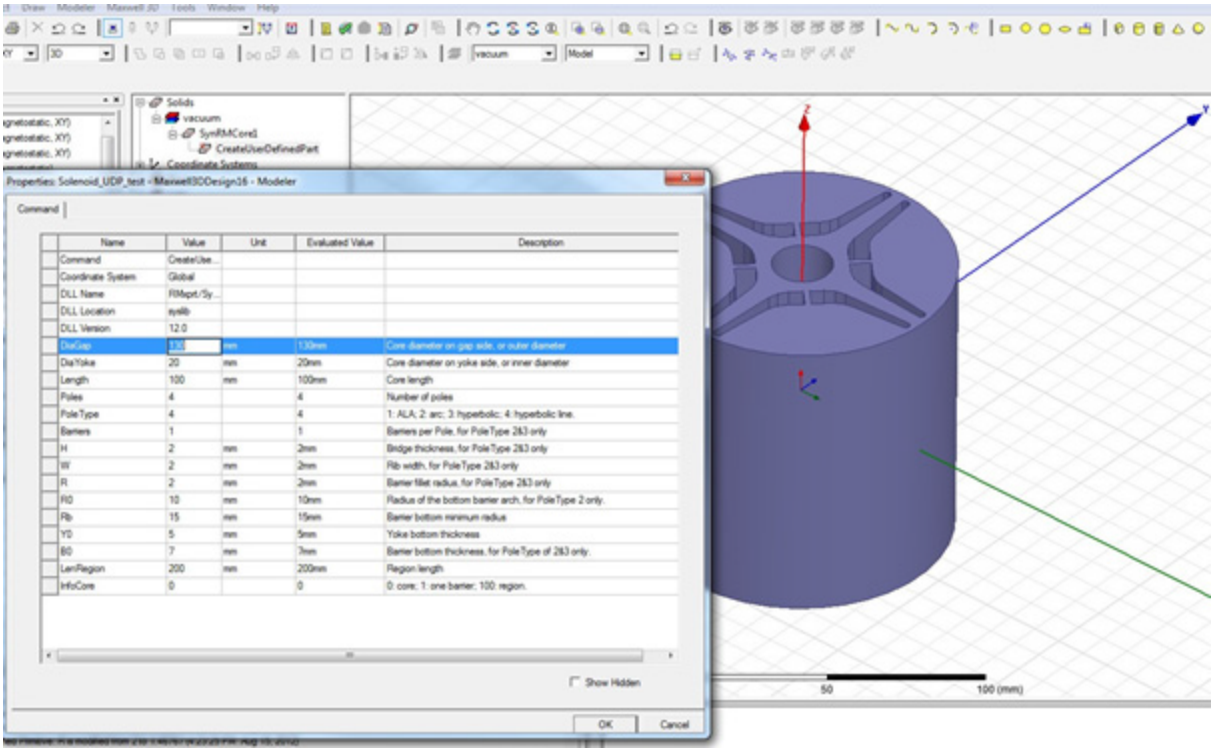

Figure 9-148 Changing the values of DiaGap and Y0

4. Make a copy (or multiple copies if more than 1 barrier is needed) of the current SynRMCore object.

   In the history tree, click **SynRMCore1**, press **Ctrl**+**C**, and then press **Ctrl**+**V** to duplicate the SynRMCore. After these processes, the history tree looks like the following figure (only for 1 copy situation):

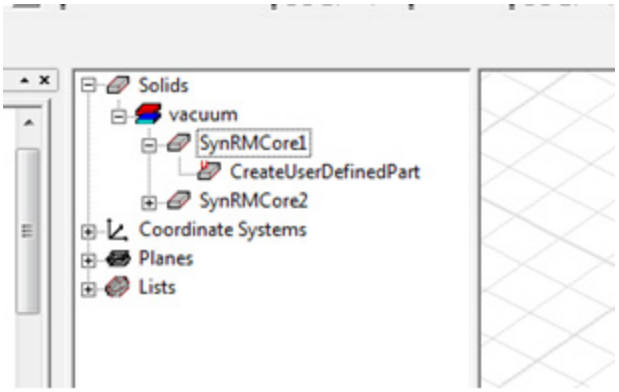

Figure 9-149 Make a copy of SynRMCore

5. Change the value of **InfoCore** of SynRMCore2 to 1 to create a barrier.

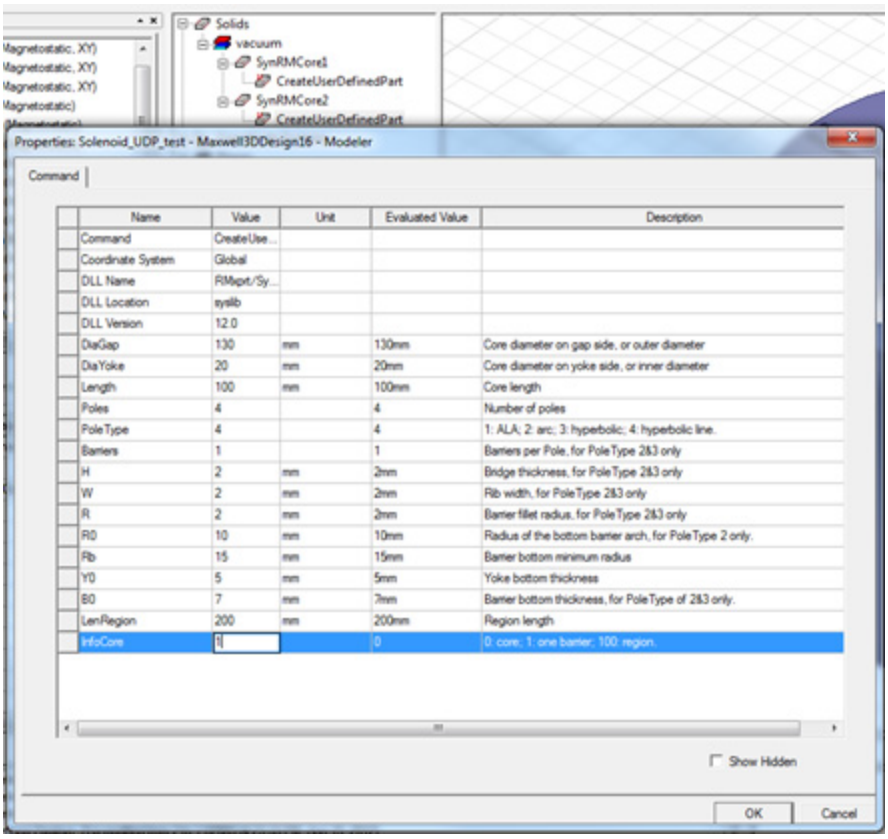

Figure 9-150 Changing the value of InfoCore of SynRMCore2

The result of this change is shown in the following figure.

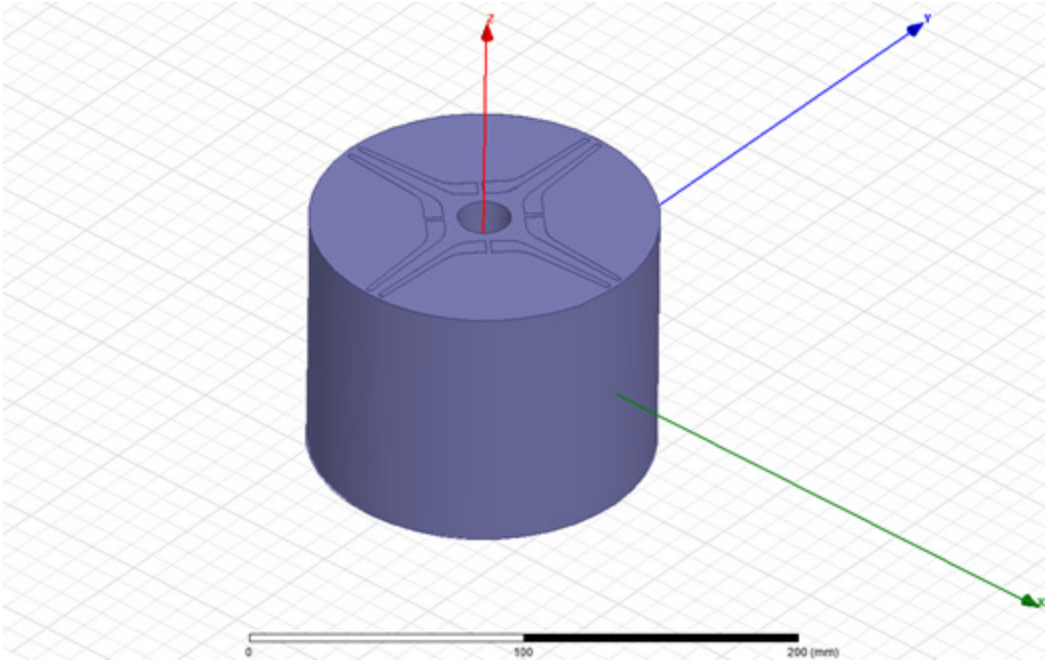

Figure 9-151 Result of InfoCore of SynRMCore2 being changed

6. Change the value of **Rb** of SynRMCore2 (barrier) to make it larger, and thus make the barrier away from the center of the core.

   As an example, the value of **Rb** of SynRMCore2 is changed from 15 to 25 by clicking on **CreateUserDefinedPart** in the history tree under the SynRMCore2, as shown in the following figure.

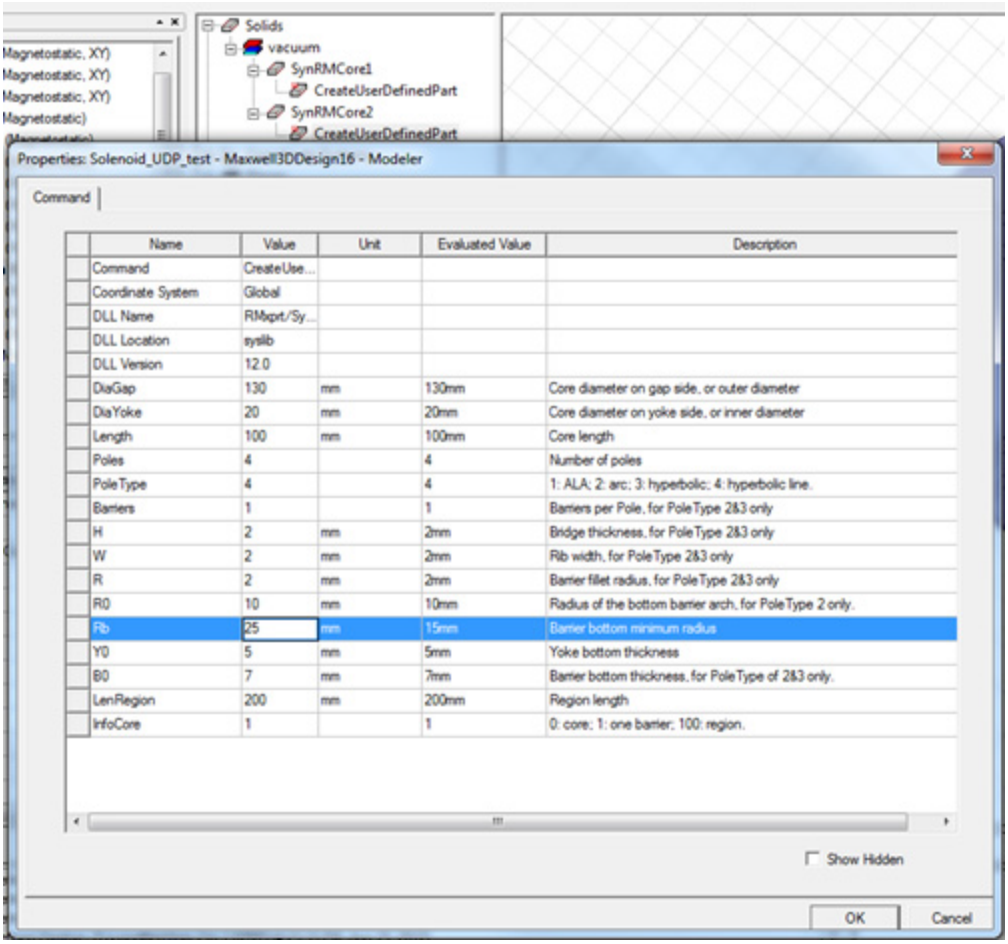

Figure 9-152 Changing the value of Rb of SynRMCore2

Another option is to change other values of SynRMCore2 (barrier) according to different needs, such as set the value of **W** to 0.

7. Then rotate the coordinate system. Objects in it should look like those in the following figure:

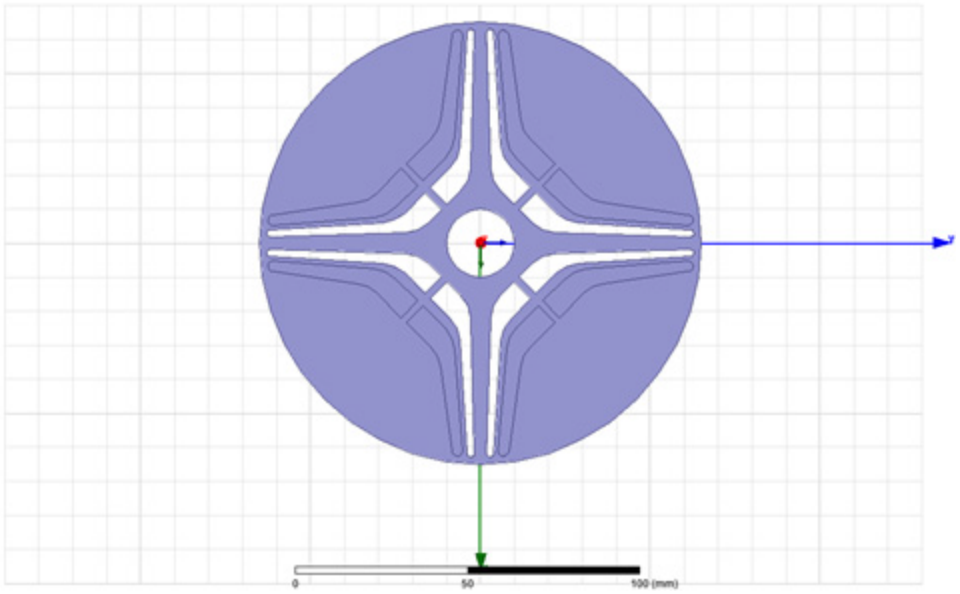

Figure 9-153 Before subtraction of two objects

8. Make a subtraction for two objects

   Choose both objects simultaneously by pressing **Ctrl** and clicking on two objects in the history tree on the screen.

   Then click **Modeler>Boolean>Subtract** to do the subtraction.

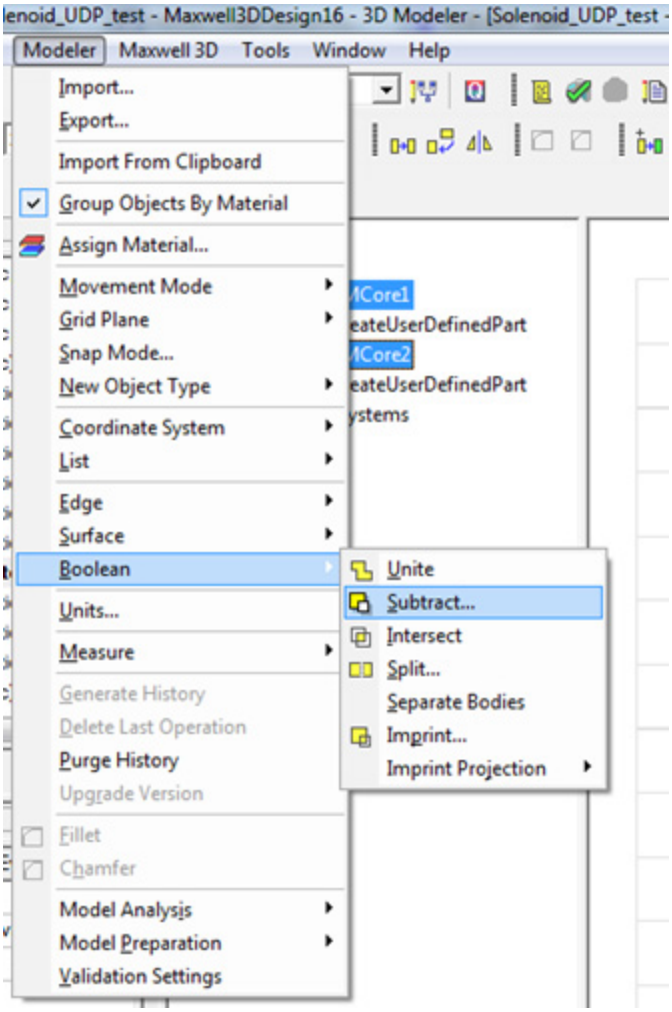

Figure 9-154 Make a subtraction

The SynRMCore1 should be in **Blank Parts** whereas SynRMCore2 is in **Tool Parts**, as shown in the follow figure.

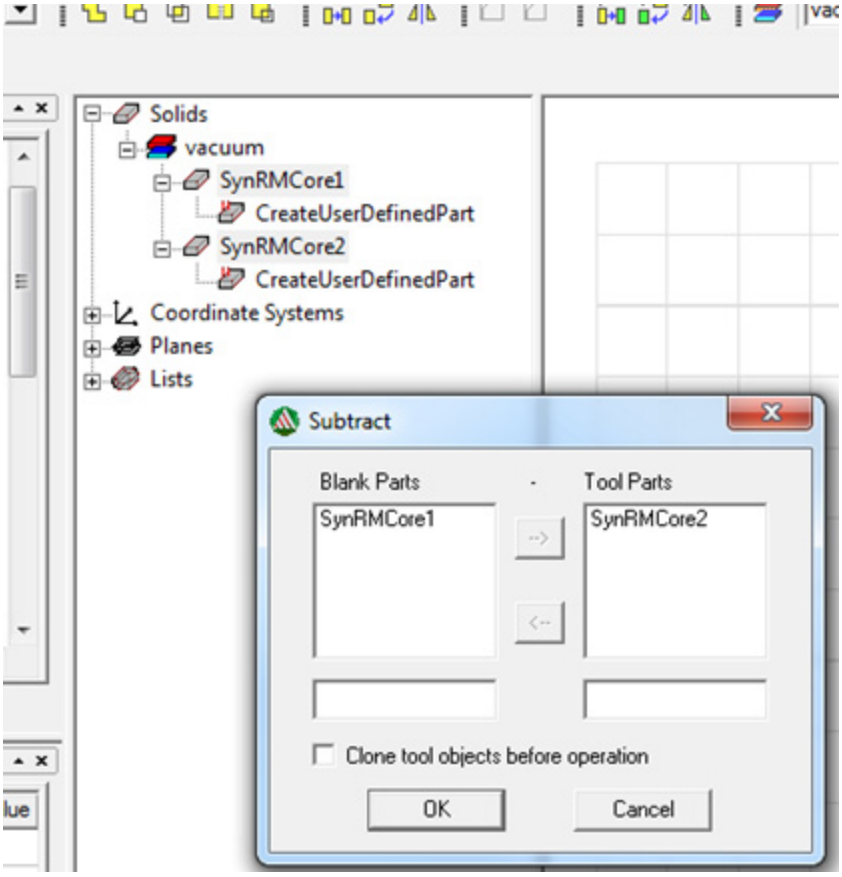

Figure 9-155 Choosing Blank Parts and Tool Parts

9. Click **OK** to finish subtraction. A SynRMCore with different barriers is shown in the following figure.

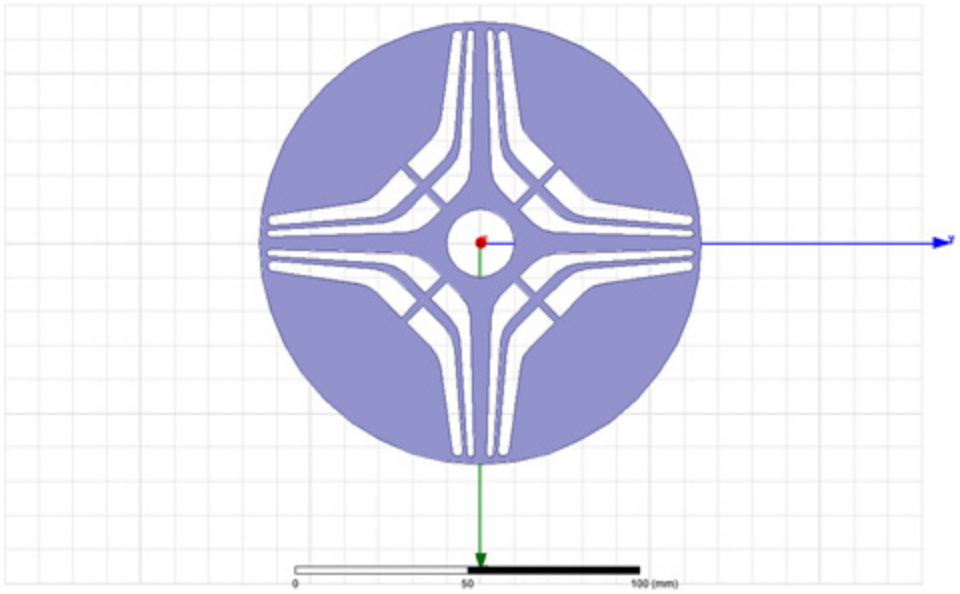

Figure 9-156 After subtraction

To make the barriers look different, you can change the parameters of barriers like **W** and **B0**. Also, repeating the processes can make multiple barriers.

ClawPoleCore UDP

The ClawPoleCore UDP is used to create the claw-pole rotor core, a field winding and/or a PM for claw-pole alternators. It can also create a coil terminal for current assignment.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaShaft for outer cores.
DiaShaft	Core diameter on shaft side, DiaShaft<DiaGap for inner cores.
Length	Core length.
Poles	Number of poles.
EmbraceTip	Embrace of pole tip.
EmbraceRoot	Embrace of pole root.
ThickTip	Thickness of pole tip.
ThickRoot	Thickness of pole root.
ThickShoe	Thickness of side shoes.
DepthSlot	Depth of slot between two poles.
ThickYoke	Thickness of yoke.

Property	Description
LengthPole	Length of pole from tip to tip.
LengthMag	Length of magnet or the second air-gap.
SegAngle	Deviation angle for skewed pole sides (1~10, <1 for true surface).
LenRegion	Region length.
InfoCore	0: core; 1: core & coil; 2: coil; 3: magnet; 4: terminal; 100: region.

These parameters are used in the following figures. Figure 9-158 is in transparent to show parameters **EmbraceTip** and **EmbraceRoot** which otherwise are hard to show. For **LengthMag** parameter, refer to Figure 9-163 .

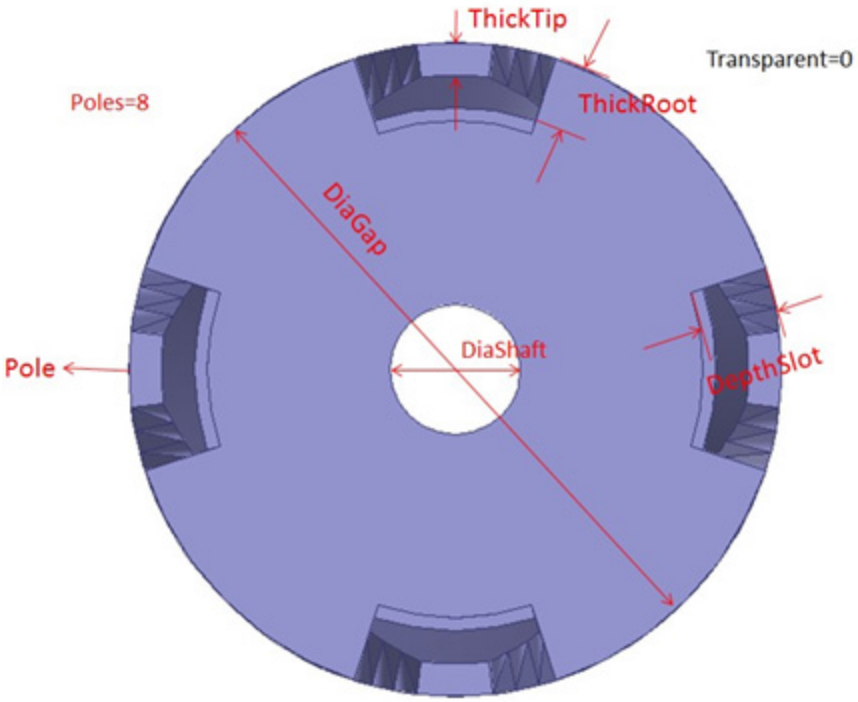

Figure 9-157 Claw Pole Core (InfoCore set to 0)

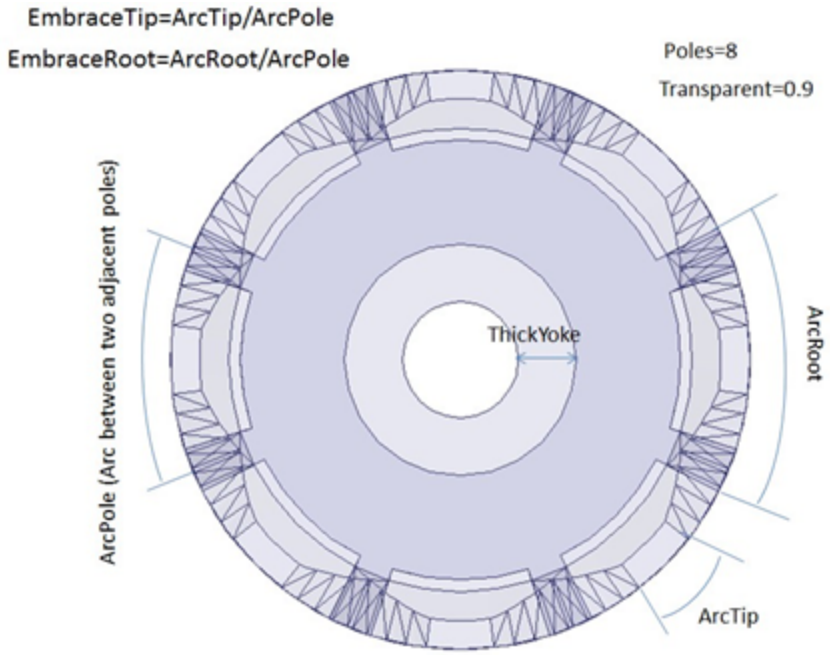

Figure 9-158 Transparent Claw Pole Core (InfoCore set to 0)

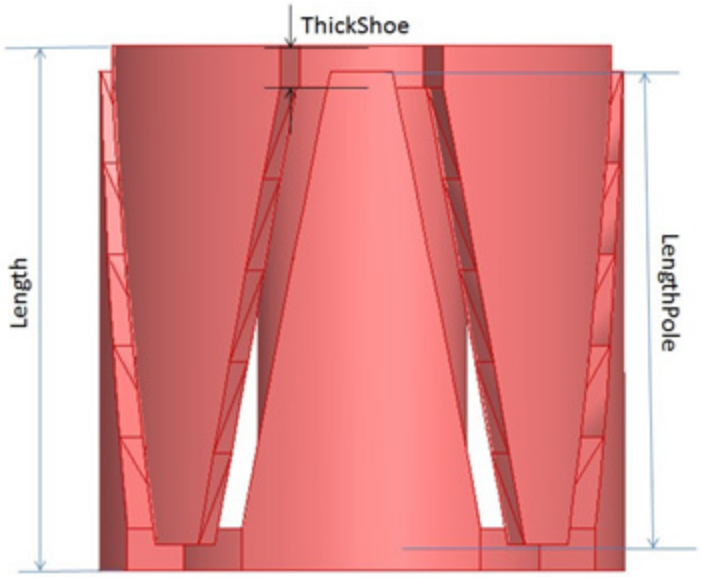

Figure 9-159 3D Claw Pole Core (InfoCore set to 0)

Creating an Inner Claw Pole Core

Set the value of **DiaShaft** and **DiaGap** as **DiaShaft<DiaGap** to create an inner claw pole core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value 0.

Examples of inner claw-pole core are shown in Figure 9-157 , Figure 9-158 , and Figure 9-159 .

Creating a Coil and its Terminal (Claw Pole)

You can create a coil of a claw pole core manually by setting the value of **InfoCoil** to 2. An example is shown inFigure 9-160 .

You can create a terminal of a claw pole core manually by setting the value of **InfoCoil** to 4. Figure 9-161 gives an example of this terminal.

You can assign the value of this property either when creating a claw-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

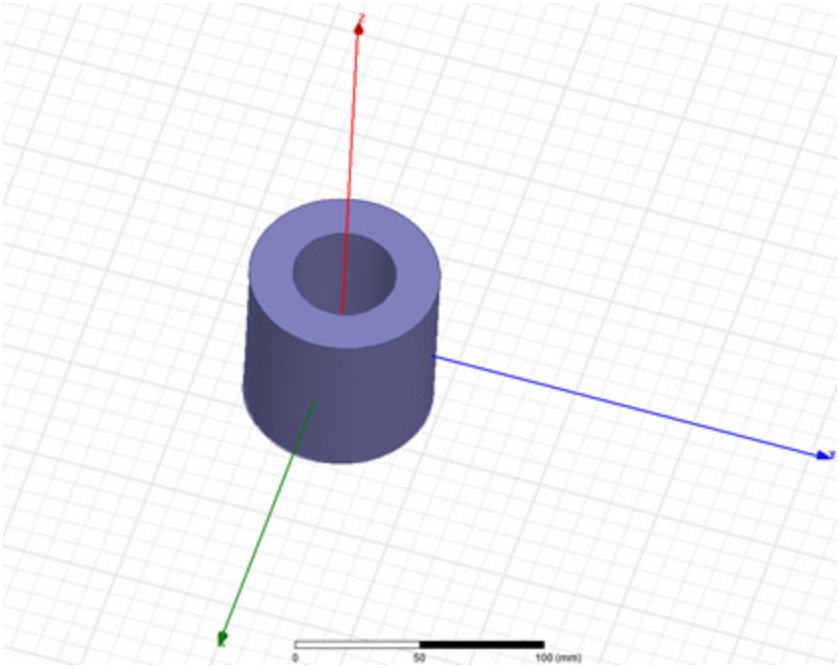

Figure 9-160 Coil of a claw-pole core

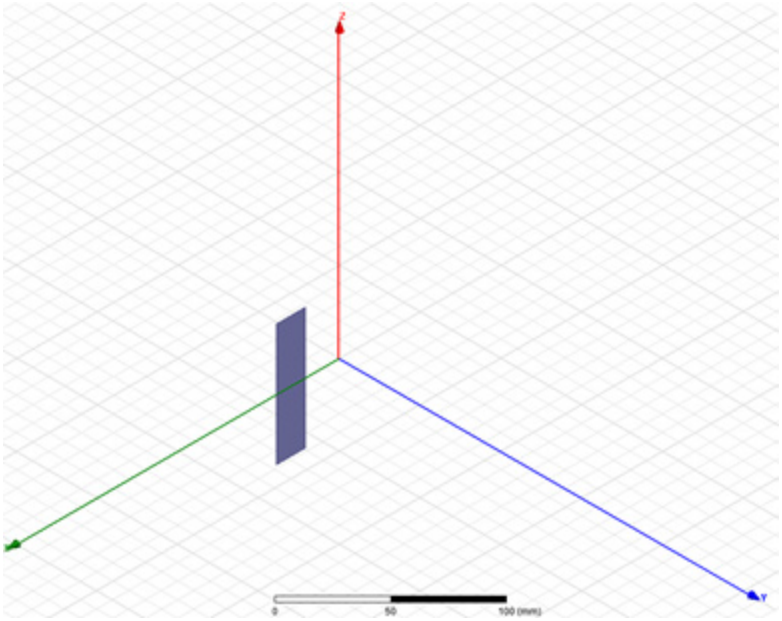

Figure 9-161 A terminal of coil in this claw-pole core

Creating a Magnet (Claw Pole)

To create a magnet, you need to set the value of **LengthMag** larger than 0 (by default, it is 0) and value of **InfoCore** to be 3. An example is shown in the following figure.

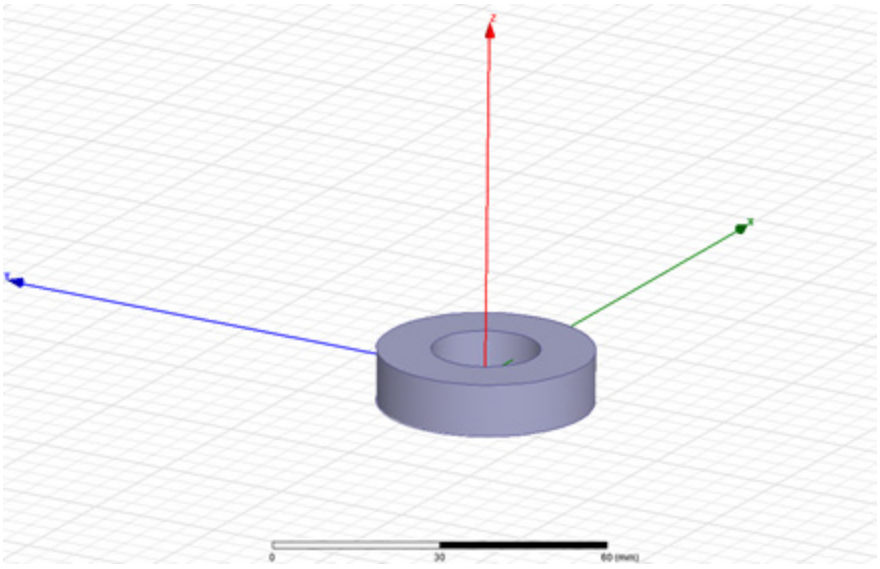

Figure 9-162 A magnet of ClawPoleCore

The following figure visualizes the **LengthMag** parameter.

Figure 9-163 LengthMag of a magnet of ClawPoleCore

You can assign the value of these properties either when creating a claw-pole core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

PMCore UDP

The PMCore UDP is used to create a PM stator/rotor core and a PM for PM commutating DC machines, PM adjustable-speed synchronous machines, or PM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, DiaGap<DiaYoke for outer cores.
DiaYoke	Core diameter on yoke side, DiaYoke<DiaGap for inner cores.
Length	Core length.
Poles	Number of poles.
PoleType	Pole type: 1 to 5.
Embrace	Pole embrace (not for type 4).
ThickMag	Max thickness of magnets.
WidthMag	Magnet width (for types 4 & 5).
Offset	Pole arc offset (for types 1, 2 & 3).
Bridge	Bridge thickness (for type 5 only).
Rib	Rib width (for type 5 only), Rib=0 for rectangle ducts.
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: magnet; 100: region.

These parameters are used in the following figures:

Figure 9-165 shows the **Offset** parameter when value of **PoleType** is 3.

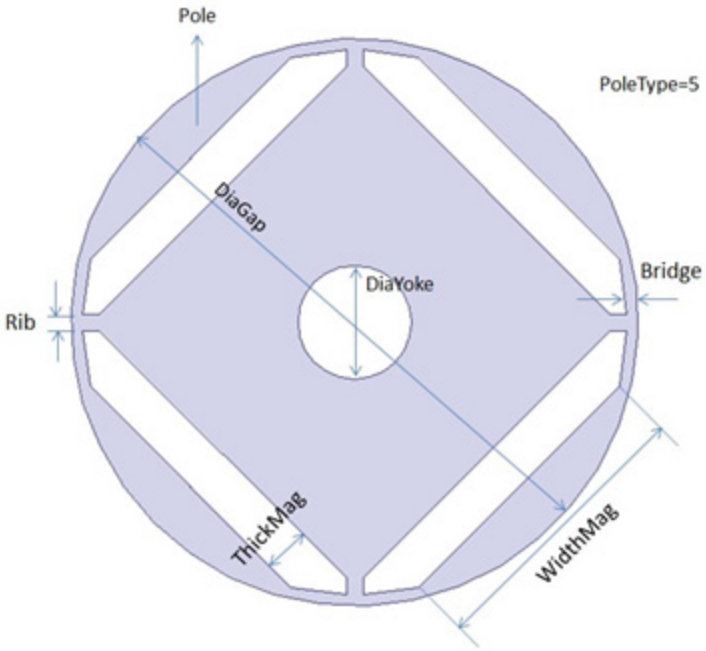

Figure 9-164 PM Core with PoleType set to 5 (InfoCore set to 0)

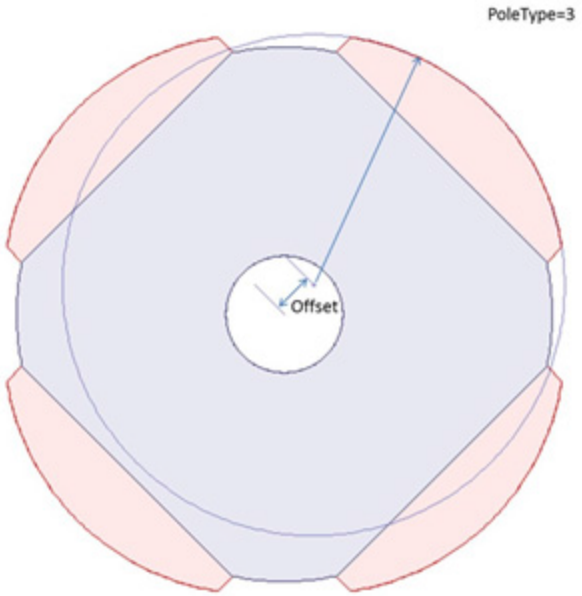

Figure 9-165 PM Core with PoleType set to 3 (InfoCore set to 0)

Creating an Inner or Outer PM Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores. In addition, r to create an outer core, the **Pole Type** must be 1 or 2. You can set the values either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An inner PM core and an outer PM core are shown in Figure 9-166 and Figure 9-167 , respectively.

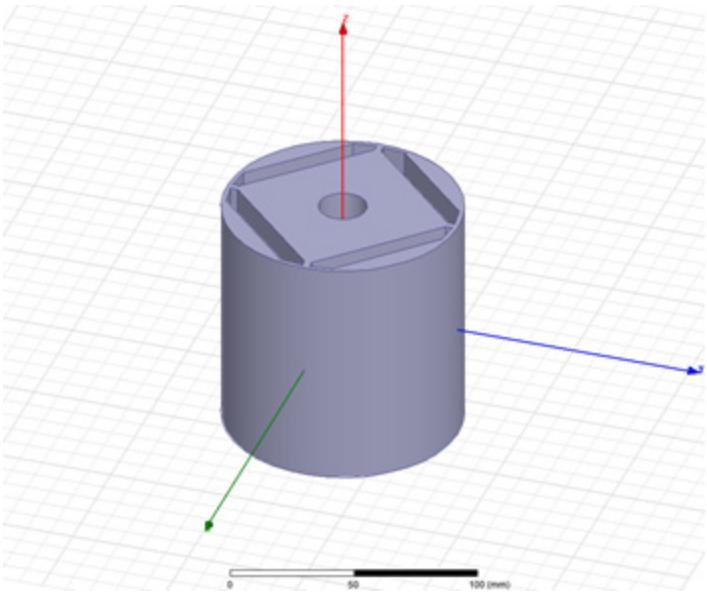

Figure 9-166 Inner PM core with PoleType set to 5 (InfoCore set to 0)

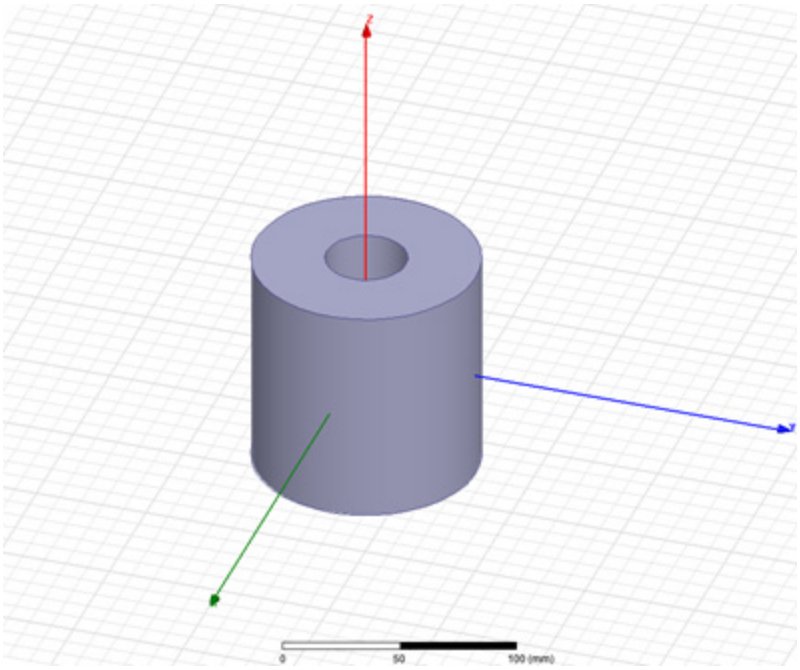

Figure 9-167 Outer PM core with PoleType set to 2 (InfoCore set to 0)

Creating All Magnets (PMCore)

You can create all magnets of a PM core manually by setting the value of **InfoCore** to 1. An example is shown by the four inner blue objects in the following figure, for which InfoCore has been set to 0 allowing the OuterPM core (gray object) and all magnets for PoleType=2 to be shown.

You can assign the value of this property either when creating a PM Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

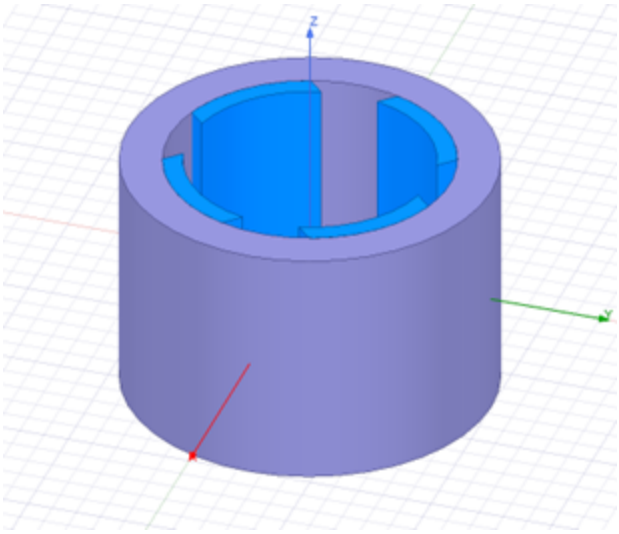

Figure 9-168 All magnets of a PM core

Creating a Magnet (PM Core)

You can create a magnet of a PM core manually by setting the value of **InfoCore** to 2. An example is shown in the following figure.

You can assign the value of this property either when creating a PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

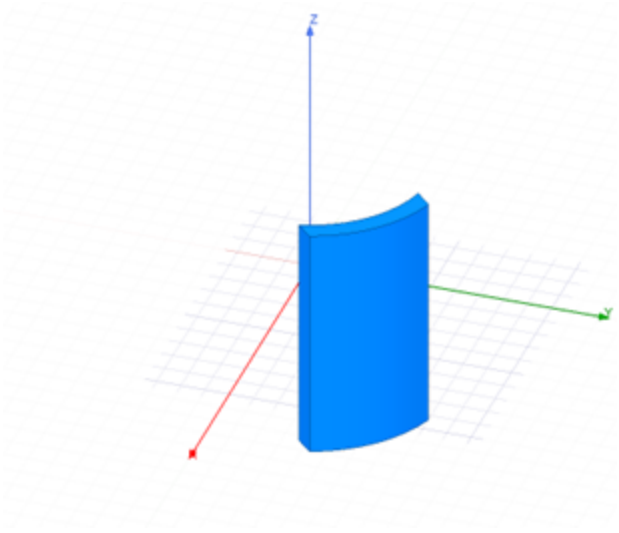

Figure 9-169 A magnet of PM Core

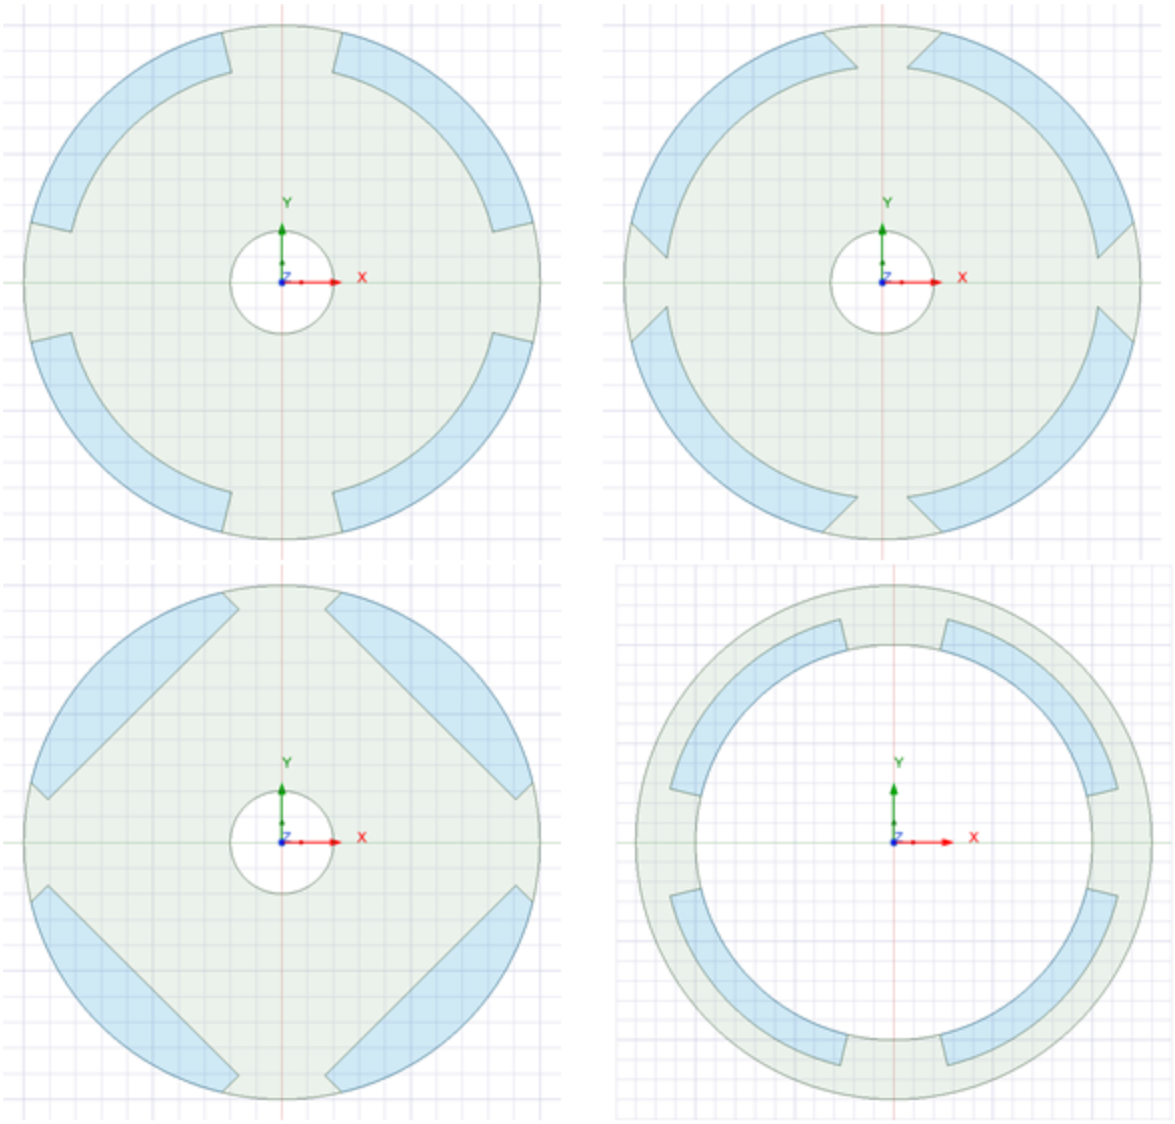
Creating an Insert Surface PM Core

When the value of **PoleType** is 1 to 3, you can create an insert surface PM core by setting **Embrace** to a negative value as shown in the examples below.



IPMCore UDP

The IPMCore UDP is used to create an IPM core and a PM for IPM synchronous machines or IPM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.
PoleType	Pole type: 1 to 6.
D1	Limited diameter of PM ducts.
O1	Bottom width for separate or flat-bottom duct (for types 3~6).
O2	Distance from duct bottom to shaft surface (for types 2~6).
B1	Duct thickness.
Rib	Rib width.
HRib	Rib height (for types 3~5).
DminMag	Minimum distance between side magnets (for types 3~5).
ThickMag	Magnet thickness.
WidthMag	Total width of all magnet per pole.
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: one-pole magnet; 100: region.

Most parameters of IPMCore UDP are shown in the following figure except those common parameters like **DiaGap**, **DiaYoke** and **Length**.

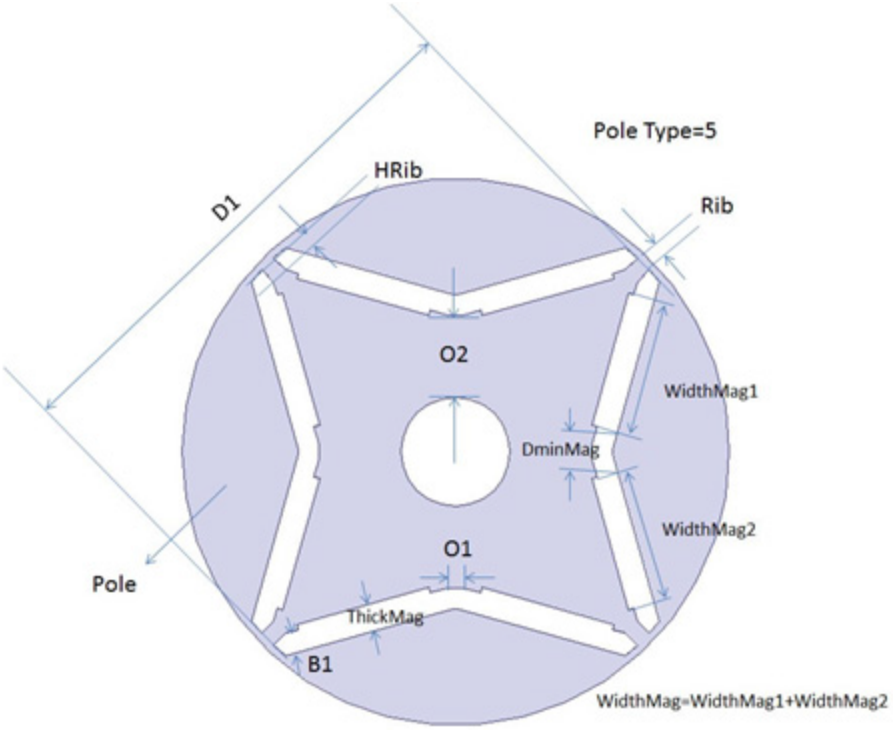


Figure 9-170 Parameters of IPM Core

Creating an Inner IPM Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke<DiaGap** to create an inner IPM core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An example is shown in the following figure.

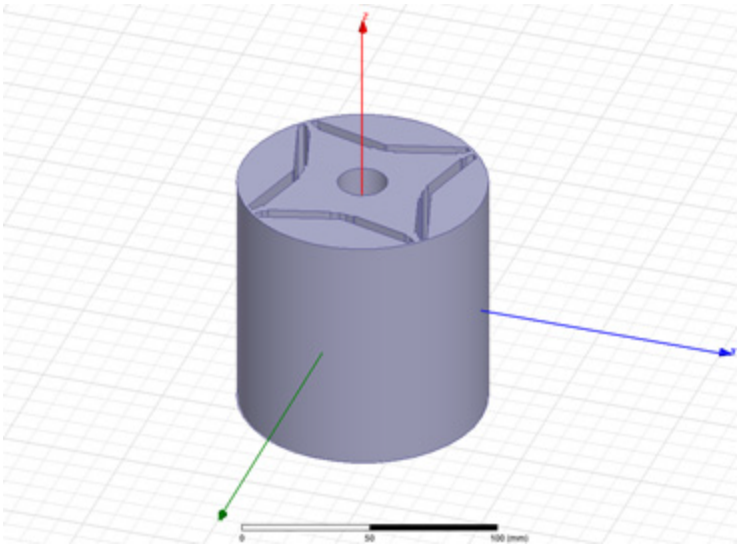

Figure 9-171 Inner IPM Core

Creating All Magnets (IPM Core)

You can create all magnets of an IPM core manually by setting the value of **InfoCoil** to 1.

You can assign the value of this property either when creating an IPM Core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example is shown in the following figure.

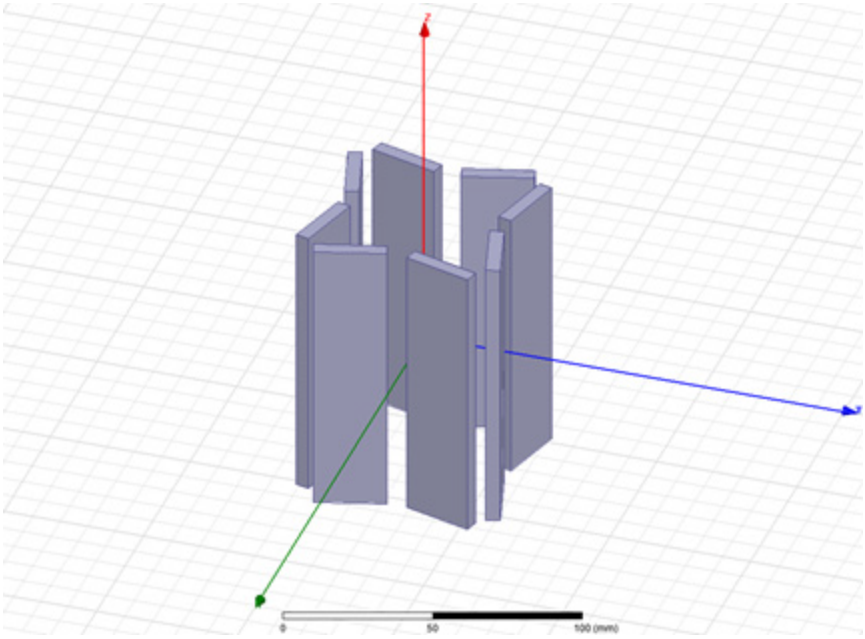

Figure 9-172 All magnets of IPM core

Creating One-Pole Magnets

You can create one-pole magnets of an IPM core manually by setting the property of **InfoCoil** to 3.

You can assign the value of this property either when creating an IPM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

The following figure shows an example of one-pole magnets.

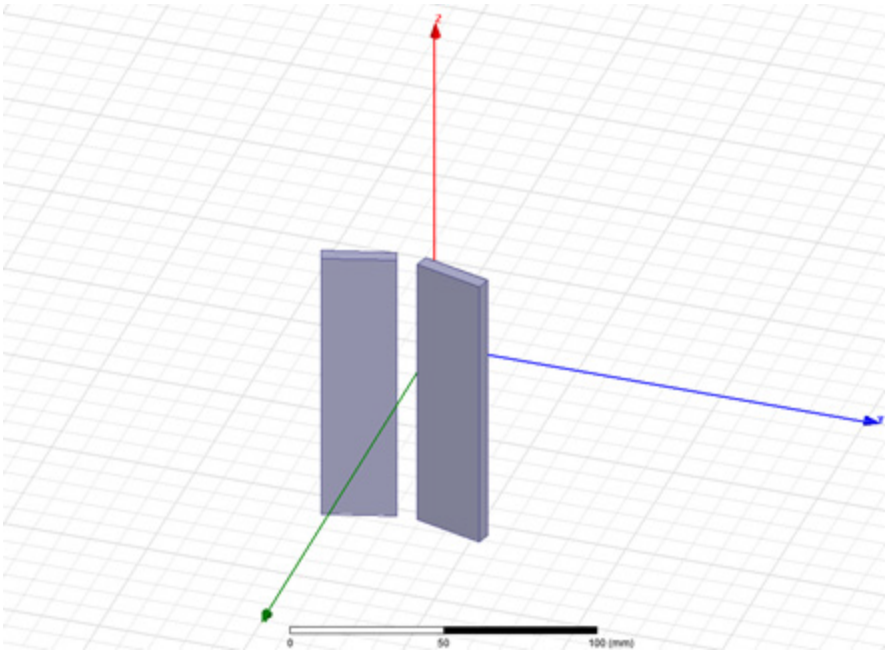

Figure 9-173 One-pole magnets of an IPM Core

PMDamperCore UDP

The PMDamperCore UDP is used to create the PM rotor core with damper for line-start PM synchronous machines.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Skew	Skew angle in core length range.
Slots	Number of damper slots per pole.

Property	Description
SlotType	Slot type: 1 to 4.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: tangent connection; 2&3: arc bottom.
Poles	Number of poles.
PoleType	Pole type: 1 to 8.
D1	Limited diameter of PM ducts.
O1	A locating dimension of PM ducts, for pole types 3, 4, 7 & 8.
O2	A locating dimension of PM ducts, for pole types 1, 3, 5, 6, 7 & 8.
B1	Barrier width, for pole types 1, 2 & 3.
Rib	Rib to hold PM ducts, for pole types 1 to 7.
ThickMag	Magnet thickness.
WidthMag	Total width of all magnet per pole.
BarEndExt	One-side damper bar end extended length.
RingLength	One-side axial ring length.
RingHeight	Radial ring height.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: damper; 100: region.

These parameters are used in the following figures:

Note	• Parameters O1 and O2 are locating dimensions of PM ducts. They may have different meanings in different pole types. For example, Figure 9-174 shows what O1 and O2 refer to in PMDamper Core with Pole Type 3. • In Figure 9-175 and Figure 9-176 , the gray object (a PMDamperCore with InfoCore set to 0) is used as reference to show the red object (a PMDamperCore with InfoCore set to 2) • For parameters such as **DiaGap, DiaYoke, Length,Skew**, **FilletType**, **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters.

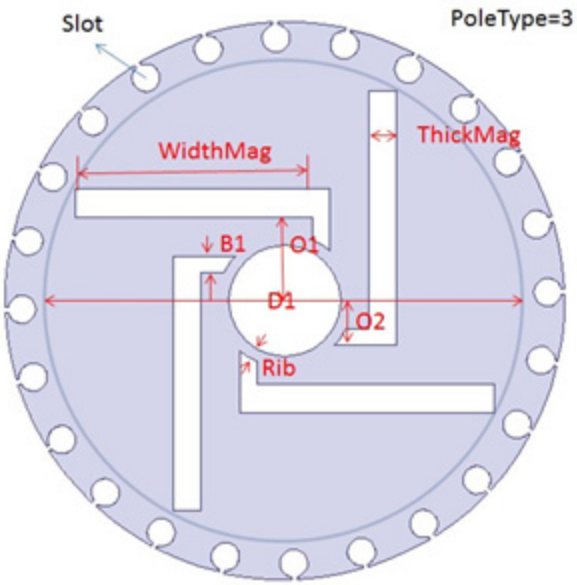

Figure 9-174 PMDamperCore with Pole Type set to 3

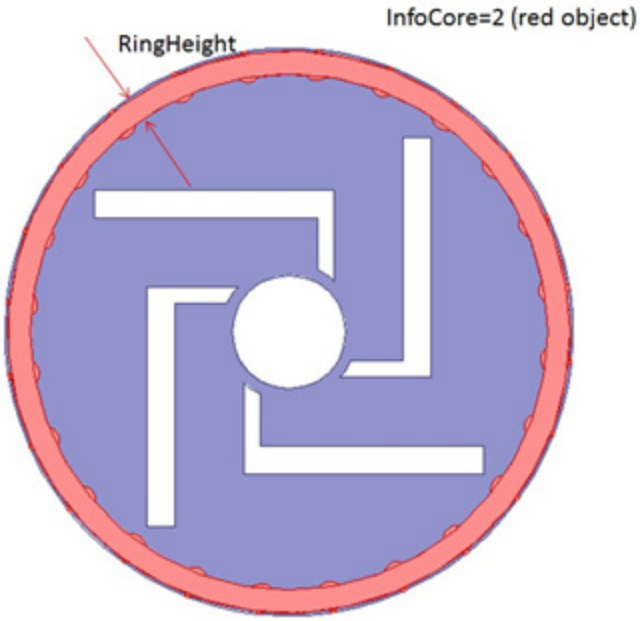

Figure 9-175 Damper of PMDamperCore (red)

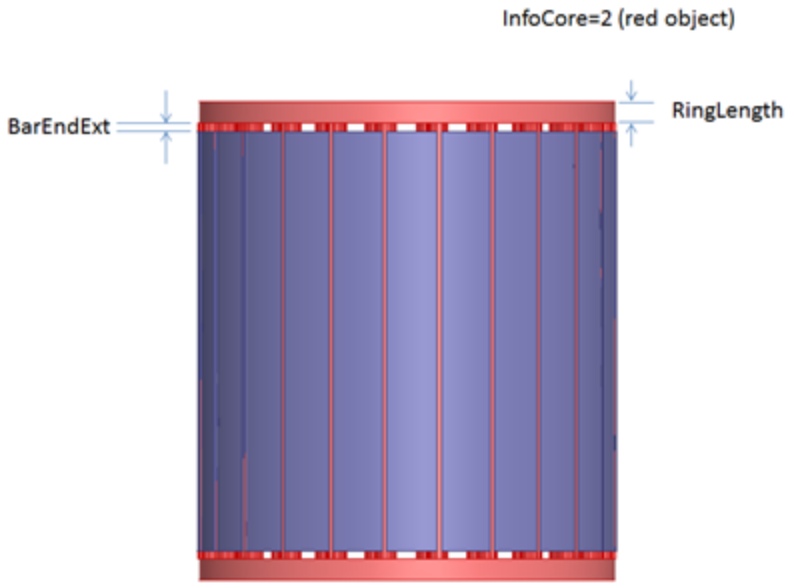

Figure 9-176 3D Damper of PMDamperCore (red)

Creating an Inner PM Damper Core

Set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create an inner PM damper core. You can set the value either when creating the core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Set the **InfoCore** value to 0.

An example is given in the following figure.

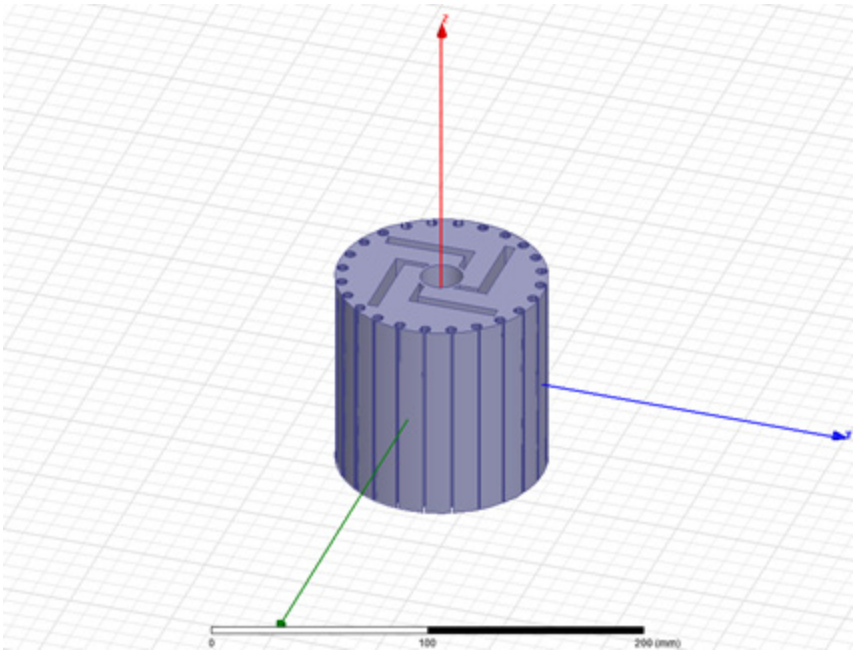

Figure 9-177 Inner PM damper core

Creating a Damper (PM Damper Core)

You create a damper of a PM damper core manually by setting the value of **InfoCoil** to 2.

You can assign the value of this property either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Examples are shown in Figure 9-176 as a red object and Figure 9-178 .

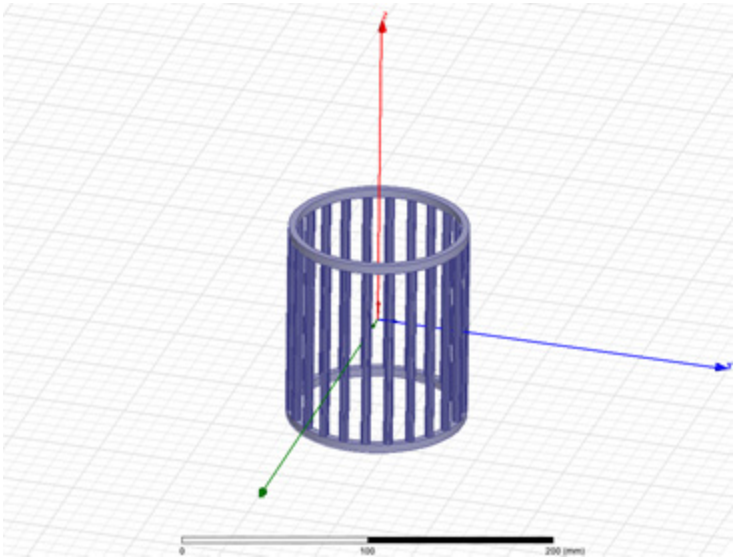

Figure 9-178 A damper

Creating all Magnets (PM Damper Core)

You can create all magnets of a PM damper core manually by setting the value of **InfoCoil** to 1.

You can assign the value of this property either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

An example is shown in the following figure. Note that this example is realized when the value of **PoleType** is 3.

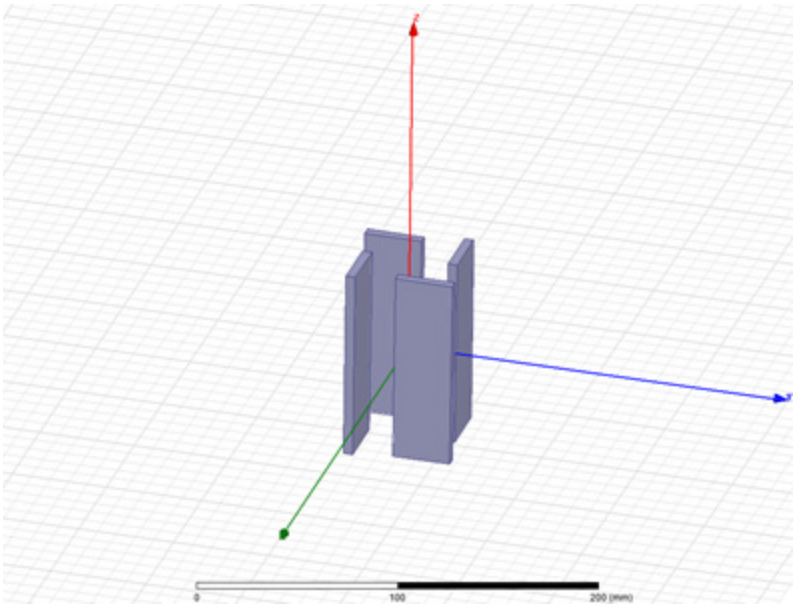

Figure 9-179 All Magnets

Creating a Magnet (PM Damper Core)

You can create a magnet of a PM damper core by setting the **InfoCore** value to -1, -2 or -3 according to the number of magnets for each pole of the core.

For instance, when **Pole Type** is equal to 3 (which is shown in Figure 9-179), there is only 1 magnet for a pole. In this situation, setting the value of **InfoCore** to be -1 can create a magnet. An example is shown in the following figure.

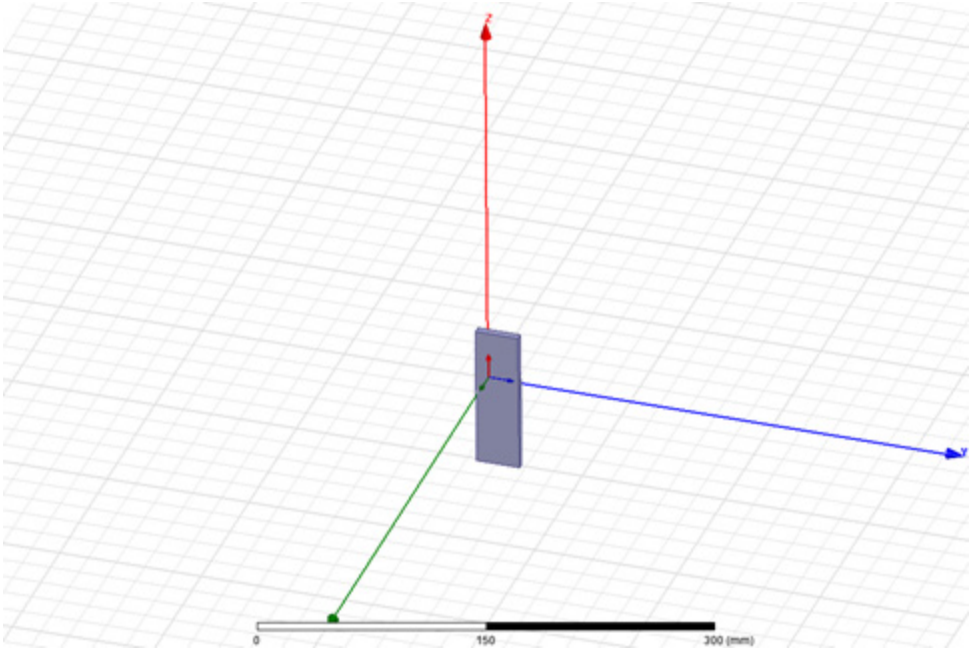

Figure 9-180 A magnet when Pole Type is set to 3

When there are 2 magnets for a pole of a PM damper core (for example, when **Pole Type** is 5), setting the value of **InfoCore** to be -1 can create one of these 2 magnets while setting the value of **InfoCore** to be -2 can create another one.

For instance, Figure 9-181 shows all magnets of a PM damper core when **Pole Type** is 5, whereas Figure 9-182 and Figure 9-183 present one of two magnets for a pole, by setting **InfoCore** value to be -1 and -2 respectively.

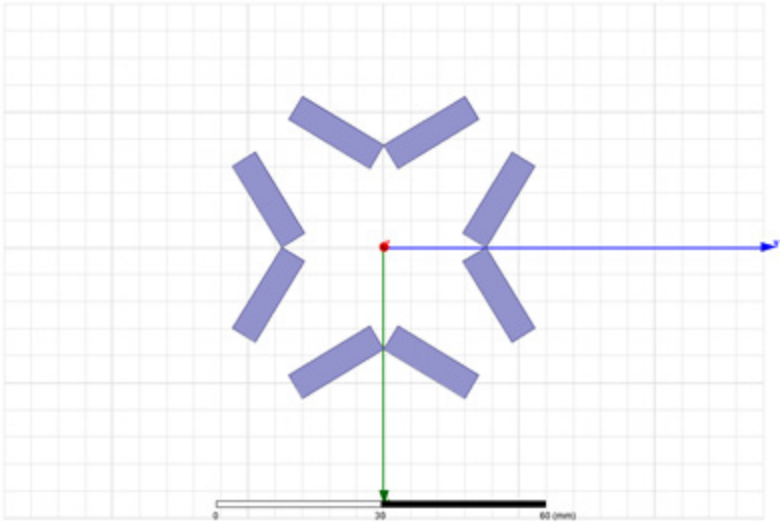

Figure 9-181 A PM damper core when Pole Type is 5 and InfoCore is 1

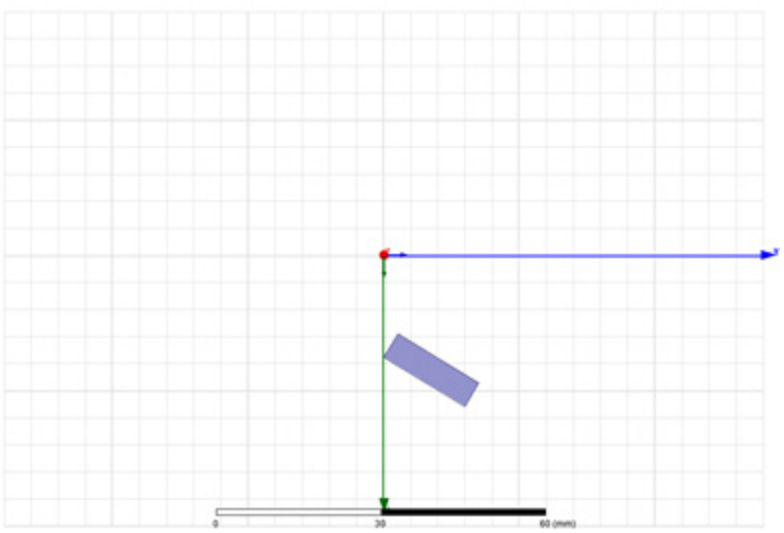

Figure 9-182 A PM damper core when Pole Type is 5 and InfoCore is -1

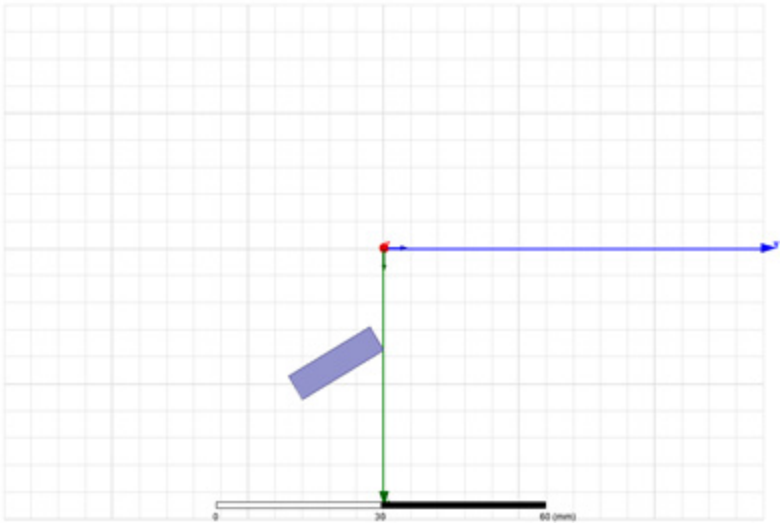

Figure 9-183 A PM damper core when Pole Type is 5 and InfoCore is -2

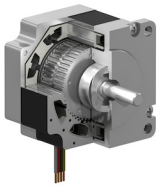
Similarly, when a pole of PM damper core has 3 or more magnets (such as when **InfoCore** is 6), you can create a single magnet by setting the value of InfoCore to -1, -2, -3 and so on.

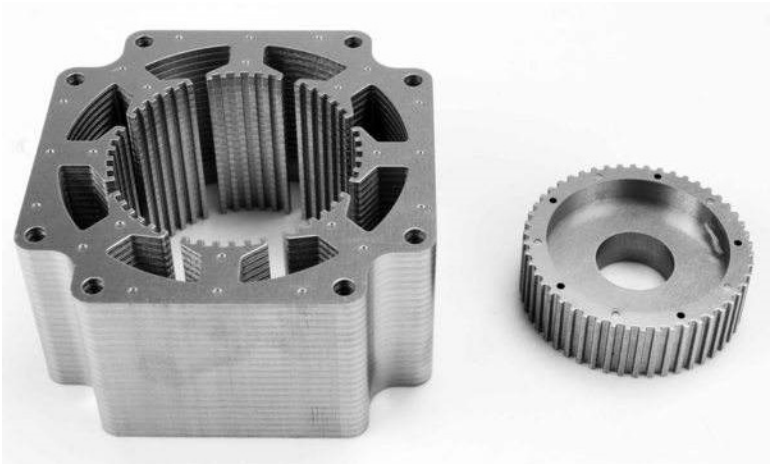
You can assign the value of these properties either when creating a PM damper core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

StepMCore UDP

The StepMCore UDP is used to create stator and rotor cores for Variable Reluctance (VR), or Hybrid, stepper motors, as shown as in Figure 2.3.11.a for a stepper motor, Figure 2.3.11.b for the stator and rotor.



Hybrid Stepper Motor



Stator and rotor of a stepper motor

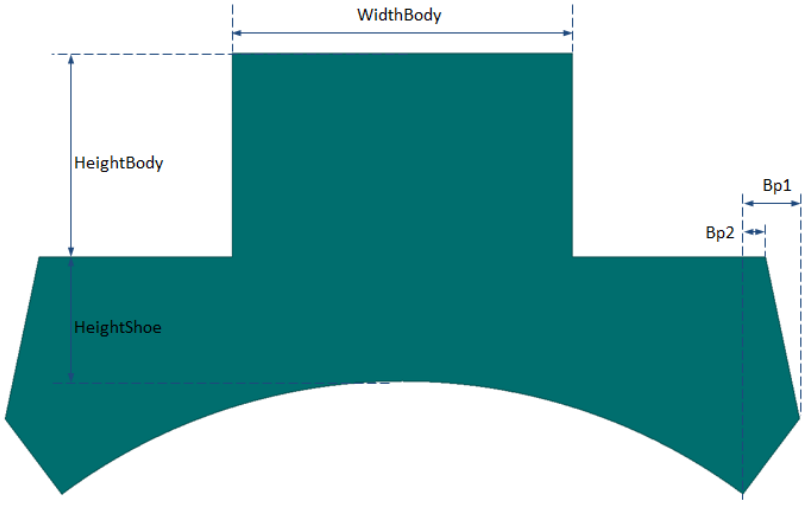
Parameter Definitions

Property	Description
DiaGap	Core diameter on gap side, DiaGap < DiaYoke for outer cores
DiaYoke	Core diameter on yoke side, DiaYoke < DiaGap for inner cores
Length	Core Length
Poles	Number of poles
PoleType	Pole type: 0, 1, or 2 (not valid for inner cores)
EmbraceShoe	Pole shoe embrace related to pole pitch for WidthShoe computation
HeightShoe	Pole shoe height at pole center
WidthBody	Pole body width
HeightBody	Pole body height

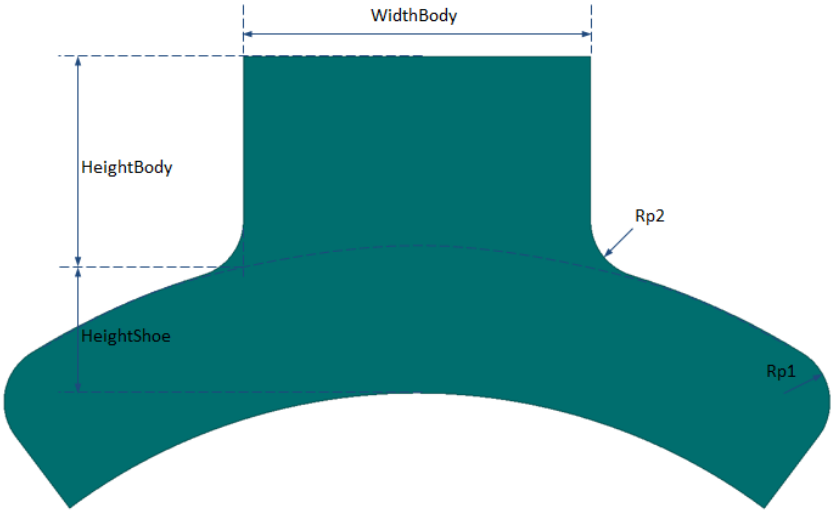
Property	Description
Bp1/Rp1	Bp1 for pole type 1; or Rp1 for pole type 2; not valid for type 0
Bp2/Rp2	Bp2 for pole type 1; or Rp2 for pole type 2; not valid for type 0
SurfaceTeeth	Number of surface teeth per pole (>=1)
IndexingTeeth	Number of indexing teeth for tooth pitch computation, not valid for SurfaceTeeth=1
EmbraceTooth	Tooth embrace related to tooth pitch, not valid for SurfaceTeeth=1
HeightTooth	Surface tooth height, or slot depth, not valid for SurfaceTeeth=1
FilletSlot	Fillet radius at slot bottom
GapCore	Gap of two core sections in radial direction (>0 for Hybrid core)
ThickYoke	Thickness of solid yoke in radial direction for Hybrid core
ThickMag	Magnet thickness in radial direction for Hybrid core
LengthMag	Magnet length in axial direction for Hybrid core (>=GapCore)
CoilEndExt	One-side coil end extended Length
LenRegion	Region length
InfoCore	0: core; 1: core & coils; 2: coil; 3: magnet; 4: terminal1; 5: terminal2; 6: poles; 7: yoke; 100: region

Main parameters described in the table above for different pole types are shown in the figures below.

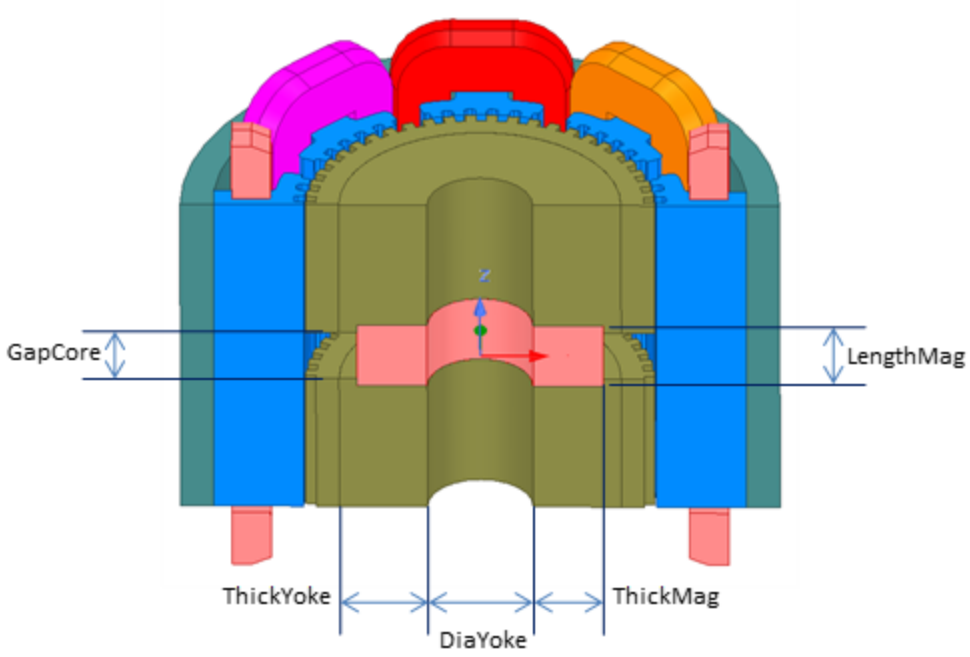
Pole parameters for PoleType = 0



Pole parameters for PoleType = 1



Pole parameters for PoleType = 2



Pole parameters for hybrid rotor

EmbraceShoe is the ratio of the pole shoe angle to pole pitch, and **EmbraceTooth** defines the ratio of a tooth angle to tooth pitch is: ToothPitch = 360°/**IndexingTeeth**.

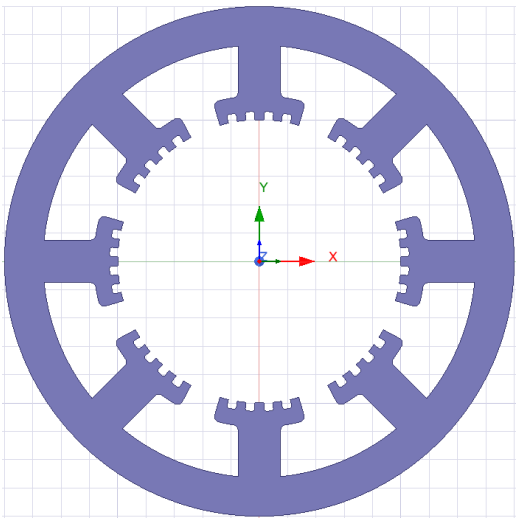
When **SurfaceTeeth** = 1, which means there are no slots on the shoe surface, the shoe width, noted as WidthShoe, will be directly obtained from **EmbraceShoe**. When **SurfaceTeeth** > 1, the minimum shoe angle AngShoeMin will be obtained from the minimum angle to be able to create the specified number of surface teeth, that is

AngShoeMin = (**SurfaceTeeth** – 1 + **EmbraceTooth**) x ToothPitch

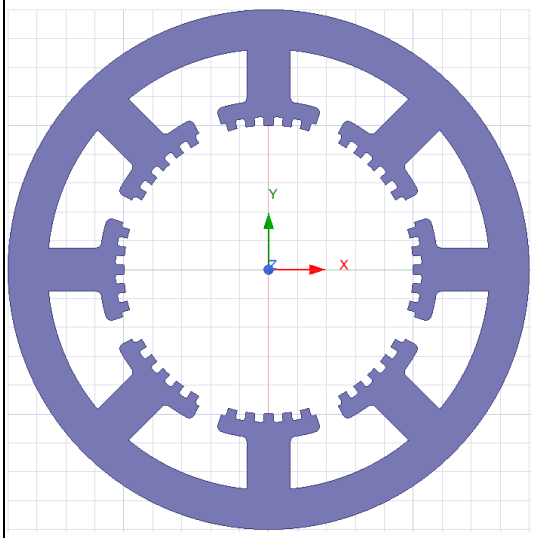
and the maximum shoe angle is defined to add a half slot in each shoe side, that is

AngShoeMax = AngShoeMin + (1 – **EmbraceTooth**) x ToothPitch = **SurfaceTeeth** x ToothPitch.

When the shoe angle corresponding to the specified **EmbraceShoe** is out of the range of (AngShoeMin, AngShoeMax), the UDP will automatically adjust the value of **EmbraceShoe**, as shown below.



EmbraceShoe = 0.7
(Automatically adjust to 0.72)



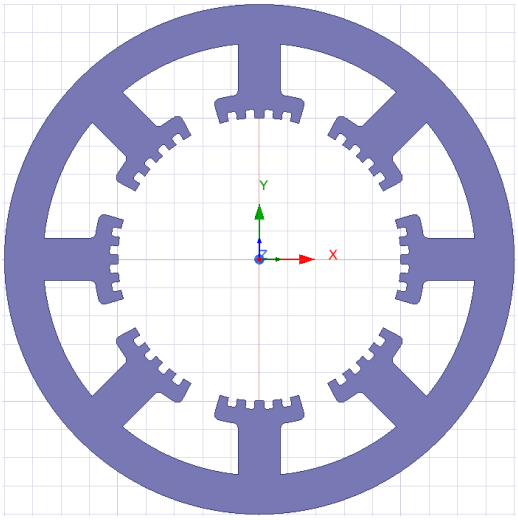
EmbraceShoe = 0.9
(Automatically adjust to 0.8)

In this example, an 8-pole stepper motor stator has **SurfaceTeeth** = 5, **IndexingTeeth** = 50 and **EmbraceTooth** = 0.5. Therefore, ToothPitch = 7.2°, and AngShoeMin and AngShoeMax will be 32.4° and 36°, corresponding to minimum and maximum shoe embrace of 0.72 and 0.8, respectively. The value of **EmbraceShoe** will automatically be adjusted to 0.72, or 0.8, if the input value is out of the range.

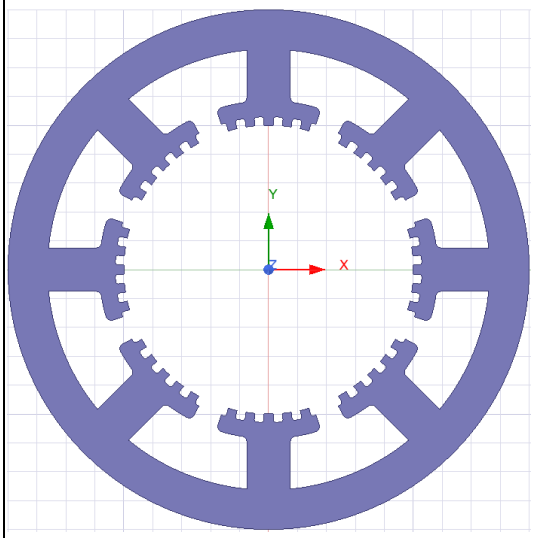
Creating an Inner or Outer Core for a Variable Reluctance Stepper Motor

You can set the value of **DiaYoke** and **DiaGap** as **DiaYoke**<**DiaGap** to create inner cores or **DiaGap**<**DiaYoke** for outer cores.

Keeping **GapCore** = 0 and **InfoCore** = 0, outer stator cores of a variable reluctance stepper motor with different **EmbraceShoe** are created, as shown in the figures below.

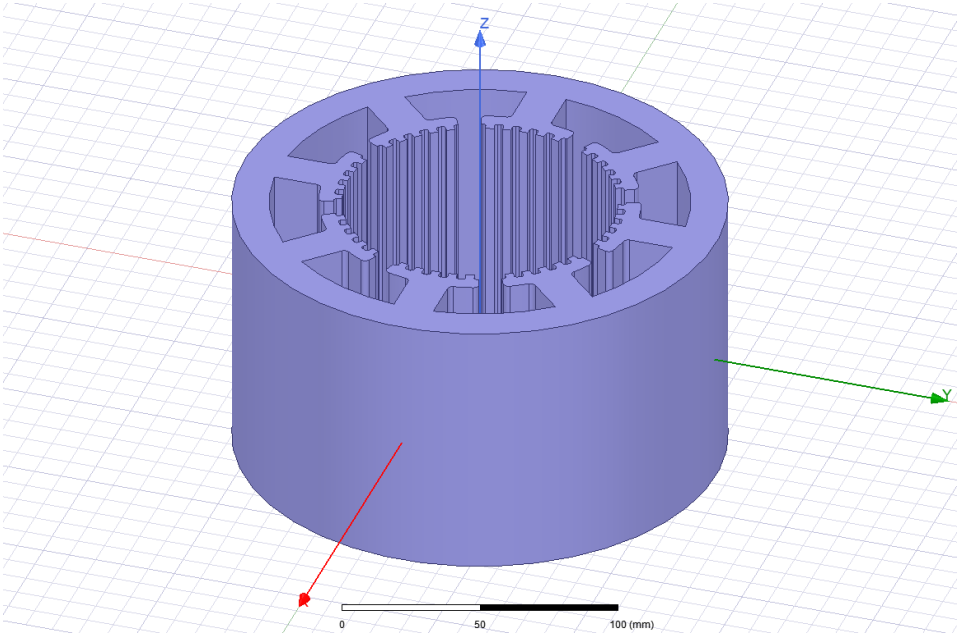


EmbraceShoe = 0.7
(Automatically adjust to 0.72)



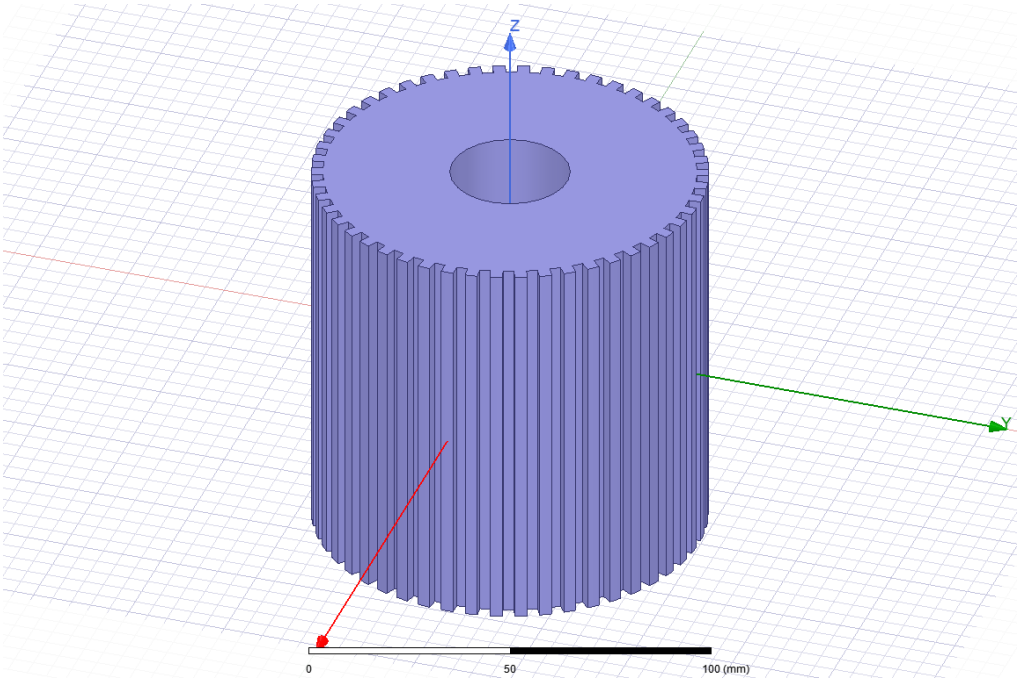
EmbraceShoe = 0.9
(Automatically adjust to 0.8)

Outer stator cores with different shoe embraces in 2D.



Outer stator core in 3D (PoleType = 2).

A 3D inner rotor core with 50 poles, which is the same number as the stator indexing teeth, is shown below



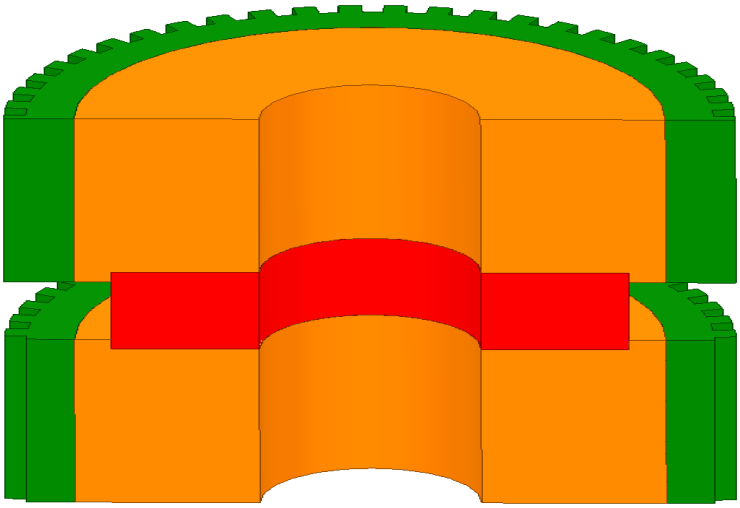
Inner rotor core in 3D (PoleType = 0)

Creating an Inner Rotor Core for a Hybrid Stepper Motor

The stator structure of a hybrid stepper motor is similar to that of a variable reluctance stepper motor, but the rotor structure is quite different. The rotor core is divided into two separate parts. The two parts are shifted by a half tooth pitch in circumferential direction, as shown below. The top pole part, in green color created with **InfoCore** = 6, is cut by the symmetry plan through the pole center, or the tooth center, however, the bottom pole part is cut through the slot center.

The rotor core could be laminated, solid, or laminated for poles and solid for yoke. In the example, the poles, in green color, are laminated, and the yoke, in golden color created with **InfoCore** = 7, is solid. The magnet, in red color created with **InfoCore** = 3, is magnetized in vertical direction. The fluxes in both top and bottom parts are in the radial direction, one from rotor to stator, and the other from stator to rotor.

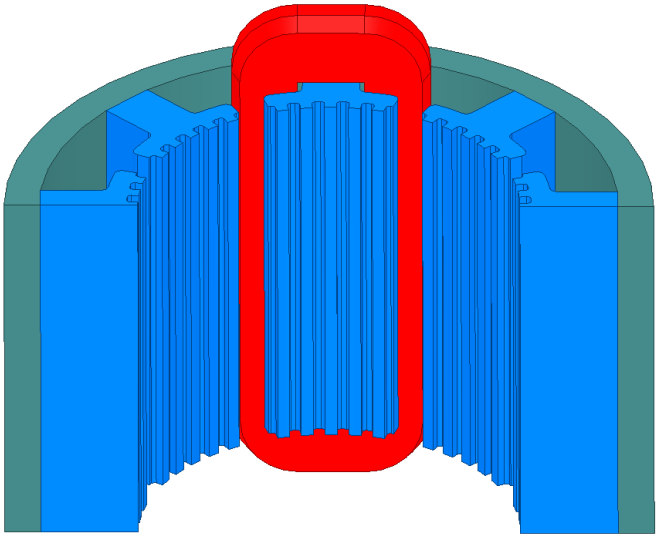
The hybrid rotor can be created only in 3D.



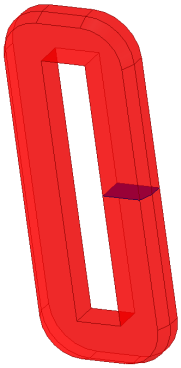
Inner rotor core in 3D (PoleType = 0)

Creating a Coil and Coil Terminals for a Stepper Motor

A coil can be created by setting **InfoCoil** = 2, as shown below,



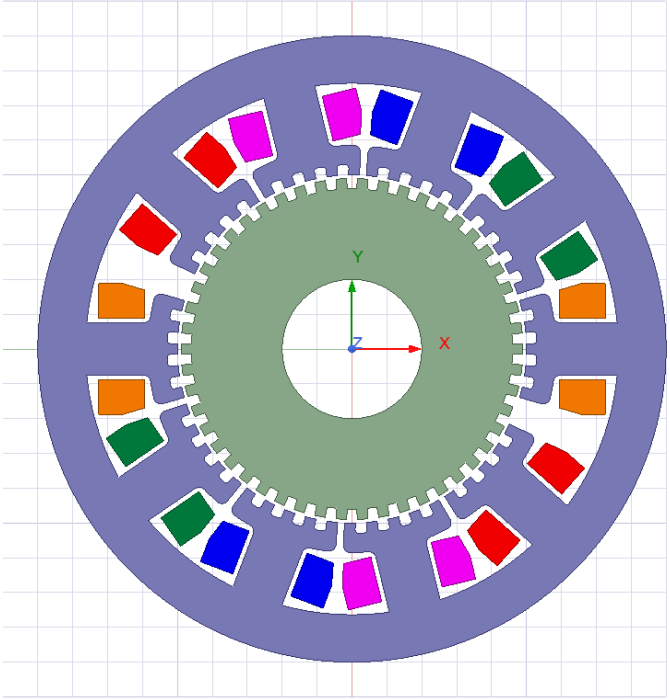
and a coil terminal can be created by setting **InfoCoil** = 4 or 5. (Coil terminal created by **InfoCore** = 4 shown below.)



In 2D, you can create a coil by setting **InfoCoil** = 2 with two united terminals. You can also create two separate terminals by setting **InfoCoil** = 4 and 5 for convenient coil setup.

Creating a Stator Core with Non-uniform Pole Pitch

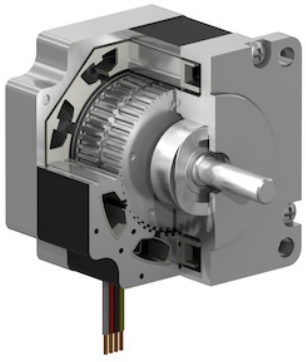
To be able to create torque when stator windings are excited phase by phase (a phase winding normally consists of two coils in two poles shifted by 180 degrees), the number of rotor poles should be the same as the number of indexing teeth for the stator pole surface teeth, and the number of indexing teeth should not be integer multiples of the number of stator poles. However, in some applications, the number of indexing teeth may be integer multiples of the number of stator poles. For example, in widely used 5-phase stepper motors, the stator contains 10 poles, while the rotor has 50 poles, or teeth. The tooth pitch in both stator and rotor is 7.2°. In order to be able to produce continuous torque, the 5 stator pole pairs should be shifted from their uniform positions by 0, 1.44, 2.88, 4.32, 5.76, successively.

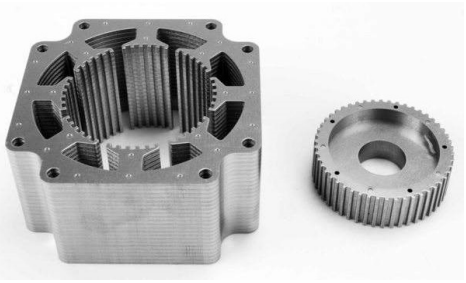


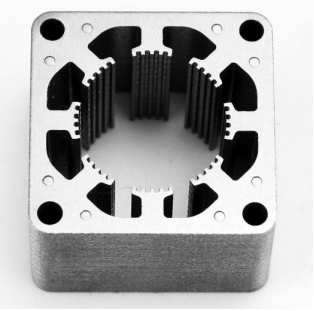
2D Stator core and coils with non-uniform pole pitch

Square Yoke UDP

The SquareYoke UDP is used to create outer square yokes, which can be combined with various stator types to be able to directly mount with end caps for small-size machines, as shown in the examples below.



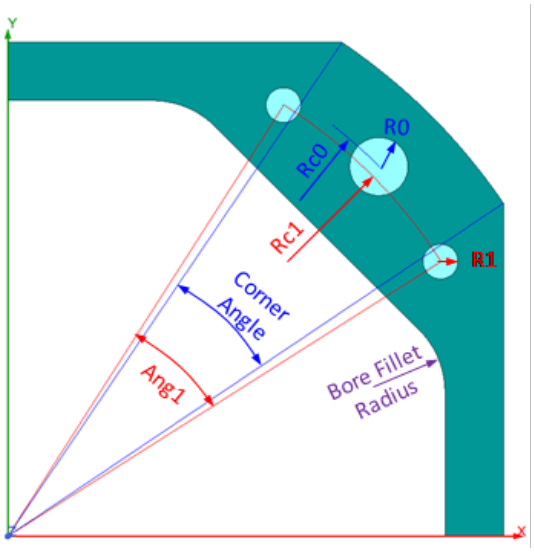




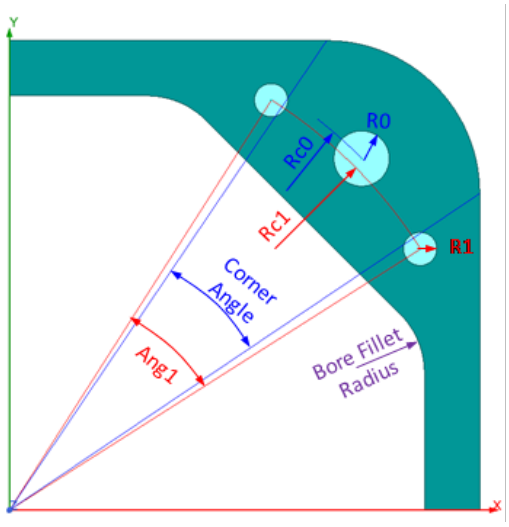
Parameter Definitions

Property	Description
WidOuter	Outer width of square profile
DiaInner	Inner diameter or minimum width
Length	Yoke Length
YokeType	0: Circle; 1: Square Circle; 2: Square Bulged; 3: Square Flat; 4: Square Dented
AngCorner	Corner angle related to bore center, not valid for CornerType = 0
BoreType	1: Circle; 2: Square; 3: Octagon; BoreType is always 1 for CornerType = 0
BoreFillet	Inner bore fillet radius, for square or octagon bore type only
R0	Radius of mounting hole or dented fillet, not valid for CornerType = 0
Rc0	Radius of mounting hole location or bulged fillet, not valid for CornerType = 0
R1	Radius of two corner holes, not valid for CornerType = 0
Rc1	Radius of corner hole location, not valid for CornerType = 0
Ang1	Angle of two corner-hole centers related to bore center, not valid for CornerType = 0
LenRegion	Region length
InfoCore	0: core; 1: holes; 2: 100: region

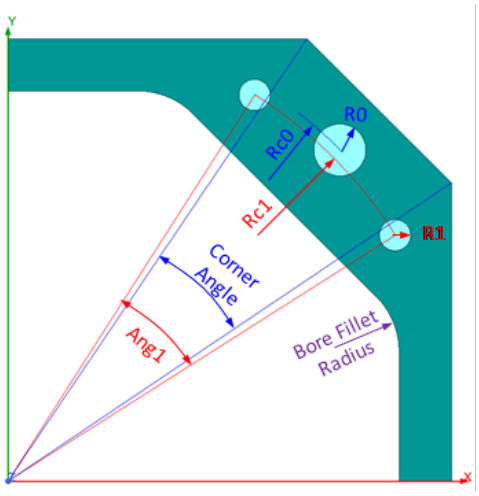
Main parameters described in the table above for the four yoke corner types are shown below, where "Corner Angle" is **AngCorner**, and "Bore Fillet Radius" is **BoreFillet**.



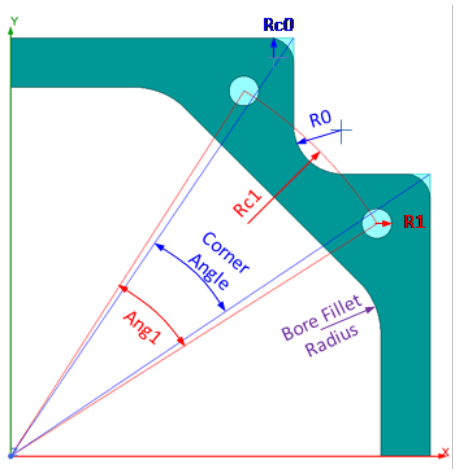
Yoke parameters for YokeType = 1



Yoke parameters for YokeType = 2

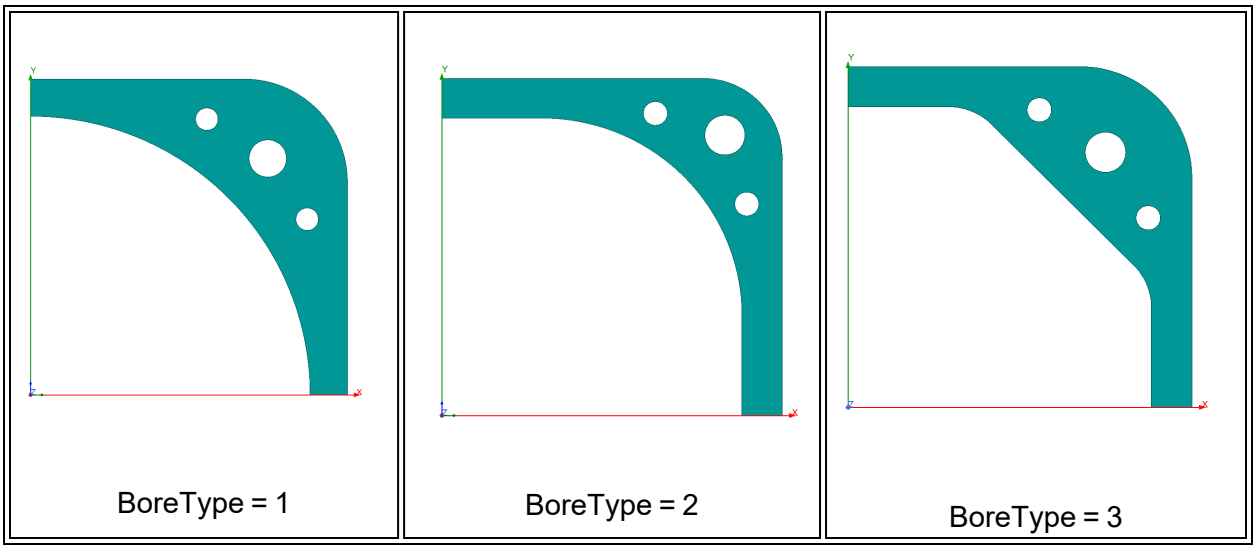


Yoke parameters for YokeType = 3



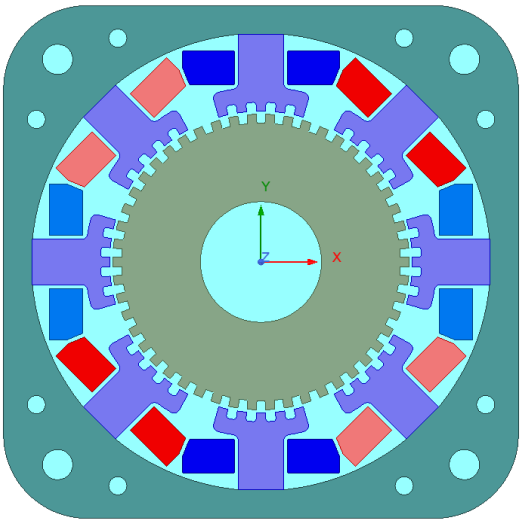
Yoke parameters for YokeType = 4

The three bore types are shown below.

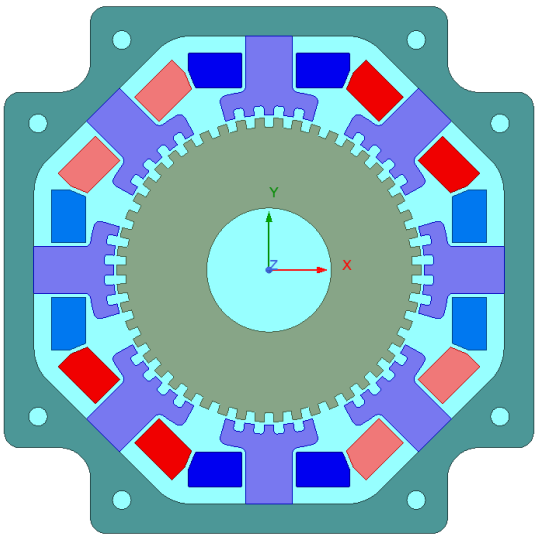


Creating a Stator Yoke to Match Stator Poles of Stepper Motors

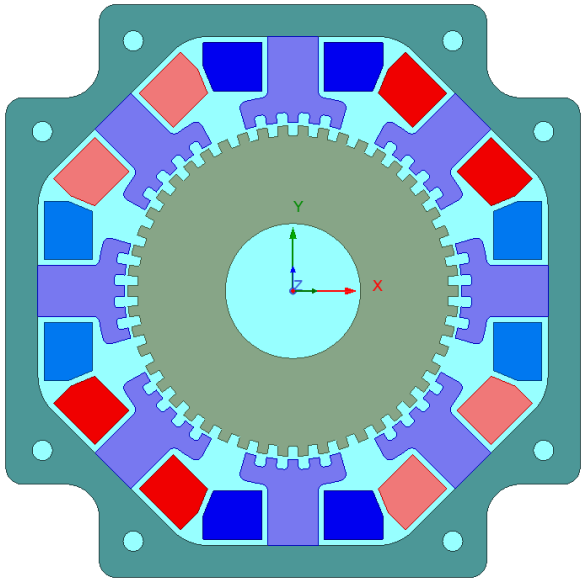
The figure below shows an example for a variable reluctance stepper motor in which the stator poles are mounted to a square yoke with **YokeType**= 2 and **BoreType**= 1, where **BoreFillet** is set as **WidthBody** in StepMCore UDP to fit the pole bottom.



The figure below shows a stepper motor in which the stator poles are mounted to a square yoke with **YokeType**= 4 and octagon **BoreType**= 3 in which the coil area is that of circular bore type (**BoreType**= 1) as shown in the previous figure.



For bore type (**BoreType**= 3), the coil area can be larger. To do this, you can set a negative value for StepMCore UDP parameter **CoilEndExt** to create the coils. The modified coils are shown below.



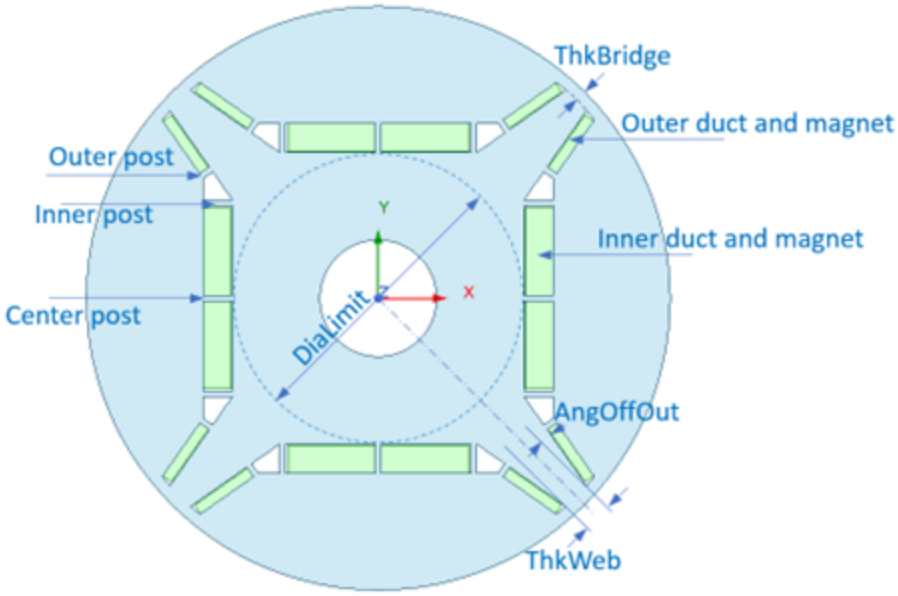
Coil area modified by setting StepMCore UDP parameter **CoilEndExt**< 0.

UPMCore UDP

The UPMCore UDP is used to create a single- or poly-layer U-type IPM core and PMs for IPM synchronous machines, or IPM brushless DC motors.

Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.
DiaLimit	Inner limited diameter of PM ducts
ThkBridge	Bridge thickness
ThkWeb	Web thickness
AngOffOut	Outer (web) angle offset
ThkDuctOut	Outer duct thickness
ThkDuctIn	Inner duct thickness
ThkPostOut	Outer post thickness
ThkPostIn	Inner post thickness, <0 for duct bottom corner radius
ThkPostMid	Center post thickness
WidMagOut	One-side width of outer magnets
GapMagOut	Two-side gap of outer magnets (ThkMagOut = ThkDuctOut – GapMagOut)
WidMagIn	Total width of inner magnets per pole
GapMagIn	Two-side gap of inner magnets (ThkMagIn = ThkDuctIn – GapMagIn)
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: inner magnet; 4: left magnet; 5: right magnet; 100: region.

Most parameters for a UPMCore UDP are shown in the figure below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.



Parameters of a UPMCore UDP with **AngOffOut** = -10°.

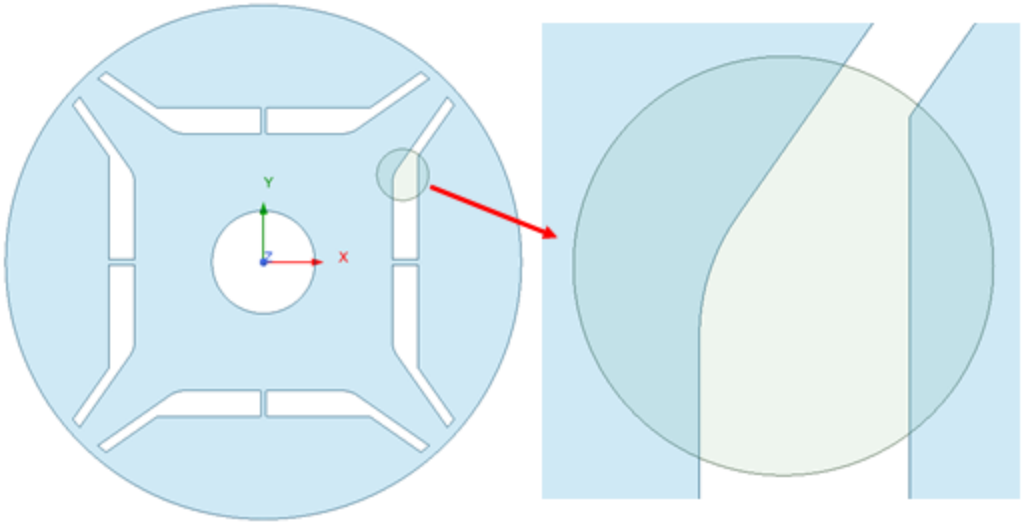
Please notice that when **AngOffOut** = 0, the edges of outer PM ducts between two adjacent poles are parallel. When **AngOffOut** > 0, the inner web thickness is smaller than the outer web thickness which is labeled as **ThkWeb**. When **AngOffOut** < 0, the inner web thickness is larger than the outer web thickness, as shown above.

Creating a U-Type IPM Core

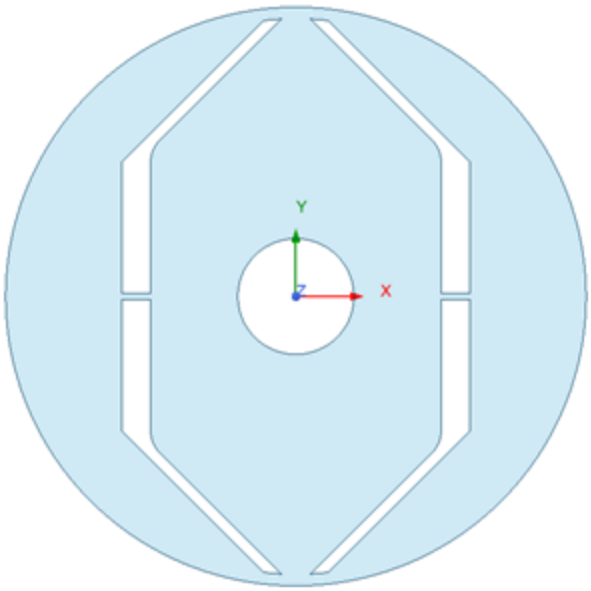
You can create a U-type IPM core with **InfoCore** = 0.

With the default settings of the UPMCore UDP, the created U-type IPM core is shown below.

You can input a negative value for **ThkPostIn**. When **ThkPostIn** < 0, its absolute value, Rc = abs (**ThkPostIn**), is the radius of a fillet at the bottom corner of the PM ducts. The upper limited value of Rc is the maximum value of thickness of the inner and outer ducts. That is, the center point of the fillet arc will always within PM ducts. When **ThkPostIn** < 0, there will be no outer post, that is, the value of **ThkPostOut** will be automatically changed to 0.



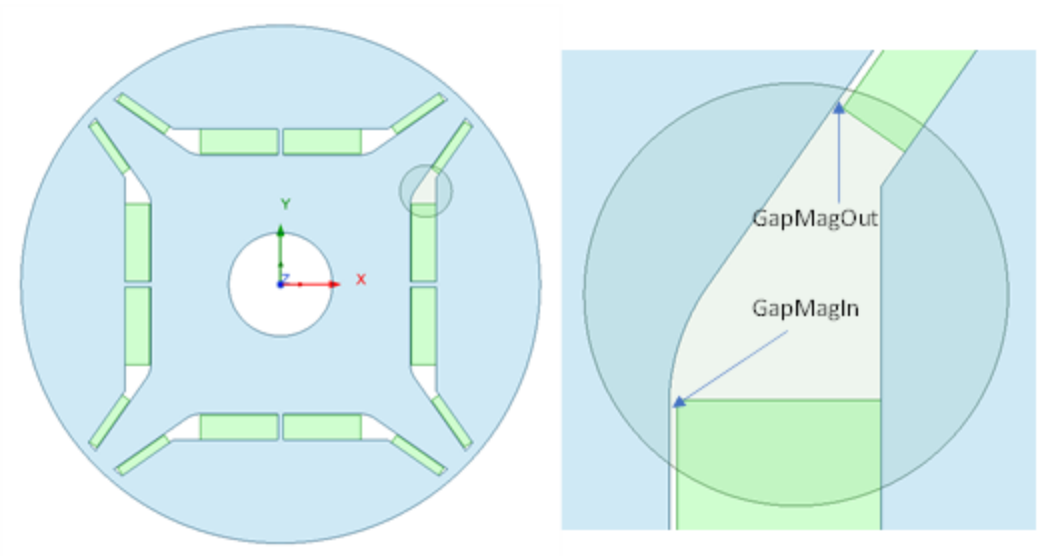
You can also create a U-type IPM core of 2 poles. The following figure is an example of a 2-pole U-type IPM core, where the setting value of **AngOffOut** is -45.



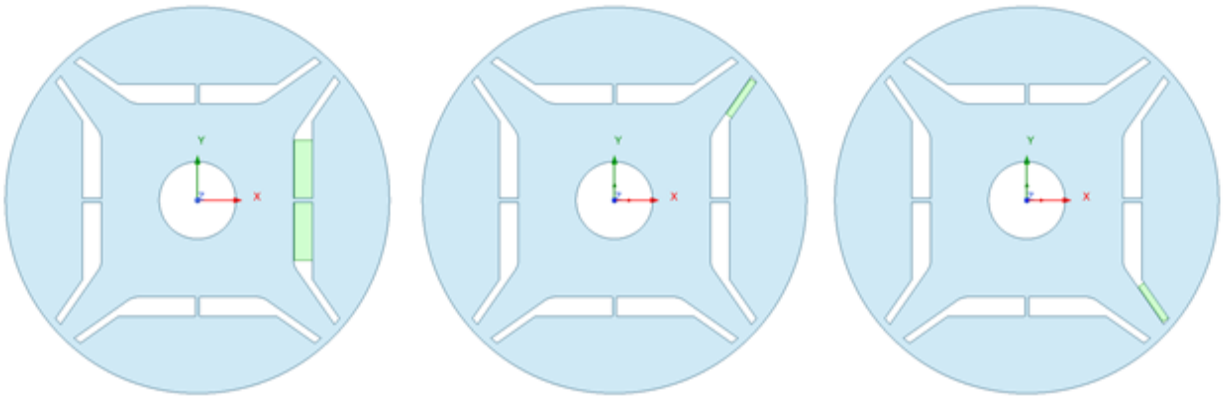
Creating Magnets (UPM Core)

All magnets of a U-type IPM Core are created by setting the value of **InfoCore** to 1, as shown below.

Please notice that **GapMagOut** and **GapMagIn** include all gaps of both top and bottom sides. If both top and bottom gaps are 0.1mm, the created magnets will be located inside the PM ducts in such a way that the top gap is 0, and the bottom gap is 0.2mm. This will not affect the performance solutions. However, this enhances the mesh quality greatly.



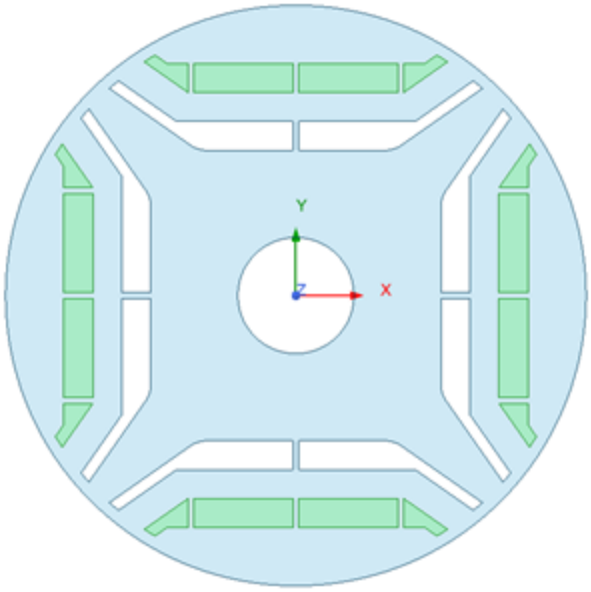
To easily assign the direction of magnet excitation, magnets can be created one-by-one by setting the value of **InfoCore** to 3, 4, or 5. The setting of **InfoCore** = 3 is used to create inner magnet(s) as one object no matter whether it is separated by the center post or not, and the value of **WidMagIn** stands for the total width of inner magnet(s). **InfoCore** = 4 is used to create the left-side magnet, and **InfoCore** = 5 to create the right-side magnet, as shown below.



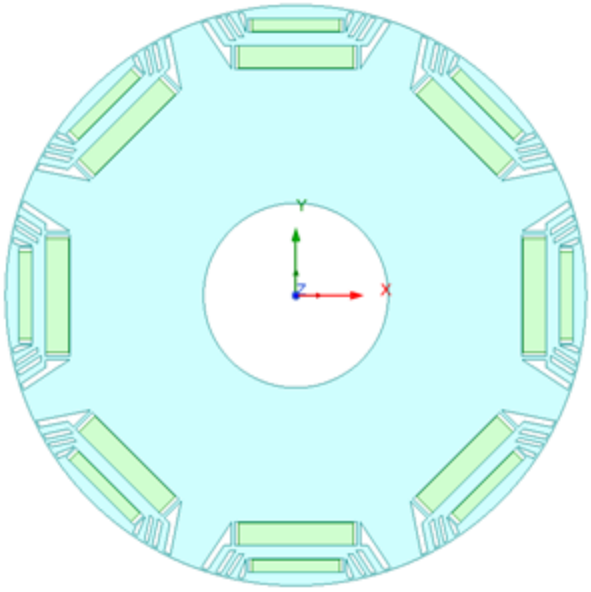
Creating PM Ducts (UPM Core)

All PM ducts of a U-type IPM Core are created by setting the value of **InfoCore** to 2. Subtracting a PM duct set, we can create a poly-layer U-type IPM core

A U-type PM duct set, together with a U-type IPM core, is shown below. The parameters of the additional ducts can be totally different from those of the original core



If you subtract the additional PM duct set from the core, you can get a core with two-layer PM ducts. Continuing to create and subtract additional PM duct sets, we can create an IPM core with an arbitrary number of layers of PM ducts. The figure below shows an IPM core with 4-layer PM ducts. Please notice that when **ThkDuctIn** = 0, the PM ducts will have only the outer parts, and when **ThkDuctOut** = 0, the PM ducts will have only the inner parts.



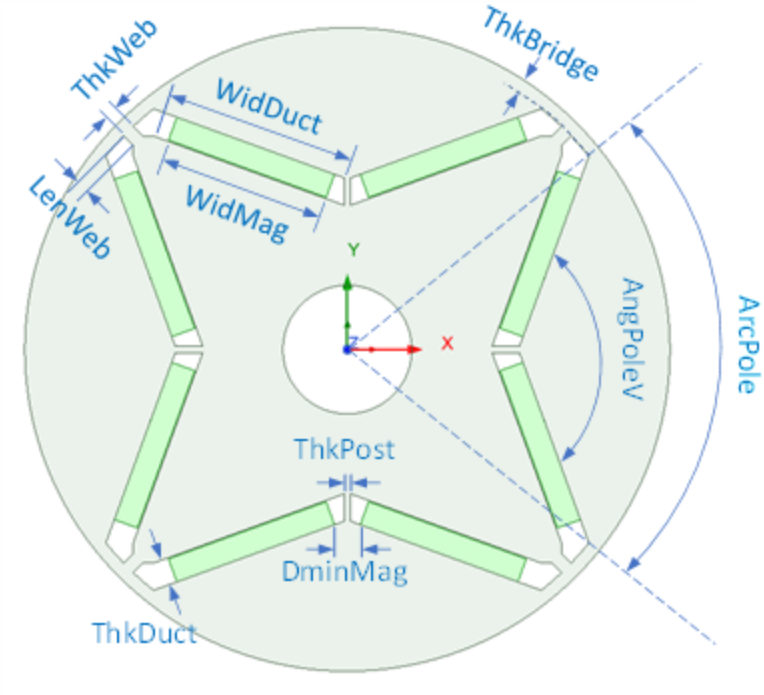
VPMCore UDP

The VPMCore UDP is used to create a single- or poly-layer V-type IPM core and PMs for IPM synchronous machines, or IPM brushless DC motors.

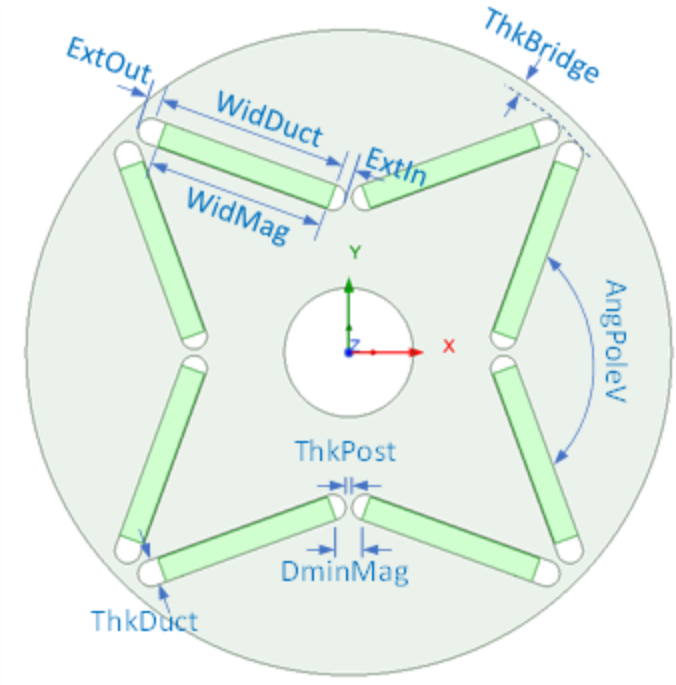
Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles.
PoleType	0: web; 1: simple.
ThkBridge	Bridge thickness.
ThkDuct	Magnet duct thickness.
WidDuct	Magnet duct width.
ThkWeb/ExtOut	Web thickness (web type), or outer extension (simple type).
LenWeb/ExtIn	Web length (web type), or inner extension (simple type).
AngPoleV	Pole-V angle
ArcPole	Pole arc, in electric degrees, for web pole type only.
ThkPost	Center post thickness, < 0 for duct bottom corner radius (web type)
DminMag	Minimum distance between two-side magnets

Property	Description
WidMag	One-side width of magnets
GapMag	Two-side gap of magnets (ThkMag = ThkDuct – GapMag)
LenRegion	Region length.
InfoCore	0: core; 1: magnets; 2: ducts; 3: left magnet; 4: right magnet; 100: region.

Most parameters for a VPMCore UDP are shown in the figures below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.



Parameters of VPMCore UDP (**PoleType** = 0).



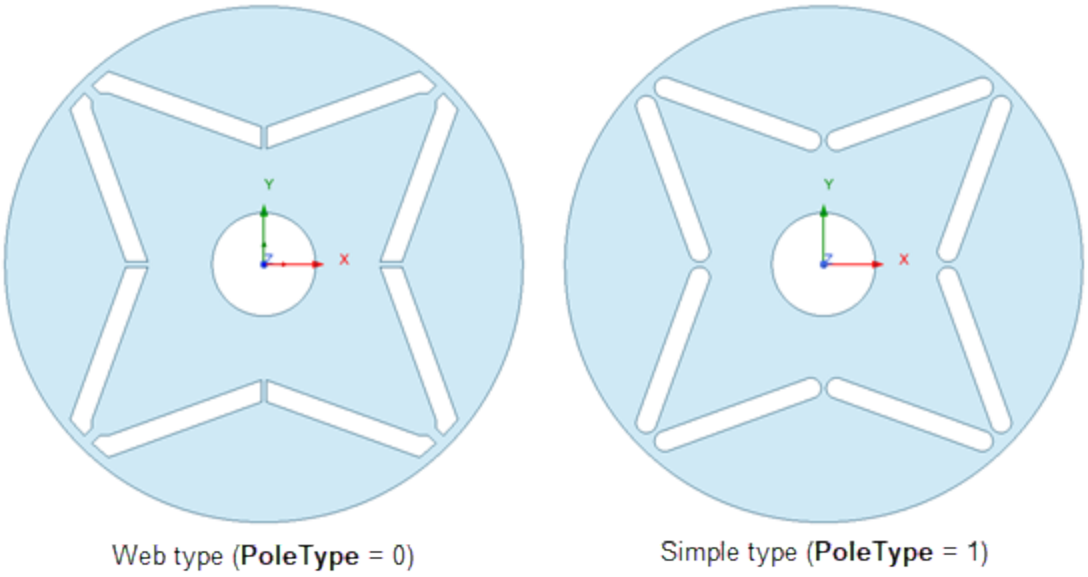
Parameters of VPMCore UDP (**PoleType** = 1).

Creating a V-Type IPM Core

You can create a V-type IPM core by setting **InfoCore** = 0.

With the default settings of the VPMCore UDP, the created V-type IPM cores of web type (**PoleType** = 0) and simple type (**PoleType** =1) are shown below.

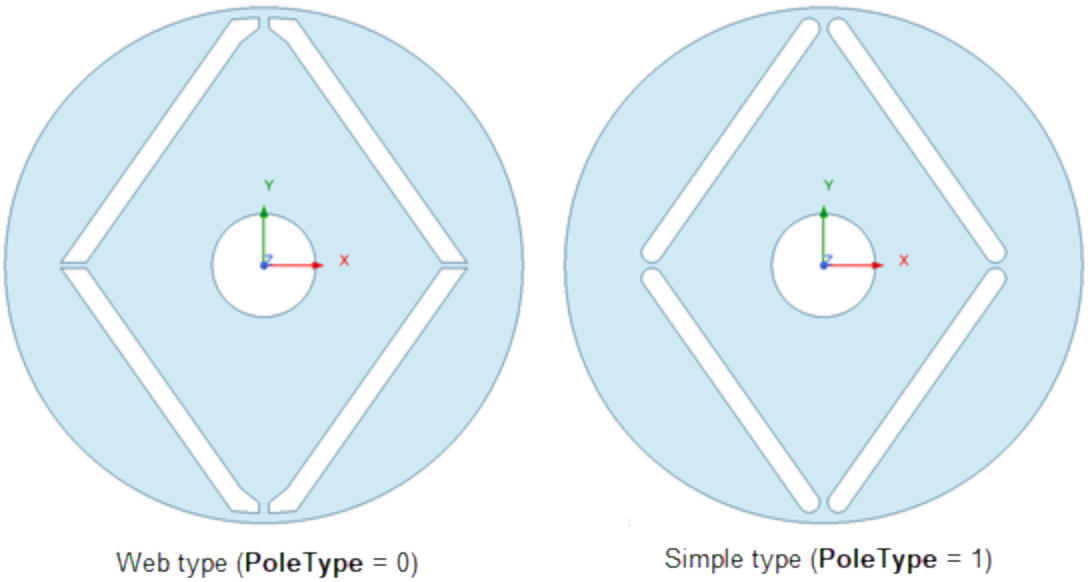
For a web-type core, you can input a negative value for **ThkPost**. When **ThkPost** < 0, its absolute value, Rc = abs(**ThkPost**), is the radius of a fillet at the bottom corner of the PM ducts. The upper limited value of Rc is the thickness of the PM ducts. For a simple-type core, the upper limit value for **ExtOut** and **ExtIn** is a half thickness of PM ducts.



Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

4-pole V-type IPM cores

We can create a V-type IPM core of 2 poles. The figure below is an example of 2-pole V-type IPM core, where the value of **AngPoleV** is 250.



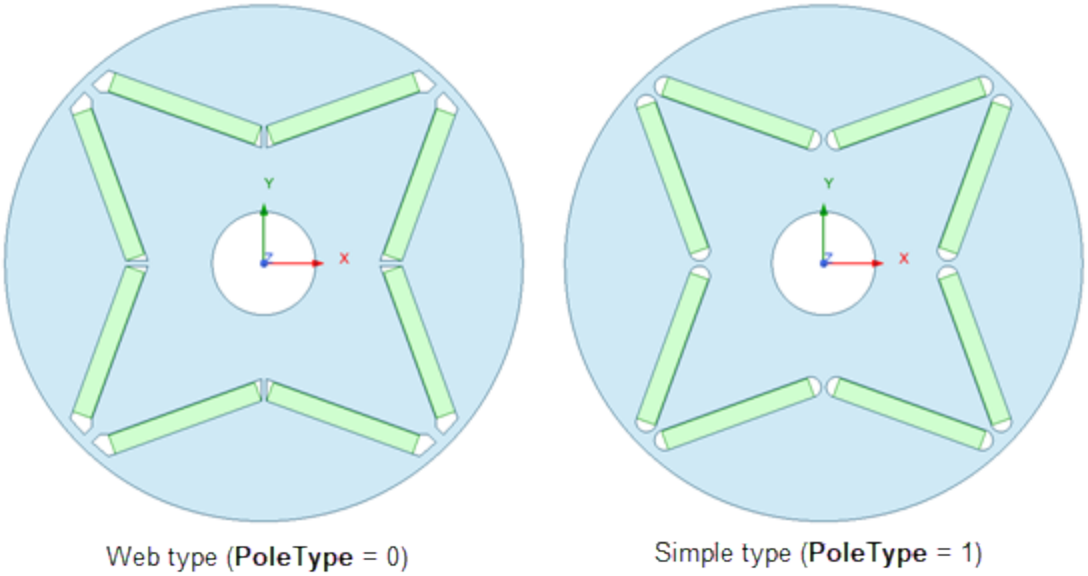
Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

2-pole V-type IPM cores

Creating Magnets (VPM Core)

All magnets of a V-type IPM Core are created by setting the value of **InfoCore** to 1. V-type IPM cores of web type and simple type with all magnets are shown below.

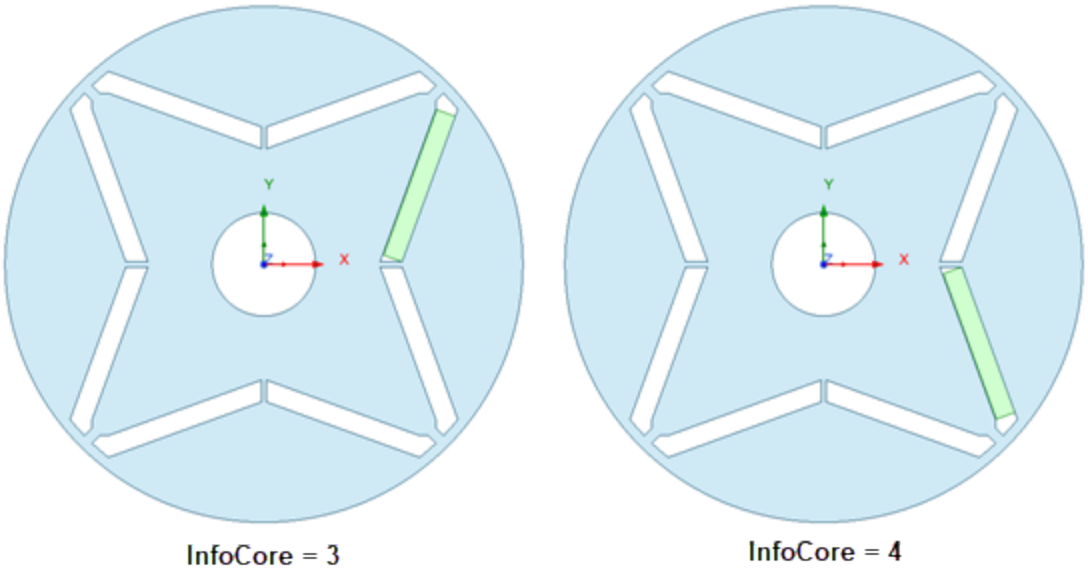
Please notice that **GapMag** includes total gaps of both top and bottom sides. If both top and bottom gaps are 0.1mm, the created magnets will be located inside the PM ducts in such a way that the top gap is 0, and the bottom gap is 0.2mm. This will not affect the performance solutions. However, this enhances the mesh quality greatly.



Web type (**PoleType** = 0) Simple type (**PoleType** = 1)

V-type IPM cores with all magnets

To easily assign the direction of magnet excitation, magnets can be created one-by-one by setting the value of **InfoCore** to 3, or 4. The setting of **InfoCore** = 3 is used to create the left-side magnet and **InfoCore** = 4 is used to create the right-side magnet as shown below.



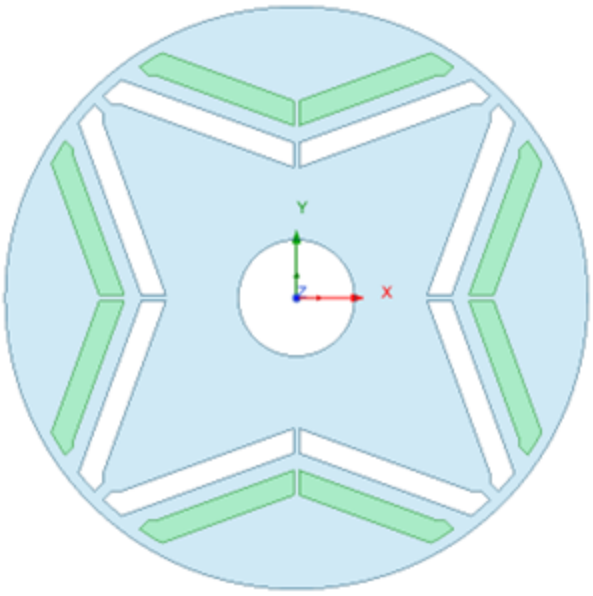
V-type IPM core with a single magnet

When the input values of magnet width are too large to fit in the PM ducts, they will be modified based on the maximum possible sizes.

Creating PM Ducts (VPM Core)

All PM ducts of a V-type IPM Core are created by setting the value of **InfoCore** to 2. Subtracting a PM duct set, you can create a poly-layer V-type IPM core

A V-type PM duct set, together with a V-type IPM core, is shown below. The parameters of the additional ducts can be totally different from those of the original core.



If you subtract the additional PM duct set from the core, you can get a core with two-layer PM ducts. Continuing to create and subtract additional PM duct sets, we can create an IPM core with an arbitrary number of layers of PM ducts.

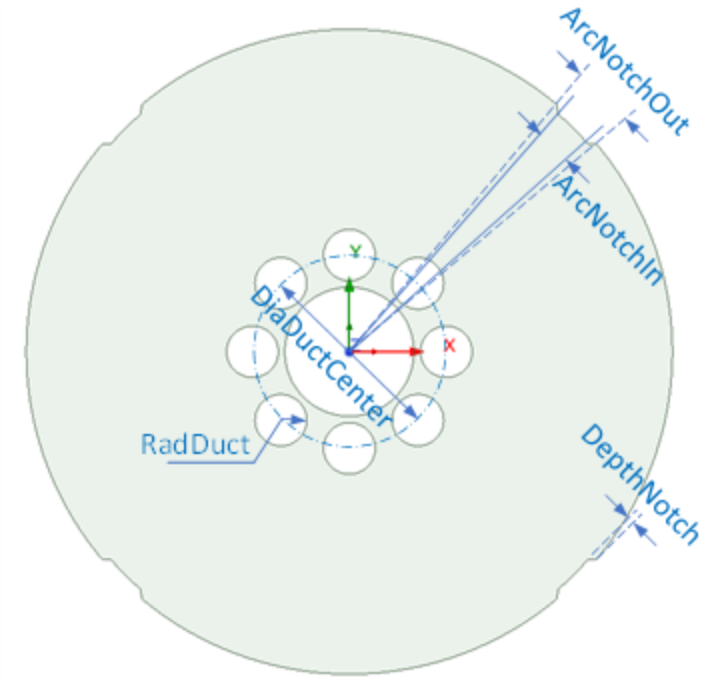
VentCore UDP

The VentCore UDP is used to create a vent core, a vent shaft, vent ducts, as well as notches, for various cores of electrical machines. A vent core can be used as a base object from which some tool objects can be subtracted to form various machine cores. The vent ducts and notches can also be used as tools to be subtracted from other machine cores.

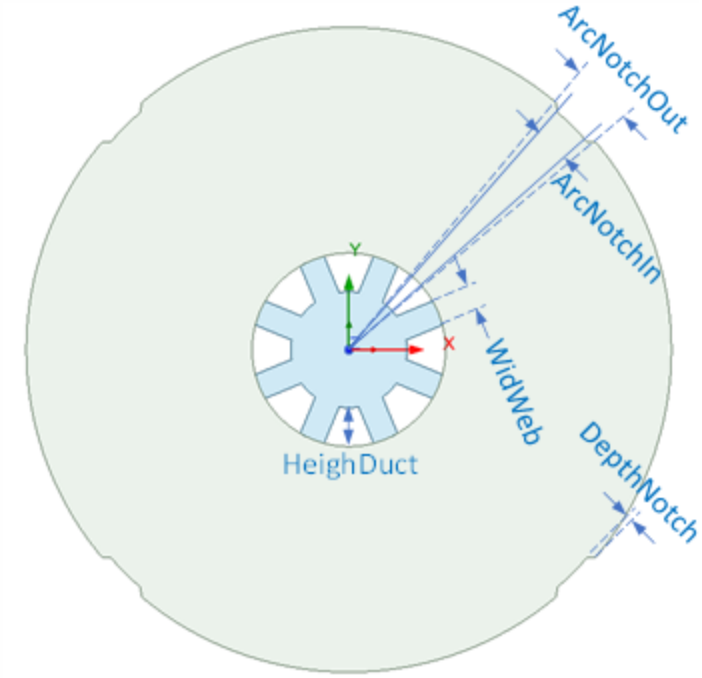
Property	Description
DiaGap	Core diameter on gap side, or outer diameter.
DiaYoke	Core diameter on yoke side, or inner diameter.
Length	Core length.
Poles	Number of poles for notches.
DepthNotch	Notch depth.
ThkBridge	Bridge thickness.
ArcNotchOut	Notch outer arc, in electric degrees.
ArcNotchIn	Notch inner arc, in electric degrees.
Ducts	Number of axial vent ducts.
DuctType	0: none; 1: circular; 2: shaft spoke; 3: arc; 4: rectangular.

Property	Description
DiaDuctCenter	Diameter of duct center (not for shaft spoke).
HeightDuct	Duct height in radial direction.
WidDuct/WidWeb	Duct width (rectangular) or web width (shaft spoke, arc).
RadDuct	Duct radius (circular) or corner radius (arc, rectangular).
AngDuctShift	Duct shift angle.
LenRegion	Region length.
InfoCore	0: core; 1: shaft; 2: ducts; 3: notches; 100: region.

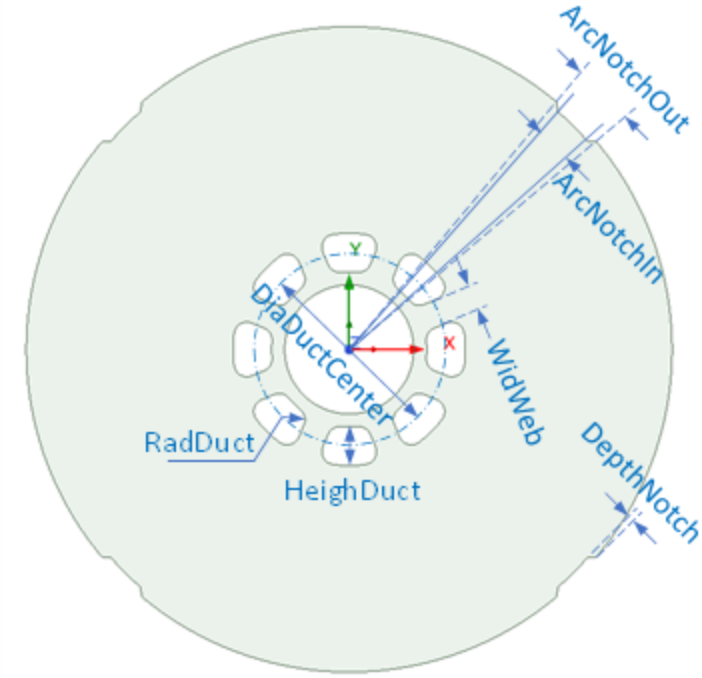
Most parameters for a VentCore UDP are shown in the figures below except common parameters like **DiaGap**, **DiaYoke**, and **Length**.



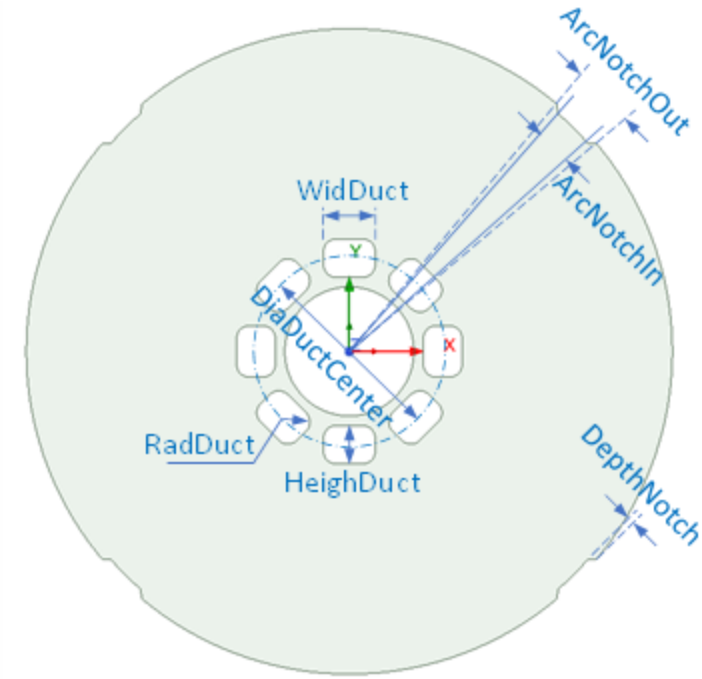
Parameters of VentCore UDP (**DuctType** = 1).



Parameters of VentCore UDP (**DuctType** = 2).



Parameters of VentCore UDP (**DuctType** = 3).

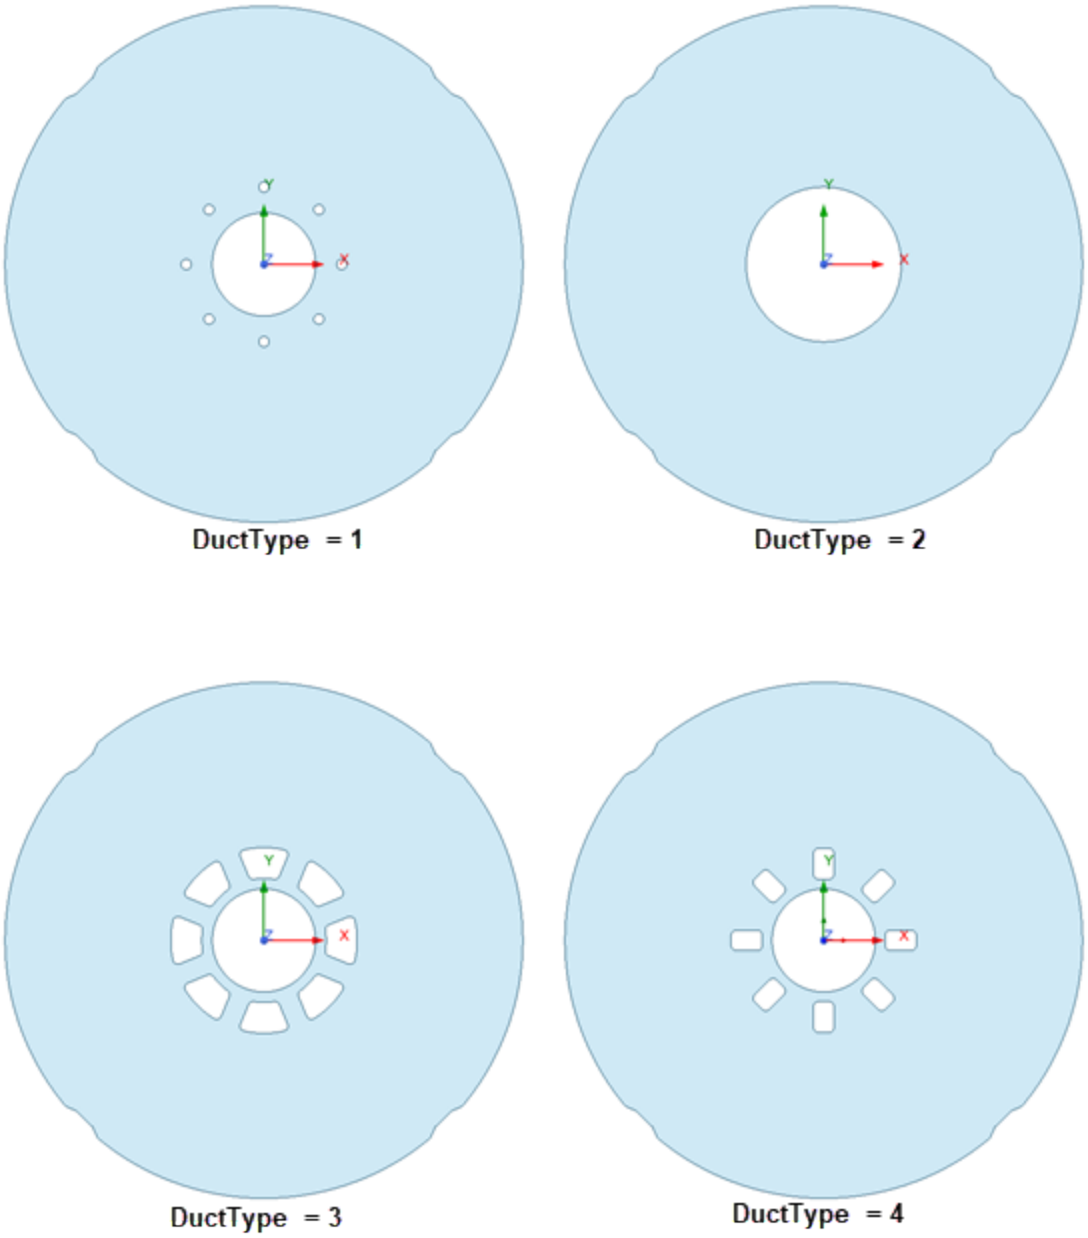


Parameters of VentCore UDP (**DuctType** = 4).

Creating a VentCore

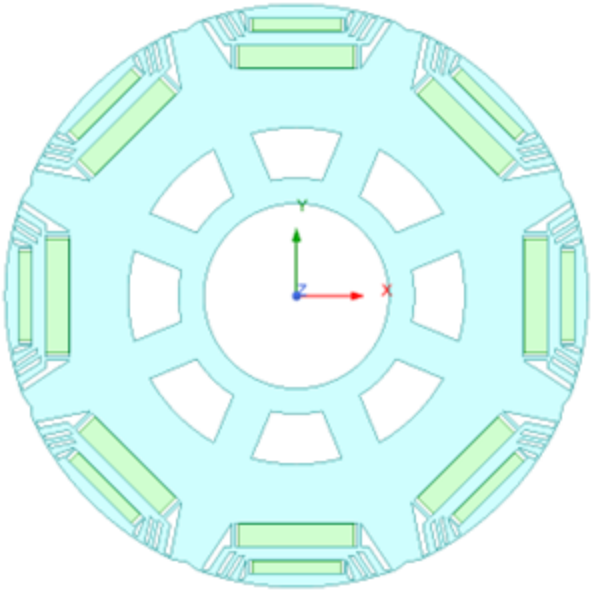
You can create a vent core from VentCore UDP by setting **InfoCore** = 0.

With the default parameter settings of the VentCore UDP, the created vent cores of different duct types are shown in the figures below. Note that the value of **DiaYoke** for **DuctType** = 2 is modified to 30mm to pass the validation.



VentCores of various Duct Types

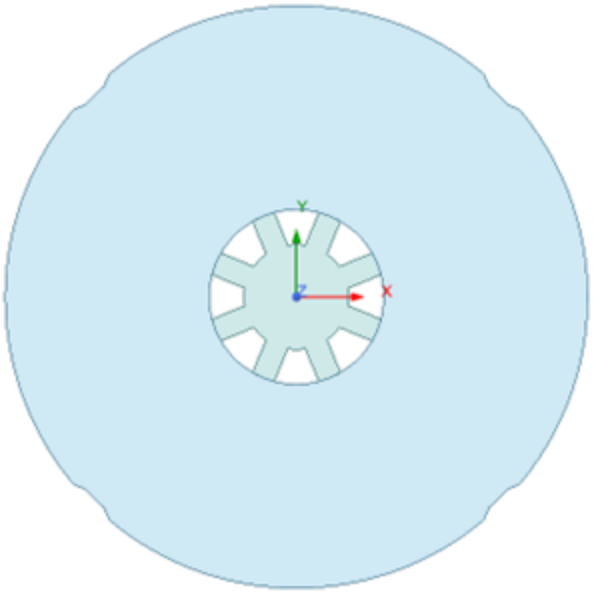
The following figure shows an example in which a vent core is used as a base object, and several U-type IPM ducts are used as tool objects to be subtracted from the vent core to form a poly-layer IPM core with vent ducts.



A poly-layer IPM core with vent ducts.

Creating a Shaft (VentCore)

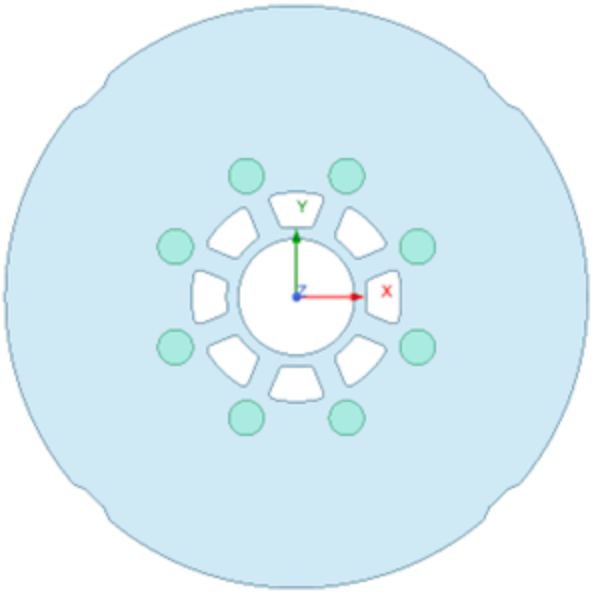
You can create a vent core shaft using the VentCore UDP by setting the value of **InfoCore** to 1. A shaft, together with a V-type IPM core with **DuctType** = 2, is shown below.



Creating Vent Ducts (VentCore)

All vent ducts of a vent core are created by setting the value of **InfoCore** to 2. Subtracting a vent duct set, you can create a vent core with poly-layer vent ducts.

A vent duct set, together with a vent core, is shown in the figure below. The parameters of the additional ducts can be totally different from those of the original core.



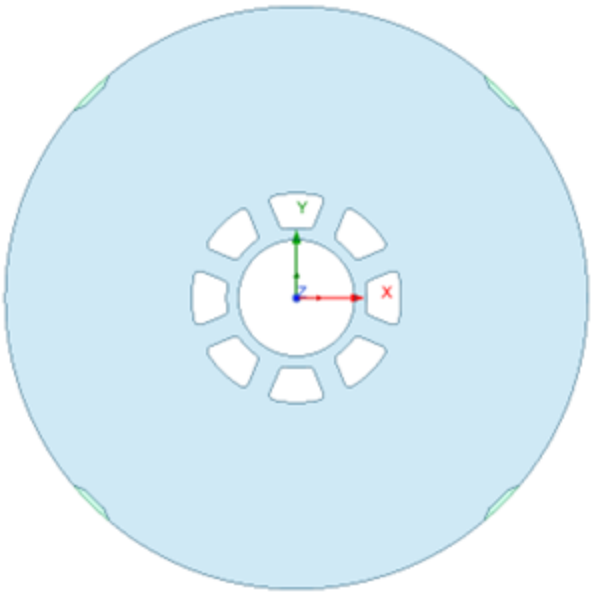
A vent duct set of **DuctType** = 1, with a vent core of **DuctType** = 3.

If you subtract the additional vent duct set from a vent core, you can get a core with two-layer vent ducts. Continuing to create and subtract additional vent duct sets, you can create a vent core with an arbitrary number of layers of vent ducts.

Creating Notches (VentCore)

All notches of a vent core are created by setting the value of **InfoCore** to 3, which can be subtracted from an IPM core to improve the air-gap flux density waveforms.

All created notches, together with a vent core of **DuctType** = 3, are shown in the figure below. The parameters of the additional Notches can be totally different from those of the original core.



Notches together with a vent core of **DuctType** = 3.

UDPs for Other Cores and Coils

UDPs defined for other cores and coils include:

- DiskSlotCore UDP
- DiskCoil UDP
- DiskPMCore UDP
- LinearMCore UDP
- TransCore UDP
- TransCoil UDP
- TransTwist UDP

DiskSlotCore UDP

The DiskSlotCore UDP is used to create a stator/rotor core for axial-flux machines. It can also create a squirrel-cage winding of the axial-flux type.

Property	Description
DiaOuter	Core outer diameter.
DiaInner	Core inner diameter.
Thickness	Core axial thickness per side.
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided).

Property	Description
Skew	Skew angle.
Slots	Number of slots.
SlotType	Slot type: 1 to 6.
Hs0	Slot opening height.
Hs01	Slot closed bridge height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: tangent connection.
HalfSlot	0: symmetric slots; 1: half slots.
RingLength	One-side radial ring length.
RingHeight	Axial ring height.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
InfoCore	0: core only; 1: squirrel cage only.

These parameters are used in the following figures.

Note	
	• For parameters such as **Skew**, **FilletType**, **SegAngle**, **HalfSlot** and parameters related to slots, refer to SlotCore UDP parameters. • Figures are shown in pairs to compare parameters when the **InfoCore** value varies.

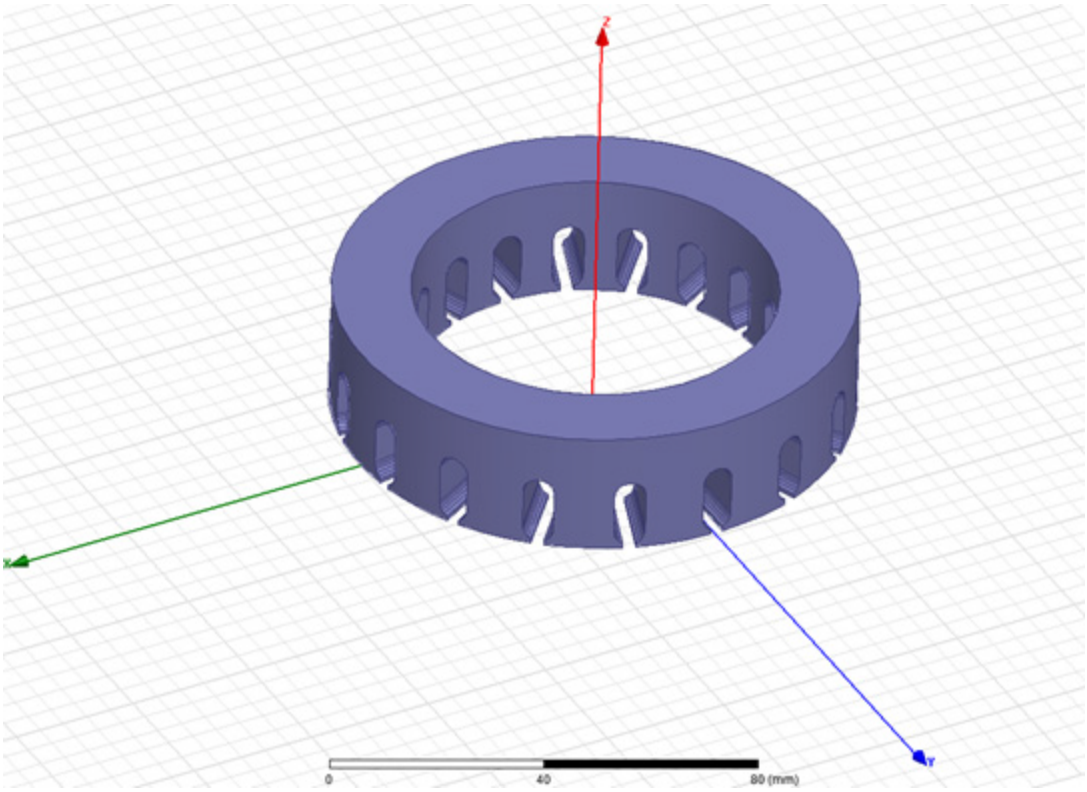


Figure 9-184 Overview of DiskSlotCore (InfoCore set to 0)

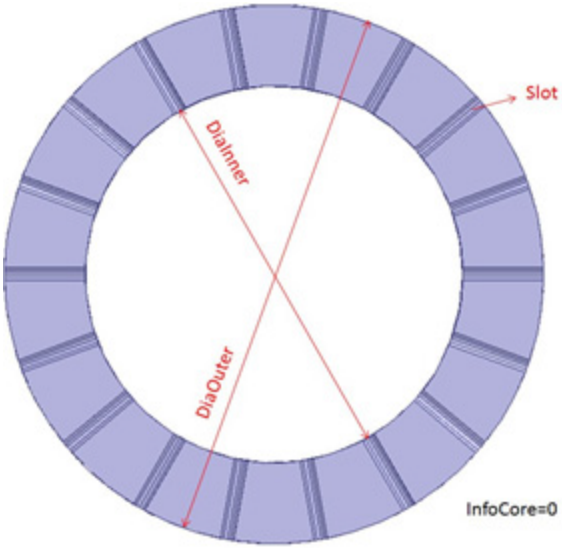

Figure 9-185 DiskSlot Core (InfoCore set to 0)

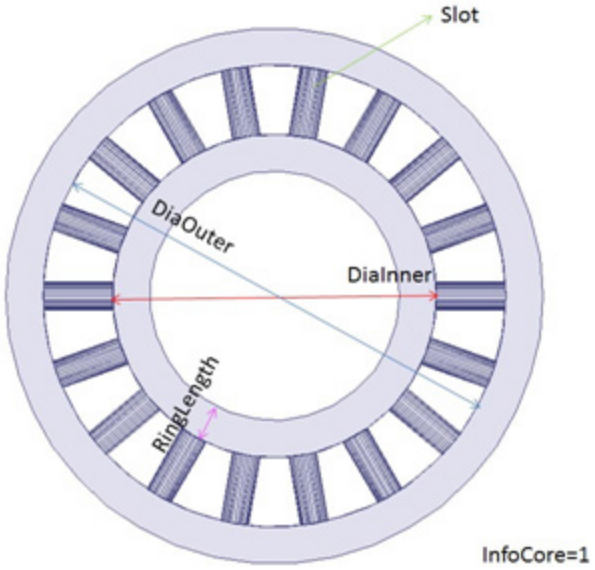

Figure 9-186 DiskSlot Core (InfoCore set to 1)

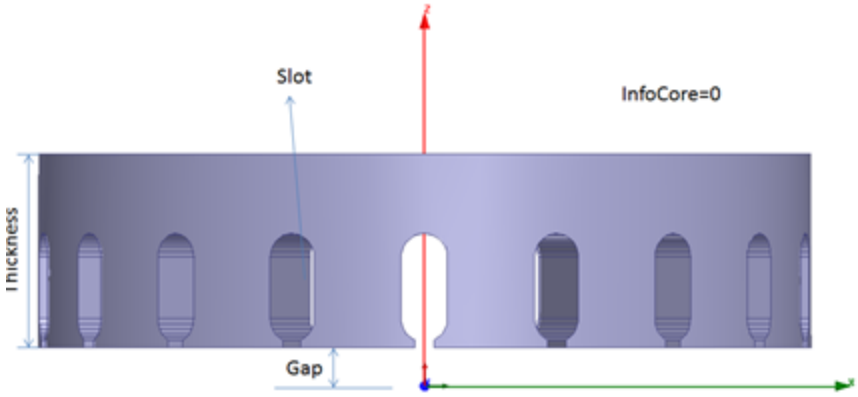

Figure 9-187 3D DiskSlot Core (InfoCore set to 0)

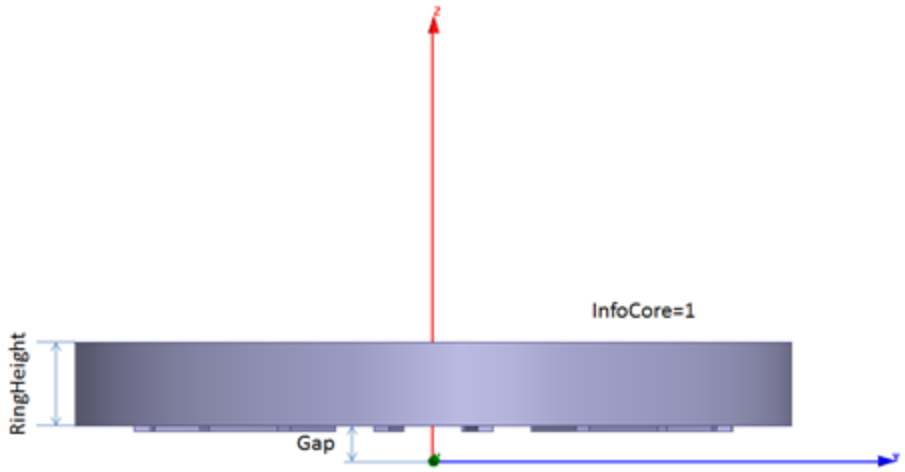

Figure 9-188 3D DiskSlot Core (InfoCore set to 1)

Creating an Upper or Lower Axial-FluxSlot Core (DiskSlot Core)

You can create an axial-flux slot core of a DiskSlot Core manually by setting the value of **InfoCore** to 0.

For an upper core, set the value of **Gap** to be larger than 0, as shown in Figure 9-184 and Figure 9-187 ; for a lower core, set this value to be smaller than 0, which is shown in Figure 9-189 .

You can assign the value of this property either when creating a DiskSlot core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

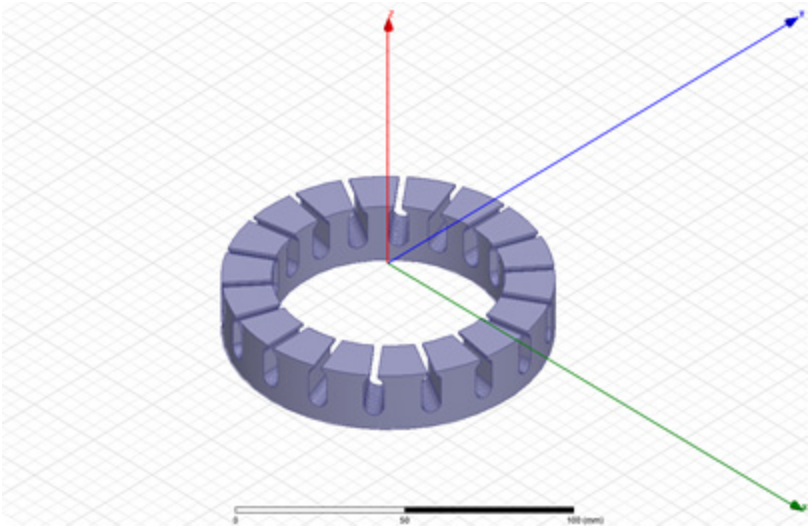

Figure 9-189 Lower axial-flux slot core

Creating a Squirrel-Cage Winding

You can create squirrel-cage winding of a DiskSlot core manually by setting the property of **InfoCore** to 1. An example of squirrel-cage winding is shown in Figure 9-186 .

You can assign the value of this property either when creating an axial-flux slot core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

DiskCoil UDP

The DiskCoil UDP is used to create a lap-type coil in an axial-flux slotted core created by the DiskSlotCore UDP for axial-flux machines. It can also create a coil terminal for current assignment.

Property	Description
DiaOuter	Core outer diameter.
DiaInner	Core inner diameter.
Thickness	Core axial thickness per side.
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided).
Skew	Skew angle.
Slots	Number of slots.
SlotType	Slot type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
FilletType	0: a quarter circle; 1: tangent connection.
Layers	Number of winding layers.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side radial end extended length.
EndClr	Clearance between two end spans; 0 for no span.
SegAngle	Deviation angle for end span (5~15, <5 for true surface).
InfoCoil	0: winding; 1: coil; 2: terminal.

Note	• For parameters such as **Skew**, **FilletType**, **SegAngle**, **HalfSlot** and parameters

	related to slots, refer to SlotCore UDP parameters. • Figure 9-191 can be used in comparison to Figure 9-190 to show **CoilPitch** parameter. • A DiskSlot core is used as reference in Figure 9-192 to show **EndExt** and **EndClr** parameters.

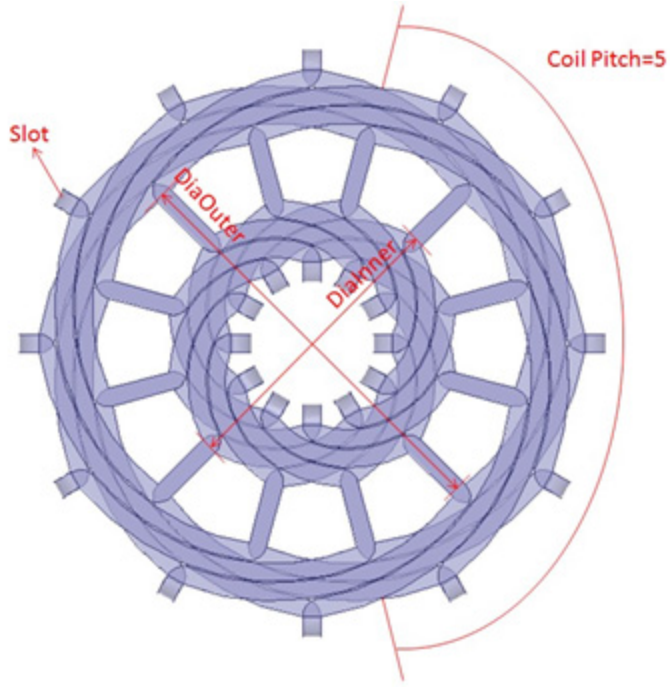

Figure 9-190 All disk coils (InfoCore set to 0)

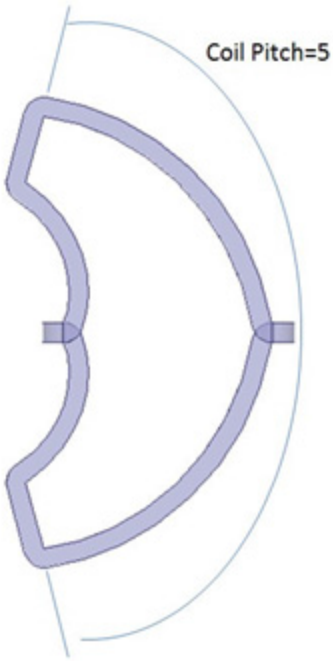

Figure 9-191 One disk coil (InfoCore set to 1)

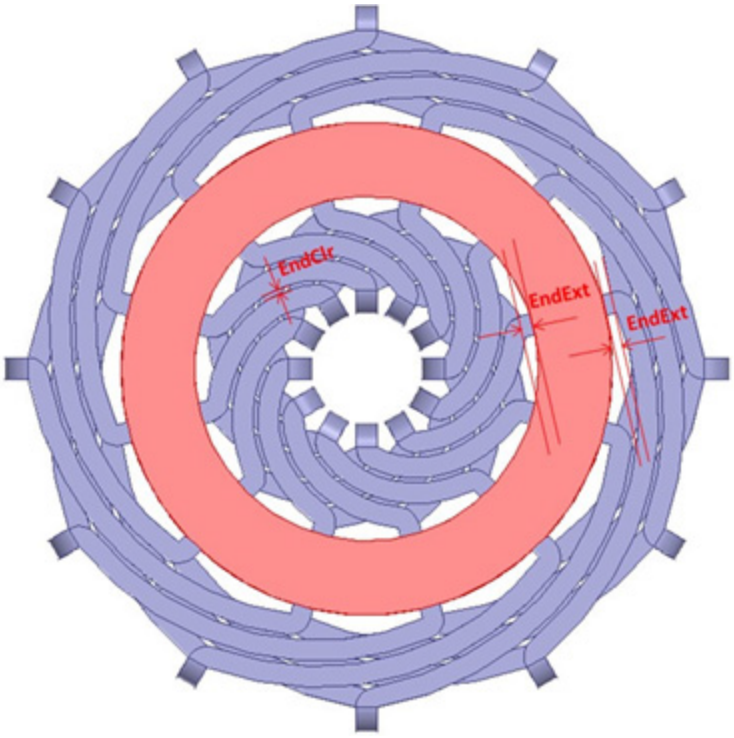

Figure 9-192 EndExt and EndClr parameters (InfoCore set to 0)

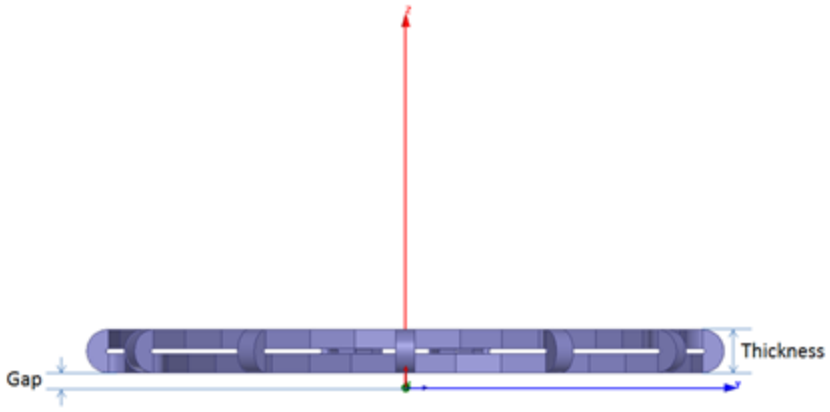

Figure 9-193 Gap and Thickness parameters (InfoCore set to 0)

Creating a Whole Winding (Upper or Lower)

You can create a whole winding of a DiskCoil Core manually by setting the property of **InfoCoil** to 0.

For an upper core, set the value of **Gap** to be larger than 0, which is shown in Figure 9-193 ; for a lower core, set this value to be smaller than 0, which is shown in Figure 9-194 .You can assign the value of this property either when creating the DiskCoil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

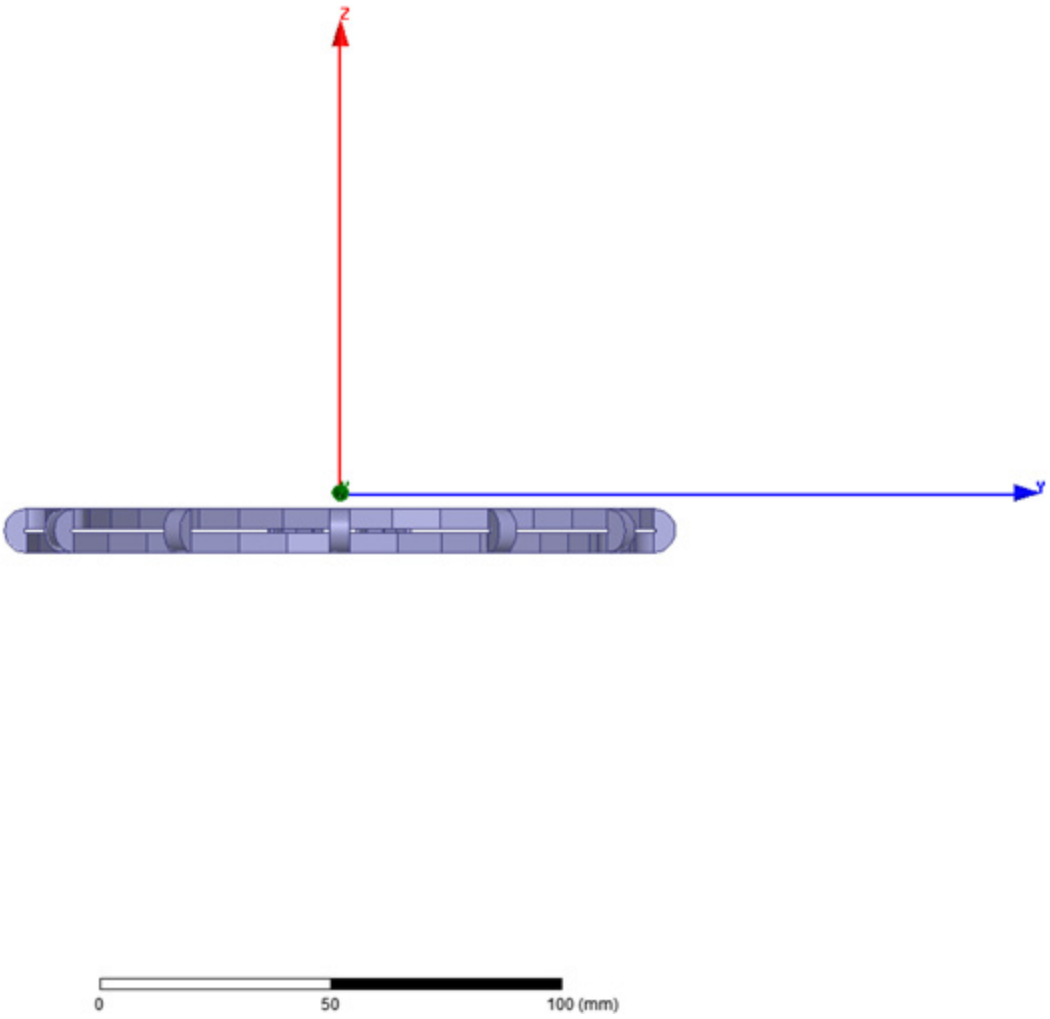

Figure 9-194 Lower whole winding

Creating a Lap Coil and its Terminals

You can create a lap coil of a DiskCoil manually by setting the value of **InfoCoil** to 1. An example is shown in Figure 9-191 .

You can create a terminal of a DiskCoil manually by setting the value of **InfoCoil** to 2. An example is shown in Figure 9-195 .

You can assign the value of this property either when creating a DiskCoil or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

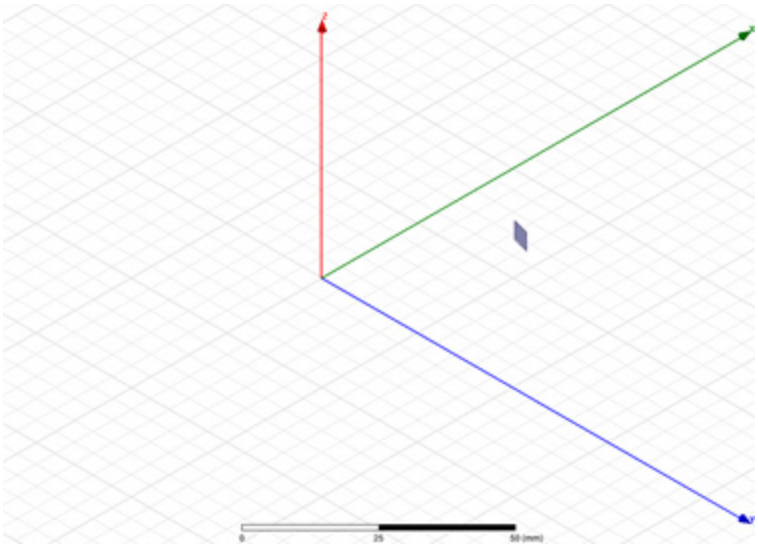

Figure 9-195 A terminal of a DiskCoil UDP

DiskPMCore UDP

The DiskPMCore UDP is used to create a PM core of the axial-flux type for axial-flux PM machines.

Property	Description
DiaOuter	Core outer diameter.
DiaInner	Core inner diameter.
Thickness	Core axial thickness per side.
Gap	Gap between core & xy plane (>0: upper; <0: lower; =0: double-sided).
Skew	Skew angle.
Poles	Number of poles.
Embrace	Pole embrace.
ThickMag	Magnet axial thickness per side.
InfoCore	0: core only; 1: all PMs; 2: one PM only.

Note	There are two objects in each of the following figures. Both objects in each figure are DiskPMCore. The value of **InfoCore** of one DiskPMCore is 1 (red object), the other's is 0 (gray object).

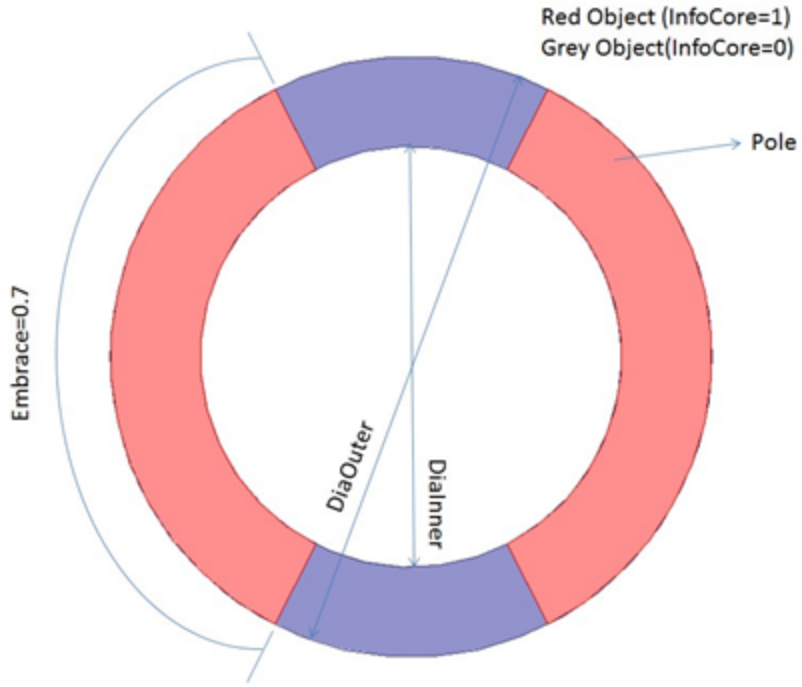

Figure 9-196 DiskPM core parameters on x-y plane

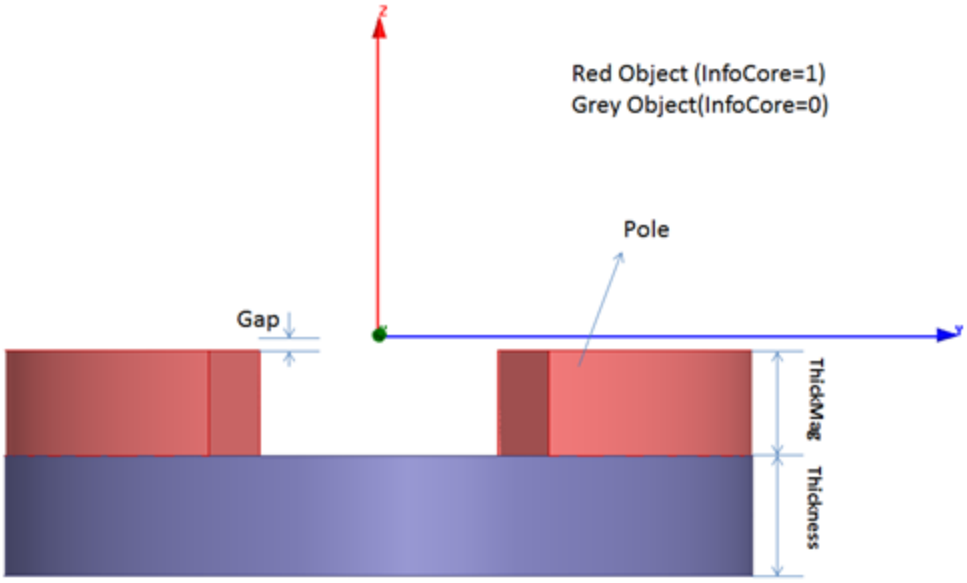

Figure 9-197 DiskPM core parameters in axial direction

Creating an Upper or Lower Axial-Flux PM Core

You can create an axial-flux PM core of a DiskPM core manually by setting the value of **InfoCore** to 0.

For an upper core, set the value of **Gap** to be larger than 0; for a lower core, set this value to be smaller than 0.

An example of an upper core is shown in Figure 9-198 , whereas a lower core is in Figure 9-199 .

You can assign the value of this property either when creating a Disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

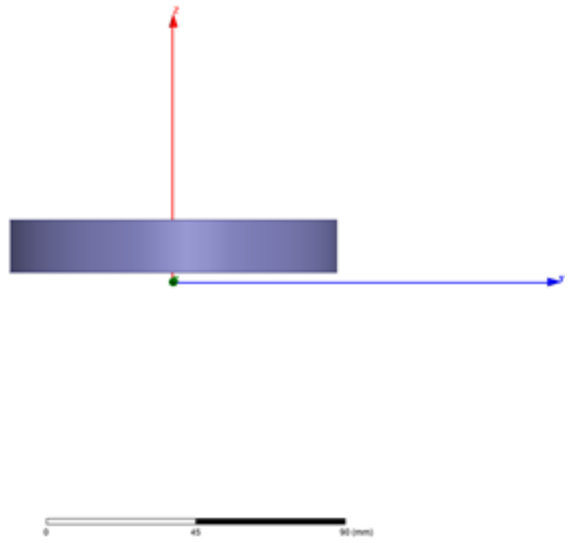

Figure 9-198 . Upper axial-flux PM core

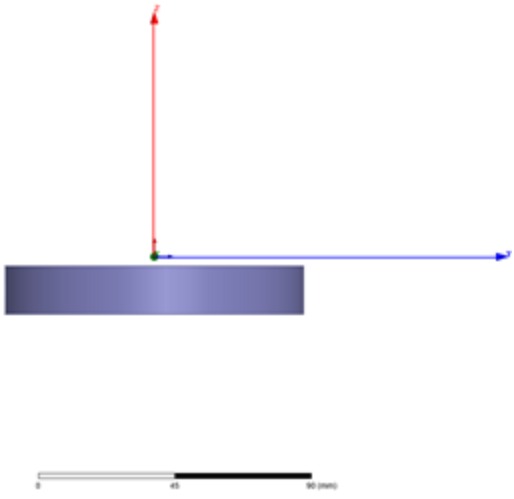

Figure 9-199 Lower axial-flux PM core

Creating All Magnets (Disk PM Core)

You can create all magnets of a disk PM core manually by setting the value of **InfoCoil** to 1. An example of all magnets is shown in Figure 9-196 and Figure 9-197 as a red object.

You can assign the value of this property either when creating a disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating One Magnet Only (Disk PM Core)

You can create a single magnet of a disk PM core manually by setting the property of **InfoCoil** to 2. An example of one magnet is shown in Figure 9-200 .

You can assign the value of this property either when creating a disk PM core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

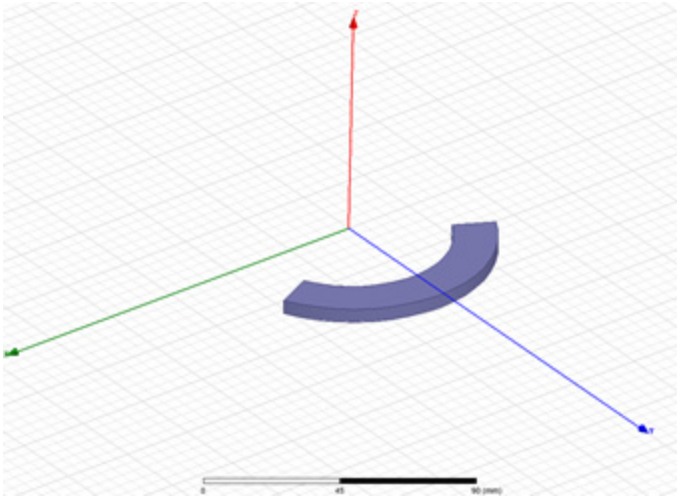

Figure 9-200 One magnet of disk PM core

LinearMCore UDP

The LinearMCore UDP is used to create the mover core and the armature winding for linear motors. It can also create a coil terminal for current assignment.

Property	Description
WidthCore	Core width in motion direction.
ThickCore	Core thickness.
Length	Core length.
SlotPitch	The distance between two slots.

Property	Description
Slots	Number of slots.
SlotType	Slot type: 1 to 7.
Hs0	Slot opening height.
Hs1	Slot wedge height.
Hs2	Slot body height.
Bs0	Slot opening width.
Bs1	Slot wedge maximum width.
Bs2	Slot body bottom width, 0 for parallel teeth.
Rs	Slot body bottom fillet.
Layers	Number of winding layers.
CoilPitch	Coil pitch measured in slots.
EndExt	One-side end extended length.
SpanExt	Axial length of end span; 0 for no span.
SegAngle	Deviation angle for slot arches (10~30, <10 for true surface).
InfoCore	0: core only; 1: core & all coils; 2: one coil only.

Note	
	• For parameters such as **SegAngle** and parameters related to slots, refer to SlotCore UDP parameters. • The InfoCore values of the following two figures are both 1 to better describe other parameters such as **EndExt** and **SpanExt**.

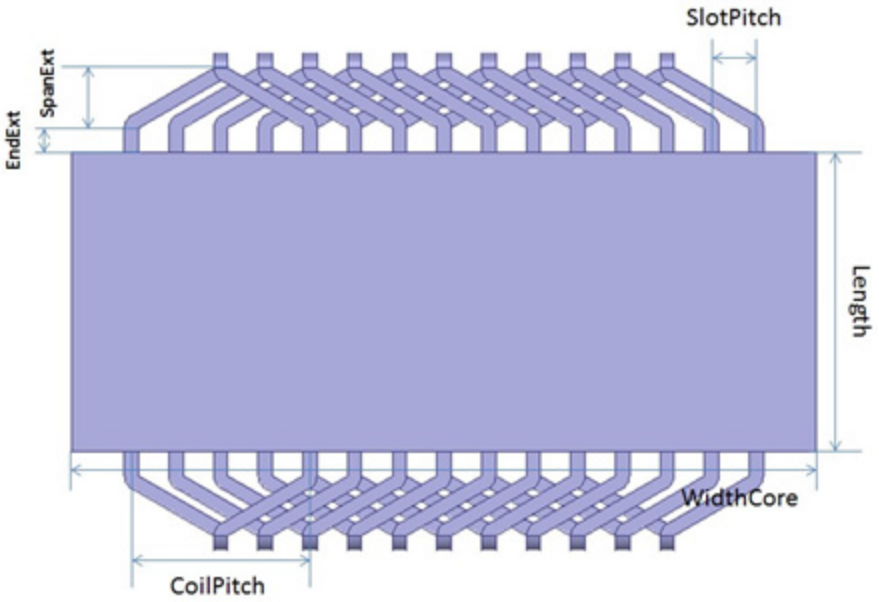

Figure 9-201 Parameters of LinearMCore in x-y plane (InfoCore set to 1)

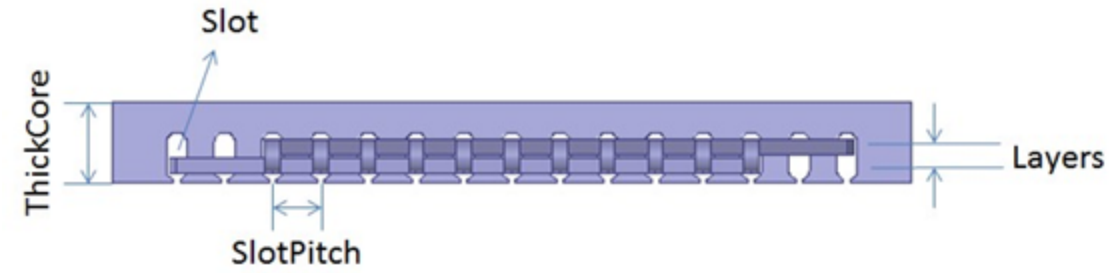

Figure 9-202 Parameters of LinearMCore in axial direction (InfoCore set to 1)

Creating a Linear Machine Core

You can create a linear machine core manually by setting the value of **InfoCore** to 0.

An example of a linear machine core is shown in Figure 9-203 .

You can assign the value of this property either when creating a linear-machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

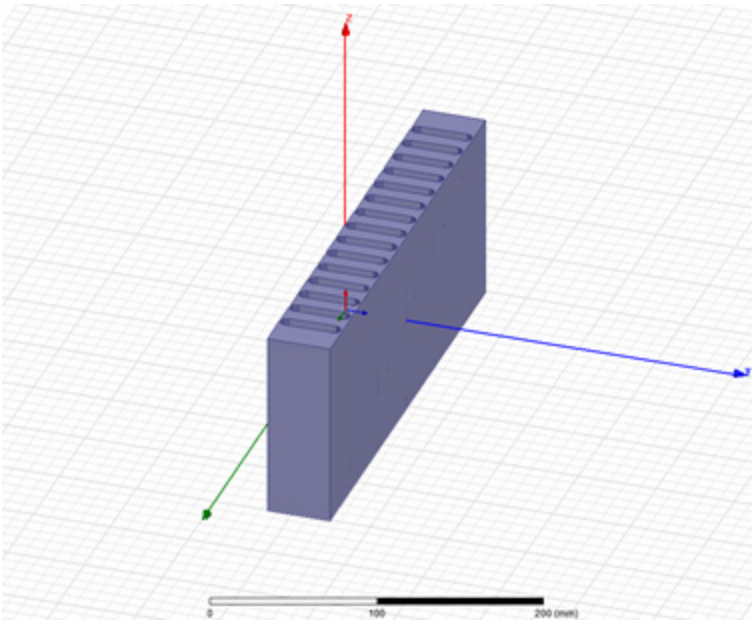

Figure 9-203 Linear Machine Core (InfoCore set to 0)

Creating a Core and All Coils (Linear Machine Core)

You can create a core and all coils manually by setting the value of **InfoCore** to 1. An example of a core and all coils of a linear-machine core is shown in Figure 9-204 .

You can assign the value of this property either when creating a linear machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

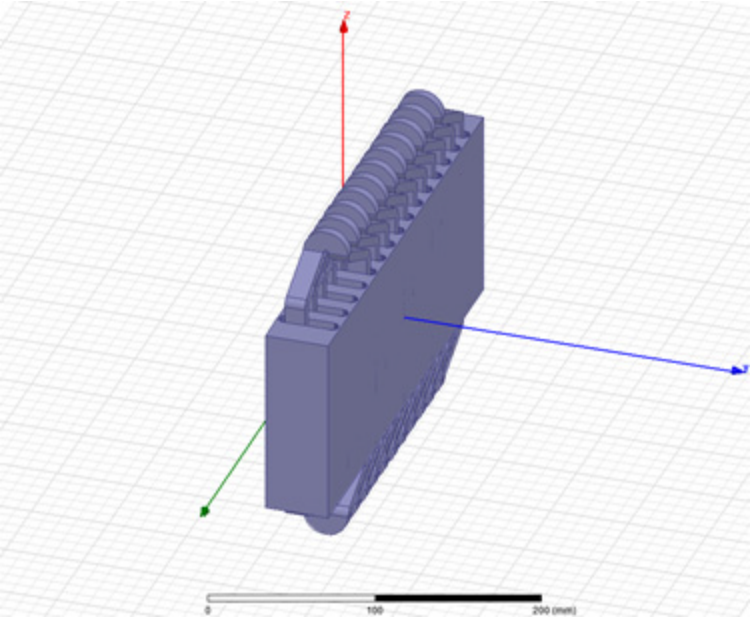

Figure 9-204 A core and all coils of a linear machine core (InfoCore set to 1)

Creating One Coil Only (Linear Machine Core)

You can create a one coil only manually by setting the value of **InfoCore** to 2.

An example of a coil of a linear machine core is shown in Figure 9-205 .

You can assign the value of this property either when creating a linear machine core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

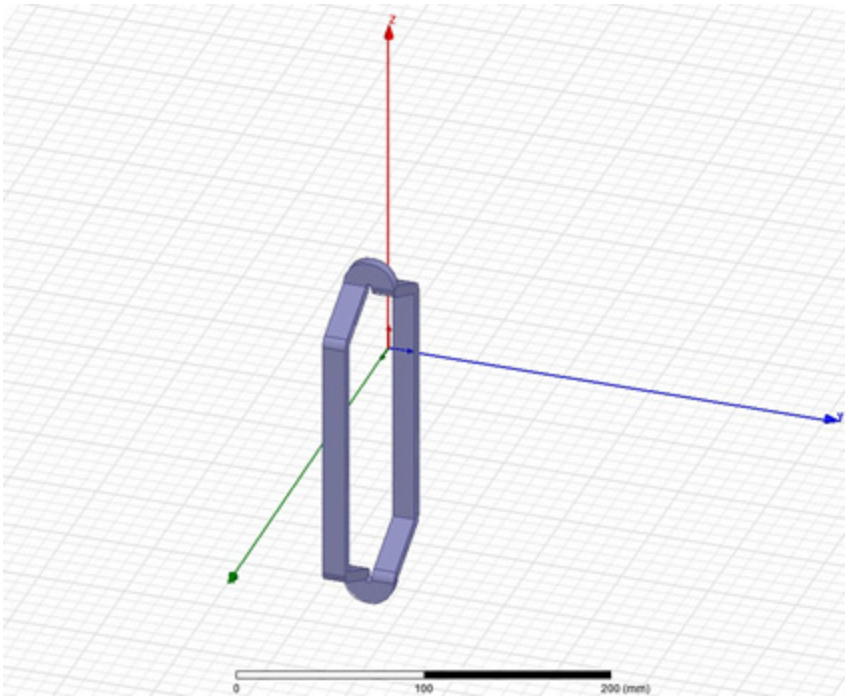

Figure 9-205 One coil of a linear machine core (InfoCore set to 2)

TransCore UDP

The TransCore UDP is used to create a three-leg transformer core for three-phase transformers.

Property	Description
DiaLeg	Outer diameter of leg cross-section.
DistLeg	Leg center to center distance.
DistYoke	Yoke center to center distance.
Stages	Number of stages of leg cross-section.
ThickCore	Core thickness, only used for Stages = 1.
WidthYoke	Yoke width, =0 for same cross-section as leg's.
InfoCore	0: whole core; 1: legs only; 2: yokes only.

Note	Figure 9-206 , Figure 9-207 , and Figure 9-208 show a TransCore UDP with different values of **Stages** and **WidthYoke**.

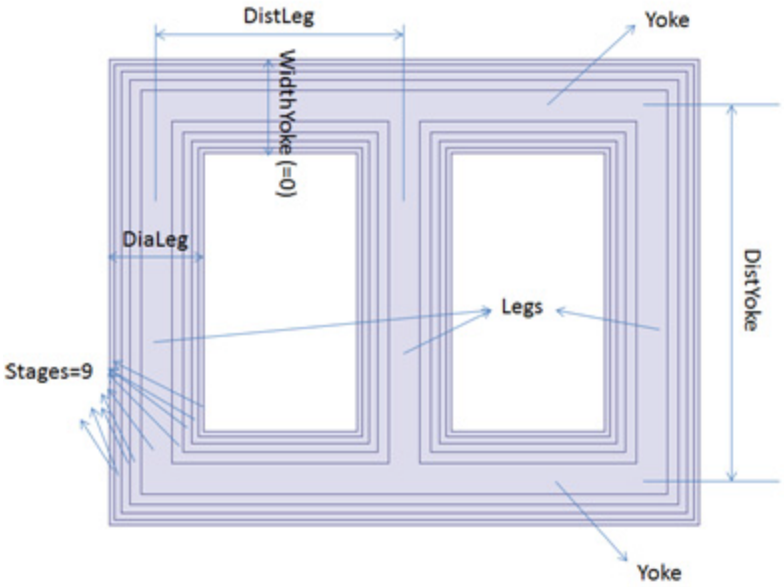

Figure 9-206 TransCore when Stages is not 1 and WidthYoke is 0

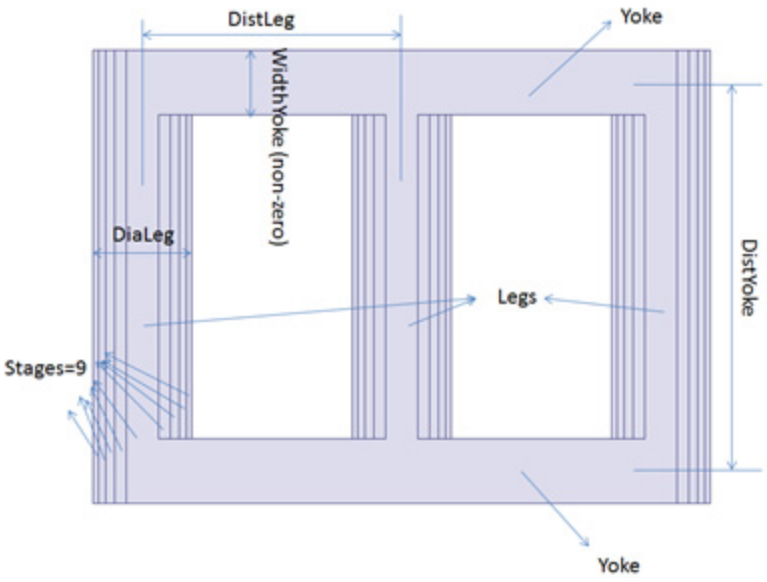

Figure 9-207 TransCore when Stages is not 1 and WidthYoke is not 0

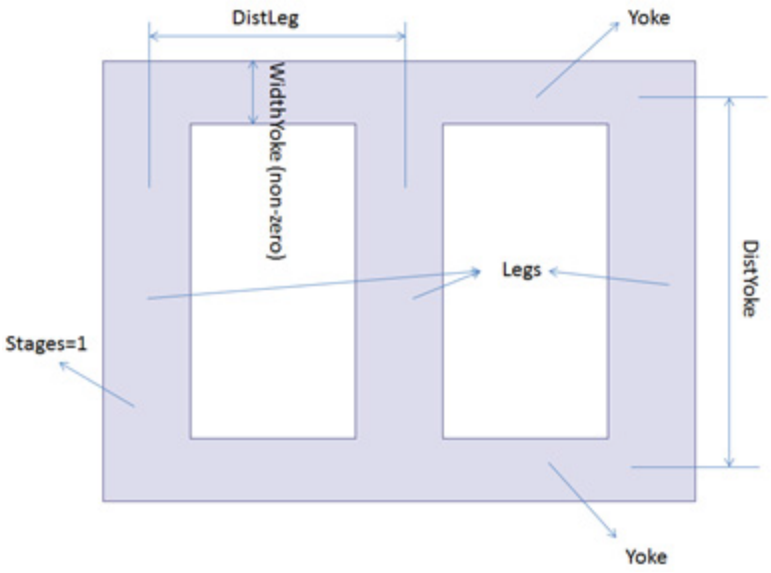

Figure 9-208 TransCore when Stages is 1 and WidthYoke is not 0

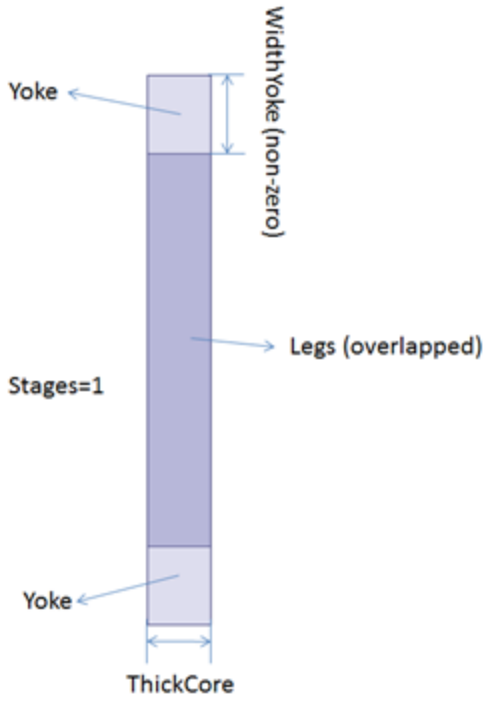

Figure 9-209 Parameters of TransCore in axial direction (when Stages is 1 and WidthYoke is not 0)

Creating a Three-Leg Transformer Core

You can create a three-leg transformer core manually by setting the value of **InfoCore** to 0.

Examples of a three-leg transformer core are shown in Figure 9-206 , Figure 9-207 , Figure 9-208 , and Figure 9-209 .

You can assign the value of this property either when creating a three-leg transformer or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating Three Legs Only

You can create three legs of the core manually by setting the value of **InfoCore** to 1.

An example of three legs is shown in Figure 9-210 .

You can assign the value of this property either when creating a three-leg transformer core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

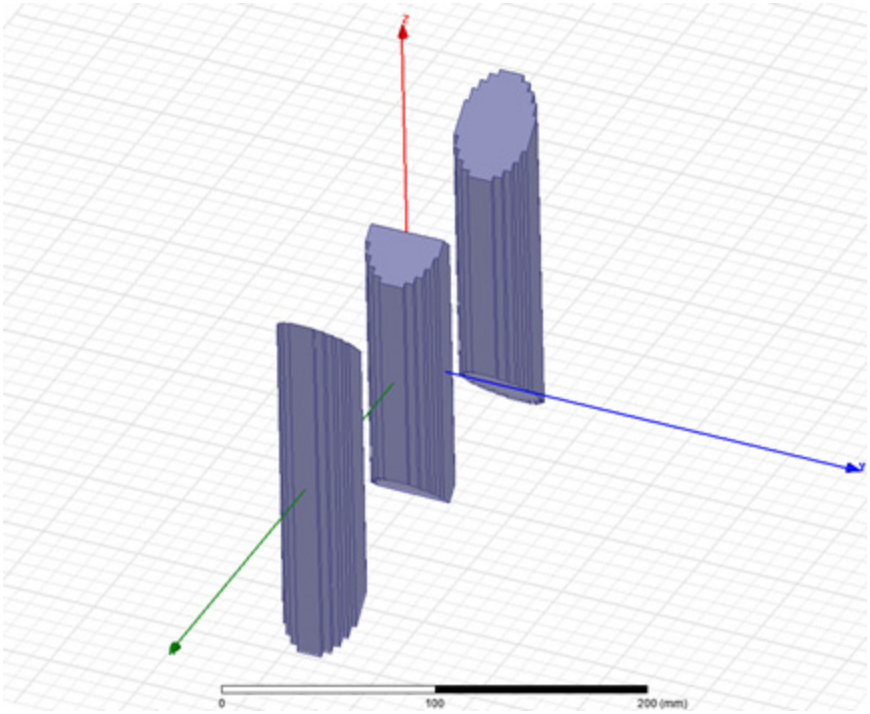

Figure 9-210 Three legs of TransCore (InfoCore set to 1)

Creating Two Yokes Only

You can create two yokes of the core manually by setting the value of **InfoCore** to 2.

An example of two yokes is shown in Figure 9-211 .

You can assign the value of this property either when creating a three-leg transformer core or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

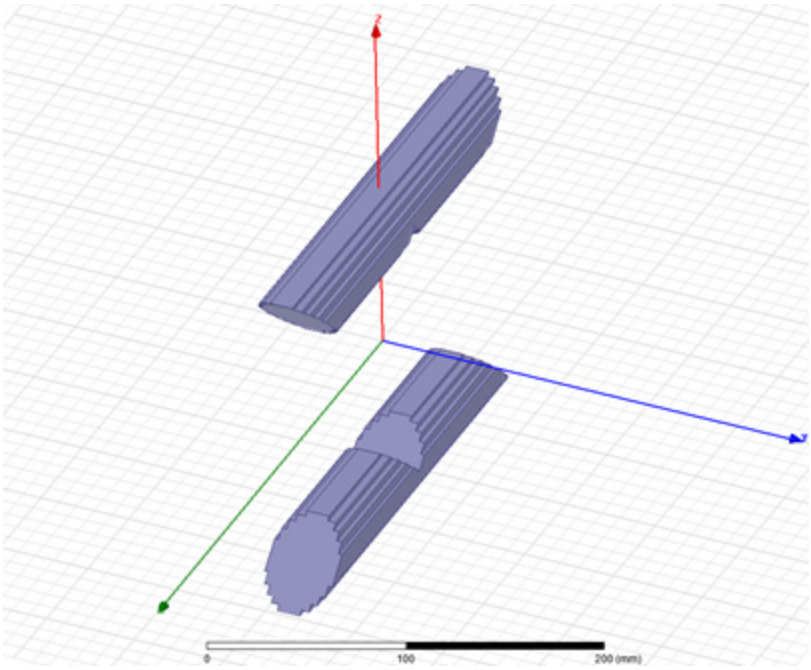

Figure 9-211 Two Yokes of TransCore (InfoCore set to 2)

TransCoil UDP

The TransCoil UDP is used to create a coil in a three-leg transformer core created by the TransCore UDP for three-phase transformers. It can also create a coil terminal for current assignment.

Property	Description
DistLeg	Leg center to center distance.
CoilType	Coil type: 1 for solenoid coil; 2 for pancake coil.
WidthIn	Coil width between two inner sides.
DepthIn	Coil depth between two inner ends.
RadiusIn	Coil inner fillet radius.
ThickCoil	Coil thickness of one side.
HighCoil	Coil height.
Layers	Number of layers.
GapLayer	Gap between two layers.
InfoCore	0: all coils; 1: one coil only.

Note	The key to making the cross-section of each layer of a coil to be a circle is to set the value of **WidthIn** equal to that of **DepthIn** and at the same time set the value of **RadiusIn** to be half of that of **WidIn**. That is, **WidthIn**=**DepthIn**=2***RadiusIn**. The cross-section of a layer could be a non-circle if the value of **WidthIn** is not equal to that of **DepthIn** or **RadiusIn**'s value is not half of **WidthIn**'s. Figure 9-214 shows a situation where a layer is a non-circle.

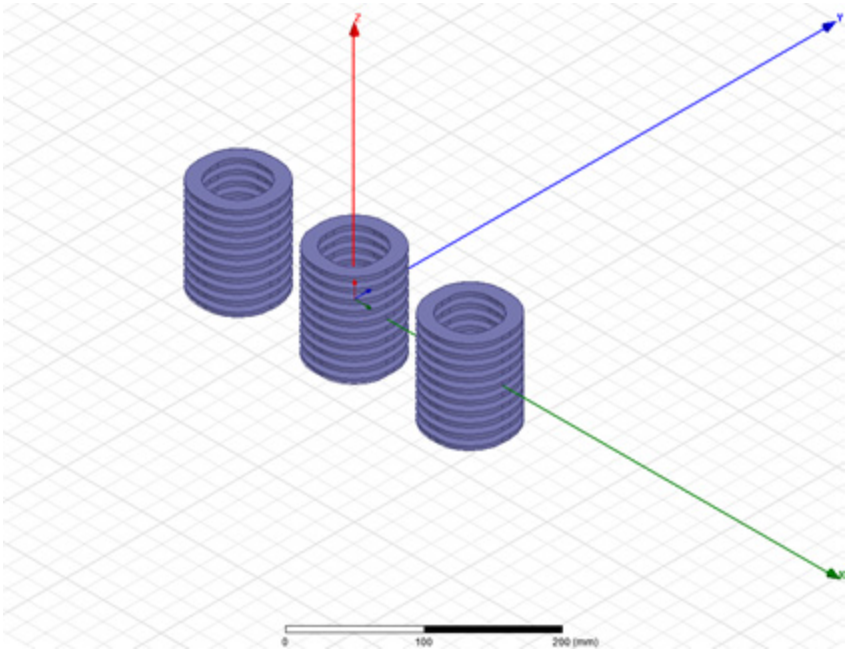

Figure 9-212 Overview of TransCoil (InfoCore set to 0)

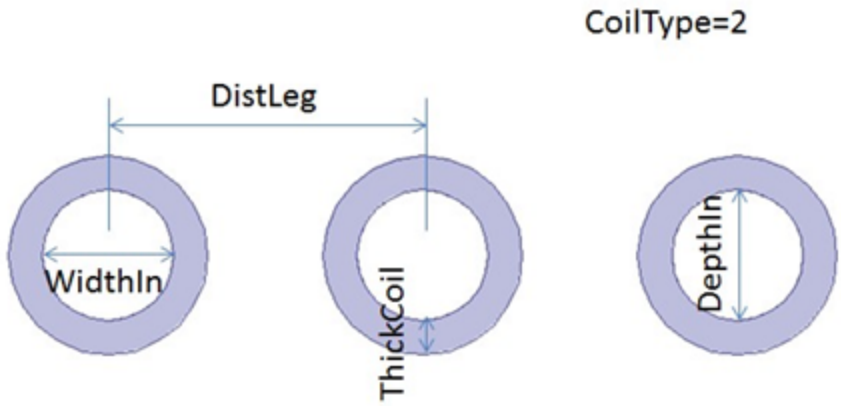

Figure 9-213 Parameters of TransCoil in x-y plane (InfoCore set to 0)

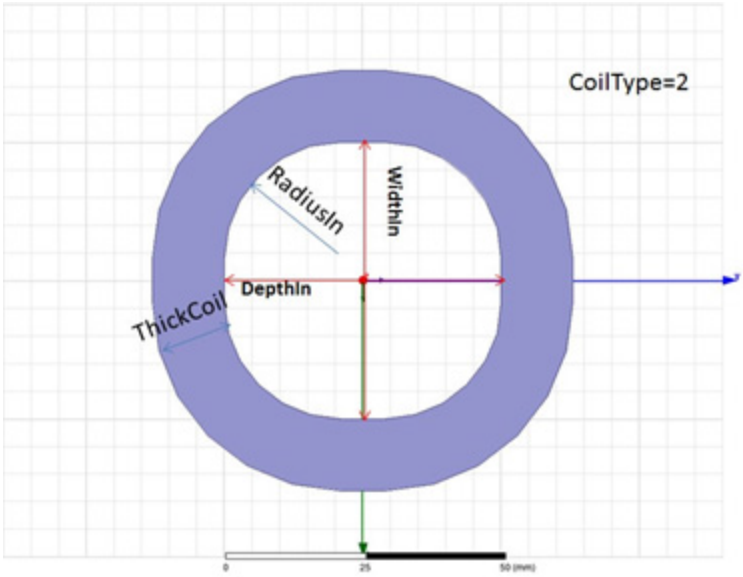

Figure 9-214 RadiusIn of TransCoil

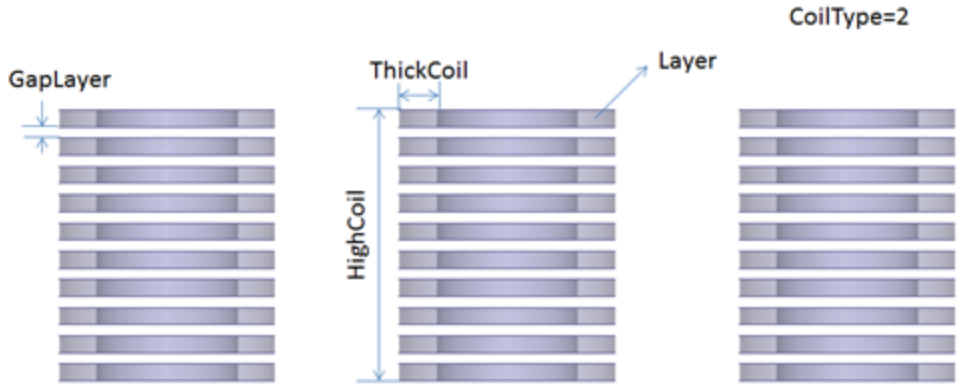

Figure 9-215 Parameters of TransCoil in axial direction (InfoCore set to 0)

Creating Coils for All Three Legs

You can create coils for three legs manually by setting the value of **InfoCore** to 0.

Examples of coils for TransCoil UDP are shown in Figure 9-212 , Figure 9-213 , and Figure 9-215 .

You can assign the value of this property either when creating a TransCoil UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

Creating One-Leg Coil Only

You can create a one-leg coil manually by setting the value of **InfoCore** to 1.

An example of a one-leg coil for a TransCoil UDP is shown in Figure 9-216 .

You can assign the value of this property either when creating a TransCoil UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

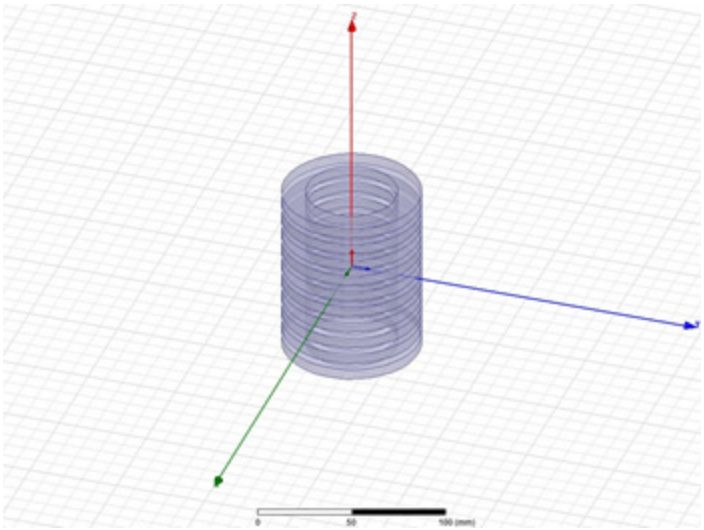

Figure 9-216 One-leg coil for TransCoil UDP

TransTwist UDP

Property	Description
CoreType	1: shell-type; 2: core-type.
WidthOut	Core outer width.
DepthOut	Core outer depth in coil turn direction.
RadiusOut	Core outer fillet radius.
WidthIn	Core window width.
DepthIn	Core window depth in coil turn direction.
RadiusIn	Core window fillet radius.
DistCenters	Window center-to-center distance, for shell-type only.
HeightCore	Core height.
Coils	Number of coils: 1 or 2.
WiresCoil	Wires per coil: 1, 2, 3, or 4 (no twist for 1 wire).

Property	Description
TurnsCoil	Number of turns per coil.
TurnsTwist	Total twist turns in one coil turn; 360 degrees in one twist turn.
DiaWire	Wire diameter.
Segments	Polygon segments for wire cross section: <=2 for true circle.
InsType	Insulator type: 1: round insulator; 2: filleted square insulator.
ThickIns	Outer minimum thickness of insulator.
GapWires	The gap between two round wire profiles.
GapEndTurns	The gap between two end turns of round insulator profiles.
GapCoreIns	The gap between core and round insulator profiles inside two windows and at two ends.
LeadExt	Lead extension from lead terminal to core end terminal.
InfoCore	0: All; 1: Core; 2: Insulator; 3-6: Wires of coil#1; 7-10: Wires of coil#2.
InfoTerm	0: 3D wire; 1: 2D go-term; 2: 2D re-term (for InfoCore = 3-10 only).

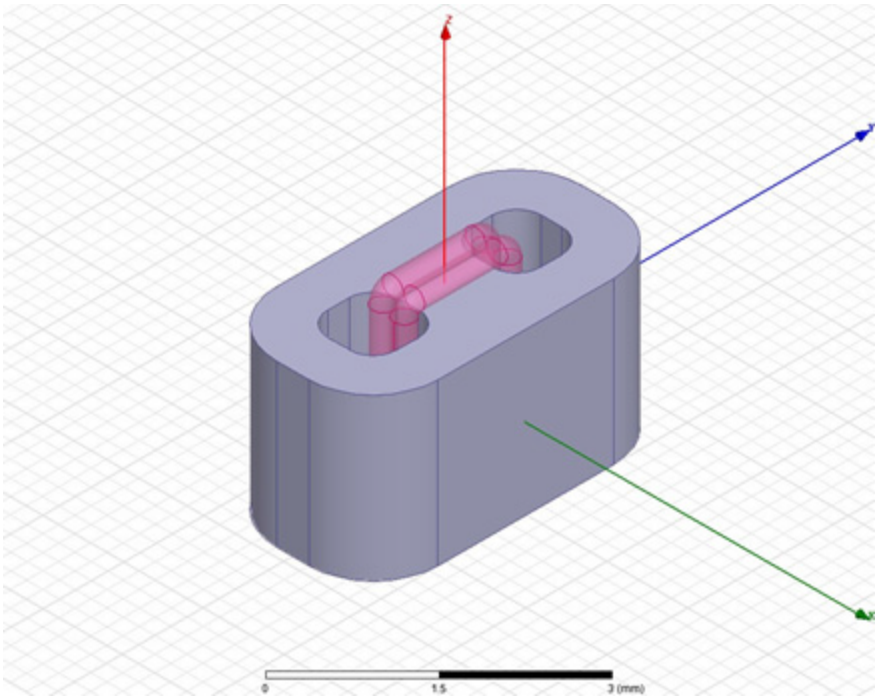

Figure 9-217 Overview of TransTwist UDP (without wires)

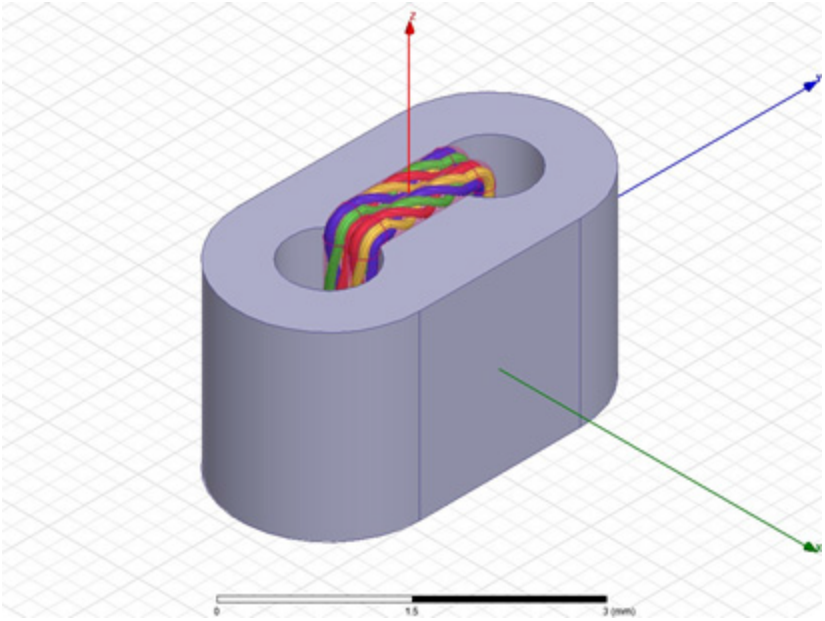

Figure 9-218 Overview of TransTwist UDP (with colorful wires)

Note	• Figure 9-217 and Figure 9-218 give an overview of the TransTwist UDP. The difference between them is Figure 9-218 has 4 colorful wires inside the insulator whereas Figure 9-217 has nothing in its insulator. • InFigure 9-217 and Figure 9-218 and also other figures like Figure 9-222 , objects in different colors are all TransTwist UDP but with different **InfoCore** values. For example, in Figure 1-6 , the gray object is a TransTwist UDP whose **InfoCore** value is 1(core), while red, blue, green and yellow objects (wires) are also TransTwist UDPs whose **InfoCore** values are 3, 4, 5, and 6 respectively. Also, the value of the **InfoCore** of pink tube that covers the wires is 2 (insulator). To draw this kind of figure, copy and paste the TransTwist UDP (or manually create multiples of this UDP) and then change their **InfoCore** values and colors. • The reason for making colorful figures here is to show the parameters of the TransTwist UDP more clearly. • The difference between Figure 9-220 and Figure 9-221 is the parameter **TurnsCoil**, which means the number of turns for each coil (only one coil in each figure). There are 2 turns for the coil in Figure 1-4 whereas there is only 1 turn for the coil in Figure 9-221 . • The purpose ofFigure 9-223 is to show the concept of the parameter **Coils**. Note that when the value of **Coils** is 2 in this figure, the two coils are disconnected. For a comparison, see the one coil shown in Figure 9-222 . • The purpose of Figure 9-224 is to show the parameter of **GapEndTurns**, which is useful only when the value of **TurnsCoil** is larger than 2. • The results of parameter **TurnsTwist** are difficult to show in a figure. It is used to define the number of twist turns in one coil turn for each coil (or wire). As shown in

	Figure 9-226 , the green wire is twisted 0.5 turn at the bottom of the core. Then, for the entire coil turn, it may be twisted 3 to 3.5 twist turns (0.5 to 1 turn on the top of the core, and 1 turn on each side of the core).

Creating a Core and All Twist Coils

You can create a core and all twist coils manually by setting the value of InfoCore to 0, which is set by default in Maxwell.

An example of a core and all twist coils is shown in Figure 9-227 .

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

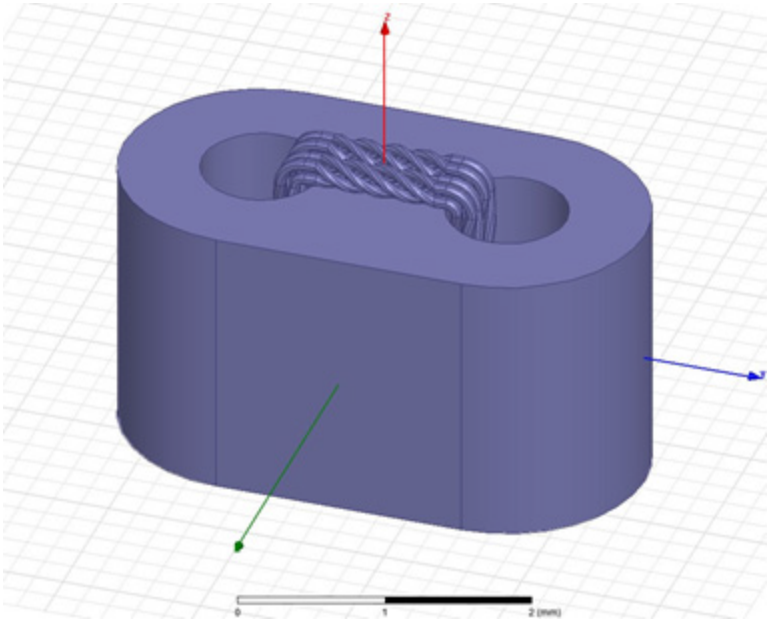

Figure 9-227 TransTwist UDP (InfoCore set to 0)

Creating a Twist Wire and its Terminals

You can create a twist wire of a TransTwist manually by setting the value of **InfoCore** to 3 to 6 (or 7-10 for coil #2) and **Info Term** to 0. Examples are shown in Figure 9-218 , Figure 9-221 , Figure 9-225 , and Figure 9-226 as red, green, blue and yellow objects.

You can create a terminal of a wire manually by setting the value of **InfoCore** to 3 to 6 (or 7-10 for coil #2) and **Info Term** to 1 or 2 (for 2D go-term and 2D re-term respectively). An example is shown in Figure 9-228 below.

You can assign the value of this property either when creating a TransTwist or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

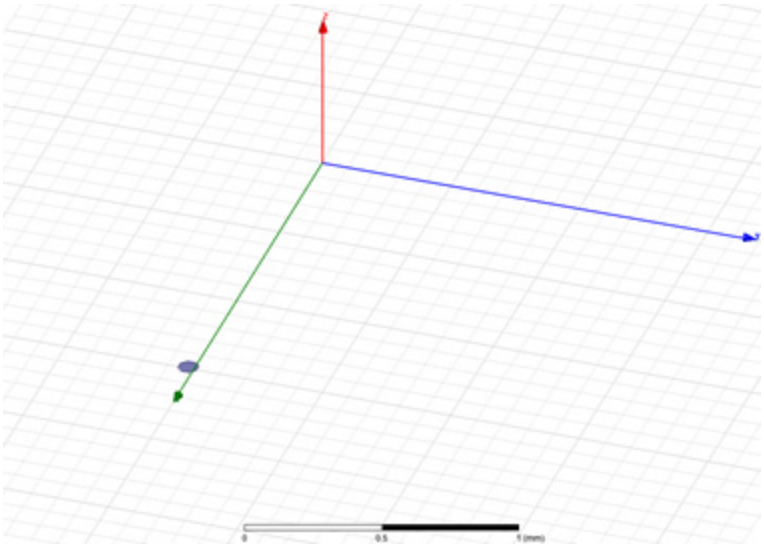

Figure 9-228 2D go-terminal of a wire

Creating a Twist Insulator of All Coils

You can create an insulator of all coils manually by setting the value of **InfoCore** to 2 and **Info Term** to 0. An example is shown in Figure 9-229 .

You can assign the value of this property either when creating a TransTwist or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

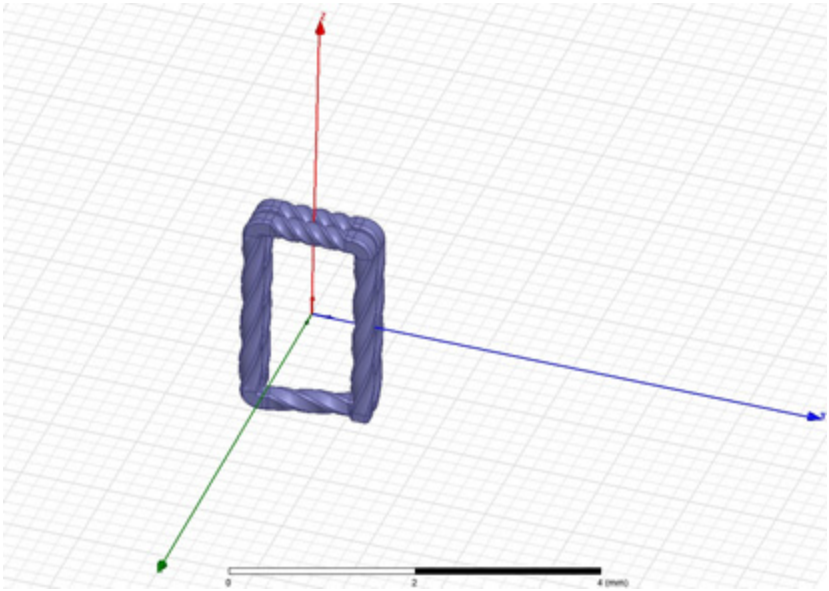

Figure 9-229 Twist insulator of all coils

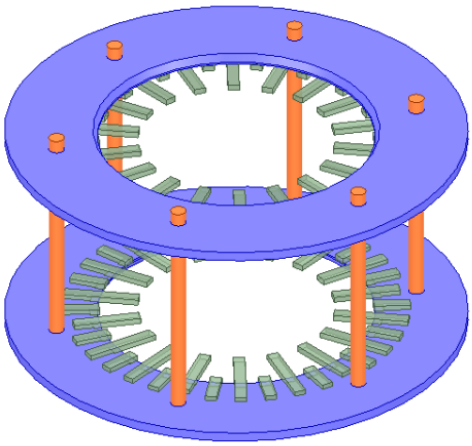
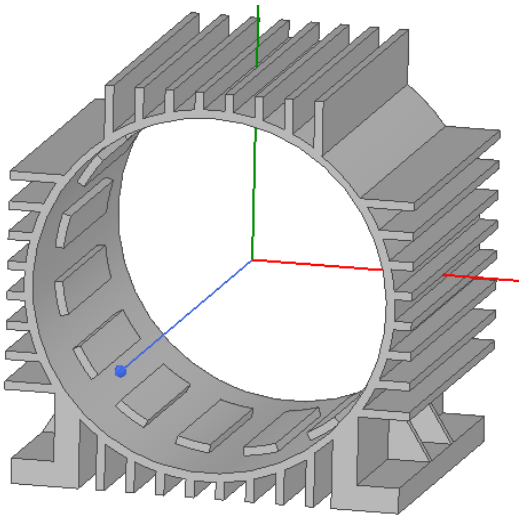
UDPs for Other Machine Parts

RMxprt includes UDPs to add various other types of machine parts. These include:

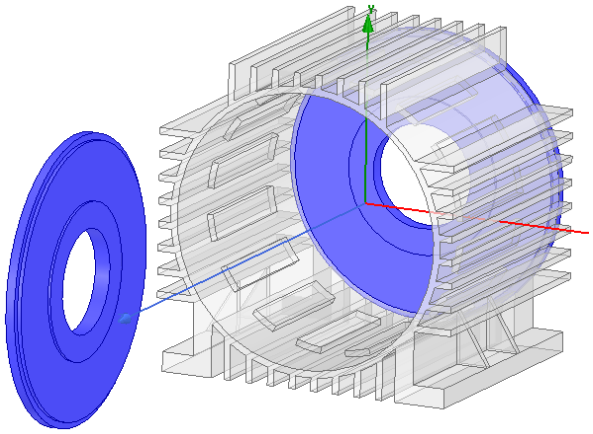
- PressPlate UDP - used to add press plates, fingers, and stems that are used to hold together the stack of core laminations in large AC and DC machines.



- Housing UDP - used to add machine housings and their associated fins, cooling ducts, and support feet.



- EndCap UDP - used to add the end caps and associated bearing surfaces for a housing.



Related Topics

Adding Machine Housings in RMxprt

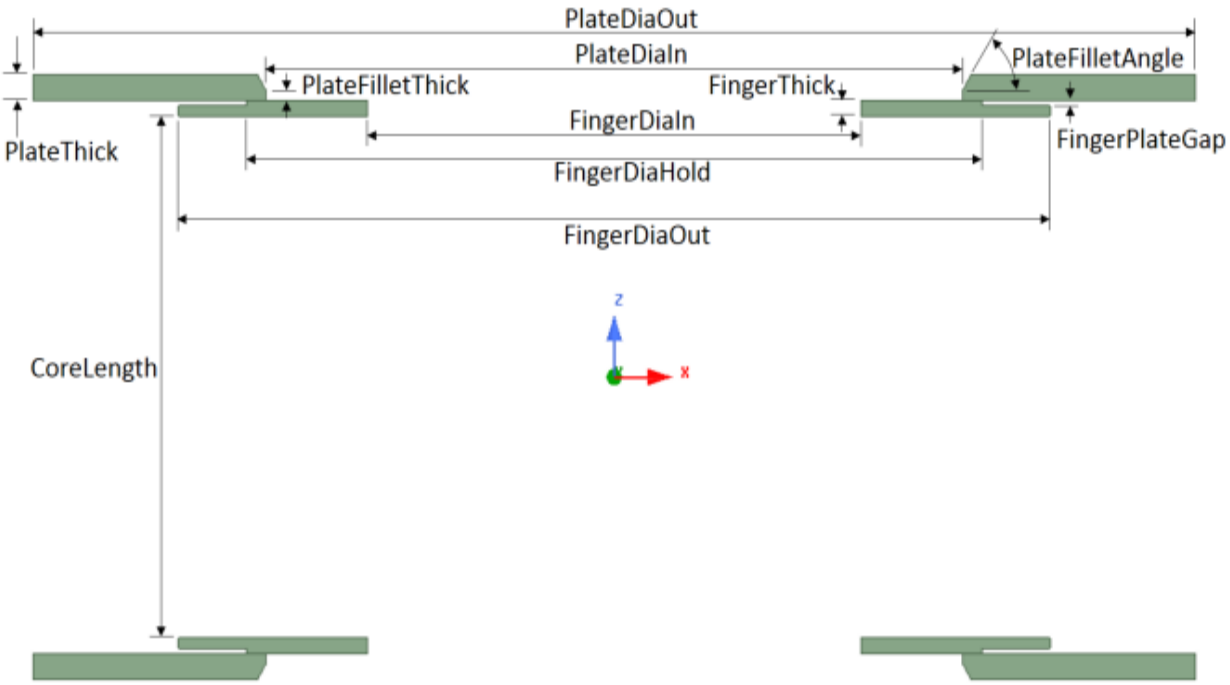
PressPlate UDP

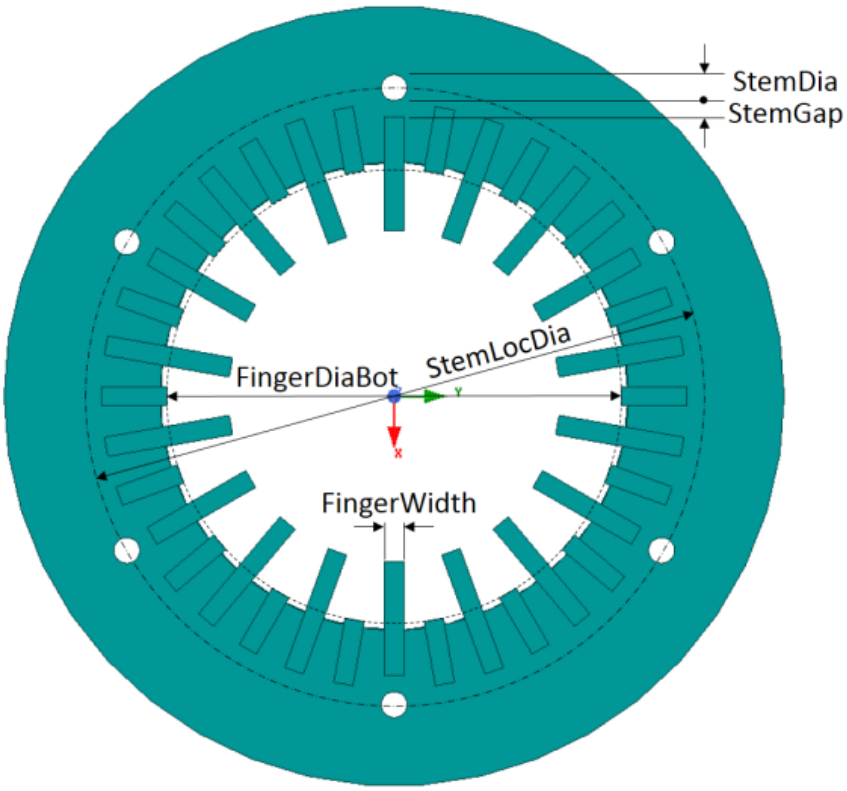
The PressPlate UDP is used to create press plates, fingers, and stems for large AC or DC machines. Press plates and fingers are put at two ends of a large laminated slot core and are locked in place by the stems so that the core laminations can be pressed tightly together.

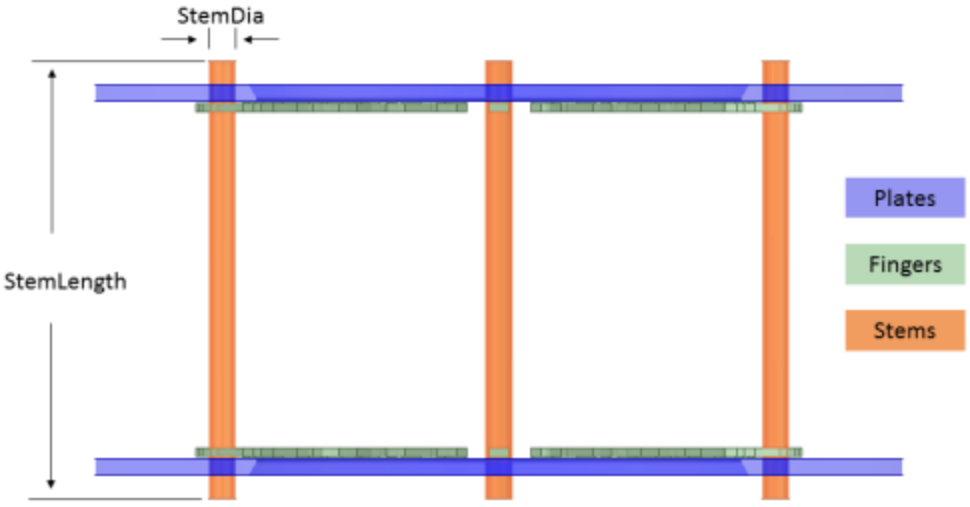
Property	Description
CoreLength	Axial length of the core inside press plates.
PlateDiaIn	Press plate inner diameter.
PlateDiaOut	Press plate outer diameter.
PlateThick	Press plate axial thickness.
PlateFilletThick	Plate fillet thickness at inner diameter.
PlateFilletAngle	Plate fillet angle at inner diameter.
Fingers	Number of end fingers, or the number of core slots.
FingerDiaIn	Inner diameter for distributed fingers.
FingerDiaOut	Outer diameter for distributed fingers.
FingerDiaHold	Finger holder outer diameter.
FingerDiaBot	Inner diameter for slot-bottom fingers, 0 without bottom fingers.
FingerWidth	Finger width to cover tooth width.
FingerThick	Finger holder axial thickness.
FingerPlateGap	Length of the axial gap between fingers and plates.
Stems	Number of stems to lock two end press plates.

Property	Description
StemLength	Axial stem length.
StemDia	Stem diameter.
StemLocDia	Diameter of stem center layout circle.
StemGap	Clearance gap around a stem.
InfoPart	Enter 0 to generate all parts (plates, fingers, and stems); 1 for press plates only; 2 for fingers; 3 for stems.

These parameters are shown in the following 2D examples:

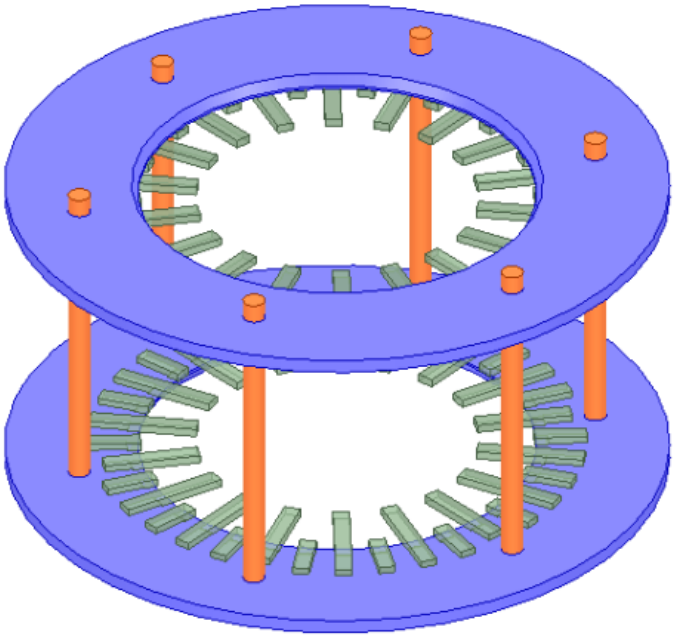






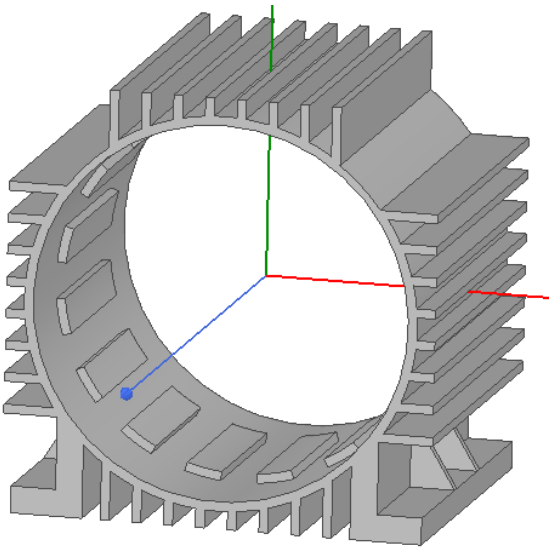
The following figure shows a typical arrangement of press plates, fingers, and stems in which their are 18 fingers under the press plates. The 6 stems serve to "lock" these parts at the two ends of the machine's laminated core (not shown), holding the entire assembly firmly together.

Press plates with fingers, and stems



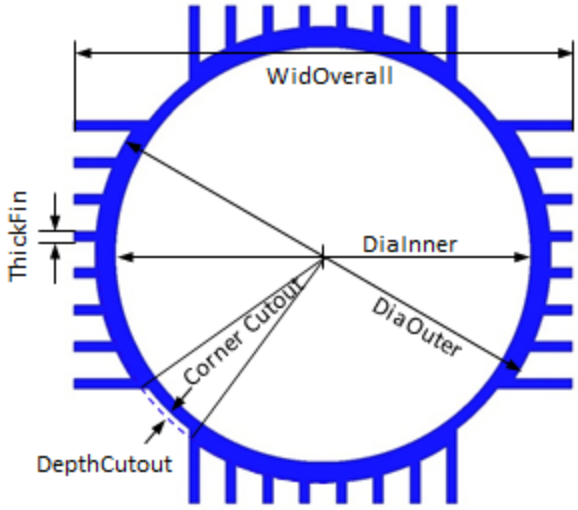
Housing UDP

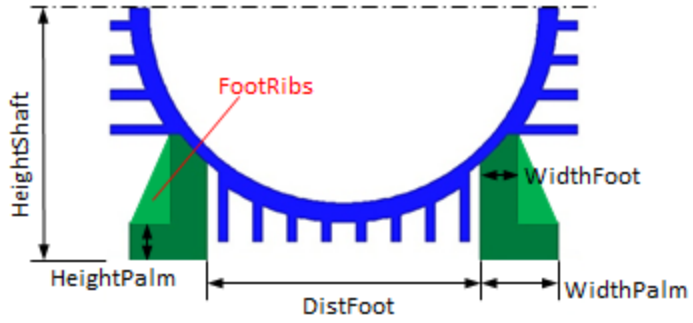
The Housing UDP is used to create the housing parts for machines. These include the fins, cooling ducts, and feet that support machines.

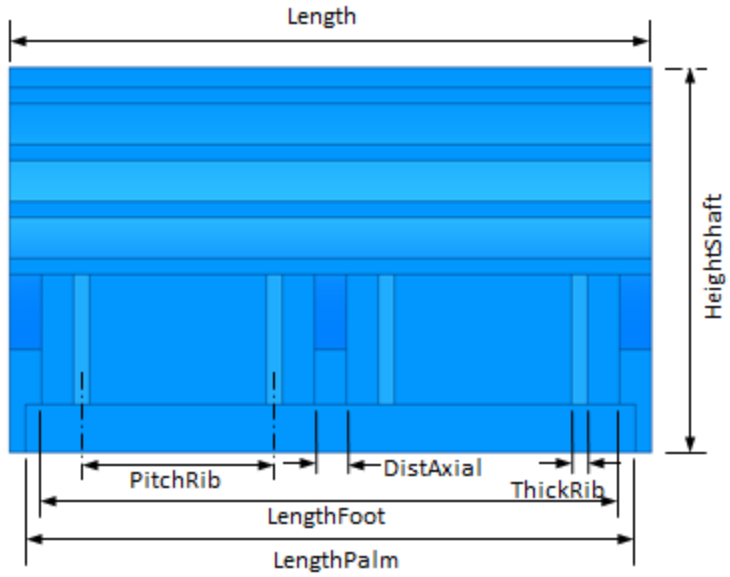


Property	Description
DiaOuter	Housing outer diameter
DiaInner	Housing inner diameter
WidOverall	Housing overall width
Length	Housing length
Fins	Number of fins; Fins = 0 for uniform distribution
FinType	1: radial round; 2: radial square; 3: parallel round; 4: parallel square; 5: squre ring; 6: servo ring
RatioCutout	Corner cutout ratio for FinType≠5
DepthCutout	Corner cutout depth for FinType≠5; min fin depth for FinType=5.
ThickFin	Fin thickness
Ducts	Number of ducts
DuctType	1: axial wind duct; 2: axial water jacket; 3: spiral water jacket (see below)
HeightDuct	Duct height in radial direction
EmbraceDuct	Ratio of the duct span, or duct width, to duct pitch. 0 < EmbraceDuct < 1
LengthDuct	Axial duct length for axial wind ducts only
SegAngle	Deviation angle for spiral water jacket; 0 for true-surface circular jacket
WidthFoot	Foot width at the junction with housing
LengthFoot	Foot end-to-end length in axial direction
DistFoot	Distance between two feet
DistAxial	Foot distance in axial direction
WidthPalm	Palm width at the junction with base plate
HeightPalm	Palm Height
LengthPalm	Palm length in axial direction
HeightShaft	Shaft-center Height from palm bottom
FootRibs	Number of reinforcing ribs for foot and palm
ThickRib	Reinforcing-rib thickness
PitchRib	Pitch between two reinforcing ribs
OffsetFoot	Axial offset of foot center to housing center (not currently used)
OffsetPalm	Axial offset of palm center to housing center (not currently used)
InfoPart	0: housing; 100: ducts.

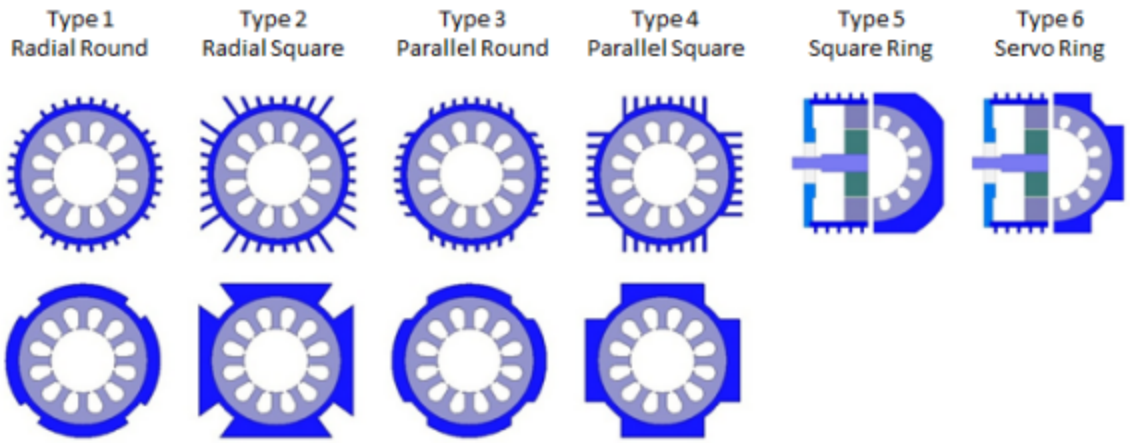
These parameters are shown in the following 2D examples:



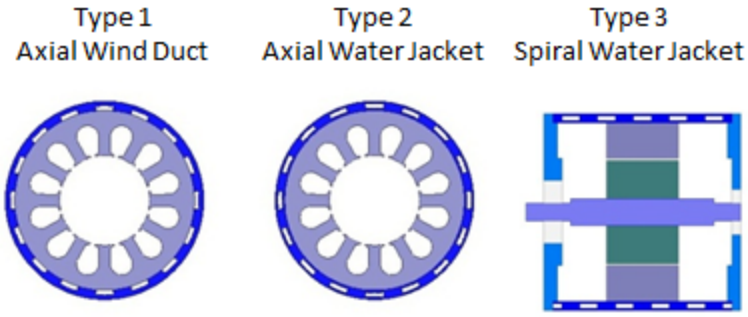




Housing FinType

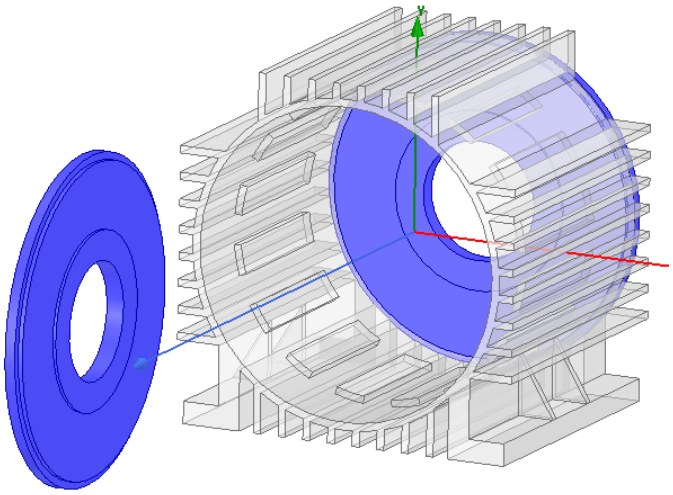


Housing DuctType



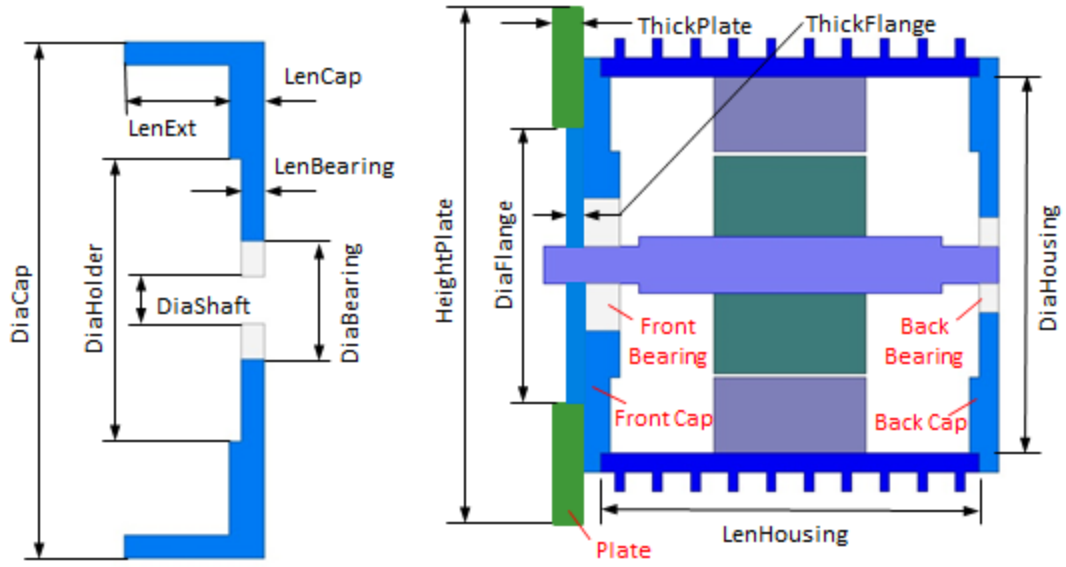
EndCap UDP

The EndCap UDP is to used to add the end caps, bearing surfaces, and rectangular cooling plate for a housing.



Property	Description
DiaHousing	Housing rabbet inner diameter
LenHousing	Housing axial length
DiaCap	End cap outer diameter
LenCap	Axial length, or thickness, of end cap
LenExt	Length from housing end to cap inner surface, <0 for rabbet length
DiaHolder	Outer diameter of bearing holder
DiaBearing	Bearing outer diameter
LenBearing	Bearing axial length
DiaShaft	Shaft diameter, or bearing inner diameter
DiaFlange	Diameter of the flange section that covers the front bearing
ThickFlange	Thickness of the flange section that covers the front bearing
HeightPlate	Height of the rectangular cooling plate
WidthPlate	Width of the rectangular cooling plate
ThickPlate	Thickness of the rectangular cooling plate
InfoPart	0: front cap; 1: back cap; 2: front bearing; 3: back bearing; 4: flange.

These parameters are shown in the following 2D examples:



Helix UDPs

Helix UDPs are shapes of inductance design and are widely used in electronic devices and signal integrity area.

Helix UDPs consist of the following types:

- PolygonHelix UDP
- RectHelix UDP

PolygonHelix UDP

The shape of the cross-section of a PolygonHelix is a polygon.

Property	Description
PolygonSegments	Number of cross-section polygon segments, 0 for circle.
PolygonRadius	Outer radius of cross-section polygon.
StartHelixRadius	Start radius from polygon center to helix center.
RadiusChange	Radius change per turn.
Pitch	Helix pitch.
Turns	Number of turns.
SegmentsPerTurn	Number of segments per turn, 0 for true surface.
RightHanded	Helix direction, non-zero for right handed.

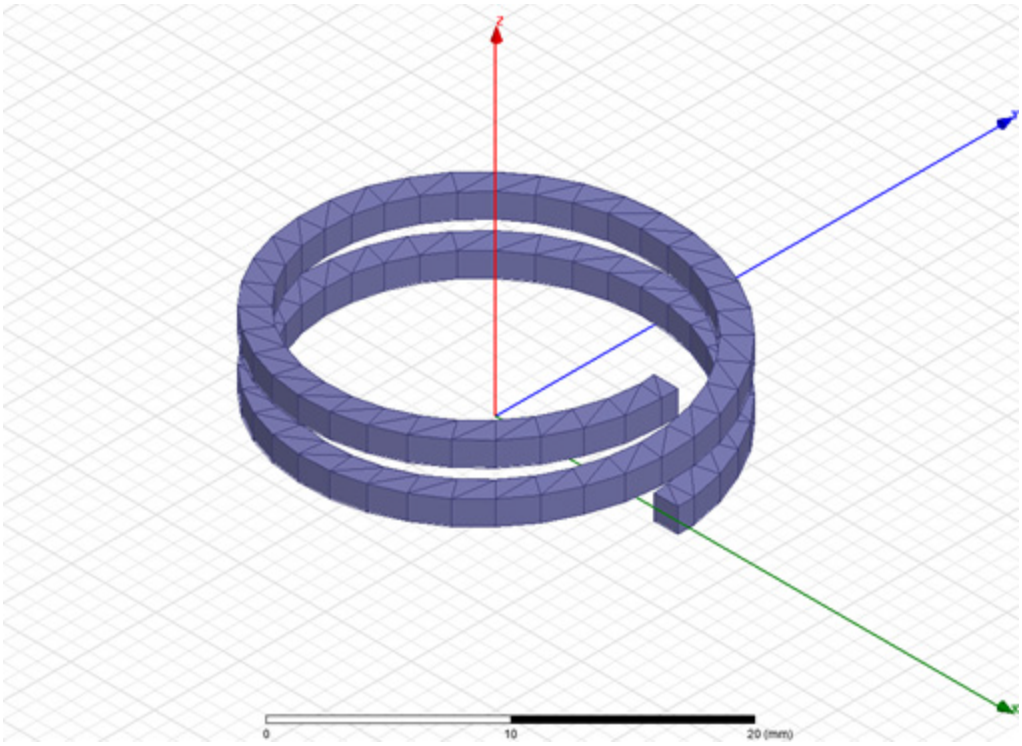


Figure 9-1 Overview of PolygonHelix UDP

Note	Figure 9-1 is an overview of the PolygonHelix UDP. “Polygon” means the cross-section of the helix is a polygon, which by default is a square (**PolygonSegments** set to 4). Polygon helices in Figure 9-2 and Figure 9-3 have the default settings of this UDP, whereas each of the polygon helices in Figure 9-4 to Figure 9-8 has only one parameter value that is different from the defaults shown in Figure 9-2 and Figure 9-3 .

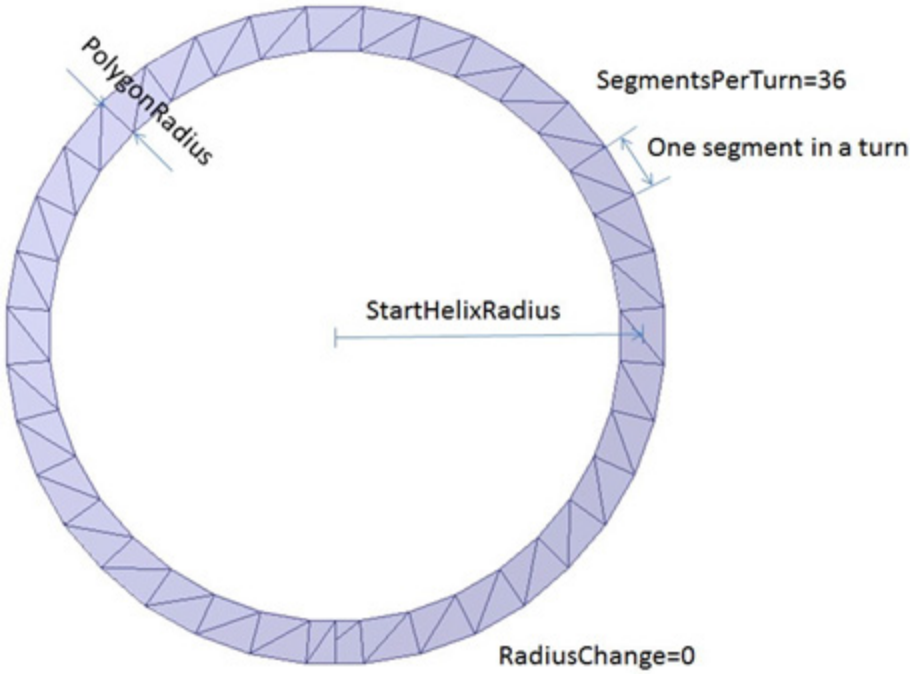

Figure 9-2 Parameters of PolygonHelix UDP on x-y plane.

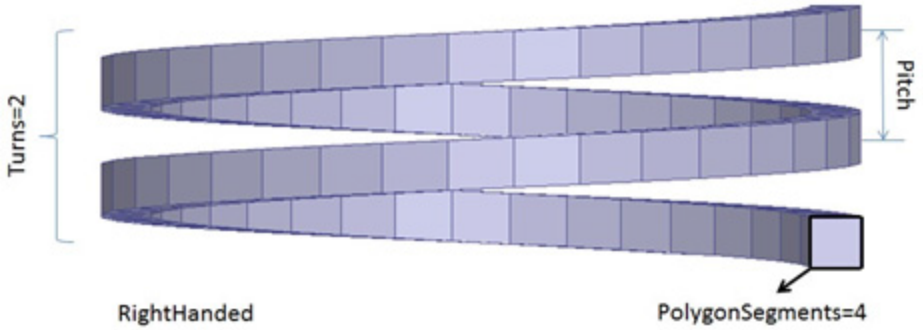

Figure 9-3 Parameters of PolygonHelix UDP on axial direction.

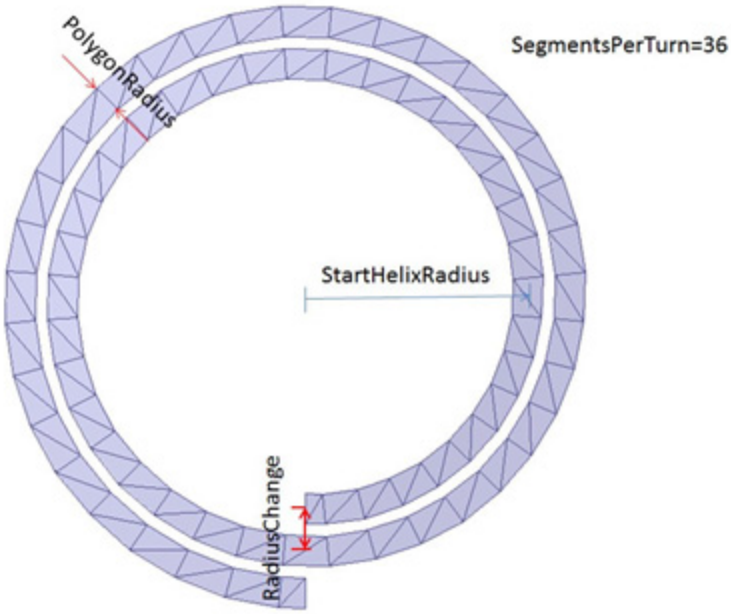

Figure 9-4 Different RadiusChange value (non-zero); the value in Figure 9-2 is 0.

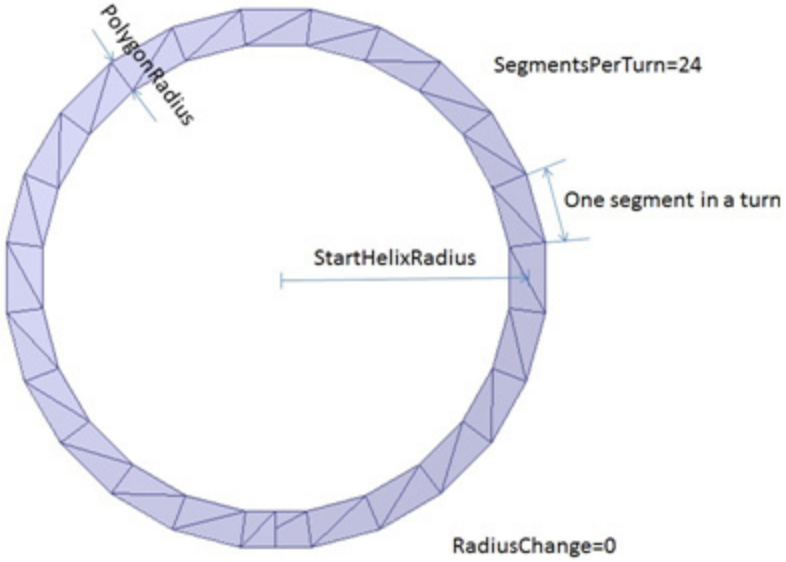

Figure 9-5 Different SegmentsPerTurn value (24); the value in Figure 9-2 is 36.

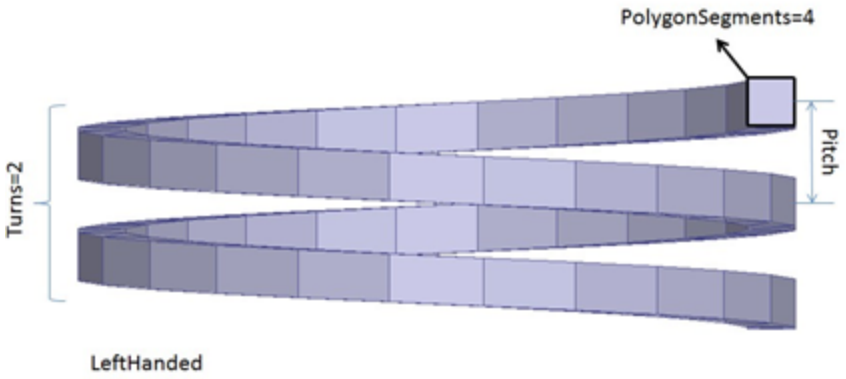

Figure 9-6 Left-handed (RightHanded set to 0) helix; Figure 9-3 shows a right-handed helix.

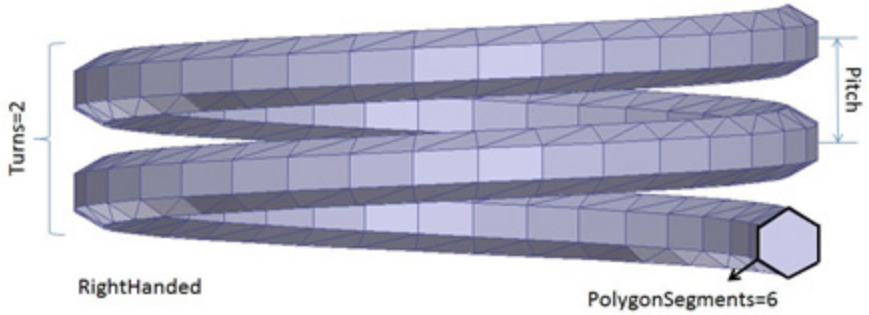

Figure 9-7 Different PolygonSegments value (6); the value in Figure 9-3 is 4.

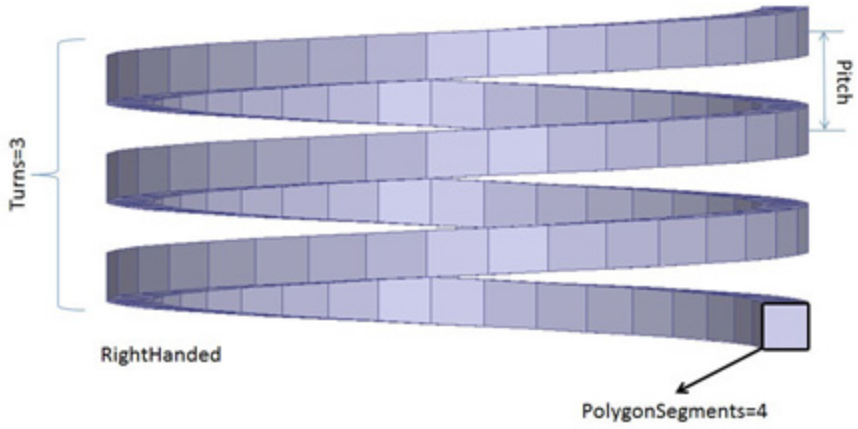

Figure 9-8 Different Turns value (3); the value inFigure 9-3 is 2.

Creating a Right-Handed or Left-Handed Polygon Helix

You can create a right-handed polygon helix manually by setting the value of **RightHanded** to 1 (or any non-zero value), which is set by default in Maxwell.

You can create a left-handed polygon helix by setting **RightHanded** to 0.

Examples of right- and left-handed polygon helices are shown in Figure 9-3 and Figure 9-6 , respectively.

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

RectHelix UDP

The shape of the cross-section in a RectHelix is a rectangle.

Property	Description
RectHeight	Cross-section rectangle height in z direction.
RectWidth	Cross-section rectangle width in r direction.
StartHelixRadius	Start radius from rectangle center to helix center.
RadiusChange	Radius change per turn.
Pitch	Helix pitch.
Turns	Number of turns.
SegmentsPerTurn	Number of segments per turn, 0 for true surface.
RightHanded	Helix direction, non-zero for right handed.

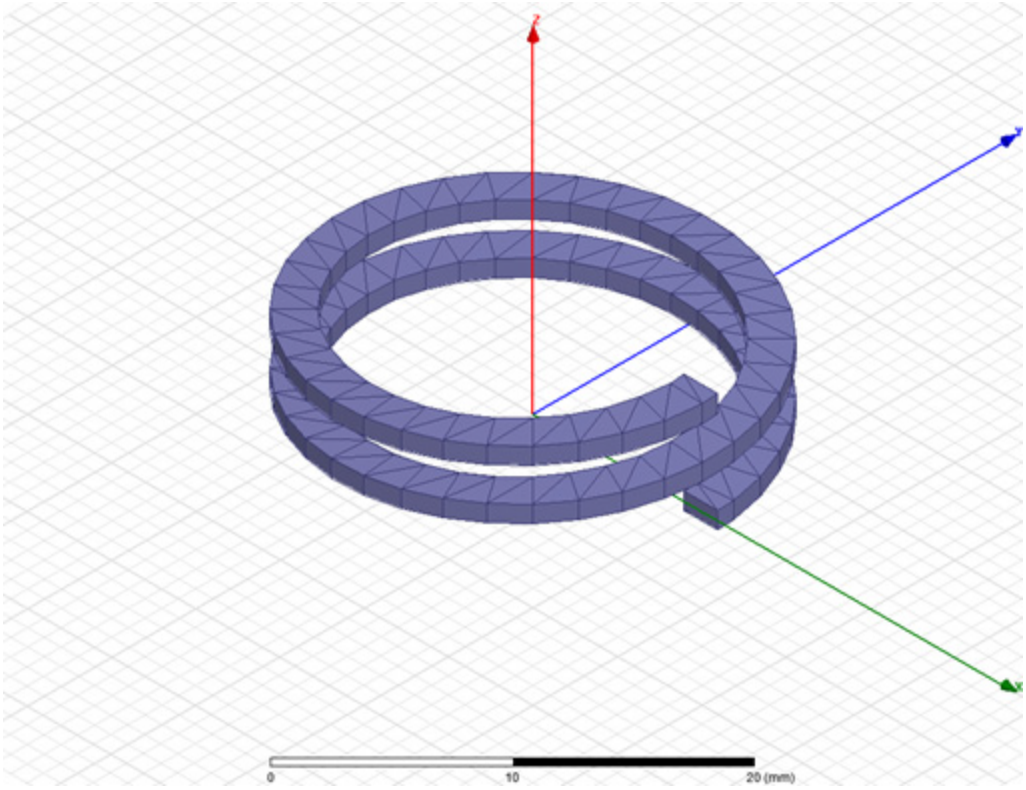

Figure 9-9 Overview of RectHelix UDP

Note	• The major difference between the RectHelix UDP and the PolygonHelix UDP is the shape of the cross-sections of the helices. In RectHelix, the shape of its cross-section is a rectangle whereas that of PolygonHelix is a polygon. • Except for **RectHeight** and **RectWidth**, parameters are the same as those in the Polygon Helix UDP. The one figure in this section describes **RectHeight** and **RectWidth**. • For *all other* parameters, refer to Polygon Helix UDP.

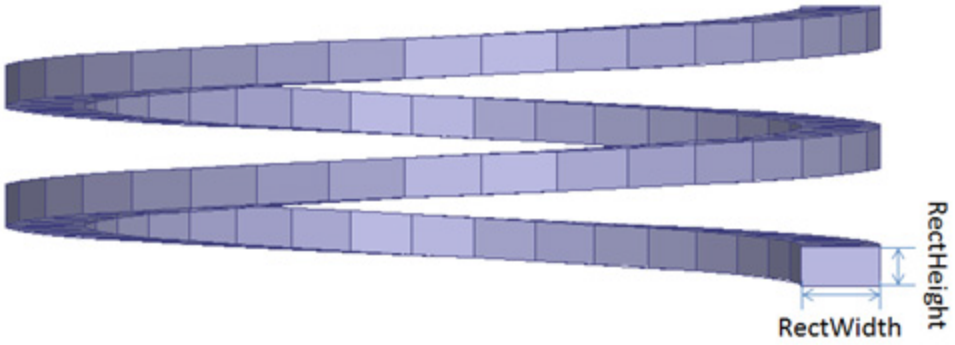

Figure 9-10 RectHeight and RectWidth in RectHelix UDP

Creating a Right-Handed or Left-Handed Rectangle Helix

You can create a right-handed rectangle helix manually by setting the value of **RightHanded** to 1 (or any non-zero value), which is set by default in Maxwell.

You can create a left-handed rectangle helix by setting **RightHanded** to 0.

Examples of right-handed and left-handed rectangle helices are shown in Figure 9-8 and Figure 9-11 , respectively.

You can assign the value of this property either when creating the UDP or after creating it, as described in Creating a Band and Creating an Outer Region, respectively.

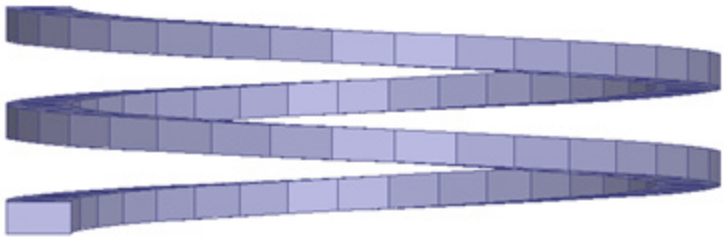

Figure 9-11 Left-handed rectangle helix

Information about Coding UDPs

This chapter uses an example of a Band UDP to provide information about how to write source code for a new UDP class when needed.

- Intrinsic Head Files presents some of the intrinsic structures and functions for all UDPs
- Code Implementation uses a Band UDP to illustrate what functions or procedures are needed to create a new UDP

Intrinsic Head Files

The following sections provide information on Intrinsic Structure Definitions and Intrinsic Function Declarations.

Head File for Intrinsic Structure Definition

Many intrinsic structures are written in C++ for UDPs. These intrinsic structures are provided in the UserDefinedPrimitiveStructures.h file (under directory: AnsysEM\Maxwell [x.x]\Win64\UserDefinedPrimitives\Examples\Headers).

Here are some common intrinsic structures that you need to know before starting coding for UDPs:

UDPPosition

Defines the most common and basic structure in a coordinate system, which is used to describe a point in the system.

```
struct UDPPosition
{
double x;
double y;
double z;
};
```

UDPPolylineDefinition

Defines the structure of polyline in a UDP, which is used to create sheets or lines in a UDP.

```
struct UDPPolylineDefinition
{
int noOfPoints;
struct UDPPosition* arrayOfPosition;
int noOfSegments;
struct UDPPolylineSegmentDefinition* arrayOfSegmentDefinition;
int isClosed;
int isCovered; /* Only if it is closed, then it can be covered
*/
```

```
};
```

UDPPrimitiveParameterDefinition

Defines the parameter/property definition of each UDP, such as *DiaGap*, *DiaYoke* and *Length* in the Properties window of each UDP. A definition for a parameter includes the name of the parameter, description of the parameter, unit of parameter, and default value of it.

```
struct UDPPrimitiveParameterDefinition
{
char* name; /* Name of the parameter */
char* description; /* some description of the parameter */
UDPUnitType unitType; /* No unit/length/angle */
double defaultValue;
};
```

UDPPolylineSegmentDefinition

Defines line segments used to form a polyline.

```
struct UDPPolylineSegmentDefinition
{
UDPPolylineSegmentType segmentType;
int segmentStartIndex;

/* Below information is required to be set only if you are
using Spline */
int numberOfPoints;

/* Below information is required to be set only if you are
using Angular Arc */
double angle; /* in degrees */
UDPPosition centerPoint;
UDPCoordinateSystemPlane arcPlane;
};
```

UDPSweepOptions

Sweep is a kind of operation to move an object from one position to another and meanwhile creating another object based on the track of the movement. For instance, sweep operations can be used to create a sheet from a line or a 3D object from a sheet. Different kinds of sweep types (and sweep angles) are used in SweepAlongAxis and SweepAroundAxis functions to make a sheet or a 3D object.

```
struct UDPSweepOptions
{
UDPSweepDraftType draftType;
```

```
double draftAngle;
double twistAngle;
};
```

UDPVector

Vector structures are used in UDP coding, mainly for rotation, moving or other kinds of transformations of geometry.

```
struct UDPVector
{
double x;
double y;
double z;
};
```

Head File for Intrinsic Function Declaration

Intrinsic function declarations are inside the same file (UserDefinedPrimitiveStructures.h) as intrinsic structure definitions. Functions are declared by 'typedef' keyword and function pointer. Some function declarations are shown below as examples:

Add a message to the message window, with desired severity level

This declaration is used in the DisplayInfo function in UDPs.

```
typedef void (*UDPAddMessageFP)
(
 UDPMessageSeverity, /* Message severity */
const char*, /* message string */
void* /* callbackData */
);
```

Function pointers used to create primitives

```
/* The return type for all primitives (except for spiral and
helix) is the ID of
 * the body created -1 is an invalid ID, which means the
operation failed.
 *
 * Spiral and helix are like sweep operations and operate on a
profile.
 * The return value indicates if the operation succeeded,
 * return value 0 means operation failed, any other value
 * means operation succeeded.
 */
```

```
/* 1D/2D ENTITIES */
typedef long (*UDPCreatePolylineFP)
(
const struct UDPPolylineDefinition* , /* polylineDefinition */
void* /* callbackData */
);

/* 3D ENTITIES */
typedef long (*UDPCreateCylinderFP)
(
UDPCoordinateSystemAxis, /* axis */
const struct UDPPosition*, /* center */
double, /* radius */
double, /* height */
void* /* callbackData */
);
```

Sweep functions

Sweep functions are used to create a sheet from a line or create a solid (3D object) from a sheet, as shown below.

```
  /* Sweep operations (Sweep along vector, around axis and
 * along path) modify the profile body. The resultant body
 * id is same as the profile id.
 *
 * In case of path sweep, the path body is consumed during the
 * sweep operation.
 *
 * The return value indicates
 * if the operation succeeded, return value 0 means operation
 * failed, any other value means operation succeeded.
 */
/* SweepAlongPath is used to sweep along a specific path to
create a sheet (from a line) or a solid (from a sheet)*/
typedef long (*UDPSweepAlongPathFP)
(
long, /* profileID */
long, /* pathID */
const struct UDPSweepOptions*, /* sweepOptions */
```

```
void* /* callbackData */
);

/* SweepAroundAxis is used to sweep around a specific axis (x,
y or z) to create a sheet (from a line) or a solid (from a
sheet)*/
typedef long (*UDPSweepAroundAxisFP)
(
long, /* profileID */
UDPCoordinateSystemAxis, /* sweepAxis */
double sweepAngle, /* sweepAngle */
const struct UDPSweepOptions*, /* sweepOptions */
void* /* callbackData */
);
```

Transform operations

The following two functions are used for transformations.

```
/* Transform operations (Translate i.e.move, rotate, mirror and
 * scale) modify the part body. The resultant body
 * id is same as the part id. The return value indicates
 * if the operation succeeded, return value 0 means operation
 * failed, any other value means operation succeeded.
 */

/* Translate function is used to do translational motion for a
given object. */
typedef long (*UDPTranslateFP)
(
long, /* partID */
const struct UDPVector*, /* translation vector */
void* /* callbackData */
);

/* Rotate function is used to rotate a given object. */
typedef long (*UDPRotateFP)
(
long, /* partID */
UDPCoordinateSystemAxis, /* axis */
double, /* angle */
```

```
void* /* callbackData */
);
```

Duplicate operation

```
/* Duplicate operations (Duplicate along line, around axis
 * and duplicate and mirror) create new bodies.
 *
 * In case of duplicate and mirror, only 1 duplicate can be
 * created. The ID of the duplicate body is returned by the
 * function. ID of -1 means the operation failed.
 *
 * For the other two cases multiple duplicates can be created.
 * The IDs of all such duplicates are returned in the function
 * parameter. The function return value indicates if the
operation
 * succeeded, return value 0 means operation failed, any other
 * value means operation succeeded.
 */
/* Duplicate an object around a given axis (of course can be
used to create either single or multiple copies around the
axis) */
typedef long (*UDPDuplicateAroundAxisFP)
(
long, /* partID */
UDPCoordinateSystemAxis, /* axis */
double, /* angle */
int, /* num of clones (including original) */
long*, /* returned clone ids */
void* /* callbackData */
);
```

Boolean operations

Boolean operations are used to unite, subtract, or intersect two objects.

```
/* Boolean operations (unite, subtract and intersect) modify
the
 * blank body. The resultant body id is same as the blank id.
 * Tool bodies are consumed during the operation.
 * The return value indicates if the operation succeeded,
 * return value 0 means operation failed, any other value
```

```
 * means operation succeeded.
 */
/* Unite two objects */
typedef long (*UDPUniteFP)
(
long*, /* objectIDs */
int, /* numObjects */
void* /* callbackData */
);

/* Subtract two objects */
typedef long (*UDPSubtractFP)
(
long*, /* blankIDs */
int, /* numBlanks */
long*, /* toolIDs */
int, /* numTools */
void* /* callbackData */
);
```

Function library with a collection of UDP functions

When coding for a UDP, you should declare an instance of UDPFunctionLib in the UDP and then use functions directly when needed.

For example:

```
UDPFunctionLib* functionLib;
functionLib->addMessage(kUDPInfoMessage, msg0, callbackData);

struct UDPFunctionLib
{
/* Utility functions */
UDPAddMessageFP addMessage;
UDPNameAFaceFP nameAFace;
UDPNameAEdgeFP nameAEdge;
UDPNameAVertexFP nameAVertex;
UDPGetFaceIDFromPositionFP getFaceIDFromPosition;
UDPGetEdgeIDFromPositionFP getEdgeIDFromPosition;
UDPGetTempDirPathFP getTempDirPath;
UDPGetInstallDirPathFP getInstallDirPath;
```

```
UDPGetSysLibDirPathFP getSysLibDirPath;
UDPGetUserLibDirPathFP getUserLibDirPath;
UDPGetPersonalLibDirPathFP getPersonalLibDirPath;
UDPSetProgressFP setProgress;

/* Primitives */
/* 1D/2D ENTITIES */
UDPCreatePolylineFP createPolyline;
UDPCreateRectangleFP createRectangle;
UDPCreateArcFP createArc;
UDPCreateCircleFP createCircle;

UDPReservedForFutureFP reservedOperation20;
/* END - RESERVED FOR FUTURE OPERATIONS */
};
```

Code Implementation

This section provides several sample functions and structures to show how to write real code for a UDP. All codes are from a sample source file written for Band UDP.

There are two files, UDPBase.h and UDPBase.cpp files, that include basic structures and functions for all UDPs. All UDPs should be built based on these two files.

Define UDP Parameters and Default Values

A structure is needed for parameters and default values at the beginning of each UDP. In the following code, UDPPrimitiveParameterDefinition, an intrinsic structure of UDP shown in Head

File for Intrinsic Structure Definition, is used to create an array of parameters for a UDP.

```
struct UDPPrimitiveParameterDefinition primParams[] =
{
{"DiaGap", "Band diameter in gap center, DiaGap<DiaYoke for
outer band",
kUDPLengthUnit, 101},
{"DiaYoke", "Band diameter on yoke side, DiaYoke<DiaGap for
inner band",
kUDPLengthUnit, 40},
{"Length", "Band length", kUDPLengthUnit, 200},
{"SegAngle", "Deviation angle for band (0.1~5 degrees).",
kUDPAngleUnit, 3},
{"Fractions", "Number of circumferential fractions, 1 for
circular region.",
kUDPNoUnit, 1},
{"HalfAxial", "0: full model; 1: half model in axial
direction.", kUDPNoUnit, 0},
{"InfoCore", "0: band; 1: tool; 2: independent; 3: dependent;
100: region.", kUDPNoUnit, 0}
};
```

The function inside band UDP

```
int AreParameterValuesValid(char ** error, double* paramValues)
{
obj.IniParameters(paramValues, numOfParameters);
return obj.AreParametersValid(error);
}
```

IniParameters() and AreParametersValid() are two member functions, which are defined in the UDP base class (in UDPBase.cpp file) and shown below.

Initialize parameters and check for validity

First initialize parameters using IniParameters(), and then check the validity of values for parameters. These two functions are inside the UDPBase class and do not need to be implemented.

```
// set oriParams pointer, and make a copy of data to
paramValues
void CUDPBase::IniParameters(double* paramValues0, int num)
```

```
{
oriParams = paramValues0; // set oriParams pointer
numOfParams = num;
delete[] paramValues;
paramValues = new double [num];
for (int i=0; i<num; i++) paramValues[i] = oriParams[i]; //
make a copy
}
```

The following function is not required to be implemented, but it calls three other functions, GetParameters(), ValidateParameters and PutParameters(), which should be implemented in the new UDP class.

```
int CUDPBase::AreParametersValid(char ** error)
{
GetParameters(); // the implementation is shown below
checkOK = 0;
char *err = ValidateParameters(); // the implementation is
shown below
if (err) {
*error = err;
return 0;
}
PutParameters(); // the implementation is shown below
checkOK = 1;
return 1;
}
```

Parameter Validation Functions

This section covers the three functions that you need to implement in the new UDP classes. The functions could be used as templates for new UDP classes.

These functions are very straightforward. You should follow the examples to add or remove parameters for a new UDP.

GetParameters()

```
/* To get the values from array of parameters*/
void CBand::GetParameters()
{
diaGap = diaYoke = 0;
```

```
length = 0;
infoCore = 0;
infoOut = -1;

segAng = 3;
numFras = 1;
infoHalf = 0;

for (int i=0; i<numOfParams; i++) {
if (GetValue(i, "DiaGap", diaGap)) continue;
if (GetValue(i, "DiaYoke", diaYoke)) continue;
if (GetValue(i, "Length", length)) continue;

if (GetValue(i, "SegAngle", segAng)) continue;
if (GetValue(i, "Fractions", numFras)) continue;
if (GetValue(i, "HalfAxial", infoHalf)) continue;
if (GetValue(i, "InfoCore", infoCore)) continue;
}
rRegion = diaYoke / 2;
}
```

PutParameters()

```
/* To store the values into array of parameters*/
void CBand::PutParameters()
{
for (int i=0; i<numOfParams; i++) {
if (PutValue(i, "DiaGap", diaGap)) continue;
if (PutValue(i, "DiaYoke", diaYoke)) continue;
if (PutValue(i, "Length", length)) continue;

if (PutValue(i, "SegAngle", segAng)) continue;
if (PutValue(i, "Fractions", numFras)) continue;
if (PutValue(i, "InfoCore", infoCore)) continue;
}
}
```

ValidateParameters()

```
/* To check parameters one by one to see if their values are
valid */
char* CBand::ValidateParameters()
{
if (!paramValues) return 0;

if (diaYoke < 0) diaYoke = 0;
if (diaGap <= 0) return "DiaGap must be larger than 0.";

}
```

Implement Main Function to Create Primitive

In this part, functions are used to create the UDP. You need to write two functions for UDP creation.

- The first function is the main function to create this UDP. It calls two other functions, one of which is shown in part 2.

```
extern "C" DLLEXPORT
long CreatePrimitive(struct UDPFunctionLib* functionLib, void*
callbackData,
double* paramValues)
{
obj.SetParameterPointer(paramValues);
return obj.CreatePrimitive(functionLib, callbackData);
}
```

- The following function is used to create a UDP based on different **InfoCore** values. For instance, a region is created when **InfoCore** is equal to 100 while a tool is created when **InfoCore** is equal to 2.

  For functions to create specific object like region, tool and independent, refer to Source Code Files for more detail.

```
long CBand::CreatePrimitive(UDPFunctionLib* functionLib, void*
callbackData)
{
if (!checkOK) return 0;

// display infomation of modified parameters
SetFunctionLib(functionLib, callbackData);
DisplayInfo();

// create region
if (infoCore == 100) {
long region = CreateRegion();
return region==-1 ? 0 : 1;
}

// create tool
if (infoCore == 1) {
```

```
long tool = CreateTool();
return tool==-1 ? 0 : 1;
}

// create independent
if (infoCore == 2) {
long independent = CreateIndependent();
return independent==-1 ? 0 : 1;
}

// create dependent
if (infoCore == 3) {
long dependent = CreateIndependent(false);
return dependent==-1 ? 0 : 1;
}

// create band
long band = CreateBand();
return band==-1 ? 0 : 1;
}
```

Map Parameters between Different Versions

Parameters mapping function is used when the UDP version changes or some new parameters are added into a UDP.

- You should implement the following function MapParametersDefinitionVersions(). It calls two other functions IniParameters() and MapParameters(), which is in the UDPBase class.

```
extern "C" DLLEXPORT
int MapParametersDefinitionVersions(double** newParamValues,
char* oldVersion,
int oldNumberOfParams, struct UDPPrimitiveParameterDefinition*
oldParamDefinition)
{
obj.IniParameters(*newParamValues, numOfParameters);
obj.MapParameters(oldParamDefinition, oldNumberOfParams);// map
para by keywords

int verN = getVerNum(oldVersion);
```

```
if (verN < 200) {
obj.SetDefaultParameter(*newParamValues, "HalfAxial", 0);
}

return 1;
}
```

- The following function is the MapParameters() function, which has already been implemented in the UDPBase class.

```
// map parameter values of old version to new version based on
keywords,
// which is written in UDPBase class and does not need to be
implemented by user
void CUDPBase::MapParameters(UDPPrimitiveParameterDefinition*
params, int oldNum)
{
if (!primParams) return;
int i, j, j0=0;
for (i=0; i<numOfParams; i++) {
oriParams[i] = primParams[i].defaultValue;
if (j0<oldNum && strcmp(primParams[i].name, params
[j0].name)==0) {
oriParams[i] = params[j0++].defaultValue;
continue;
}
for (j=0; j<oldNum; j++) {
if (strcmp(primParams[i].name, params[j].name) == 0) {
oriParams[i] = params[j].defaultValue;
j0 = j+1;
break;;
}
}
}
}
```

}

// create band
long band = CreateBand();
return band==-1 ? 0 : 1;
}
```

10 - Assigning Materials

You can add, remove, and edit materials in two main ways:

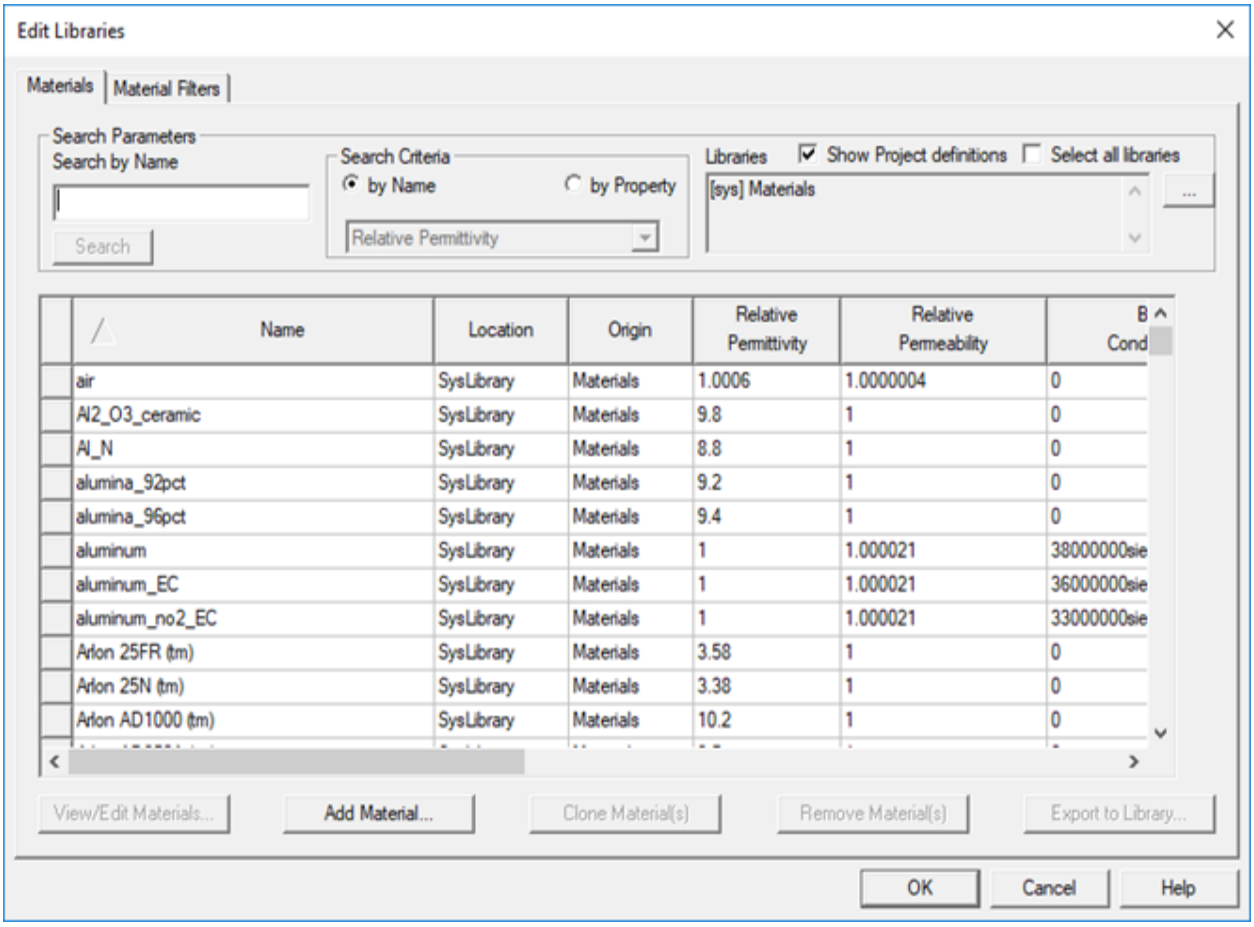
- Using the **Tools>Edit Libraries>Materials** menu command.
- Right-clicking **Materials** in the project tree and selecting **Edit Library**.

Regardless of which of the preceding two methods you use to edit a library, any new material you create exists only in the current project. Similarly, if you edit an existing material, the edited version becomes a *Project* material and exists only within the current project. To make a new or modified material available for other projects, you must export it to a user library and choose that library (or select **Show all libraries**) within the *Select Definition* dialog box.

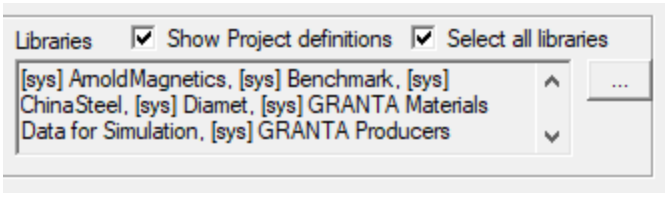
To assign a material to an object, follow the general procedure:

1. Select the object to which you want to assign a material.
2. Click **Modeler>Assign Material**  or select the Material field in the **Properties** window for the selected object, and select **Edit...** from the drop down menu.

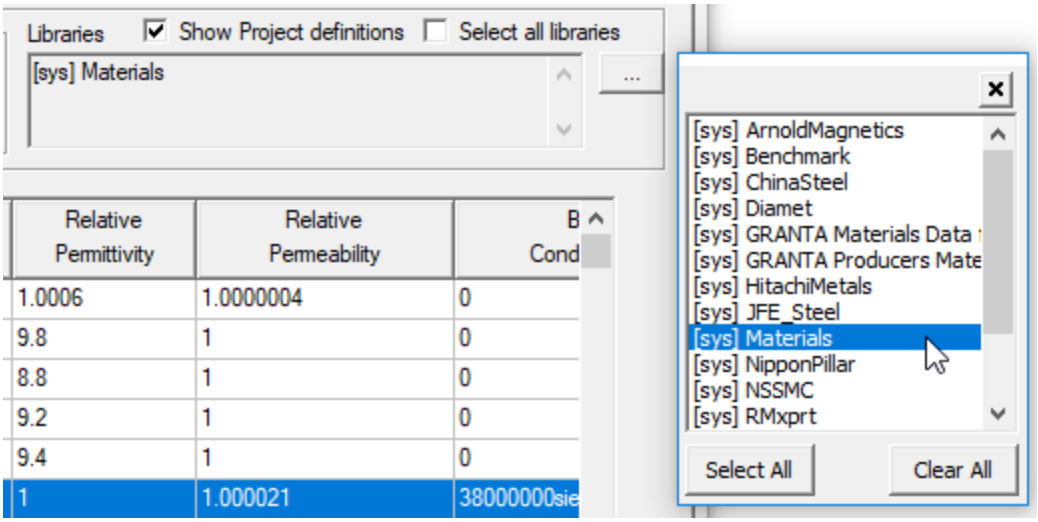
   The **Select Definition** window appears. The current material is highlighted, with the Name, Location, Origin library, and parameter values shown.



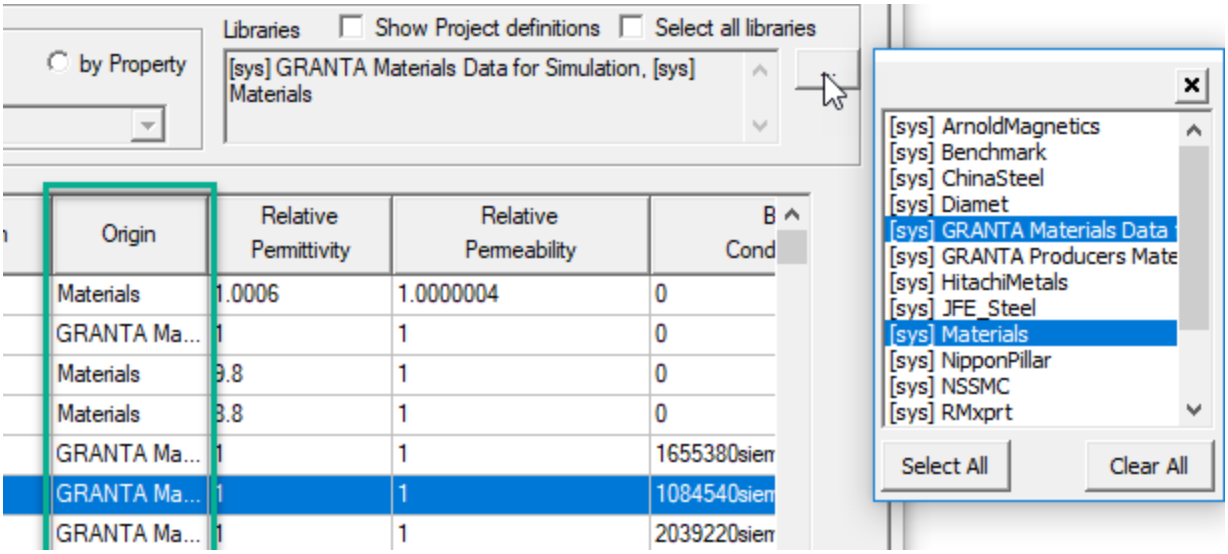
When the **Select all libraries** check box is selected, the window lists all of the materials in Ansys Electronics Desktop's global material library as well as the project's local material library.



If you click the ellipsis button **[...]**, you see a list of all available libraries. Any selected libraries are highlighted. Shift-Click allows you select a range. Ctrl-Click allows you to select any libraries.



The **Origin** column shows the originating library for each material, whether the **sys** library, or one of the additional libraries listed in the **Libraries** pane.



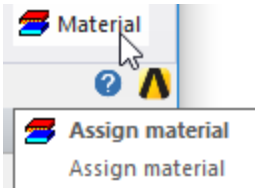
For further information on the materials and their intended uses, you can refer to the published information on materials from those libraries. For example, the Schott materials are described in detail in the Wily Series in Materials for Electronic & Optoelectronic Applications, *Microwave Dielectric Materials and Applications*, edited by M. T. Sebastian, Rick Ubic, and Heli Jantunen, volumes 1 and 2.

The GRANTA Materials Data for Simulation are an optional, licensed feature, including more than 700 generic materials and 500 producer-specific magnetic materials. When you use or view the GRANTA licensing libraries, the GRANTA license is checked out and held for 30 minutes. Viewing the contents of a GRANTA library in the Materials dialog or

modifying an object to use a GRANTA material causes a license check out and hold. If the license is already checked out, the hold time is reset to 30 minutes.

You can also open the **Select Definition** window in one of the following ways:

- In the **Properties** dialog box for the object, click the material name under the **Attributes** tab. A drop-down menu shows an **Edit...** button that opens the **Select Definition** window.
- With an object selected in the **Modeler** window, on the **Draw** ribbon, select the **Material** icon.



The menu also lists materials included in the current project. Selecting one of these materials provides another way to assign materials to an object.

- Right-click **Model** in the project tree, and then click **Assign Material** on the shortcut menu.
- Right-click the object in the history tree, and then click **Assign Material** on the shortcut menu.

3. Select a material from the list.

Note	You can search the listed materials by name or property value.

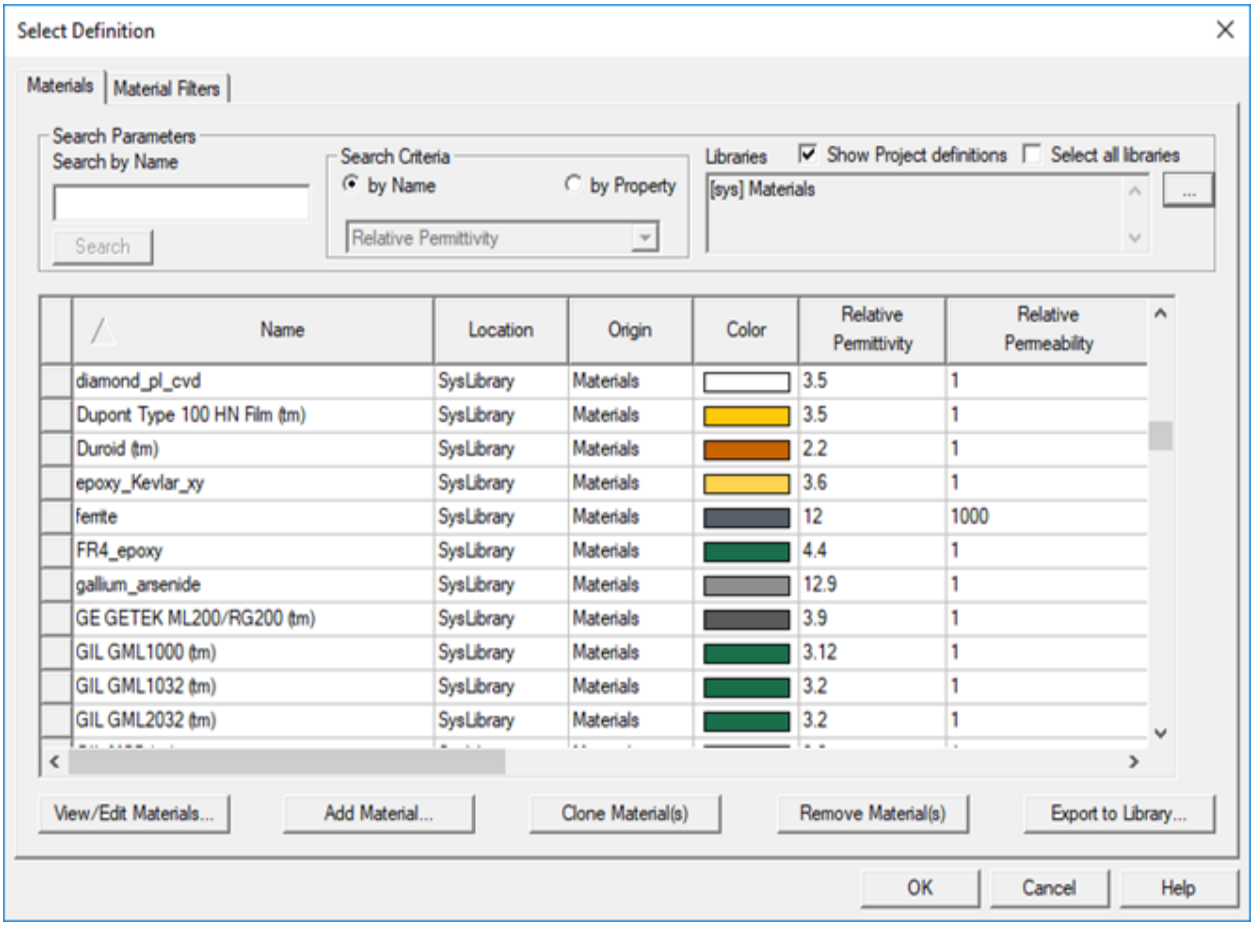
The list displays the currently set values for many of a material's properties such as Relative Permeability, Bulk Conductivity, and Composition. If the material you want to assign is not listed, you can add a new material to the global or local material library, and then select it.

4. Click **OK**.

The material you chose is assigned to the object.

Note	In the history tree, by default, objects are grouped by material. To change the default, select the object icon and right-click to display the **Group Objects by Material** check box.

If you have checked **Show Material Colors** on the Material Filters tab, the Materials tab includes a column showing a color swatch for each listed material.



You can edit the color and transparency values for materials in the View/Edit Material dialog.

Solving Inside or on the Surface

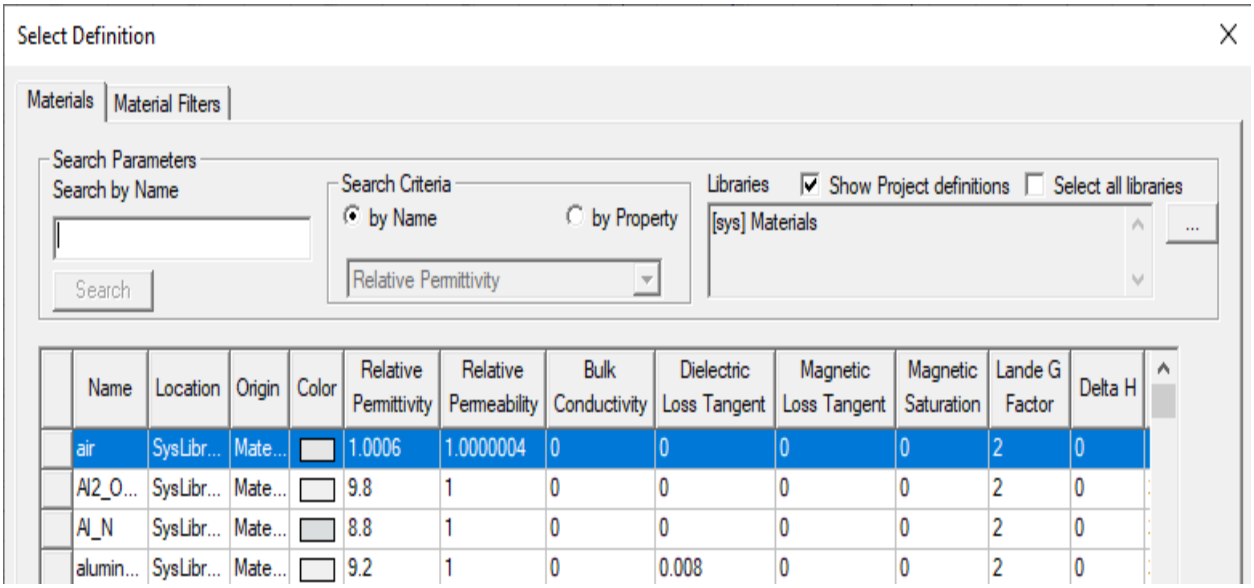
For Maxwell designs, when you assign a material to an object, you can specify whether to generate a field solution inside the object or on the surface of the object. If you elect to generate a solution inside the object, Maxwell will create a mesh inside the object and generate a solution from the mesh. If you elect to generate a solution on the surface of the object, Maxwell will create only a surface mesh for the object.

If you want a solution to be generated inside an object, select **Solve Inside** in the **Properties** window. Conversely, if you want a solution to only be generated on the surface of an object, clear the **Solve Inside** option in the **Properties** window.

By default, **Solve Inside** is selected for all objects with a bulk conductivity less than 10^5 siemens/meter and for perfect insulators. By default, the **Solve Inside** option in the **Properties** window is clear for perfect conductors.

Searching for Materials

You can search for materials in the **Select Definition** dialog box. The default Search Criteria is **by Name**, which is shown in the following example. Alternatively, you can choose to search by Property.



To search for a material **by Name**:

1. Access the **Select Definition** dialog box using one of the following methods:

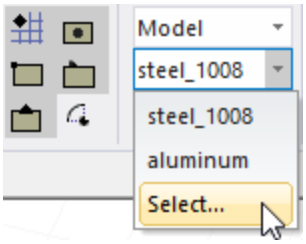
   With one or more objects selected (that is, to assign a material to selected objects):

   - Click **Modeler** > **Assign Material**
   - Click the **Material***value* in the docked **Properties** window, and select **Edit...** from the drop-down menu.

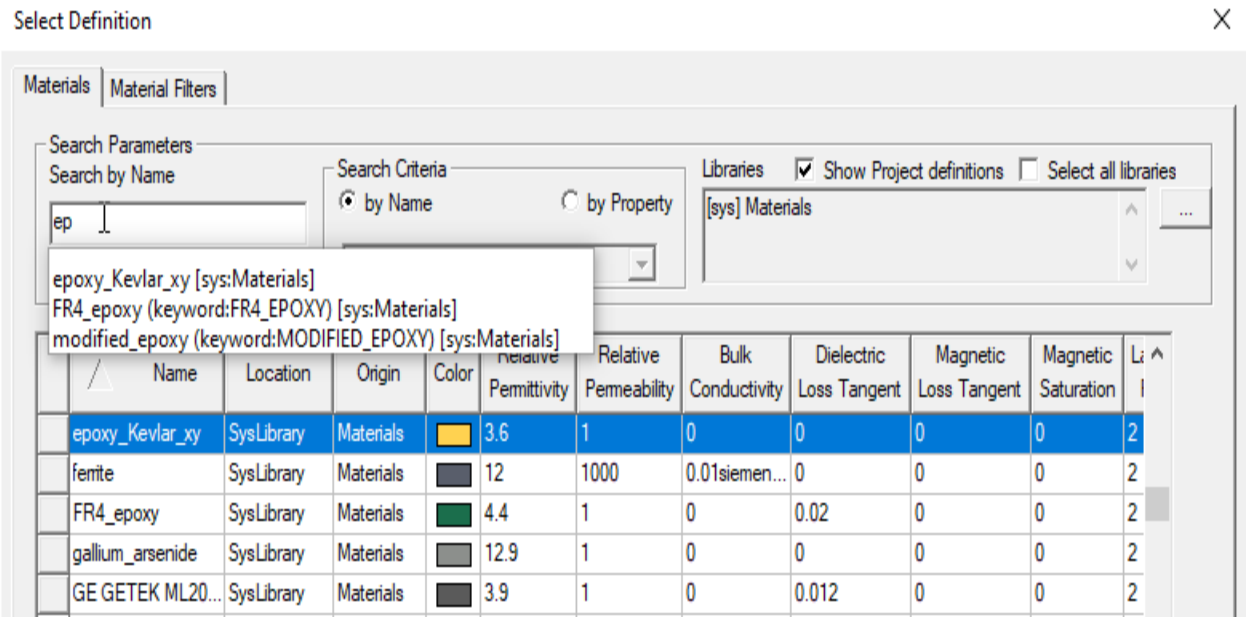
   - On the **Draw** ribbon tab, click **Assign material**.

   With nothing selected (that is, to set the default material):

- On the **Draw** ribbon tab, choose **Select** from the **Default material** drop-down menu:



2. In the **Search Criteria** section, ensure that **by Name** is selected, and in Libraries, specify the Libraries that you want to search. Only loaded libraries participate in text and keyword matching.
3. In the **Search by Name** text box, type a portion of the desired material name. The search text is case-insensitive.



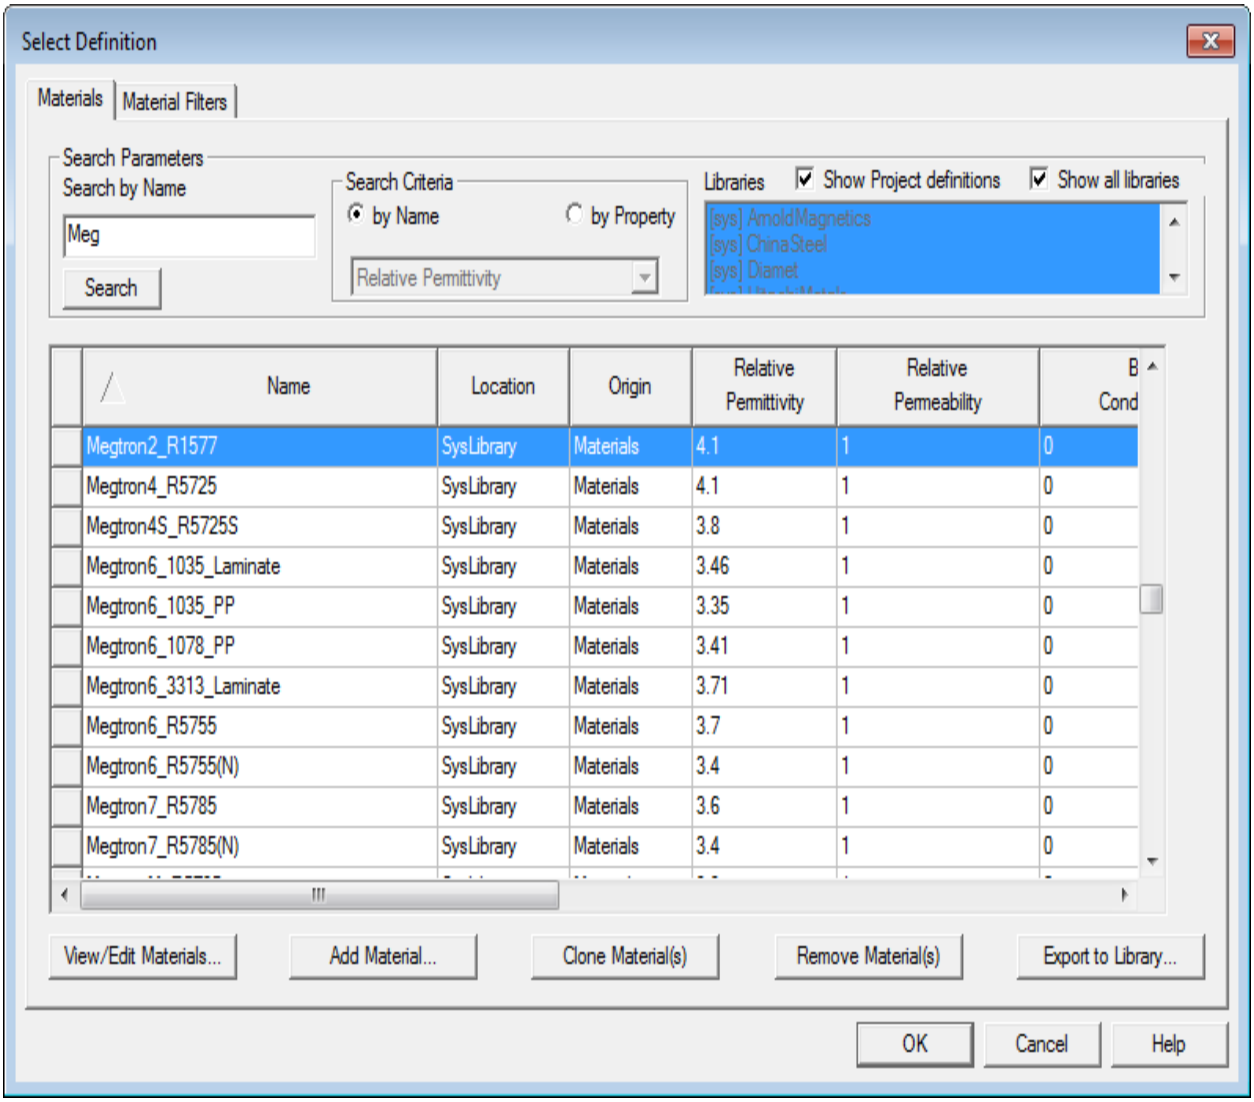
A drop down under the Search Parameters field will show the a list of the materials from selected libraries matching any part of the current text, and, if the Granta Materials library is selected, matching keywords in the material definitions. The first row containing the material name most similar to the characters you typed will be selected.

If the selected material is not the one you are searching for, do one of the following:

- Use the keyboard's arrow keys to select the material above or below the currently selected row.
- Use the scroll bar to scroll the listed materials upward or downward and click the desired material when it is visible.
- Type different characters in the **Search by Name** text box.

.

When the **Select all libraries** option is selected, the window lists all of the materials in Ansys Electronics Desktop's global material libraries that are applicable to the current design type as well as those in the project's local materials library. The Granta Materials Data for Simulation library now includes keywords that are used in the auto-complete matching. For example, entering "glass" will generate an auto-complete list of all materials with a name containing "glass" or with a keyword that contains "glass", all case-insensitive, for materials showing in the grid. The drop down of potential matches under the search field applies to all libraries. What shows in the grid is defined by which libraries are selected, what material filters are selected, project/design-specific validation, and whether project materials are selected for display.



Searching by Material Property

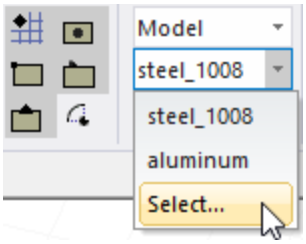
1. Access the **Select Definition** dialog box using one of the following methods:

   With one or more objects selected (that is, to assign a material to selected objects):

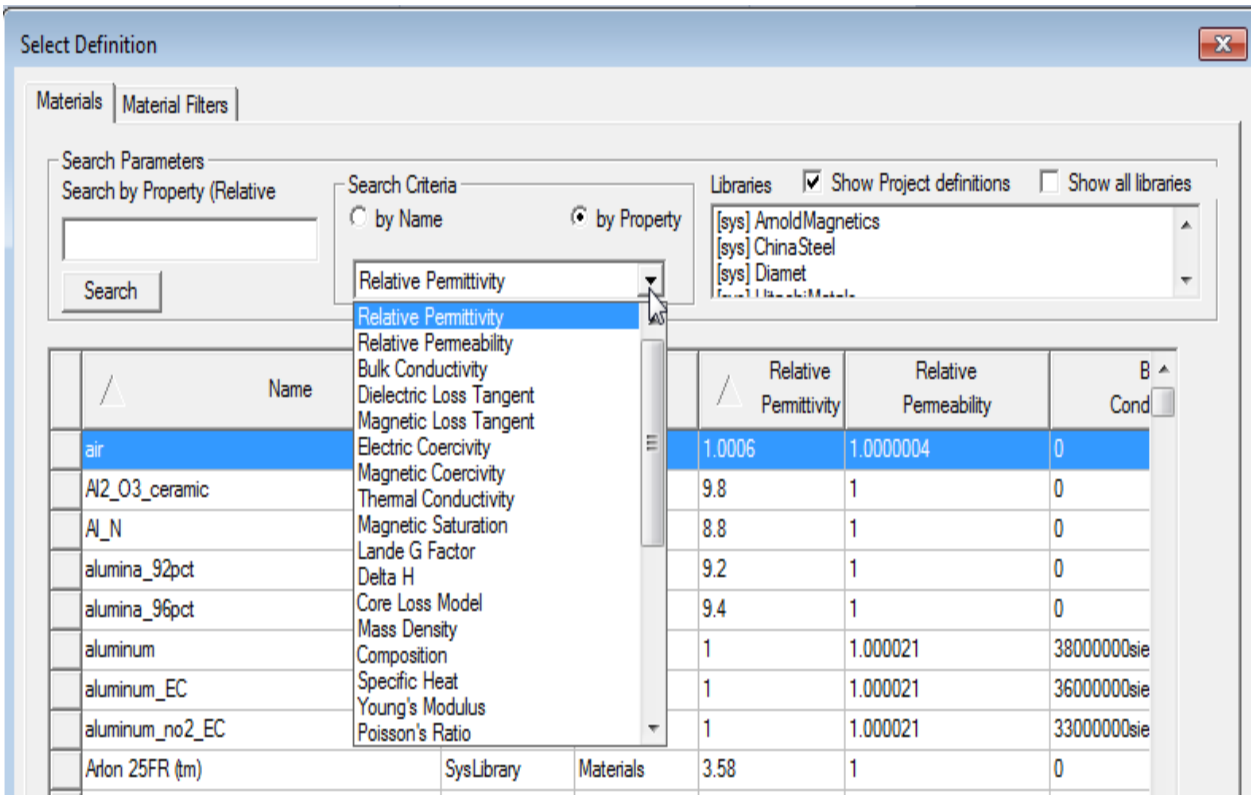
   - Click **Modeler** > **Assign Material**
   - Click the **Material***Value* in the docked *Properties* window, and select **Edit...** from the drop-down menu.
   - On the **Draw** ribbon tab, click **Assign material**.
   - On the **Draw** ribbon tab, click **Assign surface material**.

   With nothing selected (that is, to set the default material):

   - On the **Draw** ribbon tab, choose **Select** from the **Default material** drop-down menu:



2. In the **Search Criteria** area of the **Select Definition** dialog box, select **by Property**.



3. Select a material property from the pull-down list.

Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

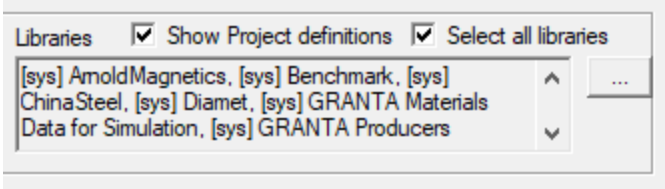
4. In the **Search Parameters** area, type a value for the property in the **Search by Property** box, and then click **Search**.

   The materials are sorted according to the value you entered. The material with the property value closest to the one you typed is selected.

   If the selected material is not the one you are searching for, do one of the following:

   - Use the keyboard's arrow keys to select the material above or below the currently selected row.
   - Use the scroll bar to scroll the listed materials upward or downward and click the desired material when it is visible.
   - Type a different numerical in the **Search by Property** text box and click **Search** again.

   When the **Show all libraries** check box is selected, the window lists all of the materials in Ansys Electronics Desktop's global material library as well as the project's local material library.



Adding New Materials

You can add a new material to a project or to the global user-defined material library. To make the new project material available to all projects, you must export the material to a global user-defined material library.

Materials are added using the **View/Edit Material** dialog box, which can be opened from either the **Select Definition** dialog box or the **Edit Libraries** dialog box.

To open the **Select Definition** dialog box:

- Click **Modeler>Assign Material**.

  The **Select Definition** dialog box appears.

To open the **Edit Libraries** dialog box:

- Click **Tools>Edit Libraries>Materials**. (In the project tree, you can also right-click **Materials**, and select **Edit Library**.)

  The **Edit Libraries** dialog box appears.

To add a new material:

1. From either the **Select Definition** dialog box or the **Edit Libraries** dialog box, click **Add Material**.

   The **View/Edit Material** dialog box appears.
2. Type a name for the material in the **Material Name** text box, or accept the default.
3. Select one of the following from the **Material Coordinate System Type** pull-down list:
   - **Cartesian** (default)
   - **Cylindrical**
   - **Spherical**
4. Under **View/Edit Material for** select:
   - **Active Design** to display properties used in the active design.
   - **Active Project** to display properties used in the active project.
   - **All Properties** to display all properties available. This enlarges the table of properties to show all properties possible for the selected Physics type(s). You can use the scroll bars or size the dialog to see all properties.

     Selecting **All Properties** also enables the three **Physics** check boxes: **Electromagnetic**, **Thermal**, and **Structural**. These check boxes are used to filter the properties displayed in the table by physics type. Clearing a check box hides properties of that physics type.
5. You can also enable the **View/ Edit Modifier** check box for **Thermal Modifier**.

   Checking this box causes the Thermal Column to display at the right side of the Properties of the Material table. Selecting **Edit** rather than **None** causes display of the Edit Thermal Modifier dialog.
6. Type a new name for the material in the **Material Name** text box or accept the default.
7. Select a material property type – **Simple** (i.e., *linear*), **Anisotropic**, **Nonlinear**, **Vector**, or **Custom** – for each property from the **Type** pull-down list. For Composition, values are **Solid**, **Lamination**, or **Litz Wire**. Some properties only use the Simple type. For thermal materials, select **Solid** or **Fluid** for the **Thermal Material Type**.

   Available selections vary with the property and solution type, and with the **View/Edit** selection as described above.

   For example, for an Eddy Current active design, if the material is **Simple** (i.e., *linear*), enter values for the following material properties in the **Value** boxes:
   - Relative Permeability (See also *Relative Permeability* in the Technical Notes.)
   - Relative Permittivity
   - Bulk Conductivity
   - Dielectric Loss Tangent
   - Magnetic Loss Tangent
   - Core Loss Model

- Composition: **Solid**, **Lamination**, or **Litz Wire**.

Note	The **Litz Wire** selection that appears under Composition is valid only for Maxwell 2D/3D Transient, and 2D/3D Eddy Current designs. Selecting **Litz Wire** for any other design type will generate an error message.

- Mass Density

If the material is a *ferrite*, enter a value greater than 0 in the Magnetic Saturation**Value** box. You may also choose to enter values in the Lande G Factor and Delta H**Value** boxes. Because Delta H values are measured at specific frequencies, you should also enter a - Measured Frequency value (default 9.4 Ghz).

Note	You may enter a variable name or mathematical expression in the **Value** box.

9. To modify the units for a material property, click the **Units** box, and then select a new unit system.
10. For **Material Appearance**, you can check the **Use Material Appearance** box to enable the fields for you to specify a color and transparency for the material.
    - Clicking the **Color** bar opens a standard color selection window.
    - Clicking the **Transparency** box opens a **Transparency** dialog with a text field and slider bar for selection.
11. If you want to add descriptive notes for the new material, click the ellipsis button [**...**] by the **Notes** field. This opens a dialog in which you can enter text. To enter multiple lines of notes, use **CTRL-Enter** to start a new line. (**Enter** by itself will save the Notes field and close the dialog.)
12. Below the list, in the **Calculate Properties for** pull-down list, do the following if your project contains a permanent magnet:
    a. Select **Permanent Magnet**.
    The **Properties for Permanent Magnet** dialog box appears.
    b. Select which parameters you want to define (**Mu**, **Hc**, **Br**, **Mp**).
    c. Type values in the text boxes, and select the units.
    d. Click **OK**.

Note	An error message displays if your project type does not support permanent magnets.

11. For transient and 3D eddy current projects, you may also be able to set the core loss from the **Calculate Properties for** pull-down list.
12. Click **Validate Material**.
13. Click **OK**.

    The new material is added to the local material library.

Assigning Material Property Types

Each material property can be assigned one of the following material property types:

Simple	The material is homogeneous and linear.
Anisotropic	The material's characteristics vary with direction. • If the material property is **Anisotropic**, its characteristics are defined by its anisotropy tensor. You must define three diagonals for: anisotropic permittivity, electric loss tangent, conductivity, permeability, and magnetic loss tangent. Each diagonal represents a tensor of your model along an axis. These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.
Nonlinear	For Relative Permittivity (valid only for 3D Electrostatic designs): • The material's relative permittivity varies according to its associated D-E curve. Refer to *Relative Permittivity for a Maxwell Material* for details on using nonlinear relative permittivity. For Bulk Conductivity (valid only for 3D DC Conduction designs): • The material's bulk conductivity varies according to its associated J-E curve. Refer to *Bulk Conductivity for a Maxwell Material* for details on using nonlinear bulk conductivity. For Relative Permeability: • The material's relative permeability varies according to its associated BH curve. Refer to *Relative Permeability for a Maxwell or RMxprt Material* for details on using nonlinear relative permeability.
Vector	For Magnetic Coercivity: • If the Relative Permeability Type is either Simple or Anisotropic, enter a Value for the Magnitude. • If the Relative Permeability Type is Nonlinear, Magnitude becomes uneditable, and three additional fields of Type Unit Vector: X Component, Y Component, and Z Component appear in which you can enter values or specify functions. For Electric Coercivity, enter a Value for the Magnitude.
Custom	Magnetostriction can be Linear, Nonlinear, or Anisotropic. Inverse

	Magnetostriction can be either Linear or Nonlinear. Refer to Magnetostriction and Inverse Magnetostriction Materials for details on using these properties.

Select a material property type from the **Type** pull-down list. Of the possibilities, only those applicable to the named material will be listed. Some material properties only use the **Simple** type. Others include several types.

- If the material property is **Anisotropic**, its characteristics are defined by its anisotropy tensor. You must define three diagonals for: relative permittivity, dielectric loss tangent, bulk conductivity, relative permeability, and magnetic loss tangent. Each diagonal represents a tensor of your model along an axis.

  These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.
- The Relative Permeability, Relative Permittivity, and Bulk Conductivity properties can also be assigned a **Nonlinear** property type.
- Magnetostriction and Inverse magnetostriction are **Custom** properties. Refer to Magnetostriction and Inverse Magnetostriction Materials for details on using these properties.

Relative Permeability for a Maxwell or RMxprt Material

Select one the following for relative permeability and specify the units:

Type	Value
Simple	Type a value for the **Relative Permeability**.
Anisotropic	The following parameters appear: • T(1,1)

	• T(2,2) • T(3,3) Select either a **Simple** or **Nonlinear** Type for each of these parameters.
Nonlinear	Click **BH Curve**, and specify the coordinates for the BH-curve (or curves if multiple temperature dependencies are used) in the BH Curve dialog box. Also enables X, Y, and Z Component unit vector fields for Magnetic Coercivity.

Note	The Anisotropic type is not used in RMxprt design.

Defining Anisotropic Relative Permeability Tensors

Eddy or frequency domain solutions only.

The relative permeability of materials is assumed to be a complex quantity expressed as the following:

$$\mu = \mu' - j \cdot \mu''$$

where μ' is the real part of the complex permeability (same as the usual relative permeability), μ'' is the imaginary part of the complex permeability, and j is the imaginary unit.

The relationship above can also be written as the following:

$$\mu = \mu'\left(1 - j \cdot \frac{\mu''}{\mu'}\right) = \mu'(1 - j \cdot \tan\delta)$$

where $\tan\delta$ is the magnetic loss tangent.

For anisotropic magnetic materials, a tensor material property needs to be used. The anisotropic relative permeability tensor has the following expression:

$$\bar{\mu} = \begin{vmatrix} \mu_1'(1 - j \cdot \tan\delta_1) & 0 & 0 \\ 0 & \mu_2'(1 - j \cdot \tan\delta_2) & 0 \\ 0 & 0 & \mu_3'(1 - j \cdot \tan\delta_3) \end{vmatrix}$$

Magnetostatic, Eddy, and transient solutions only.

Maxwell allows the anisotropic magnetic material to exhibit nonlinear characteristics (magnetostatic, Eddy, and transient solutions only) on all three principle axes of the chosen coordinate system, in which case the respective nonlinear characteristics must be specified.

For example, for laminations with anisotropic behavior in the plane of the lamination, the **Anisotropic** type of material should be specified for the **Relative Permeability** property, and the two respective B-H curves should be entered. For the third direction (lamination stacking direction), one of the specified two B-H curves should also be applicable. The composition field should be set to lamination, and the stacking factor and stacking direction should be specified (see also lamination model).

General

If the material property is anisotropic, its characteristics are defined by its anisotropy tensor. You must define three diagonals for anisotropic permeability. Each diagonal represents a tensor of your model along an axis.

These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.

1. In the **Relative Permeability** row in the **View/Edit Material** window, select **Anisotropic** from the **Type** pull-down list.

   Three rows named **T(1,1)**, **T(2,2)** and **T(3,3)** are added below the **Relative Permeability** row.
2. Enter the relative permeability along one axis of the material's permeability tensor in the **Value** box of the **T(1,1)** row.
3. Enter the relative permeability along the second axis in the **Value** box of the **T(2,2)** row.
4. Enter the relative permeability along the third axis in the **Value** box of the **T(3,3)** row.

If the relative permeability is the same in all directions, use the same values for each axis.

These values can also be defined as variables.

Dielectric Loss Tangent for a Maxwell Material

Specify the following for dielectric loss tangent.

Type	Value
Simple	Type a value for the**Dielectric Loss tangent**.
Anisotropic	The following parameters appear: • T(1,1) • T(2,2) • T(3,3) Type a simple value for each.

Defining Anisotropic Dielectric Loss Tangent Tensors

To represent a dielectric that dissipates the power of a high-frequency electric field, enter a dielectric loss tangent, $\varepsilon''/\varepsilon'$, property value for the material. The smaller the loss tangent, the less lossy the material.

If the material property is anisotropic, its characteristics are defined by its anisotropy tensor. You must define three diagonals for electric loss tangent. Each diagonal represents a tensor of your model along an axis.

These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.

If electric loss tangent is anisotropic, do the following:

1. In the **Dielectric Loss Tangent** row in the **View/Edit Material** window, select **Anisotropic** from the **Type** pull-down list.

   Three rows named **T(1,1)**, **T(2,2)** and **T(3,3)** are added below the **Dielectric Loss Tangent** row.
2. Enter the ratio of the imaginary relative permittivity to the real relative permittivity in one direction in the **Value** box of the **T(1,1)** row.
3. Enter the ratio of the imaginary relative permittivity to the real relative permittivity in the second direction in the **Value** box of the **T(2,2)** row.

4. Enter the ratio of the imaginary relative permittivity to the real relative permittivity in the third orthogonal direction in the **Value** box of the **T(3,3)** row.

If the electric loss tangent is the same in all directions, use the same values for each direction.

These values can also be defined as variables.

The dielectric loss tangent may vary with frequency. To simulate the variances, define a function for the dielectric loss tangent.

Relative Permittivity for a Maxwell Material

Specify the following for Relative Permittivity and specify the units.

Type	Value
Simple	Type a value for the **Relative Permittivity**.
Anisotropic	The following parameters appear: • T(1,1) • T(2,2) • T(3.3) Type a simple value for each.
Nonlinear	The material's relative permittivity varies according to its associated D-E curve. Refer to *Specifying a D-E Curve for Nonlinear Relative Permittivity* for details.

Related Topics

Defining Anisotropic Relative Permittivity Tensors
Specifying a D-E Curve for Nonlinear Relative Permittivity

Defining Anisotropic Relative Permittivity Tensors

Eddy or frequency domain solutions only.

The relative dielectric permittivity of dielectrics is assumed to be a complex quantity, expressed as the following:

$$\varepsilon = \varepsilon' - j \cdot \varepsilon''$$

where ε' is the real part of the complex permittivity (the same as the usual relative dielectric constant), ε'' is the imaginary part of the complex permittivity, and j is the imaginary unit.
The relationship above can also be written as the following:

$$\varepsilon = \varepsilon'\left(1 - j \cdot \frac{\varepsilon''}{\varepsilon'}\right) = \varepsilon'(1 - j \cdot \tan\delta)$$

where $\tan\delta$ is the dielectric loss tangent.
For anisotropic dielectrics, a tensor material property needs to be used. The anisotropic relative permittivity tensor has the following expression:

$$\bar{\varepsilon} = \begin{vmatrix} \varepsilon_1'(1 - j \cdot \tan\delta_1) & 0 & 0 \\ 0 & \varepsilon_2'(1 - j \cdot \tan\delta_2) & 0 \\ 0 & 0 & \varepsilon_3'(1 - j \cdot \tan\delta_3) \end{vmatrix}$$

If the material property is anisotropic, its characteristics are defined by its anisotropy tensor. You must define three diagonals for anisotropic permittivity. Each diagonal represents a tensor of your model along an axis.
These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.

1. In the **Relative Permittivity** row in the **View/Edit Material** window, select **Anisotropic** from the **Type** pull-down list.
   Three rows named **T(1,1)**, **T(2,2)** and **T(3,3)** are added below the **Relative Permittivity** row.
2. Enter the material's relative permittivity along one tensor axis in the **Value** box of the **T(1,1)** row.

3. Enter the relative permittivity along the second axis in the **Value** box of the **T(2,2)** row.
4. Enter the relative permittivity along the third axis in the **Value** box of the **T(3,3)** row.

If the relative permittivity is the same in all directions, use the same values for each axis.

These values can also be defined as variables.

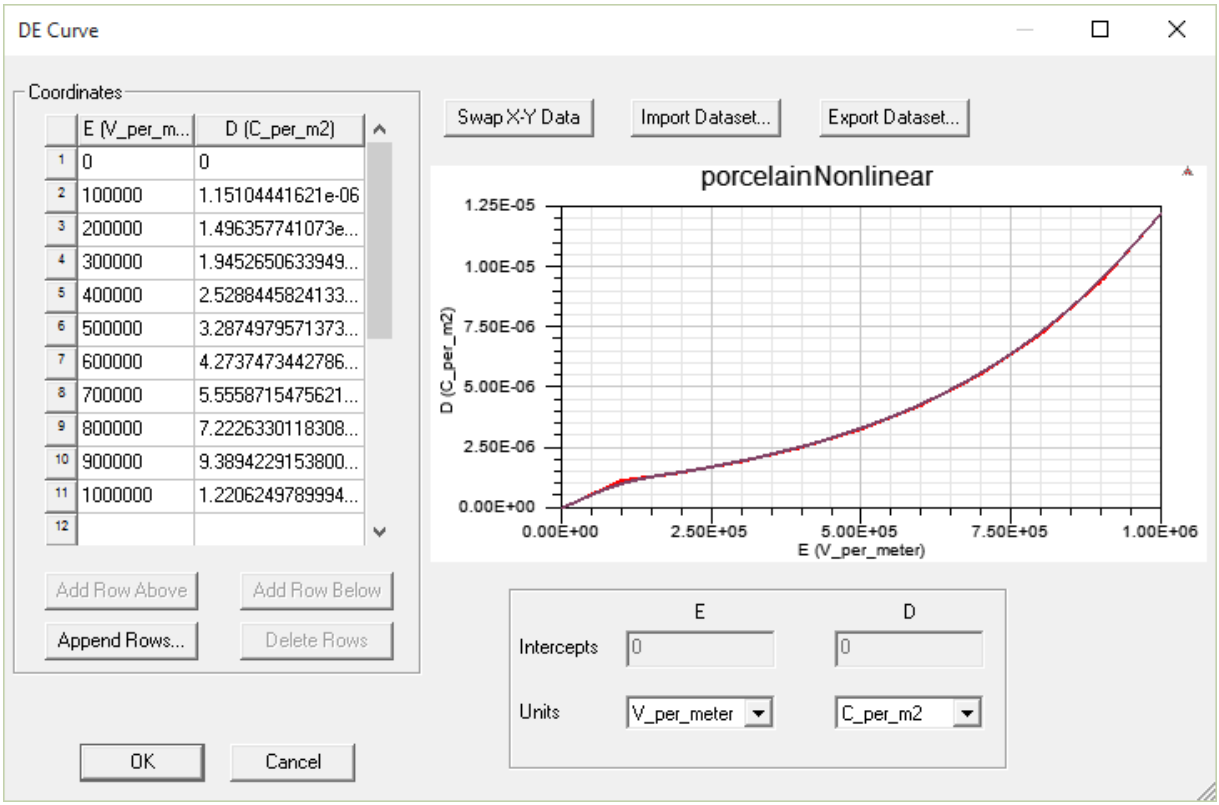
Specifying a D-E Curve for Nonlinear Relative Permittivity

Note	The D-E curve is supported only for the Maxwell 3D Electrostatic design types. A material property defined using a D-E curve will fail validation check in the other product/design types.

When you define a new material or edit an existing material in the **View /Edit Material**s window with a nonlinear relative permittivity, you need to specify the electric flux density vs. electric field strength characteristics (**D-E Curve**).

1. Open the **View / Edit Materials** dialog from the **Edit Materials** window either by:
   - Selecting an existing material that you need to edit, and click **View / Edit Material**.
   - Clicking **Add Material.**

   Any of these actions open the **View/ Edit Materials** dialog box.
2. For the **Relative Permittivity** select **Nonlinear** as the **Type**. A **D-E Curve** button appears in the **Value** column.
3. Input the D-E curve by clicking the **D-E Curve** button opens the **DE Curve** dialog box.



4. Set the **Units** for **D** and **E** by selecting from the drop down menus.

   For a material property without an existing D-E curve definition, the dialog opens with an empty list of coordinates.

5. Enter D and E values in each row of the **Coordinates** table. Placing the cursor in a table cell enables the **Add Row Above**, **Add Row Below**, and **Delete Rows** buttons.

   Note the following requirements for creating a valid curve:

   - The slope of the curve can not be less than 0.
   - The values of D and E must increase along the curve.
   - The initial values of D and E must be 0 (zero) - the curve must begin at the origin.
   - Since D-E operating points in the FEA solution may extend beyond the input D-E data set, the D-E data set is extrapolated. The slope of the last two user-defined data points is used to extrapolate the D-E curve.
   - The data points representing the D-E curve should have enough points for accurate representation of the curve. A minimum of three data points must be specified. Twenty (20) or more points should be specified with increased representation on the "knee" of the curve.

   As you enter values, the graph is updated.

   To Add or Edit rows, you can click the following buttons:

   - **Add Row Above**
   - **Add Row Below**

- **Append Rows** (to specify the number of rows to append to the table)
- **Delete Rows**

6. Optionally, click **Import Dataset** to import D-E curve data from a file, and if they are in the wrong columns, click **Swap X-Y Data** to switch the J values and E values in the graphics display. You can also use the SheetScan tool to extract curve data from sources such as manufacturer datasheets to a dataset, which can then be exported to a tab-delimited file, and imported via **Import Dataset**. (Refer to *Adding Datasets* and *Exporting Datasets* for related information on working with datasets. Refer to *Using SheetScan* for working with the SheetScan tool.)
7. When finished entering data, click **OK** to close the window.

   When you **OK** the dialog box, an error message displays if a slope is out of tolerance, identifying the out of tolerance parameter. Out of tolerance data points must be corrected before you can successfully exit the dialog.

Relative Permittivity for a Maxwell Material

Bulk Conductivity for a Maxwell Material

Specify the following for bulk conductivity and specify the units:

Type	Value
Simple	Type a value for the **Bulk Conductivity**.
Anisotropic	The following parameters appear: • T(1,1) • T(2,2) • T(3,3) You can enter a simple value for each of these parameters.
Nonlinear	The material's bulk conductivity varies according to its associated J-E curve. Refer to *Specifying a J-E Curve for Nonlinear Bulk Conductivity* for details.

Related Topics

Defining Anisotropic Conductivity Tensors
Specifying a J-E Curve for Nonlinear Bulk Conductivity

Defining Anisotropic Conductivity Tensors

Electric conductivity can be simple or anisotropic. In either case, the corresponding values are entered in S/m (Siemens per meter).

If the material property is anisotropic, its characteristics are defined by its anisotropy tensor. You must define three diagonals for anisotropic conductivity. Each diagonal represents a tensor of your model along an axis.

These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.

1. In the **Bulk Conductivity** row in the **View/Edit Material** window, select **Anisotropic** from the **Type** pull-down list.

   Three rows named **T(1,1)**, **T(2,2)** and **T(3,3)** are added below the **Bulk Conductivity** row.
2. Enter the conductivity along one axis of the material's conductivity tensor in the **Value** box of the **T(1,1)** row.
3. Enter the conductivity along the second axis in the **Value** box of the **T(2,2)** row.
4. Enter the conductivity along the third axis in the **Value** box of the **T(3,3)** row.

The values of the conductivity along the first and second axis apply to all axes that lie in the xy cross-section being modeled. The values of the conductivity along the third axis applies to the z-component. These values affect current flowing in dielectrics between the conductors.

These values can also be defined as variables.

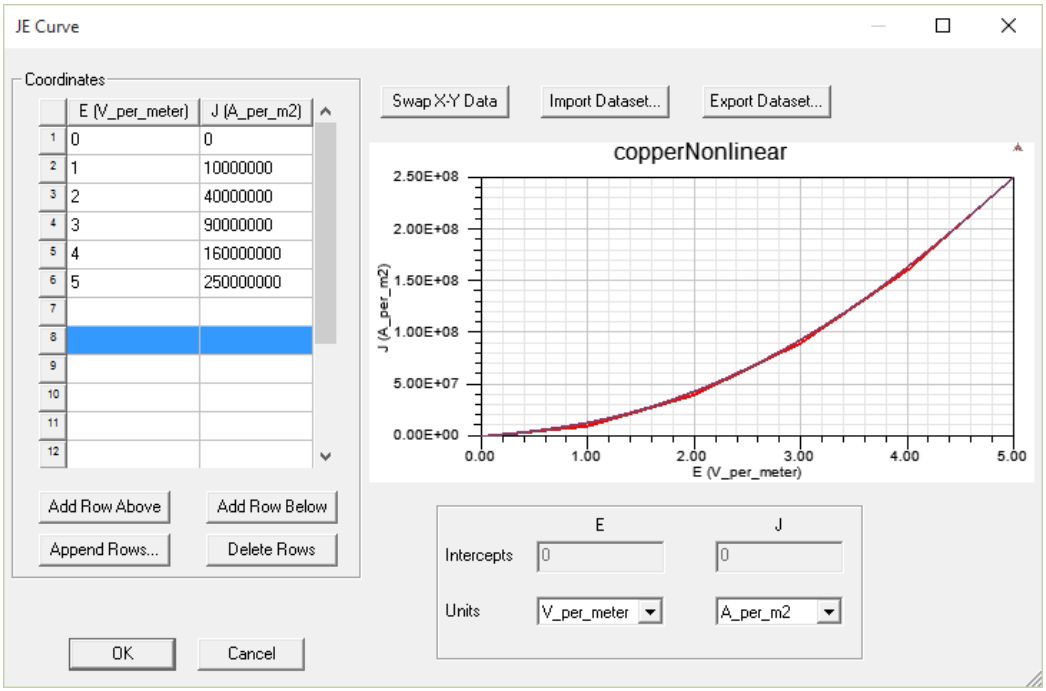
Specifying a J-E Curve for Nonlinear Bulk Conductivity

Note	The J-E curve is supported only for the Maxwell 3D DC Conduction design types. A material property defined using a J-E curve will fail validation check in all the other product/design types.

When you define a new material or edit an existing material in the **View /Edit Material**s window with a nonlinear bulk conductivity, you need to specify the current density vs. electric field characteristics (**J-E Curve**).

1. Open the **View / Edit Materials** dialog from the **Edit Materials** window either by:
   - Selecting an existing material that you need to edit, and click **View / Edit Material**.
   - Clicking **Add Material.**

   Any of these actions open the **View/ Edit Materials** dialog box.
2. For the **Bulk Conductivity** select **Nonlinear** as the **Type**. A **J-E Curve** button appears in the **Value** column.
3. Input the J-E curve by clicking the **J-E Curve** button opens the **JE Curve** dialog box.



4. Set the **Units** for **J** and **E** by selecting from the drop down menus.

   For a material property without an existing J-E curve definition, the dialog opens with an empty list of coordinates.
5. Enter J and E values in each row of the **Coordinates** table. Placing the cursor in a table cell enables the **Add Row Above**, **Add Row Below**, and **Delete Rows** buttons.

   Note the following requirements for creating a valid curve:
   - The slope of the curve can not be less than 0.
   - The values of J and E must increase along the curve.
   - The initial values of J and E must be 0 (zero) - the curve must begin at the origin.
   - Since J-E operating points in the FEA solution may extend beyond the input J-E data set, the J-E data set is extrapolated. The slope of the last two user-defined data points is used to extrapolate the J-E curve.
   - The data points representing the J-E curve should have enough points for accurate representation of the curve. A minimum of three data points must be specified. Twenty

(20) or more points should be specified with increased representation on the "knee" of the curve.

As you enter values, the graph is updated.

To Add or Edit rows, you can click the following buttons:

- **Add Row Above**
- **Add Row Below**
- **Append Rows** (to specify the number of rows to append to the table)
- **Delete Rows**

6. Optionally, click **Import Dataset** to import J-E curve data from a file, and if they are in the wrong columns, click **Swap X-Y Data** to switch the J values and E values in the graphics display. You can also use the SheetScan tool to extract curve data from sources such as manufacturer datasheets to a dataset, which can then be exported to a tab-delimited file, and imported via **Import Dataset**. (Refer to *Adding Datasets* and *Exporting Datasets* for related information on working with datasets. Refer to *Using SheetScan* for working with the SheetScan tool.)
7. When finished entering data, click **OK** to close the window.

   When you **OK** the dialog box, an error message displays if a slope is out of tolerance, identifying the out of tolerance parameter. Out of tolerance data points must be corrected before you can successfully exit the dialog.

Bulk Conductivity for a Maxwell Material

Magnetic Loss Tangent

To represent a magnetic material such as ferrite that dissipates the power of a high-frequency magnetic field, enter a magnetic loss tangent, μ''/μ', property value for the material. The smaller the loss tangent, the less lossy the material.

Note	If you plan to do a fast frequency sweep for a design that includes dielectrics, make sure that the dielectric or magnetic loss tangent does not vary significantly over the requested frequency range. If they do, the results may not be what you expect. In cases where the loss tangent does vary significantly over the frequency range in which you are interested, copy and solve the design several times, adjusting the loss tangent and associated frequency range for the copied design so that the loss tangent is relatively stable over the design's requested frequency range.

Note	When magnetic loss tangent is used, the resulting hysteresis core loss will be reflected in the resistance term for both the impedance matrix and the Simplorer Dynamic Eddy Current ROM.

Imaginary Permeability

Eddy Current

Some materials exhibit a permeability that includes both a real and imaginary component. The imaginary component is used to model magnetic losses in a time-varying field using the relationship:

$$B = (\mu_r' - j(\mu_r''))\mu_0 H$$

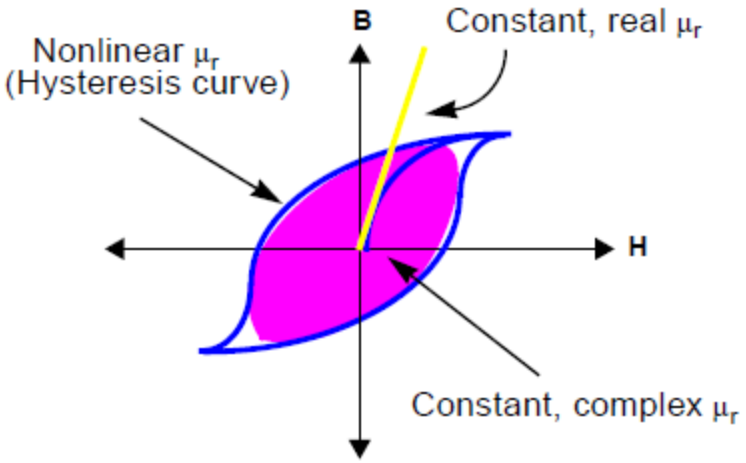
where:

μ_r' is the real component of the relative permeability.

μ_r'' is the imaginary component of the relative permeability.

μ_0 is the permeability of free space.

As shown below, a complex relative permeability causes the B field to lag behind the H field – similar to the behavior of a nonlinear, lossy material. The power loss during this cycle (the color shaded area) is approximately equal to the hysteresis loss (the area within the blue lines). The hysteresis curve for a material with a constant, real permeability (the straight yellow line) is shown as a reference.



When the nature of losses is also due to magnetic hysteresis, Maxwell allows you to model such effects using complex permeability by allowing the specification of the tangent of magnetic loss. When a linear material exhibits hysteresis effects, it should be characterized using a complex permeability, as below:

$$\underline{\mu} = \mu' - j\mu'' = \mu'\left(1 - j\tan\delta\right)$$

where $\tan\delta$ is the magnetic loss tangent, $\frac{\mu''}{\mu'}$

Enter the imaginary relative permeability of a material, μ'', in the **Imag. Permeability** field. The default imaginary permeability of zero is that of a material that exhibits no magnetic loss in a time-varying field.

Defining Magnetic Loss Tangent Tensors

If the material property is anisotropic, its characteristics are defined by its anisotropy tensor. You must define three diagonals for anisotropic magnetic loss tangent. Each diagonal represents a tensor of your model along an axis.

These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.

1. In the **Magnetic Loss Tangent** row in the **View/Edit Material** window, select **Anisotropic** from the **Type** pull-down list.

   Three rows named **T(1,1)**, **T(2,2)** and **T(3,3)** are added below the **Magnetic Loss Tangent** row.
2. Enter the ratio of the imaginary relative permeability to the real relative permeability in one direction in the **Value** box of the **T(1,1)** row.
3. Enter the ratio of the imaginary relative permeability to the real relative permeability in the second direction in the **Value** box of the **T(2,2)** row.
4. Enter the ratio of the imaginary relative permeability to the real relative permeability in the third direction in the **Value** box of the **T(3,3)** row.

If the magnetic loss tangent is the same in all directions, use the same values for each direction. These values can also be defined as variables.

Defining Variable Material Properties

When defining or modifying a material's properties, each material property value in the **View/Edit Material** window can be assigned a project variable. Simply type the project variable's name in the appropriate **Value** box. Project variables are used for material properties because materials are stored at the project level.

For example, define a project variable with the name **MyPermittivity** and define its value as **4**. To assign this property value to a material, type **$MyPermittivity** in the **Value** box for the material. Be sure to include the prefix **$** before the project variable name, which notifies Maxwell that the variable is a project variable.

Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

Specifying Thermal Modifiers

Specifying Thermal Modifiers

To specify Thermal modifiers for a material:

1. In the View/ Edit materials dialog you must enable the View/ Edit Modifier check box for Thermal Modifier.

   This causes the Properties of the Material table to expand to include a Thermal Modifier column. By default, the Thermal Modifier property is set to **None**.
2. Selecting **Edit...** from the drop down menu, rather than **None** causes the **Edit Thermal Modifier** dialog to appear.
3. Select **Expression** radio button to display the **Parameters Modifier** text field or the **Quadratic** radio button to display the tabs for **Basic Coefficient Set** and **Advanced Coefficient Set**.
   - With **Expression** selected, you can write an equation for a thermal modifier in the Parameters **Modifier** text field.

     Checking **Use temperature dependent data set** disables the Modifier text field. You can then use the drop down menu to select Add/Import Dataset. This lets you define the thermal modifier as a data set.
   - With the **Quadratic** radio button selected, in the **Basic Coefficient** tab, you can edit fields for the TempRef and units, and fields for C1 and C2 for the following equation:

     P(Temp) = Pref[1+ C1(Temp - TempRef) + C2(Temp - TempRef)^2]

     where the Pref is defined as the reference relative permittivity.
   - With the **Quadratic** radio button selected, in the **Advanced Coefficient Set** tab, you can edit fields for lower and upper temperature limits (TL and TU respectively) and select their units from the drop down.

     You can also edit the constant value limit for the thermal modifier values outside the limits. By default, these are automatically calculated. Uncheck the Auto Calculate TML and TMU to specify new values for thermal modifier lower (TML) and thermal modifier upper (TMU).

4. Click **OK** to accept the edits and return to the View/ Edit materials dialog.

Defining Material Properties as Expressions

When defining or modifying a material's properties, each material property value in the **View/Edit Material** window can be assigned a mathematical expression. Simply type the expression in the appropriate **Value** box. Expressions typically contain intrinsic functions, such as sin(x), and arithmetic operators, such as +, -, *, and /, but do not include project variables.

Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

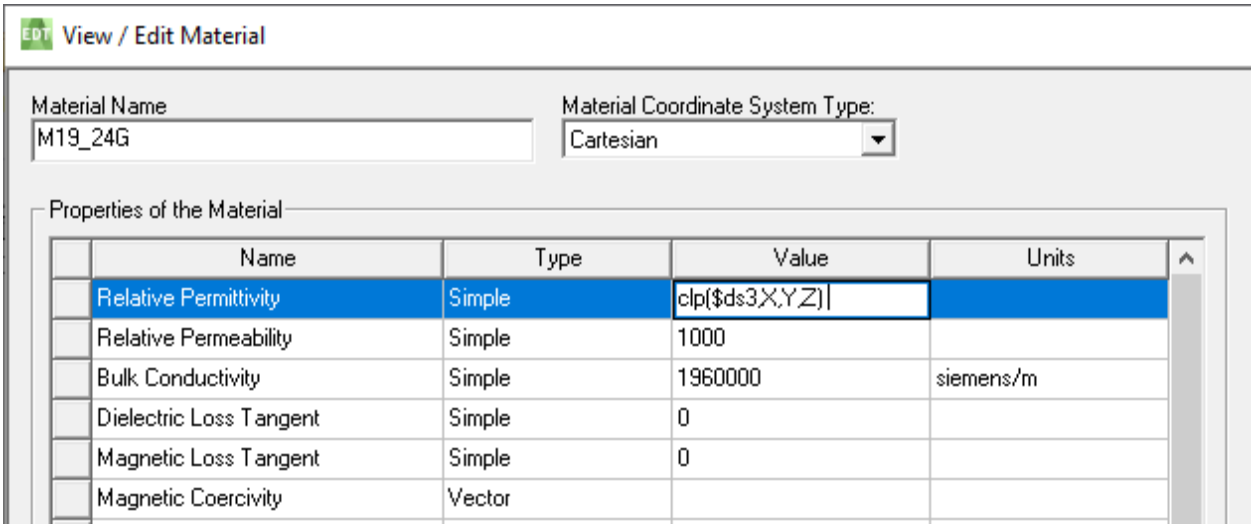
Defining Variable Material Properties

Defining Functional Material Properties

Any material property that can be specified by entering a constant can also be specified using a mathematical function. This is useful when you are defining a material property whose value is given by a mathematical relationship — for instance, one relating it to frequency or another property's value. When defining or modifying a material's properties, simply type the name of the function in the appropriate **Value** box.

Optionally, for 2D and 3D transient designs, you can enter an expression for a 3D(X,Y,Z) dataset in the Value box for the properties of conductivity, permeability, and permittivity, as shown in the figure below. The 3D dataset models the spatially varying material property change with respect to location along the object. For detailed information on using 3D(X,Y,Z) datasets, please refer to *Setting a Spatial Modifier*.



Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

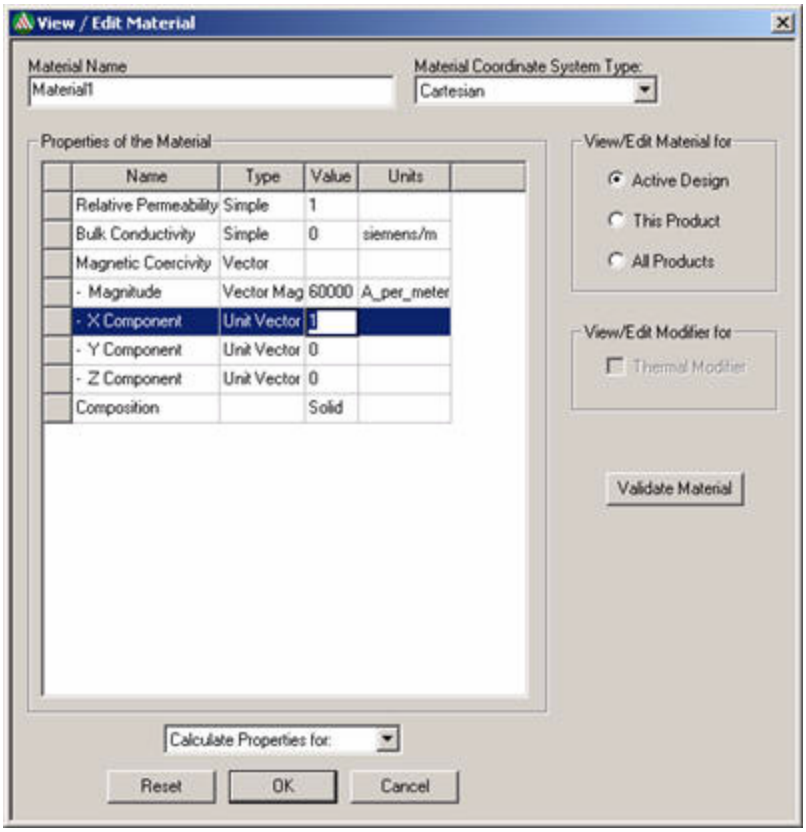
Material Coordinate Systems

Maxwell supports the following three types of coordinate systems, which can be used to define some vector or anisotropic material properties:

- Cartesian (defined by the X, Y, and Z axes)
- Cylindrical (defined by the R, Phi, and Z axes)

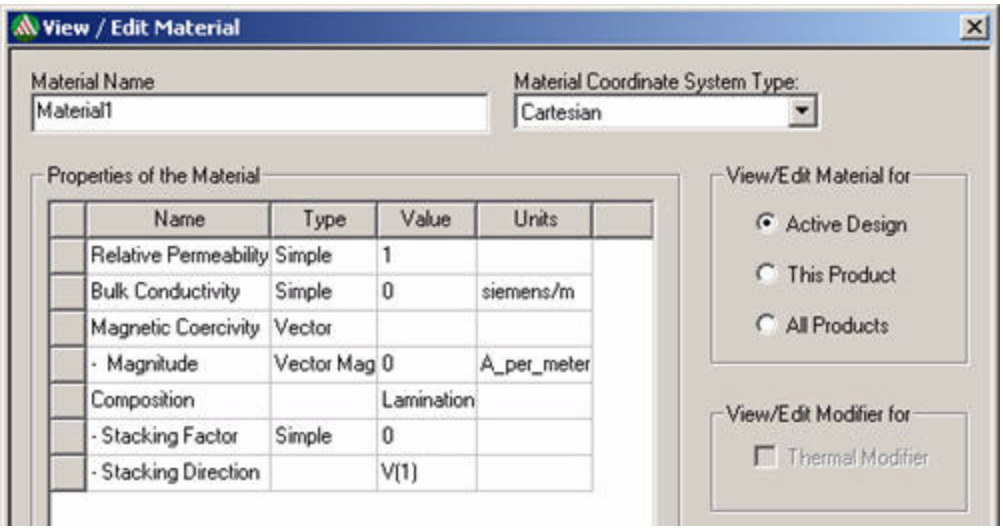
- Spherical (defined by the Rho, Theta, and Phi axes)



To get the fields for the vector magnetic coercivity vector, a non-zero value must first be specified for the magnitude of the vector. The magnitude can also be functional. The magnitude of the magnetic coercivity is expected to be < 0. If you use a positive value, the direction used will be the opposite of the unit vector specified.

Lamination Modeling

Lamination modeling allows you to specify a stacking factor and stacking direction, which represents the direction perpendicular to the plane of the lamination. Cartesian, cylindrical, or spherical coordinate systems can be used to specify the stacking direction.



This lamination model is an alternative way of specifying anisotropic behavior when using laminations (which is a special case that is frequently done). For the frequently encountered case of isotropic laminations (where the global model is anisotropic due to the existence of laminations but the laminations themselves are isotropic), the above picture shows a possible setup. Choose a nonlinear behavior for the material of the lamination with a user specified B-H curve, while the global anisotropy is modeled by specifying a stacking factor and the stacking direction, which is perpendicular to the plane of laminations. In this way, Maxwell can consider a global anisotropy with two orientations — one in the plane of the lamination, and the other in the corresponding orthogonal direction.

Note	If a stacking factor less than 1 is applied to a magnetic core, the flux density plotted will represent the AVERAGE flux density in both the air and the steel (and not the flux density in the steel laminations). The average flux density is reduced as the stacking factor is reduced.
Note	Lamination modeling is supported for magnetostatic, transient solutions and eddy current, where the stacking value is between 0 and 1. Please use appropriate materials with suitable lamination definitions for the solver. Other solvers will ignore the lamination definition in the material.
Note	When a stacking factor (SF) is used, users need to modify the electrical steel core loss coefficients based on the stacking factor as shown below. As the stacking factor decreases < 1, the core loss coefficients increase. Kh_scaled = Kh / SF Kc_scaled = Kc / SF Ke_scaled = Ke / sqrt(SF)

Stacking Direction

Core Loss Model for a Maxwell Material

Stacking Direction

When defining a lamination model, the stacking direction must be specified. The direction depend upon the Material Coordinate System Type chosen as follows:

	Cartesian Coordinates	Cylindrical Coordinates	Spherical Coordinates
V (1)	X	r	r
V (2)	Y	θ	θ
V (3)	Z	Z	ϕ

Litz Wire Modeling

Note	Litz wire modeling is currently supported for windings only (not for Conductor current sources) in Maxwell 2D/3D Transient, and 2D/3D Eddy Current designs.

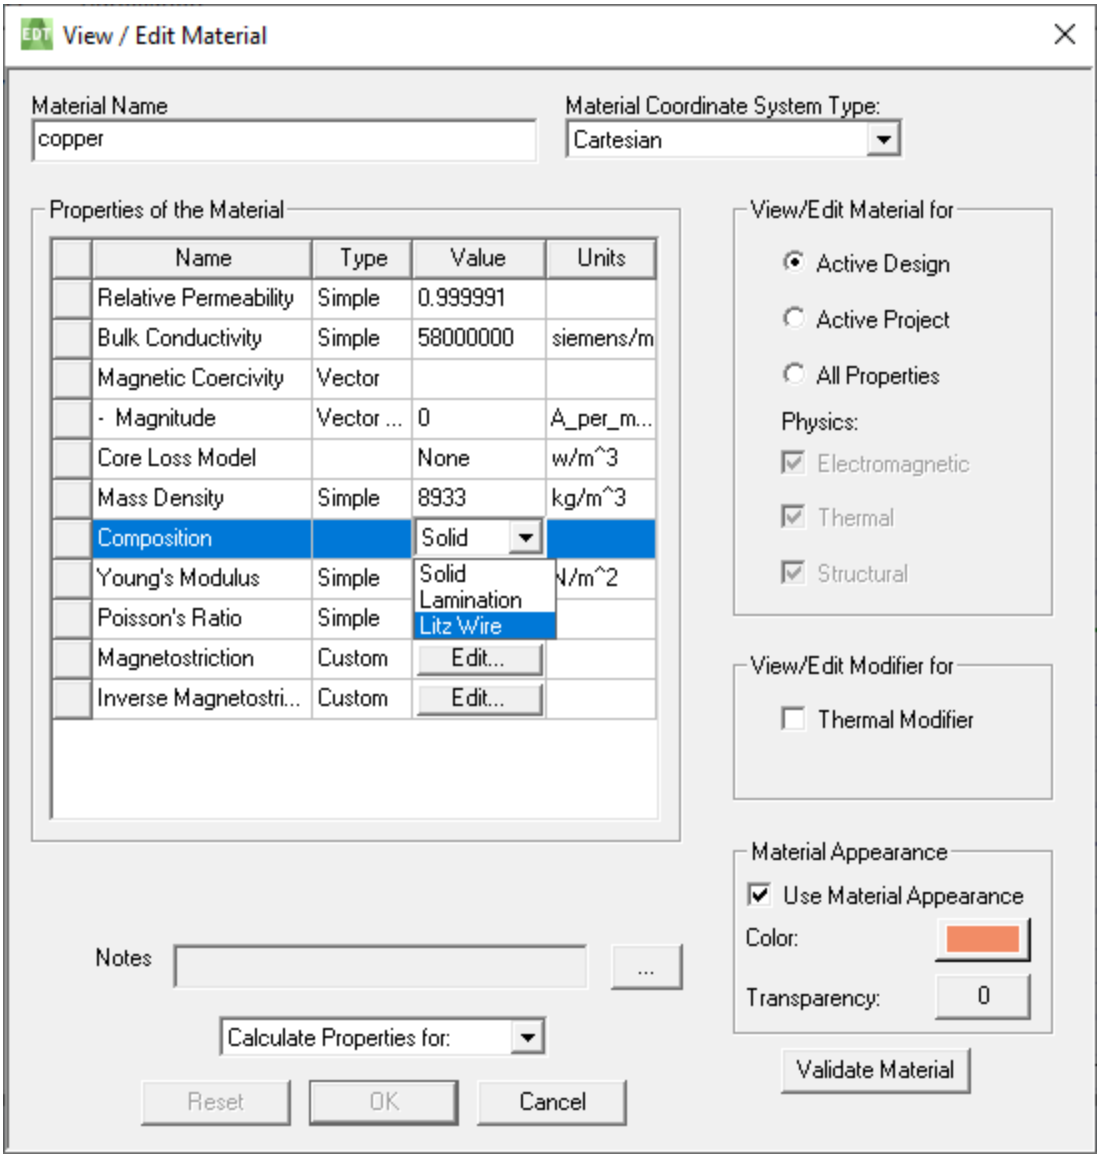
Litz wire is a multi-strand wire or cable whose primary benefit is in reducing AC losses in high frequency windings. It consists of many thin, individually insulated, wire strands, which are twisted or woven together in carefully prescribed patterns. The multiple strand construction of Litz wire allows current to divide uniformly between strands, thus reducing skin effect and proximity effect losses.

Some basic assumptions for applying this modeling approach are:

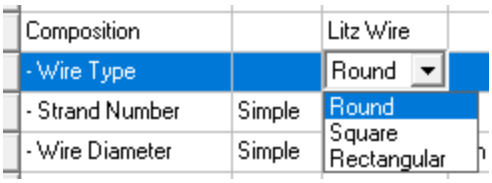
- Each Litz wire strand is insulated individually.
- Each strand is continuously and perfectly transposed so that every strand occupies every location in the cross-sectional area of the bundle over the lay length.
- The largest dimension of strands (e.g., diameter or thickness) is smaller than the skin depth δ for the strand's material.

$$\delta = 1 \Big/ \sqrt{\pi f \mu \sigma}$$

Lizt wire modeling allows you to specify the wire type, number of strands, and various other parameters that define the shape of the Litz wire bundle.



When Litz Wire is selected, **Wire Type** is displayed under **Composition**. There are three options **Round**, **Square**, and **Rectangular**, for pull-down menu Wire Type. These are the three possible shapes for a Litz wire.



Note	If **Litz Wire** is selected and any wire dimension is 0 , the **Composition** material property will be treated as **Solid**, and a warning message to that effect will appear in the Message

	Manager.

If **Round** (the default) is selected, **Strand Number** and **Wire Diameter** are displayed. Default values are as shown below. **Strand Number** is the integer value of the number of strands in the wire bundle. **Wire Diameter** is a real number that defines the diameter of a single wire in the wire bundle. You can also select the desired unit of measure.

Composition		Litz Wire	
- Wire Type		Round	
- Strand Number	Simple	1	
- Wire Diameter	Simple	0	mm

If **Square** is selected for **Wire Type**, **Strand Number** and **Wire Width** are displayed. Default values are as shown below. **Strand Number** is the integer value of the number of strands in the wire bundle. **Wire Width** is a real number that defines the width of a single wire in the wire bundle. You can also select the desired unit of measure.

Composition		Litz Wire	
- Wire Type		Square	
- Strand Number	Simple	1	
- Wire Width	Simple	0	mm

If **Rectangular** is selected for **Wire Type**, the properties **Strand Number**, **Wire Width**, **Wire Thickness**, **Thickness Direction** and **Width Direction** will be displayed. Default values are as shown below. For thickness direction and width direction The drop-down menus include three options: V(1), V(2) and V(3), representing x, y, and z directions, respectively, for the **Cartesian** Material Coordinate System Type; and r, θ, z directions, respectively, for the **Cylindrical** Material Coordinate System Type.

Composition		Litz Wire	
- Wire Type		Rectangular	
- Strand Number	Simple	1	
- Wire Width	Simple	0	mm
- Wire Thickness	Simple	0	mm
- Thickness Direction		V(1)	
- Width Direction		V(2)	

For inner/outer core types, the armature ac or dc windings inside core slots for large capacity machines rotating around z-axis usually have coils with wire thickness in r direction, and width in θ direction or, rarely, have coils with wire thickness in θ direction, and width in r direction.

For axial-flux core types, the armature ac or dc windings inside core slots of large capacity machines rotating in z-axis usually have coils with wire thickness in z direction, and width in θ direction, or rarely have coils with wire thickness in θ direction, and width in z direction.

The total loss from the Litz wire model (including DC loss and AC loss) is applied for thermal coupling. The effect of temperature on Litz wire loss calculation is taken into account in Maxwell by setting a thermal modifier for the bulk conductivity material property.

Core Loss Model for a Maxwell Material

Specify the following parameters and units for core loss model:

Note	All core loss property parameters for **Electrical Steel** and **Power Ferrite** materials can be temperature-dependent, as defined using a thermal modifier.

Name	Value
None	No core loss is to be calculated for this material.
Electrical Steel	The following parameters appear: • **Kh** – Type can be either **Simple** or **Anisotropic** • **Kc** – Type can be either **Simple** or **Anisotropic** • **Ke** – Type can be either **Simple** or **Anisotropic** • **Kdc** (not used for Eddy Current solution type) **Note**: In 2019.R1 and earlier versions, the default value for Kdc is 0.65, that is, if it is set as 0 in the UI, solvers will handle it as 0.65. In 2019.R2 and later versions, solvers will get the value as it is specified. • **Equiv. Cut Depth** (Refer to *Cut Edge Effects on Core Loss for Lamination Steels* for details on the use of this parameter.) For **Kh**, **Kc**, and **Ke**, if the type is anisotropic, The following parameters appear: • T(1,1) • T(2,2) • T(3,3) These characteristics are defined by their anisotropy tensors. Each diagonal represents a tensor of your model along an axis. You can enter a simple value for each of these parameters. These tensors are relative to the coordinate system specified as the object's Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently. **Note**: Selecting **Electrical Steel** also enables the Calculate Properties for Core Loss Coefficient pull-down list at the bottom of the dialog box. Selecting either **Core Loss at One Frequency** or **Core Loss versus Frequency** allows you to edit the **BP Curve**.
Power Ferrite	The following parameters appear: • **Cm** – Type can be either **Simple** or **Anisotropic** • **X** – Type can be either **Simple** or **Anisotropic**

<table>
<tr><td></td><td>

Y – Type can be either Simple or Anisotropic
Kdc (not used for Eddy Current solution type)
<table>
<tr><td>Note</td><td>In 2019.R1 and earlier versions, the default value for Kdc is 0.65, that is, if it is set as 0 in the UI, solvers will handle it as 0.65. In 2019.R2 and later versions, solvers will get the value as it is specified.</td></tr>
</table>

Equiv. Cut Depth (Refer to Cut Edge Effects on Core Loss for Lamination Steels for details on the use of this parameter.)

For Cm, X, and Y, if the type is anisotropic, The following parameters appear:

T(1,1)
T(2,2)
T(3,3)

These characteristics are defined by their anisotropy tensors. Each diagonal represents a tensor of your model along an axis. You can enter a simple value for each of these parameters.
These tensors are relative to the coordinate system specified as the object’s Orientation property. By specifying different orientations, several objects can share the same anisotropic material but be oriented differently.
<table>
<tr><td>Note</td><td>

Selecting Power Ferrite also enables the Calculate Properties for Core Loss Coefficient pull-down list at the bottom of the dialog box. Selecting either Core Loss at One Frequency or Core Loss versus Frequency allows you to edit the BP Curve.
In Transient Solver, X must be less than Y.

</td></tr>
</table>
</td></tr>
<tr><td>B-P Curve</td><td>
The following parameter appears:

Core Loss. Click the B-P Curve button to define temperature-dependent core loss curves. (Refer to Calculating Properties for Temperature-dependent Core Loss Curves in Maxwell for details on the use of this parameter.)

If view/edit parameters for Active Project is selected, the following additional parameters appear:

Kdc Coefficient Considering DC Bias Effects
Equiv. Cut Depth (Refer to Cut Edge Effects on Core Loss for Lamination Steels for details on the use of this parameter.)

</td></tr>
<tr><td>Hysteresis Model</td><td>
The following parameters appear:

Intrinsic Coercivity Hci
Remanence Br
Kc
Equiv. Cut Depth (Refer to Cut Edge Effects on Core Loss for Lamination Steels for details on the use of this parameter.)

</td></tr>
</table>

	Note	Selecting **Hysteresis Model** also enables the Calculate Properties for Hysteresis Loop pull-down list item at the bottom of the dialog box. Selecting **Hysteresis Loop** opens the **Properties for Hysteresis Loop** window.

Some additional considerations:

DC-biased effects

The core loss computation is based on the traditional three core loss coefficients **Kh**, **Kc**, and **Ke**, plus the optional **Kdc**. In order to properly consider the impact of DC-bias on core loss, an additional factor derived from Kdc is applied to scale the hysteresis loss from the Bertotti's formula. The additional factor is expressed as Kph = 1 + Kdc * Bdc^2. If the user leaves the default value of Kdc as zero, this indicates that the impact of DC-bias will not be considered because of the additional factor Kph = 1. If a user wants to consider the DC-bias effect, the user needs to do an experiment to measure core loss at various DC-bias flux densities Bdc, and extract Kdc based on the Kph expression as given above using a linear regression. If the measured data are not available, you can input 0.65 for Kdc.

Note	The use of Kdc when computing DC-biased effects has no effect on the hysteresis model-based core loss computation approach since in such a case, the hysteresis model has inherently consider the impact of DC-biased effects on hysteresis loss.

Hysteresis model-based core loss computation approach

Using this approach, the computation of the hysteresis loss component is based on the input of a hysteresis loop, and the computation of the eddy current loss component based on the classic eddy current loss coefficient Kc. This means that the impact of classic excess loss must be included in the hysteresis loss (sometime called: dynamic hysteresis loss). There are two ways to enable computation of core loss for the hysteresis model-based approach:

- Define the descending limiting branch of the hysteresis loop in the nonlinear BH curve input panel together with the input of **Kc**, which is defined by choosing **Electrical Steel** as the **Core Loss Model** on the **Properties of the Material** panel. Please note that any values entered for **Kh** and **Ke** will be ignored.

Note	This approach requires use of a material that has a vector magnitude direction set to (0,0,0) to enable the hysteresis loss calculation; and must also have its **Core Loss Setting** checked in the **Set Core Loss** dialog to include the eddy current component of core loss.

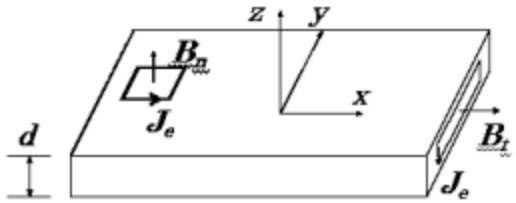
- Define the hysteresis loop by the input of a normal nonlinear BH curve together with the selection of **Hysteresis Model** as the **Core Loss Model** and the input of values for **Intrinsic Coercivity Hci**, **Remanence Br** (optional) and **Kc**.

Note	The second approach is able to more accurately model minor loop loss behavior.

Additional core loss due to flux normal to laminations

When the lamination model is used in the Maxwell 3D transient solver, an additional eddy current component of core loss will be automatically calculated due to the normal component of flux (B_n)

on the lamination stack and will be added to the total core loss, if conductivity > 0 has been specified in the material manager. The basic idea of the algorithm for considering this additional eddy current component of core loss is to force induced eddy current only occurring in the plane of lamination by introducing anisotropic conductivity.



Lamination stacked in Z direction

To compute this additional core loss component:

- The material conductivity which is taken from the project material library (not from the core loss input panel) must be specified as non-zero.
- The object must be defined as a lamination.
- The eddy effect must always be turned off for laminated objects.
- Core Loss Setting should be activated on the Set Core Loss panel, General tab under Excitations.
- A fine mesh in the object is required to accurately calculate the additional eddy current loss due to this effect.
- For adjacent lamination stacks that are touching, insulating boundaries should be applied to prevent eddy currents from circulating between the stacks.

Additional core loss due to manufacturing processes

Lamination steel is cut to the final shape by manufacturing processes such as punching or laser cutting. These processes deteriorate the magnetic properties of the material due to the plastic deformation and residual stress near the cut edge that directly cause core loss increase in the deformation region. These losses can be taken into account for the accurate prediction of the core losses using the **Equiv. Cut Depth** property value.

To compute this additional core loss component:

- The Edge Cut Based mesh operation must be specified;
- The **Composition** property for the assigned material must be set to **Lamination**;
- The **Equiv. Cut Depth** material property must be set to a value greater than zero (default is 1mm).

Cut Edge Effects on Core Loss for Lamination Steels

Lamination steel is cut to the final shape by manufacturing process such as punching and laser cutting, which deteriorates the magnetic properties of the material. This is because the plastic deformation and residual stress near the cut edge cause core loss increase in the deformation region. These losses should be taken into account for the accurate prediction of core losses.

Cut-edge loss model

Assume core loss per unit volume without considering cut-edge effects is p_0.

If the cut-edge deformation depth is d_c, the cut-edge area is S_c, and the core loss increasing factor is k_0, the core loss considering cut-edge effects will be:

$$P_c = (p_0 + k_0 p_0)\, d_c\, S_c$$

Thus, the loss increase due to cut-edge effects is:

$$\Delta P_c = p_0 (k_0 d_c) S_c$$

Since parameters d_c and k_0 cannot normally be derived individually, we introduce an equivalent cut-edge depth:

$$d_{eq} = k_0 d_c$$

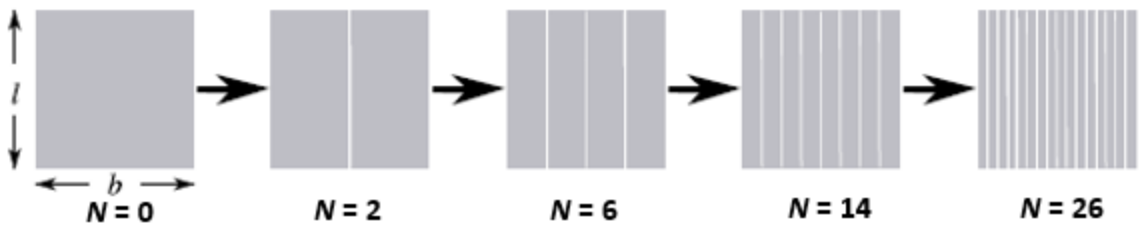
such that d_{eq} can be identified by:

$$d_{eq} = \Delta P_c / (p_0 S_c)$$

Parameter d_{eq} derivation

Based on the measurement of core loss of lamination sheets with variable width to consider the cut-edge effects, manufacturers can use single sheet testing method to measure the impact of cut-edges on core loss. The steps for deriving the parameter d_{eq} are as follows:

- Cut lamination to N edges of different widths as shown below.



- Measure the loss *Pij* with different width (*j*) under different magnetic polarization (*i*).

- Derive the loss *Pij'* using the cut-edge loss model to obtain one equation for every combination of *i* and *j* with parameter d_{eq} to be identified:

$$P_{ij}' = P_{i0} + \Delta P_{ij} = P_{i0}(1 + d_{eq} N_j / b)$$

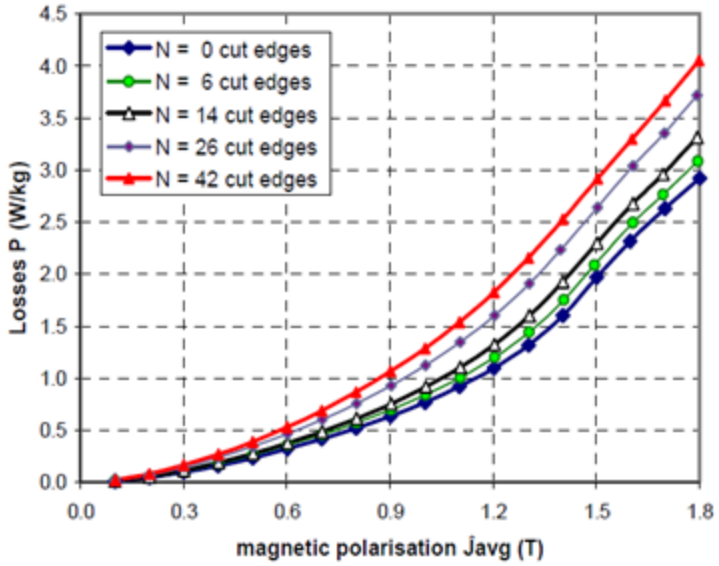
- Find the error ε between derived and measured:

$$\varepsilon = \sum_{i=1}^{n} \sum_{j=1}^{m} (P_{ij}' - P_{ij})^2$$

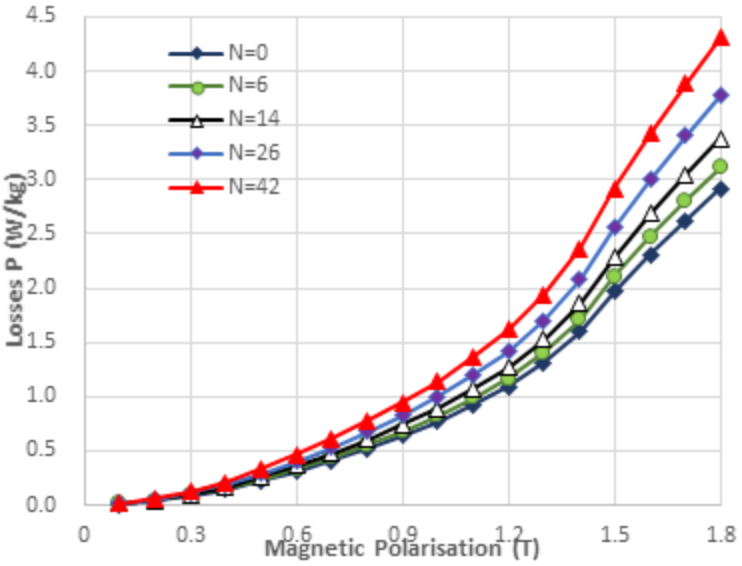
- Derive parameter d_{eq} by minimizing the error:

$$d_{eq} = b \frac{\sum_i \sum_j (P_{ij} - P_{i0}) P_{i0} N_j}{\sum_i \sum_j (P_{i0} N_j)^2}$$

For example, the following shows the *measured* core loss varying with magnetic polarization for several values of the number of cut edges;

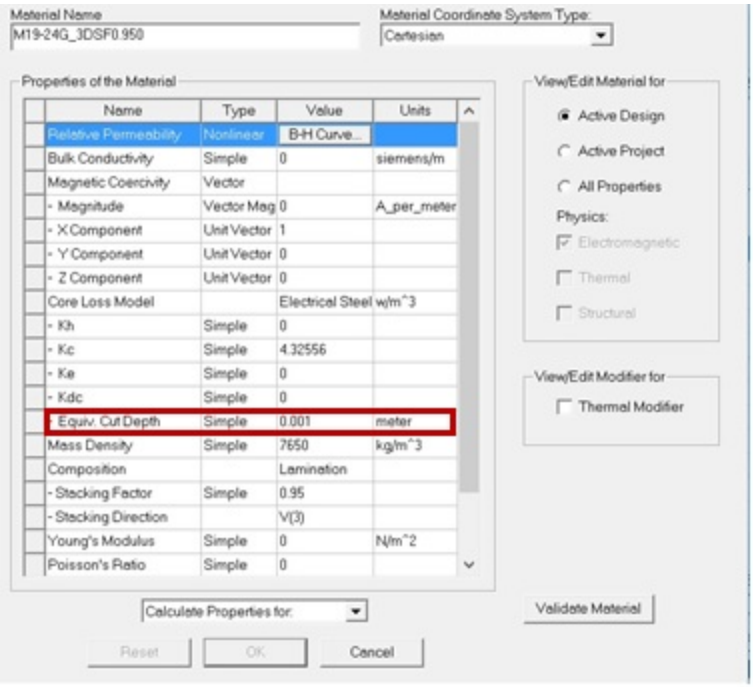


and the following shows the *simulated* core loss varying with magnetic polarization for several values of the number of cut edges



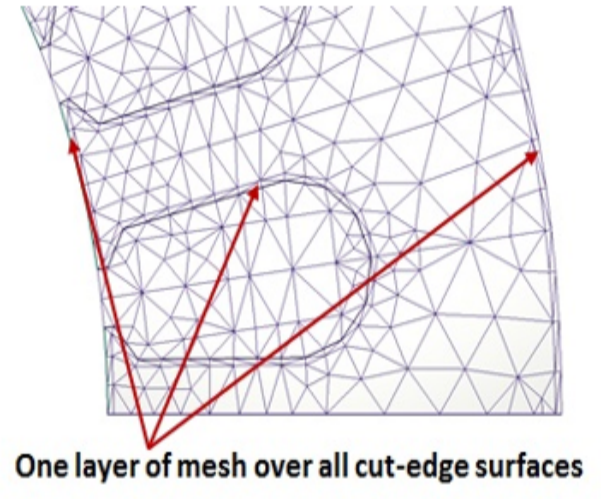
Maxwell Implementation of Cut Edge Effects

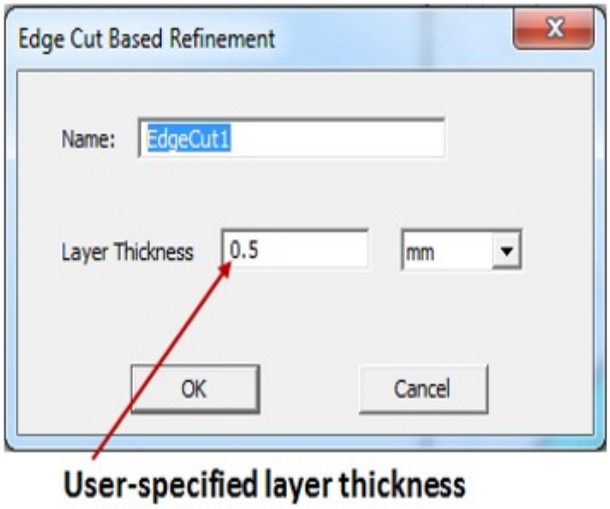
Maxwell uses the parameter d_{eq} described above as an additional input material property, **Equiv. Cut Depth**.



To implement cut edge effects, the Maxwell solver:

1. Constructs one layer of mesh over all cut-edge surfaces with user-specified layer thickness d_{LT}





2. The solver then computes core loss considering cut-edge effects P_c on all elements inside the layer:

$$\begin{aligned} P_c &= P_0 + \Delta P_c \\ &= p_0\, d_{LT}\, S_c + p_0\, d_{eq}\, S_c \\ &= \left(1 + \frac{d_{eq}}{d_{LT}}\right) p_0\, d_{LT}\, S_c \\ &= k_c\, P_0 \end{aligned}$$

Additional Considerations

It is not necessary for the layer thickness d_{LT} to be equal to the equivalent cut-edge depth d_{eq} since the above equation is able to ensure the derived core loss increase matches the measurements.

To take into account the cut-edge effects in core loss computation, the following three conditions must be fulfilled at the same time:

- The Edge Cut Based mesh operation must be specified;
- The **Composition** property for the assigned material must be set to **Lamination**;
- The **Equiv. Cut Depth** material property must be set to a value greater than zero (default is 1 mm).

Core Loss Model for a Maxwell Material

Calculating Properties for Core Loss (BP Curve)

To be able to extract parameters from the loss characteristics (B-P Curve), you first set the **Core Loss Model** of the material to **Electrical Steel** or **Power Ferrite** as a material property in the **View / EditMaterial** dialog box.

Note	• If the Core Loss Model is set to **Hysteresis Loop**, refer to *Calculating Properties Using a Hysteresis Loop in Maxwell*. • If the Core Loss Model is set to **B-P Curve,** refer to *Calculating Properties for Temperature-dependent Core Loss Curves in Maxwell*.

To calculate core loss properties for an electrical steel material:

1. Click **Tools>Edit Configured Libraries>Materials**.
   - Alternatively, in the project tree, you can right-click **Materials**, under **Definitions**, and select **Edit All Libraries**.

   The **Edit Libraries** dialog box appears.
2. Click **Add Material**.
   The **View / Edit Material** dialog box appears.
3. In the **Core Loss Model** row, select **Electrical Steel** or **Power Ferrite** from the **Value** pull-down list.

   Additional parameters appear in the following table **Core Loss Model** (**Kh**, **Kc**, **Ke**, **Kdc**, and **Equiv. Cut Depth** for electrical steel, and **Cm**, **X**, **Y**, **Kdc**, and **Equiv. Cut Depth** for power ferrite). For **Electrical Steel**, the **Core Loss Coefficient** selection in the **Calculate Properties for** pull-down list at the bottom of the dialog box is also enabled. This allows the electrical steel coefficients **Kh**, **Kc**, **Ke**, and **Kdc**, or the power ferrite coefficients **Cm**, **X**, **Y**, and **Kdc** to be derived from a manufacturer-provided core loss curve.

Note	The Kdc core loss quantity is not used for the Eddy Current solution type.

4. If you selected **Electrical Steel**, do the following:
   a. Select **Core Loss Coefficient** from the **Calculate Properties for** pull-down list at the bottom of the dialog box.
      The **BP Curve** dialog box appears.
   b. Do one of the following to specify a BP curve:
      - Import the curve from a saved file.
      - Enter the coordinates manually.

Note	The accuracy in inputting the data for B-P Curve for the electrical steel material has significant effect on the correctness of the analyses to the electromagnetic devices. You should input the data for B-P Curve according to accurate data provided by material manufacturers. Typically core material suppliers provide the average loss over a cycle for a peak B, of sinusoidal nature. Therefore for BP curve input in Maxwell, B(Tesla) should be peak and P should be average.

c. Select the units in which the B-P curve is measured from the **Core Loss Unit** pull-down list.

d. Type values and select units for the following:

- **Mass Density**
- **Frequency**
- **Thickness**
- **Conductivity**

As the input data changes, the following parameters are dynamically updated with both the specified unit and the standard unit (w/m^3):

- **Kh** - Hysteresis Coefficient
- **Kc** - Classical Eddy Coefficient
- **Ke** - Excess Coefficient
- **Kdc** - Coefficient Considering DC Bias Effects (not used for Eddy Current solution type)

e. Click **OK**.
The **View / Edit Material** dialog box reappears. The property values for **Kh**, **Kc**, **Ke**, and **Kdc** are updated as new default values.

5. If you selected **Power Ferrite**, do the following:
   a. Select a type for **Cm**, **X**, **Y**, and **Kdc** from the **Type** column.
   b. Type values for the coefficients **Cm**, **X**, **Y**, and **Kdc** in the **Value** column.
6. Click **OK** to close the **View / Edit Material** dialog box.
7. Click **OK** to close the **Edit Libraries** dialog box.

Core Loss Coefficients for Electrical Steel

Under sinusoidal flux conditions, core loss is computed in the frequency domain as follows:

$$P_v = P_h + P_c + P_e = K_h f(B_m)^2 + K_c(fB_m)^2 + K_e(fB_m)^{1.5}$$

For a material with anisotropic core losses, the coefficients Kh, Kc, and Ke have different values in different principal directions, that is, (Kh_x, Kh_y, Kh_z), (Kc_x, Kc_y, Kc_z), and (Ke_x, Ke_y, Ke_z) in (x, y, z) directions, respectively.

When a DC component exists in the flux density, the core loss is modified to the following:

$$P_v = C_{dc} K_h f(B_m)^2 + K_c(fB_m)^2 + K_e(fB_m)^{1.5}$$

where

- **B_m** is the amplitude of the AC flux component,
- **f** is the frequency,
- **K_h** is the hysteresis core loss coefficient,
- **K_c** is the eddy-current core loss coefficient, and
- **K_e** is the excess core loss coefficient.

C_{dc} is computed from the following equation:

$$C_{dc} = 1 + K_{dc} B_{dc}^2$$

where

- **B_{dc}** is the DC flux component, and
- **K_{dc}** is the coefficient considering the DC flux bias effects. The default value of K_{dc} is 0.65, that is, when the input value is 0, K_{dc} will be automatically set to 0.65.

Related Topics

Core Loss Coefficient Extraction

Core Loss Coefficient Extraction

The principles of the computation algorithm for **Kh**, **Kc**, and **Ke** are summarized as below.

Note	Since the manufacturer-provided loss curve is obtained under sinusoidal flux conditions at a given frequency, these coefficients can be derived in the frequency domain.

The iron-core loss without DC flux bias is expressed as the following:

$$P_v = P_h + P_c + P_e = K_h f(B_m)^2 + K_c(fB_m)^2 + K_e(fB_m)^{1.5} = K_1 B_m^2 + K_2 B_m^{1.5}$$

where

$$K_1 = K_h f + K_c f^2$$

$$K_2 = K_2 f^{1.5}$$

The classical eddy-current loss coefficient is calculated directly as

$$K_c = \pi^2 \cdot \sigma \cdot \frac{d^2}{6}$$

where σ is the conductivity and *d* is the thickness of one lamination sheets.
Minimize the quadratic form to obtain K_1 and K_2.

$$f(K_1, K_2) = \Sigma \left[P_{vi} - \left(K_1 B_{mi}^{\ 2} + K_2 B_{mi}^{\ 1.5} \right) \right]^2 = min$$

where P_{vi},B_{mi} – the i-th point of the data on the measured loss characteristics curve.
The other two loss coefficients are obtained as

$$K_h = \left(K_1 - K_c f_0^{\ 2} \right) / f_0$$

$$K_e = K_2 / f_0^{\ 1.5}$$

where f_0 is the testing frequency for **Loss Curve**.

Core Loss Coefficients for Electrical Steel

Importing a BP Curve From a File

For the loss characteristics (B-P Curve), you first set the **Core Loss Model** of the material to **Electrical Steel** or **Power Ferrite** as a material property in the View/Edit Material window. When you do so, this enables the Calculate Properties selection for drop down at the bottom of the window. Select either **Core Loss at One Frequency** or **Core Loss versus Frequency** from the drop down menu to open the B-P Curve window.

For **Core Loss at One Frequency**:

1. In the BP Curve dialog box, click **Import Dataset** to open **Import Dataset**dialog box.
2. Find and select the tab separated points file containing the BP curve data points.
3. Click **Open**.
4. Optionally, click **Swap X-Y Data** to switch the B values and P values if they are in the wrong columns.

For **Core Loss versus Frequency**:

1. In the Core Loss versus Frequency dialog box, if needed, enter the desired **Frequency** and click **Add**.
2. Click **Edit Dataset** for the desired frequency to open the **Edit Dataset** dialog box.
3. Click **Import Dataset** to open **Import Dataset**dialog box.
4. Find and select the tab separated points file containing the BP curve data points.
5. Click **Open**.
6. Optionally, click **Swap X-Y Data** to switch the B values and P values if they are in the wrong columns.

Manually Specifying BP Curve Coordinates

For the loss characteristics (B-P Curve), you first set the **Core Loss Model** of the material to **Electrical Steel** or **Power Ferrite** as a material property in the **View/Edit Material** window. When you do so, this enables the Calculate Properties selection for drop down at the bottom of the window. Select either **Core Loss at One Frequency** or **Core Loss versus Frequency** from the drop down menu to open the B-P Curve window.

Select **Core Loss Coefficient** from the **Calculate Properties for** pull-down list to open the **BP Curve** dialog box.

Do the following in the **BP Curve** dialog box:

- Enter **B** and **P** values in each row of the **Coordinates** table.

Note	The value of B must increase along the curve. Placing the cursor in the field in the **Coordinates** table enables the **Add Row** and **Delete Row** buttons.

  As you enter values, the graph is updated.

To add or edit rows, click the following buttons:

- **Add Row Above**
- **Add Row Below**

- **Append Rows** (In the dialog box that appears, specify the number of rows to append to the table, and click **OK**.)
- **Delete Rows**

Calculating Properties for Temperature-dependent Core Loss Curves in Maxwell

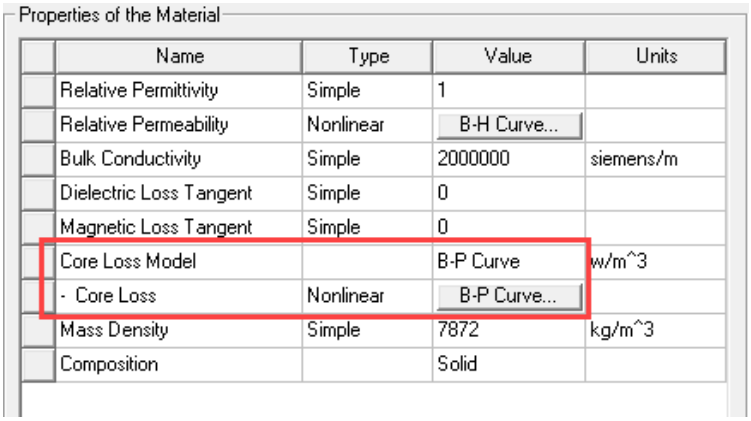
To be able to extract parameters from the temperature-dependent core loss characteristic curves, you first set the **Core Loss Model** of the material to **B-P Curve** as a material property in the **View / EditMaterial** dialog box.

Note	When a material has temperature-dependent core loss curves defined, neither the Thermal Modifier nor the Spatial Modifier are applicable to the material.

To calculate temperature-dependent core loss properties for a material:

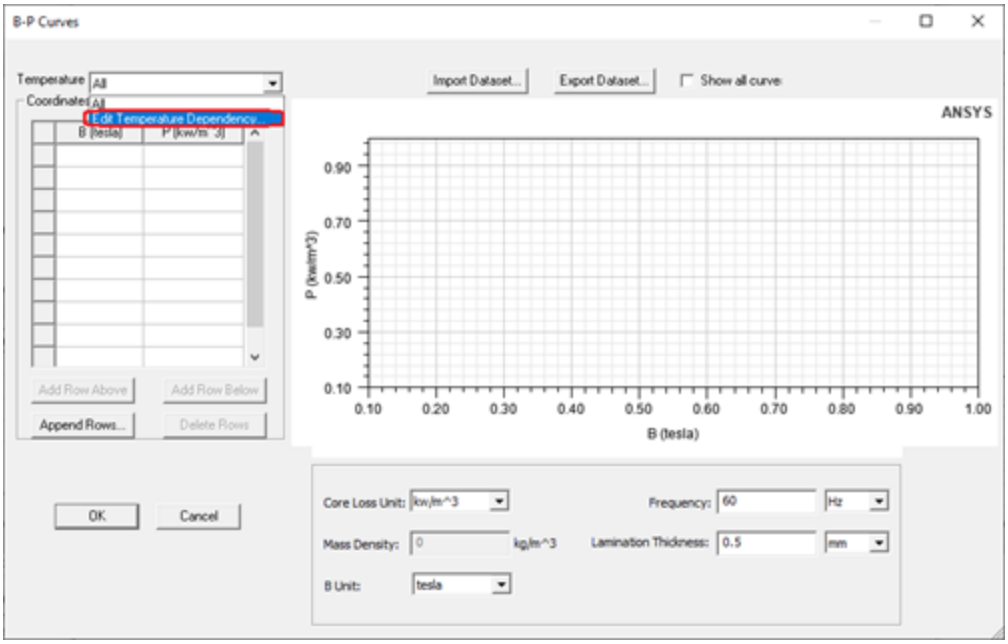
1. Click **Tools>Edit Configured Libraries>Materials**.
   - Alternatively, in the project tree, you can right-click **Materials**, under **Definitions**, and select **Edit All Libraries**.

   The **Edit Libraries** dialog box appears.
2. Click **Add Material**.
   The **View / Edit Material** dialog box appears.
3. In the **Core Loss Model** row, select **B-P Curve** from the **Value** pull-down list.



For **Core Loss**, click the **B-P Curve** button.

The **B-P Curve** dialog box appears.



4. From the **Temperature** pull-down list you can do either of the following:
   a. Select **All** to specify a single core loss curve.
   b. To create (or edit) multiple core loss curves, select **Edit Temperature Dependenc**.

   - Click **Add** to add temperatures; then select the desired units. You can also select rows and **Delete** them, or **Delete All**.
   - Check **Temperature dependent** to enable use of the temperature-dependent B-P curves by the solver.
   - Click **OK** to close the dialog box and return to the **B-P Curves** dialog box.
5. Do one of the following to specify a BP curve:

a. Click **Import Dataset** to open the **Import Dataset** dialog box. Find and select the tab separated file containing the B-P curve data points. (Data points must start at the origin.)
b. Enter the coordinates manually. (Data points must start at the origin.)

6. Select the units in which the B-P curve is measured from the **Core Loss Unit** and **B Unit** pull-down lists.
7. Type values and select units for the following parameters:
   - **Mass Density**
   - **Frequency**
   - **Lamination Thickness**
8. Click **OK**.
   The **View / Edit Material** dialog box reappears.
9. Click **OK** to close the **View / Edit Material** dialog box.
10. Click **OK** to close the **Edit Libraries** dialog box.

Core Loss Model for a Maxwell Material

Extracting Equivalent Cut Depth Based on Multiple Curves

The manufacturing effects on core loss computation can be considered in Maxwell transient simulation. To consider the manufacturing effects, you need to input a parameter called **Equivalent Cut Depth**. The default value for this parameter is 1mm, which is close to the average results extracted from some measurements.

A tool is featured to extract this parameter. If you have multiple core loss curves varying with flux density under different number of cut edges (two cut edges are produced by each cut) measured by the single sheet tester method, you can use this tool to extract the parameter.

To be able to use this feature, you must first set the **Core Loss Model** of the material.

To extract the equivalent cut depth:

1. Click **Tools>Edit Configured Libraries>Materials**. The **Edit Libraries** dialog box appears.
   - Alternatively, in the project tree, you can right-click **Materials**, under **Definitions**, and select **Edit Libraries**. The **Edit Libraries** dialog box appears.
   - Or select an object, and click **Modeler>Assign Materials**. The **Select Definition** dialog box appears.
2. Click **View / Edit Material**.
   The **View / Edit Material** dialog box appears.
3. Select **Electrical Steel**, or **Power Ferrite**, or **Hysteresis Model**, from the **Core Loss Model** drop-down menu. The **Equiv. Cut Depth** property is available under **Core Loss Model**, and the **Extract Equiv. Cut Depth** is added in the **Calculate Properties for** drop-down menu.

4. Select **Extract Equiv. Cut Depth** from the **Calculate Properties for** drop-down menu. The **Extract Equiv. Cut Depth** dialog box appears. Click **Add** to add a new row for a loss curve input. Enter a value for number of cut-edges in the **Number** column, and enter the loss curve data in the **Edit Dataset** column.
5. Click the **Edit Dataset…** button. The **Edit Dataset** dialog box appears. Enter values for loss curve **P** and the sinusoidal flux density **B**. Click **OK** to return to the **Extract Equiv. Cut Depth** dialog box .
6. Select the type of curve you want to plot. You can plot for **Selected Number** or **All Numbers**, and plot the **Original Curve** or the **Regression Curve**. To identify the equivalent cut depth, you need to input various measured loss curves with different number of cut edges.
7. Select the **Core Loss Unit**.
8. Type a value for **Mass Density**. This field can only be edited when **Core Loss Unit** is w/lb or w/kg.
9. Enter a value for the **Band Width**. As the input data changes, the parameters are dynamically updated with both the specified unit and the standard unit (w/kg).
10. Click **OK**.

The **View/ Edit Material** dialog box reappears. The extracted values are updated as new default values.

11. Click **OK** to close the **View / Edit Material** dialog box.
12. Click **OK** to close the **Select Definition** or **Edit Libraries** dialog box.

Core Loss Coefficient Extraction

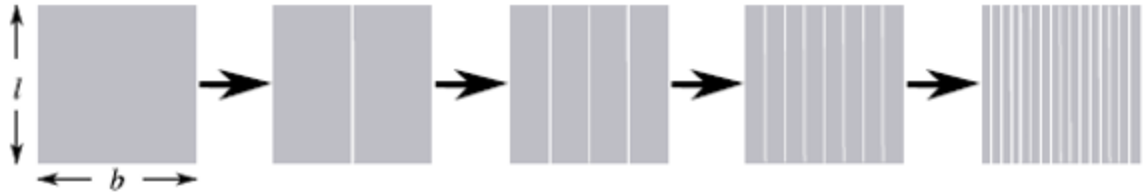
Setting Core Loss for Transient and Eddy Current Solvers

Calculating Properties Using a Hysteresis Loop in Maxwell

Principle of Parameter Identification based on Single Sheet Tester

The device for single sheet tester is shown below:

The single-sheet specimen to be measured with different numbers of cut edges is shown below:



At each cut-edge number N_j, we can measure a loss curve P_{ij} varying with the amplitudes of sinusoidal flux density B_i. Then equivalent cut depth is identified by minimizing the total error between the predicted and measured losses.

$$\varepsilon = \sum_{i=1}^{n}\sum_{j=1}^{m}(P_{ij}'-P_{ij})^2$$

where:

- P_{ij}' and P_{ij} are predicted and measured losses for all points, respectively,
- m is the number of measured loss curves,
- n is the number of points for each loss curve.

In a single sheet tester, the predicted losses can be derived from:

$$P_{ij}' = P_{i0} + \Delta P_{ij} = P_{i0} \cdot (1 + w_e N_j / b)$$

where:

- P_{i0} are the intact losses, the loss curve without cut-edge effects,
- ΔP_{ij} are the increased losses due to the cut-edge effects,
- w_e is Equiv. Cut Depth to be identified, and
- b is the original band width of the single sheet.

In general, the intact losses P_{i0} are unknown, and can be determined by:

$$\frac{\partial \varepsilon}{\partial P_{i0}} = \frac{\partial}{\partial P_{i0}} \left(\sum_{i=1}^{n} \sum_{j=1}^{m} [P_{i0}(1 + w_e N_j / b) - P_{ij}]^2 \right) = 0$$

based on which we derive:

$$P_{i0} = \frac{\sum_{j=1}^{m} P_{ij}(1 + w_e N_j / b)}{\sum_{j=1}^{m} (1 + w_e N_j / b)^2}$$

Similarly, based on:

$$\frac{\partial \varepsilon}{\partial w_e} = 0$$

we get:

$$w_e = b \frac{\sum_{i=1}^{n} \sum_{j=1}^{m} (P_{ij} - P_{i0}) P_{i0} N_j}{\sum_{i=1}^{n} \sum_{j=1}^{m} (P_{i0} N_j)^2}$$

In above equations, intact losses P_{i0} depend on parameter w_e, which in turn depends on the intact losses. An iteration process is required to get the solution. Therefore, to identify the equivalent cut depth, and show the regression curves, we need to input various measured loss curves P_{ij} at different number of cut edges N_j, as well as the band width of the single sheet b.

Assigning Materials from the Object Properties Window

The Properties dialog for each object includes a materials property. If you click on the current material property you see a drop-down list that includes an Edit command and a list of materials in the current project. You can select from the list of current materials to assign the selected material to that object.

Assigning Materials
Auto-Complete for Variables and Properties in Electronics Desktop

Viewing and Modifying Material Attributes

1. In the **Select Definition** dialog box or the **Edit Libraries** dialog box, select the material you want to view or modify.

Note	Maxwell's global material library cannot be modified. Materials from the library can be modified, but not saved back to the system library. They can be saved to a User Library or Personal Library.

2. Click **View/Edit Materials**.

   The **View/Edit Material** dialog box appears. The material name and its property values are listed.

Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

3. Under **View/Edit Material for**, select:
   - **Active Design** to display properties used in the active design.
   - **Active Project** to display properties used by this project.
   - **All Properties** to display all properties available. This enlarges the table of properties to show all properties possible. You can use the scroll bars or size the dialog to see all properties.

     Selecting **All Properties** also enables the three **Physics** check boxes: **Electromagnetic**, **Thermal**, and **Structural**. These check boxes are used to filter the properties displayed in the table by physics type. Clearing a check box hides properties of that physics type.
4. You can modify the material as follows:
   a. Provide a new name for the material in the **Material Name** text box.
   b. Under **Type**, specify whether a material property is **Simple,Anisotropic**, **Vector** and **Vector Mag**, or for Relative Permeability, **Nonlinear**, as required for that property.

      For **Simple**, you provide a value or variable.

      For **Anisotropic**, you provide tensor values.

      For **Vector**, you provide a **Vector Mag**, or **Unit Vector** X, Y, and Z Component values.

      For **Non-Linear**, you provide a Data Set.
   c. Provide new material property values in the **Value** boxes.
   d. Change the units for a material property.
5. For **Material Appearance**, you can check the **Use Material Appearance** box to enable the fields for you to specify a color and transparency for the material.
   - Clicking the **Color** bar opens a standard color selection window.
   - Clicking the **Transparency** box opens a **Transparency** dialog with a text field and slider bar for selection.
6. If you want to add descriptive notes for the new material, click the ellipsis button [**...**] by the **Notes** field. This opens a dialog in which you can enter text. To enter multiple lines of notes,

use **CTRL-Enter** to start a new line. (**Enter** by itself will save the Notes field and close the dialog.)

7. Click **OK** to save the changes and return to the **Select Definition** or **Edit Libraries** dialog box.

Warning	If you modify a material that is assigned in the active project after generating a solution, the solution becomes invalid.

Setting the Material Threshold

The material thresholds tell the **Maxwell 2D** and **Maxwell 3D** solvers how to deal with conductors and insulators. Materials with conductivities above the **Perfect Conductor** threshold are treated as having infinite conductivity and surface current only. Materials with conductivity values below the **Insulator/Conductor** threshold are treated as insulators with no conductivity and no current carrying capability. Materials that fall between the two thresholds are treated as normal conductors that can carry current throughout the volume of the material.

1. Click **Maxwell>Design Settings.** The **Design Settings** dialog box appears. The material thresholds are set in the **Material Thresholds** tab.
2. Type a value in the **Perfect Conductor** text box.
3. Type a value in the **Insulator/Conductor** text box.
4. Click **OK**.

Validating Materials

Maxwell and RMxprt can validate a material's property parameters for an Ansys Electromagnetics software product. For example, it checks if the range of values specified for each material property is reasonable.

If a material's property parameters are invalid, an error message will appear in the lower-right corner of the **View/Edit Material** window. If the parameters are valid, a green check mark will appear there.

To validate the material attributes listed in the **View/Edit Material** window:

- Select a name from the **Properties of the Material** list, and then click **Validate Material**.

Copying Materials

1. In the **Select Definition** dialog box or the **Edit Libraries** dialog box, select the material you want to copy.
2. Click **Clone Material(s)**.

   The **View/Edit Material** dialog box appears.
3. To modify the material's attributes, follow the directions for modifying materials.
4. Click **OK** to save the copy in the active project's material library.

Removing Materials

1. In the **Select Definition** dialog box or the **Edit Libraries** dialog box, select a material you want to remove from the active project's material library.
2. Click **Remove Material(s)**.
   A message appears asking if you want to continue.
3. Click **Yes**.
   The material is deleted from the project material library.

Note	The following materials cannot be deleted: • Materials stored in Ansys Electromagnetics global material library. • Materials that have been assigned to objects in the active project.

In a project library, you may want to use the **Project>Remove Unused Definitions** command to remove selected materials definitions that your project does not require.

Exporting Materials to a Library

1. In the **Select Definition** dialog box or the **Edit Libraries** dialog box, select the material you want to export.
2. Click **Export to Library**.

   The **Save As** file browser appears.
3. Do one of the following to specify the location:
   - Click **PersonalLib** to export the material to a local project directory, accessible only to the user that created it.
   - Click **UserLib** to export the material to a library that is shared by more than one user, usually in a central location.
4. Type the library's file name.
5. Click **Save**.

Sorting Materials

You can change the order of the materials listed in the **Select Definition** dialog box or the **Edit Libraries** dialog box. You can sort the list of materials by name, library location, or material property value.

To change the order of the listed materials:

- Click the column heading by which you want to order the materials.

If the arrow in the column heading points up, the material data are listed in ascending order (1 to 9, A to Z) based on the values in the column you chose. If you want the material data to be listed in descending order (9 to 1, Z to A), click the column heading again. The arrow then points down.

Note	By default, not all of the available properties are displayed in the materials table. Only the properties commonly used by the product are displayed. To view the complete table of properties, see Filtering Materials.

The **Material Filters** tab of the **Edit Libraries** dialog box allows you to specify the default for whether to filter for **This Product** or **All Products**.

Filtering Materials

If you want to remove certain materials or material properties from the list in the **Select Definition** window, use the filter options under the **Material Filters** tab.

You can filter out materials based on the product or library with which they are associated. You can also filter out material properties and types of material properties. And you can remove the filtering in order to see all available material properties.

To filter materials or material properties listed in the **Select Definition** window, using the choices in the **Materials** tab:

1. The field under **Libraries** lists the libraries for the project. Selecting the listed library highlights it and cause the table to display the materials in that library.
2. Above the Libraries area, you can check or uncheck boxes to show or hide Project definitions and all libraries.
   - With both unchecked, nothing appears in the materials table. With both checked, the table shows all materials and highlights those used in the project.
   - With only Project Definitions checked, the materials table shows only the materials used in the project.
   - With All Libraries checked, the table displays all materials, but may not show all available properties.

To filter out or show additional material properties in the **Materials** tab:

1. Click the **Material Filters** tab.
2. Under **Show Materials and Properties for**, select one of the radio buttons:
   - **Active Design** to display properties used in the active design.
   - **Active Project** to display properties used by the current project.

- **All Materials and Properties** to display all available materials and properties. Selecting this enlarges the table of properties shown under the **Materials** tab to show all properties possible. You can use the scroll bars or size the dialog to see all properties.

3. Under **Show Material Types**, click **Select All** to select all of the products listed. Click **Clear** to clear all product selections.
4. Click the **Materials** tab to save your selections.

   Click **Cancel** to revert back to the last saved selections.

Working with Materials Libraries

Working with Material Libraries

There are two different kinds of materials libraries in Maxwell, a system library and a user library.

Related Topics

Editing Libraries

Working with the System Material Library

The library files that ship with Maxwell are stored under the **syslib** directory. These libraries are intended to be read-only and should not be modified. They are available for any material assignment in any project.

Working with User Material Libraries

In addition to the system libraries, Maxwell recognizes two user-configurable library structures: the User Library and the Personal Library. These are used to add user (or company) defined materials. Typically, **userlib** is a network repository for proprietary or corporate definitions available to all seats in an enterprise. **personalLib** contains project and design-specific libraries as needed by individual designs.

A root library directory is set up at installation. If none is specified, the default is the root Maxwell directory.

Materials from libraries in both the User Library and Personal Library, as well as the System Library, are available for use in projects.

Managing Library Files

You can use **Manage Files** to change the names of libraries in the UserLib and PersonalLib directories; move libraries to another location in the directories specified for UserLib or PersonalLib, or delete libraries. In addition, you can change the names of sub-directories of the UserLib and PersonalLib directories, move directories to another location in the directories specified for UserLib or PersonalLib, or delete directories.

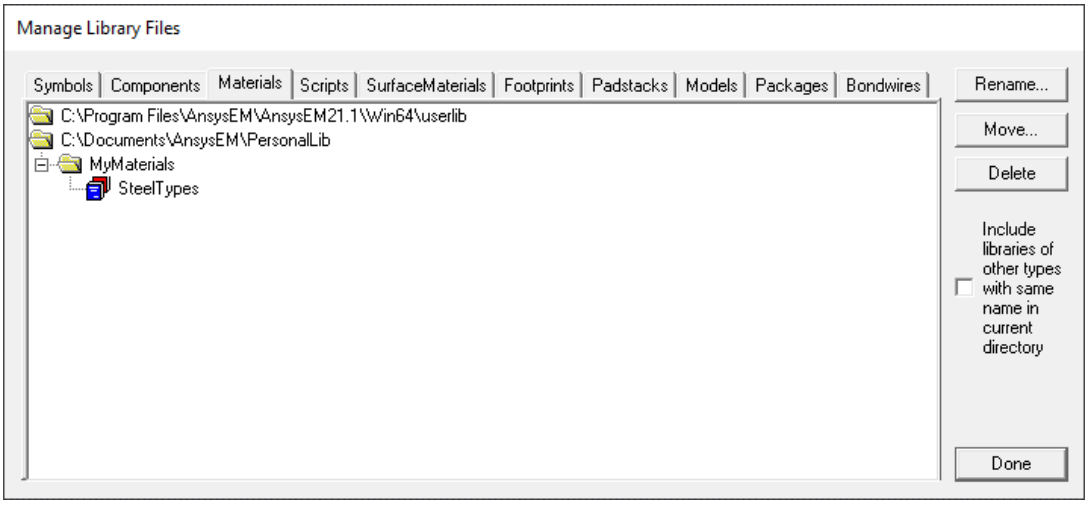
> **Note:**
>
> - You cannot move libraries out of the UserLib or PersonalLib hierarchies.
> - To move a library or directory to a subfolder, that subfolder must already exist.

Materials, components, and other definitions in libraries directly affected by an action which refer to definitions changing library name or location will have those references adjusted. Definitions in libraries indirectly affected – that is, those not having their names or locations modified by an action – with references to definitions in directly affected libraries, are updated.

To manage library files:

1. Click **Tools >Library Tools >Manage Files**.

   The **Manage Library Files** dialog opens on the Components tab. There is a tab for each library type: Symbols, Components, Materials, Scripts, Surface Materials, Footprints, Padstacks, Models, Packages, and Bondwires.



2. Click the tab you want.
3. Select an individual library or a directory on which you want to perform the action.
4. Click one of the following buttons:
    - Rename
    - Move
    - Delete
5. Select the **Include libraries of other types with same name in current directory** check box to cause the action to be performed on other types with the same name in the same directory. For example, if you select “MyProbes” on the Components tab, the action is extended to a symbol library called “MyProbes.aslb” in the same directory.
6. Click **Done** when finished managing libraries.

Related Topics

General Options:Directories

Editing Libraries

There are two different methods of editing libraries.

- Using right-click on Materials in the project window and selecting the **Edit Library** shortcut to display the **Edit Libraries** window.

  Editing definitions from the project window does not modify the configured libraries for any particular design, since this is editing in general.
- Using **Tools>Edit Libraries>Materials** from the menu bar takes the current design into account and adds any new libraries to the configured list for the design.

Adding New Materials

Editing Material Definitions

When editing material definitions or adding a material to the user/personal library, use the menu command (**Tools>Edit Libraries>Materials**) rather than the project tree. Editing or defining definitions by right-clicking in the project tree window does not modify the configured libraries for any particular design – it only edits the material in general. When you use the menu command, the current design is considered, and any new materials are made available to assign in that current design. New or modified materials can also be exported to a library in the User Library or Personal Library from the **Edit Libraries** dialog.

To edit a material's definition:

1. Click **Tools>Edit Libraries>Materials**.

   The **Edit Libraries** dialog appears.
2. In the **Search Parameters** section under **Libraries**, select the library database. By default the **[sys] Materials** system library is selected.
3. Select the material you want to edit, and click **View/Edit Materials**.

   The **View/Edit Material** dialog appears.
4. Make the desired changes to the **Material Name**, the **Material Coordinate System Type**, and the properties listed in the **Properties of the Material** section.
5. From the **View/Edit Material for** section, select whether the changes shall apply to the (**Active Design**, **Active Project**, or **All Properties**).
6. You may optionally set a *Thermal Modifier* to specify that certain material properties have characteristics that vary with temperature.
7. Click **Validate Material** to make sure your changes are valid.

   If the material properties are valid, a green check mark appears below the **Validate Material** button.
8. Optionally, use the **Calculate Properties for...** drop down list to calculate properties for a permanent magnet or a Non-Linear Permanent Magnet.
9. Optionally, to calculate properties for core loss, select **Core Loss Coefficient** from the **Calculate Properties for...** drop down list.
10. When you are done making changes to the material properties, click **OK**.
    The **Edit Libraries** dialog reappears.
11. If you are finished in the **View/Edit Material** dialog box, click **OK** to close it.

Setting a Thermal Modifier

Materials used in 3D Designs, and for sheet objects in 2D Designs, may have a Thermal Modifier assigned to change specific material properties with temperature, primarily for use when coupling to thermal analysis.

To specify Thermal modifiers for a material:

1. In the View/ Edit materials dialog you must enable the View/ Edit Modifier check box for Thermal Modifier.

   This causes the Properties of the Material table to expand to include a Thermal Modifier column. By default, the Thermal Modifier property is set to **None**.
2. Selecting **Edit...** from the drop down menu, rather than **None** causes the **Edit Thermal Modifier** dialog to appear.
3. Select the **Expression** radio button to display the **Parameters Modifier** text field or the **Quadratic** radio button to display the tabs for **Basic Coefficient Set** and **Advanced Coefficient Set**.
   - With **Expression** selected, you can write an equation for a thermal modifier in the Parameters **Modifier** text field.

     Checking **Use temperature dependent data set** disables the Modifier text field. You can then use the drop down menu to select Add/Import Dataset. This lets you define the thermal modifier as a data set.
   - With the **Quadratic** radio button selected, in the **Basic Coefficient Set** tab, you can edit fields for the TempRef and units, and fields for C1 and C2 for the following equation:

     $$P(Temp) = Pref[1+ C1(Temp - TempRef) + C2(Temp - TempRef)^2]$$

     where the Pref is defined as the reference relative permittivity.
   - With the **Quadratic** radio button selected, in the **Advanced Coefficient Set** tab, you can edit fields for lower and upper temperature limits (TL and TU respectively) and select their units from the drop down.

     You can also edit the constant value limit for the thermal modifier values outside the limits. By default, these are automatically calculated. Uncheck **Auto Calculate TML, TMU** to specify new values for thermal modifier lower (TML) and thermal modifier upper (TMU) limits.
4. Click **OK** to accept the edits and return to the View/ Edit materials dialog.

Note	Thermal modifier for permeability is disabled when temperature-dependent BH curves are specified.

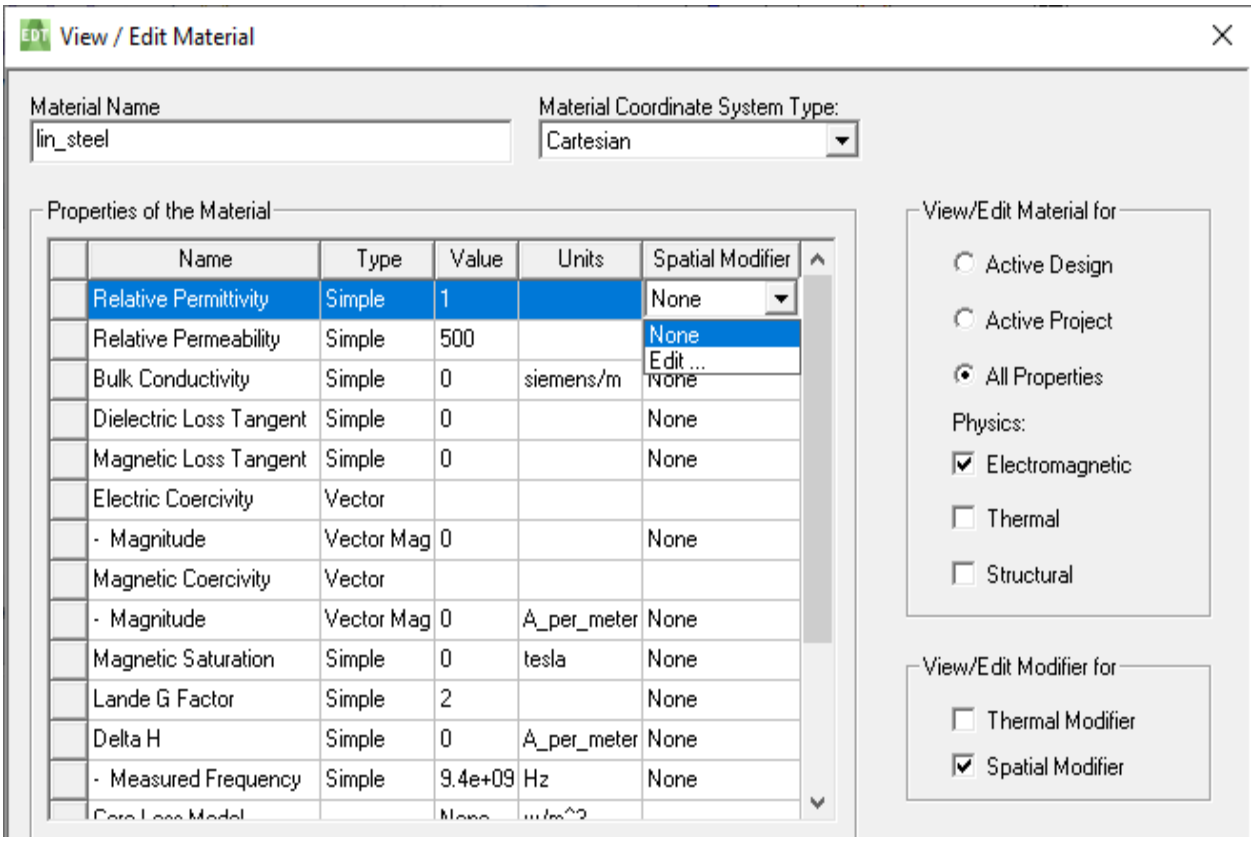
Setting the Temperature of Objects

Setting a Spatial Modifier

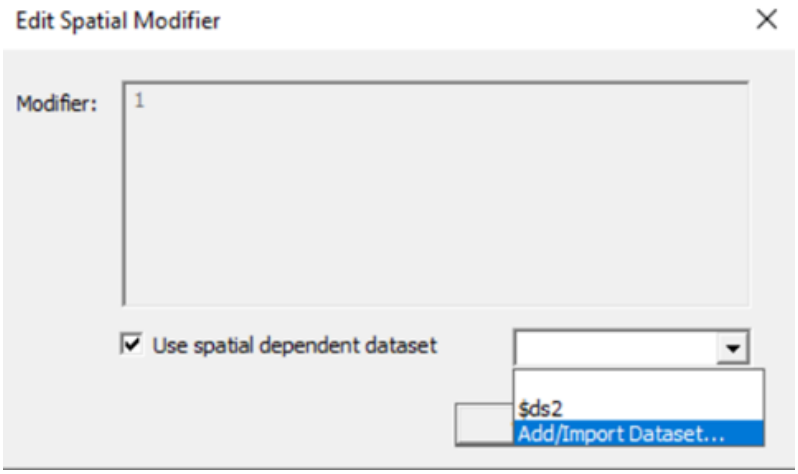
Maxwell magnetic transient solvers support use of a 3D Dataset as a Spatial Modifier to modify spatially varying properties of conductivity, permeability, and permittivity. In general, Thermal Modifier and Spatial modifier cannot be applied to one material property simultaneously.

To specify 3D dataset as Spatial modifiers for a material:

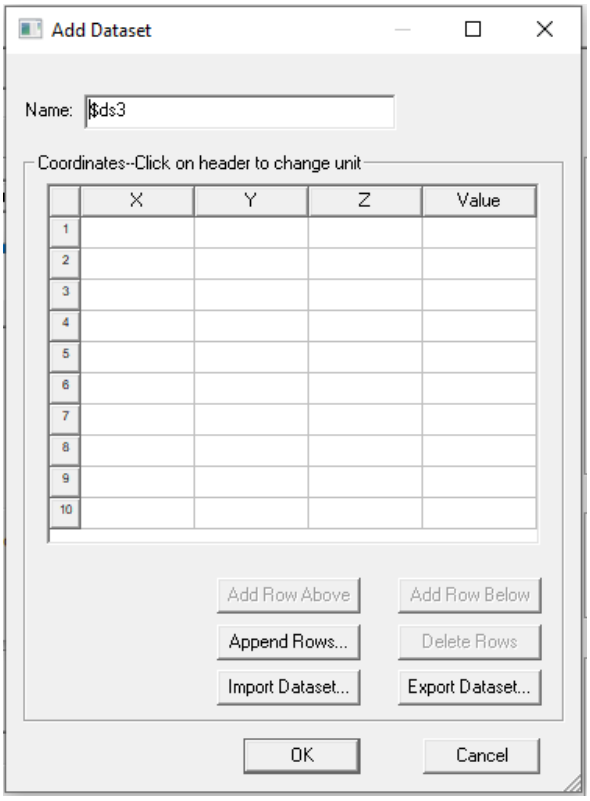
1. In the View/Edit materials dialog you must enable the **Spatial Modifier** check box in the **View/Edit Modifier for** panel. This causes the Properties of the Material table to expand to include a **Spatial Modifier** column. By default, the **Spatial Modifier** property is set to **None**.



2. Selecting **Edit...** from the dropdown menu causes the **Edit Spatial Modifier** dialog to appear.



3. Check **Use spatial dependent dataset**. If a predefined dataset is available, you can select it. Or you can select **Add/Import Dataset**. This opens the **Add Dataset** dialog box for specifying 3D object coordinates and associated values of the material property (conductivity, permeability, or permittivity) to be used in the design. (You can click the column heads to select the units.)



You can also import a tab delimited text file containing predefined coordinates and property values.

Imported datasets must be tab-delimited files (*.tab) containing sets of X, Y, and Z coordinates and associated property Values. For example:

```
2 4 4 68
2 5 5 70
3 5 5 71
```

You can also edit existing datasets as needed.

4. The spatial modifier expression models the material property change with respect to location along the object. The expression appears in the Spatial Modifier column for the associated property.

   The expression is of the form: `clp(dataset_name,X,Y,Z)`

   where `clp` is the closest point interpolation function, and *dataset_name* is the name of the design dataset containing the set of 3D object coordinates and associated property values to be used in the design. For example: `clp(ds2,X,Y,Z)` is the expression that uses the `ds2` dataset.

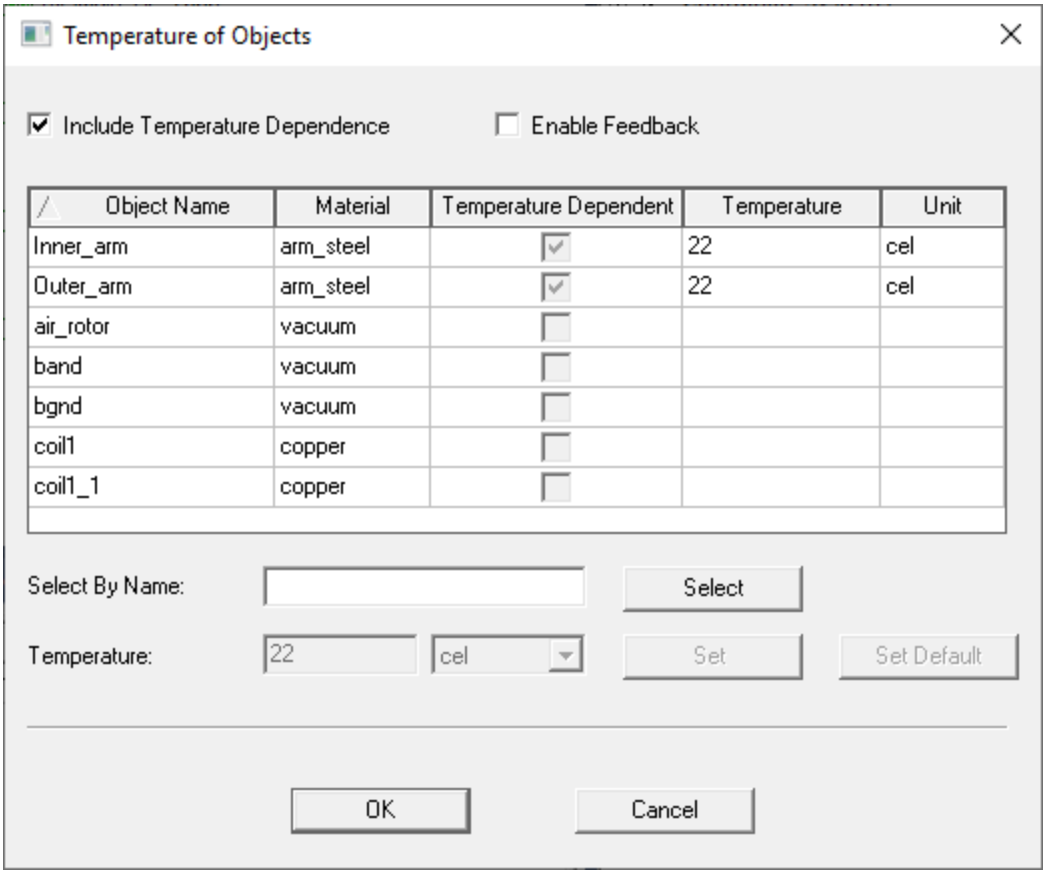
Setting the Temperature of Objects

To set the temperature of temperature dependent objects:

1. Use the **Maxwell>Set Object Temperature** command to display the **Temperature of Objects** dialog box.
   - For all design types the dialog includes a table of the objects in the design. It lists the **Object Name**, the **Material** assigned to the object, a non-editable **Temperature Dependent** check box to show whether that object has temperature dependent features (such as those specified by *Setting a Thermal Modifier*). For temperature dependent items, the remaining columns give the associated **Temperature** and **Unit**

of measure.



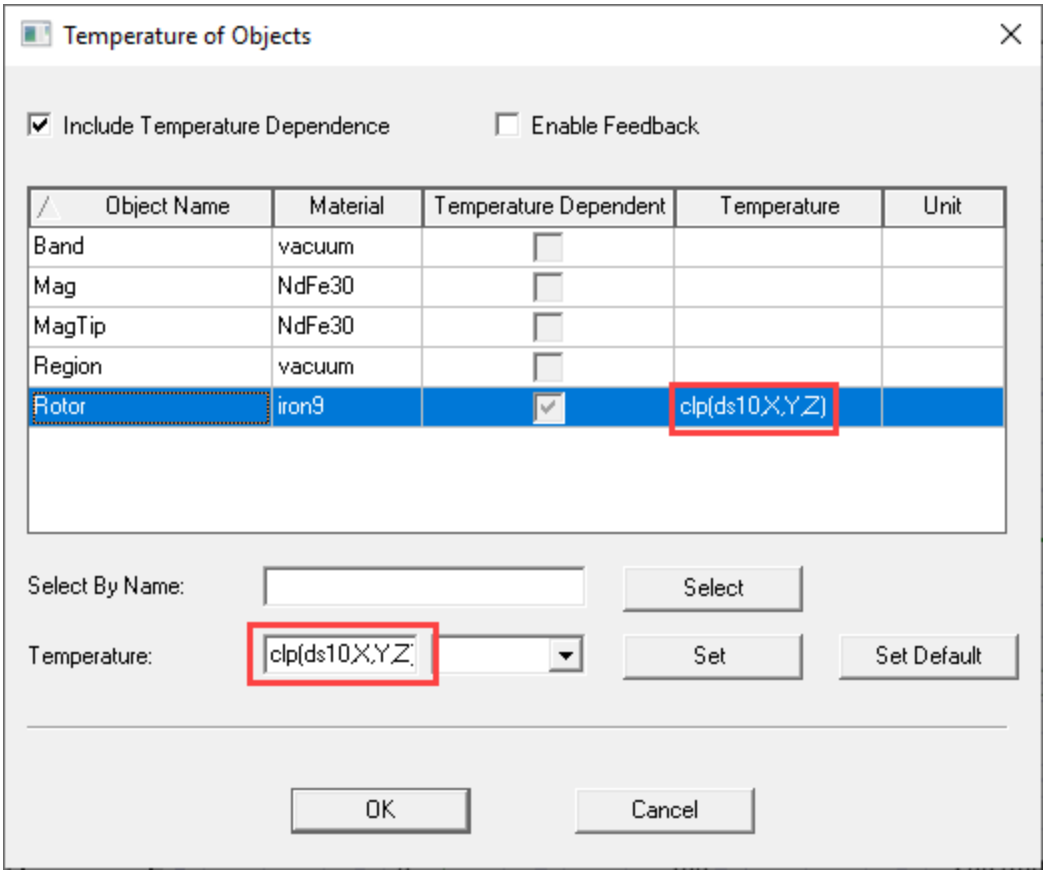
2. Maxwell allows you to enable/disable temperature dependency independently for each design in the same project. To include temperature dependency and enable the editing features, check **Include Temperature Dependence**. This makes the table rows editable.
    - The headers for each of the columns – except the **Temperature Dependent** column – include sort direction capability. You can invert the sort direction in each column by clicking the header. If the list is longer than the display, you can use a scroll bar on the right of the table.
    - In the **Select By Name** field, you can enter the name of the object (or boundary for 3D eddy current designs) you want to select, then click **Select** to highlight the selected row. You can make multiple selections.
3. To set the initial temperature for selected **Temperature Dependent** objects (or boundaries):
    a. Type a value, an existing variable name, or a *spatial modifier expression* in the **Temperature** text field; then select the unit of measure from the drop down menu.

    Refer to step 4 for detailed information on using a *spatial modifier expression*.

b. Click **Set** to apply the value to the selected temperature dependent objects (or boundaries); or click **Set Default** to make the specified values the default. (If you click **Set Default**, the rows for the selected objects (or boundaries) display the Temperature value and units.)

Note	You can also edit the **Temperature** and **Unit** for temperature dependent objects (or boundaries) directly in the table.

4. *Optionally*, for 2D and 3D transient designs, you can enter a *spatial modifier* expression in the **Temperature** field in the **Temperature of Objects** dialog as shown in the figure below. The spatial modifier expression models the temperature material property change with respect to location along the object. You can enter the expression either in the Temperature column at the top, or the Temperature text edit field at the bottom.

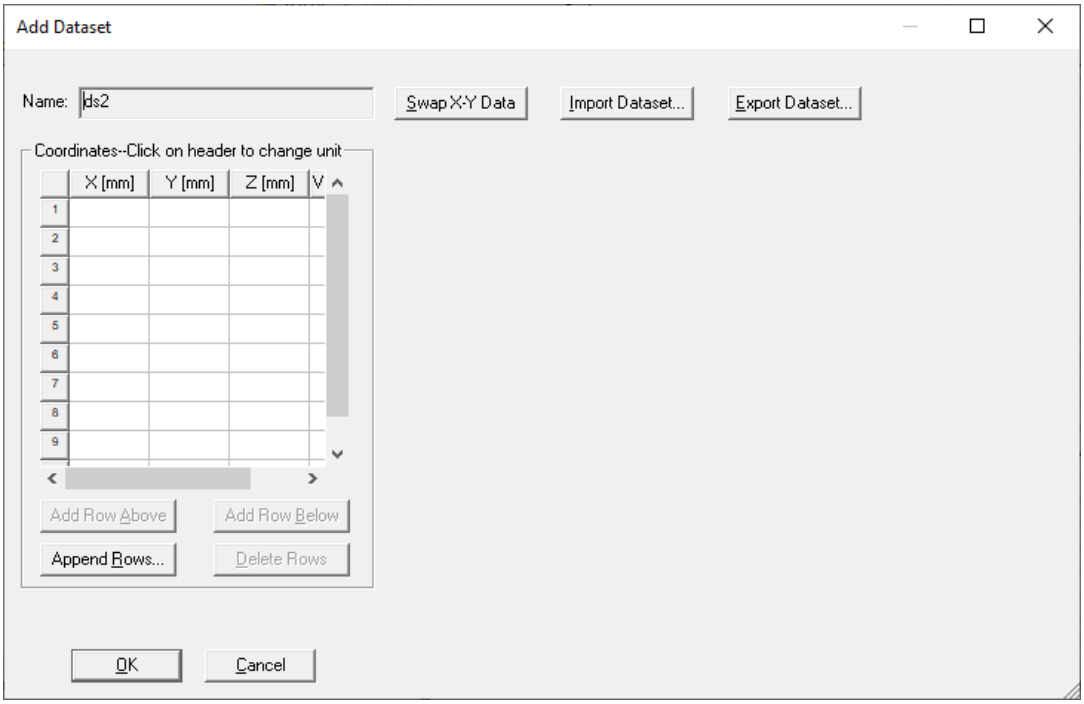


The expression is of the form: `clp(`*`dataset_name`*`,X,Y,Z)`

where `clp` is the closest point interpolation function, and *dataset_name* is the name of the design dataset containing the set of 3D object coordinates and associated temperatures to be used in the design. For example: `clp(ds2,X,Y,Z)` is the expression that uses the `ds2` dataset.

If the expression contains an undefined dataset, when you click **OK** and close the **Temperature of Objects** dialog box, an **Add Dataset** dialog for creating a new design

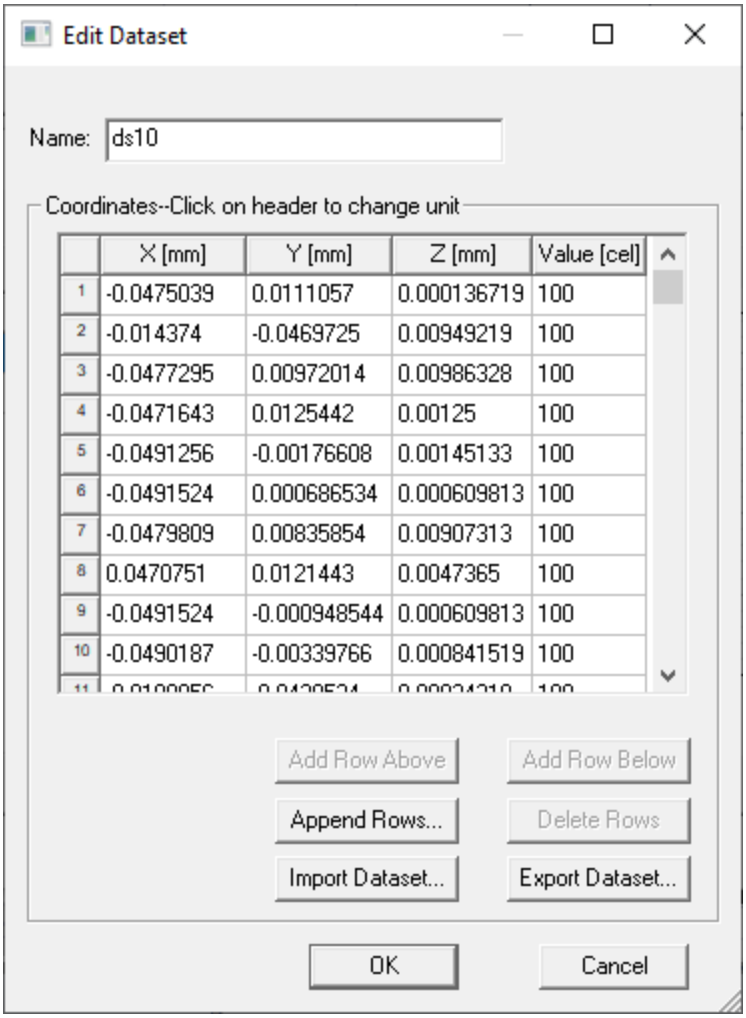
dataset will pop up for inputting or importing the spatial data. You can click the column heads to select the units.



Imported datasets must be tab-delimited files (*.tab) containing sets of X, Y, and Z coordinates and associated temperature Values. For example:

```
2 4 4 68
2 5 5 70
3 5 5 71
```

You can edit existing datasets as needed.



5. When **Include Temperature Dependence** is enabled, you can edit the material for an object (or boundary) by clicking on the material in the row to display a drop down menu listing the current material, and an **Edit...** menu item.

   Select **Edit**... to display the Materials dialog in which you can edit the current material – or select a different material for the object (or boundary). The material editor also allows you to set a thermal modifier. When finished, close the dialog to return to the Temperature of Objects dialog box. If you set a thermal modifier, the Temperature Dependent column for that object (or boundary) will be checked.
6. The **Enable Feedback** check box appears when Maxwell is used with the Ansys Workbench. If checked, you can perform thermal analysis based on a Maxwell solution.
7. To close the **Temperature of Objects** dialog and accept the changes, click **OK**.

Setting a Thermal Modifier

Core Loss Model for a Maxwell Material

Reverting Objects to Initial Temperature

When a design is enabled for thermal feedback, a **Revert to Initial Temperature** menu item is added to the context menu of the solution setup item and analysis setup folder in the project tree. This menu item is enabled when there are exported thermal data from Mechanical or when thermal data has been incorporated into the current Maxwell solution. Choosing **Revert to Initial Temperature** reverts the temperatures of objects to their initial temperatures.

Setting Deformation of Objects for Stress Feedback

For Maxwell systems that are coupled to Ansys Structural via Workbench., users can enable objects for stress feedback in the **Deformation of Objects** dialog box.

To set the deformation of stress dependent objects:

1. Use the **Maxwell>Deformation of Objects** command to display the **Deformation of Objects** dialog box.

   This dialog box includes a table of objects in the design. The first column lists the **Object Name**. The second column lists the **Material**. The **Deformation Dependent** column displays a check box to show whether that object has deformation-dependency enabled.

   Objects without an assigned material, non-model objects, non-3D objects in Maxwell 3D designs, and non-2D objects in Maxwell 2D designs cannot be handled by the solver and thus do not appear in the table.

2. To include deformation dependency, check **Enable Stress Feedback**.

This makes the table objects selectable. The headers for the **Object Name** column and the **Material** column include sort direction arrows. You can invert the sort direction in each column by clicking the header. If the list is longer than the display, you can use a scroll bar on the right of the table.

3. Check the **Deformation Dependent** check box for those objects you wish to include in the stress feedback analysis.

Note	Switching the state of **Enable Stress Feedback** or **Deformation Dependent** for any object invalidates the existing solution. Existing solutions include all field and non-field solutions, such as force and torque. When these options are switched from on to off, existing field solutions include previously incorporated displacement data. On the next simulation, the design will re-solve the last solved pass.

4. To close the **Deformation of Objects** dialog box and accept the changes, click **OK**.

Reverting Objects to Zero Displacement

Reverting Objects to Zero Displacement

When a design is enabled for stress feedback, a **Revert to Zero Displacement** menu item is added to the context menu of the solution setup item and analysis setup folder in the project tree. This menu item is enabled when there are exported displacement data from structural or when displacement data has been incorporated into the current Maxwell solution. Choosing **Revert to Zero Displacement** reverts the displacement values of objects to zero.

Permanent Magnets

A permanent magnet is defined as a material that generates a magnetic flux due to permanent magnetic dipoles in that material.

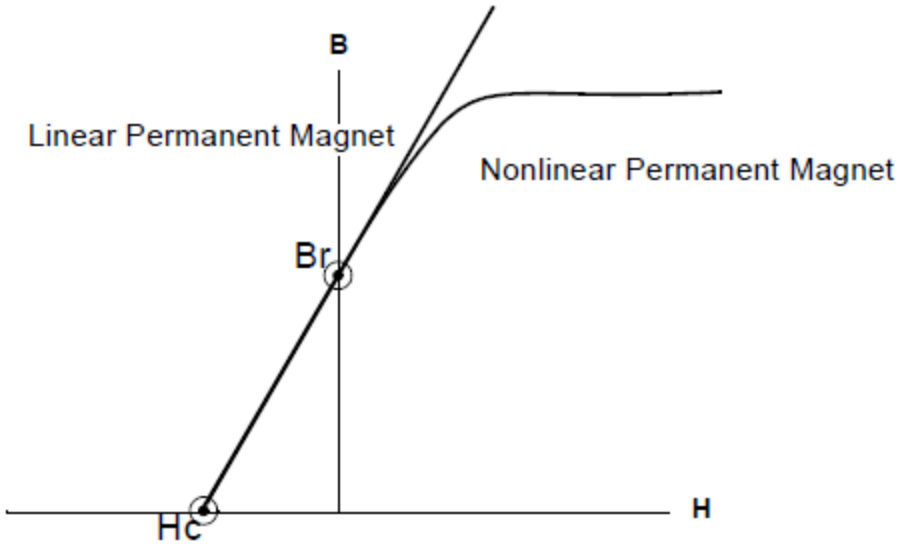
Nonlinear vs. Linear Permanent Magnets

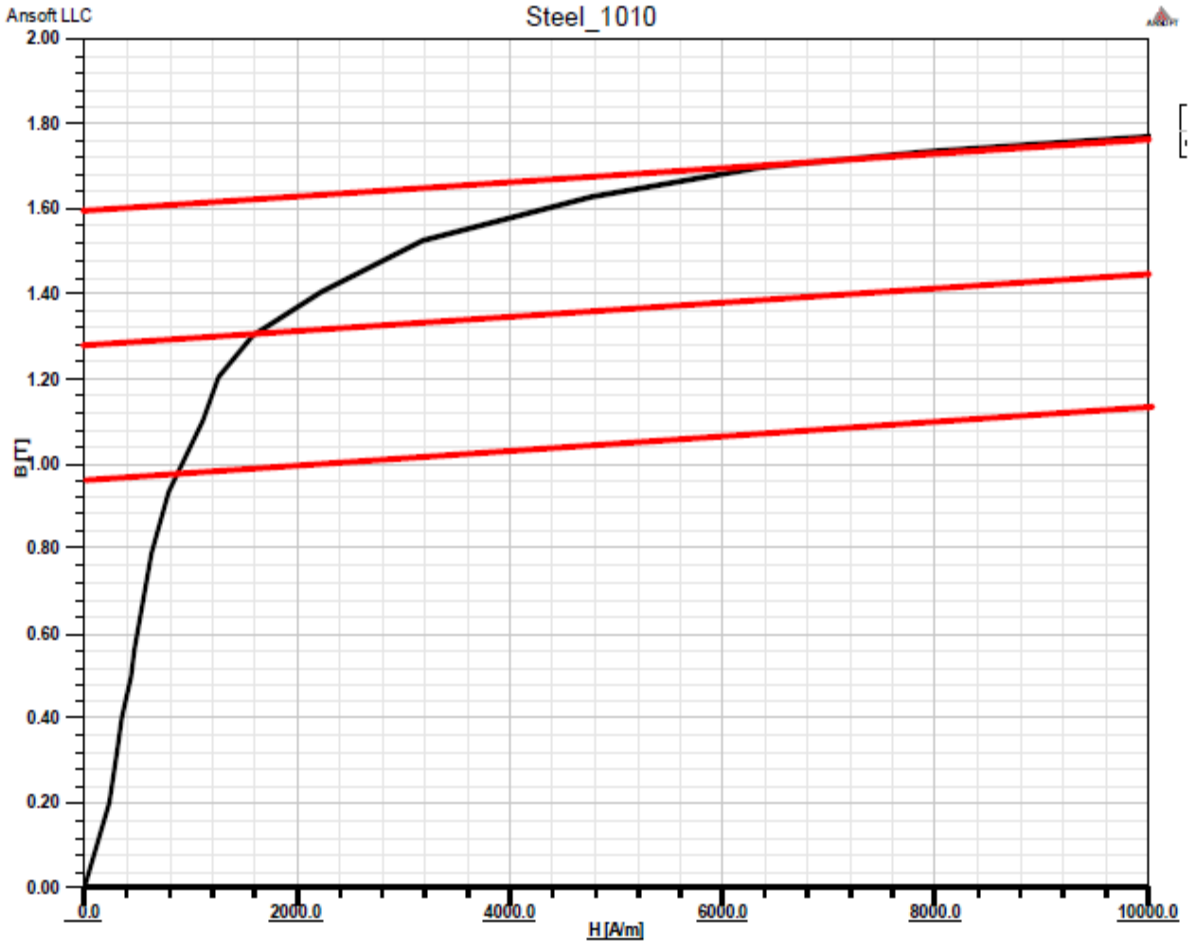
In general, permanent magnets are nonlinear and should be modeled via a B-H curve as shown below. The magnetic coercivity, H_c, is defined as the B-H curve's H-axis intercept, and the magnetic remanence, B_r, as its B-axis intercept.



In many applications, however, the permanent magnet's behavior can be approximated using a linear relationship between **B** and **H**. In these cases, there is no need to create a nonlinear material. Simply enter the appropriate values of B_r or H_c for the material when defining its properties.

Compute Remanent Br from B-H curve

The value of the remanent Br of the individual element after the magnetization field is computed is determined in such a way: after having located the operating point on the original non-remanent B-H curve, draw a line which is parallel to the original recoil curve with the slope of $\mu_0\mu_r$ and passes the operating point, the intersection of this line with B-axis is the remanent Br as the result of the applied magnetization field.



Temperature Dependent Nonlinear Permanent Magnets

To consider the temperature dependence of the demagnetization behavior, the demagnetization curve is described by temperature dependent parameters, which can be derived from supplier datasheets. For a better representation of any types of magnets by a function, it is advantageous to work with an intrinsic flux density $\boldsymbol{B_i}$ versus $\boldsymbol{H}$ curve, instead of a flux density $\boldsymbol{B}$ vs $\boldsymbol{H}$ curve. The relationship between $\boldsymbol{B_i}$ and $\boldsymbol{B}$ is:

$B = B_i + \mu_0 H$	(1)

The temperature dependency of an intrinsic BH curve can be specified by two temperature dependent parameters: remanent flux density B_r and intrinsic coercivity H_{ci}. Here B_r is the value of B_i (and B) when H=0 and H_{ci} is the value of H at B=0. Both B_r and H_{ci} can be described using second order polynomials of temperature T as:

$$B_r(T) = B_r(T_0)(1 + \alpha_1(T - T_0) + \alpha_2(T - T_0)^2) = B_r(T_0)P(T) \quad (1)$$

and

$$H_{ci}(T) = H_{ci}(T_0)(1 + \beta_1(T - T_0) + \beta_2(T - T_0)^2) = H_{ci}(T_0)Q(T) \quad (1)$$

where T_0 is the reference temperature, and α_1, α_2, β_1, and β_2 are coefficients which can be identified from supplier datasheets. In general, the thermal modifiers *P(T)* and *Q(T)* also can be described by any user-defined function of temperature T, in addition to the above second order polynomials.

Consequently, once a B_i-H curve is constructed by a function using certain techniques, such as curve fitting at the reference temperature T_0, any B_i-H curves at other temperatures can be dynamically reconstructed in terms of the temperature dependence of $B_r(T)$ and $H_{ci}(T)$. Finally, the B-H curve in the second and the third quadrants can be further derived through the conversion using equation (1).

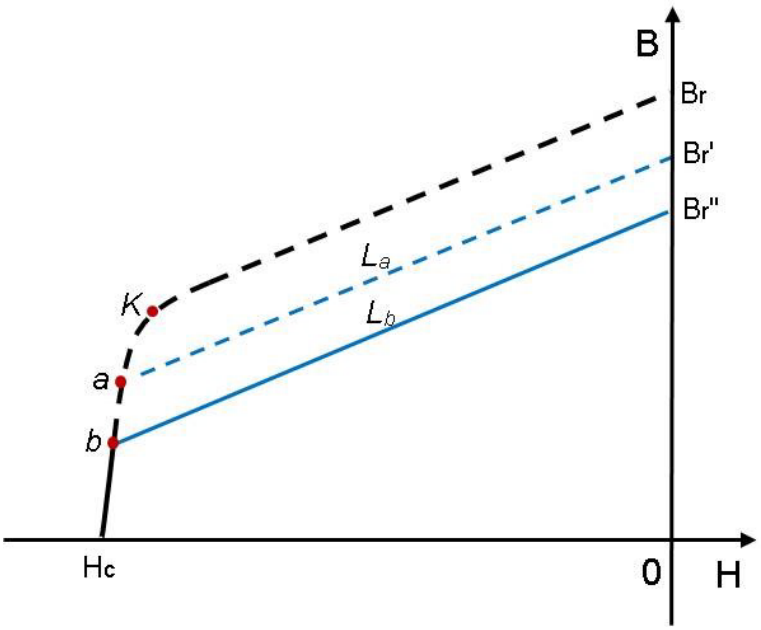
Since the model specifies two temperature dependent parameters: remanent flux density B_r (α) and intrinsic coercivity H_{ci}(β), the thermal modifier *P(T)* is specified in the field associated with the input of relative permeability (or B_i-H curve), and the thermal modifier *Q(T)* is specified in the field associated with the magnitude of coercivity for H_{ci}.

Irreversible Demagnetization Due to Temperature Change

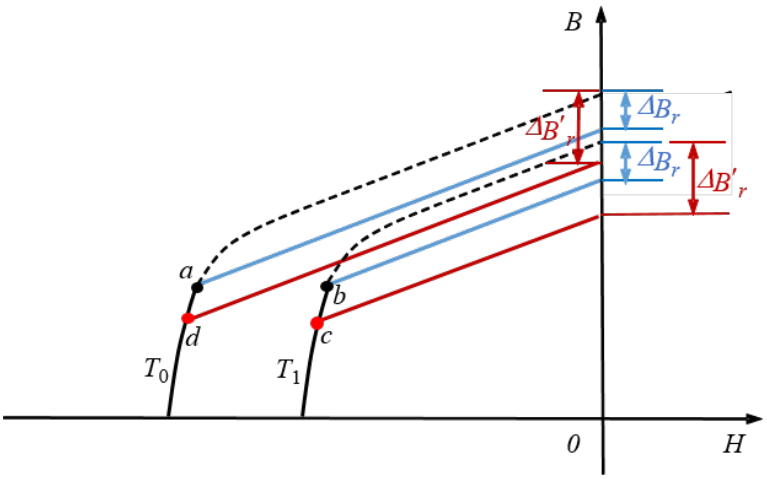
Permanent magnets exposed to heat can lose strength which cannot be recovered. For example, if a permanent magnet motor is operated under a torque overload condition, the motor will draw more current to produce the required torque. The increased current causes some demagnetization, further increasing the current draw. Over a period of time, this overload may cause the motor to overheat. The resulting rise in temperature can lower the magnet material's intrinsic coercivity thus making the magnet prone to demagnetization. If the temperature exceeds the magnet's operating point, some of the magnet's domains become permanently demagnetized.

Consequently, when the magnet's temperature decreases to its initial value, the operating point does not return to its original value. This effect is irreversible.

The following image shows that when a new working point ***a*** goes below the knee point ***K***, the subsequent working point will change along a new constructed B-H curve which consists of two curve segments: the recoil line L_a and the demagnetizing curve part below point ***a***. The residual flux density of the recoil line is *Br'*, and the difference between *Br* and *Br'* is the irreversible *Br* loss, which is denoted as $\Delta Br = Br - Br'$.



When the temperature of a permanent magnet with operating point ***a*** (as shown below) increases from T_0 to T_1, based on user-defined thermal modifiers, a new demagnetization curve can be constructed element by element at the new temperature, T_1. Since the initial irreversible *Br* loss ΔBr remains unchanged, the initial operating point on the new demagnetization curve can be identified as point ***b*** (the intersection of the new demagnetization curve and the recoil line which passes ($Br - \Delta Br$). It follows that the worst-case operating point at temperature T_1 can be further evaluated as indicated by point ***c*** from the field solution. This new worst-case operating point, *c*, causes the irreversible *Br* loss to increase from ΔBr to $\Delta B'r$. If the temperature then changes from T_1 back to T_0, the operating point will not return to point *a*. Instead, it will be located at ***d*** – associated with temperature T_0 based on the new irreversible loss $\Delta B'r$. The Maxwell solution is able to store the design's irreversible demagnetization values for different working temperatures.



Characteristics and Main Parameters of Permanent-magnetic Materials

The permanent-magnetic material belongs to hard-magnetic material. It is characterized with "fat" hysteresis loop, which encloses large area as shown in the figure. When magnetized, it keeps high magnetic property with the external magnetic field removed, therefore is used in the permanent-magnet electric machine to produce magnetic field. The characteristics of the permanent-magnetic material are represented with its main parameters: residual flux density B_r, coercive field force H_c and maximum magnetic energy product $(BH)_{max}$.

Characteristics and Main Parameters of Permanent-magnetic Materials
Calculating the Properties for a Non-Linear Permanent Magnet
Temperature Dependent Nonlinear Permanent Magnets
Irreversible Demagnetization Due to Temperature Change

Calculating the Properties for a Nonlinear Permanent Magnet

Nonlinear permanent magnet properties may be specified in one of two ways:

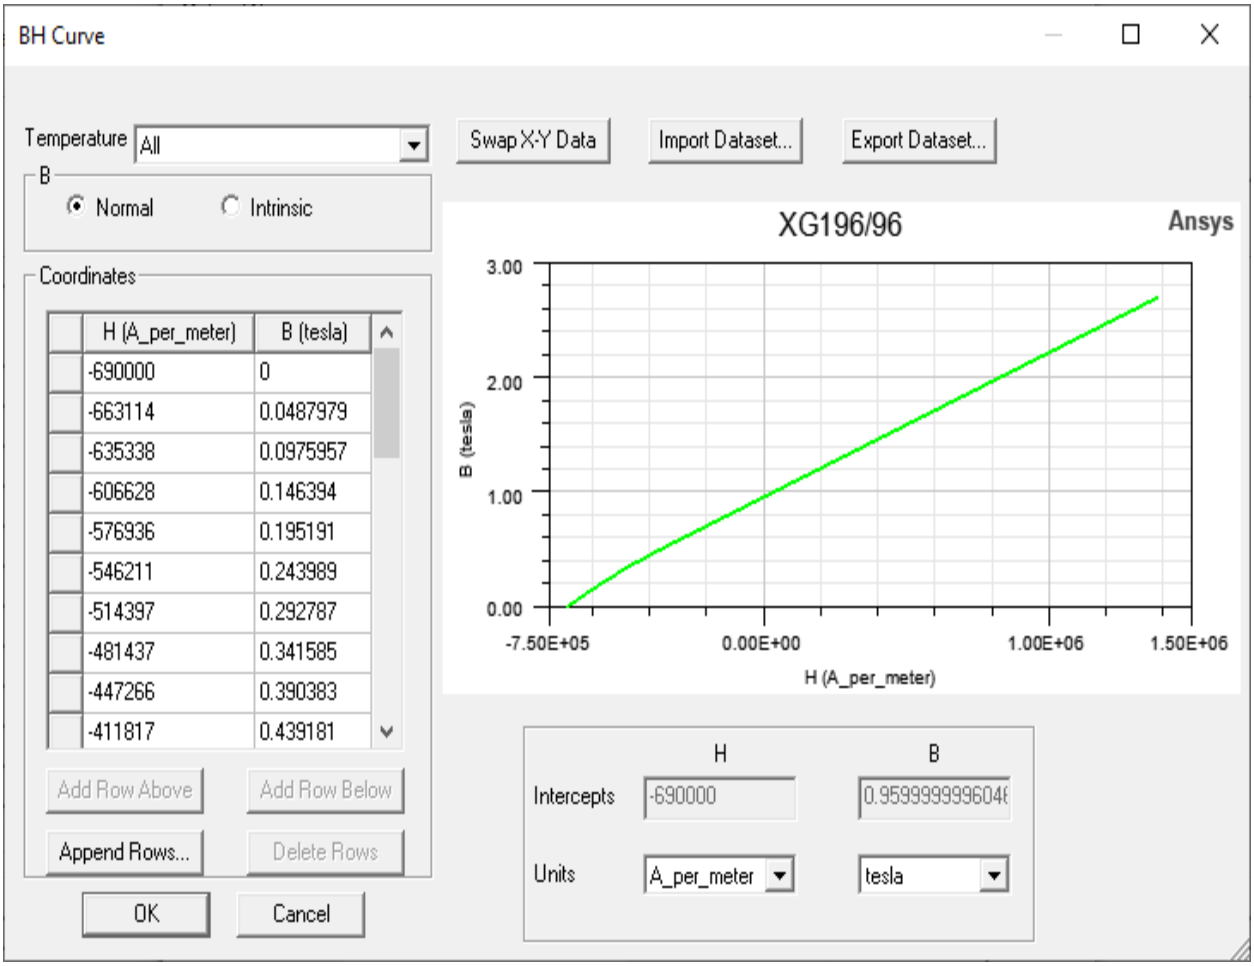
- Input a BH Curve directly
- Using the **Properties for Non-Linear Permanent Magnet** dialog box

Input a BH curve directly as follows:

> **Note:** You can model multiple temperature dependencies of a nonlinear material property by providing two or more temperature-dependent BH curves. Refer to *Specifying BH Curves for Nonlinear Relative Permeability* for detailed information.

1. Click the **View/Edit Materials…** button in the **Edit Libraries** dialog box.
   The **View/Edit Material** dialog box appears.
2. The nonlinear BH curve is defined by setting the **Relative Permeability** **Type** to **Nonlinear**.

   A **B-H Curve** button appears in the nonlinear property's **Value** column.
3. Input the BH curve by clicking the **B-H Curve** button in the property **Value** column.
   This opens the **BH Curve** dialog box in which you can input (or modify) curve data. (Refer to *Adding Datasets* for general information on working with datasets.



- For a **Normal** BH curve, the slope of the curve can not be less than that of free space anywhere along the curve.
- For an **Intrinsic** BH curve, the slope of the curve can not be less than 0.

Note	• The **Intrinsic** BH curve is supported only in Maxwell 2D/3D magnetostatic and transient design types. A material property defined using an Intrinsic BH curve will fail validation check in all the other product/design types. • When an **Intrinsic** BH curve is added, the **Relative Permeability Value** button label changes to **Bi-H Curve** as visual indication of the type of curve currently defined for the material.

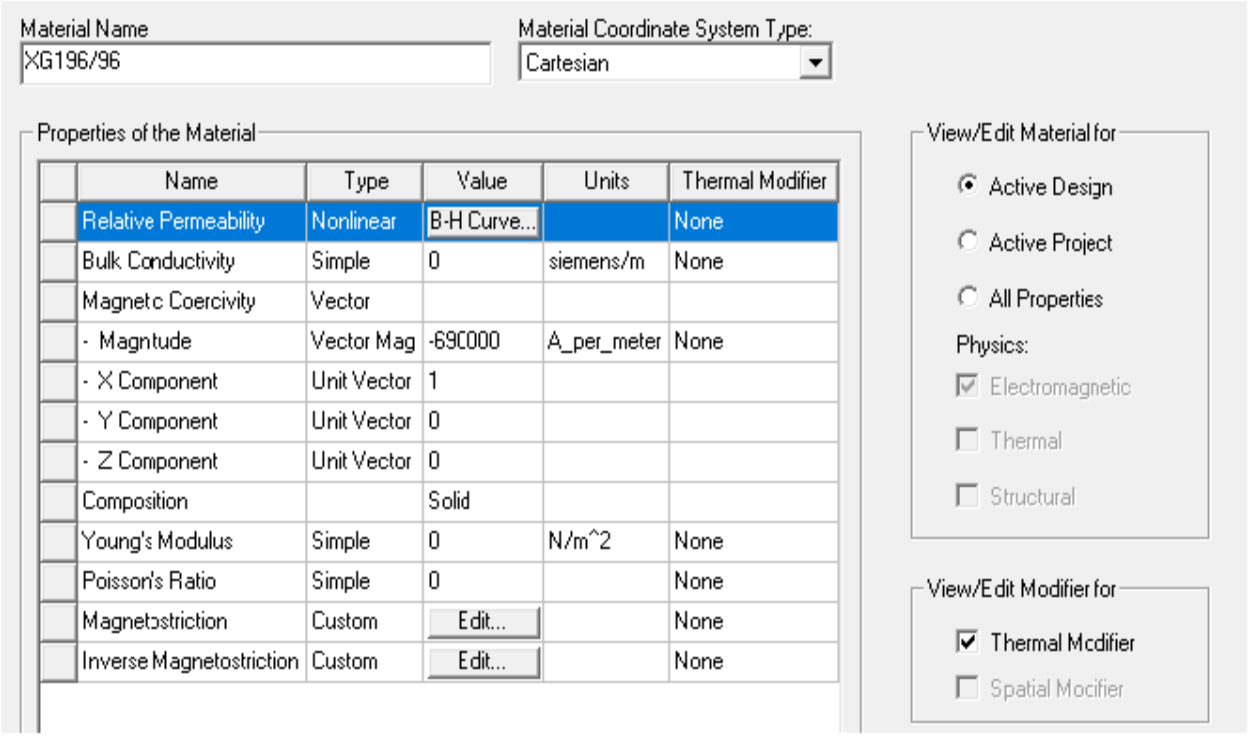
When you **OK** the dialog box, an error message displays if a slope is out of tolerance, identifying the data points between which the slope is less than that of free space.

The operations to input a nonlinear demagnetization curve are the same as entering a BH curve for Steel material. When a BH curve goes through the second quadrant or third quadrant, the curve is treated as a demagnetization curve.

4. To model a single *temperature dependency* for a nonlinear permanent magnet you must:

> **Note:** You can model multiple temperature dependencies of a nonlinear material property by providing two or more temperature-dependent BH curves. Refer to *Specifying BH Curves for Nonlinear Relative Permeability* for detailed information.

- Use an **Intrinsic** BH curve to model the **Relative Permeability**
- Specify a Thermal Modifier for both **Relative Permeability** and the **Magnitude** of **Magnetic Coercivity**. Apply a thermal Modifier by selecting the **Thermal Modifier** check box. Checking this box causes the **Thermal Modifier** column to display at the right side of the **Properties of the Material** table. Selecting **Edit** rather than **None** causes display of the **Edit Thermal Modifier** dialog.



Alternatively, a non-linear BH curve can be modeled by the following four parameters:

- residual flux density B_r
- coercive field force H_c
- maximum energy product $(BH)_{max}$
- relative recoil permeability μ_r

From the **View/Edit Materials** window:

1. Set the **Relative Permeability** to **Nonlinear**.
   This enables the **Calculate Properties for...** drop down menu at the bottom of the window.
2. Click **Non-Linear Permanent Magnet** from the drop down menu.

This displays the **Properties for Non-Linear Permanent Magnet** dialog box, which contains the following fields into which you enter the appropriate values.

Mur	Provide a value for relative permeability.
Hc	Coercive field force H_c in the units specified. Provide a value and select units from the drop down menu.
Br	Residual flux density B_r, in Tesla. If enabled, provide a value and select units from the drop down menu.
BH max	Maximum magnetic energy product $(BH)_{max}$ If enabled, provide a value and select units form the drop down menu.

3. Click **OK** to close the dialog and return to the **View/Edit Materials** window.

   The values for **Relative Permeability** and **Magnitude** under **Magnetic Coercivity** are updated as new default values.

Characteristics and Main Parameters of Permanent-magnetic Materials

Calculating the Properties for a Permanent Magnet

Temperature Dependent Nonlinear Permanent Magnets

Irreversible Demagnetization Due to Temperature Change

Calculating Properties Using a Hysteresis Loop in Maxwell

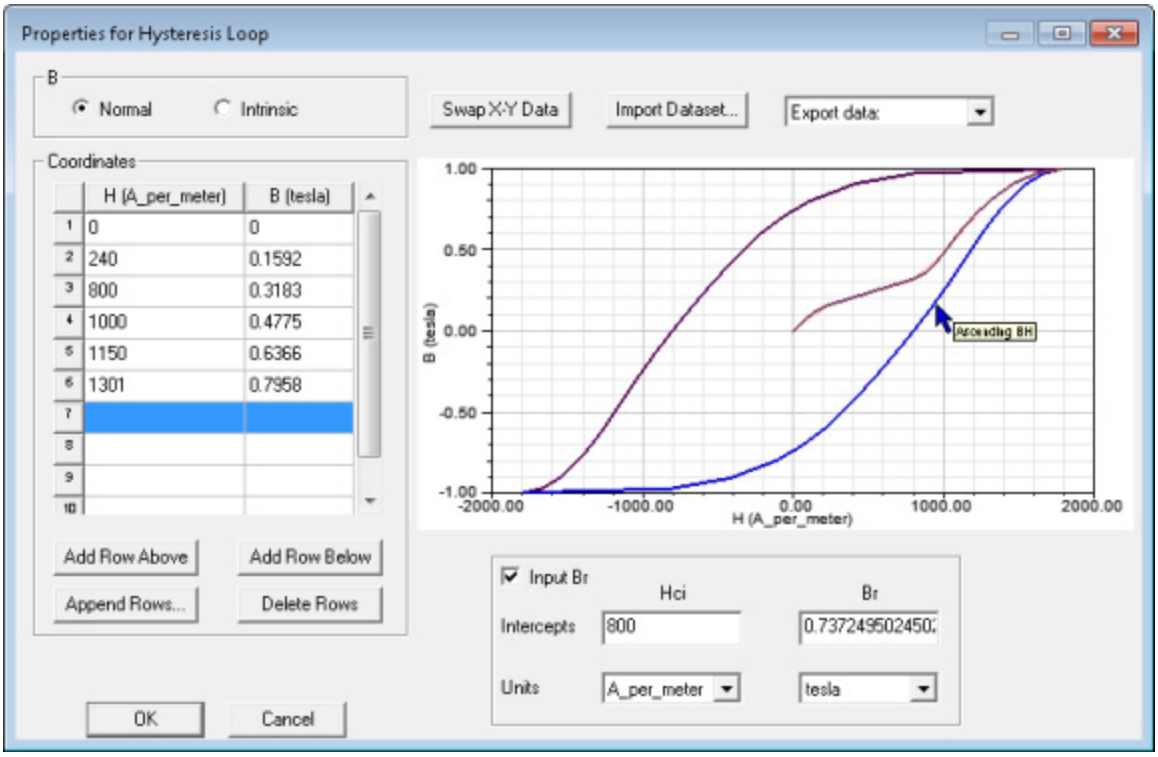
For a material whose Relative Permeability is Nonlinear (refer to *Calculating the Properties for a Non-Linear Permanent Magnet*), and whose **Magnitude** of **Magnetic Coercivity** is zero, you can calculate core loss properties using a hysteresis loop as follows:

1. Click **Tools>Edit Configured Libraries>Materials**. to open the **Edit Libraries** dialog box.
   - Alternatively, in the project tree, you can right-click **Materials**, under **Definitions**, and select **Edit All Libraries**.
2. Click **Add Material** to open the **View/ Edit Material** dialog box.
3. In the **Core Loss Model** row, select **Hysteresis Model** from the **Value** pull-down list.

   If you select either **View/Edit Material for: This Product** or **All Products** radio button, additional parameters appear in the table below **Core Loss Model** (**Intrinsic Coercivity Hci**, **Remanency Br**, **Kc**, and **Equiv. Cut Depth**). You can input these values directly. You can also supply the **Hci** and **Br** values in the **Properties for Hysteresis Loop** dialog box as described below.

   The **Hysteresis Loop** selection in the **Calculate Properties for** pull-down list at the bottom of the dialog box is also enabled. This allows the coefficients **Hci**, and **Br** to be derived from a manufacturer-provided core loss curve.

4. Select **Hysteresis Loop** from the **Calculate Properties for** pull-down list at the bottom of the dialog box to open the **Properties for Hysteresis Loop** dialog box The current BH Curve coordinates are loaded by default. **Hci** and **Br** values from the **Intrinsic Coercivity Hci**, **Remanency Br** fields in the **View / Edit Material** dialog box are also displayed.



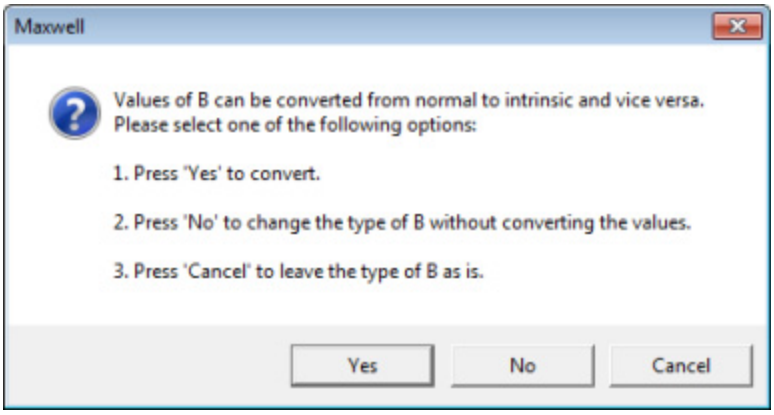
5. Do one of the following to specify the hysteresis loop curve:
   - Enter the **B** and **H** values in each row of the **Coordinates** table manually. The graph updates as you enter values. Buttons allow you Add, Append, and Delete table rows as needed.

Note	• The value of B must increase along the curve. • The accuracy of input data for the curve has significant effect on the correctness of the analyses of the electromagnetic devices. You should ensure curve data provided by material manufacturers is accurate.

   - You can also import the hysteresis loop coordinates from a saved file.
     a. Click **Import Dataset** to open the **Import Dataset** dialog box.
     b. Find and select either the BH Data .bh file, or the tab-delimited .tab file containing the curve data points. Click **Open** to import the data.
     c. Optionally, click **Swap X-Y Data** to switch the B and H values if they are in the wrong columns.
6. Optionally, enter the Hci and Br values and choose appropriate units for them. Input Br must be enabled to enable the Br entry box; otherwise, the default zero value indicates that **Br** will be determined automatically by the software. (These fields may already have values in them if previously supplied in the **View / Edit Material** dialog box.) Disabling Input Br resets

the Br value to zero.

7. Optionally, select either **Normal** (the default) or **Intrinsic** for BH curve input and plot display. When changing from Normal to Intrinsic (or vice-versa) the following dialog displays, allowing you to choose whether or not to convert B values.



8. Optionally, you can export data for the descending and ascending curve of the hysteresis loop. You can also export the BH curve as well as the smoothed BH curve.
9. Click **OK** to close the Properties for Hysteresis Loop dialog.

   The values of Magnetic Coercivity Magnitude, **Hci**, and **Br** are updated in the **View/Edit Material** dialog.

Note	In the **View/Edit Material** dialog box, if the **Magnetic Coercivity Magnitude** is changed to a non-zero value by modifying the **Relative Permeability B-H Curve** property, the **Core Loss Model** property is reset from **Hysteresis Model** to **None**.

10. Click **OK** to close the **View / Edit Material** dialog box.
11. Click **OK** to close the **Edit Libraries** dialog box.

Core Loss Model for a Maxwell Material

Magnetostriction and Inverse Magnetostriction

Magnetostriction is a property of ferromagnetic materials that causes their deformation during the process of magnetization. The structure of such materials is divided into *domains*, each of which is a region of uniform magnetic polarization. When a magnetic field is applied, the domains rotate causing a change in the material's dimensions. This change in the material's dimensions is due to the anisotropic crystalline structure of the material – it takes more energy to magnetize a crystalline material in one direction than another. For example, the steel used for the thin laminations in transformers is manufactured by passing it through a series of rollers to achieve the desired thickness. Consequently its crystalline structure – and associated magnetic domains – differs along the direction in which it was rolled (the *rolling* direction) versus the *transverse* direction.

Magnetostriction – and Inverse Magnetostriction – can be regarded as an energy transduction (or transformation) from magnetic to mechanical and vice-versa. It can also be described as a bidirectional magneto-mechanical coupling between the mechanical and magnetic fields in the magnetostrictive material. It is magnetostriction that causes the low-pitched humming sound that can be heard coming from transformers – caused by the changing magnetic field produced by oscillating AC currents. For detailed information on these properties, refer to *Magnetostriction Modeling of Magnetic Materials* in the technical notes section.

- Magnetostriction/inverse magnetostriction properties can be applied to Maxwell 2D/3D magnetosatic and transient solutions through customizable Magnetostriction and Inverse Magnetostriction material properties.
- Maxwell desktop supplies the Magnetostriction and Inverse Magnetostriction material properties to the Maxwell solver. The solver then calculates force density with magnetostriction force components included.
- For Maxwell Magnetostatic solutions, if any material used has the Inverse Magnetostriction property defined, Maxwell desktop saves the initial H field, which is generated by the solver without exterior stress/strain applied, in the project results.
- Magnetostriction and inverse magnetostriction are applicable to Maxwell 2D/3D Magnetosatic design one-way and two-way coupling with Ansys Mechanical system.

Note	Inverse magnetostriction for materials having cylindrical and spherical coordinate systems is not supported.

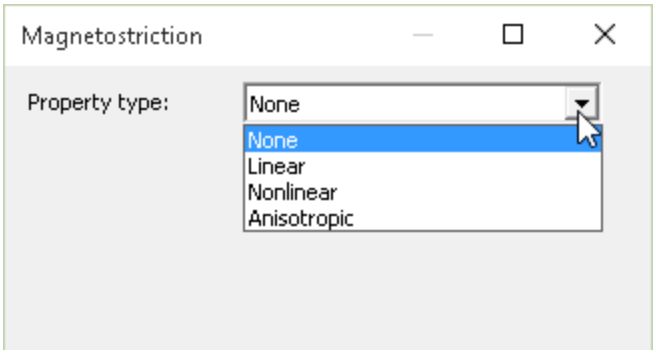
Magnetostriction Modeling of Magnetic Material

Calculating the Properties for Magnetostriction

The magnetostriction property supports three models: Linear, Nonlinear, and Anisotropic. The property values you enter typically come from manufacturer data sheets.

To define these model properties, from the **View/Edit Material** dialog:

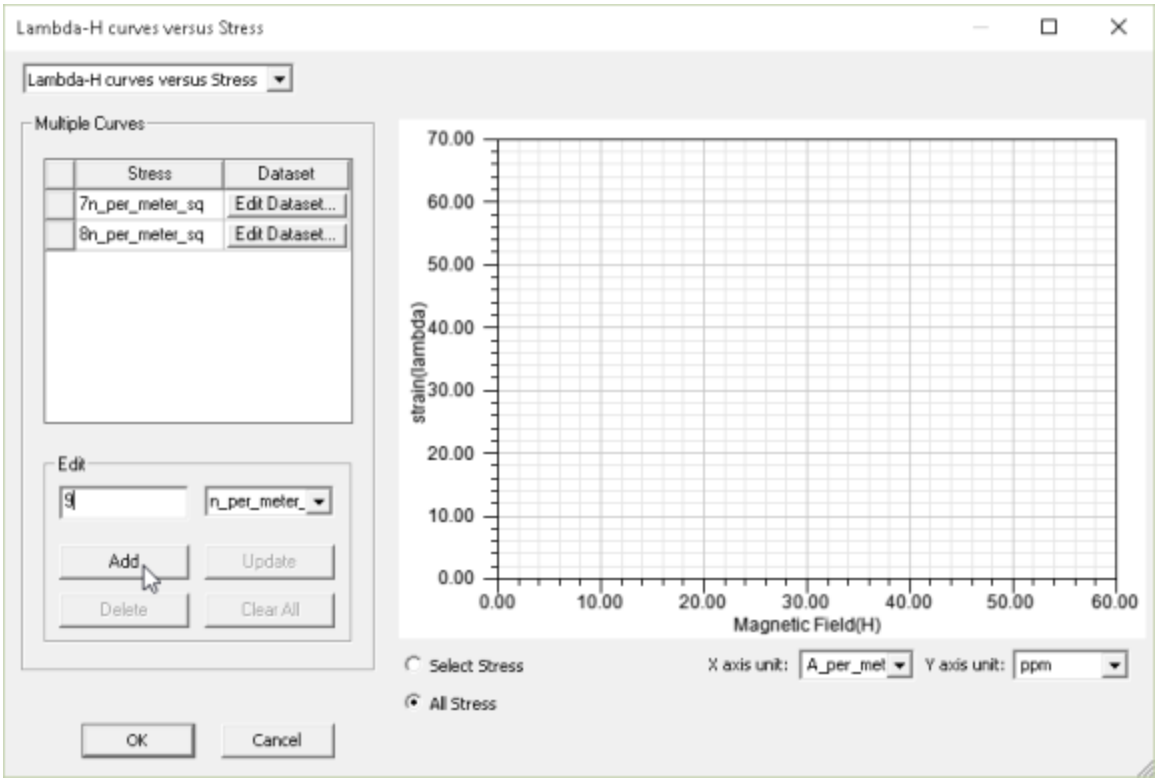
1. Click the **Edit** button to the right of **Magnetostriction Custom** to open the Magnetostriction properties dialog.



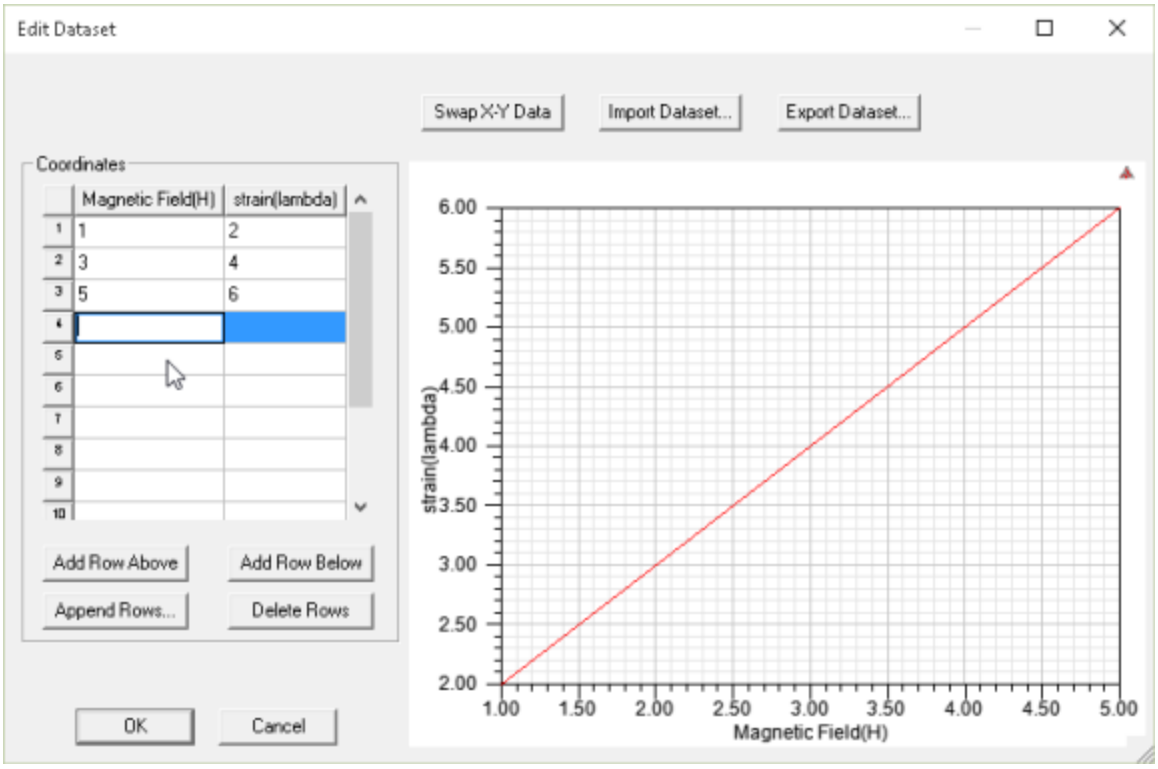
2. Choose a **Property type** from the drop-down menu: **Linear**, **Nonlinear**, or **Anisotropic** and do one of the following:
   a. For **Linear**, enter values for **Magnetostrictive Coefficient**, **H max**, and **H min**.

   b. For **Nonlinear**, click the **Multi-curves** button

   to add one or more Stress dependent Lambda-H curves.



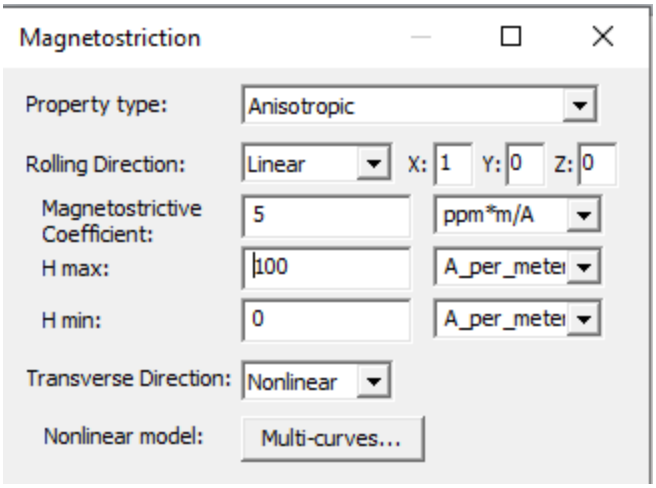
Enter a stress value in the **Edit** text box and click **Add**, then click **Edit Dataset** to open the **Edit Dataset** dialog box, in which you enter coordinate values for the **Magnetic Field (H)** and **strain (Lambda)**.



When finished, click **OK** to close the dialogs and return to the **Magnetostriction** dialog.

c. For **Anisotropic**, select either **Linear** or **Nonlinear** from the **Rolling Direction** and **Transverse Direction** drop-down menus. Rolling Direction refers to the alignment of the crystalline structure (and associated magnetic domains) in the direction along which the material (such as the steel laminations used in transformers) passed through the rollers during manufacture. Transverse Direction is at right angle to the Rolling Direction. Magnetostriction property values typically differ in each direction.

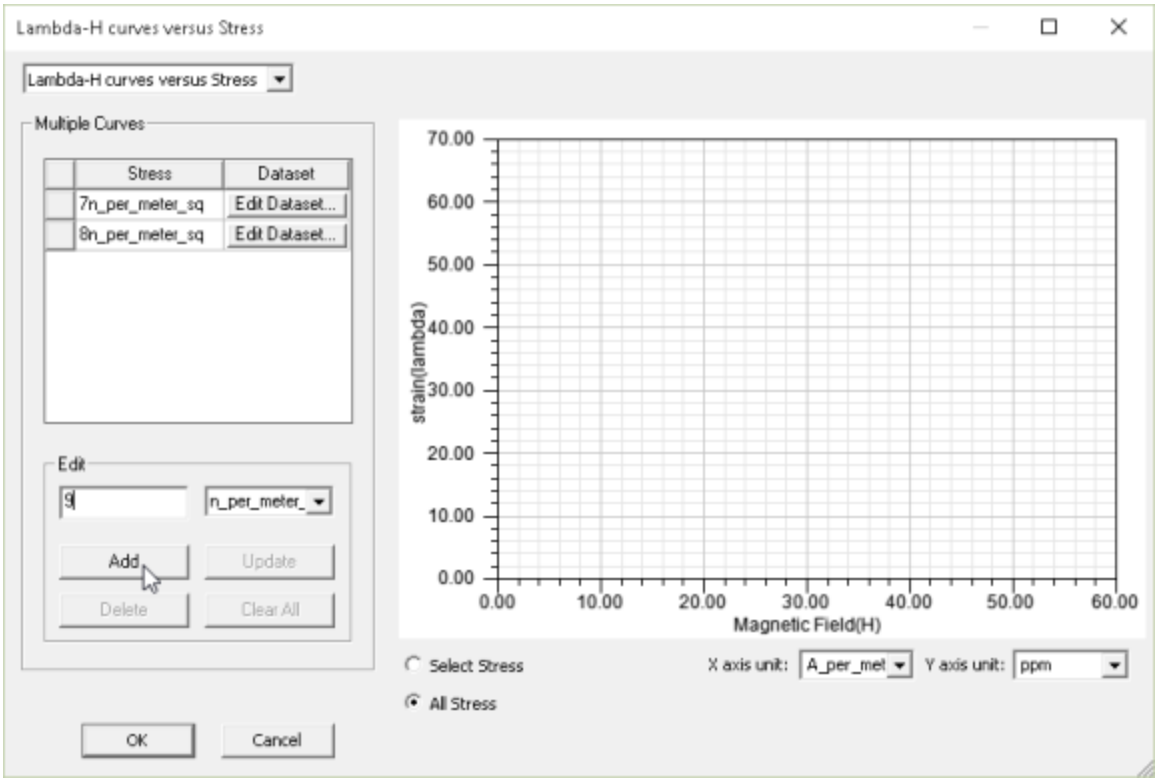
Note	The type you select for each of the directions need not be the same. For example, you could select Linear for Rolling Direction and Nonlinear for the Transverse Direction, and vice versa.



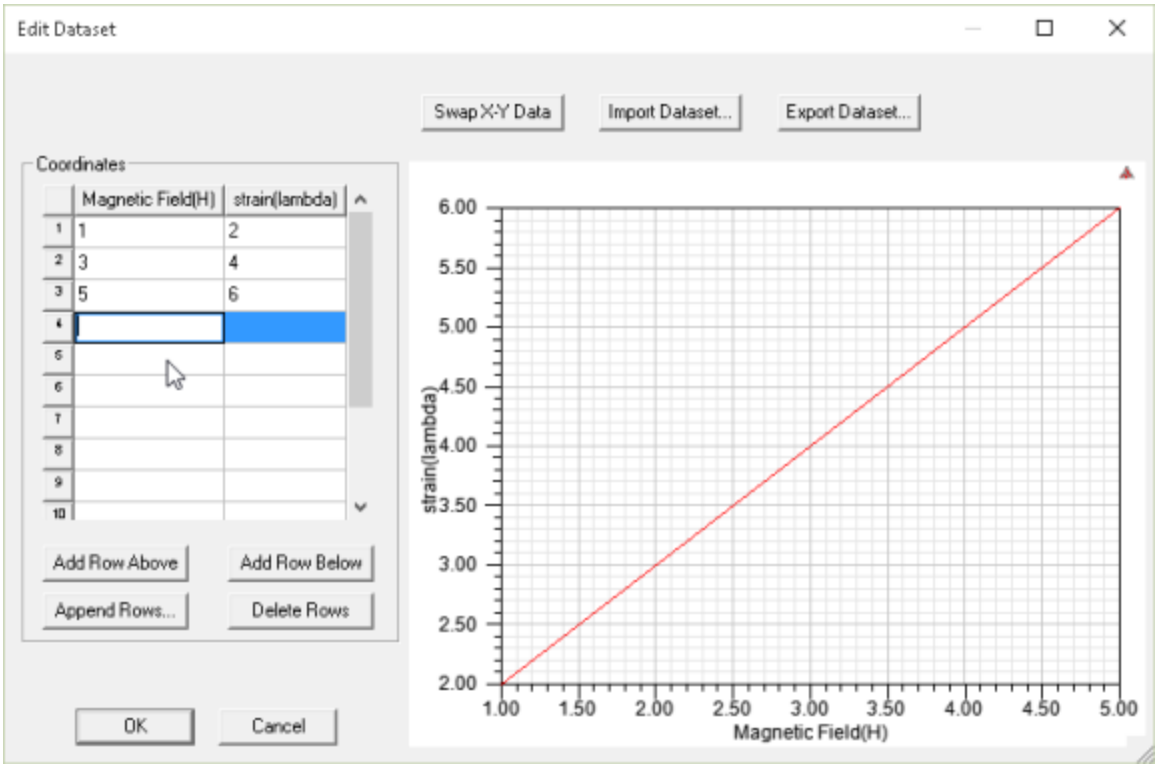
- For **Linear**, enter values for **Magnetostrictive Coefficient**, **H max**, and **H min**; and for **Rolling Direction** only, enter the **X**, **Y**, and **Z** coordinate values.

Note	The X, Y, and Z components of the Rolling Direction correspond to the **Material Coordinate System Type** set in the **View/Edit Material** dialog. • For **Cartesian**: X=X, Y=Y, Z=Z • For **Cylindrical**: X=R, Y=Phi, Z=Z • For **Spherical**: X=Rho, Y=Theta, Z=Phi

- For **Nonlinear**, click the **Multi-curves** button to add one or more Stress dependent Lambda-H Curves.



Enter a stress value in the **Edit** text box and click **Add**, then click **Edit Dataset** to open the **Edit Dataset** dialog box, in which you enter coordinate values for the **Magnetic Field (H)** and **strain (Lambda)**.



When finished, click **OK** to close the dialogs and return to the **Magnetostriction** dialog.

3. Click **OK** to close the **Magnetostriction** dialog and return to the **View/Edit Materials**dialog.

Magnetostriction and Inverse Magnetostriction

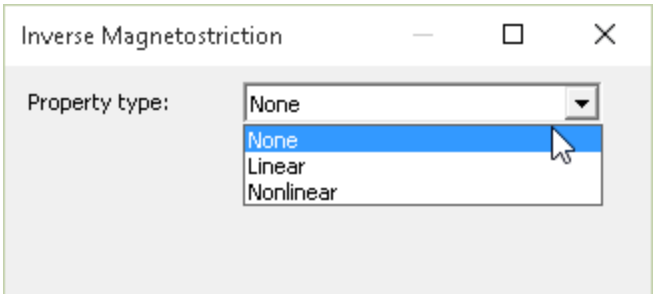
Calculating the Properties for Inverse Magnetostriction

Calculating the Properties for Inverse Magnetostriction

The inverse magnetostriction property supports two models: Linear, and Nonlinear. The property values you enter typically come from manufacturer data sheets.

To define these model properties, from the **View/Edit Material** window:

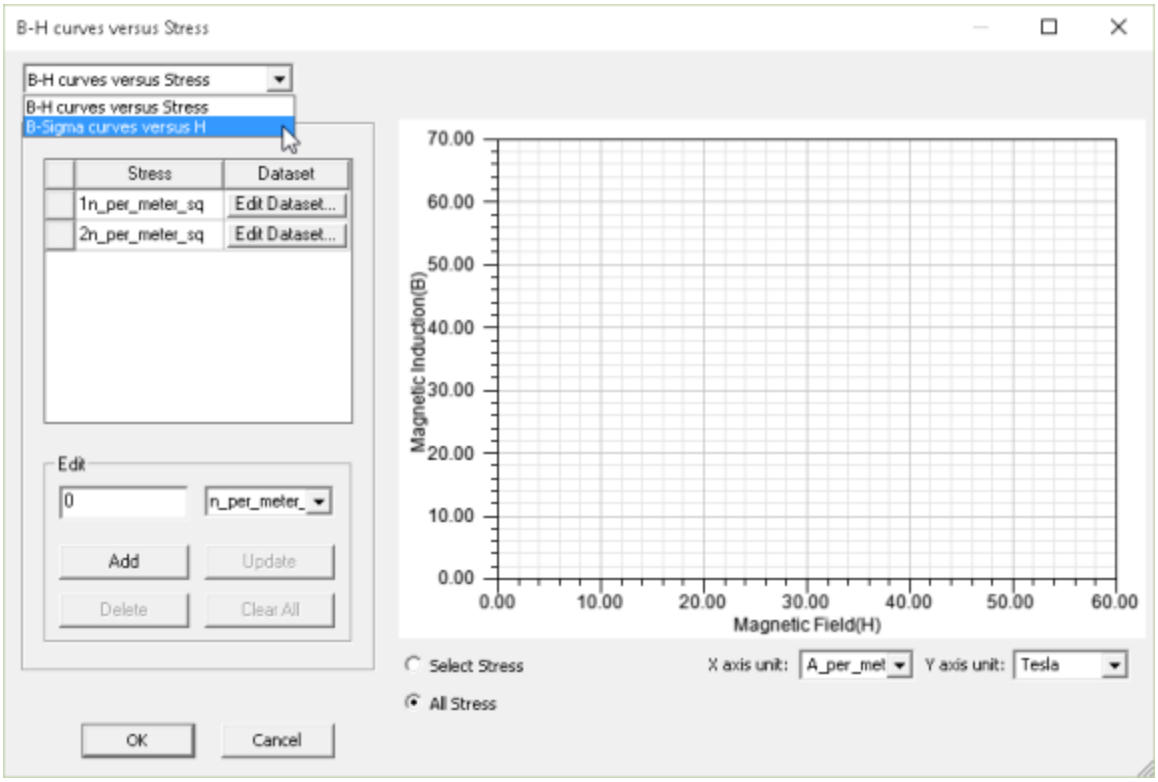
1. Click the **Edit** button to the right of **Inverse Magnetostriction Custom** to open the Inverse Magnetostriction properties dialog box.



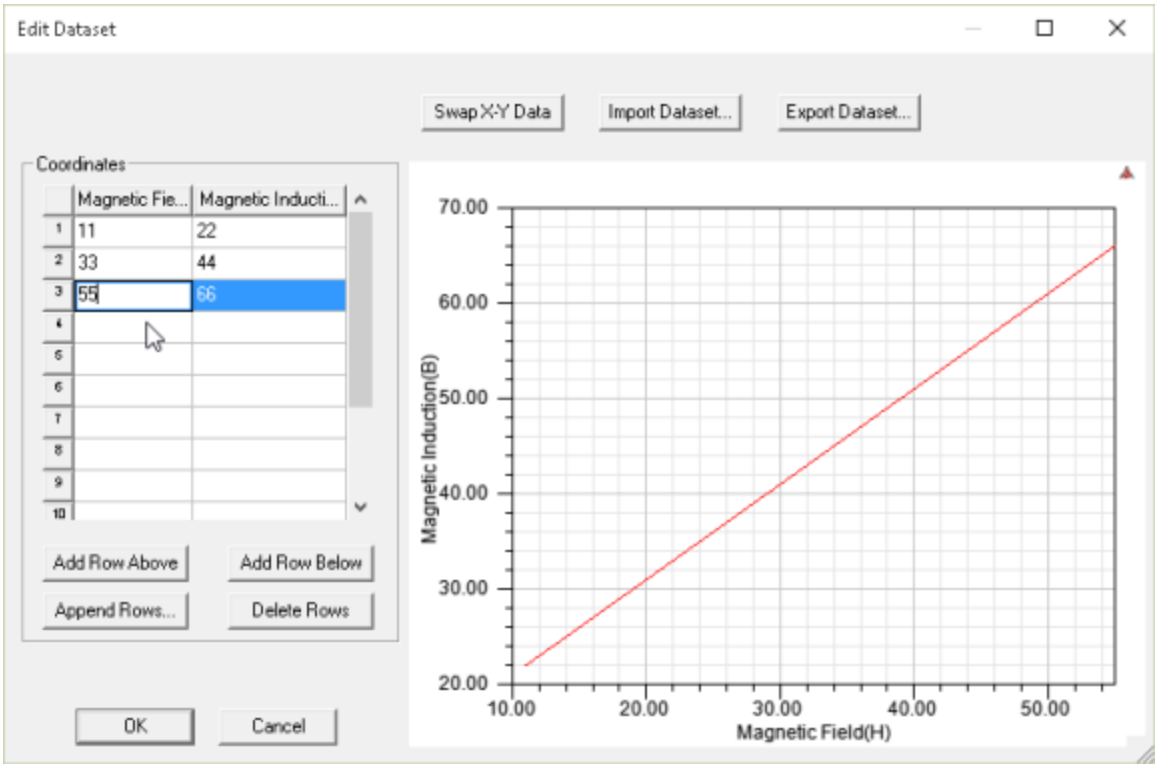
2. Choose a **Property type** from the drop-down menu: **Linear**, or **Nonlinear**, and do one of the following:
    a. For **Linear**, enter values for **Inverse Coefficient**, **Sigma max**, and **Sigma min**, where sigma represents mechanical stress.

    b. For **Nonlinear**, click the **Multi-curves** button

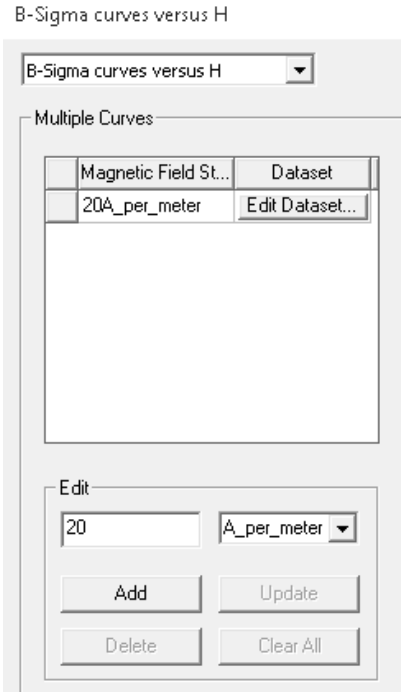
    to add one or more Stress dependent B-H curves, or H dependent B-Sigma curves.



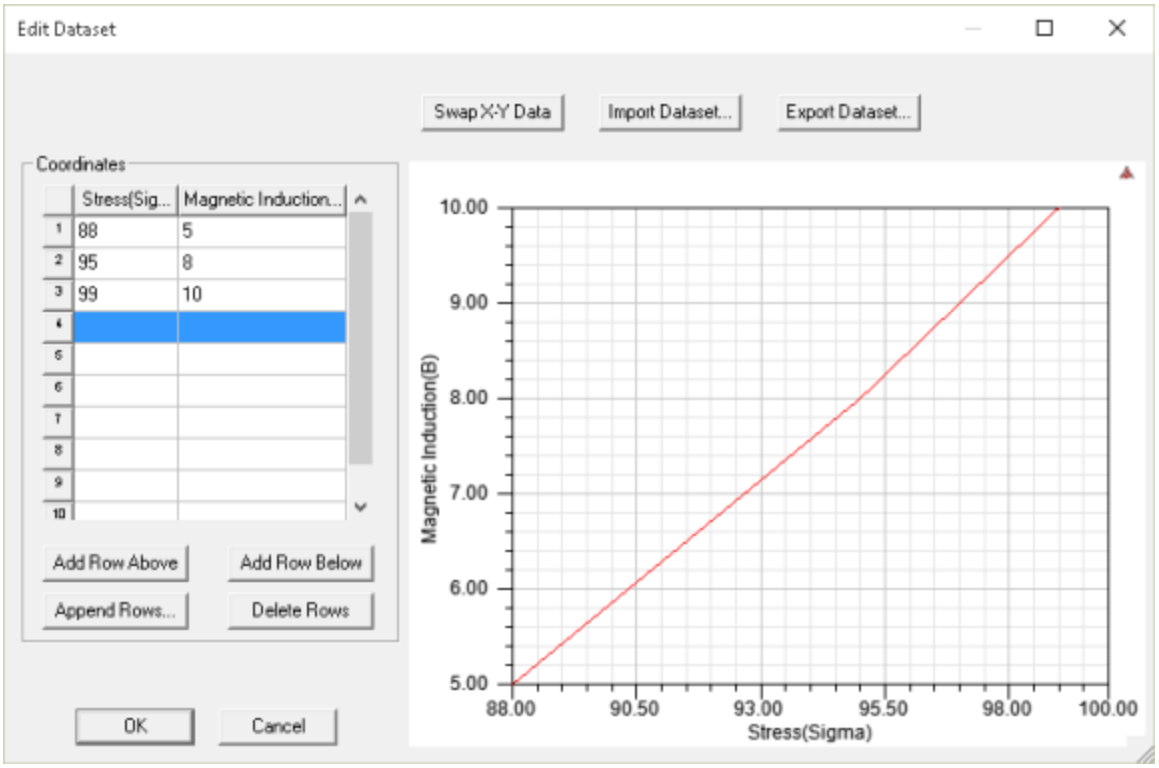
- For **B-H curves versus Stress** (as shown above) – Enter a stress value in the **Edit** text box and click **Add**; then click **Edit Dataset** to open the **Edit Dataset** dialog box, in which you enter coordinate values for the **Magnetic Field (H)** and **Magnetic Induction(B)**.



- For **B-Sigma curves versus H** (as shown below) – Enter a magnetic field strength value in the **Edit** text box and click **Add**;



then click **Edit Dataset** to open the **Edit Dataset** dialog box, in which you enter coordinate values for the **Stress (Sigma)** and **Magnetic Induction(B)**.



Note	Multiple BH curves vs stress are interpolated, but not extrapolated. Therefore, BH curves over the entire range of expected stress levels must be entered for positive stress (tensile stress pointing out of the object) and if anticipated negative stress (compressive stress pointing into the object).

When finished, click **OK** to close the dialogs and return to the **Inverse Magnetostriction** dialog.

3. Click **OK** to close the dialog and return to the **View/Edit Materials** window.

Calculating the Properties for Magnetostriction

Perfect Conductors

Perfect conductors are used in Maxwell to approximate the following:

- Magnetic field effects at a conductor surface when current flow is restricted to the conductor surface. This condition can exist in conductors with very high conductivity.
- The magnetic field at the surface of a conductor carrying high frequency current, modeled in the eddy current solver when the frequency is very high. Perfect conductors are used in

conjunction with Impedance Boundaries in the Eddy Current solvers to handle the following conditions:

a. The skin depth in the conductor is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the meshmaker may not be able to create a fine enough mesh in the conductor to compute eddy currents.
b. The magnetic field decays much more rapidly inside the conductor in the direction that's normal to the surface than it does in directions that are tangential to the surface.
c. The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

- Conductors in the Electrostatic solver where the voltage is constant in the conductor and there is no electric field penetration in the conductor.
- In the DC Conduction solver where a material contains a high conductivity.
- In conjunction with boundaries requiring the material on one side of the boundary to be the background region such as impedance or resistance boundaries.

Because of the special treatment of perfect conductors, no field solution is performed in these objects, saving time and computer resources when the approximation does not significantly change the field solution outside the conductor.

In order to define an object as a perfect conductor, do one of the following:

- Assign the Perfect Conductor material to the object in the Material Manager.
- Set the object to have a material with a conductivity greater than the conductivity defined in the *Material Threshold* section of the Design Settings dialog.

11 - Assigning Boundaries and Excitations for 3D Designs

For every project, you need to assign boundaries and excitations. For 3D designs, you can use the **Maxwell3D** menu or the project tree to do the following:

- Define boundary conditions that control how the electric or magnetic field behaves at object faces, planes of symmetry and periodicity, and edges of the problem region.
- Define excitations of voltage, charge, coil, and current.
- Identify conductors in which eddy currents are induced.
- For eddy current and magnetic transient projects, set up a winding and an external circuit connection.

Each field solver requires you to specify excitations of electric or magnetic fields and references for computing these fields.

- Magnetostatic Boundaries and Excitations
- Eddy Current Boundaries and Excitations
- Transient Boundaries and Excitations
- Transient A-Phi Formulation Boundaries and Excitations
- Electrostatic Boundaries and Excitations
- DC Conduction Boundaries and Excitations
- Electric Transient Boundaries and Excitations
- AC Conduction Boundaries and Excitations

You must specify at least one of the boundary conditions or excitations listed in these sections, so that the simulator can compute accurate values for fields and parameters.

Related Topics

Specifying the Solver Type

Selecting Objects and Faces in the Geometry

Before creating a boundary or excitation, you must specify its location by selecting the object or surface on which to assign the boundary condition or source excitation.

Defining Boundary Conditions

To assign a boundary condition:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell 3D>Boundaries>Assign**, or right-click **Boundaries** in the project tree and click **Assign**.

3. Select the desired boundary type from the sub-menu. The specific boundary types you can define depend on the solver you have chosen for your project.
    - Magnetostatic Boundary Conditions
    - Electrostatic Boundary Conditions
    - DC Conduction (Electric) Boundary Conditions
    - Eddy Current Boundary Conditions
    - Transient Boundary Conditions
    - Transient A-Phi Formulation Boundary Conditions
4. Enter the name for the boundary or accept the default.
5. Depending on the boundary type, you may need to define additional parameters.
6. Click **OK** to create the new boundary.

The new boundary is added to the boundary list in the project tree.

Related Topics

Setting a Symmetry Multiplier

Defining Excitations

The specific excitations you can define depend on the solver you have chosen for your project.

- Magnetostatic Excitations
- Electrostatic (Electric) Excitations
- AC Conduction (Electric) Excitations
- DC Conduction (Electric) Excitations
- Eddy Current Excitations
- Transient Excitations
- Transient A-Phi Formulation Excitations
- Electric Transient Excitation

To assign an excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D>Excitations>Assign**, or right-click **Excitations** in the project tree and click **Assign**.

   A submenu appears.
3. Select an excitation type from the submenu. The choices vary depending on the solver type you have chosen. Choices include:
    - Voltage
    - Voltage Drop
    - Charge
    - Volume Charge Density
    - Current Density
    - Current

- Permanent Magnet Field
- Sink

4. Enter the name for the excitation type or accept the default.
5. Enter the desired parameter values, units, and other settings for the excitation in the dialog box. You can also enter a mathematical function to determine values for voltage, current density, charge density, and other parameters. The Permanent Magnet Field excitation also requires you set up a link to a source project.

Note	When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Swap Direction** if you want to reverse the direction of the arrow.

6. Click **OK** to create the new excitation.

The new excitation is added to the excitation list in the project tree.

Viewing Boundaries and Excitations

To view a list of all boundaries or excitations set for the project:

1. In the project tree, right-click **Boundaries** or **Excitations**.
   A shortcut menu appears.
2. Select **List** from the shortcut menu.
   The **Design List** window appears, with the tab page visible for the item you selected. This window contains tabs for **Model**, **Boundaries**, **Excitations**, **Parameters**, **Mesh Operations**, and **Analysis Setup**.
3. To view the properties for an item in the list, select the item, and click **Properties**.
4. To delete an item from the list, select the item, and click **Delete**.
5. When you are finished in the **Design List** window, click **Done** to close it.

Setting the Visibility for Boundaries and Excitations

To show or hide a boundary:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Boundaries** tab.
3. Select or clear the **Visibility** check box for each boundary listed.
4. Click **Done**.

To show or hide a excitation:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Excitations** tab.

3. Select or clear the **Visibility** check box for each excitation listed.
4. Click **Done**.

Functional Boundaries and Excitations

Functional boundaries and excitations can be used to do the following:

- Define the value of a boundary or excitation quantity (such as the voltage, magnetic field, or current density) using a mathematical relationship — such as one relating its value to that of another quantity.
- Define the value of a boundary or excitation as a function of position.
  - Current Density Excitation (Magnetostatic or Eddy Current solver type)
  - Voltage Excitation (Electric solver types)
  - Volume Charge Density Excitation (Electrostatic or Electrostatic + DC solver types)
- If the parametric analysis capability was purchased, identify which boundary or excitation quantities are to be varied during a parametric sweep. These variables are always set to constant values in the parametric analysis.

Setting Eddy Effects and Displacement Current

(Eddy Current and/or Transient Solvers)

For both eddy current and transient solvers, you may need to specify the following additional setting:

- The behavior of eddy currents and the AC magnetic field in conductors. When you activate the **Eddy Effect** setting, the solver computes the induced eddy currents.

For eddy current solvers only, you may need to specify the following additional setting:

- The **Displacement Current** on the objects in the model.

Typically, background objects are excluded from eddy and displacement current settings.

To set eddy effects:

1. Select the elements of the geometry on which you want to apply the excitation.
2. Click **Maxwell3D>Excitations>Set Eddy Effects**.
   The **Set Eddy Effect** dialog box appears.
3. For each object in the list, select or clear the check boxes for **Eddy Effect** and **Displacement Current**. When selecting multiple entries, the changes are synchronized for all selected rows.

Note	Multi-select is supported by holding the **CTRL** or **Shift** key while clicking.

4. Click the **Select Object By Name** button to enter the name of a specific object for selection.
5. Optionally, click the **Use suggested values** button to set the **Eddy Effects** for all elements recommended by Maxwell3D.
6. Click **OK**.

The **Deselect All** button will deselect all selected objects in the list.

Setting Core Loss for Transient and Eddy Current Solvers

For a Transient or an Eddy Current solver design, you may include core loss calculations in the simulation on any object that has a corresponding **core loss definition** (with core loss coefficient settings) in the material library.

To set core loss, in the **General** tab of the dialog box:

1. Click **Maxwell>Excitations>Set Core Loss**.

   The **Set Core Loss** dialog box appears.

   You can also open the **Set Core Loss** dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Core Loss** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation> Set Core Loss**.
2. For each **Object** in the list, select or clear the check box for **Core Loss Setting** (if a corresponding core loss definition has been set). The **Defined in Material** column indicates whether the material assigned to each object contains a core loss definition. When selecting multiple entries, the changes are synchronized for all selected rows. Multi-select is supported by holding the **CTRL** or **Shift** key while clicking.
3. Click the **Select By Name** button to enter the name of a specific object for selection. Regular expressions are also supported.
4. Optionally, click the **Deselect All** button to deselect all selected objects in the list.
5. For 3D and 2D Transient solvers only, on the **Advanced** tab of the dialog box, you may select the option to **Consider core loss effect on field**. When selected, this option will estimate the core loss and subsequently modify the field solution, causing the resulting fields to be affected by the presence of the core loss. This option provides improved solution accuracy for materials exhibiting high core loss at the expense of increased solution time.

Note	• If the core loss model “hysteresis model” is chosen, then the “Consider core loss effect on field” checkbox is ignored, as the hysteresis model always models the effects of the hysteresis loss. • An iteration is required to consider loss effects on the field. For most really soft materials, the iteration is converged. However, if the loss coefficients kh and ke for magnetic steels, or Cm for power ferrites, are too large, the iteration could be diverged. In such cases, users need to double check the specified values, or not to consider core loss effects.

   The default is to exclude this effect. In this case, the field calculation is performed without the core loss and the loss calculation is performed after the field solution is complete.
6. Click **OK**.

Permanent Magnet Field Excitations for 2D and 3D Transient and Magnetostatic Solvers

(Maxwell 2D/3D Transient and Magnetostatic Solvers)

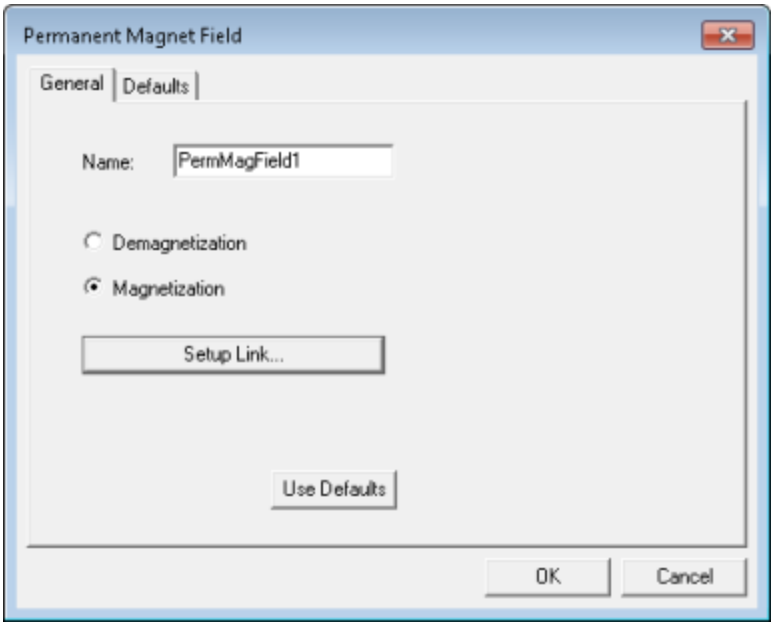
Links to demagnetization and magnetization computation *source* designs can be added as permanent magnet field excitations in *target* designs. A permanent magnet field excitation can be either *object-based* (assigned to geometry) or *design-based* (not assigned to geometry).

To add or edit a permanent magnet field excitation:

Note	The following procedure assumes that a *source* design, in which either the demagnetization or magnetization operating points computations of the magnet have been modeled, is available for linking. The *target* design object on which the Permanent Magnet Field is assigned should have a local coordinate system assigned. • This coordinate system must be right-(or left-)handed, the same as in the *source* design. • The *target* design object should be in the same quadrant of the new local coordinate system as the matching object in the *source* design.

1. Do one of the following:
   - If you are adding a new *design-based* permanent magnet field excitation, select **Maxwell 2D** or **3D>Excitations>Assign> Permanent Magnet Field**. Alternatively, in the Project Manager you can right-click **Excitations** to open its context menu, then select **Assign>Permanent Magnet Field**.
   - If you are adding a new *object-based* permanent magnet field excitation, select one or more objects (magnets) that you wish to include in the permanent magnet field excitation, then either select **Maxwell 2D** or **3D>Excitations>Assign> Permanent Magnet Field**, right-click **Excitations** in the Project tree to open its context menu and select **Assign>Permanent Magnet Field**.
   - If you are editing an existing permanent magnet field excitation, right-click on the excitation in the project tree and select **Properties** from the context menu.

2. In the **Permanent Magnet Field** dialog box, enter (or edit) the **Name** for the excitation - or accept the default.



3. Depending on how the *source* design which is to be linked has been configured using **Set Demagnetization/Magnetization Computations**, choose either **Demagnetization** or **Magnetization** for the excitation type, then click **Setup Link**.
4. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.  To enable settings, you can select **Edit Link**.

5. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to

Open as read only.

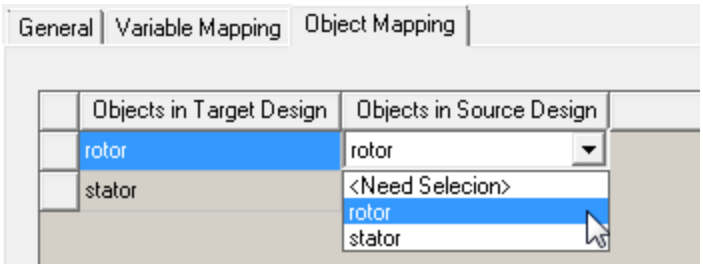
Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.

6. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.”
7. Use the check box to specify whether to **Simulate source design as needed**.
8. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
9. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variable by Name** to automatically map same named variables.
10. For object-based permanent magnet field excitations only, the **Object Mapping** tab lets you map objects in the target design to objects in the source design.



11. Click **OK** to close the **Setup Link** dialog box and return to the **Permanent Magnet Field** dialog.
12. Optionally, the **Defaults** tab allows you either to save the user-defined data for the excitation as the default for initializing new excitations of this type, or to clear any existing user-defined defaults and revert to standard defaults.
13. When finished, click **OK** to accept the settings and close the dialog.

"Setting Demagnetization/Magnetization Computations for Source Designs " below

Setting Demagnetization/Magnetization Computations for Source Designs

(2D and 3D Magnetostatic and Transient Solvers)

When a magnetic device with permanent magnets is overloaded, or after a short circuit, irreversible demagnetization may occur due to magnetic field and temperature changes. As a result, the subsequent operating point will no longer lie along the original BH curve, but along the demagnetized recoil line at the worst operating condition.

This process can be modeled in Maxwell using **Set Demagnetization/Magnetization Computations**. The demagnetization/magnetization process of the magnet is modeled in the *source* design, and the practical normal application is modeled in the *target* design.

The linked demagnetization or magnetization designs act as sources (excitations) in the target design. These links are managed as Permanent Magnet Field excitations. Users can setup either object-based or design-based links. The Hc outputs from the source design are mapped to the target design mesh, thus eliminating the restriction of target/source designs employing the same geometries.

Note	This mapping is straightforward for non-hysteresis based models because the Hc output from the source design is a single value plus direction per mesh element. For hysteresis-based models, the Hc output from the source design is a demagnetizing curve per mesh element, and a mapping approach is non-trivial. Thus this process is not applicable when the design has any object modeled with hysteresis materials. Demagnetization/magnetization links for this type of design continues to require the same mesh between target and source designs. **Limitations** • A design can only be the target for either magnetization or demagnetization, but not both. • A design can compute either magnetized or demagnetized operating points, but not both. • Object-based and design-based links cannot coexist. • Object-based links are not supported when there is any object assigned with a hysteresis-based material model.

For the magnetization computation, Maxwell provides two possibilities: **anisotropic magnetization**, and **isotropic magnetization**.

For **anisotropic magnetization** the magnetization direction is determined by the direction specified by the user in the field for the Unit Vector input of Magnetic Coercivity on the panel of View/Edit Material during material setup.

For **isotropic magnetization**, the magnetization direction is determined by the orientation of the computed magnetizing field from the field solution. In such a case, the user has to set *all three* components of the Unit Vector input of Magnetic Coercivity to *zero (0)* on the panel of View/Edit Material during material setup so that Maxwell knows the direction is computed, rather than specified by user.

General Procedure for Setting Demagnetization/Magnetization Computations for Source Designs

To set demagnetization/magnetization process computations for a *source* design:

Note	Demagnetization/Magnetization points computation settings specific to the Hysteresis Model-Based Magnetization Approach are described in the *Using the Hysteresis Model-Based Magnetization Approach* section.

1. Click **Maxwell>Excitations>Set Magnetization Computation** to open the **Set Demagnetization/Magnetization Computations** dialog box. You can also open the dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Magnetization Computation** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation> Set Magnetization Computation**.

   By default, **No operating points computation** is selected.

2. Select either the **Compute demagnetized operating points** or **Compute magnetized operating points** radio button. At least one object must be selected to compute data if **Compute magnetized operating points** is selected.

Note	Multi-select is supported by holding the **CTRL** or **Shift** key while clicking.

Note	An object coordinate system (CS) must be created and assigned to each magnet object in the history tree.

3. Click **OK** to accept the settings and close the dialog.

The configured source design can now be linked to if you want to create "Permanent Magnet Field Excitations for 2D and 3D Transient and Magnetostatic Solvers " on page 11-6 .

Technical Notes: *3D Transient Excitations (Sources)*

Technical Notes: *2D Sources/Excitations*

Using the Hysteresis Model-Based Demagnetization/Magnetization Approach

(Transient Solver Only)

> **Note:** Transient A-Phi Formulation does not support the Hysteresis Model.

Currently, demagnetization is modeled based on single demagnetization curve in the 2nd quadrant, possibly extended to the 3rd quadrant in the user-specified direction. Hysteresis-based demagnetization is able to consider magnetization and demagnetization behavior at the same time in all directions, not just user-specified initial direction.

To enable hysteresis model-based demagnetization, and set the Demagnetization/Magnetization computations for source designs:

- Define the hysteresis loop by inputting the descending branch of a hysteresis loop (not supported by defining Hysteresis Model under Core Loss Model).
- Set the initial demagnetizing direction for the starting point on the hysteresis loop by setting the direction in the field for the Unit Vector input of Magnetic Coercivity on the panel of View/Edit Material during material setup. (The initial value is inherently described by the point (Hc = 0 and B = Br).

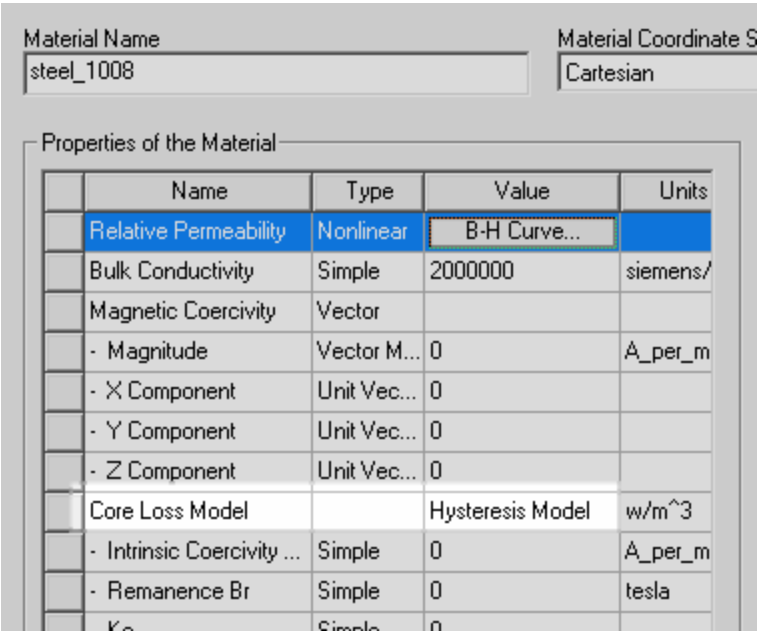
If a problem setting does not satisfy the above two conditions at the same time, the transient solver will use the “classic” approach to simulate demagnetization process if possible. Note that the valid descending branch of a hysteresis loop should be input with the same absolute values (H and B) for the 1st point and the last point. This modeling approach is not supported for TDM since the modeling of hard hysteresis material cannot be supported by Time decomposition Method (TDM).

Using the Hysteresis Model-Based Magnetization Approach

(Transient Solver Only)

> **Note:** Transient A-Phi Formulation does not support the Hysteresis Model.

With the introduction of vector hysteresis modeling capability in the transient solver, it is now possible to simulate the hysteresis model-based magnetization process if a user defines a normal nonlinear BH curve in the 1st quadrant together with the input of Hc (or additional Br for better accuracy of hysteresis loop construction) by selecting **Hysteresis Model** under **Core Loss Model** for the material.



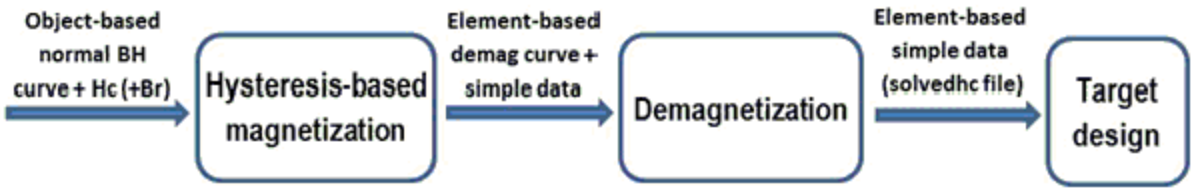
In such a case, magnetization is always considered as isotropic magnetization, that is, magnetization direction is determined by the orientation of the computed field. If a user defines only a normal nonlinear BH curve in the 1st quadrant without defining the Hysteresis model, the transient solver will use the “classic” approach to simulate magnetization process.

Classic Magnetization Approach

Using the classic magnetization approach, if the geometry in the source and target designs is the same, Maxwell maps the computed magnetization data element–by–element. However, the geometry in the source and target designs need not be identical, in which case the geometries in the two designs will be mapped by the solver using the object name. For example, magnetization data on “Box1” in the source design will be applied to the object called “Box1” in the target design. The user must ensure that the source and target object names are identical. The source design

will compute magnetization data on the selected objects, while the target design will use the dynamic data in its simulation.

Hysteresis Model-Based Magnetization Approach



Using the hysteresis model-based magnetization approach, after the completion of the last time step before stop, the hysteresis model for each element will generate the element-based demagnetization curve originated at the last operating point. As a result, the output from the magnetization modeling process is an element-based demagnetization curve, rather than a constant. Consequently an additional demagnetization process is required based on the element-based demagnetization curve. In this approach, use of the same mesh between the source and the two target designs is required due to the use of the element-based demagnetization curve as the output of magnetization simulation.

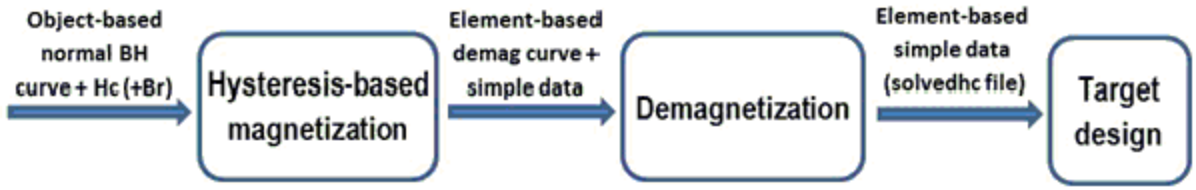
Note	• If an object is defined as hysteresis model, but not selected for magnetization, the object is no longer considered as a hysteresis material because magnetization and hysteresis modeling cannot be conducted in the same design. • Hysteresis based magnetization is always considered as isotropic magnetization, that is, its direction is determined by the orientation of the computed field. • For objects that have been selected for magnetization, but not defined as hysteresis models, the existing classic approach (*simple data* in the diagram above) will be used. Mixing hysteresis model-based magnetization method with the classic magnetization method is supported. • For the classic approach, no demagnetization step is required; while for the hysteresis model-based magnetization approach, a demagnetization step is normally required. For the demagnetization step, the input is the element-based demagnetization curve derived from the magnetization run. • When **Clean Stop** is invoked for projects in which a TDM transient source design is linked to a transient target design, after completion of the source design the solution process can continue from the target design. In such a case, the target design must be non-TDM.

Design Criteria

- The source design must have objects assigned with non-linear, non-permanent-magnet material properties.
- The same design cannot be the source for both magnetization and demagnetization links.

- The source design cannot also be a target of a demagnetization link.
- The target design cannot also be a target or source of a demagnetization link.

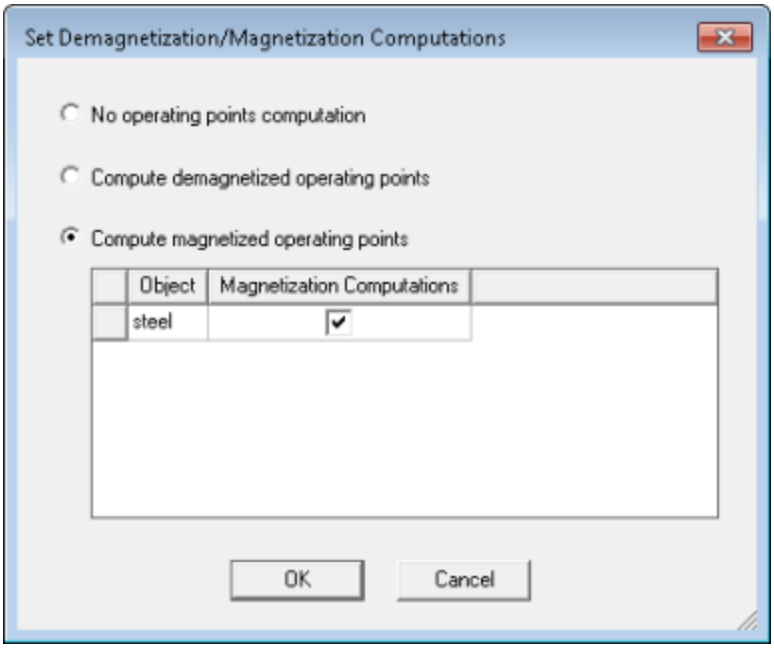
The hysteresis model-based magnetization approach requires three designs.



First Design: Set up a *Hysteresis-based magnetization computation* design (the source design)

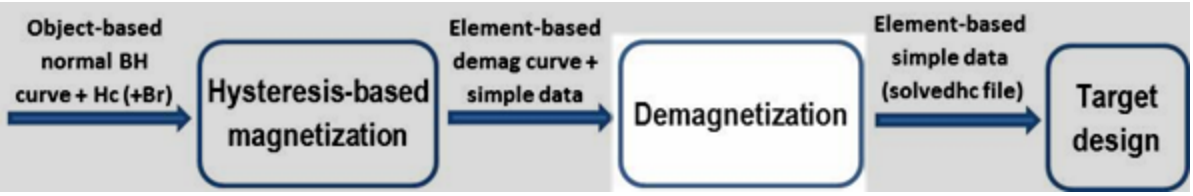
1. Create a Maxwell 2D or 3D magnetic transient design (the *Hysteresis-based magnetization* design in the figure shown above).
2. Click **Maxwell>Excitations>Set Magnetization Computation** to open the **Set Demagnetization/Magnetization Computations** dialog box .

   You can also open the **Set Demagnetization/Magnetization Computations** dialog box by right-clicking **Excitations** in the Project Manager, then selecting **Set Magnetization Computation** on the context menu; or by right-clicking in the Modeler window and selecting **Assign Excitation> Set Magnetization Computation**.
3. Select **Compute magnetized operating points**, and select the objects for magnetization and/or hysteresis-based magnetization computation, then click **OK** to accept the settings and close the dialog.

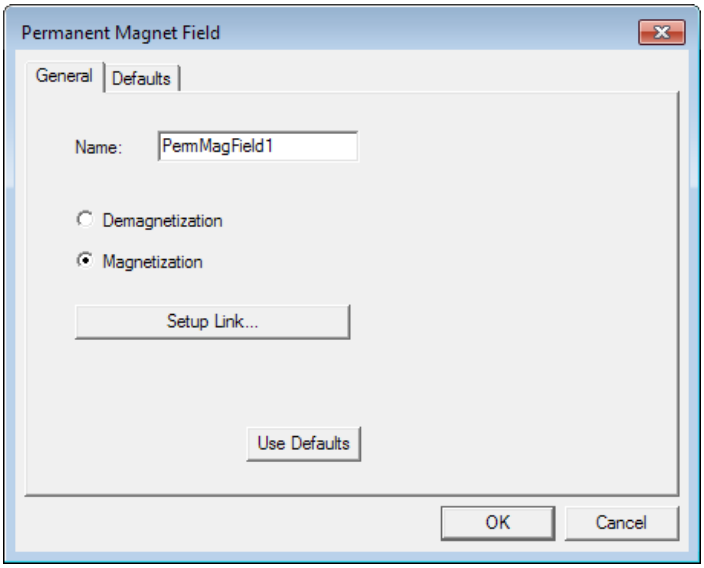


4. Solve the design and the solution will include the element-based magnetization data, and/or Hysteresis-based demagnetization curve if the design uses nonlinear materials with non-zero Hc defined.

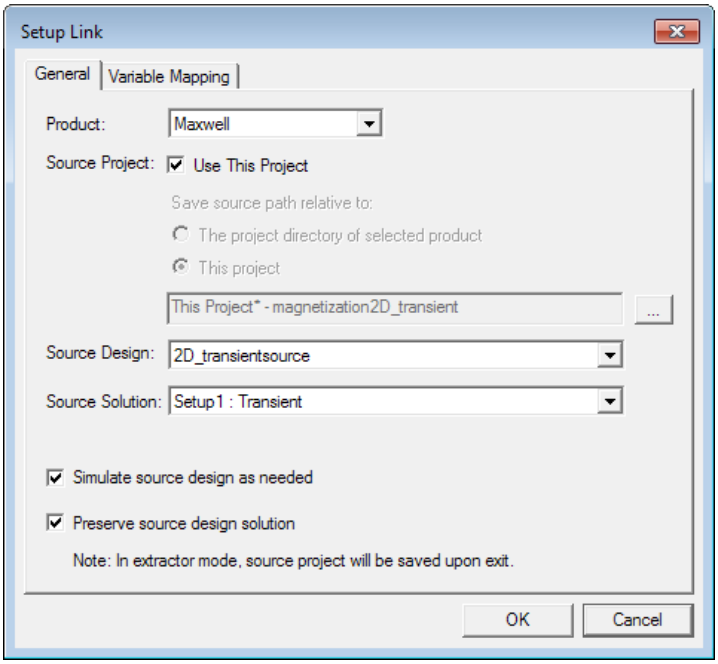
Second Design: Set up a *Demagnetization* design using the output of the Hysteresis-based magnetization computation



1. Create another Maxwell 2D or 3D magnetic transient design to be used as the *Demagnetization* design (highlighted above).
2. In the Project tree, right-click **Excitations** and select **Assign> Permanent Magnet Field**.
3. In the **Permanent Magnet Field** dialog box, select **Magnetization**, then click **Setup Link.**

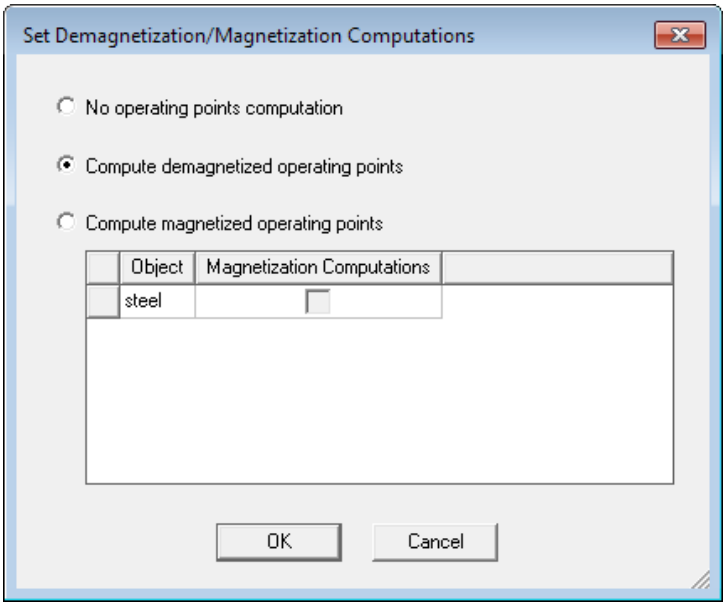


4. Set up a link to the *Hysteresis-based magnetization computation* source design (the first design you set up), which provides the hysteresis-based magnetization solution data. Check **Simulate source design as needed** and **Preserve source design solution**. If the source design is not set up to **Compute magnetized operating points**, an error message will be issued.



5. Right-click **Excitations** in the Project tree and select **Set Magnetization Computation** on the context menu to open the **Set Demagnetization/Magnetization Computations** dialog

box, and select **Compute demagnetized operating points**.

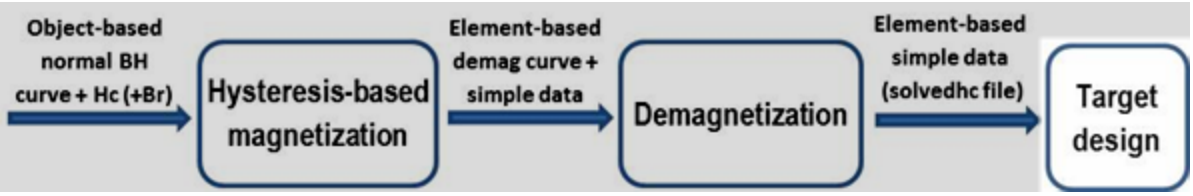


Note	Steps 6 and 7 are applicable only for *object-based* magnetization/demagnetization links. Omit these steps if *design-based* magnetization/demagnetization links are used.

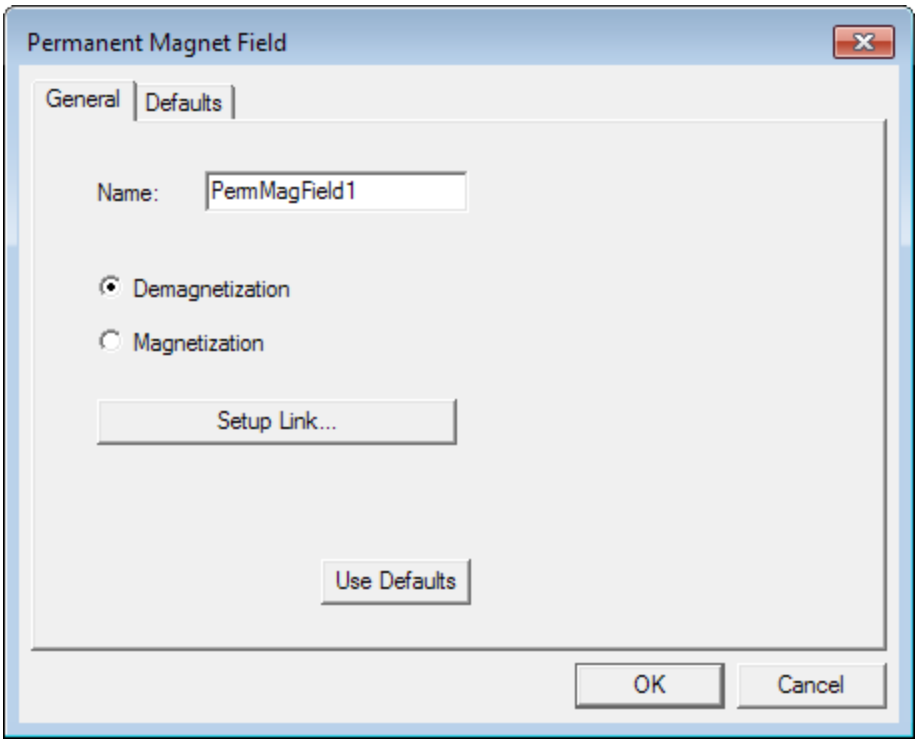
6. Open the **Solve Setup** dialog and select **Import mesh** on the **Advanced** tab to open the **Setup Link** dialog.
7. In the **Setup Link** dialog box, for the **Source Design**, choose the *Hysteresis-based magnetization computation* (the first design you set up).
8. Solve the design and the solution will include the element-based demagnetization distribution curve (which is based on the Hysteresis-based magnetization data). If the source design has not been solved, solving the current (demagnetization) design causes the source design to be solved first.

Note	To ensure that new data from the source design is used if the source design has been modified, right-click the Analysis icon of the source design in the project tree, and click **Clear Linked Data**. This flushes existing linked data so that solving the current design will force the source design to be solved first.

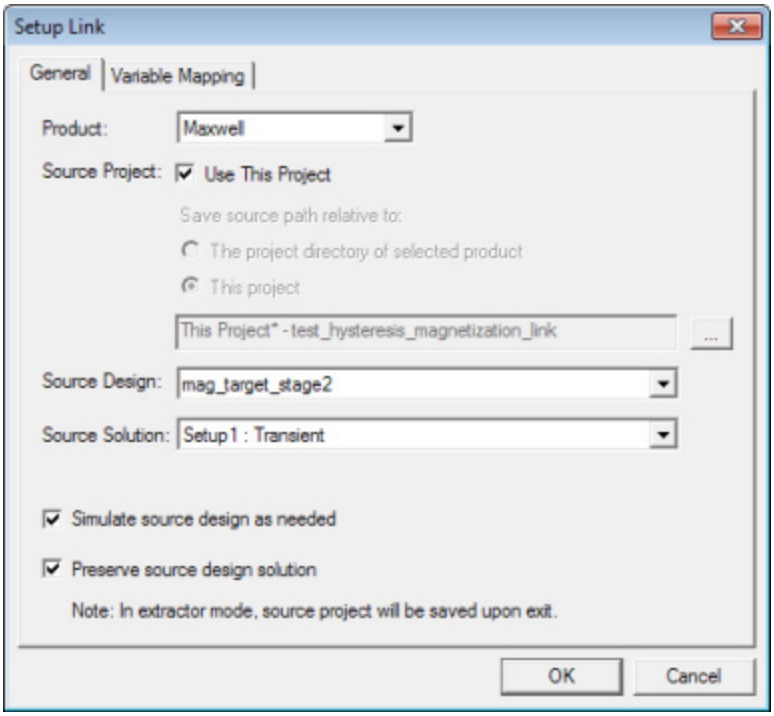
Third Design: Set up the *Target* design



1. Create a third Maxwell 2D or 3D magnetic transient design to be used at the *Target* design (highlighted above).
2. In the Project tree, right-click **Excitations** and select **Assign> Permanent Magnet Field**.
3. In the **Permanent Magnet Field** dialog box, select **Demagnetization**, then click **Setup Link.**



4. Set up a link to the *Demagnetization* design (the second design created above), which provides the dynamic demagnetization distribution solution data (based on the *Hysteresis-based magnetization* solution data from the first design). Be sure to check **Simulate source design as needed** and **Preserve source design solution**.



Note	Steps 5 and 6 are applicable only for *object-based* magnetization/demagnetization links. Omit these steps if *design-based* magnetization/demagnetization links are used.

5. Open the **Solve Setup** dialog and select **Import mesh** on the **Advanced** tab to open the **Setup Link** dialog.
6. In the **Setup Link** dialog box, for the **Source Design**, choose the *Demagnetization* design (the second design created above).
7. Solve the *Target* design. If the source designs for Hysteresis-based magnetization computation and Demagnetization are not yet solved, solving the current (target) design causes the two source designs to be solved in sequence first.

Note	To ensure that new data from the source designs is used if the source designs have been modified, right-click the Analysis icon of each source design in the project tree, and click **Clear Linked Data**. This flushes existing linked data so that solving the current design will force the source designs to be solved first.

Showing and Verifying Conduction Paths

To show the conduction paths in the geometry:

1. Click **Maxwell>Excitations>Conduction Paths>Show Conduction Paths**.
   The **Conduction Path Visualization** window appears.
2. Click a path in the list.
   The path is highlighted in the model.
3. Click **Close** when you are done viewing conduction paths.

To verify conduction paths:

- Click **Maxwell>Excitations>Conduction Paths>Verify Conduction Paths**.
  The paths are traced in the model diagram.

Related Topics

Recalculating Conduction Paths

Recalculating Conduction Paths

Conduction paths are not recalculated unless a design changes results in a different outcome.

You can force a recalculation by using the **Maxwell>Excitations>Conduction Paths>Recalculate Conduction Paths** command.

The **Recalculate Conduction Paths** command is similar to the **Verify Conduction Paths** command. The only difference is that the **Recalculate** command recalculates every time, even if there are no changes that influence the conduction paths.

Note	The **Recalculate Conduction Paths** command does not apply for electrostatic solution types.

To recalculate conduction paths for the active project:

- Click **Maxwell>Excitations>Conduction Paths>Recalculate Conduction Paths**.

Showing and Verifying Conduction Paths

Modifying Boundary Conditions and Excitations

Save your project before modifying boundary conditions and excitations. You can modify boundary conditions and excitations after a solution has been generated, but you may lose some solution data.

Duplicating Boundaries and Excitations

To duplicate a boundary or excitation when its geometry is pasted or duplicated:

1. Click **Tools>Options>General Options** to open the **Options** dialog box, displaying a hierarchical list of options. Click the + next to **Maxwell 2D** and select **Boundary Assignment**.
2. Select **Duplicate boundaries/mesh operations with geometry**.
3. Click **OK**.

   All boundaries and excitations are duplicated with their associated geometries until you clear this option.

Hint	Use this option to copy and paste boundaries. For example, do the following to use the same boundary on multiple objects: 1. Select the face to which you want to assign the boundary. 2. Click **Modeler**>**Surface**>**Create Object From Face** to create a new object from the existing face. 3. Assign the boundary to the new face object. 4. Copy and paste the new face object to copy and paste the boundary.

Copying and Pasting Objects

Showing and Hiding Boundaries and Excitations

You can choose to show or hide a boundary or excitation's geometry, name, or vectors, in the active view window or in all view windows.

Showing and Hiding Boundaries and Excitations in Every View Window

1. Click **Maxwell>Boundaries>Visualization** or **Maxwell>Excitations>Visualization**. The **Visualization Options** window appears.
2. Select one of the following from the **Select** pull-down menu:
   - All
   - All Boundaries
   - All Excitations
   - All Ports
   - By Name
3. If you select **By Name**, enter a name in the **Select By Name** window, and click **OK**.
4. To clear the selection of all boundaries and excitations, click **Deselect All**.
5. Click **Close** to close the **Visualization Options** window.

Setting Default Values for Boundaries and Excitations

When assigning a boundary or excitation, many of the fields in the boundary and excitation dialog boxes have default values associated with them. These default values are initially set by Maxwell, but can be overridden.

To modify the default values associated with a specific boundary or excitation type:

1. Assign a boundary or excitation.
2. Modify any default values.
3. Close the boundary or excitation's dialog box.
4. Re-open the new boundary or excitation's dialog box. It now includes a **Defaults** tab.
5. Under the **Defaults** tab, click **Save Defaults**.

   The values assigned to this boundary are saved as the default values and are assigned when new boundaries of this type are created.
6. Optionally, click **Revert to Standard Defaults**.

   The default values you set for this boundary type are cleared and will revert to the default values set by Maxwell.

Reassigning Boundaries

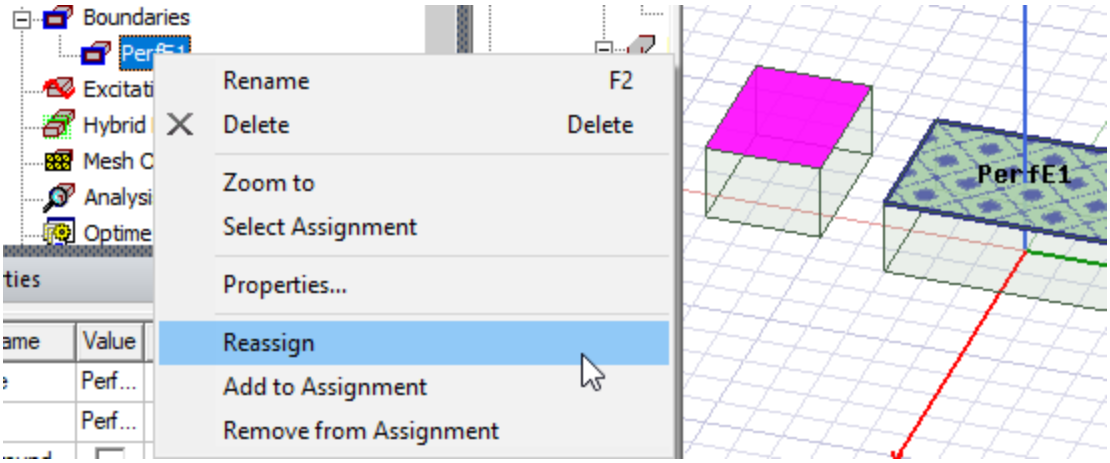
You can reassign a boundary to another surface. This is useful when you have modified objects with assigned boundaries, invalidating the boundaries. For example, if you unite two objects with assigned boundaries, the second object's boundary will become invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the boundary or delete it. You can use a **Reassign Boundary** dialog box accessed through the **Maxwell>Boundary>Reassign** menu, or right-click on the Boundary of interest in the **Project** tree, and select from the shortcut menu to **Reassign**, **Add to Assignment**, or **Remove from Assignment**. You can also determine current assignments by right-clicking on the boundary on the Project tree and using the **Select Assignment** command on the short cut menu.

Prerequisites:

- You must first select the surface or object that you want to reassign, or add to an assignment, or remove from an assignment.

To use the short-cut menu to reassign, add assignment, or remove from assignment:

1. With the target surface selected, right-click on the Boundary of interest to invoke the menu.



2. Select from the menu to make the change you want.

   The boundary assignments change.

Note	When reassigning a boundary that includes vectors in its definition, Ansys Electronics Desktop attempts to preserve the vectors with the new assignment, but this is not always possible.

Deleting Boundaries

Reassigning Excitations

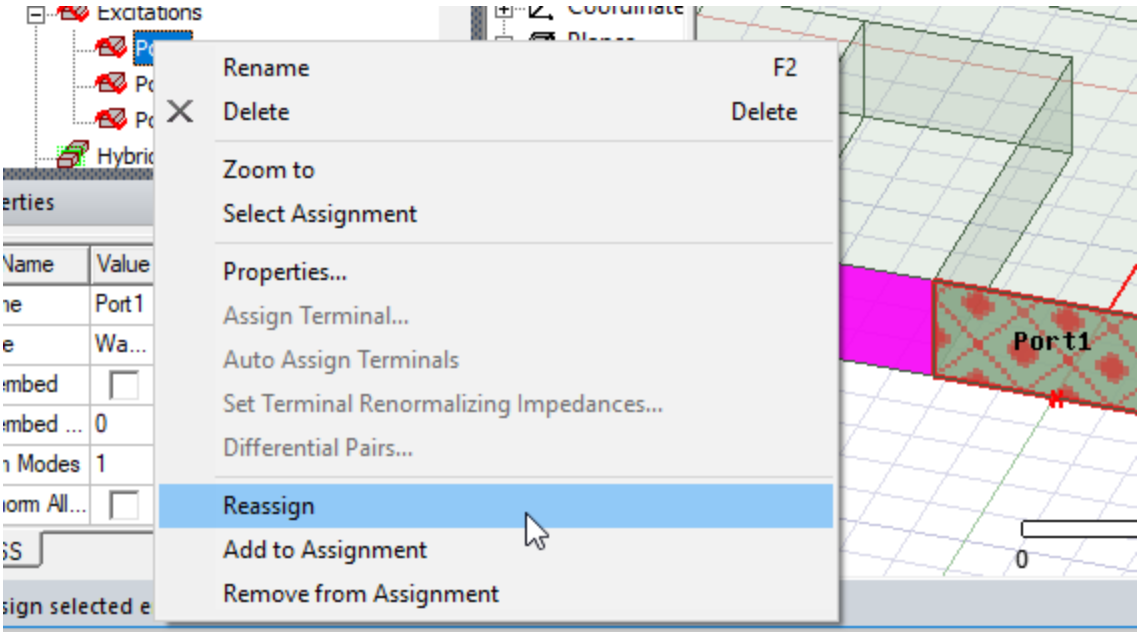
You can reassign an excitation to another surface. This is useful when you have modified objects with assigned excitations, invalidating the excitations. For example, if you unite two objects with assigned excitations, the second object's excitation will become invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the excitation or delete it. You can use a **Reassign Excitation** dialog box accessed through the **Maxwell>Excitation>Reassign** menu, or right-click on the Excitation of interest in the Project tree, and select from the shortcut menu to **Reassign**, **Add to Assignment**, or **Remove from Assignment**. You can also determine a current assignment by right-clicking on the excitation in the **Project** tree and by using the **Select Assignment** command on the short cut menu.

Prerequisites:

- The surface to which you want to **Reassign**, or **Add to Assignment** must be on the same plane as existing assignment. It does not have to be in contact to **Reassign**, but must be in contact to **Add to Assignment**.
- You must first select the surface that you want to reassign or add to an assignment.

To use the short-cut menu to reassign or add an excitation:

1. With the target surface selected, right-click on the Excitation of interest to invoke the menu.



2. Select **Reassign** to change the assignment to the selected surface, or **Add to Assignment** to include surface.

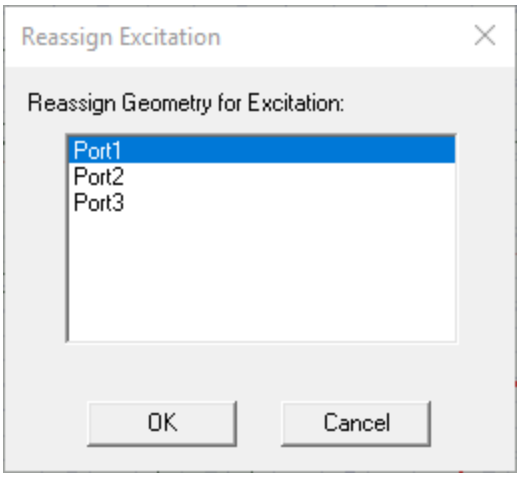
To use the shortcut menu to Remove a selected surface from an assignment:

1. With the target surface selected, right-click on the Excitation to invoke the menu.
2. Click **Remove from Assignment**.

To use the Maxwell Menu and the Reassign Excitation dialog box:

1. Select the object or object face to which you want to assign an existing excitation.
2. Click **Maxwell>Excitations>Reassign**.

   The **Reassign Excitation** window appears.



3. Select an existing excitation from the list, and then click **OK**.

   The excitation is reassigned to the object or object face.

Hint	When reassigning an excitation that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Showing and Hiding Boundaries and Excitations

Modifying Boundaries

Deleting Boundaries

Deleting All Boundaries and/or Excitations

To delete all boundaries or excitations:

- Click **Maxwell>Boundaries>Delete All** or **Maxwell>Excitations>Delete All**.

Reprioritizing Boundaries

Each boundary you assign overwrites any existing boundary with which it overlaps. You can change the priority of a previously assigned boundary to be greater than a more recently assigned boundary.

The order of boundaries and excitations is important because, for any given triangle of the mesh, only one boundary or excitation can be visible to the solvers. The highest priority boundary condition applied on a certain surface overwrites the lower priority one(s) applied on the same surface. If any surfaces with boundary conditions have a partial overlap, then in the overlap region, the precedence rule applies. The highest priority boundary condition takes precedence over the lower one(s) such that for all mesh nodes on any surface carrying a boundary condition, only one boundary condition is actually enforced and visible to the solver.

Excitations cannot be reprioritized. Only boundaries can be reprioritized.

To reprioritize boundaries:

1. Click **Maxwell>Boundaries>Reprioritize**.

   The **Reprioritize Boundaries** window appears.

Note	The order the boundaries initially appear in the **Reprioritize** dialog box list indicates the order in which they were defined. The lowest priority assignment **always** appears at the top of the list.

2. Drag the boundary you want to change to the desired order of priority (to select the entity, click in the left-most column).

Note	The order of boundaries and excitations in the project tree is alphabetical. The order does not correspond to the order in which boundaries and excitations are visible to the solvers.

3. Click **OK**.

Viewing and Editing Boundary or Excitation Properties

To open the **Properties** window for a boundary or excitation that is already assigned:

1. In the project tree, under either **Boundaries** or **Excitations**, right-click a specific boundary or excitation, and select **Properties**.
   The **Properties** window for that boundary/excitation appears.
2. Make the desired changes, and click **OK**.

Set Default Boundary/Excitation Base Name

When setting boundaries and excitations on multiple selected surfaces, separate boundary or excitation definitions may be made automatically. Individual entries in the **Project Tree** will be identified with a **Base Name** and assigned a sequential numerical value appended to the base name.

The **Set Default Boundary/Excitation Base Name** dialog allows the base names for all boundary and excitation type to be specified for the current project. To set the base name for a boundary or excitation type:

1. Scroll the table to the boundary or excitation of interest.
2. Select the value in the **Default Name** column in the row of interest and enter the new base name.
3. Click **OK** to accept the changes and dismiss the dialog box.

All base names may be reset to the factory default list by clicking **Revert All**, or individuals may be reset by first selecting the **Default Name** to be reset and clicking the **Revert Selected** button.

Magnetostatic Boundaries and Excitations

Define at least one of the following as a source of static magnetic fields:

- The current in a conduction path, which can be either stranded or solid.

Note	For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- The current density in a conductor.
- The voltage differential across a conduction path.
- The magnetic field on an outside surface.
- A permanent magnet.

If currents or current densities are the only sources of static magnetic fields in your model, set at least one of the following as the outer boundary:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Technical Notes: Magnetostatic Field Calculation

Specifying the Solver Type

Magnetostatic Boundaries

The magnetostatic field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — **H** is continuous across the boundary. • Neumann boundaries — **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Zero Tangential H Field	Flux is perpendicular if tangent components are zero or if a zero tangential H-field boundary was applied.	External magnetic fields.
Tangential H Field	The tangential components of **H** are set to pre-defined values.	External magnetic fields.
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary	Cases such as the boundary around the hole that remains when a motor's shaft is excluded.

	(where integration of the tangential H field is non-zero), nor the Zero Tangential H Field boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	
Insulating	Same as Neumann, except that current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **H** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.

Default Boundary Conditions for a Magnetostatic Solver

These boundary conditions are automatically defined for a magnetostatic model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Magnetic H Field for a Magnetostatic Solver

This type of boundary defines external magnetic fields in a model. Assign it only to the outer surfaces of the problem region.

Warning	When using tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated.

Note	The specific boundary types you can define depend on the solver you have chosen for your project. • Electrostatic Boundary Conditions • DC Conduction Boundary Conditions • Magnetostatic Boundary Conditions • Eddy Current Boundary Conditions

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

To define a tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell>Boundaries>Assign>Tangential H Field**.
   The **Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the field component in the x-direction in the **U (X)** box and the value of the field component in the y-direction in the **V(Y)** box.
5. In the **Coordinate System** section, do the following to define the vectors:
   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face.
   b. Click two points to specify the vector.
      The vector is set, and the **Tangential H Field** window reappears, with **Defined** listed for **U Vector**.
   c. To reverse the direction of the vector, click the **Reverse Direction** check box.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Integrated Zero Tangential H Field Boundary for a Magnetostatic Solver

This type of boundary is applied when the integral of the tangential H field is zero.

Warning	When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated.

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Integrated Zero Tangential H Field**.
   The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Insulating Boundary for a Magnetostatic Solver

This boundary condition is used to model very thin sheets of perfectly Insulating material between touching conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Insulating**.
   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Symmetry Boundary Condition for a Magnetostatic Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** window appears.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**H** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**H** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Warning	When using even symmetry boundaries, double-check that Ampere's law is not violated.

Assigning an Independent Boundary for a Magnetostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears

5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a Magnetostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
      When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.
6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Magnetostatic Excitations

The following excitations of magnetic fields are available for magnetostatic problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or a sheet object.
Voltage Drop	The voltage drop across a sheet object.
Current Density	The known current density distribution in a conductor. In this case, the current density terminal must also be defined.
Current	The total current in a conductor.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Resistance Voltage Drop	Resistance Voltage Drop for both a stranded and solid conductor.

In addition, permanent magnets serve as sources of magnetic fields.

Warning	If voltage sources are used as excitations, for current to flow, you must define a minimum of two voltage excitations or a voltage drop per conduction path. Each excitation must be set to a different voltage. Current flows from surfaces at higher voltages to surfaces at lower voltages.

Note	When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

Assigning a Voltage Excitation for a Magnetostatic Solver

This type of excitation sets the voltage on a surface to a specific value. Use it to set up a voltage drop across a conduction path to cause current to flow.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell>Excitations>Assign>Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter a value for the voltage in the **Value** box, and select the units from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Warning	For current to flow, you must define a minimum of two voltage excitations or a voltage drop. Each excitation must be set to a different voltage. Current flows from surfaces at higher voltages to surfaces at lower voltages.

Assigning a Voltage Drop Excitation for a Magnetostatic Solver

This type of excitation sets the voltage drop across a sheet object to a specific value. The voltage drop applies only to sheet objects:

To set a voltage drop:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell>Excitations>Assign>Voltage Drop**.
   The **Voltage Drop Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the voltage drop on the surface in the **Value** box, and select the units from the pull-down list.
5. To change the direction of the voltage drop, click **Swap Direction**.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation for a Magnetostatic Solver

This command specifies the x-, y-, and z-components of the current density in a conduction path. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell>Excitations>Assign>Current Density**.
   The **Current Density Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **X Component**, **Y Component**, and **Z Component** values to define the respective components of the current density vector.
   b. Do the following in the two **Coordinate System** pull-down lists:
      - From the first pull-down list, select either **Global** or **RelativeCSx** (where x = 1,2,3… if any relative coordinate systems have been defined).
      - From the second pull-down list, select **Cartesian**, **Cylindrical**, or **Spherical**.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

To complete the current density definition, you also need to specify any related current density terminals, which must be assigned to a 2D object or face of the respective conduction path.

To define a current density terminal:

1. Select the 2D object or face to which to assign the terminal.
2. Click **Maxwell>Excitations>Assign>Current Density Terminal**.
   The **Current Density Terminal Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a Magnetostatic Solver

Specifies the total current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To set a current excitation:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a face or other 2D planar object).
2. Click **Maxwell>Excitations>Assign>Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current in the **Value** box, and select the units from the pull-down list.
   b. Select **Solid** or **Stranded** as the **Type** of conductor. For a stranded conductor, a uniformly distributed current density is assumed.
   c. Click **Swap Direction** to change the direction of the current flow.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup for a Magnetostatic Solver

Note	• If you wish to define a winding for an Eddy Current solution type, refer to "Assigning a Winding Setup for an Eddy Current Solver " on page 11-81 . • If you wish to define a winding for a Transient solution type, refer to Assigning a Winding Setup for a Transient Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 3D>Excitations>Add Winding**. to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, or **Resistance Voltage Drop** from the **Type** drop-down menu.
   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
   c. Enter values in the following fields (enabled according to winding type), and select the desired units.

For a current winding	For a resistance voltage drop winding[1]
Current	Resistance
	Voltage

Note	You can also type a function as an expression for any of these fields.

   d. Enter a value in the **Number of parallel branches** text box.

Note	Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

Note	To add a coil terminal to this winding, do the following: 1. In the project tree, right-click the winding, and select **Add Terminals**. The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding. 2. Select the coil terminal (s) you want to add. To select multiple terminals, press **CTRL** and click each terminal. 3. Click **OK**. To assign a coil terminal excitation and add it to this winding, do the following:

	1. Select the section of the geometry on which you want to apply the coil terminal excitation. 2. In the project tree, right-click the winding, and select **Assign Coil Terminal**. The **Coil Terminal Excitation** dialog box appears. 3. Enter a name for the excitation in the **Name** box, or accept the default. 4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductor**s box. **Note**: This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled. 5. Click **Swap Direction** to change the reference direction for the coil terminal. You can also change this direction in the coil terminal's Properties window by selecting either **Point into terminal**, or **Point out of terminal** for the **Direction** parameter. 6. Optionally, click **Use Defaults** to revert to the default values in the dialog box. 7. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding. To delete all coil terminal excitations that belong to this winding, do the following: • In the project tree, right-click the winding, and select **Delete All Terminals**. All coil terminal excitations are removed from the winding and deleted from the excitations.

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Assigning a Coil Terminal for a Magnetostatic Solver

To assign a coil terminal as a magnetostatic excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell>Excitations>Assign>Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)
The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.

4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box.

Note	This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

Note	The direction is shown in the model by a bold red arrow.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

Note	To add this coil terminal to an existing winding, do the following: 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following: • In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).

Electrostatic Boundaries and Excitations

Specify at least one of the following excitations as a source of electric fields:

- The charge on a surface or object.
- The volume charge density inside an object.
- The voltage difference between conducting surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

Note	If a conductor is not assigned any excitation, it is automatically assigned a floating excitation with zero charge.

Technical Notes: Electric Field Calculation

Electrostatic Boundaries

The following boundary conditions are available for 3D electrostatic problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — The normal component of **D** changes by the amount of surface charge density. No special conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	Ordinary E-field behavior on boundaries. Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.
Insulating	E-fields can be discontinuous across the insulating boundary.	Thin layer with two input values: **relative permittivity** and **thickness** of the thin layer.

Default Boundary Conditions for an Electrostatic Solver

These boundary conditions are automatically defined for an electrostatic model:

- Natural boundaries are assigned to the surfaces between dielectrics.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for an Electrostatic Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	**E** is normal to the boundary; its tangential components are zero.
Even (Flux Tangential)	**E** is tangential to the boundary; its normal components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for an Electrostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the E-field at every point on the dependent boundary surface is forced to match the E-field of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary

	exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

a. Select **New Vector** from the **U Vector** pull-down list.
The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
c. Select a point on the u-axis.
The **Independent Boundary** dialog box reappears

5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for an Electrostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Note	You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Matching>Dependent**.
The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

a. Select **New Vector** from the **U Vector** pull-down list.
The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box

disappears while you draw the U vector.

b. Select the U vector's origin in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

c. Select a point on the u-axis in the same way.
   When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.

d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Assigning an Insulating Boundary for an Electrostatic Solver

To set an insulating boundary:

1. Select the geometry face on which you want to apply the insulating boundary condition.
2. Click **Maxwell 3D>Boundaries>Assign>Insulating**.
   The **Insulating Boundary** dialog box appears.
3. On the **Insulating Boundary** tab, enter a name for the boundary in the **Name** box, or accept the default.
4. The **Parameters** section of the **Insulating Boundary** tab allows you to set the relative permittivity and thickness of the insulating boundary. Values can be defined using variables and also support Optimetrics.
   a. Enter the desired value for **Relative Permittivity**, or accept the default value of 1.
   b. Enter the desired value for **Thickness**, or accept the default value of 0.

   Note that changing data values will invalidate the solutions.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Electrostatic Excitations

The following excitations are available for electrostatic problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object. This excitation type is available for both electrostatic and DC conduction Electric solvers.
Charge	The total charge on a surface or object (dielectric). This excitation type is available for electrostatic solvers only.
Floating	Used to model conductors at unknown potentials. This excitation type is available for electrostatic solvers only.
Volume Charge Density	The volume charge density in an object. This excitation type is available for electrostatic solvers only.

Note	If a conductor is not assigned any excitation, it is automatically assigned a floating excitation with zero charge.

Assigning a Voltage Excitation for an Electrostatic Solver

Voltage excitations are identical to voltage boundaries in previous versions of Maxwell. Maxwell no longer has voltage boundaries in the electric solvers. Instead, a voltage excitation can be assigned to any surfaces, 2D objects, or solids. These assignments could include spatial functions. This type of excitation sets the electric potential (voltage) on a surface to a specific value.

Note	When calculating capacitance, a voltage source should be assigned to an entire object, not just a single face located on that object.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the pull-down list. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Excitation for an Electrostatic Solver

This type of excitation defines the total charge on a surface or object. The potential on the charge is computed during the solution.

To define a charge excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Charge**.
   The **Charge Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Floating Excitation for an Electrostatic Solver

This type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.

To define a floating conductor:

1. Select the section of the geometry on which you want to apply the excitation. This can be a 2D surface or a 3D solid.
2. Click **Maxwell>Excitations>Assign>Floating**.
   The **Floating Excitation** window appears.
3. Click the **General** tab.
4. Enter a name for the excitation in the **Name** box, or accept the default.
5. In the **Parameters** section, enter the charge on the boundary in the **Value** box.
6. Optionally, click **Use Defaults** to revert to the default values in the window. You can also click the **Defaults** tab to save new default settings or to revert to the standard default values.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Volume Charge Density Excitation for an Electrostatic Solver

This type of excitation defines the volume charge density on an object.

To define the charge density on a 3D object:

1. Select the 3D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Volume Charge Density**.
   The **Volume Charge Density Excitation** window appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge density in the **Value** box.
5. In the **Parameters** section, select the type of coordinate system from the **Coordinate System** pull-down list.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

3D AC Conduction Boundaries and Excitations

The following boundaries can be specified for this solver:

- Symmetry
- (Matching) Independent/Dependent
- Thin Layer
- Insulating

The following excitations can be specified for this solver:

- Voltage
- Current
- Sink

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation (with a potential difference)
- An odd symmetry (flux normal) boundary
- A sink excitation

Technical Notes: 3D AC Conduction Solver Theory

Specifying the Solver Type

3D AC Conduction Boundaries

The following boundary conditions are available for 3D AC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries - The normal and tangent components of **J** and **E** are continuous across discontinuity surfaces. • Neumann boundaries - **E** and **J** vectors are	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to

	tangential to the boundary. Flux cannot cross a Neumann boundary.	Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) - **E and J vectors are** tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) - **E and J vectors are** normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude of the E-field on the independent boundary if the "plus" sign is used. If the "minus" sign is used, the field on the dependent boundary will oscillate with opposite phase angle (180 degrees phase shift).	Planes of symmetry in periodic structures where **E** is oblique to the boundary.
Insulating	The current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductive domains.
Thin Layer	When two parts of the domain are separated by thin volume, it can be modeled by a Thin Layer. This boundary creates a field discontinuity (voltage drop) between the two sides of the selected surface based on the material bulk properties and thickness.	Thin and non-perfect (possibly lossy) domains.

Default Boundary Conditions for a 3D AC Conduction Solver

These boundary conditions are automatically defined for a AC conduction model:

- Natural boundaries are assigned to the surfaces between objects. The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for a 3D AC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Symmetry**.

   The **Symmetry Boundary** dialog box appears.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Voltages have opposite sign on the two sides of the symmetry plane.
Even (Flux Tangential)	Voltages have same sign on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for a 3D AC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell 3D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
   The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the U-axis.
   The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the E-field on this boundary and maps it to the dependent boundary.

Assigning a Dependent Boundary for a 3D AC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Note	You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Matching>Dependent**.

   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
   The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.

   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
   When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.

   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.
6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same

	magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Assigning an Insulating Boundary for the 3D AC Conduction Solver

This boundary condition is generally used to model very thin sheets of perfectly insulating material between touching conductors, as well as infinitely thin cracks inside conductors. Current cannot cross an insulating boundary, that is, $n \cdot J = 0$.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Insulating**.

   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

> **Note:** If you apply the insulating boundary condition on sheet objects (inside conductors), always make sure that the respective entities are selected as faces and not as objects before attempting to assign the insulating boundary condition to them.

Assigning a Thin Layer Boundary for a 3D AC Conduction Solver

When two parts of the domain are separated by a thin volume, it can be modeled using a “thin layer” boundary condition. This boundary creates a field discontinuity (voltage drop) across the two sides of the surface based on the material bulk parameters and thickness.

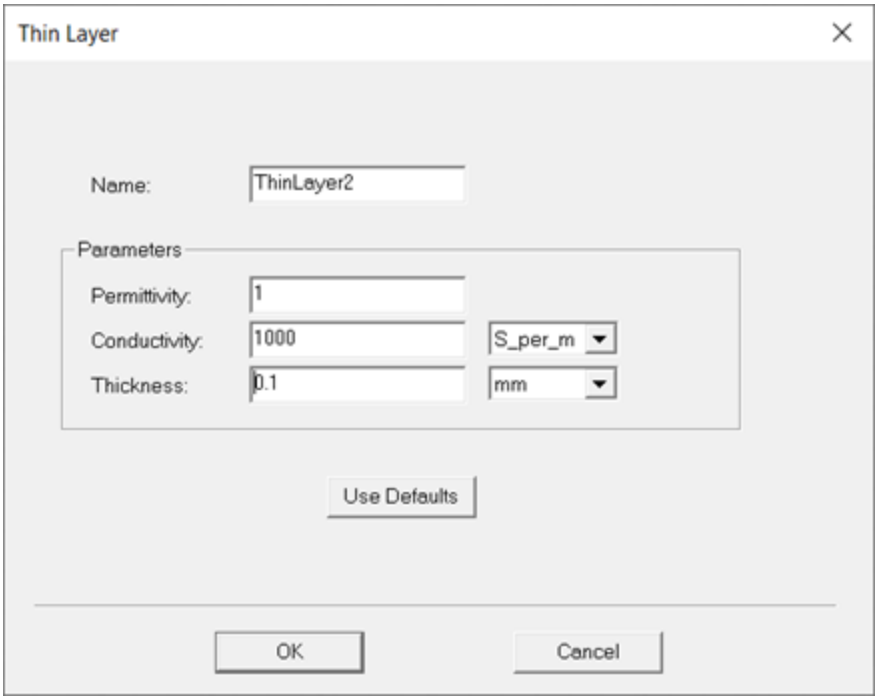
This boundary condition can be used to model thin domains, for example: the contact resistance between two conductive domains, the capacitive effect of thin insulating materials or thin lossy domains in electronic boards without needing to explicitly model (and mesh) a 3D object having a finite thickness.

> **Note:** The thin layer can be only applied to a coincident surface shared by two different bodies. It cannot be applied to a 2D cross-sectional sheet inside of a single body.

For the 3D AC conduction solver the thin layer is defined by its bulk conductivity, permittivity, and thickness.

To define a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D>Boundaries>Assign>Thin Layer** to open the Thin Layer dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thin layer parameters in the **Conductivity**, **Permittivity**, and **Thickness** fields, and select the units of measure. Use of variables is supported.



5. Optionally, click **Use Defaults** to revert to the default values in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.
6. Click **OK** to assign the boundary to the selected object.

The Project Manager lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the thin layer dialog box.

3D AC Conduction Excitations

The following excitations are available for 3D electric AC conduction problems:

Excitation	Type of Excitation
Voltage	The AC voltage on a surface or object.
Current	The current across a surface.
Sink	Applied only to surfaces which are grounded with reference potential value. It is the same as applying zero voltage excitation on those surfaces.

Note	All field quantities oscillate with the same frequency, equal to the frequency specified in the solution setup. The phase of quantities computed in the solution space however will be different in general.

Assigning a Voltage Excitation for a 3D AC Conduction Solver

This excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D>Excitations>Assign>Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section:
   a. Enter the electric potential in the **Value** box, and select the unit from the pull-down list. You can enter a numerical value or a spatial function.

      For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.
   b. Enter a value in the **Phase** text box, and select a unit from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a 3D AC Conduction Solver

To define a current across a surface:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 3D>Excitations>Assign>Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section:
   a. Enter the current strength in the **Value** box, and select the unit from the pull-down list.
   b. Enter the phase angle in the **Phase** box, and select the unit from the pull-down list.
   c. Optionally, to change the direction of the current flow, click **Swap Direction**.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Sink Excitation for a 3D AC Conduction Solver

To define a sink excitation on a surface:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell 3D>Excitations>Assign>Sink**.
   The **Sink Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

DC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.
- Using the current excitation, define the total current flowing through a surface or a 2D object.
- Using the sink excitation, define a collection of surfaces or 2D objects as a sink. We apply sink excitations when only current excitations are defined in a conduction path and there is no voltage excitation. In fact, in this case, a sink excitation has to be defined and it ensures that the total current flowing through the outside surface of a conduction path is exactly zero.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- A sink excitation.
- An odd symmetry (flux normal) boundary.

Specifying the Solver Type

DC Conduction Boundaries

The following boundary conditions are available for DC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary	Field behaves as follows: • Natural boundaries — The normal	Ordinary E-field behavior on boundaries. Object

Conditions (Natural and Neumann)	component of **D** changes by the amount of surface charge density. No special conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Insulating	Same as Neumann, except that current cannot cross the boundary. An insulating boundary is *only* available for electrostatic solutions that include a DC conduction analysis.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.
Thin Layer	When two parts of the domain are separated by a thin volume, it can be modeled by a Thin Layer. This boundary creates a field discontinuity (voltage drop) between the two sides of the selected surface based on the material bulk properties and thickness.	Thin conducting domains

Default Boundary Conditions for a DC Conduction Solver

These boundary conditions are automatically defined for a DC conduction model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning an Insulating Boundary for a DC Conduction Solver

This boundary condition is used to model very thin sheets of perfectly insulating material between touching conductors. Current cannot cross an insulating boundary.

An insulating boundary is *only* available for electrostatic solutions that include a DC conduction analysis.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Insulating**.
   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Symmetry Boundary Condition for a DC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Current flows in opposite directions on either side of the symmetry plane.
Even (Flux Tangential)	Current flows in the same direction on both sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Warning	When using even symmetry boundaries, double-check the following two points: • Do not violate Ampere's law! • All magnetic field boundaries must be connected to each other. Defining disconnected magnetic field boundaries and even symmetry boundaries can produce unexpected results, as there is no unique solution to such problems.

Assigning a Independent Boundary for a DC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the E-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a DC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Note	You must define a Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
      When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

Note	When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Assigning a Thin Layer Boundary for a 3D DC Conduction Solver

When two parts of the domain are separated by a thin volume, it can be modeled using a “thin layer” boundary condition. This boundary creates a field discontinuity (voltage drop) across the two sides of the surface based on the material bulk parameters and thickness.

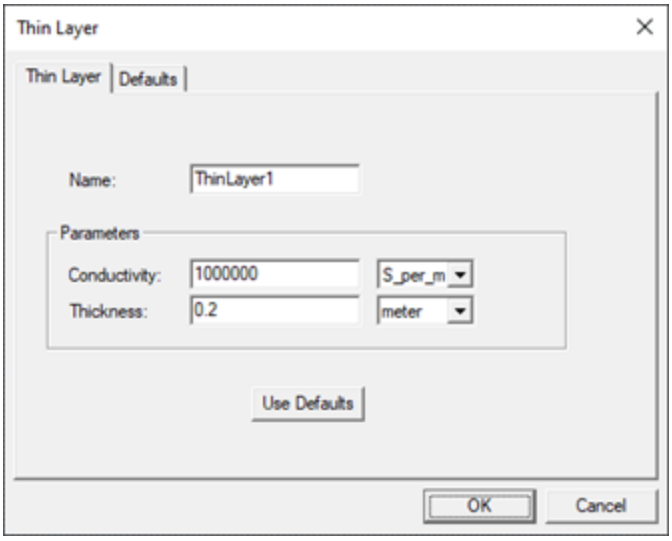
This boundary condition can be used to model thin domains, for example, the contact resistance between two conductive domains without needing to explicitly model (and mesh) a 3D object having a finite thickness.

> **Note:** The thin layer can be only applied to a coincident surface shared by two different bodies. It cannot be applied to a 2D cross-sectional sheet inside of a single body.

For the 3D DC conduction solver, the thin layer is defined by its bulk conductivity, and thickness.

To define a thin layer boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D body).
2. Click **Maxwell 3D>Boundaries>Assign>Thin Layer** to open the Thin Layer dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the thin layer parameters in the **Conductivity** and **Thickness** fields, and select the units of measure. Use of variables is supported.



5. Optionally, click **Use Defaults** to revert to the default values in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **Thin Layer** tab as the defaults to be assigned to new boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.
6. Click **OK** to assign the boundary to the selected object.

The Project Manager lists the newly assigned thin layer boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the thin layer dialog box.

DC Conduction Excitations

The following excitations are available for electric DC conduction problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object. This excitation type is available for both electrostatic and DC conduction solvers.
Current	The current across a 2D object. This excitation type is available for DC conduction solvers only. A current excitation must be applied across a 2D surface.
Sink	This excitation type is available for DC conduction solvers only.

For a DC conduction solution, if a current excitation is assigned, at least one sink or voltage excitation must also be defined. However, you cannot define both a voltage excitation and a sink excitation at the same time.

Assigning a Voltage Excitation for a DC Conduction Solver

This type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Voltage**.
   The **Voltage Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the pull-down list. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a DC Conduction Solver

To define a current across a surface:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Current**.
   The **Current Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the current strength in the **Value** box.
5. Optionally, to change the direction of the current flow, click **Swap Direction**.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Sink Excitation for a DC Conduction Solver

To define a sink excitation on a surface:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell>Excitations>Assign>Sink**.
   The **Sink Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected object.

DC Conduction + Electrostatic Boundaries and Excitations

In the case of a problem when you are interested in the electric solution in both the conductors and the insulators, you can define a **DC Conduction + Electrostatic**solution type. The Insulator/Conductor threshold defines which objects are conductors or insulators. The solver first solves the conduction problem in all conduction paths and then, using the calculated voltage on the conductors as a voltage excitation, computes the electrostatic field in the insulators. As a consequence, you can define the DC-conduction excitations and boundary conditions in the conducting regions and the electrostatic excitations and boundary conditions in the insulators.

Related Topics

Technical Notes: Electric Field Calculation

Specifying the Solver Type

Eddy Current Boundaries and Excitations

Specify at least one of the following as a source of AC magnetic fields in your model:

- The current in a conduction path, which can be either stranded or solid.

Note	For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- The current density in a conductor.
- The magnetic field on an outside surface.

If currents or current densities are the only sources of AC magnetic fields in your model, set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Specifying the Solver Type

Eddy Current Boundaries

The eddy current field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model…
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — **H** is continuous across the boundary. • Neumann boundaries — **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries and excluded objects are Neumann

Boundary Type	H-Field Behavior	Used to model…
		boundaries.
Zero Tangential H Field	Flux is perpendicular if tangent components are zero or if a zero tangential H-field boundary condition was applied.	External AC magnetic fields.
Tangential H Field	The tangential components of **H** are set to pre-defined values.	External AC magnetic fields
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary (where integration of the tangential H field is non-zero), nor the Zero Tangential H Field boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	Cases such as the boundary around the hole left when a motor's shaft is excluded.
Insulating	Same as Neumann, except that current cannot cross the boundary.	Perfectly insulating sheets between conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **H** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Radiation	No restrictions on the field behavior.	Unbounded eddy currents.
Impedance	Includes the effect of induced currents beyond the boundary surface.	Conductors with very small skin

Boundary Type	H-Field Behavior	Used to model…
		depths.
Resistive Sheet	When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.	Voltage drop and loss on the contact surface between two different objects within a conduction path.

Default Boundary Conditions for the Eddy Current Solver

These boundary conditions are automatically defined for an eddy current model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Magnetic H Field for the Eddy Current Solver

This type of boundary defines external magnetic fields in a model. Assign it only to the outer surfaces of the problem region. Regardless of the model's drawing units, magnetic field values are entered in s/m.

Warning	When using tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

To define a tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell>Boundaries>Assign>Tangential H Field**.
   The **Tangential H Field** window appears.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the field component in the x-direction in the **U (X)** box and the value of the field component in the y-direction in the **V(Y)** box.
5. In the **Coordinate System** section, do the following define the vectors:
   a. Select **New Vector** from the **U Vector** pull-down list.
   The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face.
   b. Click two points to specify the vector.
   The vector is set, and the **Tangential H Field** window reappears, with **Defined** listed for **U Vector**.
   c. To reverse the direction of the vector, click the **Reverse Direction** check box.
6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Integrated Zero Tangential H Field Boundary for the Eddy Current Solver

This type of boundary is applied when the integral of the tangential H field is zero.

Warning	When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Integrated Zero Tangential H Field**.
   The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Insulating Boundary for the Eddy Current Solver

This boundary condition is generally used to model very thin sheets of perfectly insulating material between touching conductors, as well as infinitely thin cracks inside conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Insulating**.
   The **Insulating Boundary** window appears.

3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Note	An insulating boundary condition can be used to control the flow of induced eddy currents inside conductors that contain sheet objects with an applied insulating boundary condition. In case you apply the insulating boundary condition on sheet objects (inside conductors), always make sure that the respective entities are selected as faces and not as objects before attempting to assign the insulating boundary condition to them.

Assigning a Symmetry Boundary for the Eddy Current Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	H is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	H is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Warning	When using even symmetry boundaries, always double-check that Ampere's law is not violated!

Related Topics

Setting a Symmetry Multiplier

Assigning an Independent Boundary for the Eddy Current Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-

field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.
   c. Select a point on the u-axis.
      The **Independent Boundary** dialog box reappears
5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for the Eddy Current Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define a independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
   The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

   c. Select a point on the u-axis in the same way.
   When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.
   d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

Note	When entering current, current density terminals, or coil terminals, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Assigning a Radiation Boundary for the Eddy Current Solver

To simulate problems that allow fields to radiate infinitely far into space, you can define surfaces to be radiation boundaries. The system absorbs the field at the radiation boundary, essentially ballooning the boundary infinitely far away from the structure. In a far field region, field components are expressed by:

$$\boldsymbol{E} = -Zn \times \boldsymbol{H}$$

where:

$$Z = \sqrt{\frac{\mu}{\varepsilon}}$$

and Z is the component of the E-field that is tangential to the surface.

Using the field impedance, the equation becomes:

$$n \times \boldsymbol{E} = -Zn \times (n \times \boldsymbol{H})$$

which is used as a radiation boundary. The radiation boundary condition should be placed far enough from the source of radiation so that the approximation of the far field in the region of the boundary holds.

The second-order radiation boundary condition is an approximation of free space. The accuracy of the approximation depends on the distance between the boundary and the object from which the radiation emanates.

A radiation surface does not have to be spherical. However, it should be exposed to the background, convex with regard to the radiation source, and located at least one-quarter of a wavelength away from the radiating sources. In some cases you may want to use smaller distances.

To assign a radiation boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).

2. Click **Maxwell>Boundaries>Assign>Radiation**.
   The **Radiation Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the boundary to the selected object.

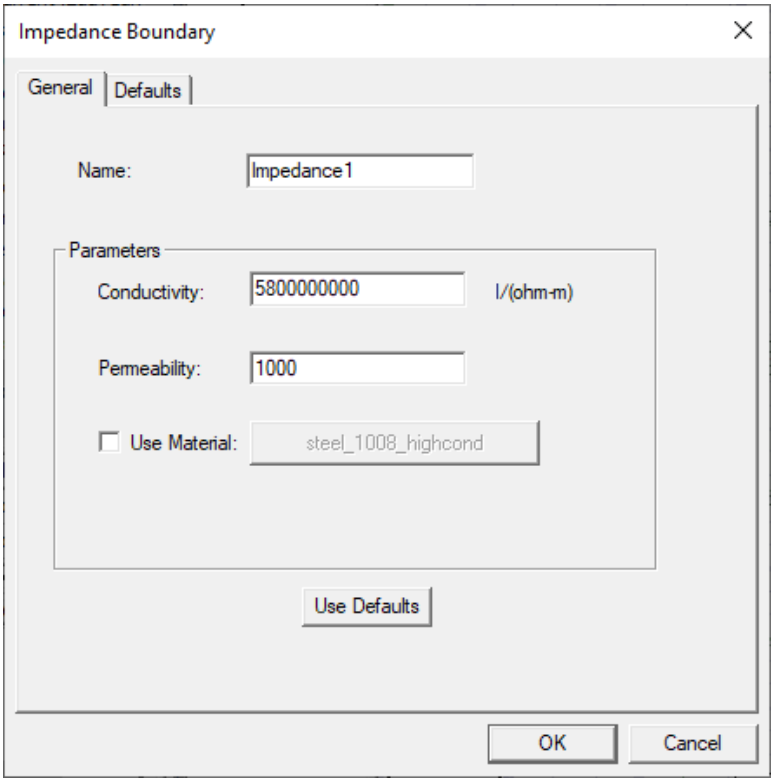
Assigning an Impedance Boundary for the Eddy Current Solver

> **Note:** To define an impedance boundary for the transient solver, refer to *Assigning an Impedance Boundary for the Transient Solver*.

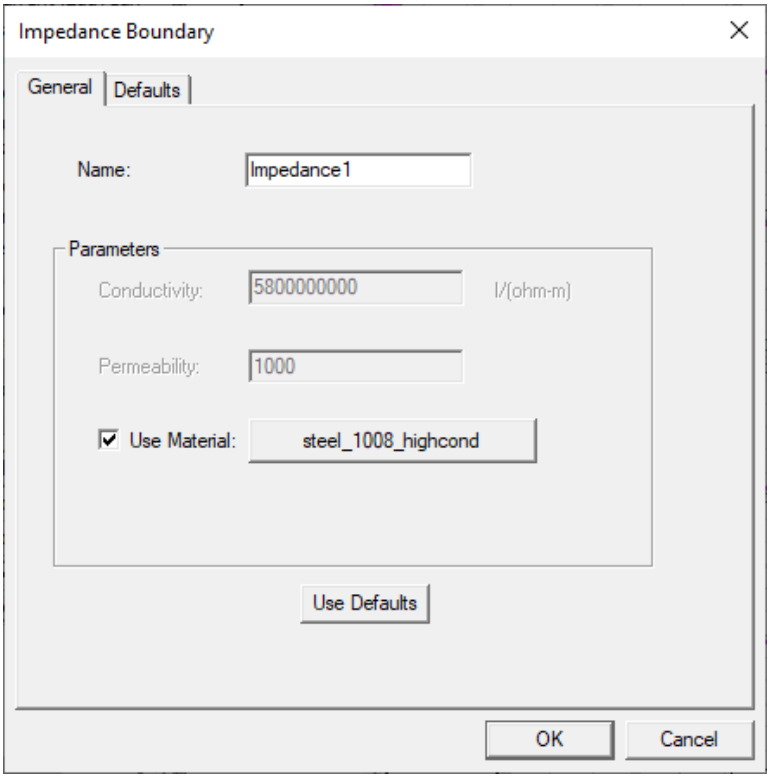
This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. Since the conductor must be excluded from the model (saving time needed to mesh and solve for currents), assign the impedance boundary condition to an outside edge of the problem region or to an excluded object.

To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Impedance** to open the **Impedance Boundary** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Do one of the following:
   - If the **Use Material** check box is unchecked, enter the conductivity (in inverse ohm-meters) in the **Conductivity** field, and the conductor's relative permeability in the **Permeability** field.



- If you wish to select a material from the library, check the **Use Material** check box, then use the button to select the desired material.

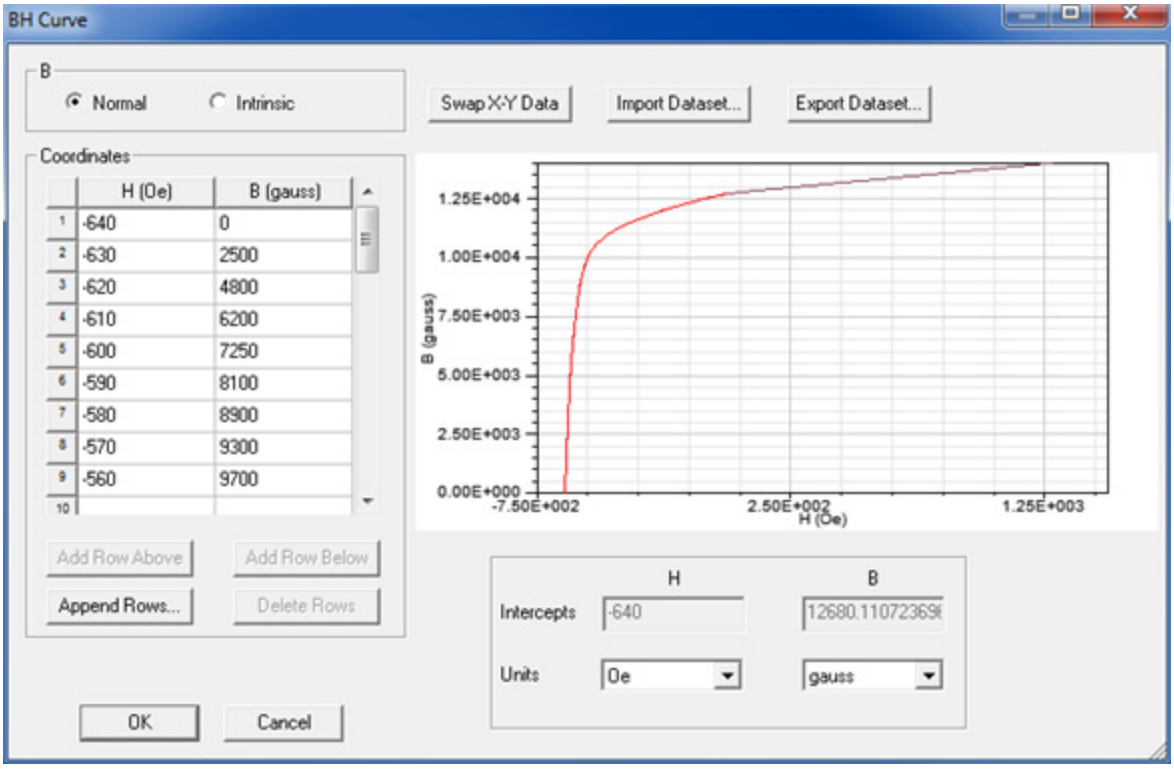


- **Nonlinear Permeability**

  If you select a material that has nonlinear permeability, the non-linear coefficient is computed automatically.

  The nonlinear relative permeability of the material is determined by the B-H curve. If the desired B-H curve of the permeability belongs to an existing material, you can directly use that existing material.

  Otherwise, you can edit a new material with the desired B-H curve.



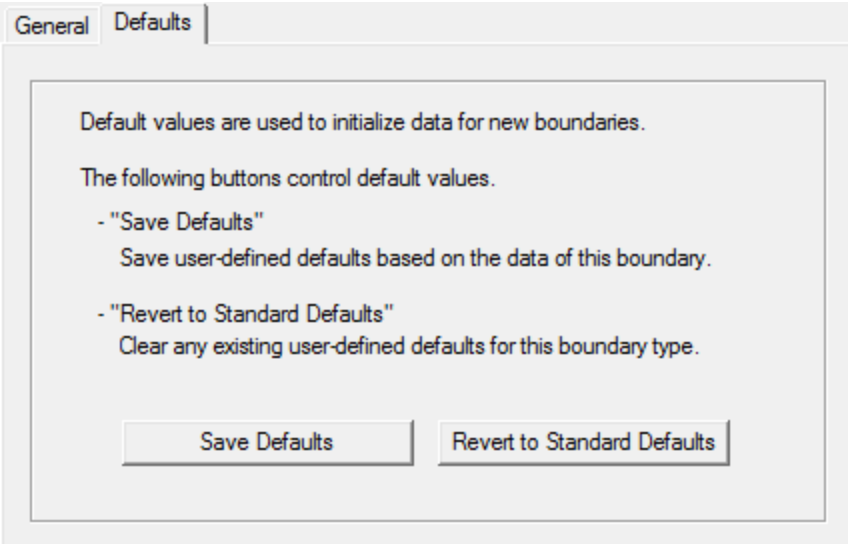
Refer to *Relative Permeability for a Maxwell or RMxprt Material* for details on using nonlinear relative permeability.

- **Temperature Dependent Impedance Boundary**

  The electrical conductivity and permeability of a material used for an impedance boundary condition can be temperature dependent. The Maxwell 3D eddy solver provides an option to allow you to input functions as thermal modifiers to consider the effect of temperature on those properties. To enable this feature, check the **Use Material** check box as above. You can then click **Material** to open the material properties panel in which you can add a thermal modifier. (Refer to *Setting the Temperature of Objects* for additional information on using temperature dependent impedance boundaries).

5. Optionally, click **Use Defaults** to revert to the default values in the window.

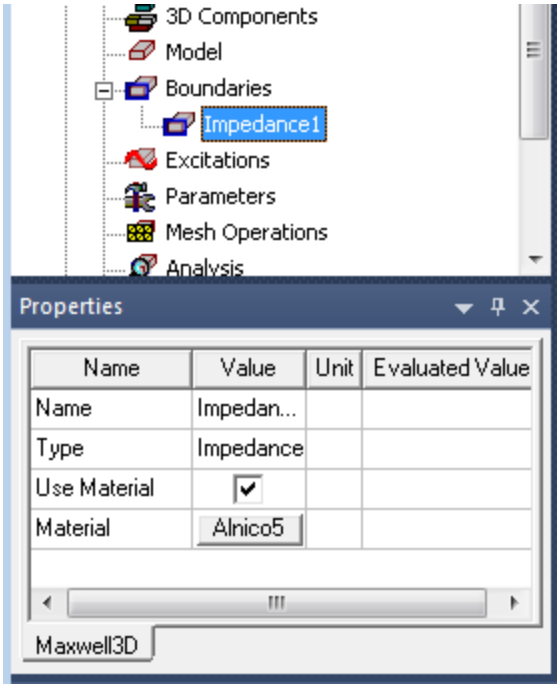
The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



6. Click **OK** to assign the boundary to the selected object.

   The Project Manager lists the newly assigned impedance boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You

can also double-click the boundary entry in the tree to open it for editing in the Impedance Boundary dialog box.



Related Topics

Impedance Boundary

Setting a Thermal Modifier

Setting the Temperature of Objects

Impedance Boundary

Impedance boundaries allow you to simulate the effect of induced currents in a conductor without explicitly computing them. Use this boundary condition for models where:

- The skin depth in the conductor is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the meshmaker may not be able to create a fine enough mesh in the conductor to compute eddy currents.
- The magnetic field decays much more rapidly inside the conductor in the direction that's normal to the surface than it does in directions that are tangential to the surface.
- The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

The conductor itself must be excluded from the solution region. When setting up the model, do one of the following:

- For external boundaries, when drawing the model, make the surface along which eddy currents are to be computed an outer surface of the problem region.

- For internal impedance boundaries, assign perfect conductor to the object in the Material Manager or uncheck **Solve Inside** to exclude the object from the solution domain.

Then, when defining boundaries, assign an impedance boundary to the individual surfaces of the problem region (for external boundaries) or to the entire object (for internal boundaries). By entering the conductivity, s, and the relative permeability, mr, of the object, you specify the skin depth of induced eddy currents. The simulator uses this skin depth value when computing the electromagnetic field solution. It assumes that the H-field falls off exponentially inside the conductor. The ohmic loss due to induced currents can then be computed from the tangential components of the H-field along the impedance boundary — the surface of the object that you are interested in.

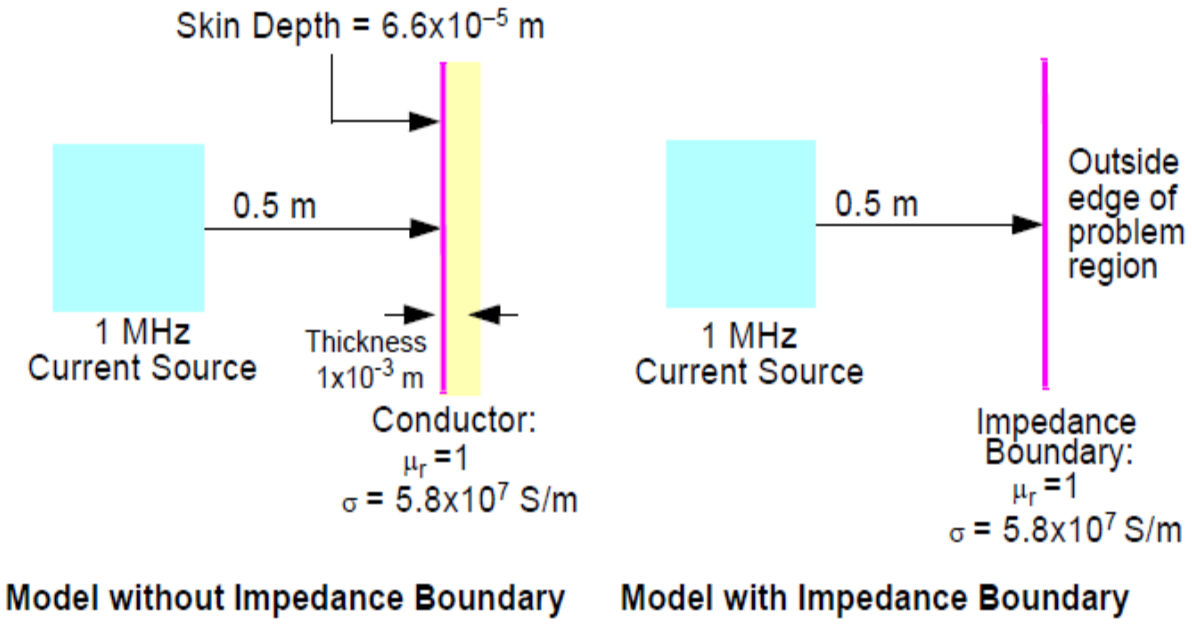
Note	An impedance boundary only approximates the effect of eddy currents acting at a shallow skin depth. It does not directly compute them. In general, the fields modeled using an impedance boundary will closely match the field patterns that would actually occur in the structure. However, at discontinuities in the surface (such as corners), the field patterns may be different.
Note	For the current version of the Maxwell solver, when a project includes all three of the following at the same time: an impedance boundary condition, a material with anisotropic permeability, and a winding, the project cannot be solved by the Maxwell eddy current solver and the Maxwell 3D transient solver.

Related Topics

When to use Impedance Boundaries

When to Use Impedance Boundaries

A typical situation where impedance boundaries can be used to reduce the complexity of a model is shown below. Suppose you want to compute eddy current losses in the conductor next to the current source shown below on the left. If the source carries AC current at a frequency of 1 MHz, the skin depth in the conductor is 6.6 x 10–5 meters. This is several orders of magnitude smaller than the conductor's thickness. Since the conductor where currents are induced is also relatively far away from the current source, an impedance boundary can be used to model the induced currents — as shown on the right.



The conductor itself must be excluded from the model. Instead, the outside boundary of the model is moved to the inside surface of the conductor. This outside surface is defined as an impedance boundary, using the conductivity and permeability specified previously. Since the simulator does not have to actually compute a solution inside the conductor, the field solution is computed more quickly and uses less memory. After solving, you can compute the ohmic loss for the surface using the solution calculator and plot the loss density on the boundary.

Assigning a Resistive Sheet Boundary for the 3D Eddy Current Solver

Note	For Transient designs refer to *Assigning a Resistive Sheet Boundary for the Transient Solver*.

When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.

The following are usages of the resistive sheet boundary:

- **Typical usage**: Modeling contact resistance by applying Resistive Sheet boundary to a contacting surface (face) of two conductive objects.
- **Other possible usages**: Resistive Sheet boundary can be applied to any sheet object inside a conductive object or on a conductive object surface in order to increase the total resistance of the conducting path and to introduce localized loss density to the place of the sheet location.

This boundary can also be used to model terminal contact resistance (for stranded or solid conductors). For example, by applying it to the conductor cross section touching the Region. In this case the Excitation Terminal and Resistive Sheet boundary are not allowed to be on the same sheet object.

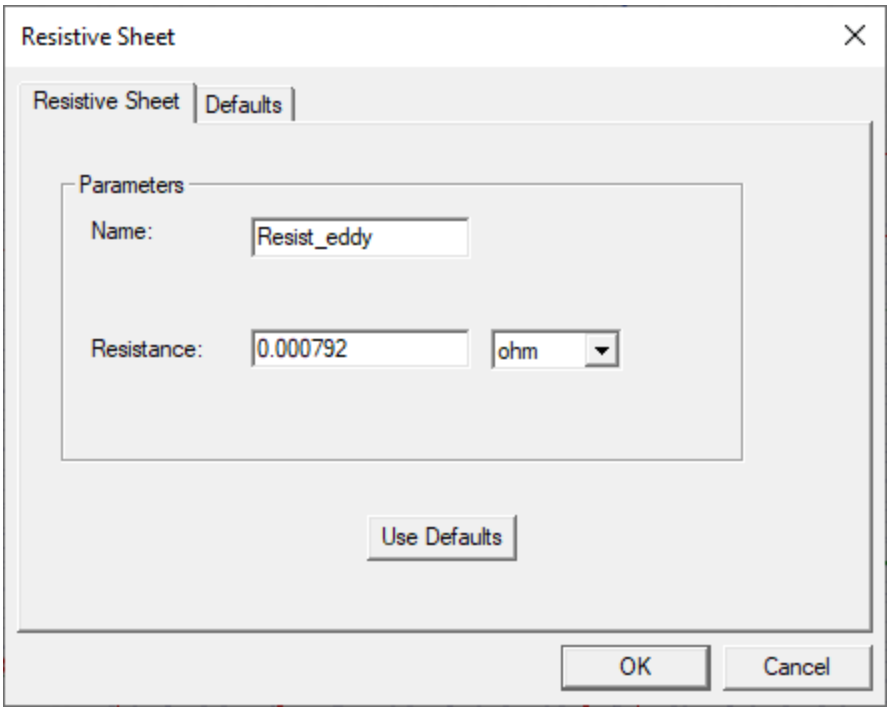
The losses incurred due to a Resistive Sheet boundary are output as Surface Loss Density. These losses are counted as losses in solid conductors and are reported together with the losses in other solid conductors under Solid Loss. If the Surface Loss Density is mapped to Mechanical, it should be assigned to a face as Heat Flux.

To define a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D conducting body touching another conducting body or face of a 3D conducting body touching the Region).

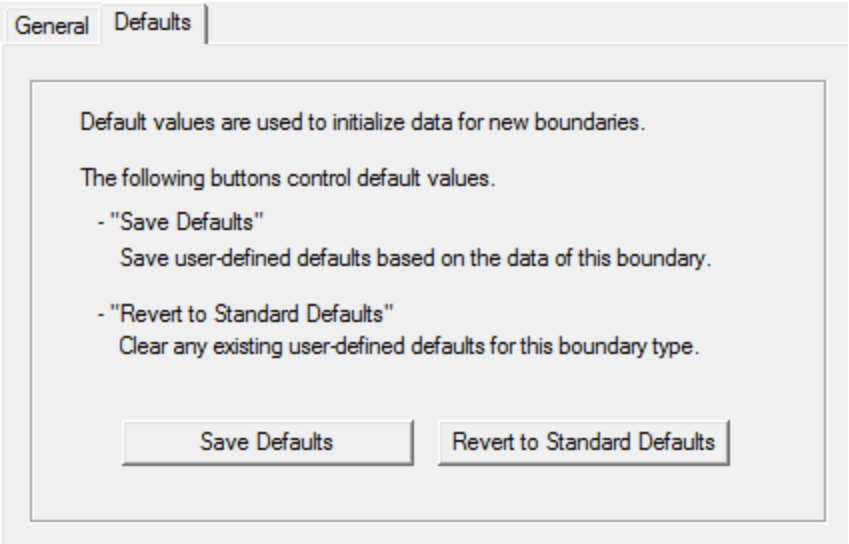
Note	• The sheet must be completely inside a conductor or on its surface. • The sheet must have conductors touching both of its faces. • The resistance value cannot be dependent on intrinsic variable.

2. Click **Maxwell 3D>Boundaries>Assign>Resistive Sheet** to open the **Resistive Sheet** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the resistance value in the **Resistance** field, and select a unit of measure. Use of variables is supported.



5. Optionally, click **Use Defaults** to revert to the default value (1 ohm) in the window.

   The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



6. Click **OK** to assign the boundary to the selected object.

   The Project Manager lists the newly assigned resistive sheet boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You can also double-click the boundary entry in the tree to open it for editing in the **Resistive Sheet** dialog box.

> **Note:** When switching the solution type between transient and eddy current, resistive sheet boundaries will be kept.

Assigning a Resistive Sheet Boundary for the Transient Solver

Eddy Current Excitations

The eddy current solver allows you to define the following sources of AC magnetic fields:

Excitation	Type of Excitation
Current Density	The current density in a conductor. In this case, you must also define the current density terminals for the conductor.

Current Density Terminal	Specifies the cross-section of the conductor where current density is specified, to be used as a terminal object. Current Density and Current Density Terminal are required to be used in conjunction.
Current	The total current in a conductor.
Coil Terminal	Used to define one or more model windings.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

Note	When entering current, the arrow associated with current in the selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Reverse Direction** if you want to reverse the direction of the arrow.

Note	When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

Assigning a Current Density Excitation for the Eddy Current Solver

This command specifies the x-, y-, and z-components of the AC current density in a conduction path. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) in which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell>Excitations>Assign>Current Density**.
   The **Current Density Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **X Component**, **Y Component**, and **Z Component** values to define the respective components of the current density vector.
   b. Do the following in the two **Coordinate System** pull-down lists:

- From the first pull-down list, select either **Global** or **RelativeCS1** (where x = 1,2,3… if any relative coordinate systems have been defined).
- From the second pull-down list, select **Cartesian**, **Cylindrical**, or **Spherical**.

c. Enter the phase angle, θ, of the current density in the **Phase** field.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the excitation to the selected object.

To complete the current density definition, you also need to specify any related current density terminals, which must be assigned to a 2D object or face of the respective conduction path.

Note	Select the names of the sheet objects to serve as the current density terminals. This object must form an exact cross-section of the current density conduction path.You must create 2D objects which represent locations where current flows into and out of the problem region, or branches at any location in the conduction path. In current loops, any exact 2D cross-section may serve as a terminal.

Related Topics

Assigning a Current Density Terminal

Assigning a Current Density Terminal Excitation for the Eddy Current Solver

To define the current density terminal:

1. Select the section of the geometry (i.e., the conductor) in which you want to apply the excitation (typically a 3D object).
2. Click **Maxwell>Excitations>Assign>Current Density Terminal**.
   The **Current Density Terminal Excitation** window appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Click **OK** to assign the excitation to the selected target(s).

Related Topics

Assigning a Current Density Excitation

Assigning a Current Excitation for the Eddy Current Solver

Specifies the total AC current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To specify the total AC current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell>Excitations>Assign>Current**.
   The **Current Excitation** window appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select either **Solid** or **Stranded** to define the **Type** for the conductor. For a stranded conductor, a uniformly distributed current density is assumed without considering eddy effects.
7. Optionally, click **Swap Direction** to change the direction of the current flow.
8. Optionally, click **Use Defaults** to revert to the default values in the window.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Coil Terminal for an Eddy Current Solver

To assign a coil terminal as an Eddy current excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell>Excitations>Assign>Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)

   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box. For a solid winding, the number should be 1.

Note	This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

Note	The direction is shown in the model by a bold red arrow.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

Note	To add a coil terminal to an existing winding, do the following: 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following: • In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level

	in the project tree (directly beneath **Excitations**).

Assigning a Winding Setup for an Eddy Current Solver

Note	• If you wish to define a winding for a Transient solution type, refer to "Assigning a Winding Setup for a Transient Solver " on page 11-101 . • If you wish to define a winding for a Magnetostatic solution type, refer to Assigning a Winding Setup for a Magnetostatic Solver.

You can use the pre-defined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell>Excitations>Add Winding**. to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, **Voltage**, or **External** from the **Type** pull-down list. The winding type selected enables only those fields (Initial Current, Resistance, Inductance, Voltage, Phase) applicable for the chosen type.
   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
   c. Enter values in the following fields (enabled according to winding type), and select the desired units. You can also type a function as an expression for any of these fields except Initial Current.

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	(no settings required)
Phase	Inductance	
	Voltage	
	Phase	

   d. Enter a value in the **Number of parallel branches** text box.

Note	Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
5. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

Note	For an external winding, you must also set up an external circuit connection.
Note	To add a coil terminal to this winding, do the following:

	1. In the project tree, right-click the winding, and select **Add Terminals**. The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding. 2. Select the coil terminal (s) you want to add. To select multiple terminals, press **CTRL** and click each terminal. 3. Click **OK**. To assign a coil terminal excitation and add it to this winding, do the following: 1. Select the section of the geometry on which you want to apply the coil terminal excitation. 2. In the project tree, right-click the winding, and select **Assign Coil Terminal**. The **Coil Terminal Excitation** dialog box appears. 3. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding. To delete all coil terminal excitations that belong to this winding, do the following: • In the project tree, right-click the winding, and select **Delete All Terminals**. All coil terminal excitations are removed from the winding and deleted from the excitations.

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

External Circuit Setup for 3D Eddy Current

The Maxwell Circuit design editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D Eddy current solutions. Because the Eddy current solver is a frequency domain solver, only linear circuit components are supported, which include Resistance, Inductance, Capacitance, and Transformer. In addition, only sinusoidal sources should be used as sources. Sinusoidal Current Source and Sinusoidal Voltage Source, designed for transient solutions, can also be used for eddy current solutions. For example, to use the sinusoidal current source, you should set the parameters as follows:

- Set **I0**, **Td**, and **Df** to zero, where I0 is offset current in Amps, Td is the delay time in seconds, and Df is the damping factor in 1/seconds.
- Set **TIME** as the **Type**.

- Use **Ia** to set the peak amplitude in Amps.
- Use **IFreq** to set the signal frequency. Note that setting IFreq is not necessary as it will be internally set to the frequency defined in the Maxwell design setup.
- Use **Phase** to set the phase delay.

With these specifications, the time signal can be written as:

$$I(t) = I_a \sin\left(2\pi I_{freq} - Phase\right)$$

Note that “Phase” is the signal phase delay. The complex source in the eddy current solver is represented in phasor form as:

$$I = I_a \ e^{j\theta}$$

and the time signal can be written in terms of (I_a, θ) as:

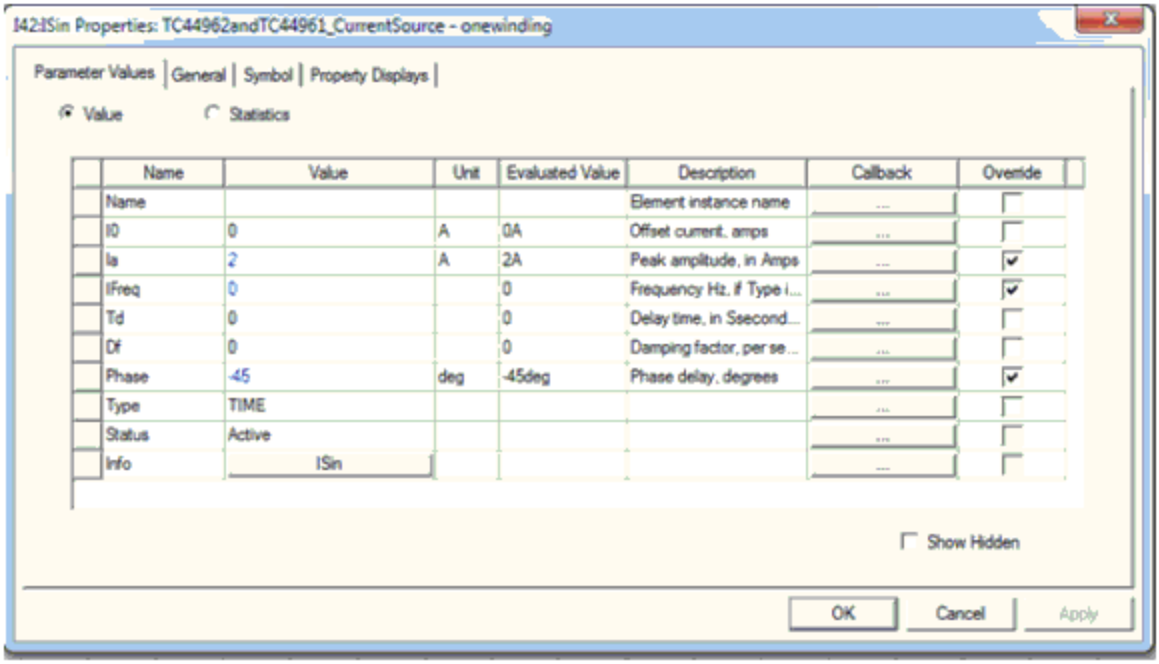
$$I(t) = Im\left\{I_a \ e^{j(2\pi I_{freq}+\theta)}\right\}$$

In the complex expression, θ is defined as phase, while in Maxwell Circuit, *Phase* is defined as phase delay. Thus:

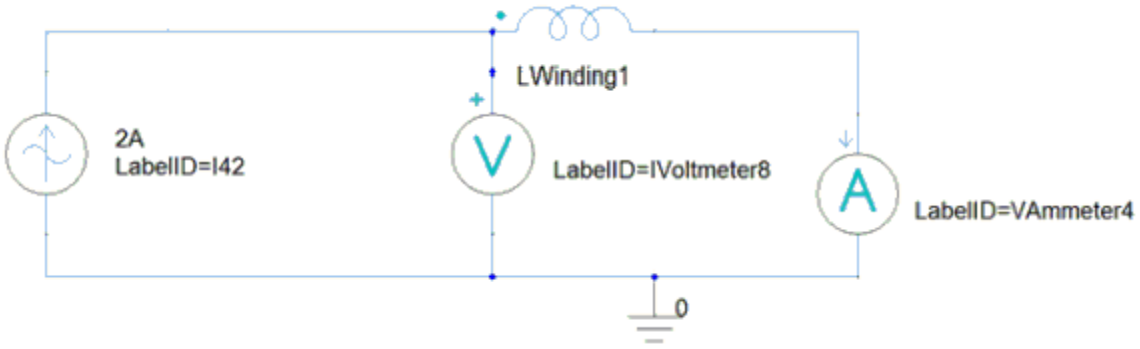
$$Phase = -\theta$$

As a result, you should enter the negative of phase of the complex signal as the Phase value.

An example of such a setup for $I = 2e^{j45^\circ}$ is shown below.



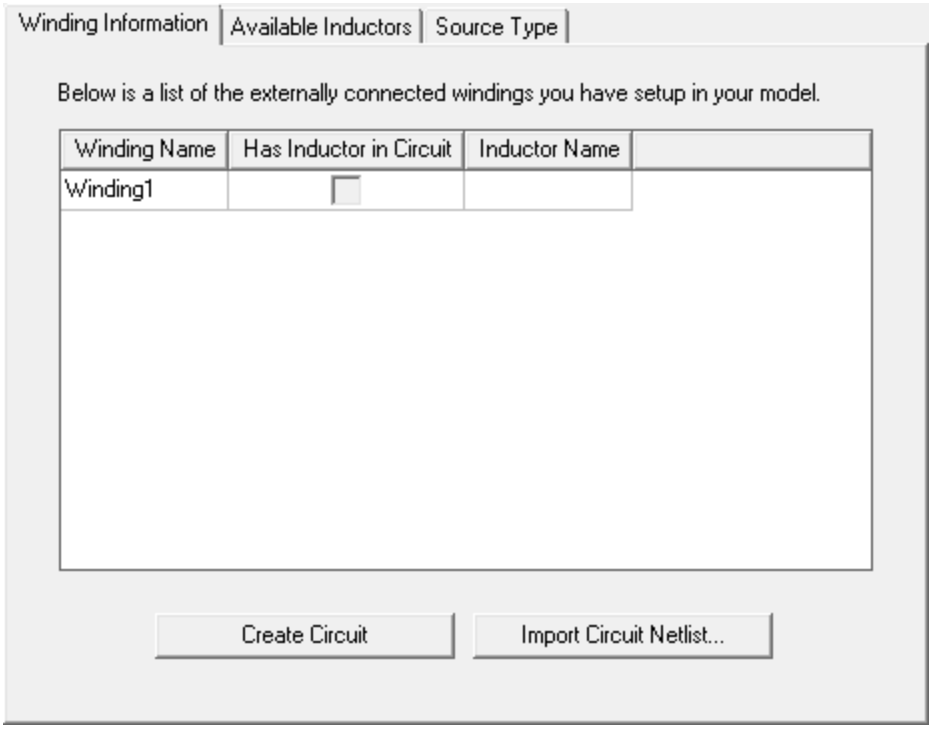
An example of an external circuit excitation for the winding for an Eddy current solver is shown below.



Note	For frequency domain eddy current solutions, only linear circuit components are supported, which include Resistor, Inductor, Capacitor, and Transformer. Only sinusoidal sources should be used as sources.

To set up an external circuit connection for an External winding type:

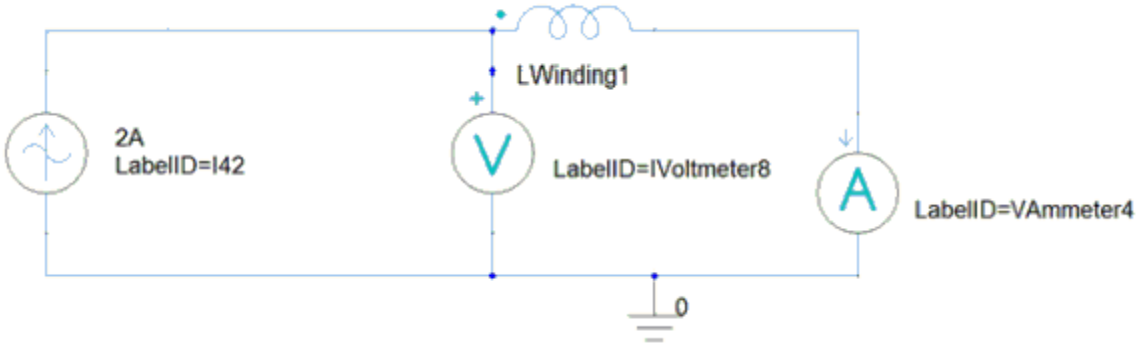
1. Click **Maxwell 3D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.



b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.

3. Add the components needed to complete the external circuit design such as shown the following example.



4. When the circuit design is finished, click **Maxwell Circuit>Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 3D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.

b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog.

c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for Optimetrics analyses.

10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

Note	After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

Transient Boundaries and Excitations

Define at least one of the following as a source of magnetic fields:

- The stranded or solid windings, with a voltage or current supply or connected to an external circuit winding.

Note	For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- A permanent magnet.

You may need to set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Technical Notes: 3D Transient Excitations (Sources)

Specifying the Solver Type

Transient Boundaries

The transient field solver allows you to define the following types of boundary conditions.

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — **H** is continuous across the boundary. • Neumann boundaries — **H** is tangential to the boundary and flux cannot cross it.	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.
Zero Tangential H Field	The tangential components of **H** are set to zero. Flux is perpendicular.	External magnetic fields.
Integrated Zero Tangential H Field	For applications such as a motor with the shaft excluded, there remains a hole in the middle. In such cases, on the hole's boundary, neither the Tangential H Field boundary (where integration of the tangential H field is non-zero), nor the Zero Tangential H Field boundary (where the tangential H field is zero everywhere) can be applied because – for the hole boundary case – integration of the tangential H field is zero, but the tangential H field is not zero everywhere. Integrated Zero Tangential H Field can be used for such applications.	Cases such as the boundary around the hole that remains when a motor's shaft is excluded.
Insulating	Same as Natural boundary, except that current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **H** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.

Matching (Independent and Dependent)	The H-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the H-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Resistive Sheet	Same as Natural boundary.	Voltage drop and loss on the contact surface between two different objects within a conduction path.
Impedance	Includes the effect of induced currents beyond the boundary surface.	Conductors with very small skin depths.
Touching	Same as Natural boundary.	Interface between a moving part and a stationary part.

Default Boundary Conditions for a Transient Solver

These boundary conditions are automatically defined for a transient model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outside edges of the problem region.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Zero Tangential H Field Boundary for a Transient Solver

This type of boundary defines external magnetic fields in a model.

Warning	When using zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define a zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).

2. Click **Maxwell>Boundaries>Assign>Zero Tangential H Field**.
   The **Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Integrated Zero Tangential H Field Boundary for a Transient Solver

This type of boundary is applied when the integral of the tangential H field is zero.

Warning	When using integrated zero tangential magnetic field boundary conditions, always double-check that Ampere's law is not violated!

To define an integrated zero tangential H field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Integrated Zero Tangential H Field**.
   The **Integrated Zero Tangential H Field** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Insulating Boundary for a Transient Solver

This boundary condition is used to model very thin sheets of perfectly insulated material between touching conductors. Current cannot cross an insulating boundary.

To set an insulating boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Insulating**.
   The **Insulating Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Note	An insulating boundary condition can operate on the source current. It can also be used to control the flow of induced eddy currents.

Assigning a Symmetry Boundary for a Transient Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).

2. Click **Maxwell>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	H is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	H is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the window.
6. Click **OK** to assign the boundary to the selected object.

Warning	When using even symmetry boundaries, always double-check that Ampere's law is not violated!

Related Topics

Setting a Symmetry Multiplier

Assigning a Independent Boundary for a Transient Solver

Independent and dependent boundaries enable you to model planes of periodicity where the H-field at every point on the dependent boundary surface is forced to match the H-field of every corresponding point on the independent boundary surface. The transformation used to map the H-field from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the face to which you want to assign the independent boundary.
2. Click **Maxwell>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Coordinate System** section, do the following to define the coordinate system:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears, asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Independent Boundary** dialog box disappears while you draw the U vector.

b. Select the U vector's origin, which must be on the boundary's surface, in one of the following ways:
   - Click the point.
   - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

c. Select a point on the u-axis.
   The **Independent Boundary** dialog box reappears

5. To reverse the direction of the vector, select the **Reverse Direction** check box.
6. Click **OK**.

Maxwell computes the H-field on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a Transient Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. To specify the coordinate system, do the following in the Coordinate System section:

Note	You must specify the coordinate system in the plane on which the boundary exists. First draw the U vector of the coordinate system. Maxwell uses the U vector you draw and the normal vector of the boundary face to calculate the v-axis. Then specify the direction of the V vector.

   a. Select **New Vector** from the **U Vector** pull-down list.
      The **Create Line** message appears asking you to draw the U vector of the coordinate system in the plane of the selected face, and the **Dependent Boundary** dialog box disappears while you draw the U vector.
   b. Select the U vector's origin in one of the following ways:
      - Click the point.
      - Type the point's coordinates in the in the **X**, **Y**, and **Z** boxes.

Note	The U vector's origin must be on the boundary's surface.

c. Select a point on the u-axis in the same way.
When the second point is identified, the vector is set, and the **Dependent Boundary** window reappears, with **Defined** listed in the **U Vector** pull-down list.

d. To specify the direction of the V vector, select or clear the **Reverse Direction** check box.

6. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Hdep = Hind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Hdep = -Hind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

7. Optionally, click **Use Defaults** to revert to the default values in the window.
8. Click **OK** to assign the boundary to the selected object.

Note	The origin must be a vertex point of one of the objects.

Assigning a Resistive Sheet Boundary for the Transient Solver

Note	For Eddy Current designs refer to *Assigning a Resistive Sheet Boundary for the Eddy Current Solver*.

When two conductors are in contact within a conduction path, a voltage drop normally exists across the contact surface due to the imperfection of the contact between the two conductors. This voltage drop should be taken into account when the winding is a voltage excitation. This boundary condition assigns a resistive sheet to consider the impact of this kind of voltage drop. The resistive sheet is defined by a lumped resistance in ohms.

To assign a resistive sheet boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a sheet object or face of a 3D conducting body touching another conducting body).

Note	• The sheet must have conductors touching both of its faces. • The sheet can not be smaller than the contacting surface. • The sheet cannot span multiple faces.

2. Click **Maxwell>Boundaries>Assign>Resistive Sheet**.
The **Resistive Sheet** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter a resistance value in the **Resistance** box and select the unit of measure, or accept the default (1 ohm).

5. Optionally, the **Defaults** tab allows you to save the current resistance value for future use, and to revert to the standard defaults.
6. Click **OK** to assign the boundary to the selected object.

> **Note:** When switching the solution type between transient and eddy current, resistive sheet boundaries will be kept.

Assigning a Resistive Sheet Boundary for the Eddy Current Solver

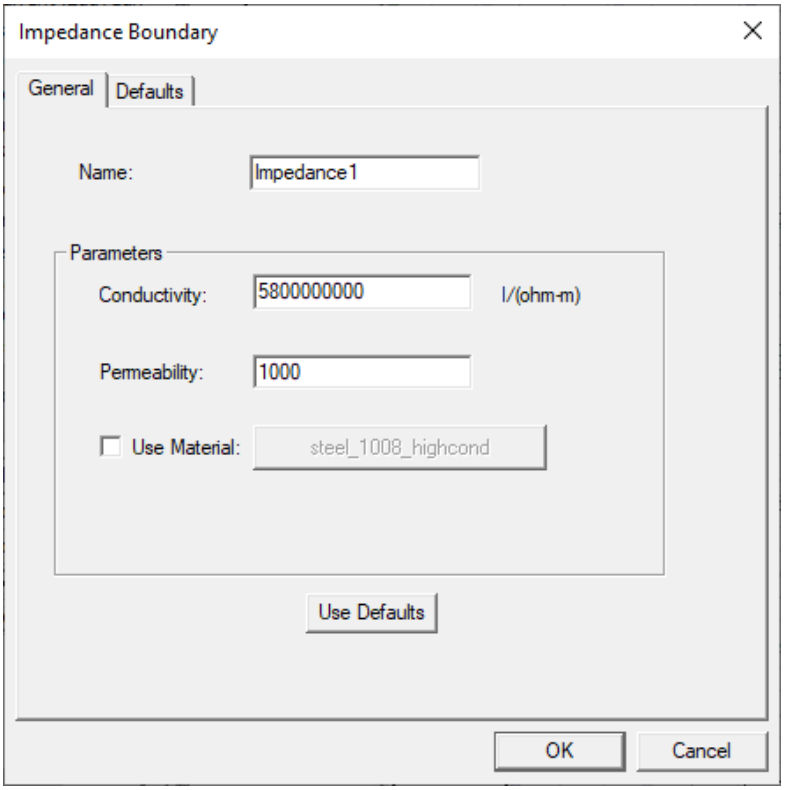
Assigning an Impedance Boundary for the Transient Solver

> **Note:** To define an impedance boundary for the eddy current solver, refer to *Assigning an Impedance Boundary for the Eddy Current Solver*.

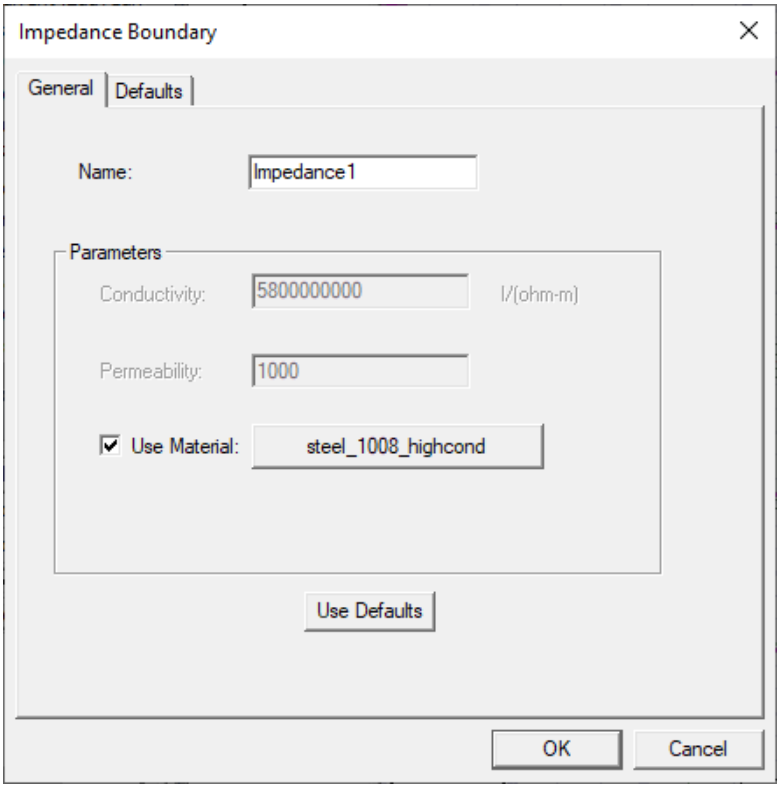
This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. Since the conductor must be excluded from the model (saving time needed to mesh and solve for currents), assign the impedance boundary condition to an outside edge of the problem region or to an excluded object.

To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).
2. Click **Maxwell 3D>Boundaries>Assign>Impedance** to open the **Impedance Boundary** dialog box.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Do one of the following:
    - If the **Use Material** check box is unchecked, enter the conductivity (in inverse ohm-meters) in the **Conductivity** field, and the conductor's relative permeability in the **Permeability** field.



- If you wish to select a material from the library, check the **Use Material** check box, then use the button to select the desired material.

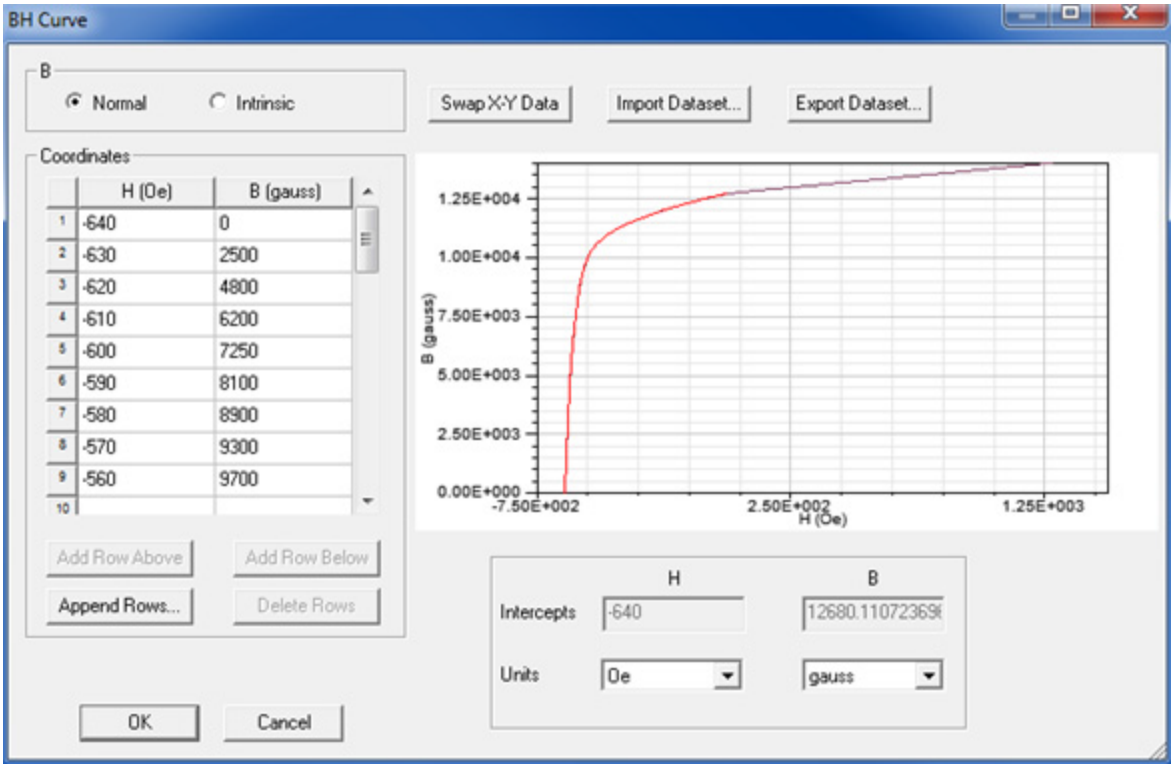


- **Nonlinear Permeability**

  If you select a material that has nonlinear permeability, the non-linear coefficient is computed automatically.

  The nonlinear relative permeability of the material is determined by the B-H curve. If the desired B-H curve of the permeability belongs to an existing material, you can directly use that existing material.

  Otherwise, you can edit a new material with the desired B-H curve.



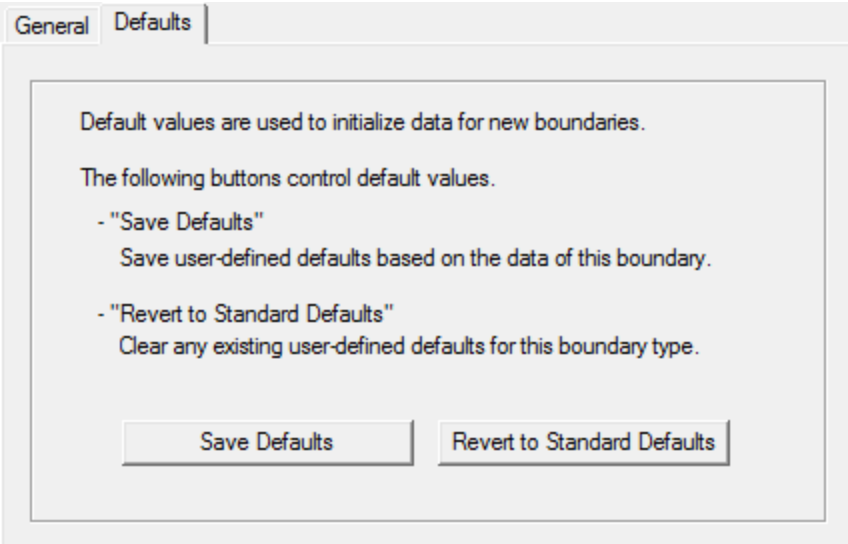
Refer to *Relative Permeability for a Maxwell or RMxprt Material* for details on using nonlinear relative permeability.

- **Temperature Dependent Impedance Boundary**

  The electrical conductivity and permeability of a material used for an impedance boundary condition can be temperature dependent. The Maxwell 3D transient solver provides an option to allow you to input functions as thermal modifiers to consider the effect of temperature on those properties. To enable this feature, check the Use Material check box as above. You can then click Material to open the material properties panel in which you can add a thermal modifier. (Refer to *Setting the Temperature of Objects* for additional information on using temperature dependent impedance boundaries).

5. Optionally, click **Use Defaults** to revert to the default values in the window.

The **Defaults** tab allows you to control default values. The **Save Defaults** button saves the values currently defined on the **General** tab as the defaults to be assigned to new impedance boundaries. **Revert to Standard Defaults** clears existing user-defined values and replaces them with the standard default values.



6. Click **OK** to assign the boundary to the selected object.

   The Project Manager lists the newly assigned impedance boundary in the tree. You can select the boundary in the tree to view and edit its properties in the Properties Window. You

can also double-click the boundary entry in the tree to open it for editing in the Impedance Boundary dialog box.

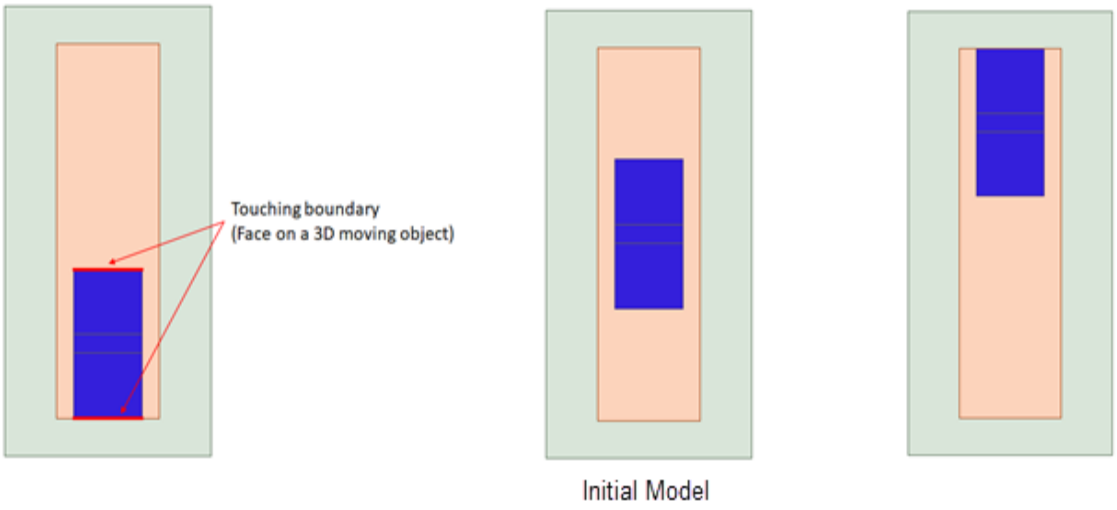
Assigning a Touching Boundary for the Transient Solver

For non-periodic translational motion designs in which a moving part contacts a stationary part this boundary condition assigns a touching boundary to the face of the moving part that contacts the stationary part. When the model is created, there must be an airgap between the moving objects and the stationary objects although these can touch during the simulation (either at beginning or end).

For example, with this feature, the linear actuator can be modeled from one end directly touching the stationary part to the other end also directly touching the stationary part as shown; however the initial model must be drawn without touching the ends as shown in the center image below.



To assign a touching boundary to a non-periodic translational motion part:

1. Select the face of the geometry on which you want to apply the boundary condition (the face of the 3D moving body that will touch a stationary part).

Note	• The touching boundary should be defined on the surface of the moving part. • The touching boundary can only be applied to the moving part with non-periodic translation motion. • At any time step, each touching boundary must either fully touch the stationary part or be completely separated from the stationary part. The touching boundary can not partially touch the stationary part at any time. • The moving and stationary parts are not allowed to be on one conduction path. • Moving object(s) cannot touch the stationary objects in the initial model.

2. Click **Maxwell>Boundaries>Assign>Touching**.
   The **Touching Boundary** window appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Band of Motion

Transient Excitations

After defining the coil terminals for the model, you can use these terminals to define one or more windings using the **Maxwell>Excitations>Add Winding** option. Transient problems use the following sources of magnetic fields:

Excitation	Type of Excitation
Coil Terminal	Used to define one or more model windings.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

Note	A winding is a flexible excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation is needed to set up a winding.

Note	When a source conductor touches an outer boundary, Maxwell assumes current will flow perpendicular to the boundary. If you do not want current to cross the outer boundary, an insulating boundary should be used.

In addition, permanent magnets serve as sources of magnetic fields.

Assigning a Coil Terminal for a Transient Solver

To assign a coil terminal as a transient excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D planar object).
2. Click **Maxwell>Excitations>Assign>Coil Terminal**. (You can also right-click an existing winding in the project tree, and select **Assign Coil Terminal**.)
   The **Coil Terminal Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil terminal in the **Number of Conductors** box.

Note	This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

5. If you want to switch the direction for the coil terminal, click **Swap Direction**.

Note	The direction is shown in the model by a bold red arrow.

6. Optionally, click **Use Defaults** to revert to the default values in the window.
7. Click **OK** to assign the coil terminal to the selected object.

Note	To add this coil terminal to an existing winding, do the following: 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following: • In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**).

Note	For 3D transient solutions using the A-Phi Formulation, refer to the Winding Excitations for A-Phi Formulation section for information on Ordering the Coil Terminals.

Related Topics

"Assigning a Winding Setup for a Transient Solver " below

Order Coil Terminals for A-Phi Formulation

Assigning a Winding Setup for a Transient Solver

Note	• If you wish to define a winding for an Eddy Current solution type, refer to "Assigning a Winding Setup for an Eddy Current Solver " on page 11-81 . • If you wish to define a winding for a Magnetostatic solution type, refer to Assigning a Winding Setup for a Magnetostatic Solver.

You can use the pre-defined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 3D>Excitations>Add Winding**. to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.

3. In the **Parameters** section:
   a. Select **Current, Voltage**, or **External** from the **Type** drop-down menu.

Note	Maxwell transient designs can be dynamically coupled to Twin Builder components through the Twin Builder user interface. You can enable this feature on the Advanced Product Coupling tab of the **Design Settings** dialog box. Source windings set to **External** are available as conservative pins in Twin Builder. For more information, refer to the Twin Builder Help.

   b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
   c. Enter values in the following fields (enabled according to winding type), and select the desired units.

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	Initial Current
	Inductance	
	Voltage	
	Initial Current	

Note	You can also type a function as an expression for any of these fields except Initial Current.

   d. Enter a value in the **Number of parallel branches** text box.

Note	For the **Number of parallel branches** setting, the basic assumption is that the windings are symmetric and balanced, so the current split is forced to be equal in parallel branches. For solid or stranded windings, the **Number of parallel branches** setting assumes there are no circulating currents in the parallel branches. For solid windings, the **Number of parallel branches** setting is intended for applications meeting these conditions: For example, a periodic electric machine wedge model having solid hairpin windings, where the parallel branches are in the symmetric parts of the periodic model. In order to include unbalanced circulating currents this **Number of parallel branches** setting is not applicable, and you must use separate windings for each parallel branch that is connected in an external circuit.

4. Optionally, click **Use Defaults** to revert to the default values in the window.
5. Click **OK** to assign the excitation to the selected object.

A winding is now defined for your model.

Note	To add a coil terminal to this winding, do the following: 1. In the project tree, right-click the winding, and select **Add Terminals**. The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding. 2. Select the coil terminal (s) you want to add. To select multiple terminals, press

	CTRL and click each terminal. 3. Click **OK**. To assign a coil terminal excitation and add it to this winding, do the following: 1. Select the section of the geometry on which you want to apply the coil terminal excitation. 2. In the project tree, right-click the winding, and select **Assign Coil Terminal**. The **Coil Terminal Excitation** dialog box appears. 3. Enter a name for the excitation in the **Name** box, or accept the default. 4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductor**s box. **Note**: This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled. 5. Click **Swap Direction** to change the reference direction for the coil terminal. You can also change this direction in the coil terminal's Properties window by selecting either **Point into terminal**, or **Point out of terminal** for the **Direction** parameter. 6. Optionally, click **Use Defaults** to revert to the default values in the dialog box. 7. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding. To delete all coil terminal excitations that belong to this winding, do the following: • In the project tree, right-click the winding, and select **Delete All Terminals**. All coil terminal excitations are removed from the winding and deleted from the excitations.

Note	For 3D transient solutions using the A-Phi Formulation, refer to the Winding Excitations for A-Phi Formulation section for information on Ordering the Coil Terminals.

Setting Up a Y Connection in 2D and 3D Transient Designs

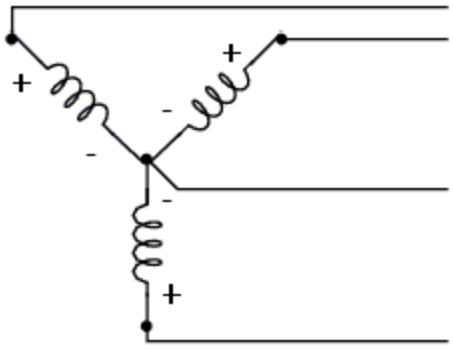
---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well

as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Setting Up a Y Connection in 2D and 3D Transient Designs

The Y Connection function available in 2D and 3D Transient solution types allows multiple windings to be connected in a classical Y (sometimes referred to as wye) configuration with the negative terminals connected to a common node as illustrated below.



Setup Y Connection requires voltage winding definitions be set and the negative voltage terminal for each winding will be connected to form the common node of the circuit.

Each voltage source specified in the winding description drives the positive side of the coil. Y Connections are commonly used in motor and transformer applications driven by 3-phase voltage; however, any number of windings may be connected to a common node in Maxwell.

Note	• Only one Y Connection is allowed in a given Maxwell design. • A Y Connection requires use of stranded voltage windings. • Duplicate windings are not allowed.

To define a Y-connection:

1. Click **Maxwell 2D** (or **Maxwell 3D**)**>Excitations>Setup Y Connection**.
   The **Setup Y Connection** dialog appears.
2. In the **Winding** list on the left, select the windings to be grouped into a Y connection.
3. Click the **Group** button to create a Y Connection group with the selected windings.
4. Click **OK** when all required grouping have been created.

Assigning a Winding Setup for a 2D Transient Solver

Assigning a Winding Setup for a 3D Transient Solver

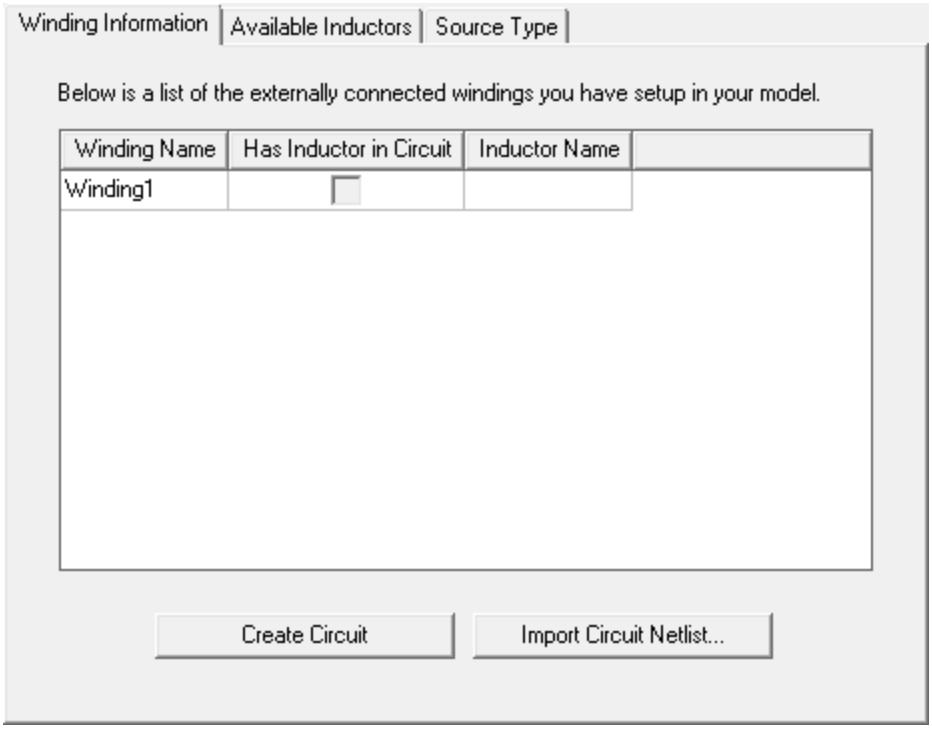
Setting Up an External Circuit Connection for an External Winding Type

The Maxwell Circuit design editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D transient solutions.

Note	External circuits intended for use with the Time Decomposition Method (TDM) can only support basic circuit elements that are solution-independent. This is because, for TDM, all time steps (or all time steps in a subdivision) are solved simultaneously - and thus the circuit topology and its parameters must be known before solving. Therefore some circuit elements, such as solution-dependent switches, diodes, capacitors, and inductors which are not directly connected to windings in series, are not supported.

To set up an external circuit connection for an External winding type:

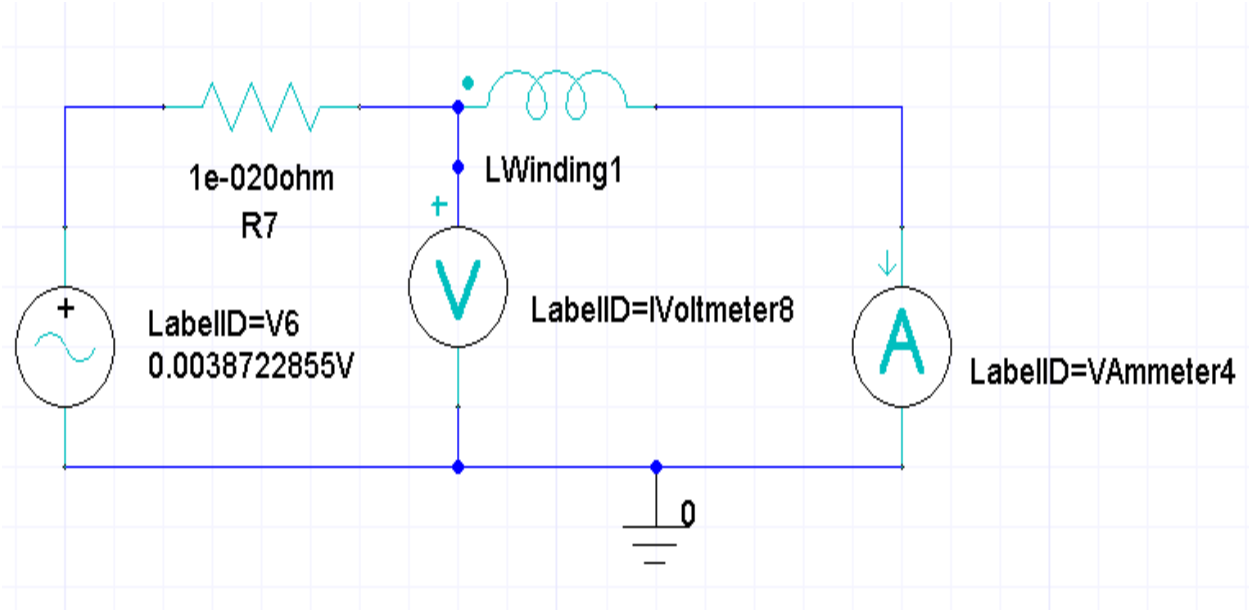
1. Click **Maxwell 3D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.



b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.

3. Add the components needed to complete the external circuit design such as shown the following example.



4. When the circuit design is finished, click **Maxwell Circuit>Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 3D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.

8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.
    b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog.
    c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for Optimetrics analyses.
10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names (which are removed after you import a non-sph file).

Note	After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

Note	For Transient designs, the user-set time steps can be modified when external circuits are used to drive the windings of a transient finite element model. Following is a list of situations that will lead to a time step change: • All power electronic switching instances that do not coincide with user-specified solve times request a new solution time from the transient solver. The respective switching generating a new solve time request for the transient solver can be time, position, or speed dependent. • When current and/or voltage sources with a piecewise linear variation are used, a new solution time is requested from the transient solver at each (time) definition point used in the corresponding source definition table. • When the change in any winding inductance value is excessive, a new time step (smaller) is calculated and a new solution generated (re-calculated) accordingly. If a user-specified save field time is missed because of the above reasons, the next solved time step fields are saved instead.

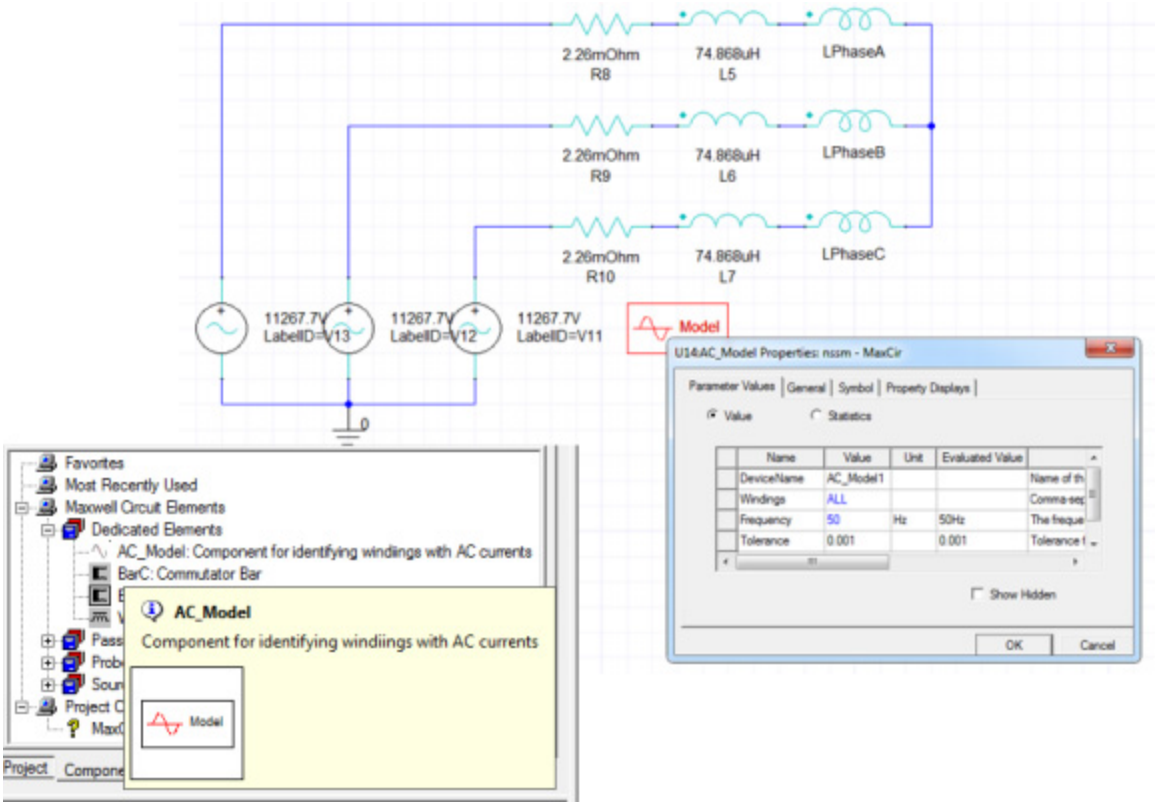
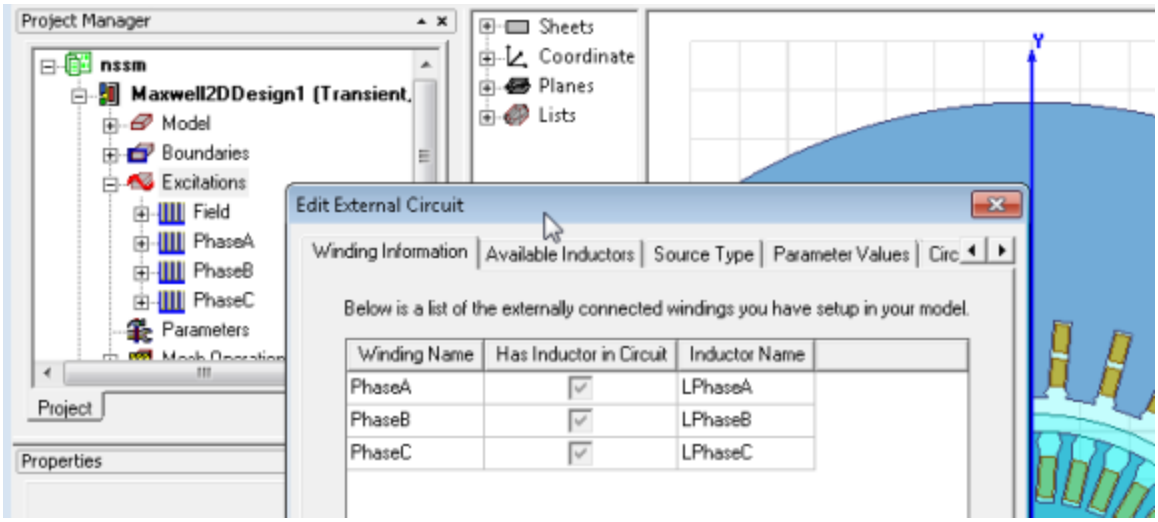
"Assigning a Winding Setup for a Transient Solver " on page 11-101

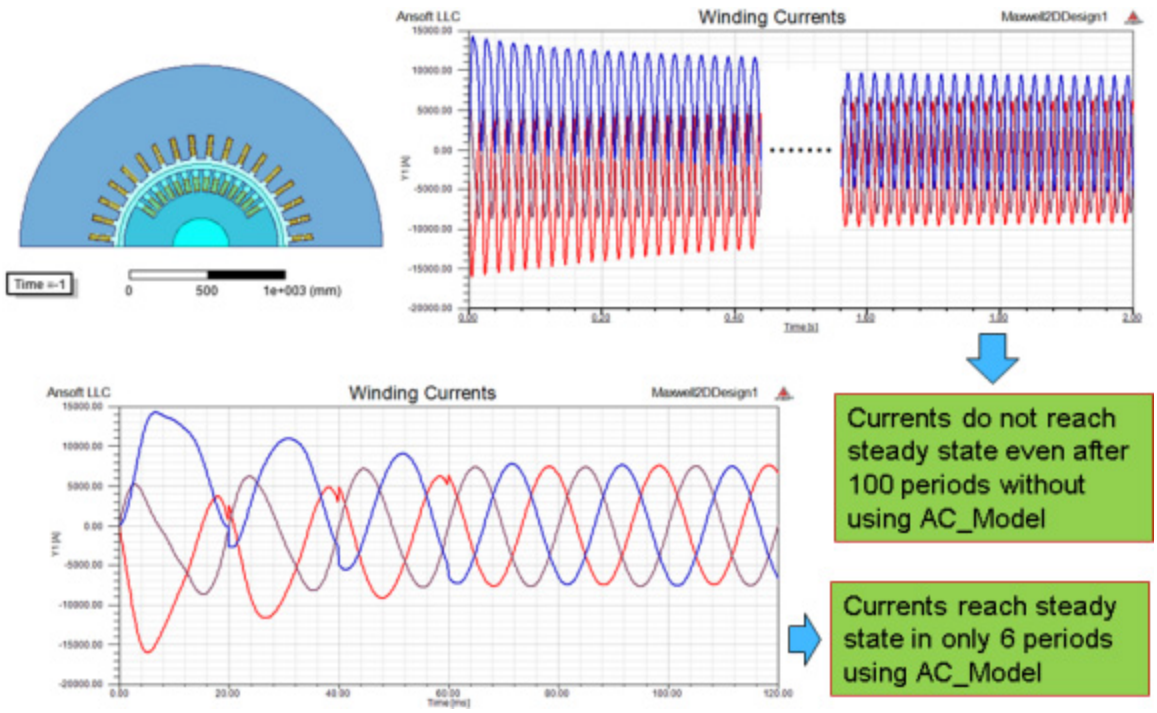
Using the AC_Model Component to Speed Up Analysis

Use of the AC_Model component when setting up an external circuit design can improve transient analysis time to steady state significantly.





In the above example the AC_Model is associated with ALL three of the phase windings. The AC_Model modifies currents for the AC windings at the beginning of each period without interrupting the transient process - thus improving the analysis time.



Setting Up an External Circuit Using Simulink

In addition to using the Maxwell Circuit Editor to set up an external circuit, you also can use Matlab® Simulink® to set up an external circuit for both Maxwell 2D and 3D transient designs.

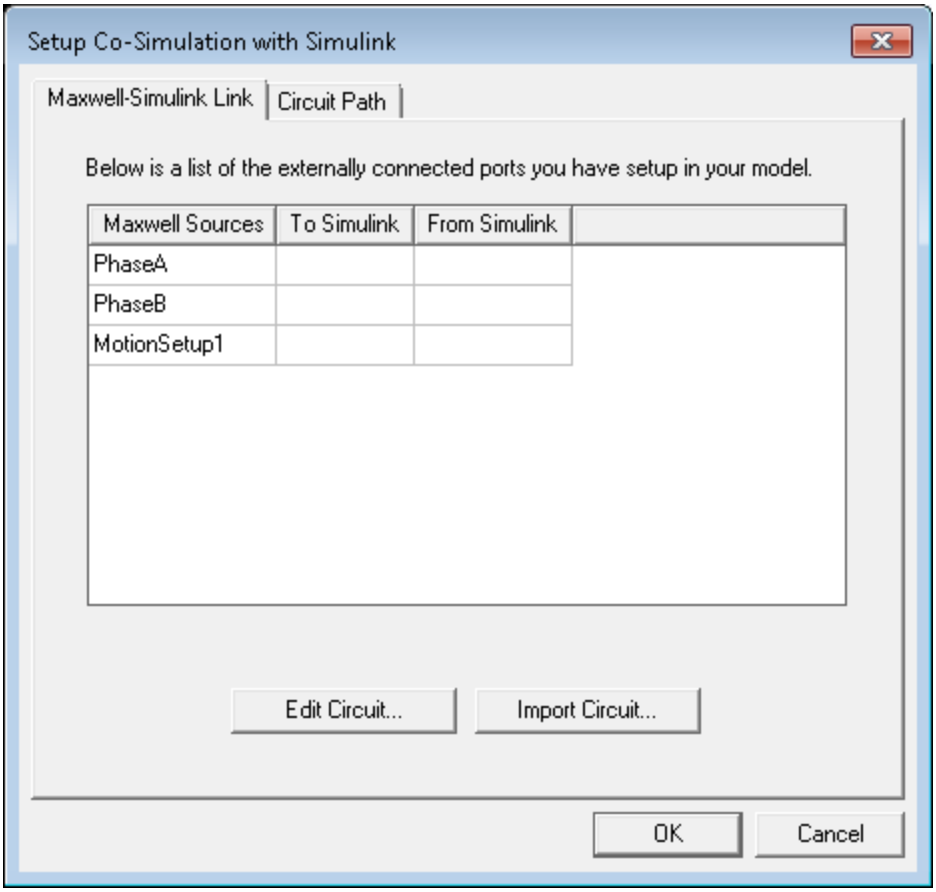
- Supported Simulink versions are: R2017b, R2018a, R2018b, R2019a, R2019b, R2020a, R2020b, and R2021a.

In addition to winding sources, motion sources can also be linked in the external circuit.

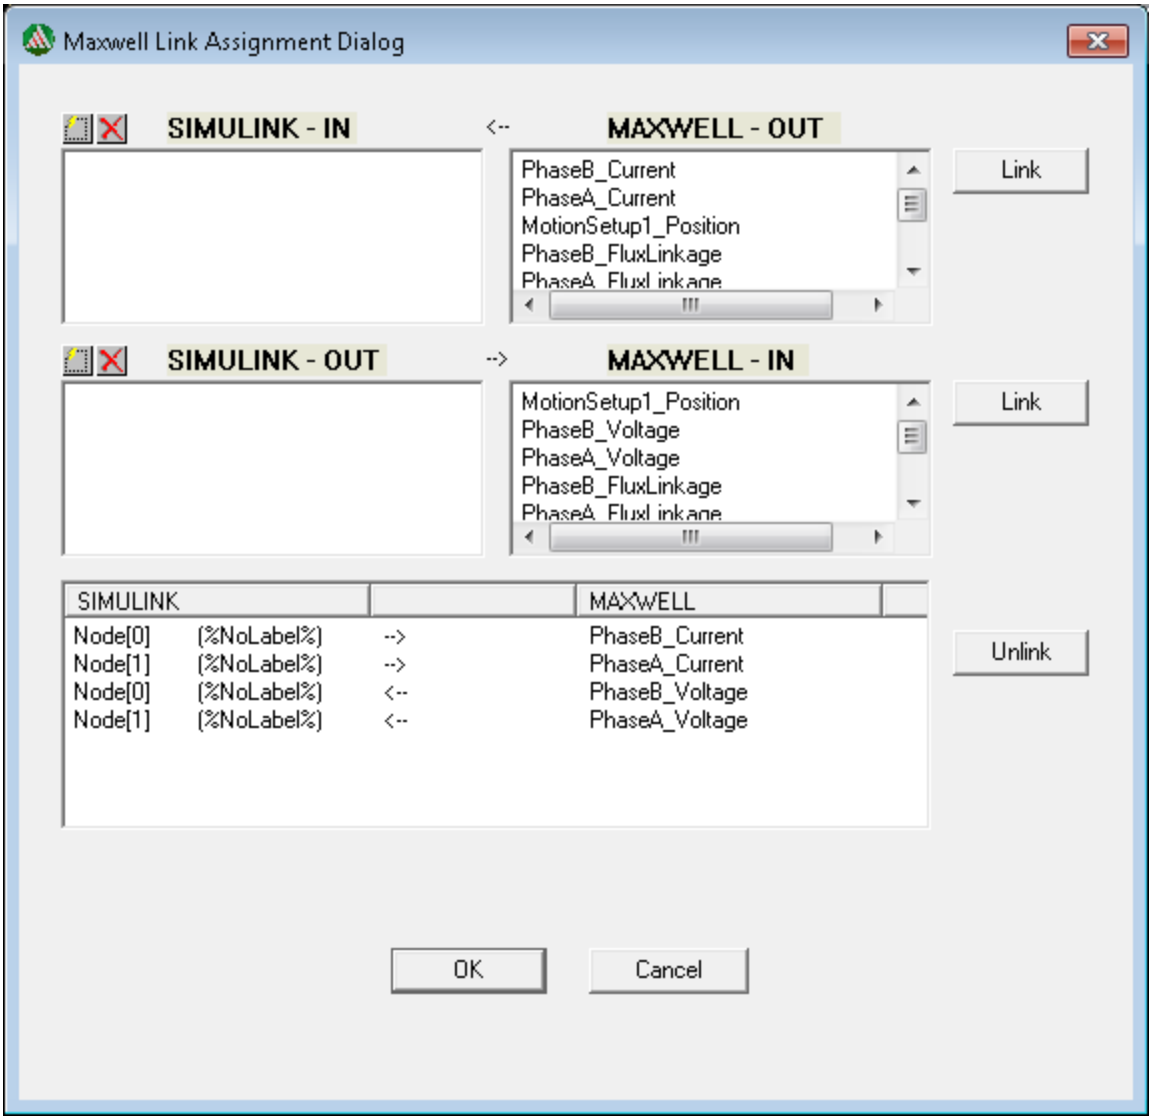
- Winding sources ("External" type only): voltage, current, and flux linkage.
- Motion sources: speed, position, and force/torque

To set up an external circuit using Simulink:

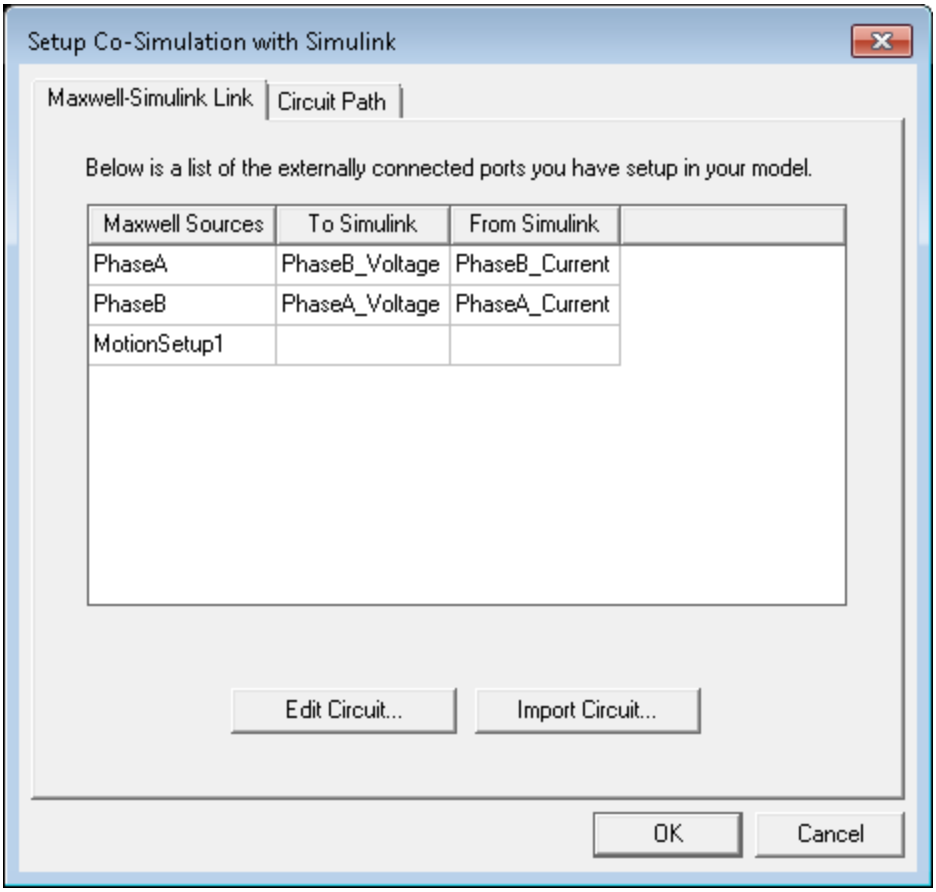
1. In the Maxwell Project Manager, right-click **Excitations** and select **Setup Co-Simulation with Simulink** to open the **Setup Co-Simulation with Simulink** dialog box. You can also open the dialog box from the main **Maxwell 2D** or **3D>Excitations** menu. If an external Simulink circuit has already been created and linked, **To Simulink** and **From Simulink** connections information is shown. Otherwise, these table cells are empty.



2. On the Maxwell-Simulink Link tab, click the **Edit Circuit** button to launch Simulink. The Maxwell sources are listed in the in the **Maxwell Link Assignment Dialog** box. If a circuit has already been created, the circuit also displays in the Simulink circuit editor window.

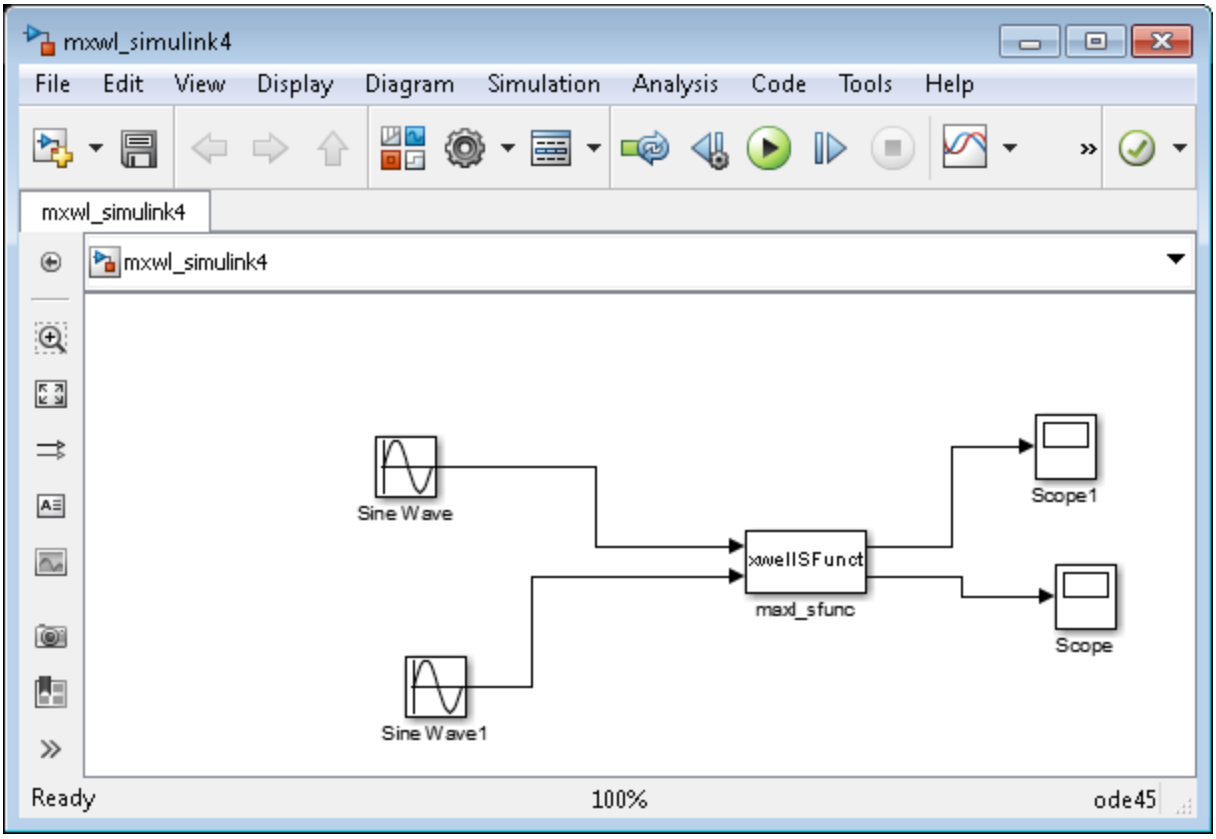


3. Add and **Link** SIMULINK - IN and SIMULINK- OUT connections to the desired Maxwell parameters to set up the Maxwell component ports. You can also **Unlink** connections as needed. Click **OK** once the ports are set up. The ports will show in the Simulink circuit editor window.

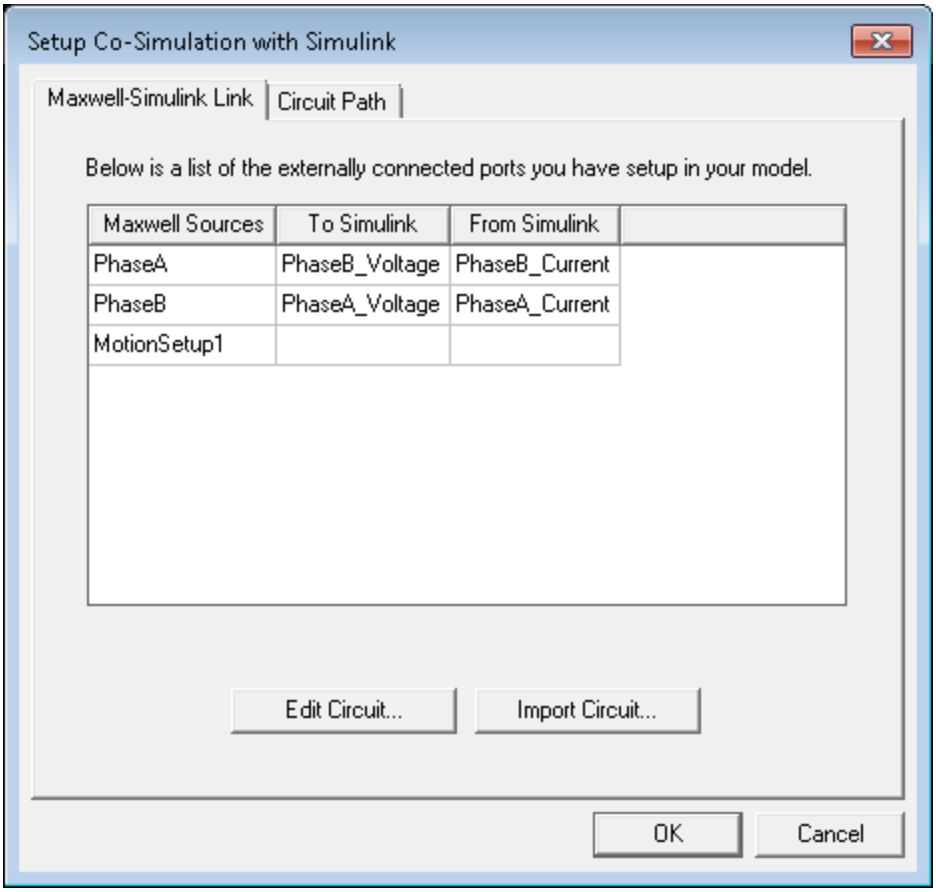


If changes are needed, click **Edit Circuit** to reopen the **Maxwell Link Assignment** dialog box.

4. Modify (or create) the circuit in the Simulink circuit editor window as needed, and save the Simulink circuit project.



5. In the Maxwell **Setup Co-Simulation with Simulink** dialog box, click the **Import Circuit** button to import the Simulink circuit project into the Maxwell project. The linked connections appear in the **Edit External Circuit** dialog box. The **Circuit Path** tab shows the path to the location from which the Simulink circuit file was imported.



Note	You can also modify an existing Simulink circuit by opening the circuit file directly in Simulink, and then importing the modified circuit file back into the Maxwell design.

6. When you start the Maxwell design analysis, the co-simulations are started between Maxwell and Simulink .

Note	• Making changes to the Maxwell winding and motion setups invalidate the external circuit. • Making changes to the external Simulink circuit setup invalidates the solutions.

Transient A-Phi Formulation Boundaries and Excitations

Define at least one of the following as a source of magnetic fields:

- A voltage or current.
- Stranded or solid windings, with a voltage or current supply or connected to an external circuit winding.

Note	For stranded conductors, it is assumed that the current density is uniform on the cross-section of the respective conductors. Thus, the stranded option for current excitations should mostly be used only in cases where the cross-section of conductors is constant, consistently with the assumption that the respective object is a coil built with strands of wire. For this reason, conductors (coils) could be created by either sweeping around an axis using zero segments or sweeping along a path having only true surface segments in order to create a smooth surface coil having a completely uniform cross-sectional area over its entire length.

- A permanent magnet.

You may need to set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Transient A-Phi Formulation Boundaries

Transient A-Phi Formulation Excitations

Maxwell 3D Transient Solution Based on A-Phi Formulation

Specifying the Solver Type

Transient A-Phi Formulation Boundaries

The transient A-Phi field solver allows you to define the following types of boundary conditions.

> **Note:** The setup for Insulating, Symmetry, Independent, Dependent, and Resistive Sheet boundaries is the same for both Transient and Transient A-Phi Formulation solvers.

Boundary Type	H-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries –The tangential component of **H** and the normal component of **J** are continuous across the boundary. • Neumann boundaries – **H** is normal	Ordinary field behavior. Initially, object interfaces are natural boundaries; outer boundaries, and excluded objects are Neumann boundaries.

	to the boundary; its tangential components are zero. **J** field is tangential to the boundary.	
Flux Tangential	**H** is tangential to the boundary and flux cannot cross it.	Problems with flux tangential at outer boundary.
Insulating	Same as Natural boundary, except that current cannot cross the boundary.	Thin, perfectly insulating sheets between touching conductors.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) – **H** is tangential to the boundary; its normal components are zero. The potential value at the boundary is zero. • Even Symmetry (Flux Normal) – **H** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The **H**-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **H**-field on the independent boundary.	Planes of symmetry in periodic structures where **H** is oblique to the boundary.
Resistive Sheet	Same as Natural boundary.	Voltage drop and loss on the contact surface between two different objects within a conduction path.

Default Boundary Conditions for a Transient A-Phi Solver

These boundary conditions are automatically defined for a transient model:

- Natural boundaries are assigned to the surfaces between objects.
- Neumann boundaries are assigned to the outer surface of the problem region. **J** field is tangential to the boundary, and **H** field is normal to the boundary.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Flux Tangential Boundary for a Transient A-Phi Solver

This type of boundary is applied when the **H** field is tangential to the boundary.

To define a zero tangential **H** field boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically a face).

2. Click **Maxwell>Boundaries>Assign>Flux Tangential**.
3. The **Flux Tangential** window appears.
4. Enter a name for the boundary in the **Name** box, or accept the default.
5. Click **OK** to assign the boundary to the selected object.

Transient A-Phi Formulation Excitations

Transient A-Phi formulation supports the following excitations:

Excitation	Type of Excitation
Coil Terminal	Used to define windings.
Winding With Current	Current for a stranded or solid conductor.
Winding With Voltage	Voltage for a stranded or solid conductor.
Winding With External Circuit Connection	External circuit connection for a stranded or solid conductor.
Voltage	Voltage for a solid conductor.
Current	Current for a stranded or solid conductor.
Permanent Magnet Field	Permanent magnets serve as sources of magnetic fields.

Note	A winding is a flexible excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation is needed to set up a winding.

Note	Winding excitation is assigned as in the transient solver. However, coil terminals must be ordered according to the physical potential distribution as explained in Boundaries and Excitations>Winding Excitations for A-Phi Formulation.

Electric Transient Solver Boundaries and Excitations

Specify at least one of the following excitations as a source of electric fields:

- The total charge on object.
- The volume charge density inside an object.
- The current.
- Define the electric potential on each surface using a voltage excitation.

Electric Transient Solver

Electric Transient Excitations

The following excitations are available for electric transient problems:

- Voltage - this excitation specifies the value of the electric scalar potential value on 2D surfaces or 3D volume bodies.
- Charge - this excitation can be applied to 2D surfaces or 3D volume bodies, if a body has net charge q. This type of excitation defines the total charge on a surface or object.
- Floating - this excitation can be applied to 2D surfaces or 3D volume bodies, then these 2d or 3d objects are with equi-potential. This type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.
- Volume Charge Density - this excitation can be applied to only 3D volume bodies. If that body has net charge q, the charge density is q/VOL, where VOL stand for the volume of that body.
- Current - this excitation can be applied to only 2D surfaces, where the total current flowing into/out that surface is specified.
- Sink - this excitation can be applied to only 2D surfaces which are grounded with reference potential value. It is the same as applying zero voltage excitation on those surfaces.

12 - Assigning Boundaries and Excitations for 2D Designs

For every design, you need to assign boundaries and excitations. You can use the **Maxwell 2D** menu or the project tree to do the following:

- Define boundary conditions that control how the electric or magnetic field behaves planes of symmetry, periodicity, or edges of the problem region.
- Define solution type specific excitations of voltage, charge, coil, and current.
- For magnetic transient designs, if needed, set up a winding and an external circuit connection.

Each field solver requires you to specify excitations of electric or magnetic fields and references for computing these fields.

- Magnetostatic Boundaries and Excitations
- Electrostatic Boundaries and Excitations
- AC Conduction Boundaries and Excitation
- DC Conduction Boundaries and Excitations
- Eddy Current Boundaries and Excitations
- Transient Boundaries and Excitations

You must specify at least one of the boundary conditions or excitations listed in these sections so that the simulator can compute accurate values for fields and parameters.

Specifying the Solver Type

Selecting Objects and Faces in the 2D Geometry

Before creating a boundary or excitation, you must specify its location by selecting the object or surface on which to assign the boundary condition or source excitation.

Defining Boundary Conditions in 2D

To assign a boundary condition:

1. Select the section of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell 2D>Boundaries>Assign**, or right-click **Boundaries** in the project tree and click **Assign**.
3. Select the desired boundary type from the sub-menu. The specific boundary types you can define depend on the solver you have chosen for your project.
    - Magnetostatic Boundary Conditions
    - Electrostatic Boundary Conditions

- AC Conduction (Electric) Boundary Conditions
- DC Conduction (Electric) Boundary Conditions
- Eddy Current Boundary Conditions
- 2D Transient Boundary Conditions

4. Enter the name for the boundary or accept the default.
5. Depending on the boundary type, you may need to define additional parameters.
6. Click **OK** to create the new boundary.

The new boundary is added to the boundary list in the project tree.

Defining 2D Excitations

The specific excitations you can define depend on the solver you have chosen for your design.

- Magnetostatic Excitations
- Electrostatic (Electric) Excitations
- AC Conduction (Electric) Excitations
- DC Conduction (Electric) Excitations
- Eddy Current Excitations
- 2D Transient Excitations

To assign an excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell 2D>Excitations>Assign**, or right-click **Excitations** in the project tree and click **Assign**.

   A submenu appears with choices that depend upon the solver type.
3. Select one of the following excitation types from the submenu:
   - Voltage
   - Charge
   - Floating
   - Charge Density
   - Current Density
   - Current
   - Coil
   - End Connection
   - Permanent Magnet Field
4. Enter the name for the excitation type or accept the default.
5. Enter the desired parameter values, units, and other settings for the excitation in the dialog box. You can also enter a mathematical function to determine values for voltage, current density, charge density, and other parameters. The Permanent Magnet Field excitation also requires you set up a link to a source project.

Note	When entering current, or coil terminals, the arrow associated with current in the

	selected object shows the direction as if a positive value is entered for the current. If a negative value is entered the actual current flow direction is opposite to what the arrow shows. Click **Swap Direction** if you want to reverse the direction of the arrow.

6. Click **OK** to create the new excitation.

The new excitation is added to the excitation list in the project tree.

Specifying the Solver Type

Viewing 2D Boundaries and Excitations

To view a list of all boundaries or excitations set for the design:

1. In the project tree, right-click **Boundaries** or **Excitations**.
   A shortcut menu appears.
2. Select **List** from the shortcut menu.
   The **Design List** dialog box appears, with the tab page visible for the item you selected. This dialog box contains tabs for **Model**, **Boundaries**, **Excitations**, **Parameters**, **Mesh Operations**, and **Analysis Setup**.
3. To view the properties for an item in the list, select the item, and click **Properties**.
4. To delete an item from the list, select the item, and click **Delete**.
5. When you are finished in the **Design List** dialog box, click **Done** to close it.

Setting the Visibility for 2D Boundaries and Excitations

To show or hide a boundary:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Boundaries** tab.
3. Select or clear the **Visibility** check box for each boundary listed.
4. Click **Done**.

To show or hide a excitation:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Excitations** tab.
3. Select or clear the **Visibility** check box for each excitation listed.
4. Click **Done**.

Functional Boundaries and Excitations in 2D

Functional boundaries and excitations can be used to do the following:

- Define the value of a boundary or excitation quantity (such as the voltage, magnetic field, or current density) using a mathematical relationship — such as one relating its value to that of another quantity.
- Define the value of a boundary or excitation as a function of position.
  - Current Density Excitation (Magnetostatic or Eddy Current solver type)
  - Voltage Excitation (Electric solver types)
  - Volume Charge Density Excitation (Electrostatic or Electrostatic + DC solver types)
- If the parametric analysis capability is installed, identify which boundary or excitation quantities are to be varied during a parametric sweep. These variables are always set to constant values in the parametric analysis.

Setting Eddy Effects and Displacement Current in 2D

(2D Eddy Current and/or Transient Solvers)

For both eddy current and transient solvers in 2D, you may need to specify the following additional settings:

- The behavior of eddy currents and the AC magnetic field in conductors. When you activate the **Eddy Effect** setting, the solver computes the induced eddy currents.
- For 2D Transient, source settings override the eddy effect settings. Objects assigned as “solid” sources will have eddy effects turned on, while objects assigned as “stranded” sources will have eddy effects turned off (regardless of the eddy effect settings). The eddy effect settings will be respected for non-sources.

Typically, background objects are excluded from eddy current settings.

To set eddy effects:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Set Eddy Effects**.
   The **Set Eddy Effect** dialog box appears showing only objects which are valid for eddy effect calculation, specifically objects with conductivity greater than 1.
3. For each object in the list, select or clear the check boxes for **Eddy Effect**. When selecting multiple entries, the changes are synchronized for all selected rows.

Note	Multi-select is supported by holding the **CTRL** or **Shift** key while clicking.

4. Click the **Select By Name** button to enter the name of a specific object for selection. Multiple objects may be selected using the * and ? wildcards.
5. Optionally, click the **Use suggested values** button to set the **Eddy Effects** for all elements recommended by Maxwell2D.
6. Click **OK**.

The **Deselect All** button will deselect all selected objects in the list.

Setting Default Values for 2D Boundaries and Excitations
Reassigning 2D Boundaries
Reassigning 2D Excitations

Duplicating 2D Boundaries and Excitations

To duplicate a boundary or excitation when its geometry is pasted or duplicated:

1. Click **Tools**>**Options**>**Maxwell 2D Options**.
   The **Maxwell 2D Options** dialog box appears.
2. Click the **General Options** tab.
3. Select **Duplicate boundaries with geometry**.
4. Click **OK**.
   All boundaries and excitations are duplicated with their associated geometries until you clear this option.

Hint	Use this option to copy and paste boundaries. For example, do the following to use the same boundary on multiple objects: 1. Select the face to which you want to assign the boundary. 2. Click **Modeler**>**Surface**>**Create Object From Face** to create a new object from the existing face. 3. Assign the boundary to the new face object. 4. Copy and paste the new face object to copy and paste the boundary.

Copying and Pasting Objects

Showing and Hiding Boundaries and Excitations in 2D

You can choose to show or hide a boundary or excitation's geometry, name, or vectors, in the active view window or in all view windows.

Related Topics

Showing and Hiding 2D Boundaries/Excitations in Every View Window

Showing and Hiding 2D Boundaries and Excitations in Every View Window

1. Click **Maxwell 2D>Boundaries>Visualization** or **Maxwell 2D>Excitations>Visualization**.
   The **Boundary Visualization Options** dialog box appears.
2. Select one of the following from the **Select** pull-down menu:
   - All
   - All Boundaries
   - All Excitations
   - By Name
3. If you select **By Name**, enter a name in the **Select By Name** dialog box, and click **OK**.
4. To clear the selection of all boundaries and excitations, click **Deselect All**.
5. Click **Close** to close the **Boundary Visualization Options** dialog box.

Setting Default Values for 2D Boundaries and Excitations

When assigning a boundary or excitation, many of the fields in the boundary and excitation dialog boxes have default values associated with them. These default values are initially set by **Maxwell 2D**, but can be overridden.

To modify the default values associated with a specific boundary or excitation type:

1. Assign a boundary or excitation.
2. Modify any default values.
3. Close the boundary or excitation's dialog box.
4. Re-open the new boundary or excitation's dialog box by right-clicking the boundary or excitation in the project manager and selecting **Properties**. The dialog now includes a **Defaults** tab.
5. Under the **Defaults** tab, click **Save Defaults**.

   The values assigned to this boundary are saved as the default values and are assigned when new boundaries of this type are created.
6. Optionally, click **Revert to Standard Defaults**.

   The default values you set for this boundary type are cleared and will revert to the default values set by **Maxwell 2D**.

Reassigning 2D Boundaries

You can reassign a boundary to another surface. This is useful when you modify objects with assigned boundaries, invalidating the boundaries. For example, if you unite two objects with assigned boundaries, the second object's boundary becomes invalid because united objects maintain the characteristics of the first object selected. In this case, you would need to reassign the boundary or delete it.

To reassign a boundary:

1. Select the object or object face to which you want to assign an existing boundary.
2. Click **Maxwell 2D>Boundaries>Reassign**.
   The **Reassign Boundary** dialog box appears.

Hint	Alternatively, select the object or object face to which you want to assign an existing boundary. Right-click the existing boundary in the project tree, and then click **Reassign** on the shortcut menu.

3. Select the boundary you want to reassign, and click **OK**.

Note	When reassigning a boundary that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Related Topics

Reassigning 2D Excitations

Reassigning 2D Excitations

To reassign an excitation:

1. Select the object or object face to which you want to assign an existing excitation.
2. Click **Maxwell 2D>Excitations>Reassign**.
   The **Reassign Excitation** dialog box appears.

Hint	Alternatively, select the object or object face to which you want to assign an existing excitation. Right-click the existing excitation in the project tree, and then click **Reassign** on the shortcut menu.

3. Select the excitation you want to reassign, and click **OK**.

Note	When reassigning an excitation that includes vectors in its definition, Maxwell attempts to preserve the vectors with the new assignment, but this is not always possible.

Related Topics

Reassigning 2D Boundaries

Deleting All 2D Boundaries and/or Excitations

To delete all boundaries or excitations:

- Click **Maxwell 2D>Boundaries>Delete All** or **Maxwell 2D>Excitations>Delete All**.

Viewing and Editing 2D Boundary or Excitation Properties

To open the **Properties** dialog box for a boundary or excitation that is already assigned:

1. In the project tree, under either **Boundaries** or **Excitations**, right-click a specific boundary or excitation, and select **Properties**.
   The **Properties** dialog box for that boundary/excitation appears.
2. Make the desired changes, and click **OK**.

Specifying the Solver Type
Permanent Magnet Excitations

2D Magnetostatic Boundaries

The magnetostatic field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model...
Default Boundary	Field behaves as follows: • At the interface between objects,	Initially, object interfaces are natural boundaries; outer boundaries, and

Conditions (Natural and Neumann)	the H tangent and B normal are continuous. • On outer boundaries, B field is normal. As a rule, this behavior needs to be modified at least for some portions of the outer boundary to insure uniqueness of the solution.	excluded objects are Neumann boundaries.
Vector Potential	Sets the magnetic vector potential A_z, or rA_ϕ, on the boundary. The behavior of H depends on whether A_z or rA_ϕ is constant or functional.	Outer boundaries at specific vector potentials; externally applied magnetic fields.
Balloon	This boundary is considered to be far away from the other sources in the problem.	Actual behavior is context dependent. In general, if a Dirichlet BC is not applied elsewhere to insure uniqueness, the "balloon" will be assigned a Dirichlet boundary condition.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Matching (Independent and Dependent)	The **Magnetic Field vector** on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **Magnetic Field** vector on the independent boundary.	Planes of symmetry in periodic structures where **Magnetic Field** is oblique to the boundary.

Default Boundary Conditions for a 2D Magnetostatic Solver

These boundary conditions are automatically defined for a magnetostatic model:

- Natural boundaries are assigned to the surfaces between objects. At the interface between objects, the H tangent and B normal are continuous.

- Neumann boundaries are assigned to the outside edges of the problem region. On outer boundaries, B field is normal. As a rule, this behavior needs to be modified at least for some portions of the outer boundary to insure uniqueness of the solution.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential for a 2D Magnetostatic Solver

To define a vector potential boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge). **Maxwell2D** requires that the Vector Potential be assigned on a 1D object such as an edge or a line.
2. Click **Maxwell2D>Boundaries>Assign>Vector Potential**.
   The **Vector Potential Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or a functional value.
5. If a functional value is specified, select a **Coordinate System** from the pull-down list:
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning a Symmetry Boundary Condition for a 2D Magnetostatic Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**Magnetic Field** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**Magnetic Field** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition for a 2D Magnetostatic Solver

To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for a 2D Magnetostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface.

To set a independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary for a 2D Magnetostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define a independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic fields on the dependent and independent boundaries have the same magnitude and direction.
Bdep = -Bind	Click this radio button if the magnetic fields on the dependent boundary have the same magnitude as but the opposite direction from the independent boundary.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Magnetostatic Excitations

The following excitations of magnetic fields are available for magnetostatic problems:

Excitation	Type of Excitation
Current Density	The known current density distribution in the cross-section of a conductor.
Current	The total current in a conductor.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Resistance Voltage Drop	Resistance Voltage Drop for both a stranded and solid conductor.

In addition, permanent magnets materials serve as sources of magnetic fields.

Assigning a Current Density Excitation for a 2D Magnetostatic Solver

This command (depending upon solution type, either **X-Y** or **R-Z**) specifies the applicable components of the current density in the cross-section of an object. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell2D>Excitations>Assign>Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current density in the **Value** box. The value may be a single numeric quantity or a functional quantity.
   b. If a functional quantity is entered in the **Value** box, which depends on the applicable coordinates, select a **Coordinate System** from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Current Excitation for a 2D Magnetostatic Solver

Specifies the total current in the cross-section of an object.

To set a current excitation:

1. Select the section of the geometry (i.e., the conductor) on which you want to apply the excitation (typically a face or other 2D planar object).
2. Click **Maxwell2D>Excitations>Assign>Current**.
   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter a value for the current in the **Value** box, and select the units from the pull-down list.
   b. Select **Positive** or **Negative** as the **Ref. Direction**.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup for a 2D Magnetostatic Solver

Note	• If you wish to define a winding for a 2D Eddy Current solution type, refer to "Assigning a Winding Setup for a 2D Eddy Current Solver " on page 12-41 . • If you wish to define a winding for a 2D Transient solution type, refer to Assigning a Winding Setup for a 2D Transient Solver.

You can use the predefined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 2D>Excitations>Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.

3. In the **Parameters** section, select **Current**, or **Resistance Voltage Drop** from the **Type** drop-down menu.
4. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
5. Enter values in the following fields, and select the desired units:

For a current winding	For a resistance voltage drop winding[1]
Current	Resistance
	Voltage

Note	You can also type a function as an expression for any of these items.

6. Enter a value in the **Number of parallel branches** text box.

Note	Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object

The definition of a winding is final only after specifying the coils which belong to it.

Note

To add a coil terminal to this winding, do the following:

1. In the project tree, right-click the winding, and select **Add Coils**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **CTRL** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding, do the following:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the project tree, right-click the winding, and select **Assign Coil**.
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

   Note: This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.
5. Select one of the following for the **Polarity**:

   • **Positive**
   • **Negative**
   • **Function**

	6. If you selected **Function** as the **Polarity**, enter a function in the text box. 7. Optionally, click **Use Defaults** to revert to the default values in the dialog box. 8. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding. To delete all coil terminal excitations that belong to this winding, do the following: • In the project tree, right-click the winding, and select **Delete All Coils**. All coil terminal excitations are removed from the winding and deleted from the excitations.

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Assigning a Coil for a 2D Magnetostatic Solver

To assign a coil as a magnetostatic excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell2D>Excitations>Assign>Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

Note	To add this coil to an existing winding, do the following:

	1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following: • In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**). • Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the project tree and selecting **Delete All Coils**.

2D Electrostatic Boundaries

2D Electrostatic Excitations

Technical Notes: Electric Field Calculation

Specifying the Solver Type

2D Electrostatic Boundaries

The following boundary conditions are available for electrostatic problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary	Field behaves as follows: • Natural boundaries — The	Ordinary E-field behavior on boundaries. Object interfaces

Conditions (Natural and Neumann)	normal component of **D** changes by the amount of surface charge density, tangent component of **E** is continuous. No special conditions are imposed. • Neumann boundaries — **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.	are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** is tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) — **E** is normal to the boundary; its tangential components are zero.	Planes of geometric and electrical symmetry.
Balloon	Two options are available: Charge — The charge at "infinity" balances the charge in the drawing region. The net charge is zero. (Use for capacitance calculations) Voltage — The voltage at "infinity" is zero.	Electrically insulated structures (Charge option) or electrically grounded structures (Voltage option). For the voltage case, the balloon boundary will not be equipotential in general.
Matching (Independent and Dependent)	The E-field vector on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the E-field vector on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Default Boundary Conditions for a 2D Electrostatic Solver

These boundary conditions are automatically defined for an electrostatic model:

- Natural boundaries are assigned to the interfaces between objects. The normal component of **D** changes by the amount of surface charge density, tangent component of **E** is continuous.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** is tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for a 2D Electrostatic Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	**E** is normal to the boundary; its tangential components are zero.
Even (Flux Tangential)	**E** is tangential to the boundary; its normal components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition for a 2D Electrostatic Solver

To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select **Voltage** or **Charge** as the **Balloon Type**.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Independent Boundary for a 2D Electrostatic Solver

Independent and dependent boundaries enable you to model planes of periodicity where the E-field vector at every point on the dependent boundary surface is forced to match the E-field vector of every corresponding point on the independent boundary surface. The transformation used to map the E-field from the independent to the dependent is determined by specifying the orientation of a local, predefined coordinate system, indicated by an arrow, on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary for a 2D Electrostatic Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Note	You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as but the opposite direction from the

	independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Electrostatic Excitations

The following excitations are available for electrostatic problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object.
Charge	The total charge on a surface or object.
Floating	Used to model conductors at unknown potentials.
Charge Density	The charge density over an object (dielectric).

Assigning a Voltage Excitation for a 2D Electrostatic Solver

Voltage excitations are identical to voltage boundaries in previous versions of Maxwell. A voltage excitation can be assigned to any surfaces or 2D objects. These assignments could include spatial functions.

This type of excitation sets the electric potential to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the pull-down list. You can enter a numerical value, parameter (design or project variable) or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Excitation for a 2D Electrostatic Solver

This type of excitation defines the total charge on a surface or object. The potential distribution on the object with charge excitation is computed during the solution.

To define a charge excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Charge**.
   The **Charge Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the numerical value, parameter (design or project variable) or a spatial function in the **Value** box.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Floating Excitation for a 2D Electrostatic Solver

This type of excitation models conductors at unknown potentials and specifies the total charge on the conductor.

To define a floating conductor:

1. Select the section of the geometry on which you want to apply the excitation. This can be a 2D or 1D geometry entity. If it is a 2D object, it doesn't have to be a conductor (but it will behave like one when the solution becomes available).
2. Click **Maxwell2D>Excitations>Assign>Floating**.
   The **Floating Excitation** dialog box appears.
3. Click the **General** tab.
4. Enter a name for the excitation in the **Name** box, or accept the default.
5. In the **Parameters** section, enter the charge value or parameter in the **Value** box.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box. You can also click the **Defaults** tab to save new default settings or to revert to the standard default values.
7. Click **OK** to assign the excitation to the selected object.

Assigning a Charge Density Excitation for a 2D Electrostatic Solver

This type of excitation defines the volume charge density on an object.

To define the charge density on a dielectric object:

1. Select the object on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Charge Density**.
   The **Charge Density Excitation** dialog box appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the charge density in the **Value** box. You can enter a numerical value, parameter (design or project variable) or a spatial function.
5. For a spatial function, select the type of coordinate system from the **Coordinate System** pull-down list.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

2D AC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

Specifying the Solver Type

2D AC Conduction Boundaries

The following boundary conditions are available for AC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries - The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed. • Neumann boundaries - **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) - **E and J**	Planes of geometric and electrical symmetry.

	vectors are tangential to the boundary; its normal components are zero. • Odd Symmetry (Flux Normal) - **E and J vectors are** normal to the boundary; its tangential components are zero.	
Balloon	Balloon boundaries model the region outside the drawing space as being nearly “infinitely” large — effectively isolating the model from other voltage sources.	Electrically insulated structures, equipotential lines can cross this type of boundary. In general, they are neither tangent nor perpendicular to the balloon boundary.
Matching (Independent and Dependent)	The E-field on the dependent boundary is forced to match the magnitude of the E-field on the independent boundary if the "plus" sign is used. If the "minus" sign is used, the field on the dependent boundary will oscillate with opposite phase angle (180 degrees phase shift).	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Default Boundary Conditions for a 2D AC Conduction Solver

These boundary conditions are automatically defined for a AC conduction model:

- Natural boundaries are assigned to the surfaces between objects. The normal component of **J** and the tangential component of **E** are continuous across discontinuity surfaces.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for a 2D AC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Voltages have opposite sign on the two sides of the symmetry plane.
Even (Flux Tangential)	Voltages have same sign on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition for a 2D AC Conduction Solver

To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for a 2D AC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Maxwell computes the E-field on this boundary and maps it to the dependent boundary.

Assigning a Dependent Boundary for a 2D AC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the Independent boundary is mapped to the dependent boundary.

Note	You must define an Independent boundary before creating the dependent boundaries

	that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. Under **Relation**, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the dependent and independent boundaries have the same magnitude and oscillate in phase.
Edep = -Eind	Click this radio button if the dependent boundary field has the same magnitude as the independent boundary field and oscillate 180 degrees out of phase.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D AC Conduction Excitations

The following excitations are available for electric AC conduction problems:

Excitation	Type of Excitation
Voltage	The AC voltage on a surface or object. This excitation type is available for all three of the 2D electric solvers.

Note	All field quantities oscillate with the same frequency, equal to the frequency specified in the solution setup. The phase of quantities computed in the solution space however will be different in general.

Assigning a Voltage Excitation for a 2D AC Conduction Solver

This type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the pull-down list. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.
6. Enter a value in the **Phase** text box, and select a unit from the pull-down list.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object.

2D DC Conduction Boundaries and Excitations

The following excitations can be specified as the source of electric fields:

- The voltage difference between surfaces and objects. Define the electric potential on each surface and object using a voltage excitation.

Include at least one of the following as a reference for computing the electric potential:

- A voltage excitation.
- An odd symmetry (flux normal) boundary.

2D DC Conduction Excitations

Technical Notes: DC Conduction Field Calculation

Specifying the Solver Type

2D DC Conduction Boundaries

The following boundary conditions are available for DC conduction electric problems:

Boundary Type	E-Field Behavior	Used to model...
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — Normal component of **J** and tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed. • Neumann boundaries — **E** and **J** vectors are tangential to the boundary. Flux	Object interfaces are initially set to natural boundaries; outer boundaries are initially set to Neumann boundaries.

	cannot cross a Neumann boundary.	
Symmetry	Field behaves as follows: • Even Symmetry (Flux Tangential) — **E** and **J** vectors are tangential to the boundary; their normal components are zero. • Odd Symmetry (Flux Normal) — **E** and **J** vectors are normal to the boundary; their tangential components are zero.	Planes of geometric and electrical symmetry.
Balloon	Balloon boundaries model the region outside the drawing space as being nearly “infinitely” large — effectively isolating the model from other voltage sources.	Electrically insulated structures.
Resistance	A resistance boundary models a very thin layer of resistive material (such as that caused by deposits, coatings or oxidation on a metallic surface) on a conductor at a known potential.	Use this boundary condition when the resistive layer’s thickness is much smaller than the other dimensions of the model.
Matching (Independent and Dependent)	The **E**-field on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **E**-field on the independent boundary.	Planes of symmetry in periodic structures where **E** is oblique to the boundary.

Default Boundary Conditions for a 2D DC Conduction Solver

These boundary conditions are automatically defined for a DC conduction model:

- Natural boundaries are assigned to the surfaces between objects. Normal component of **J** and tangential component of **E** are continuous across discontinuity surfaces. No special conditions are imposed.
- Neumann boundaries are assigned to the outside edges of the problem region. **E** and **J** vectors are tangential to the boundary. Flux cannot cross a Neumann boundary.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically revert to the default boundary conditions.

Assigning a Symmetry Boundary Condition for a 2D DC Conduction Solver

This boundary condition defines a plane of geometric or electric symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Normal)	Voltages have opposite signs on the two sides of the symmetry plane.
Even (Flux Tangential)	Voltages have same signs on the two sides of the symmetry plane.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Assigning a Balloon Boundary Condition for a 2D DC Conduction Solver

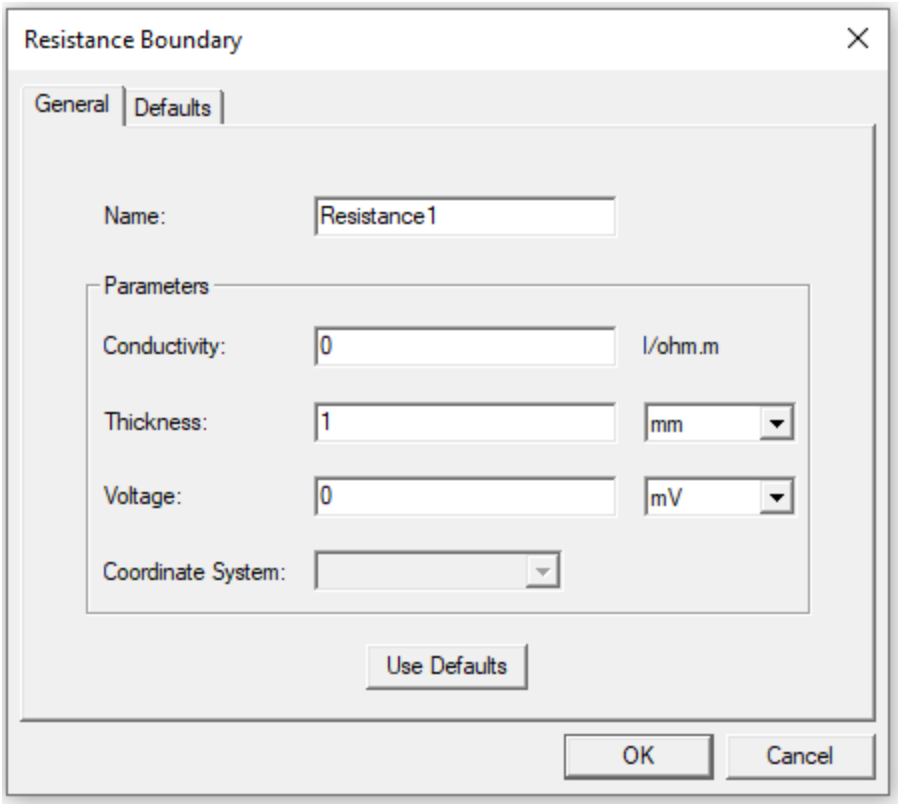
To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning a Resistance Boundary Condition for a 2D DC Conduction Solver

To set a resistance boundary:

1. Select the edge of the geometry on which you want to apply the boundary condition.
2. Click **Maxwell2D>Boundaries>Assign>Resistance**.
   The **Resistance Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the boundary parameters in the **Conductivity**, **Thickness**, and **Voltage** fields, and select the units of measure. Use of variables is supported.



5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Note	Apply resistance boundaries only to the outside edge of the problem space. The external region touching to a resistance boundary is assumed to be a PEC (perfect conductor) with a known potential value that is specified in the resistance boundary setup. Refer to *Resistance* for technical details.

Assigning an Independent Boundary for a 2D DC Conduction Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **E**-field at every point on the dependent boundary surface is forced to match the **E**-field of every corresponding point on the independent boundary surface.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary for a 2D DC Conduction Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define an Independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Edep = Eind	Click this radio button if the **E** field on the dependent and independent boundaries have the same magnitude and direction.
Edep = -Eind	Click this radio button if the **E** field on the dependent boundary field has the same magnitude as but the opposite direction from the independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D DC Conduction Excitations

The following excitations are available for electric DC conduction problems:

Excitation	Type of Excitation
Voltage	The DC voltage on a surface or object.

Assigning a Voltage Excitation for a 2D DC Conduction Solver

This type of excitation sets the electric potential (voltage) on a surface or object to a specific value.

To set a voltage excitation:

1. Select the section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Voltage**.
   The **Voltage Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the electric potential in the **Value** box, and select the units from the pull-down list. You can enter a numerical value or a spatial function.
5. For a spatial function, select a coordinate system from the **Coordinate System** pull-down list.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the excitation to the selected object.

2D Eddy Current Boundaries and Excitations

Specify at least one of the following as a source of AC magnetic fields in your model:

- The current in the cross-section (object), which can be either stranded or solid.
- The current to be divided among several parallel conductors.
- The current density in an object.
- The external magnetic field.

If currents or current densities are the only sources of AC magnetic fields in your model, set at least one outer boundary to the following:

- The default boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Related Topics

2D Eddy Current Boundaries

2D Eddy Current Excitations

Technical Notes: Eddy Current Field Simulation

Specifying the Solver Type

2D Eddy Current Boundaries

The eddy current field solver allows you to define the following types of boundaries:

Boundary Type	H-Field Behavior	Used to model…
Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — Tangential **H** and normal **B** are continuous across surfaces without current density distribution; tangential **H** has a jump if the surface has current density distribution. • Neumann boundaries — **Magnetic Field** is tangential to the boundary and flux cannot cross it.	Initially, object interfaces are natural boundaries; outer boundaries and excluded objects are Neumann boundaries.
Vector Potential	Sets the magnetic vector potential $A_Z(t)$, or $rA_\phi(t)$, on the boundary. The behavior of H depends on whether $A_Z(t)$ or $rA_\phi(t)$ is constant or functional.	Magnetically isolated structures.
Impedance	Includes the effect of induced currents beyond the boundary surface based on tangent component of **H** along the impedance boundary.	Conductors with very small skin depths.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field**is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field**is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Balloon	Models the case where the structure is “infinitely” far away from other magnetic fields or current sources.	Magnetically isolated structures.
Matching (Independent and Dependent)	The **Magnetic Field** on the dependent boundary is forced to match the magnitude and direction of the **Magnetic Field** on the independent boundary. If a 'plus" sign is used, the fields oscillate in phase, if a minus sign is used the fields will oscillate 180 degrees out of phase.	Planes of symmetry in periodic structures where **Magnetic Field**is oblique to the boundary.

Default Boundary Conditions for the 2D Eddy Current Solver

These boundary conditions are automatically defined for an eddy current model:

- Natural boundaries are assigned to the surfaces between objects. Tangential **H** and normal **B** are continuous across surfaces without current density distribution; tangential **H** has a jump if the surface has current density distribution.
- Neumann boundaries are assigned to the outside edges of the problem region. **Magnetic Field** is tangential to the boundary and flux cannot cross it.

To leave a surface set to its default boundary condition, do nothing. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential for the 2D Eddy Current Solver

To define a vector potential boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Vector Potential**.
   The **Vector Potential Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or as a spatial function.
5. If a functional value is specified, select a **Coordinate System** from the pull-down list:
6. Enter a value in the **Phase** text box, and select a unit from the pull-down list.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning an Impedance Boundary for the 2D Eddy Current Solver

This boundary condition is used to simulate the effect of induced currents in a conductor without explicitly computing them. Since the conductor must be excluded in the model (saving time needed to mesh and solve for currents), assign the impedance boundary condition to an outside edge of the problem region or to an excluded object. Exclude the object from the problem region and make the object a perfect conductor in the Material Manager.

To define an impedance boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Impedance**.
   The **Impedance Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Enter the conductivity (in inverse ohm-meters) in the **Conductivity** field.
5. Enter the conductor's relative permeability in the **Permeability** field.
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

Related Topics

Impedance Boundary

2D Impedance Boundary

Impedance boundaries allow you to simulate the effect of induced currents in a conductor without explicitly computing them. Use this boundary condition for models where:

- The skin depth in the conductor is less than two orders of magnitude smaller than the dimensions of the structure. In models like this, the meshmaker may not be able to create a fine enough mesh in the conductor to compute eddy currents.
- The magnetic field decays much more rapidly inside the conductor in the direction that's normal to the surface than it does in directions that are tangential to the surface.
- The AC current source is relatively far away from the surface where eddy currents occur, compared to the size of the skin depth.

The conductor itself must be excluded from the solution region. When setting up the model, do one of the following:

- For external boundaries, when drawing the model, make the surface along which eddy currents are to be computed an outer surface of the problem region.
- For internal boundaries: assign a perfect conductor to the object in the Material Manager, and also exclude the object from the solution by unchecking **Solve Inside** under the object attributes. The solver does not find solutions inside a perfect conductor.

Then, when defining boundaries, assign an impedance boundary to the individual surfaces of the problem region (for external boundaries) or to the entire object (for internal boundaries). By entering the conductivity, s, and the relative permeability, μ_r, of the object, you specify the skin depth of induced eddy currents. The simulator uses this skin depth value when computing the electromagnetic field solution. It assumes that the **Magnetic Field** falls off exponentially inside the conductor. The ohmic loss due to induced currents can then be computed from the **Magnetic Vector Potential** along the impedance boundary - on the surface of the object that you are interested in - according to the formula below or by using the quantity **EdgeLossDensity** in the 2D calculator.

$$EdgeLossDensity(W/m^2) = \pi f \sqrt{\frac{\pi f \sigma}{\mu_0 \mu_r}} [A_z \bullet A_z^*]$$

where:

A_z *= z component of the Magnetic Vector Potential*

A_z^* *= complex conjugate of the z component of the Magnetic Vector Potential*

μ_0 *= permeability of free space*

μ_r *= relative permeability of the impedance boundary*

σ *= conductivity of the impedance boundary (S/m)*

f = frequency (Hz)

You may also use **EdgeLossDensity** to plot the loss along an edge containing an impedance boundary.

Note	An impedance boundary only approximates the effect of eddy currents acting at a shallow skin depth. It does not directly compute them. In general, the fields modeled using an impedance boundary will closely match the field patterns that would actually occur in the structure. However, at discontinuities in the surface (such as corners), the field patterns may be different.

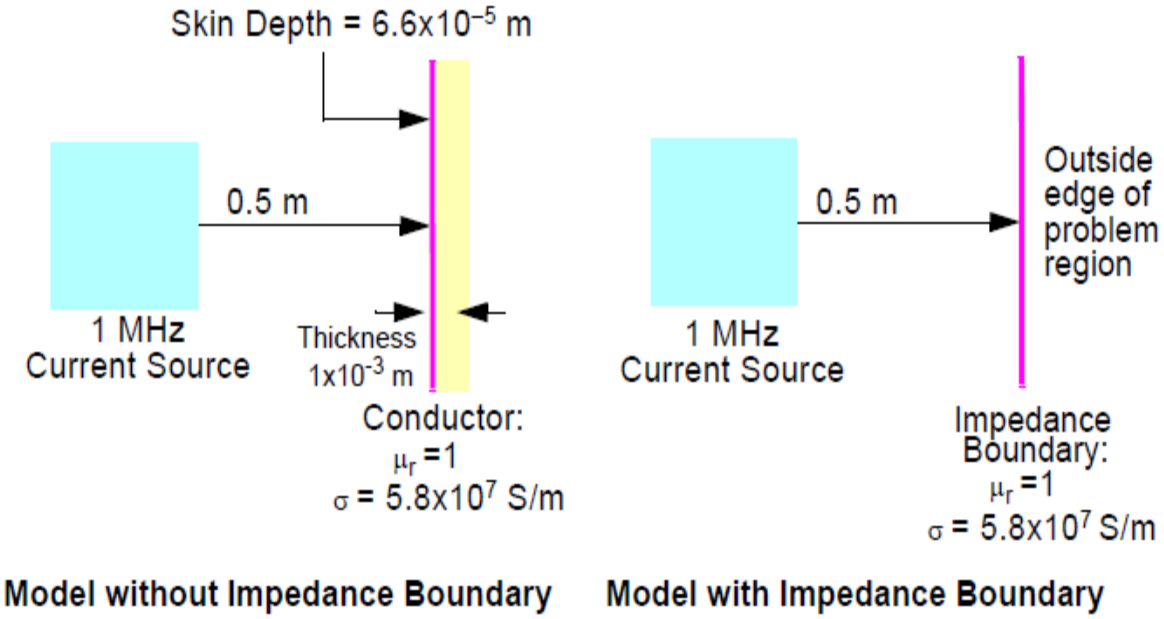
Related Topics

When to Use Impedance Boundaries

Assigning an Impedance Boundary for the 2D Eddy Current Solver

When to Use Impedance Boundaries in 2D

A typical situation where impedance boundaries can be used to reduce the complexity of a model is shown below. Suppose you want to compute eddy current losses in the conductor next to the current source shown below on the left. If the source carries AC current at a frequency of 1 MHz, the skin depth in the conductor is 6.6 x 10–5 meters. This is several orders of magnitude smaller than the conductor's thickness. Since the conductor where currents are induced is also relatively far away from the current source, an impedance boundary can be used to model the induced currents — as shown on the right



The conductor must be excluded from the model by making it a perfect conductor. The outside boundary of the model is moved to the inside surface of the conductor. This outside surface is defined as an impedance boundary, using the conductivity and permeability specified previously. Since the simulator does not have to actually compute a solution inside the conductor, the field

solution is computed more quickly and uses less memory. After solving, you can compute the ohmic loss for the surface using the solution calculator and plot the loss density on the boundary.

Related Topics

Assigning an Impedance Boundary for the 2D Eddy Current Solver

Assigning a Symmetry Boundary for the 2D Eddy Current Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	Magnetic field is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	Magnetic field is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Related Topics

Setting a Symmetry Multiplier

Assigning a Balloon Boundary Condition for the 2D Eddy Current Solver

To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for the 2D Eddy Current Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface. The transformation used to map the **Magnetic Field** from the independent to the dependent is determined by specifying a coordinate system on both the independent and dependent boundaries.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Assigning a Dependent Boundary for the 2D Eddy Current Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic fields on the dependent and independent boundaries have the same magnitude and the fields oscillate in phase.
Bdep = -Bind	Click this radio button if the magnetic fields on the dependent boundary have the same

	magnitude as the independent boundary field but the fields oscillate 180 degrees out of phase.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Eddy Current Excitations

The eddy current solver allows you to define the following sources of AC magnetic fields:

Excitation	Type of Excitation
Current	The total current in a conductor.
Parallel Current	The total current to be divided among several conductors in parallel. The method of dividing the current depends upon the choice of solid or stranded.
Current Density	The current density in a conductor. In this case, you must also define the current density terminals for the conductor.
Coil	Used to define one or more model windings.
End Connection	End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

Assigning a Current Excitation for the 2D Eddy Current Solver

Specifies the total AC current in a conduction path. The conduction path may be contained completely within the problem region (for example, a coil), or may touch the edges of the problem region.

To specify the total AC current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Current**.
   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
7. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
8. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Parallel Current Excitation for the 2D Eddy Current Solver

Specifies the total AC current in a parallel conduction path consisting of at least two conductors.

To specify the total AC current:

1. Select the 2D sections of the geometry on which you want to apply the excitation. At least two section must be specified
2. Click **Maxwell2D>Excitations>Assign>Parallel Current**.
   The **ParallelCurrent Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current strength in the **Value** box.
5. Enter the phase for the current in the **Phase** box.
6. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

Note	For parallel solid conductors, the current split will be based upon the overall field solution including eddy effects (the currents in individual parallel conductors will have complex values, which are proportional with the respective admittances, and in general will have different phase angles between them). If stranded conductors are specified, the current is split based upon the relative areas of the selected conductors.

7. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
8. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
9. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation for the 2D Eddy Current Solver

This command specifies the applicable component (depending on XY or RZ solution type) of the AC current density. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) in which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell2D>Excitations>Assign>Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the current strength in the **Value** box. The value may be a single numeric value or a spatial function.
   b. If the value is specified as a spatial function, select the **Coordinate System** from the pull-down list.
   c. Enter the phase angle, θ, of the current density in the **Phase** field, and select a unit from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Coil for a 2D Eddy Current Solver

To assign a coil as an Eddy current excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell2D>Excitations>Assign>Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)

   The **Coil Excitation** dialog box appears.
3. On the **General** tab, enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

Note	To add this coil to an existing winding, do the following: 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following:

	• In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**). • Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the project tree and selecting **Delete All Coils**.

Assigning an End Connection for a 2D Eddy Current Solver

End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.

To define an end connection:

1. Select the section of the geometry (i.e., the conductor) across which you want to apply the excitation.
2. Click **Maxwell 2D>Excitations>Assign>End Connection**.

   The **End Connection Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **End resistance between adjacent conductors**, and select a unit of measurement from the pull-down list.
   b. Enter the **End inductance between adjacent conductors**, and select a unit of measurement from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Winding Setup for a 2D Eddy Current Solver

Note	• If you wish to define a winding for a 2D transient solution type, refer to "Assigning a Winding Setup for a 2D Transient Solver " on page 12-54 . • If you wish to define a winding for a 2D magnetostatic solution type, refer to Assigning a Winding Setup for a 2D Magnetostatic Solver.

You can use the pre-defined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 2D>Excitations>Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section:
   a. Select **Current**, **Voltage**, or **External** from the **Type** pull-down list. The winding type selected enables only those fields (Initial Current, Resistance, Inductance, Voltage,

Phase) applicable for the chosen type.

b. Select the **Solid** or **Stranded** radio button to specify the type of conductor.

c. Enter values in the following fields (enabled according to winding type), and select the desired units:

For a current winding	For a voltage winding[1]	For an external winding
Current	Resistance	(no settings required)
Phase	Inductance	
	Voltage	
	Phase	

Note	You can also type a function as an expression for any of these fields except Initial Current.

d. Enter a value in the **Number of parallel branches** text box.

Note	Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

4. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
5. Optionally, on the Defaults tab, click **Save Defaults** to save the current settings or click **Revert to Standard Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

The definition of a winding is final only after specifying the coils which belong to it.

Note	To add a coil terminal to this winding, do the following: 1. In the project tree, right-click the winding, and select **Add Coils**. The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding. 2. Select the coil terminal (s) you want to add. To select multiple terminals, press **CTRL** and click each terminal. 3. Click **OK**. To assign a coil terminal excitation and add it to this winding, do the following: 1. Select the section of the geometry on which you want to apply the coil terminal excitation. 2. In the project tree, right-click the winding, and select **Assign Coil**. The **Coil Excitation** dialog box appears. 3. Enter a name for the excitation in the **Name** box, or accept the default. 4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box. **Note:** This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.

	5. Select one of the following for the **Polarity**: • **Positive** • **Negative** • **Function** 6. If you selected **Function** as the **Polarity**, enter a function in the text box. 7. Optionally, click **Use Defaults** to revert to the default values in the dialog box. 8. Click **OK** to assign the coil terminal excitation. The coil terminal excitation is assigned and is added to the winding. To delete all coil terminal excitations that belong to this winding, do the following: • In the project tree, right-click the winding, and select **Delete All Coils**. All coil terminal excitations are removed from the winding and deleted from the excitations.

"Assigning a Coil for a 2D Eddy Current Solver " on page 12-40

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

External Circuit Setup for 2D Eddy Current

The Maxwell Circuit design editor is used to set up the external circuit excitation for windings in Maxwell 2D and 3D Eddy current solutions. Because the Eddy current solver is a frequency domain solver, only linear circuit components are supported, which include Resistance, Inductance, Capacitance, and Transformer. In addition, only sinusoidal sources should be used as sources. Sinusoidal Current Source and Sinusoidal Voltage Source, designed for transient solutions, can also be used for eddy current solutions. For example, to use the sinusoidal current source, you should set the parameters as follows:

- Set **I0**, **Td**, and **Df** to zero, where I0 is offset current in Amps, Td is the delay time in seconds, and Df is the damping factor in 1/seconds.
- Set **TIME** as the **Type**.
- Use **Ia** to set the peak amplitude in Amps.

- Use **IFreq** to set the signal frequency. Note that setting IFreq is not necessary as it will be internally set to the frequency defined in the Maxwell design setup.
- Use **Phase** to set the phase delay.

With these specifications, the time signal can be written as:

$$I(t) = I_a \sin\left(2\pi I_{freq} - Phase\right)$$

Note that “Phase” is the signal phase delay. The complex source in the eddy current solver is represented in phasor form as:

$$I = I_a \; e^{j\theta}$$

and the time signal can be written in terms of (I_a, θ) as:

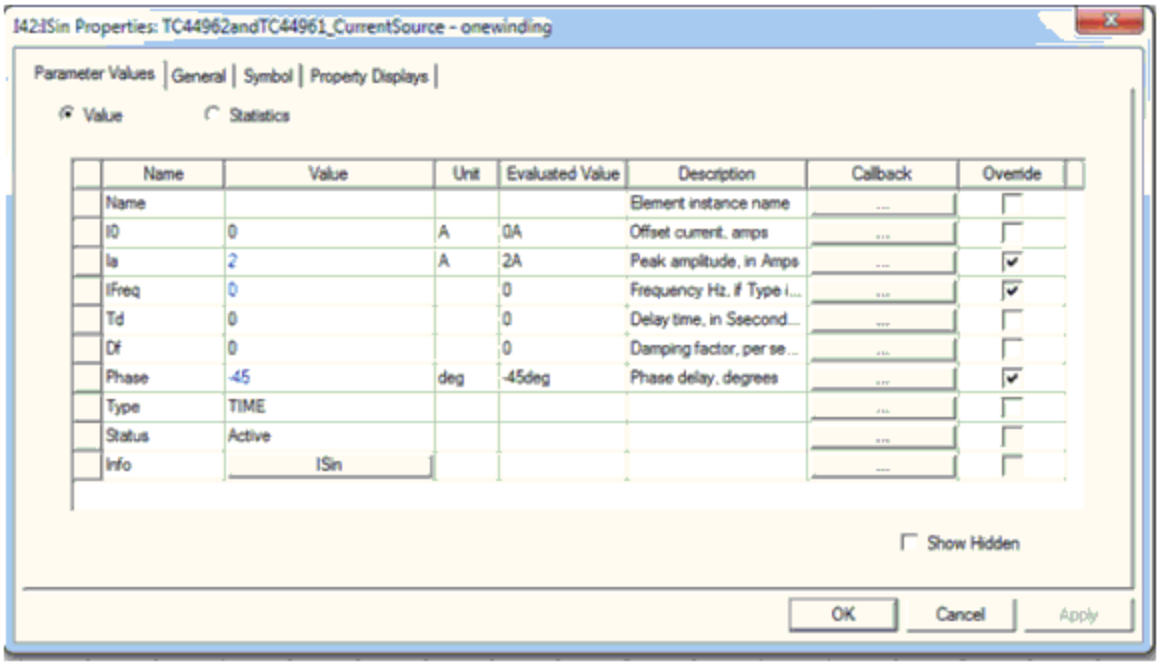
$$I(t) = Im\left\{I_a \; e^{j(2\pi I_{freq}+\theta)}\right\}$$

In the complex expression, θ is defined as phase, while in Maxwell Circuit, *Phase* is defined as phase delay. Thus:

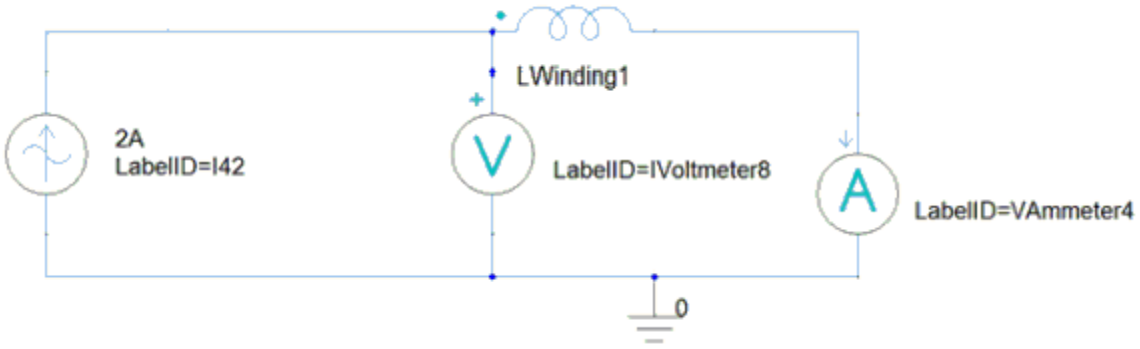
$$Phase = -\theta$$

As a result, you should enter the negative of phase of the complex signal as the Phase value.

An example of such a setup for $I = 2e^{j45^\circ}$ is shown below.



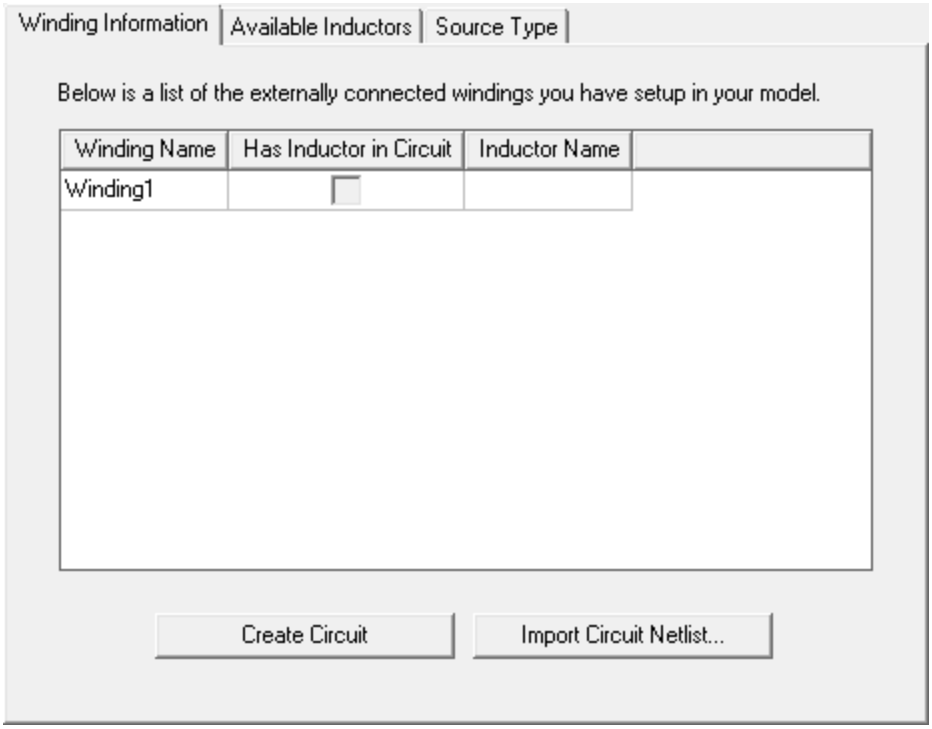
An example of an external circuit excitation for the winding for an Eddy current solver is shown below.



Note	For frequency domain eddy current solutions, only linear circuit components are supported, which include Resistor, Inductor, Capacitor, and Transformer. Only sinusoidal sources should be used as sources.

To set up an external circuit connection for an External winding type:

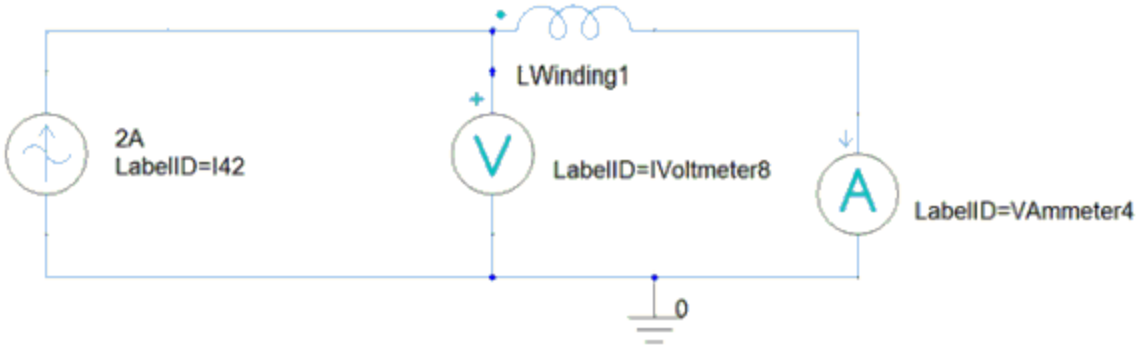
1. Click **Maxwell 2D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.



b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.

3. Add the components needed to complete the external circuit design such as shown the following example.



4. When the circuit design is finished, click **Maxwell Circuit>Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 2D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.

b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog.

c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for Optimetrics analyses.

10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

Note	After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

2D Transient Boundaries and Excitations

Define at least one of the following as a source of magnetic fields:

- The stranded or solid windings, with a voltage or current supply or connected to an external circuit.
- Permanent magnet(s).

You will need to set at least one outer boundary to the following:

- Value (vector potential) boundary conditions.
- An odd symmetry (flux tangential) boundary.
- An even symmetry (flux normal) boundary.

Related Topics

2D Transient Boundaries

2D Transient Excitations

Technical Notes: Transient Simulation

Specifying the Solver Type

Permanent Magnet Excitations

2D Transient Boundaries

The transient field solver allows you to define the same types of boundary conditions as magnetostatic ones.

Boundary Type	H-Field Behavior	Used to model...

Default Boundary Conditions (Natural and Neumann)	Field behaves as follows: • Natural boundaries — Tangential **H** and normal **B** are continuous across surfaces without current density distribution. Tangential **H** has a jump if the surface has current density distribution. • Neumann boundaries — Magnetic field is normal to the boundary.	Initially, object interfaces have natural boundaries; outer boundaries, and excluded objects have Neumann boundaries.
Vector Potential	Sets the magnetic vector potential A_z , or rA_ϕ , on the boundary. The behavior of H depends on whether A_z or rA_ϕ is constant or functional.	Outer boundaries at specific vector potentials; externally applied magnetic fields.
Symmetry	Field behaves as follows: • Odd Symmetry (Flux Tangential) — **Magnetic Field** is tangential to the boundary; its normal components are zero. • Even Symmetry (Flux Normal) — **Magnetic Field** is normal to the boundary; its tangential components are zero.	Planes of geometric and magnetic symmetry.
Balloon	Models the case where the structure is “infinitely” far away from other magnetic fields, permanent magnets, or current sources.	Magnetically isolated structures.
Matching (Independent and Dependent)	The **Magnetic Field** on the dependent boundary is forced to match the magnitude and direction (or the negative of the direction) of the **Magnetic Field** on the independent boundary.	Planes of symmetry in periodic structures where **Magnetic Field**is oblique to the boundary.

Default Boundary Conditions for a 2D Transient Solver

These boundary conditions are automatically defined for a transient model:

- Natural boundaries are assigned to the surfaces between objects. Tangential **H** and normal **B** are continuous across surfaces without current density distribution. Tangential **H** has a jump if the surface has current density distribution.
- Neumann boundaries are assigned to the outside edges of the problem region. Magnetic field is normal to the boundary.

To leave a surface set to its default boundary condition, you do not need to set any boundary conditions. Deleted boundary conditions and excitations automatically reset to the default boundary conditions.

Assigning a Vector Potential for a 2D Transient Solver

To define a vector potential boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge). **Maxwell 2D** requires that the Vector Potential be assigned on a 1D object such as an edge or a line.
2. Click **Maxwell2D>Boundaries>Assign>Vector Potential**.
   The **Vector Potential Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the value of the potential. The value may be specified as a single numeric value or a spatial function.
5. If a functional value is specified, select a **Coordinate System** from the pull-down list:
6. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
7. Click **OK** to assign the boundary to the selected object.

The new boundary is added to the boundary list in the project tree.

Assigning a Symmetry Boundary for a 2D Transient Solver

This boundary condition defines a plane of geometric or magnetic symmetry in a structure. Assign it only to the outer surfaces of the problem region.

To set a symmetry boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Symmetry**.
   The **Symmetry Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Select one of the following as the type of symmetry:

Odd (Flux Tangential)	**Magnetic Field** is tangential to the boundary; its normal components are zero.
Even (Flux Normal)	**Magnetic Field** is normal to the boundary; its tangential components are zero.

5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the boundary to the selected object.

Related Topics

Setting a Symmetry Multiplier

Assigning a Balloon Boundary Condition for a 2D Transient Solver

To set a balloon boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Balloon**.
   The **Balloon Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. Click **OK** to assign the boundary to the selected object.

Assigning an Independent Boundary for a 2D Transient Solver

Independent and dependent boundaries enable you to model planes of periodicity where the **Magnetic Field** at every point on the dependent boundary surface is forced to match the **Magnetic Field** of every corresponding point on the independent boundary surface.

To set an independent boundary:

1. Select the edge to which you want to assign the independent boundary.
2. Click **Maxwell2D>Boundaries>Assign>Matching>Independent**.
   The **Independent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.
4. To reverse the direction of the vector, select the **Reverse Direction** check box.
5. Click **OK**.

Maxwell computes the **Magnetic Field** on this boundary and maps it to the dependent boundary using the transformation defined by the independent and dependent coordinate systems.

Assigning a Dependent Boundary for a 2D Transient Solver

Assigning a dependent boundary is the second step in creating matching boundaries. The field on the independent boundary is mapped to the dependent boundary.

Note	You must define an independent boundary before creating the dependent boundaries that are associated with it. Assign dependent boundaries only to the outer surfaces of the problem region.

To set a dependent boundary:

1. Select the section of the geometry on which you want to apply the boundary condition (typically an edge).
2. Click **Maxwell2D>Boundaries>Assign>Matching>Dependent**.
   The **Dependent Boundary** dialog box appears.
3. Enter a name for the boundary in the **Name** box, or accept the default.

4. Select the independent boundary to which the dependent is to be assigned from the **Independent** pull-down list.
5. In the **Relation** section, select one of the following to specify the field behavior on the boundary:

Bdep = Bind	Click this radio button if the magnetic field on the dependent and independent boundaries have the same magnitude and direction.
Bdep = -Bind	Click this radio button if the magnetic field on the dependent boundary has the same magnitude as but the opposite direction from the independent boundary field.

6. To reverse the direction of the vector, select the **Reverse Direction** check box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the boundary to the selected object.

2D Transient Excitations

Transient problems use the following types of excitations:

Excitation	Type of Excitation
Current	The total current in a conductor
Current Density	The known current density distribution in a conductor.
Coil	Used to define one or more model windings.
End Connection	End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.
Winding With Current	Current for both a stranded and solid conductor.
Winding With Voltage	Voltage for both a stranded and solid conductor.
Winding With External Circuit Connection	External circuit connection for both a stranded and solid conductor.

Note	A winding is a versatile type of excitation. Six different combinations can be used: Current, Voltage, and External Circuit — each with a solid or stranded conductor. The Coil Terminal type of excitation needs to be defined prior to setting up a winding.

In addition, permanent magnet materials serve as sources of magnetic fields.

Assigning a Current Excitation for a 2D Transient Solver

Specifies the total transient current in an object.

To specify the total transient current:

1. Select the 2D section of the geometry on which you want to apply the excitation.
2. Click **Maxwell2D>Excitations>Assign>Current**.
   The **Current Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. Enter the current magnitude, time dependent, in the **Value** box, and select a unit from the pull-down list.
5. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
6. Select either **Positive** or **Negative** as the **Ref. Direction** for the conductor.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object.

Assigning a Current Density Excitation for a 2D Transient Solver

This command specifies the applicable component (depending on the XY or RZ type of application) of the transient current density in an object. If the current density is a function of position, the value is entered in ampere/m^2, even if you change the units in the problem.

To define the current density:

1. Select the section of the geometry (i.e., the conductor) in which you want to apply the excitation (typically a 2D object).
2. Click **Maxwell2D>Excitations>Assign>Current Density**.
   The **Current Density Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the current strength in the **Value** box. The value may be a single numeric value or a spatial function.
   b. If a spatial function is entered for the **Value**, select the **Coordinate System** from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Assigning a Coil for a 2D Transient Solver

To assign a coil as a transient excitation:

1. Select the section of the geometry on which you want to apply the excitation (typically a 2D object).

2. Click **Maxwell2D>Excitations>Assign>Coil**. (You can also right-click an existing winding in the project tree, and select **Assign Coil**.)
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil to the selected object.

Note	To add this coil to an existing winding, do the following: 1. In the project tree, right-click the coil terminal, and select **Add to Winding**. The **Add to Winding** dialog box appears. 2. Select the winding to which you ant to add the coil terminal, and click **OK**.

Note	To remove a coil terminal from an existing winding, do the following: • In the project tree, right-click the coil terminal, and select **Remove from Winding**. The terminal is removed from the winding and moved up one level in the project tree (directly beneath **Excitations**). • Alternatively, all coils assigned to a winding may be deleted by right-clicking the winding in the project tree and selecting **Delete All Coils**.

Related Topics

"Assigning a Winding Setup for a 2D Eddy Current Solver " on page 12-41

Assigning an End Connection for a 2D Transient Solver

End connection is used to model details of the "squirrel cage" winding of induction machines, dampers in synchronous machines, etc.

To define an end connection:

1. Select the section of the geometry (i.e., the conductor) across which you want to apply the excitation.
2. Click **Maxwell 2D>Excitations>Assign>End Connection**.
   The **End Connection Excitation** dialog box appears.

3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, specify the following options:
   a. Enter the **End resistance between adjacent conductors**, and select a unit of measurement from the pull-down list.
   b. Enter the **End inductance between adjacent conductors**, and select a unit of measurement from the pull-down list.
5. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
6. Click **OK** to assign the excitation to the selected object.

Technical Notes: End Connections in 2D Transient

Assigning a Winding Setup for a 2D Transient Solver

Note	• If you wish to define a winding for a 2D Eddy Current solution type, refer to "Assigning a Winding Setup for a 2D Eddy Current Solver " on page 12-41 . • If you wish to define a winding for a 2D Magnetostatic solution type, refer to Assigning a Winding Setup for a 2D Magnetostatic Solver.

You can use the pre-defined coil terminal(s) to define one or more current or voltage windings.

To define a winding for your model:

1. Click **Maxwell 2D>Excitations>Add Winding** to open the **Winding** dialog box.
2. Enter a name for the winding in the **Name** box, or accept the default.
3. In the **Parameters** section, select **Current**, **Voltage**, or **External** from the **Type** drop-down menu.

Note	Maxwell transient designs can be dynamically coupled to Twin Builder components through the Twin Builder user interface. You can enable this feature on the Advanced Product Coupling tab of the **Design Settings** dialog box. Source windings set to **External** are available as conservative pins in Twin Builder. For more information, refer to the Help for Twin Builder.

4. Select the **Solid** or **Stranded** radio button to specify the type of conductor.
5. Enter values in the following fields, and select the desired units:

For a current winding	For a voltage winding[1]	For an external winding
Current	Initial Current	Initial Current
	Resistance	
	Inductance	
	Voltage	

Note	You can also type a function as an expression for any of these items except initial current.

6. Enter a value in the **Number of parallel branches** text box.

Note	Parallel branches for solid windings assume there are no circulating currents in the parallel branches.

7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the excitation to the selected object

The definition of a winding is final only after specifying the coils which belong to it.

Note

To add a coil terminal to this winding, do the following:

1. In the project tree, right-click the winding, and select **Add Coils**.
   The **Add Terminals** dialog box appears, listing all coil terminals that do not already belong to that winding.
2. Select the coil terminal (s) you want to add. To select multiple terminals, press **CTRL** and click each terminal.
3. Click **OK**.

To assign a coil terminal excitation and add it to this winding, do the following:

1. Select the section of the geometry on which you want to apply the coil terminal excitation.
2. In the project tree, right-click the winding, and select **Assign Coil**.
   The **Coil Excitation** dialog box appears.
3. Enter a name for the excitation in the **Name** box, or accept the default.
4. In the **Parameters** section, enter the number of conductors for the coil in the **Number of Conductors** box.

   Note: This value represents only the number of conductors inside of the selected geometry. If the Coil Terminal is cut due to symmetry, then only enter the Number of Conductors in the portion modeled.
5. Select one of the following for the **Polarity**:
   - **Positive**
   - **Negative**
   - **Function**
6. If you selected **Function** as the **Polarity**, enter a function in the text box.
7. Optionally, click **Use Defaults** to revert to the default values in the dialog box.
8. Click **OK** to assign the coil terminal excitation.
   The coil terminal excitation is assigned and is added to the winding.

To delete all coil terminal excitations that belong to this winding, do the following:

- In the project tree, right-click the winding, and select **Delete All Coils**.
  All coil terminal excitations are removed from the winding and deleted from the excitations.

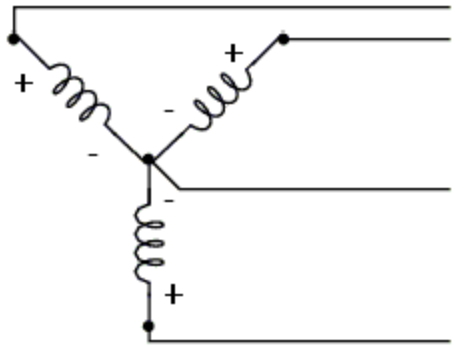
Setting Up a Y Connection in 2D and 3D Transient Designs

---

1. For a solid winding, the resistance term can represent: the resistance of a portion of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source resistance. (The main winding resistance is calculated directly by the solver.) For a stranded winding, the resistance term is the complete DC resistance of the winding (since the solver does not determine resistance of a stranded winding) as well as the resistance of the end-effects, leads, source, etc. For both solid and stranded windings, the inductance term can represent: the extra inductance for a portion of the winding of the winding which is not modeled (for instance, end-effects), the leads connecting the winding to the source, or the source inductance. (The main winding inductance itself is calculated directly by the solver.)

Setting Up a Y Connection in 2D and 3D Transient Designs

The Y Connection function available in 2D and 3D Transient solution types allows multiple windings to be connected in a classical Y (sometimes referred to as wye) configuration with the negative terminals connected to a common node as illustrated below.



Setup Y Connection requires voltage winding definitions be set and the negative voltage terminal for each winding will be connected to form the common node of the circuit.

Each voltage source specified in the winding description drives the positive side of the coil. Y Connections are commonly used in motor and transformer applications driven by 3-phase voltage; however, any number of windings may be connected to a common node in Maxwell.

Note	• Only one Y Connection is allowed in a given Maxwell

	design. • A Y Connection requires use of stranded voltage windings. • Duplicate windings are not allowed.

To define a Y-connection:

1. Click **Maxwell 2D** (or **Maxwell 3D**)**>Excitations>Setup Y Connection**.
   The **Setup Y Connection** dialog appears.
2. In the **Winding** list on the left, select the windings to be grouped into a Y connection.
3. Click the **Group** button to create a Y Connection group with the selected windings.
4. Click **OK** when all required grouping have been created.

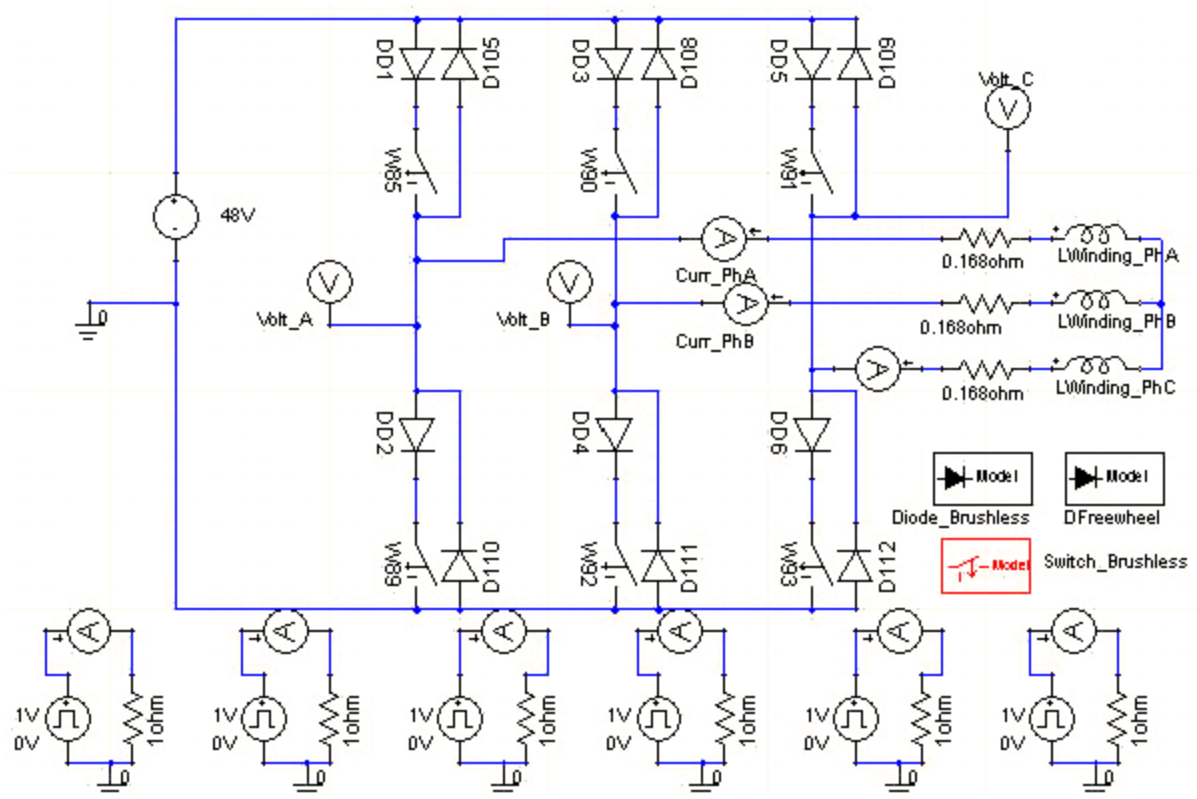
Setting Up an External Circuit in 2D Transient

Note	Use of external circuits is indicated when more complex excitation circuits such as rectifiers, inverters, etc., containing components such as diodes, transistors, complex sources, etc. are needed. There is no need to use an external circuit for simple current or voltage sources supplying the windings.

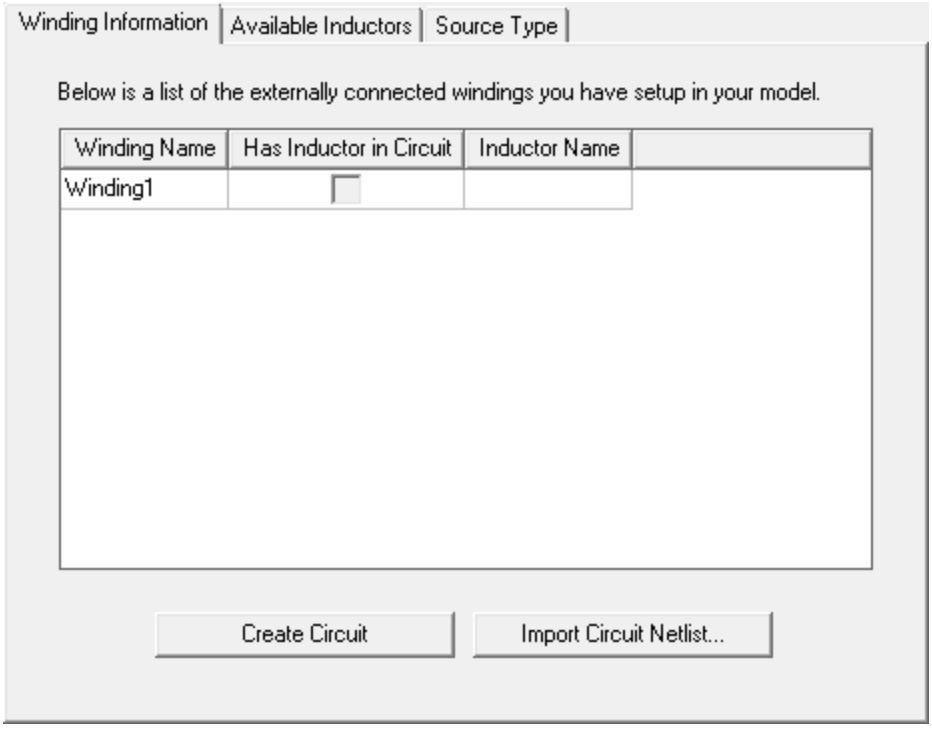
Note	External circuits intended for use with the Time Decomposition Method (TDM) can only support basic circuit elements that are solution-independent. This is because, for TDM, all time steps (or all time steps in a subdivision) are solved simultaneously - and thus the circuit topology and its parameters must be known before solving. Therefore some circuit elements, such as solution-dependent switches, diodes, capacitors, and inductors which are not directly connected to windings in series, are not supported.

An external circuit netlist can be complex as shown in the example below.



To set up an external circuit connection for an External winding type:

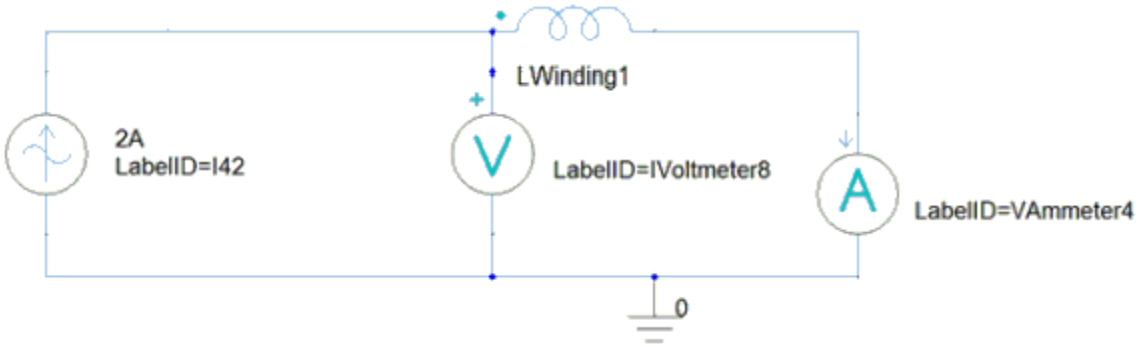
1. Click **Maxwell 2D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
    a. If no external winding connections have been set up for your model, the **Winding Information** tab lists the external winding(s) in the design. Continue with step 2.



b. If external windings have already been set up, continue with step 7.

2. On the **Winding Information** tab, click **Create Circuit** to add a circuit design to the project. The new circuit design automatically opens for editing in the Maxwell Circuit Editor. The circuit includes one inductor for each external winding in the original Maxwell transient design. The following example is for a design having one external winding.

3. Add the components needed to complete the external circuit design such as shown the following example.



4. When the circuit design is finished, click **Maxwell Circuit>Export Netlist** and export the netlist **.sph** file to the desired location.
5. Return to the Maxwell design and click **Maxwell 2D>Excitations>External Circuit>Edit External Circuit** to open the **Edit External Circuit** dialog box. You can also right-click on **Excitations** in the Project tree and select **External Circuit>Edit External Circuit**.
6. On the **Winding Information** tab, click **Import Circuit** to import the circuit.
7. To view a list of inductors in the imported circuit, click the **Available Inductors** tab.
8. To view the sources used in the externally connected windings, click the **Source Type** tab.
9. If variables are used in the imported circuit, they and their design values are listed on the **Parameter Values** tab. You can link to variables within the imported circuit as follows:
    a. On the **Parameter Values** tab, click in the **Value** column of the parameter to be mapped.
    b. Enter a new local variable name and press the `Enter` key to open the **Add Variable** dialog.
    c. Select a **Unit Type** and **Unit**, and enter a **Value** for the variable and click **OK**. The new Maxwell variable is now mapped to the variable in the imported circuit, and can be varied directly by Maxwell or used for Optimetrics analyses.
10. If the imported file is a .**sph** file, you can click the **Circuit Path** tab to view the original project and design names.

Note	After you import a circuit netlist, the **Create Circuit** button changes to **Update Netlist from Circuit**. Use **Update Netlist from Circuit** to reimport the netlist to keep it current.

11. Click **OK** to close the **Edit External Circuit** dialog box.

Note	The user-set time steps can be modified when external circuits are used to drive the windings of the transient finite element model. Following is a list of situations that will lead to a time step change: • All power electronic switching instances that do not coincide with user-specified solve times request a new solution time from the transient solver. The respective switching generating a new solve time request for the transient solver can be time,

	position, or speed dependent. • When current and/or voltage sources with a piecewise linear variation are used, a new solution time is requested from the transient solver at each (time) definition point used in the corresponding source definition table. • When the change in any winding inductance value is excessive, a new time step (smaller) is calculated and a new solution generated (re-calculated) accordingly. If a user-specified save field time is missed because of the above reasons, the next solved time step fields are saved instead.

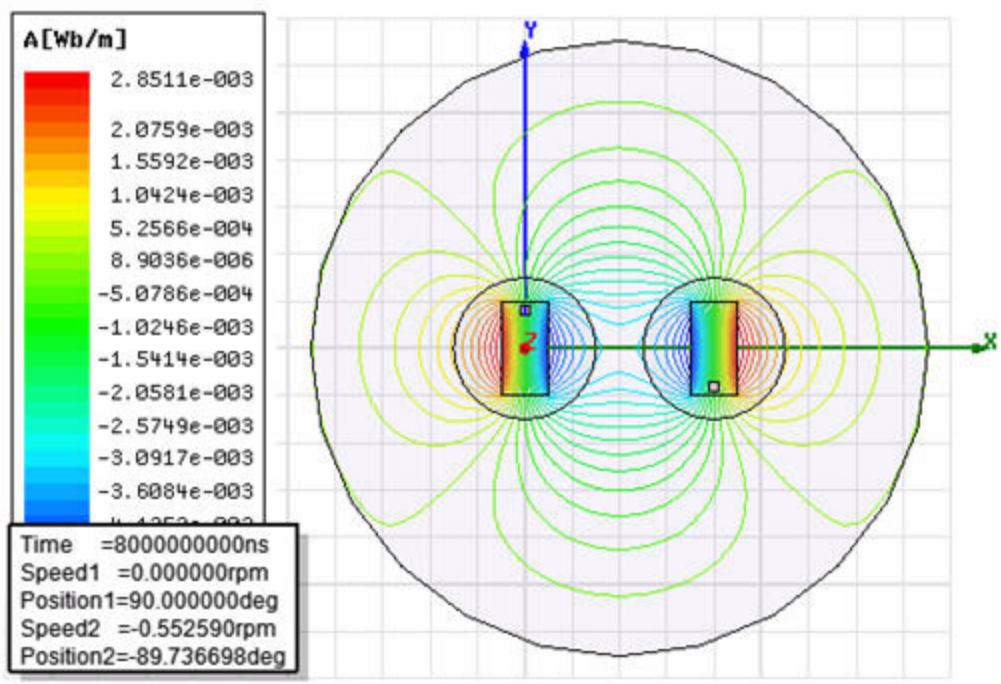
13 - Setting Up Motion for Transient Projects

For projects where you selected transient as the solution type, you can define how the model components move in relation to one another. This is accomplished by assigning a **MotionSetup** to a **Band** object. Two or more motion bands may be assigned, each with its own independent motion characteristics. Multiple motion bands are used primarily for certain types of motors where multiple rotors may rotate about a common central axis; however, other applications are possible as shown in the following examples.

Example - Two Bands of Motion

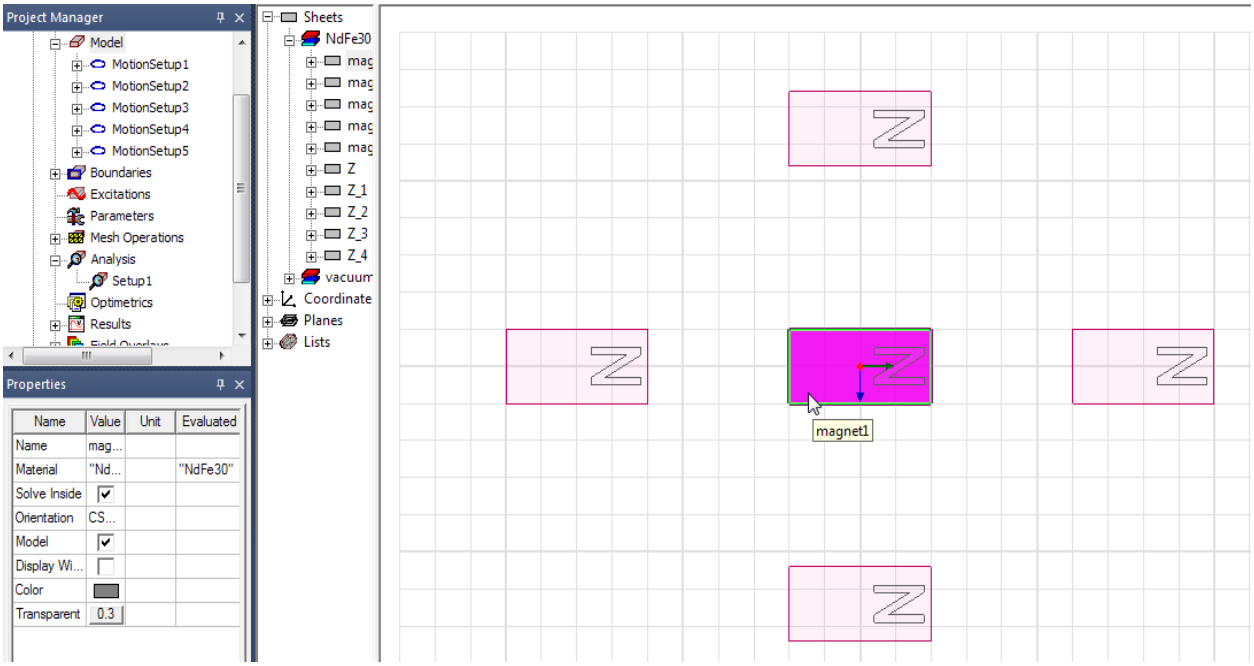
The project shown below comprises two rectangular magnets, each surrounded by a band object with a MotionSetup assigned to it. When one magnet moves, the other magnet realigns itself. Also note that the solution context display shows the position and speed for both motion setups.



Note	The two moving bands may not touch each other. There must be some stationary region between the two bands, even if it is filled only with vacuum.

Example - Multiple Bands of Motion

The magnet project shown below comprises five bar magnets. When the center magnet (MotionSetup1) moves, the other magnets also move.



Note	The moving bands may not touch each other. There must be some stationary region between the bands, even if it is filled only with vacuum.

Technical Notes: 3D Transient

Technical Notes: Meshing Aspects for 3D Transient Applications With Motion

Assigning a Band of Motion

You can assign a band of motion in both Maxwell 2D and Maxwell 3D projects. For both Maxwell 2D and 3D projects, two or more motion bands may be assigned.

Note	Overlapping bands are not supported so they cannot be located inside of each other.

For both rotational and translational problems, the band object must always enclose all of the moving objects. For rotational problems, this means the band object should be a solid cylinder or a solid wedge – not a hollow shell or segment of a shell. If the band object encloses all moving aspects, it is easier to identify the moving objects and reduces errors related to misidentifying them.

Note	An inner region (or wrapper object) enclosed by the band can normally be used as a "fake" moving object for two reasons:

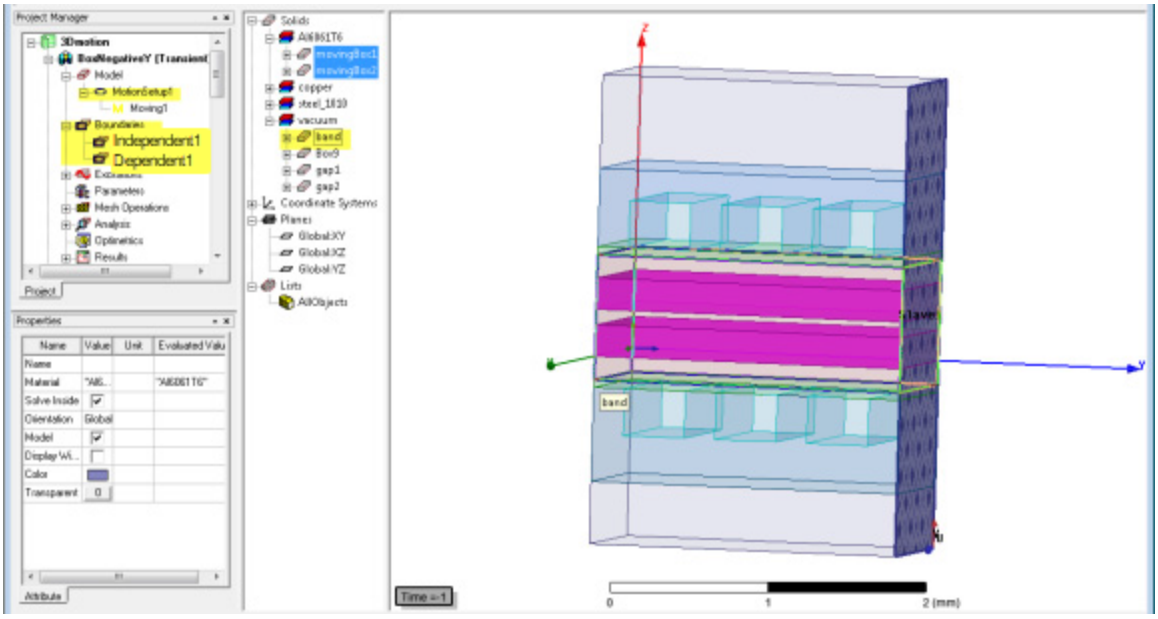
	• The first is to avoid creating holes inside the band which would result in the band having multiple connected domains. • The second is due to the torque/force computation being carried out by one layer of elements inside the band region that directly touches moving objects. If an inner region is not included, the torque/force computation will be very sensitive to mesh noise - thus leading to an inaccurate solution. For 2D and 3D translational motion, the following are some additional recommendations: • An all-encompassing inner region (non-magnetic, non-conductive wrapper such as air or vacuum) must be used around all moving objects in a band. • The inner region wrapper object, like the Band itself, should be a simplified shape, such as a rectangle or polygon in 2D, or a polyhedral or segmented sweep section in 3D. Any simplifications to the inner region and band object will result in better re-meshing for each time-step and faster overall simulation times. • In order to give more accurate forces, if there is sufficient clearance between moving and stationary objects, you can provide some padding between the inner region and the moving objects and the band. At a minimum, the inner region should be the same size as the outside of the enclosed objects (like shrink wrap) with no gap between the wrapper and objects inside. • Ansys highly recommends that the band not touch any outer stationary objects, with the only exception being for symmetry boundaries on the outer region. It is suggested to locate the band halfway in the air-gap between fixed and moving objects or equally spaced with the inner region object if there is sufficient clearance at the gap. • In order to get stable force results, length-based mesh operations (approximately equal to the distance between the band and the inner region) should be applied using the Length-Based-Inside mesh refinement assigned to the Band object so that the mesh length is refined in the band region that is re-meshed for each time-step.

To assign the band of motion:

1. Select the band object.
2. Click **Maxwell>Model>Motion Setup>Assign Band**.

   The **Motion Setup** window appears.
3. On the **Type** tab: select either **Translation** or **Rotation** as the **Motion Type**.
   - For **Rotation** about a fixed point you may select the **Non-Cylindrical** check box.
   - For **Translation**, you may select the **Periodic** check box.

   For **Periodic** motion, you must define independent and dependent boundary conditions. Both band and the object(s) inside it move, and both should touch the independent and dependent boundaries as shown in the following example.



4. Set the motion direction:
   a. For **Translation** (including **Periodic**), select the desired X, Y, or Z (for 3D) axis of motion from the **Moving Vector** pull-down list; then select either **Positive** or **Negative** direction.
   b. For **Rotation**, from the **Moving Axis** pull-down list, select an axis of rotation. Use the radio buttons to select either **Positive** or **Negative** rotation.

Note	• For 2D XY rotation, only **Positive** rotation is allowed. • If the expected moving vector does not exist, click **Modeler>Coordinate System>Create>Relative CS** to create a new coordinate system.

5. On the **Data** tab: type a value in the **Initial Position** box, and select the units from the pull-down list.
6. To set the motion limits, do the following in the **Translate Limit** or **Rotate Limit** section:

Note	For Periodic motion, you do not need to define motion limits because the solver does not consider the limits for periodic motion; thus the **Translate Limit** section is not present.

   a. For rotational motion, click the **Rotate Limit** check box.
   b. For translational (non-**Periodic**) or rotational motion, type a value in the **Negative** box, and select the units from the pull-down list.
   c. For translational (non-**Periodic**) or rotational motion, type a value in the **Positive** box, and select the units from the pull-down list.
7. On the **Mechanical** tab, do one of the following to specify the object velocity (dynamic or constant):

Note	When you select **Consider Mechanical Transient**, you are telling the solver to use the calculated force and user-specified mass, damping, and other

	parameters to dynamically determine how the object moves, rather than giving it a constant velocity.

Note	• For Maxwell 2D/3D designs for motor applications, the computed output mechanical power at given constant speed may not reach the desired rated power. Therefore, it is useful to apply constant power as the mechanical load. In Maxwell 2D/3D designs created by RMxprt, the mechanical transient is set up according to the rated mechanical output power, and equivalent damping is added to accelerate the process approaching to the rated output power. This setup is visible when **Consider Mechanical Transient** is checked. • The**Consider Mechanical Transient**setup is only for the sake of getting the operating point with given output power. it is not related to any mechanical load type you may set in RMxprt. • 2D/3D designs generated from RMxprt include the setup data, but **Consider Mechanical Transient** is unchecked initially. To ensure that the setup data is preserved, make sure that you check **Consider Mechanical Transient** before saving the project.

- To dynamically change how the object moves, click the **Consider Mechanical Transient** check box, complete the following fields, and select any corresponding units:
  - **Initial Velocity** (translational) or **Initial Angular Velocity** (rotational)
  - **Mass** (translational) or **Moment of Inertia** (rotational)

    Use the **Calculate** button to have Maxwell calculate the Mass or Moment of Inertia with the following restrictions:
    - For 2D problems, the moving bodies are assumed to be of model-unit thinness.
    - Rotating bodies must be symmetric about the axis of rotation. Partial models (e.g., half a motor with implied symmetry) are not supported.
  - **Damping** (rotational motion) – A value for damping for rotational motion (for electric machines) can be calculated by the windage and friction loss in Watts divided by the speed in rad/sec (at which those losses are defined); this is Damping with resulting units of (W / (rad/sec)^2) or (N*m * sec/rad).
  - **Damping** (linear motion) – A value for damping for linear motion can be calculated by the windage and friction loss in Watts divided by the speed in m/sec (at which those losses are defined); this is Damping with resulting units of (W / (m/sec)^2) or (N*m * sec/m).
  - **Load Force** (translational) or **Load Torque** (rotational)

Note	• For translational motion, the load force is positive if it is applied in the same direction as the moving vector and negative if applied in the opposite direction. • For rotational motion, the load torque sign is determined based on the moving vector, using the right-hand rule. Point your thumb in the direction of the moving vector. If the load torque is applied in the same

	direction as your fingers, then the load torque is positive. If it is applied in the opposite direction, then the load torque is negative.

- To set a constant velocity (and disable the mechanical transient), clear the **Consider Mechanical Transient** check box, type a value in the **Velocity** or **Angular Velocity** box, and select the units from the pull-down list.

8. For translational motion, a **Post-Processing** tab is available to set the coordinate system for post processing calculation.
9. Click **OK**.
   - A **MotionSetup*x*** is created and added to the **Model** folder in the **Project Manager** window.
   - For Maxwell 3D projects only, if cylindrical **Rotation** was specified and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted.

Modifying Motion Setup Properties

To modify existing motion setup properties:

1. In the Project Manager Model folder, right-click on **MotionSetup*x*** and select **Properties** from the context menu to open the **Motion Setup** dialog box.
   - Alternatively, you can double-click the **MotionSetup*x*** icon.
2. Edit the desired properties in the **Motion Setup** dialog box. Refer to *Assigning a Band of Motion* for detailed information on the various **Motion Setup** dialog box settings.

Note	For Maxwell 3D projects only: • If you change the motion type to cylindrical **Rotation** and a **CylindricalGap** mesh operation does not already exist, a **CylindricalGap** mesh operation is automatically added to the **Mesh** folder. Only one **CylindricalGap** mesh operation is permitted. • If you change a cylindrical **Rotation** motion type to another motion type, the **CylindricalGap** mesh operation remains in the **Mesh Operation** folder.

   - Alternatively, you can edit many of the motion setup properties in the **Properties** window.

Related Topics

Non-Cylindrical Rotational Motion

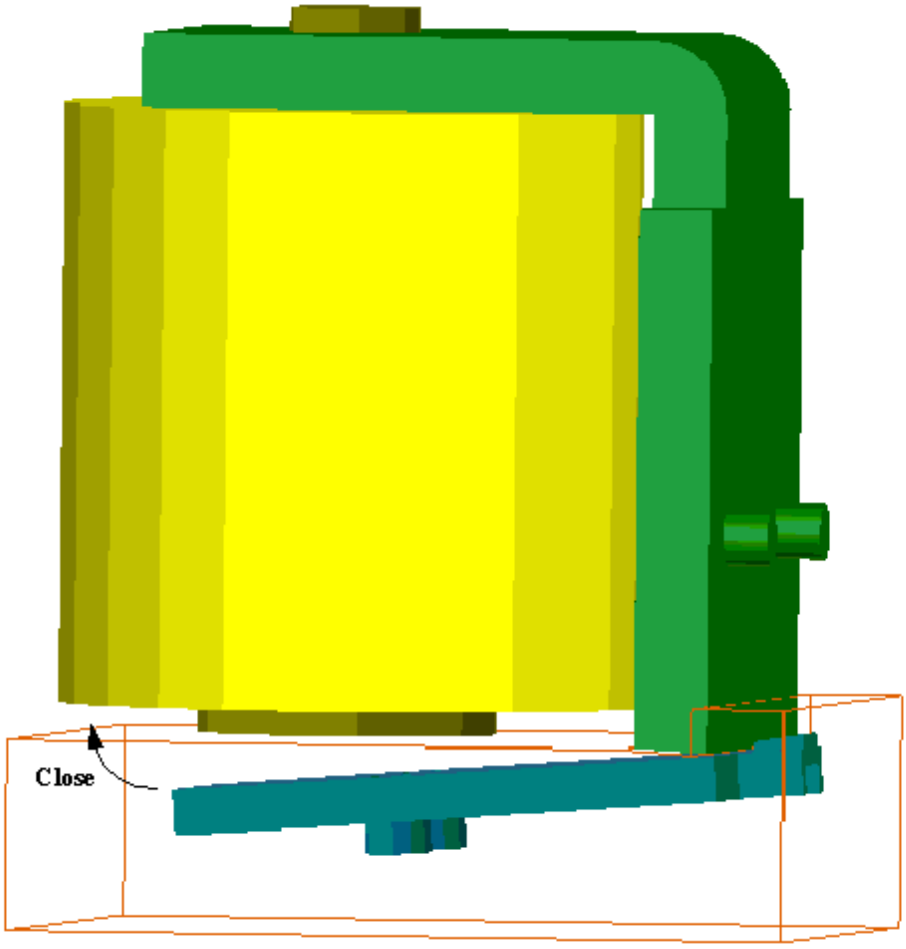
Showing and Hiding Motion Objects

Reassigning a Band of Motion

Non-Cylindrical Rotational Motion

With cylindrical rotation, the moving objects are free to rotate completely, and the mesh remains fixed as the moving objects rotate. With non-cylindrical motion, the geometry shape of the band region changes as the moving objects rotate, and the mesh is recreated.

- A motor is an example of cylindrical motion.
- A relay is an example of non-cylindrical motion.



Reassigning a Band of Motion

When a **MotionSetup** has been created, the object that the setup is assigned to is changed using the **Reassign** command, allowing you to identify the motion setup parameters with a new object

without losing the motion setup parameters themselves. To reassign a **MotionSetup**:

1. Select the object that the **MotionSetup** will be reassigned to in the modeler window or in the history tree.
2. Right-click on **MotionSetup*x*** in the Project Manager window and select **Reassign**.

Note	• An existing **CylindricalGap** mesh operation's assignment will be synced up to a rotational cylindrical motion setup's assignment when you reassign the band object of the motion setup.

Related Topics

Assigning a Band of Motion

Adding and Deleting Objects from a Band of Motion

To add objects to, or delete objects from a motion setup without changing the parameters of the **MotionSetup** do the following:

1. Select the object to be added or deleted from the **MotionSetup** in the modeler window or in the history tree.
2. Right-click **Model>MotionSetup*x*>Moving*x*** in the Project Manager window and choose **Add Selected Objects** or **Remove Selected Objects** from the shortcut menu.
3. **To verify the addition or deletion of the object from the MotionSetup definition, use Select Assignment from the shortcut menu to view the objects assigned to the band.**

Setting the Visibility for Motion Objects

To show or hide a parameter:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Motion** tab.
3. Select or clear the **Visibility** check box for each motion object listed.
4. Click **Done**.

Modeling Maxwell Motion Eccentricity

You can model motion eccentricity for Maxwell 2D and 3D transient designs that have cylindrical rotational motion set up. Ansys Electronics Desktop provides a **Maxwell Eccentricity Wizard** with settings for:

- Rotating part eccentricity
- Rotation axis eccentricity

For rotating part eccentricity modeling, the eccentricity is only applied to rotating objects, not to a motion axis. More specifically, these rotating objects are all objects enclosed by the band, but not the band itself.

For rotation axis modeling, the eccentricity is only applied to the motion axis, which is equivalent to moving the band itself, but not any rotating objects inside the band.

Using these two basic settings, you can model the following physics.

- **Static eccentricity**: To model static eccentricity, you need to set the rotating part eccentricity and rotation axis eccentricity to the same values.
- **Dynamic eccentricity**: To model dynamic eccentricity, set the rotating part eccentricity values only.
- **Mixed eccentricity**: This is the combination of static and dynamic eccentricities. To model mixed eccentricity, set both rotating part eccentricity and rotation axis eccentricity, but with different values.

14 - Adding Solution Parameters

When you assign a solution parameter, the solver calculates the parameter value as part of the solution process. The table below shows the solution parameters that may be calculated based upon the solver type.

Parameter	3D Solvers	2D Solvers
Force/Torque	Magnetostatic Electrostatic Eddy Current Transient Electric Transient	Magnetostatic Electrostatic Eddy Current Transient
Matrix	Magnetostatic Electrostatic Eddy Current DC Conduction AC Conduction	Magnetostatic Electrostatic Eddy Current AC Conduction DC Conduction

Assigning a Force Parameter

To solve for a force parameter:

1. Select the object on which you want to apply the parameter.
2. Click **Maxwell3D or Maxwell2D, and then select Parameters>Assign>Force**. You can also right-click on Parameters in the Project tree, and then select **Assign>Force** from the context menu.

   The **Force Setup** window appears.
3. Type a name for the force in the **Name** box.
4. For **Maxwell3D** projects only, select **Virtual** or **Lorentz** as the **Type** for the force.

   > **Note:**
   >
   > - For 3D Magnetostatic, Electrostatic, Eddy Current, and Transient solvers, you can select either **Virtual** or **Lorentz** force to be calculated.
   > - For 3D Electric Transient solvers, only **Virtual** force is calculated.
5. Select the **Post-Processing** tab to specify the coordinate system reference for calculating the force parameter.

> **Note:** If object or face coordinate systems are used as reference in the post processing tab of the force setup in a transient analysis with motion, it should be noted that the original position of the CS will be used for this coordinate transformation. This coordinate transformation will not consider the motion enforced by the motion setup.

6. Select the appropriate coordinate system from the **ReferenceCS** pull-down list.
7. Click **OK**.

> **Note:** Force parameters are available for calculation in the 2D and 3D Magnetostatic, Electrostatic, Eddy Current and Transient solvers, and for the 3D Electric Transient solver only.

> **Note:** The calculation of forces using the A-Phi formulation requires an extremely fine mesh, since B is solved as 0th order and is constant at each node of each tetrahedral element.

Assigning a Torque Parameter

To solve for a torque parameter:

1. Select the object on which you want to apply the parameter.
2. Click **Maxwell3D or Maxwell2D, and then select Parameters>Assign>Torque**. You can also right-click on Parameters in the Project tree, and then select **Assign>Torque** from the context menu.

   The **Torque** setup window appears.
3. Type a name for the torque in the **Name** box.
4. Select **Virtual** or **Lorentz** as the **Type** for the torque.

Note	For 3D Transient and Electric Transient solvers, only **VirtualTorque** is calculated.

5. To assign an axis:
   a. Select the axis from the **Axis** pull-down list.
   b. Select either the **Positive** or **Negative** radio button.
6. Click **OK**.

Note	Torque parameters are available for calculation in the 2D and 3D Magnetostatic, Electrostatic, Eddy Current, and Transient solvers, and for the 3D Electric Transient solver only.

Assigning a Matrix

To solve for a capacitance, inductance, impedance, or conductance matrix:

1. Click **Maxwell 3D** or **Maxwell 2D**, and then select **Parameters>Assign>Matrix**.

   The **Matrix** dialog box appears.
2. Click the **Setup** tab.
3. Type a name for the matrix in the **Name** box.
4. To specify the sources to be included in the matrix, do one of the following:
   - For 3D Electrostatic, 2D and 3D Magnetostatic, 2D and 3D Eddy Current designs, select or clear the **Include** check box for any of the listed sources.

     For **Maxwell 2D** designs, the return path for each source may be specified. By default, the return path is at infinity; however, any conductor with a source specified can act as the return path.
   - For 2D Electrostatic, 2D and 3D DC Conduction, and 2D and 3D AC Conduction, select or clear the **Signal** or **Ground** check box for any of the listed sources. Grounded terminals are treated as reference voltages with zero voltage values.

     Excitations checked as **Signal** will be in the matrix (excited one at a time with 1V during the parameters extraction process). Those excitations checked as **Ground** will be kept at 0 V and will not be part of the matrix. Any excitations not checked will not be considered.
5. For Magnetostatic designs, click the **Post Processing** tab.

   If more than one source is listed on the left side, you can click the **Post Processing** tab and **Group** them to organize multiple sources into a single group. The calculations defined in the Post Processing tab do not impact the field solution and can be set up or changed after the solution has been completed.

   To **Group** multiple sources together:
   a. If desired, set the number of **Turns** for each source.
   b. Select the sources to group in the list **Entry** list. Multiple source can be selected by holding the **CTRL** key and clicking each source line.
   c. With all sources selected, click **Group** to combine the sources into one series winding.
   d. Set the number of parallel **Branches** the winding should be divided into and click **OK**.
   e. The results of the post processing calculation on the matrix can be seen by selecting **PostProcessed** on the **Matrix** tab of the solutions dialog box.
6. Click **OK**.

Note	• For a matrix setup, the elements are defined based on excitations, not solids. Only excitations will be available in the **Matrix** dialog box, regardless of the current geometry selection. Also, changes made to the excitations after matrix setup will not be flagged until the setup validation performed prior to the solution process.

	• Matrix setups are recognized when coupling Maxwell designs to Twin Builder components such as Equivalent Circuit, Dynamic Inductance and Capacitance, and State Space. For more information on coupling Maxwell designs to Twin Builder components, refer to the *Maxwell Component Subcircuits* topic in the Twin Builder Help. • For 2D and 3D Eddy Current designs, you can also *Assign a Reduce Matrix*. • For the 3D AC Conduction solver, the current excitations might also be considered during the matrix extraction. They will be considered in the same way as the regular voltage excitations.

In a matrix calculation:

- For coil terminals, all terminals are listed and can be selected.
- For outer terminals, the solver can only handle a conduction path with two terminals, and only one terminal is listed for each conduction path:
  - If they are current terminals, the listed terminal is in the “in” direction.
  - If they are current density terminals, the first terminal is listed and can be selected.
- When setting up an inductance matrix, the source must be a current excitation. Voltage sources cannot be used in this case.
- In 2D matrix calculations the solver calculates loop currents; therefore, the direction of return path current is always opposite of the source current. If a conductor with excitation is specified as the return path, the polarity setting of the excitation in the nominal problem setup is not respected.

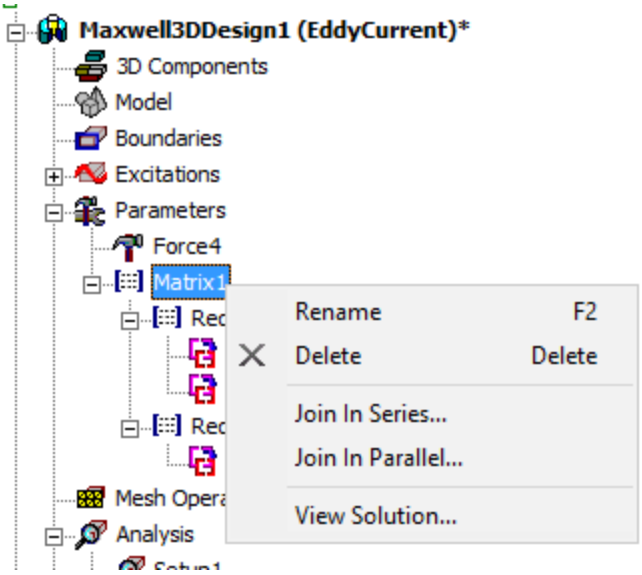
Assigning a Reduce Matrix for 2D and 3D Eddy Current Designs

For 2D and 3D Eddy Current designs, you can join (group) two or more excitations to one excitation in either a series or a parallel connection. The result of each join (group) operation is known as a Reduce Matrix. This would be useful when analyzing designs such as a motor with 4 poles, each pole having 3 wires coming into it, with the physical design having each set of three wires in series, and the four bundles of wires in parallel.

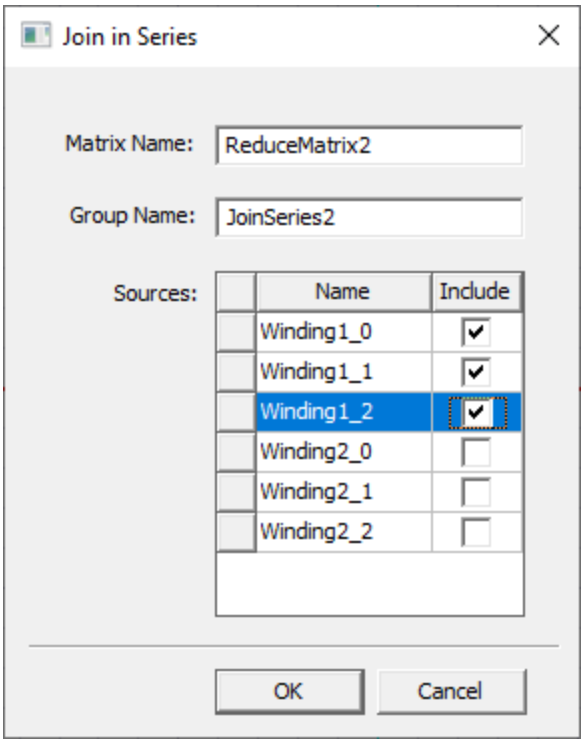
To create a reduce matrix:

1. Right-click on an existing Matrix parameter in the project tree.



2. Select either **Join in Series** or **Join in Parallel**.

   A corresponding **Join in Series** or **Join in Parallel** dialog box opens. You can accept the default reduce **Matrix Name**, or enter the desired name.



3. You can enter a **Group Name** (or accept the default), and check **Include** for those sources you wish to join in series (or parallel).

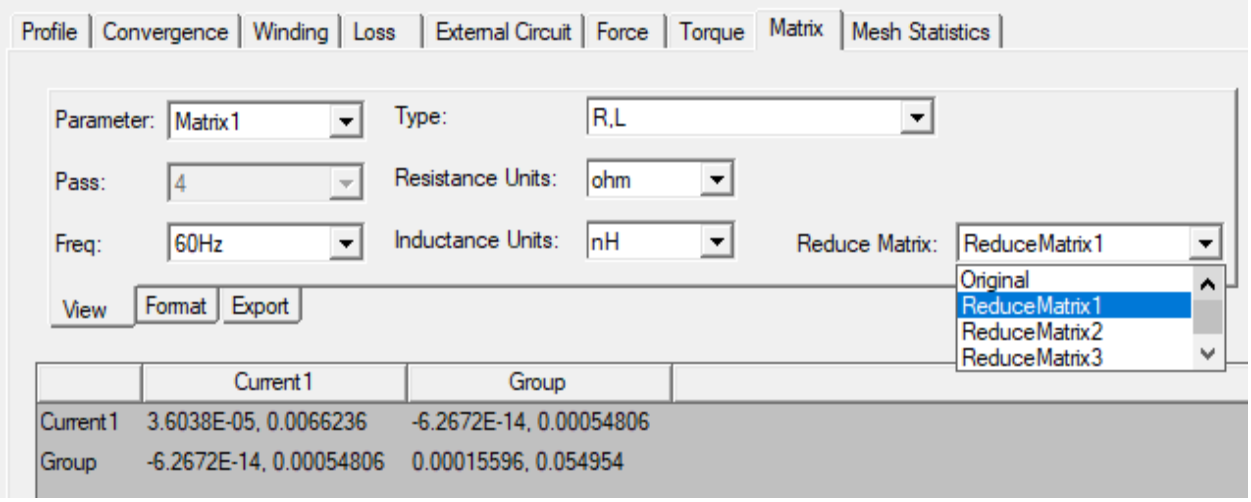
Note	Multiple group operations are supported. For example, you could join conductors 1, 2, and 3 in one series; and conductors 4, 5, and 6 in another series.

4. Click **OK** to close the dialog and add the new reduce matrix group under its parent Matrix.

Note	If you want to make changes to a reduce matrix, you can double-click on the reduce matrix group item in the tree to reopen the dialog box. You can also right-click the item to rename or delete it.

If you want to make changes, you can double-click on the reduce matrix group item in the tree to reopen the dialog box. You can also right-click the item to rename or delete it.

You can view the results of reduce matrix calculations on the Matrix tab of the Solutions dialog.



You can select reduce matrices to plot inductance and resistance quantities for various report types.

Creating a New Report

Reassigning Parameters

To reassign the geometry a parameter applies to:

1. Select the new object to which you want to assign an existing parameter.
2. Click **Maxwell3D or Maxwell2D, and then select Parameters>Reassign.**
   The **Reassign Parameter** window appears.
3. Select the force or torque you want to reassign from the **Reassign Geometry for** list.
4. Click **OK**.
   The parameter is reassigned to the new object.

Viewing Parameter List

To view a list of all parameters in the design:

1. Click **Maxwell3D** or **Maxwell2D,** and then select **Parameters>List**.
   The **Design List** window appears, with the **Parameters** tab visible.
2. To view other design choices, click one of the following tabs:
   - Model
   - Boundaries
   - Excitations

- Mesh Operations
- Analysis Setup

Deleting All Parameters

To delete all parameters assigned in the model:

- Click **Maxwell3D or Maxwell2D, and then select Parameters>Delete All**.
  All parameters are deleted.

Warning	Maxwell provides no warning or option to stop deletion. If you accidentally delete all parameters, click **Edit>Undo Delete All Parameters** before you take any other action.

Showing and Hiding Solution Parameters

1. Click **Maxwell3D or Maxwell2D, and then select Parameters>Visualization**.
   The **Parameter Visualization Options** window appears.
2. Select the type of parameter you want to view from the **Select** pull-down list, or click the row in the table. Choices include **All**, **All Forces,All Torques**, **All Matrices**, and **By Name**.
   The object is highlighted in the geometry.
3. Select or clear the check boxes for each parameter to show or hide geometry, name, and vectors for each force or torque parameter.
4. Click **Deselect All** to hide all parameters.
5. Click **Close** to close the window.

Setting the Visibility for Parameters

To show or hide a parameter:

1. Click **View>Active View Visibility**.
   The **Active View Visibility** dialog box appears.
2. Click the **Parameters** tab.
3. Select or clear the **Visibility** check box for each parameter listed.
4. Click **Done**.

Changing the Parameter Setup

To change a parameter's setup:

1. In the project tree, open the **Parameters** section.
2. Right-click the parameter you want to change.
   A shortcut menu appears.

3. Select **Properties** from the shortcut menu.
4. Make the desired changes, and then click **Close**.

15 - Defining Mesh Operations

In Maxwell, mesh operations are optional mesh refinement settings that provide Maxwell with mesh construction guidance. This technique of guiding Maxwell's mesh construction is referred to as "seeding" the mesh. Seeding is performed using the **Mesh** commands on the **Maxwell3D or Maxwell2D** menu.

When defining a mesh, you typically assign the mesh operations first (using the **Maxwell3D>Mesh** or **Maxwell2D>Mesh** commands) and then create the mesh (using the **Maxwell3D** or **Maxwell2D** menu and selecting **Analysis Setup>Generate Mesh** command). However, you can also refine the mesh after the initial mesh has been created.

You can instruct Maxwell to refine the length of tetrahedral elements on a surface or within a volume until they are below a certain value (length-based mesh refinement) or you can instruct Maxwell to refine the surface triangle length of all tetrahedral elements on a surface or volume to within a specified value (skin depth-based mesh refinement). In some circumstances, you may also want to create a mesh operation that modifies Maxwell's surface approximation settings for one or more faces. In some circumstances, you may also want to assign a cylindrical gap treatment mesh operation. For Maxwell 2D, when the TAU mesher is selected in the Initial Mesh Settings dialog box, you can define the Skin Depth Layers mesh setting corresponding to the selected edges.

Surface approximation settings are only applied to the *initial mesh* (the mesh that is generated the first time a design variation is solved). The other types of mesh operations (refining the mesh) can be performed on either the initial mesh or on the most recently generated mesh (the *current mesh*) if you are updating a previously-created mesh.

Note	Mesh operations at the target design of a mu (permeability) link are ignored.

You can also choose to override automatic choice of which mesher Maxwell uses, by using the Maxwell>Mesh>Initial Mesh Settings command.

What do you want to do?

- Perform length-based mesh refinement on object faces.
- Perform length-based mesh refinement inside objects.
- Perform skin depth-based mesh refinement on object faces.
- Assigning Cylindrical Gap Treatment
- Apply Skin Depth Layers Settings
- Modify surface approximation settings for one or more faces.
- Modifying the Model Resolution (Maxwell3D only)
- Apply mesh operations
- Specify the initial mesh settings

Assigning Length-Based Mesh Refinement on Object Faces

1. Select the faces you want Maxwell to refine.

   Alternatively, select an object if you want Maxwell to refine every face on the object.
2. Click **Maxwell>Mesh>Assign Mesh Operation>On Selection>Length Based**.

   The **Element Length BasedRefinement** dialog box appears.
3. Type a name for the mesh operation in the **Name** box, or accept the default name.
4. To restrict the length of tetrahedra edges touching the faces:
   a. Select **Restrict Length of Elements**.
   b. Type the maximum length of the tetrahedral edges touching the faces in the **Maximum Length of Elements** box, and select the units.

Note	Maxwell refines the element edges touching the selected faces until their lengths are equal to or less than this value. The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected face.
5. To restrict the number of elements added during refinement of the faces:
   a. Select **Restrict the Number of Elements**.
   b. Enter the **Maximum Number of Elements** to be added.
6. Click **OK**.

When the mesh is generated, the refinement criteria you specified are used. When the maximum number of elements is reached, some elements may exceed the requested maximum element length.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Assigning Length-Based Mesh Refinement Inside Objects

Length-based mesh operations inside volumes can be applied to non-model box primitives. If an error occurs, you may be trying to assign a mesh to a non-model box that is not a box primitive (such as boxes with chamfers or non-model cylinders).

To instruct Maxwell to refine every face of an object and its interior:

1. Select the object you want Maxwell to refine.
2. Click **Maxwell>Mesh>Assign Mesh Operation>Inside Selection>Length Based**.

   The **Element Length Based Refinement** dialog box appears.
3. Type a name for the mesh operation in the **Name** box, or accept the default name.
4. To restrict the length of the tetrahedral element edges inside the object:
   a. Select **Restrict Length of Elements**.
   b. Type the maximum length of the edges inside the object in the **Maximum Length of Elements** box, and select the units.

Note	Maxwell refines the element edges inside the object until they are equal to or less than this value. The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected object's faces.
5. To restrict the number of elements added during the refinement inside the object:
   a. Select **Restrict the Number of Elements**.
   b. Enter the **Maximum Number of Elements** to be added.
6. Click **OK**.

When the mesh is generated, the refinement criteria you specified are used. When the maximum number of elements is reached, some elements may exceed the requested maximum element length.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

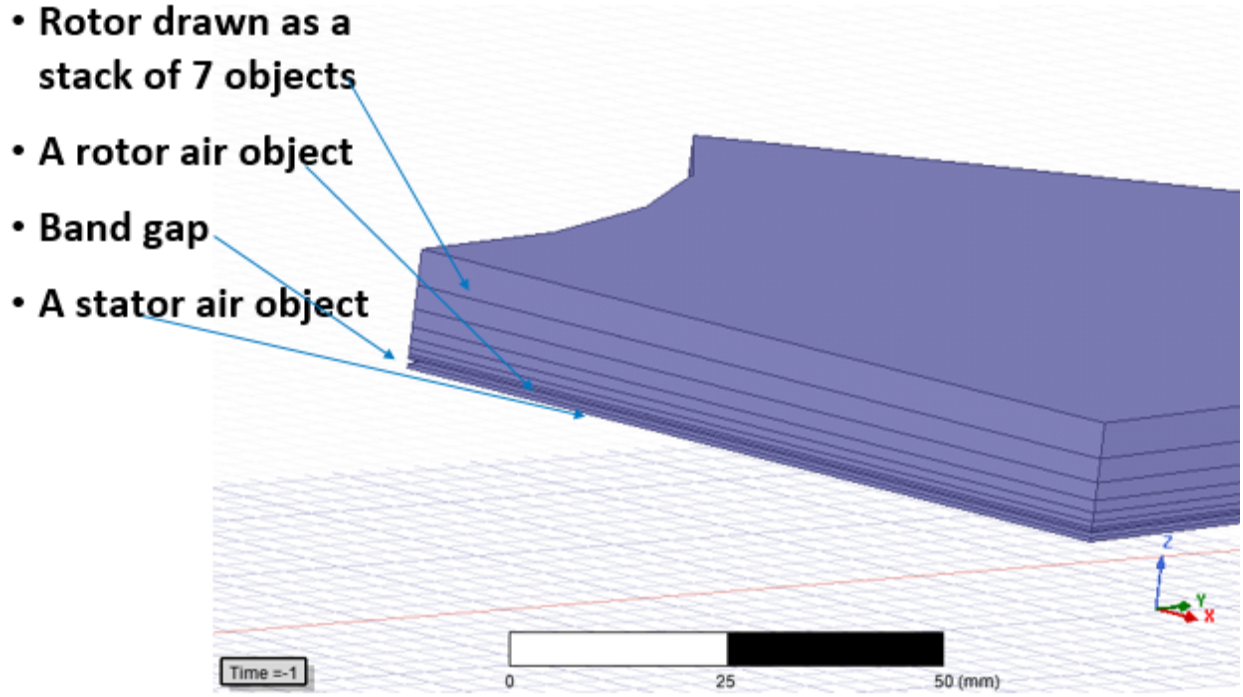
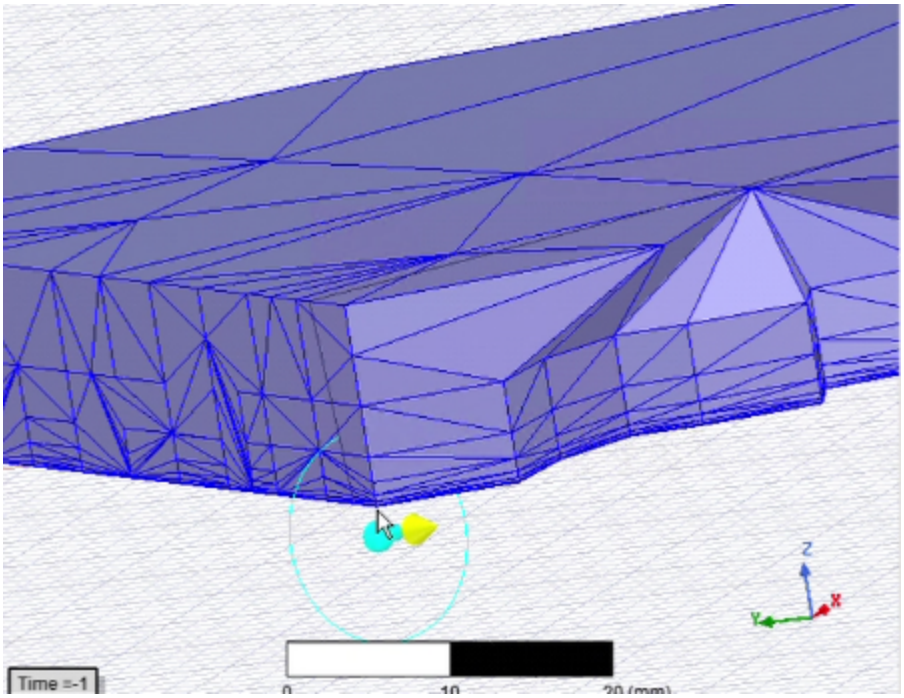
Assigning Skin Depth-Based Mesh Refinement on Object Faces

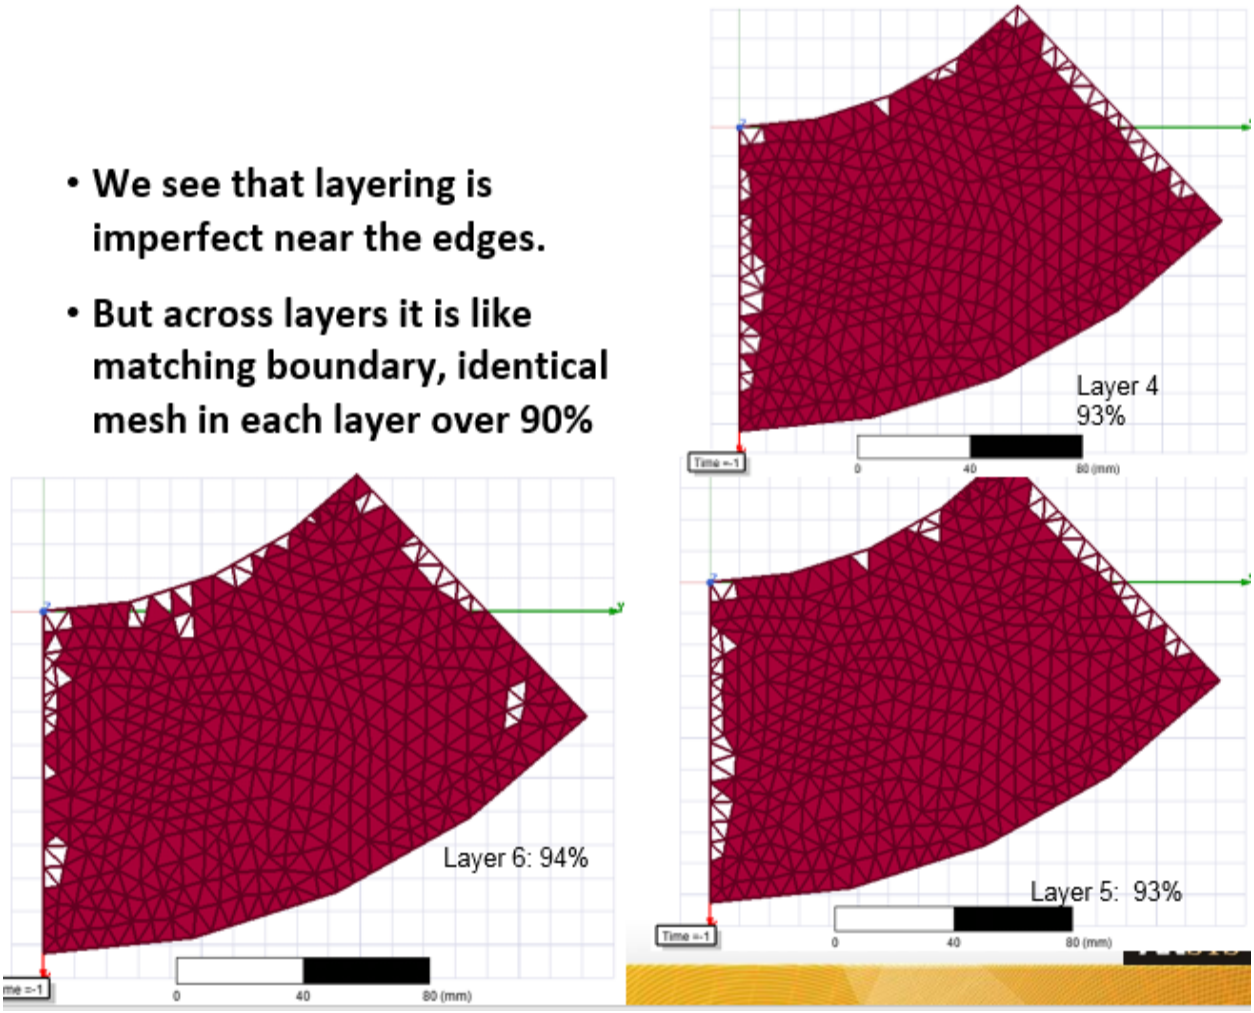
The Skin Depth-based mesh refinement lets you calculate or specify a skin-depth for mesh refinement. You can also specify the number of layers of elements for refinement where the skin depth is the total depth of all layers combined. These layers provide an easy, alternative approach than by creating physical models of each layer, pseudo-sheet bodies. Whereas creating and adjusting a complex, layered physical model is difficult, changing the skin depth parameters and number of layers is very easy. For example, consider a Maxwell rotor, drawn as a stack of seven objects:



To test various stacking models with pseudo bodies involves recreating the model with different thicknesses and remaking the entire initial mesh. The Tau mesher may not be available for all layer heights. You can achieve comparable results by using skin depth based refinement by reverting to the initial mesh, changing settings and applying mesh operations. The following figure shows a cut-plane image of the interior of a model that uses skin-depth based refinement and layers of elements. The Skin Depth is the total depth of all layers combined. Layered elements apply to the selected faces of solid bodies. The elements are stretched parallel to face, and are compressed in the normal direction.



While in some places the edges have imperfect layering, the interior is very good. You can also view the results layer by layer by using the Model Analysis dialog.



The layered skin depth mesh operation provides a tool toward finding a good solution. You can try different settings to improve results toward a good solution. For instance, for this example, these different settings were tried. For comparison, a model built with seven layers required 85K tets.

Tri length target mm	Total skin depth mm	Number of layers	Mesh Size element count	Perfect layering by tri count	Perfect layering by area
15.0	6.3	6	63K	43%	65%
10.0	6.3	6	68K	95%	94%
8.0	6.3	6	76K	96%	93%
6	6.3	6	97K	97%	94%

The goal is not to have perfect layering, but to have a good solution that is much easier to achieve.

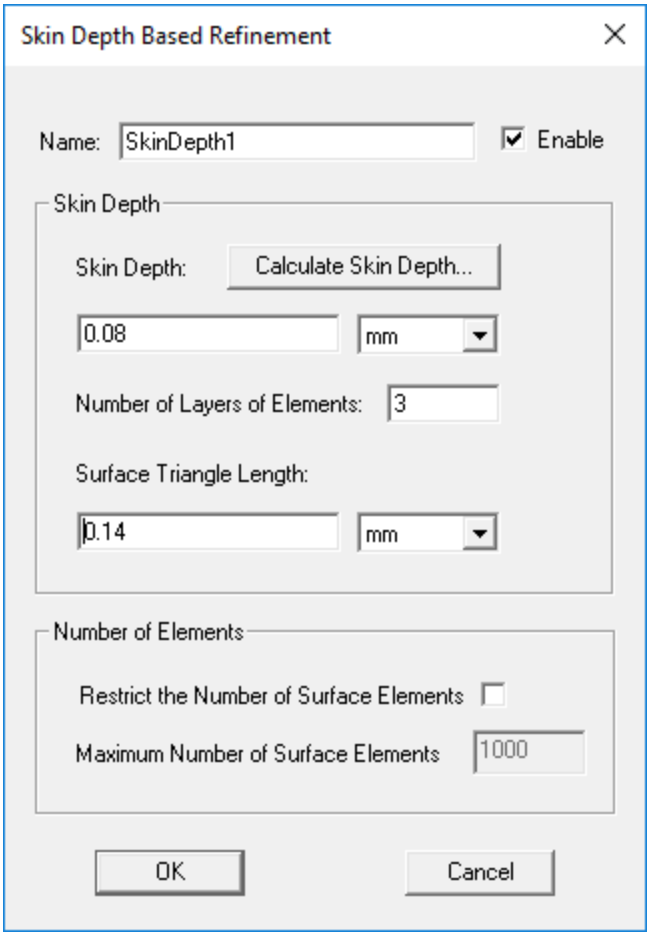
To use Skin Depth-Based Refinement:

1. Select the faces you want to be refined.

Note	It is possible to select a body and convert it to selecting all faces of the body. The user can use this method to select all faces and toggle a few faces out of selection. Selecting the whole body might select very large regions for refinement and increase the element count a lot.

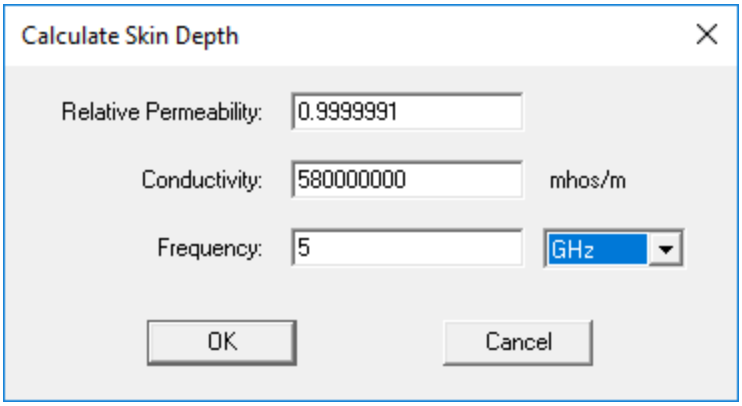
2. Click **Maxwell>Mesh>Assign Mesh Operation>On Selection>Skin-Depth-Based**.

   The **Skin Depth-Based Refinement** dialog box appears.



3. To calculate the skin depth based on the object's material permeability and conductivity and the frequency at which the mesh will be refined, click **Calculate Skin Depth**.

The **Calculate Skin Depth** dialog box appears with values based on the selected object's material properties and the solution setup frequency.



Accept or edit these values. When you click **OK** the solver calculates the skin depth and enters its value in the **Skin Depth** text box. You can accept the calculated values or provide your own.

4. In the **Number of Layers of Elements** text box, type the number of layers to add perpendicular to the object's surface. The skin depth is the total depth of all layers combined.

   The solver will add an equivalent number of mesh points to each layer. For example, if Maxwell added 10 points to satisfy the **Surface Triangle Length**, it will add 10 points to each layer.

5. Optionally, provide the maximum edge length of the surface mesh in the **Surface Triangle Length** text box. The default value is set to 20% of the maximum edge lengths of the bounding boxes of each selected face.

   The solver will refine the surface triangle mesh (the faces of the tetrahedra touching the surface) until their edge lengths are less than or equal to the specified value.

6. By default, the **Restrict Number of Surface Elements** setting is unchecked. This allows the mesher to use symmetry more effectively. If you Restrict the number of surface elements, this may affect symmetry but can be used to protect against runaway refinement in specific cases. To restrict the number of elements added during refinement on the faces uncheck the box to enable the field for **Maximum Number of Surface Elements**. With the box unchecked, the field, grayed out, the number in the box provides an estimate of mesh growth.

When the mesh is generated, the refinement criteria you specify are used. This operation will be approximately the same as having slabs of tetrahedra, but it is not guaranteed to prevent tetrahedra from crossing slab interfaces. Caution should be used with this mesh operation, as very thin layers may cause a reduction in mesh quality or unnecessarily cause the generation of a very large mesh. Further regions refined under this operation and its close neighbors do not participate in solution adaptive refinement. This is another reason to use this seeding operation with caution.

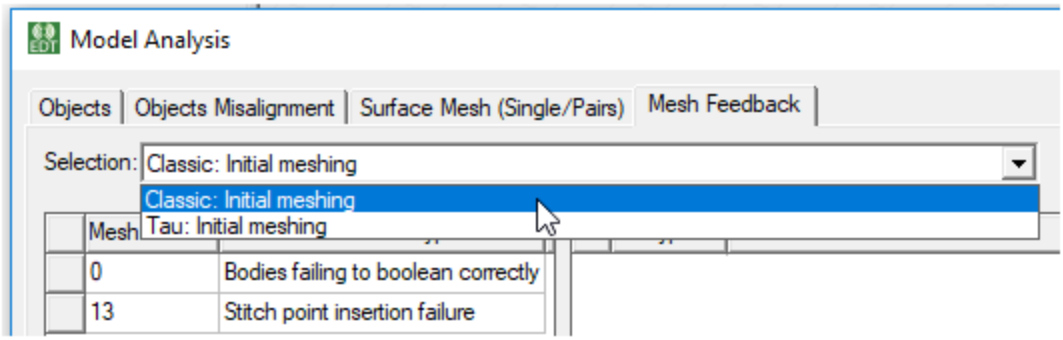
You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Visualization for Skin Depth Refinement Mesh Results

You can visualize the mesh to assess results either by using the clip-plane feature on a model with a mesh plot, or by using the Model Analysis dialog as follows:

1. Select the object on which you have generated a meshplot, and click **Modeler>Model Analysis>Show Analysis Dialog>View Mesh Feedback**.

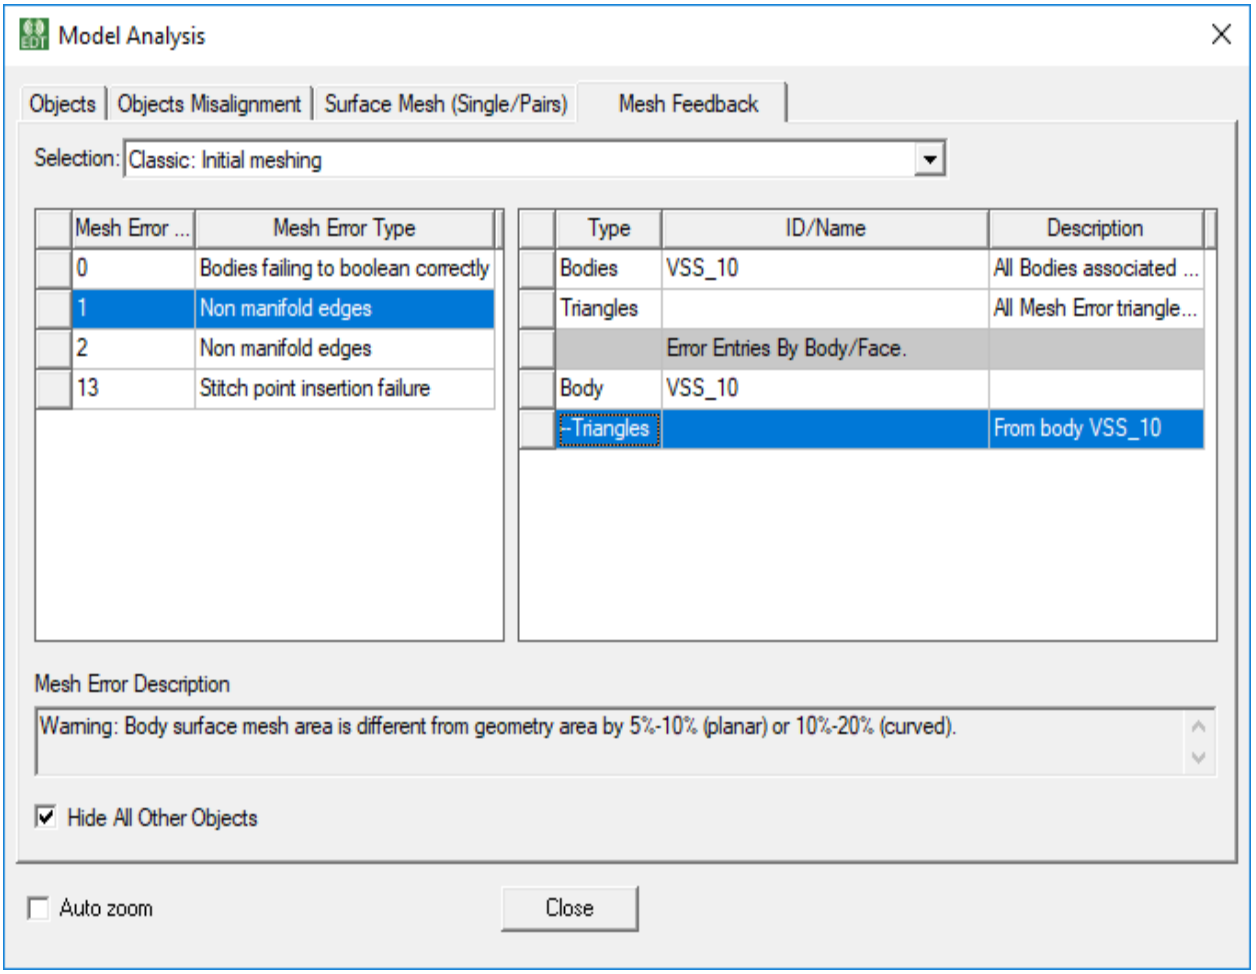
   The **Model Analysis** dialog appears. If the project has solutions by different solvers, the **Selection** drop down lets yous select which mesh to view.



2. On the upper left table, under Mesh Error, select 0 through n , where 0 is the selected body, 1 is the layer closest to the face, 2 is the next, up to layer "n" as farthest.

   Selecting one of these rows causes a **Mesh Error Description** to display for the selected layer or body. The message gives the Total Expected count for triangles, as

compared with the Success percentage by count and by area.



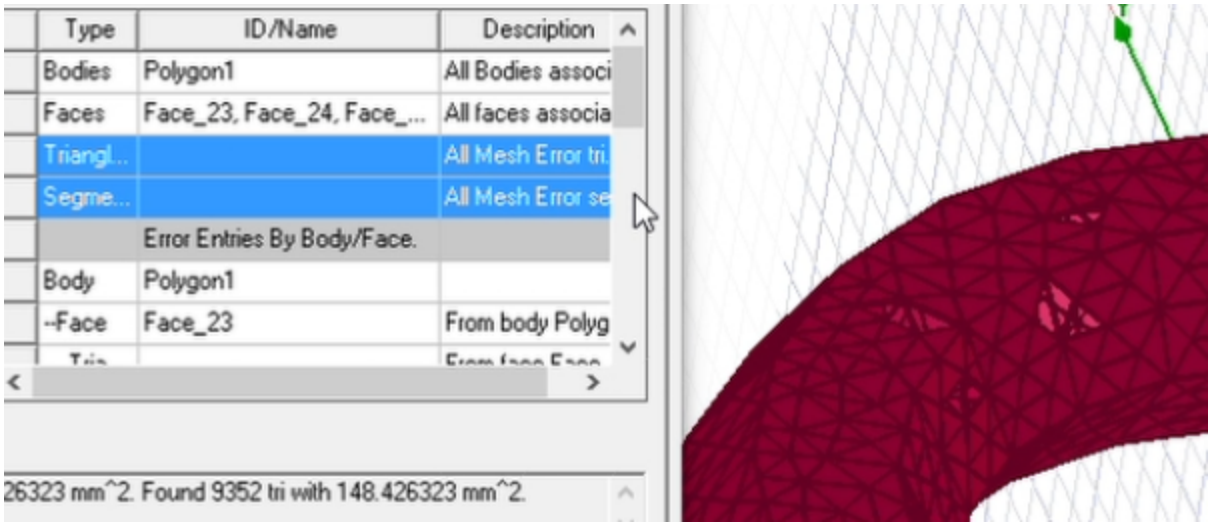
3. On the upper right table, select the body, face, or triangle desired, scrolling the list to find any object, face, triangle, or area of interest.

   Click Face, to see the selected face.

   Select Triangles to see the actual triangles created.

   Select Segment to show the triangles attempted.

   The following figure shows Triangle and Segment both selected (using shift-click). Visually, the unfilled triangles represent places where the triangle is not on the desired layer. However the mesh is still very good and supports an accurate solution.



4. Check boxes allow you to **Hide All Other Objects** checked by default, and **Auto zoom to selection**, unchecked by default.

Assigning Cylindrical Gap Treatment

1. Select the object you want Maxwell to refine.
2. Click **Maxwell 3D>Mesh>Assign Mesh Operation>Cylindrical Gap Treatment** or **Maxwell 2D>Mesh>Assign Mesh Operation>Cylindrical Gap Treatment**.

   A **CylindricalGap** mesh operation is applied to the selected object, and a **CylindricalGap** icon appears in the Project Manager Mesh folder.

   The CylindricalGap operation only works for the TAU (tolerant) mesher. It is a specific mesh operation assigned to the “Band” object for a rotational transient simulation.

   While you can select any object and assign the CylindricalGap operation to it in any Maxwell simulation, the CylindricalGap operation is effective only for rotational transient simulations for which cases the TAU (tolerant) mesher will be chosen as the default mesher; or for which you have manually selected the TAU(tolerant) mesher.

   The TAU (tolerant) mesher analyzes the “Band” object, calculates the surface normal angle for the band rotational surface, and automatically assigns the desired mesh operation; or adjusts the existing mesh operations to the adjacent true surfaces at both static and moving sides to ensure a smooth and uniform mesh for the “Band” mesh.

   If the CylindricalGap mesh operation is assigned to a regular object, TAU analysis finds the object is not suitable for transient mesh, in which case the regular TAU mesh will be applied. A warning message is then displayed in the message window.

Note	• There can be only one cylindrical gap operation per design. • The operation cannot be assigned to multiple objects.

3. If you wish to change the name of the mesh operation, you can double-click on the **CylindricalGap** icon to open the **Cylindrical Gap Mesh Operation** dialog box in which you can type a name for the mesh operation in the **Name** box.
4. Optionally for 3D transient simulations of rotational models only, if you wish to apply a clone mesh operation, check **Clone Mesh**. This option is unchecked by default.
    - When **Clone Mesh** is selected, the **Band Mapping Angle** setting is enabled. The valid range of angles is 0.1 through 3.0 degrees, inclusive. The default band mapping angle is 3 degrees. (For more information on this setting, refer to *Band Mapping Angle*.)

Note	If the model is not suitable to make a clone mesh or the clone mesh process fails, Maxwell automatically falls back to the regular TAU 3D mesher. Because the clone mesh is generated in the initial mesh, the initial mesh is deleted and regenerated once this option is changed and you click **OK**.

    - When **Clone Mesh** is selected, the **Number of Layers** setting is enabled. You can input the number of mesh layers on the **Moving Side** and **Static Side**, respectively. The valid ranges for these settings are integers ≥ 1. The default values are 1. (For more information on this setting, refer to *Layers in Band Mesh*.)

3D Clone Mesh Generation

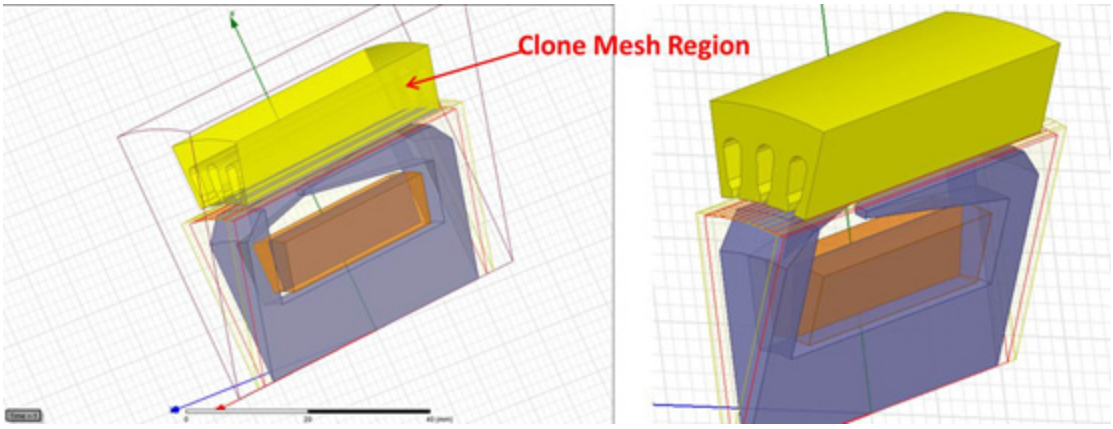
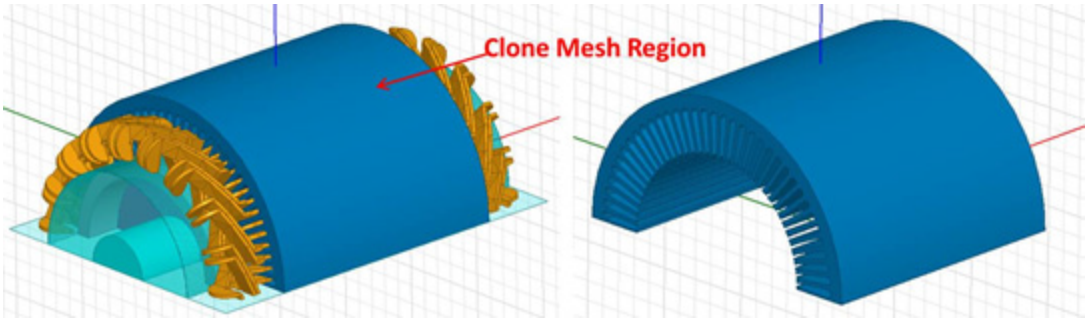
The 3D clone mesh is generated only when the following three conditions are met:

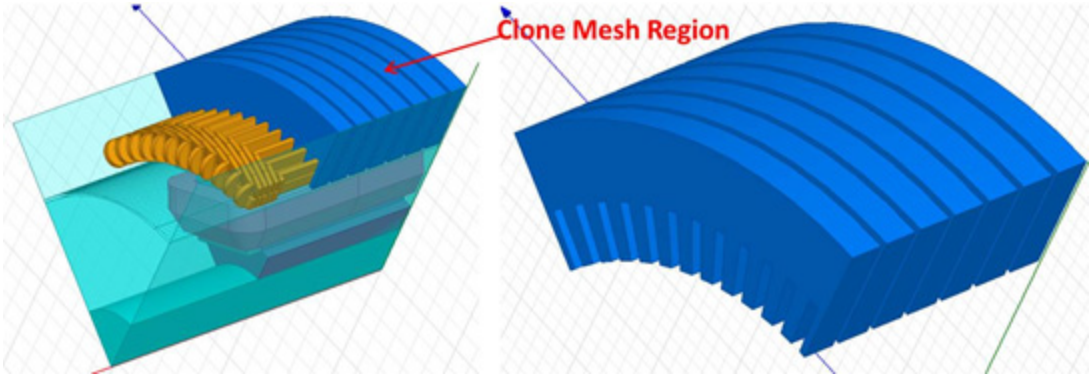
- The Clone Mesh check box is checked.
- The CylindricalGap mesh operation has been assigned.
- The model has a non-skewed stator with more than two teeth.

Note	When Clone Mesh is used, the only additional mesh operation that can be used is surface approximation. If any other mesh operation is used, the clone mesh operation will be ignored.

The solid bodies adjacent to the band are detected to identify the clone object. If the object has more than two teeth that are close to the band, the teeth will be verified to see they have the identical geometric features. If the teeth are skewed, TAU will fall back to the regular mesh. Otherwise the region from the radius of teeth to the outer edge of the object will be further classified and verified to see if the object has the multiple 3D identical sub-regions.





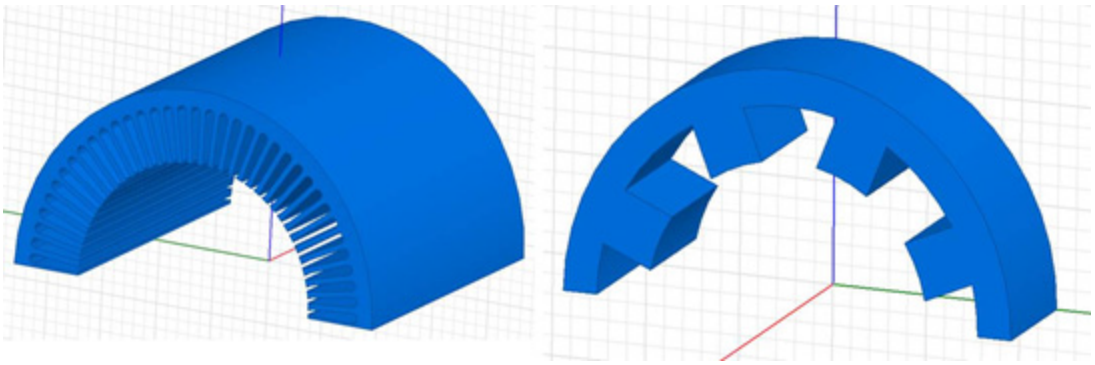


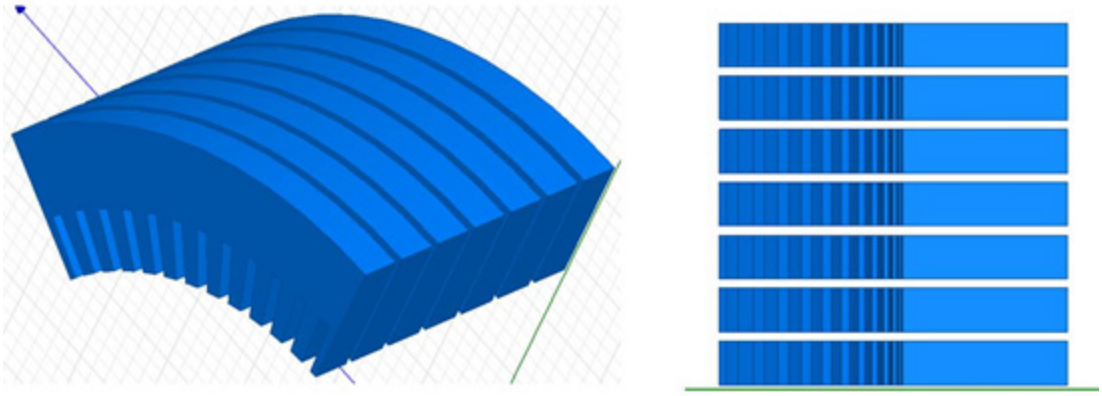
If a 3D clone region has been identified, TAU will classify the 3D rotational model into a static region and a moving region by the band object radius. The Static region includes the clone region and skewed coils regions at one side or two sides. Clone mesh method will then be used to generate the mesh in the clone region, while the TAU regular mesh method will be used to generate the mesh at other skewed regions.

The moving region includes skewed coils regions in which the TAU regular mesh method is used to generate the mesh, and also the non-skewed sweep regions in which the TAU sweep mesh method is used to make the mesh.

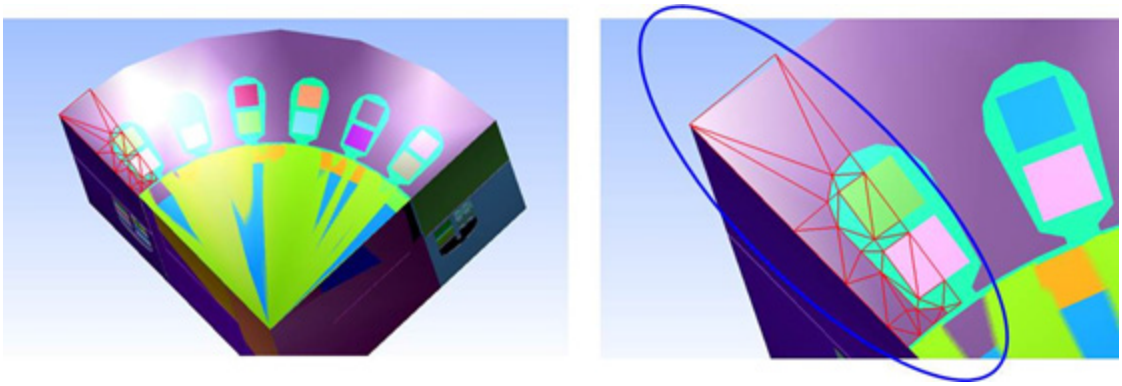
3D Clone Mesh

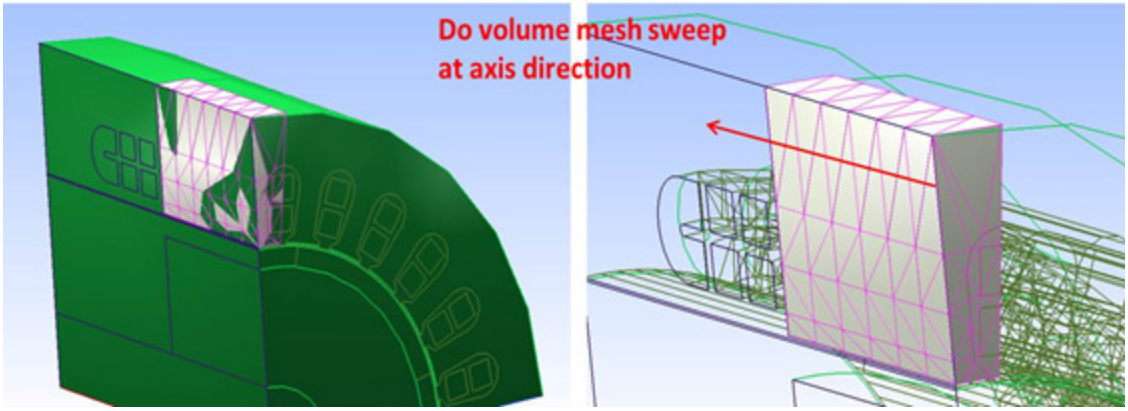
A 3D clone region may have only one simple object, or several sections of clone objects with the gap between as shown in the following images.





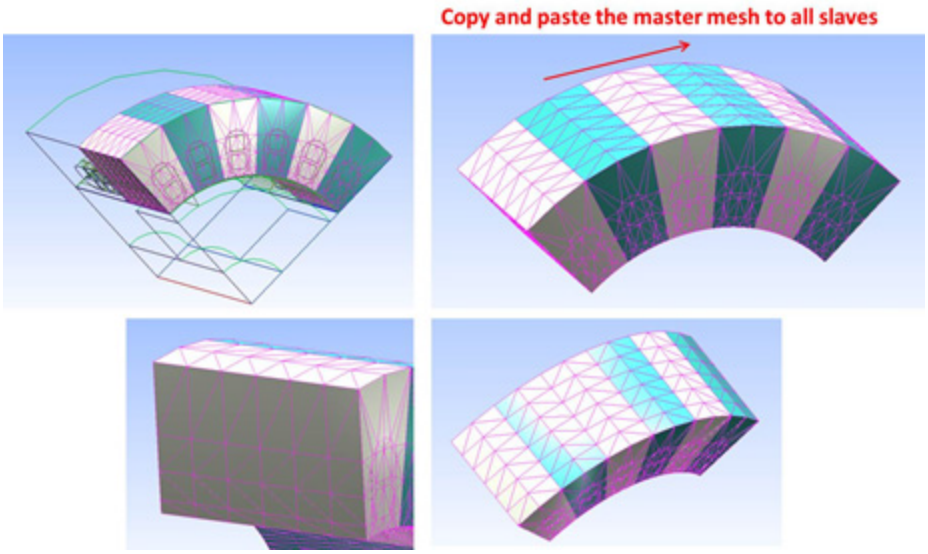
To ensure the identical volume mesh in each sub-region, the volume mesh is generated in the Master region, then by using a copy-and-paste method to duplicate the mesh at all child regions. In the 3D master region, if the region is also symmetric, then a symmetric mesh is generated. “Sweeping mesh” technology is used to make the volume mesh in the master region. In the half of the master region, a surface mesh is generated at the axis side. The volume mesh is generated by sweeping the surface mesh in the axis direction to fulfill the clone master region.





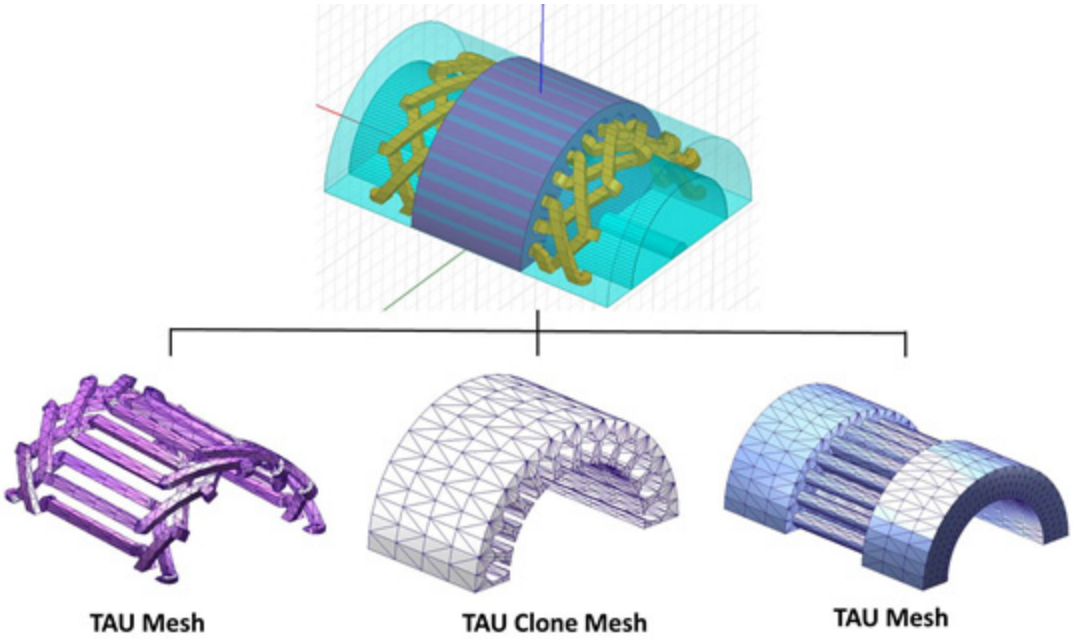
The volume mesh will be mirrored to the other half of the master region to produce the symmetric mesh in the master region.

The volume mesh in the master region is then duplicated and translated to the child regions with copy and paste technology in TAU to complete the 3D clone region mesh.



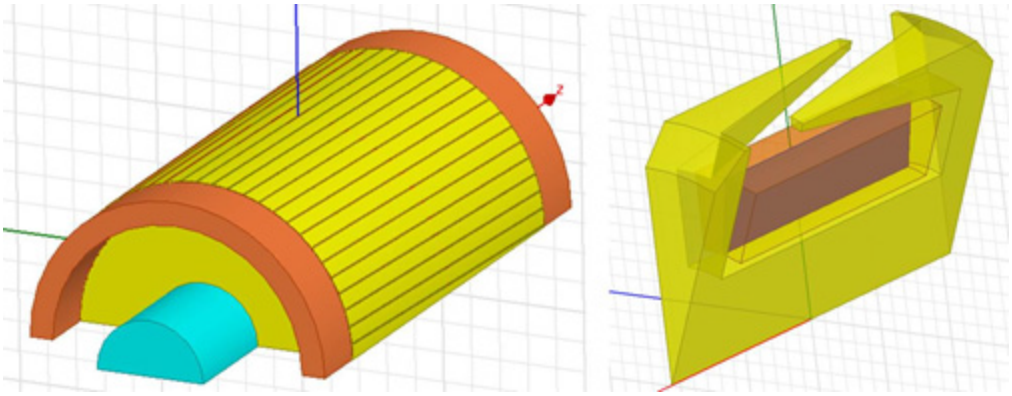
3D TAU Mesh

Beyond the 3D clone region, normally the regions have skewed coils. Therefore TAU regular mesher will be used to make the mesh.

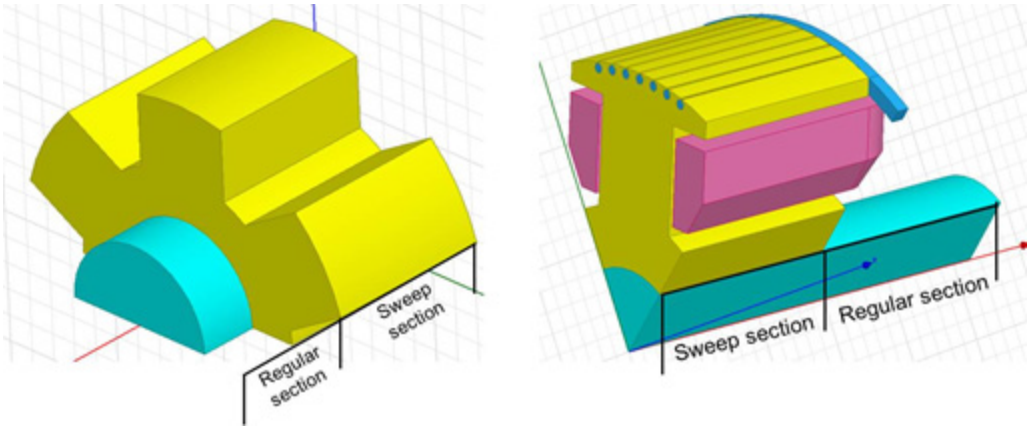


3D Sweep Mesh

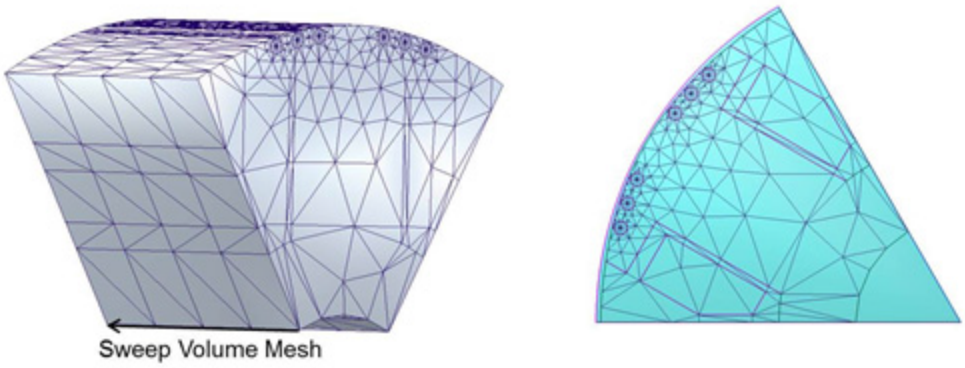
The rotational model for a moving region may have different structures. It may have all skewed coils and rotors. In this case, the TAU regular mesh will be used to make the mesh.



At the axis direction, the moving region can be classified into several specific regions. If the region has skewed objects, it is called a “regular section,” and the TAU regular mesh is applied. If the region can be geometrically sweeping at the axis direction, the region is called a “sweep region,” and the TAU sweep mesh method is applied.



For the “sweep section,” a surface mesh is generated at the side, then the volume mesh is made by sweeping the surface mesh in the axis direction. This ensures a uniform mesh in the rotational direction, while maintaining the long aspect ratio in the axis direction to keep the mesh size small.



The volume mesh for the rest of the regions is made by the TAU regular mesher.

Band Mapping Angle

Because mesh mapping errors can occur at the interface between the band of motion and the stationary objects when mesh segmentation is performed, the band mapping angle allows these errors to be corrected by making the rotating angle per time step equal to the angle of each mesh segment in the direction of rotation. Thus, the band mesh will match the mesh on the stationary region for each time step. Reducing the mesh mapping error also reduces the noise for the torque calculation and improves simulation accuracy.

The **Band Mapping Angle** setting on the Cylindrical Gap Mesh Operation dialog box, enabled when **Clone Mesh** is selected, supports 3D transient designs for which:

- The band of motion is a true surface.
- The model is not skewed.
- The model is suitable for clone mesh – that is, the model can be segmented into identical sections in the direction of rotation.

The recommended band mapping angle (the angle the rotor rotates in one time step) typically equals the rotational speed multiplied by the time step. For example, if the rotational speed is 1.5 degrees per second and the time step is 2 seconds, then the band mapping angle should be 1.5 x 2 = 3 deg.

The starting position of the simulation should also be considered. In the above example, if the starting position is 0 deg or 3 deg, then 3 deg would be a good band mapping angle. If the starting position is 1.5 deg, the mesh will not be mapped at the starting position, in which case 1.5 deg is the recommended setting.

Another approach for determining the band mapping angle is to start with the model. For example, assume that the stator has 90 slots in the full model, with the solution domain angle equaling 1/6 of the full 360 degree model or 15 slots for 60 mechanical degrees. If you would like to solve with each slot having 8 mesh segments, there would be 120 total mesh segments (15 slots x 8 segments per slot). In this case, the band mapping angle would be 60 (deg) /120 = 0.5 deg. To ensure rotation through one mesh segment per time step, assuming the rotational speed is 1200 rpm, the time step should be set as:

$$Time\ step = \frac{1}{(speed\_rpm/60_{seconds}) \times total\_segment\_number \times (360^{\circ}/domain\_angle^{\circ})}$$

$$Time\ step = \frac{1}{(1200/60) \times 120 \times (360/60)} = \frac{1}{14400}\ seconds$$

[BETA] Maxwell 2D Band Mapping Angle

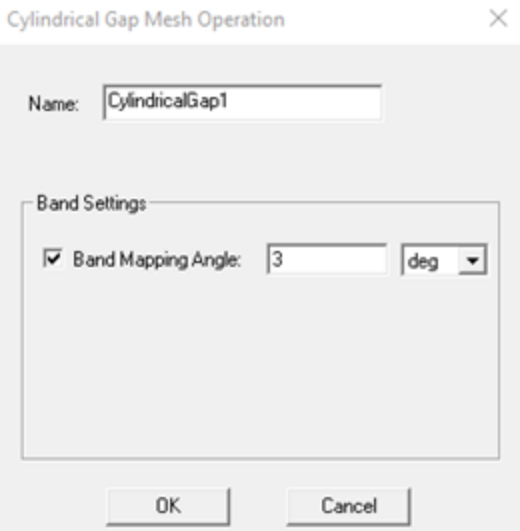
Band Mapping Angle is a new meshing option for transient simulation of motors in Maxwell 2D. When selected, the meshing process will ensure that each mesh segment on the outside of the band (the curve that separates the static and moving regions) has exactly the sweep angle that has been specified by the user. For example, for a quarter model with 90 degrees of matching boundaries, specifying a band mapping angle of 0.5 degree will result in a band outline having 180 mesh segments of equal length.

Because the meshing angle is determined by this setting, the band object must have a curved outline, using zero segments.

To enable this feature, select **Maxwell 2D Band Mapping Angle** from the **Beta Options** dialog, which can be accessed in the Desktop options. Enabling this feature will cause Electronics Desktop to automatically restart.

To use 2D band mapping angle:

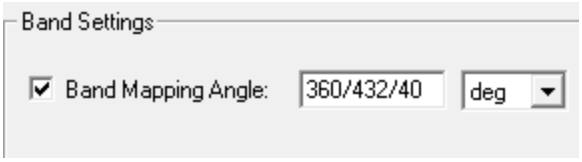
1. When you open a 2D transient project, go to **Project Manager> Mesh>CylindricalGap**, then right-click **Property**; the Cylindrical Gap Mesh Operation dialog box will be shown as:



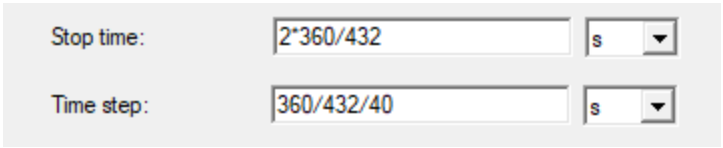
2. Select **Band Mapping Angle**, and set the desired segment angle for the band mesh, then click **OK**.

   > **Tip:** It is best to synchronize the transient simulation time step with the band mapping angle.

   For example, suppose the following mapping angle is used to accurately model the cogging torque:



If the motor's rotational velocity is 1 degree/second, then the following time step should be used:



This practice will help to remove numerical noise in the results.

There are two ways to verify that the band mapping angle has been applied to a simulation:

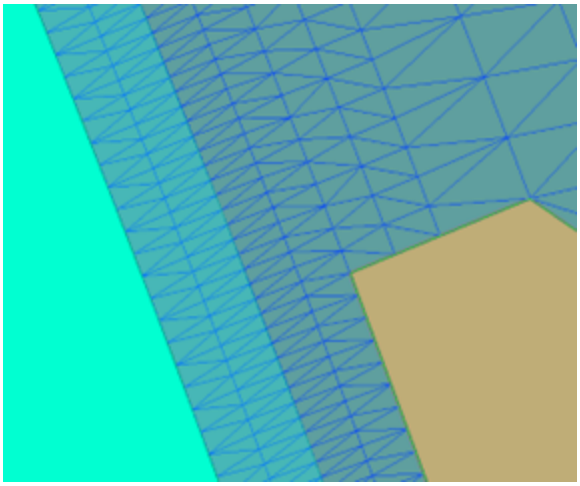
- The specified angle will appear under Initial Meshing, on the Mesh line after "TAU":

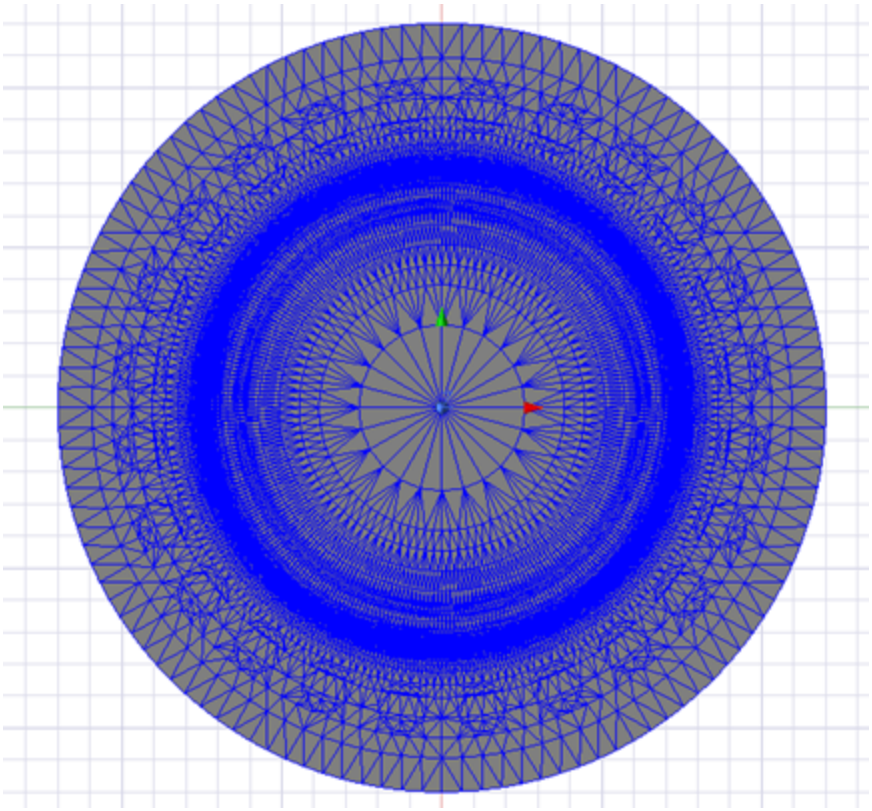
- The effects of the mapping angle will be seen in mesh plots:

  A successful band mapping angle mesh has several features in the mesh:

  - An additional layer will be created on both sides of band.
  - The triangle orientation will be exactly the same on each side of band, to eliminate noise.
  - The layered structure will extend to the moving and static regions.

- Mesh density will smoothly transition from fine to coarse with distance from the band.





Notes

- This feature is intended to replace the use of wire bodies to guide meshing in the band. However, if wire bodies are included, the mesh will respect them along with the band mapping angle.

- Mesh density control is planned for a future release. In the meantime, seed refinement or surface approximation settings can be used to control the mesh density in certain regions.
- Clone meshing is not supported. There may be some asymmetry in the meshing of teeth or slots.
- Eccentricity is not supported.
- This feature is limited to Maxwell 2D transient models with a Cylindrical Gap mesh operation.

Related Topics

Assigning Cylindrical Gap Treatment

Layers in Band Mesh *(Maxwell 3D Magnetostatic and Transient)*

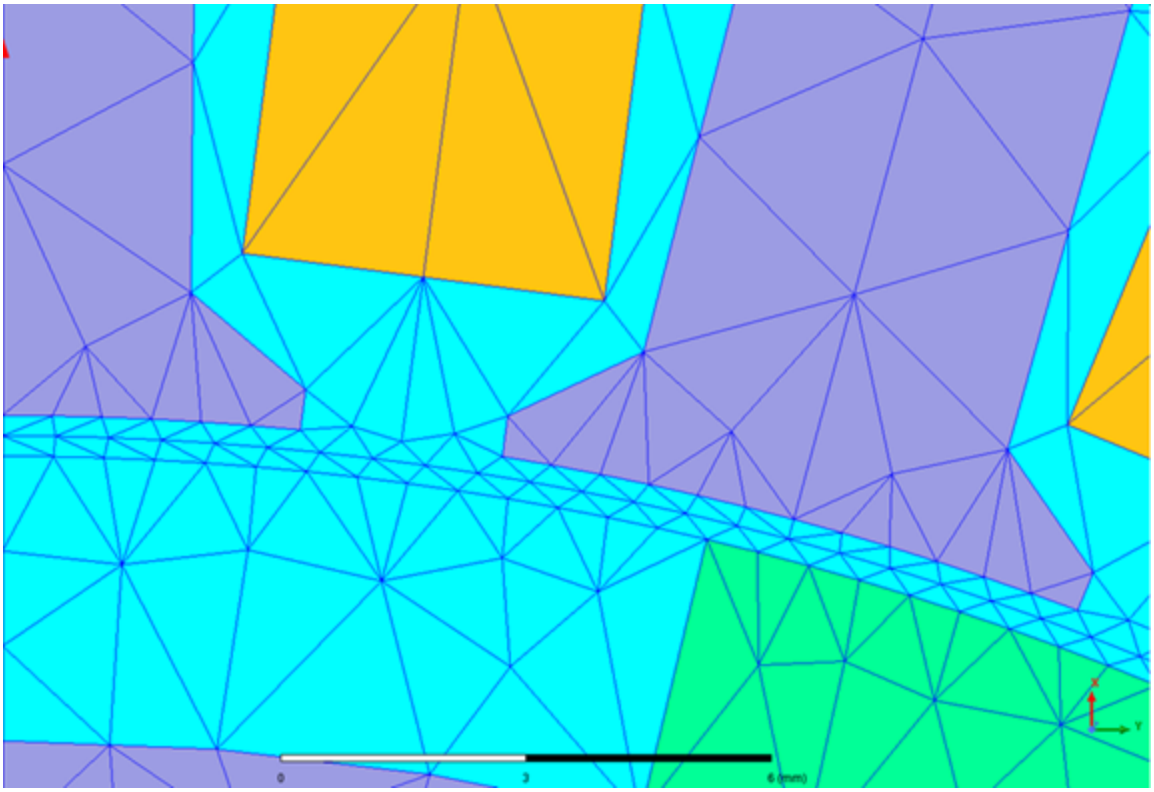
Maxwell rotating machine models need very precise cloned mesh to get accurate estimates of cogging torque. Thus, the mesh near the interface of the static side and moving side, i.e., band surface, is crucial to the accuracy of this simulation result.

Clone mesh is an initial mesh process and currently provides one layer mesh between band and stator and one layer mesh between band and rotor. However, one layer may not provide sufficient accuracy for some designs. For such cases, multiple layers in band for clone mesh can be used to improve accuracy. By assigning this mesh operation, you can control the number of layers near the band on *both* the static and the moving side without losing the repeatability of the clone mesh.

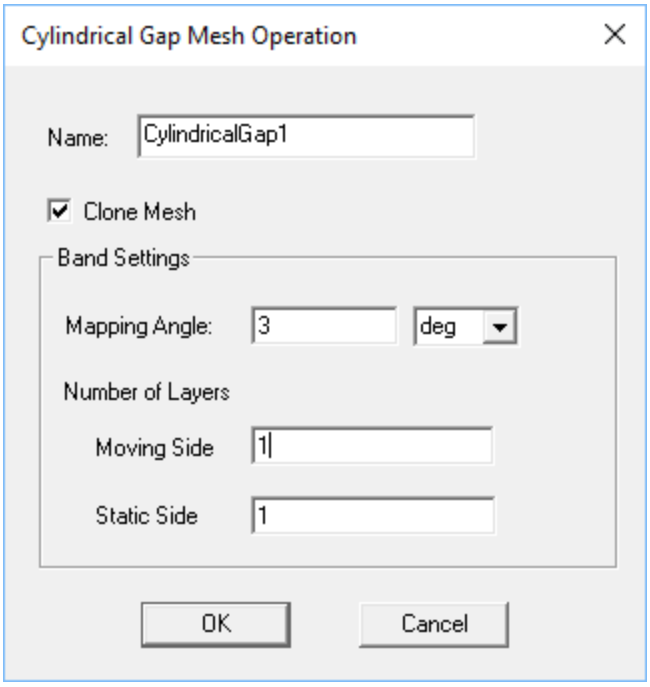
Note	This feature is applicable only to Maxwell 3D magnetostatic and transient solution types.

Example

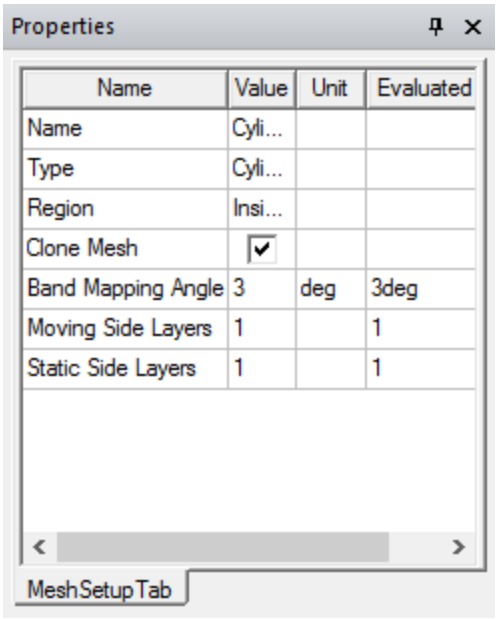
Without multiple layers in the band mesh, when the model is cloned, the static side has clone geometry for which clone mesh is provided. The moving side does not have clone geometry so sweeping mesh is provided for it. This simple mesh type is shown below.



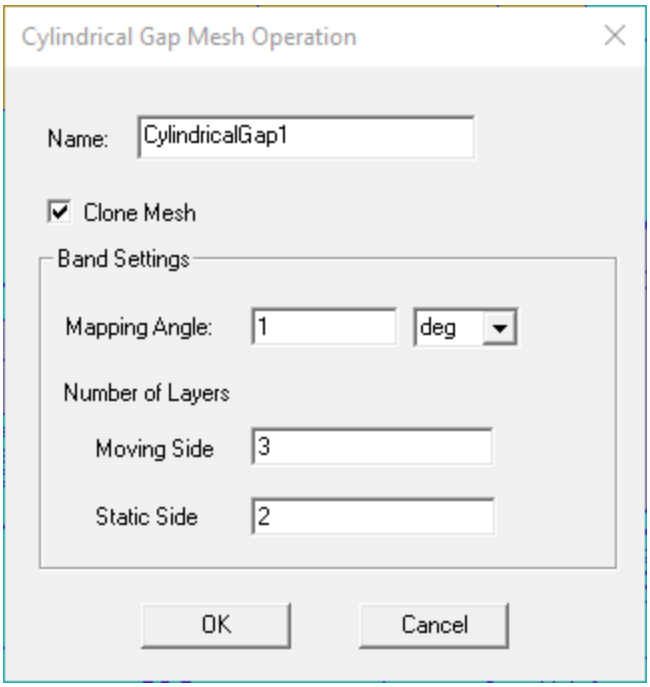
To improve accuracy of results, multiple layers can be specified for a **Clone Mesh** in the **Band Settings** section of the **Cylindrical Gap Mesh Operation** dialog box.

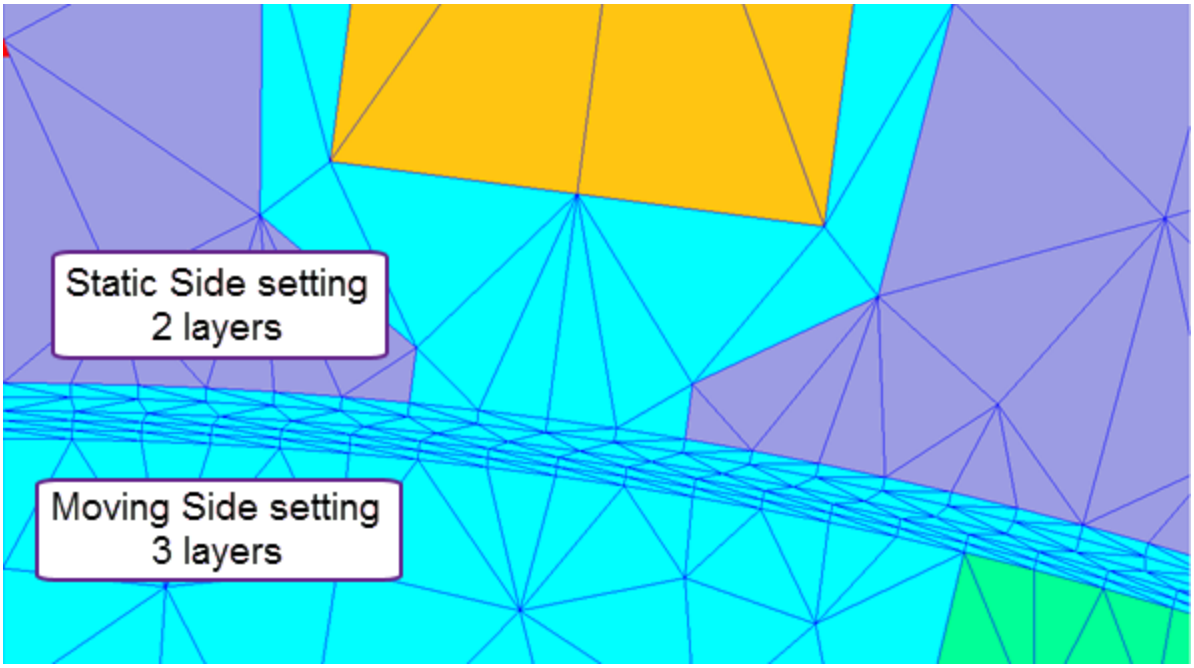


The layers options are also available in the **Properties** window **Mesh Setup Tab** when the cylindrical gap mesh operation is selected in the project tree.



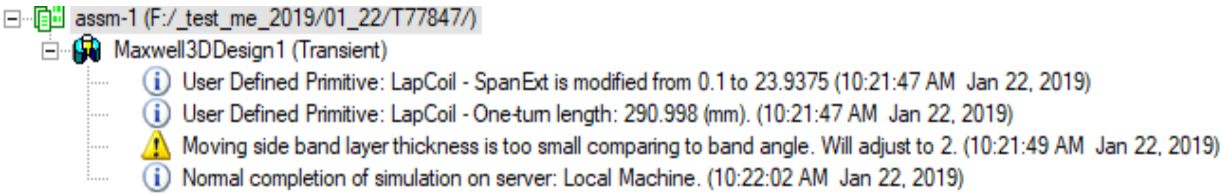
By setting the **Number of Layers** for the **Moving Side** and/or the **Static Side** to integer values greater than 1, the number of band layer meshes will be increased accordingly.





Considerations and Limitations

- If you specified a number of layers that would result in a lowering of mesh quality, clone mesh will adjust the number of layers, and give a warning message similar to the following:



- If the model it not suitable for clone mesh, or if clone mesh fails to mesh it, this setting will not be respected in TAU regular 3D mesh. A warning message will be given by mesh in this situation.
- Post processing seeding refinement will respect the layers in the mesh. Adding any post processing mesh operation will not destroy the layers; however, the clone mesh might be destroyed.

Reassigning a Band of Motion

Clone Mesh Density

For Maxwell 3D rotational transient design, this meshing operation allows you to specify the clone mesh density while keeping the identical mesh in identical sub-regions. Different from Length-Based Mesh Refinement, this Clone Mesh Density mesh operation will only be applied to clone mesh. Only when clone mesh is enabled under cylindrical mesh operation, mesh will respect this mesh operation. Mesh density can be controlled while identical mesh is maintained.

To control the clone mesh density in Maxwell:

1. Select the object.
2. Click **Maxwell>Mesh>Assign Mesh Operation>Inside Selection>Clone Mesh Density**.

   The **Clone Mesh Density** dialog box appears.
3. Type a name for the mesh operation in the **Name** box, or accept the default name.
4. To specify the radial direction density, enable the radial direction option. Type the maximum length of the element size required inside the object(s) in the **Maximum element length** box, and select the units. Maxwell refines the element edges inside the object(s) until they are equal to or less than this value. The default value is set to 10% of the maximum dimension of the bounding box of the model.
5. To specify the axial direction density, enable the axial direction option. Enter the **Number of layers** to be added. Maxwell refines the mesh in axial direction inside the object(s) until the number of mesh layers in the axial direction are equal to or more than this value.
6. Click **OK**. You need to specify mesh density in at least one direction to enable this mesh operation.

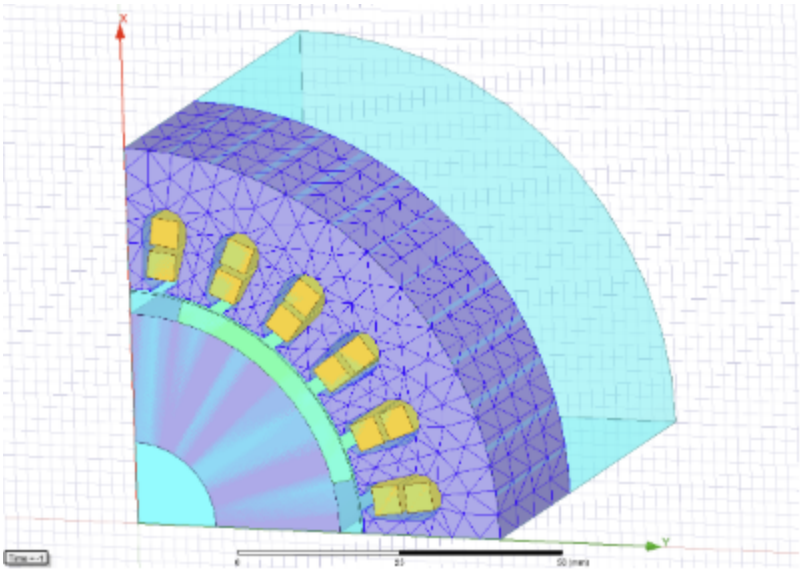
When the clone mesh is generated, the refinement criteria you specified are used. You can specify different maximum length of the element size on different objects. Note that identical density setting should be applied to identical objects to ensure the specified density to be applied on those objects.

You can also specify different axial direction number of layers on different objects. Note that the number of layers in axial direction are maintained separately inside and outside of the band. If objects share a same region in axial direction on the same side of the band, the mesh refinement will refines until the layer thickness equal or smaller than the smallest average layer thickness in this region.

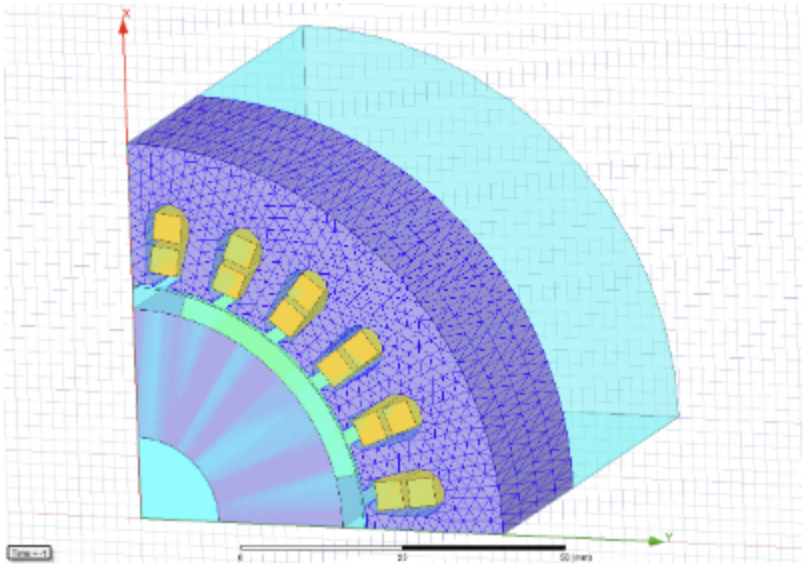
The Clone Mesh Density can not be applied to band object. To control the element size on band, use the **Band Mapping Angle** setting.

Clone Mesh Density can only be respected in clone mesh region. Mesh density in regions that are skewed or not clonable may not be controlled as precise as it is in clone region.

Original clone mesh without Clone Mesh Density mesh operation:



Clone mesh with Clone Mesh Density mesh operation on Stator. Radial direction mesh is refined according to maximum element length specification:



Clone mesh with Clone Mesh Density mesh operation on Stator . Axial direction mesh is refined according to number of layers specification:

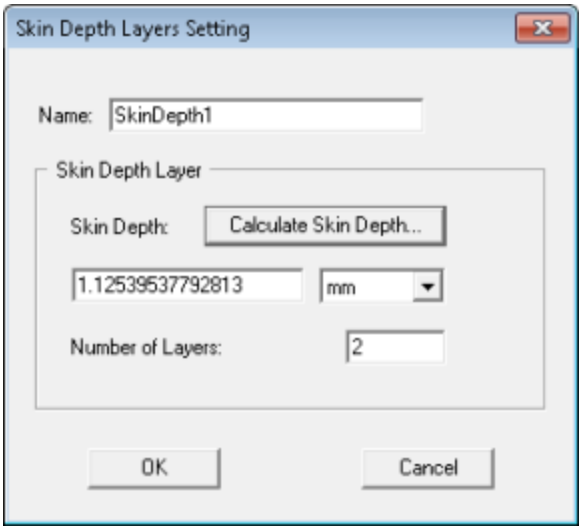
Skin Depth Layers Setting for 2D

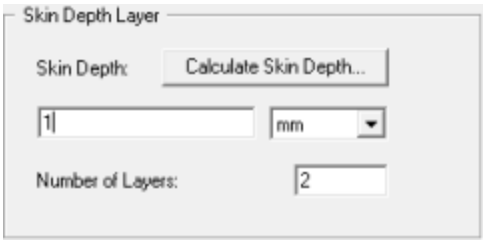
You can apply these settings only to the edges of sheet bodies in Maxwell 2D when the TAU mesher has been selected in the **Initial Mesh Settings** dialog.

Note	Any changes you make using these settings will invalidate the initial mesh, as well as the current mesh and solutions, if any.

1. Select the edge of a sheet body, and click **Maxwell2D>Mesh>Assign Mesh Operation>On Selection>Skin Depth Based...** to open the **Skin Depth Layers Setting** dialog:

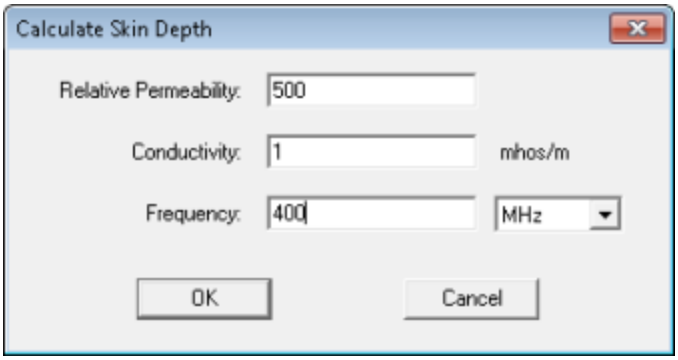


2. Type a name for the mesh operation in the **Name** text box or accept the default name.
3. Type the skin depth within which to refine the mesh in the **Skin Depth** text box.



Alternatively, calculate the skin depth based on the object's material permeability and conductivity and the frequency at which the mesh will be refined:

a. Click **Calculate Skin Depth**.
   The **Calculate Skin Depth** dialog box appears.



b. Enter the material's **Relative Permeability** and **Conductivity**.
c. Specify the **Frequency** at which to refine the mesh.

d. Click **OK**.
Maxwell calculates the skin depth and enters its value in the **Skin Depth** text box.

4. In the **Number of Layers of Elements** text box, type the number of layers to add perpendicular to the object's surface.

Maxwell will add an equivalent number of mesh points to each layer. For example, if Maxwell added 10 points to satisfy the **Surface Triangle Length**, it will add 10 points to each layer.

Note	Caution should be used with this mesh operation, as very thin layers may cause a reduction in mesh quality or unnecessarily cause the generation of a very large mesh. Furthermore, regions refined under this operation and its close neighbors do not participate in solution adaptive refinement. This is another reason to use this seeding operation with caution.

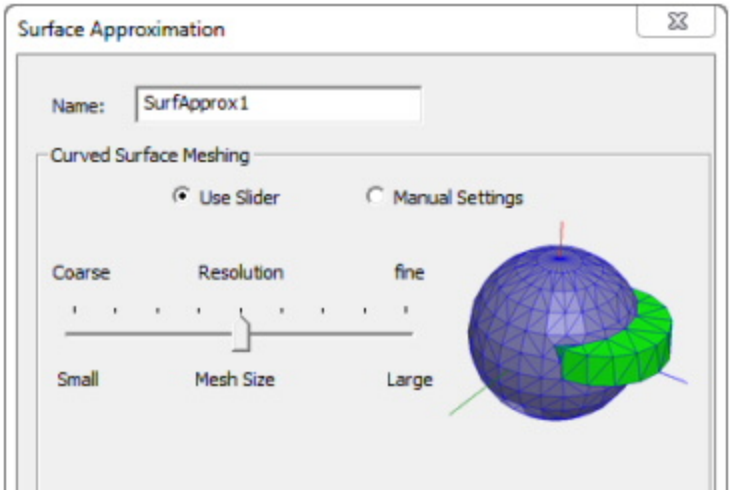
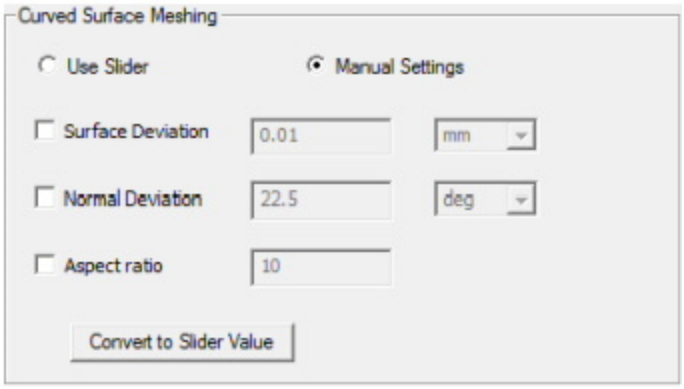
Modifying Surface Approximation Settings

Maxwell applies surface approximation settings when it generates the initial mesh. If you modify Maxwell's default settings after the initial mesh has been generated, they do not affect the mesh for that design variation. Surface approximation is useful, for example, for curved surfaces, for which the mesh will not exactly reproduce the surface shape. It also can be used to restrict the aspect ratio of triangles on planar surfaces.

1. Select the faces for which you want to modify the surface approximation settings.
   - Alternatively, select an object if you want to modify the surface approximation settings of every face on the object.
2. Click **Maxwell>Mesh>Assign Mesh Operation>Surface Approximation**. to open the **Surface Approximation** dialog box.



3. Type a name for the group of settings in the **Name** box, or accept the default name.
4. Under **Curved Surface Meshing**, you can select **Use Slider** or specify **Manual Settings**. The slider includes a visual representation of the resolution you choose, ranging from Coarse Resolution with a Small Mesh Size through a nine position scale to a fine resolution with a Large Mesh Size.
5. If you choose Manual Settings, the dialog changes to show text fields. (If you select **Use dynamic surface resolution** in the Initial Mesh Settings, use of **Manual Settings** is not permitted. You can only use slider bar to specify three levels of surface representation as: coarse (1-3), normal (4-6), and fine (7-9).)



Note	If you select **Use dynamic surface resolution (Beta)** in the Initial Mesh Settings, use of **Manual Settings** is not permitted. You can only use slider bar to specify three levels of surface representation as: coarse (1-3), normal (4-6), and fine (7-9).

6. If you select **Surface Deviation (length)**, type the distance between the true surfaces of the selected faces and the meshed faces in the text box, and select the units.

7. If you select **Normal Deviation (angle)**, type the angular distance between the normal of the true surface and the corresponding mesh surface, and select the units.
8. If you select **Aspect ratio**, type a value in the box. This value determines the shape of the triangles. The higher the value, the thinner the triangles. Values close to 1 result in well-formed, wide triangles.
9. Click **OK**.

   The settings are applied to the initial mesh generated on the selected surface. The group of settings is listed in the project tree under **Mesh**.

You can also specify Initial Mesh Settings to apply to all objects; however, if you apply separate surface approximation mesh operations to specific objects, the object settings take precedence over the general setting.

Note: Checking **Use dynamic surface resolution (Beta)** in the Initial Mesh Settings specifies the best-practice mesh operations over the geometric models. The default mesh operations or user defined mesh operations may or may not be replaced by the optimized mesh operations with model analysis. In general, large curve faces, curve faces with small gaps, or skewed cables get more smooth curvature representation while small curve faces, such as fillets, small curve objects, and so forth, get relatively coarse triangulations so that overall mesh size will be reduced. This dynamic surface resolution mesh operation supports 3D volume mesh and surface mesh in all products.

Technical Notes: The Mesh Generation Process

Surface Approximation

Object surfaces in Maxwell may be planar, cylindrical or conical, toroidal, spherical, or splines. The original model surfaces are called true surfaces. To create a finite element mesh, Maxwell first divides all true surfaces into triangles. These triangulated surfaces are called faceted surfaces because a series of straight line segments represents each curved or planar surface.

For planar surfaces, the triangles lie exactly on the model faces; there is no difference in the location or the normal of the true surface and the meshed surface. When an object's surface is non-planar, the faceted triangle faces lie a small distance from the object's true surface. This distance is called the surface deviation, and it is measured in the model's units. The surface deviation is greater near the triangle centers and less near the triangle vertices.

The normal of a curved surface is different depending on its location, but it is constant for each triangle. (In this context, "normal" is defined as a line perpendicular to the surface.) The angular difference between the normal of the curved surface and the corresponding mesh surface is called the normal deviation and is measured in degrees.

The aspect ratio of triangles used in planar surfaces is based on the ratio of circumscribed radius to the in-radius of the triangle. It is unity for an equilateral triangle and approaches infinity as the triangle becomes thinner.

You can modify the surface deviation, the maximum permitted normal deviation, and the maximum aspect ratio of triangles settings on one or more faces at a time in the **Surface Approximation** dialog box. (Click **Maxwell>Mesh>Assign Mesh Operation>Surface Approximation**.)

The surface approximation settings are applied to the initial mesh.

Note	For the initial mesh, all the vertices of the triangles lie on the true surfaces. During mesh refinement, all the points are first added to the faceted surface for all products, not to the true surfaces. Then, for all Maxwell projects, and for curvilinear meshing enabled HFSS and HFIE projects, the points on the faceted surfaces will be moved to the curved surface locations when such movement does not degrade the quality of the mesh.

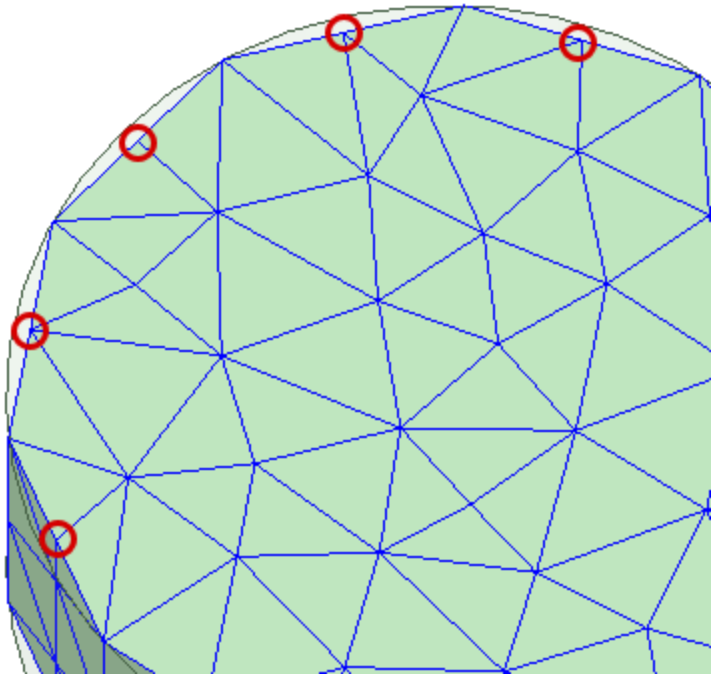
Apply Curvilinear Meshing Command

For **HFSS**, **Maxwell**, and **Mechanical** designs, Curvilinear elements provide an accurate representation of the CAD model geometry by improving the conformity of element nodes to curved CAD surfaces. You can apply curvilinear elements as a Mesh Operation on selected curved model faces see procedure below or as a global option in the Initial Mesh Settings dialog box.

When curvilinear elements are applied globally or to specific CAD faces, the meshing process attempts to pull corner nodes of elements added during mesh refinement to the curved CAD faces. The following figures explain the effects with and without curvilinear elements applied:

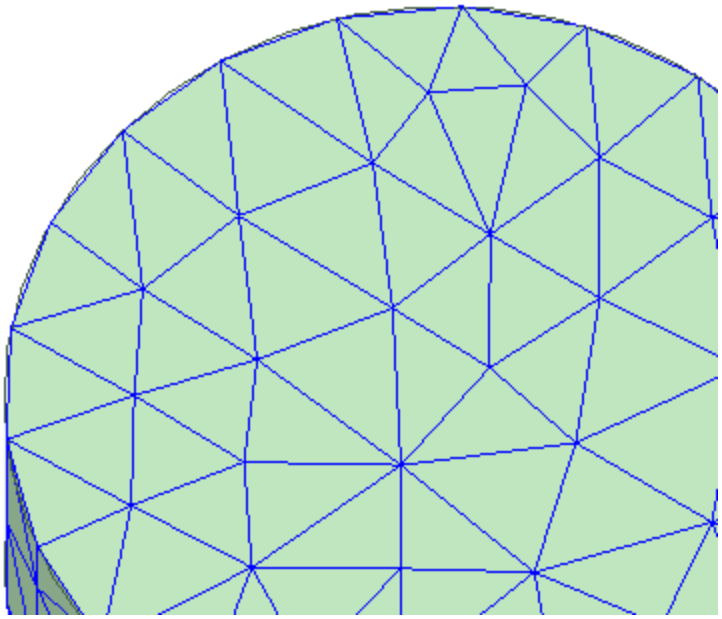
- With the **Apply Curvilinear Elements** option *not* selected:

  Corner nodes of an initial coarse mesh are located on curved CAD surfaces. However, as the mesh is refined, the corner nodes of any additional elements remain along the plane of the intial mesh's element faces. Therefore, the number of facets along a curved face (in the circumferencial direction) does not increase, and the facets remain coarse. This effect is shown in the first mesh plot below. Note the red-circled nodes. These nodes were added as a result of mesh refinement, and they were not pulled to the curved CAD face:



- With the **Apply Curvilinear Elements** option *selected*:

  The meshing process will attempt to pull all corner nodes of additional elements added during mesh refinement to the curved CAD faces. Therefore, the facets along curved faces are finer, and the conformity of the mesh to the curved CAD faces is improved. The effect is as shown in the following, second mesh plot:

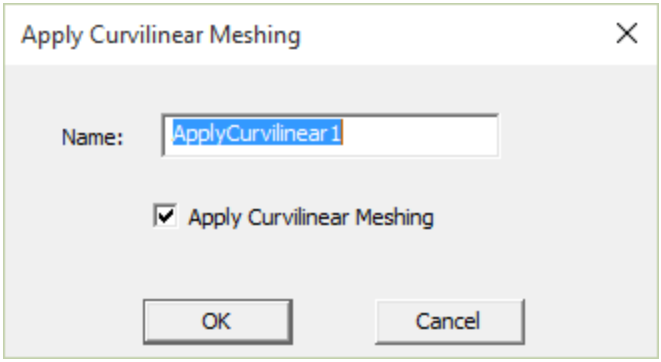


How to Apply Curvilinear Elements to Specific Curved Faces:

You can apply curvilinear meshing as a Mesh operation.

1. Select the object or face to which you want to apply curvilinear meshing.
2. Select **Mesh** in the Project Tree, then right-click for the short cut menu and select **Assign Mesh Operation>Apply Curvilinear Meshing**.

   This displays the **Apply Curvilinear Meshing** dialog.



3. You can accept the default name or provide one of your own.
4. Check the box and click **OK** to apply the curvilinear meshing operation.

Related Topics

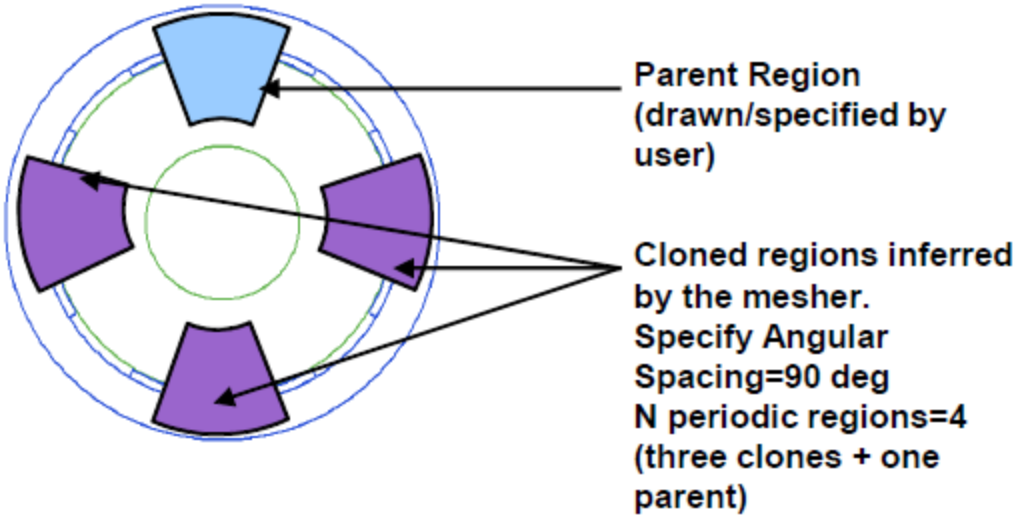
Defining Mesh Operations

Cloning a Mesh

(Cloning a Mesh applies to Maxwell2D Designs only)

The clone mesh operation allows users to use the mesh data from a user-specified parent region of a Maxwell 2D design to apply identical meshes to its cloned regions. In the example shown below, three cloned regions have been generated with an angular spacing of 90 degrees from the user-drawn parent region.

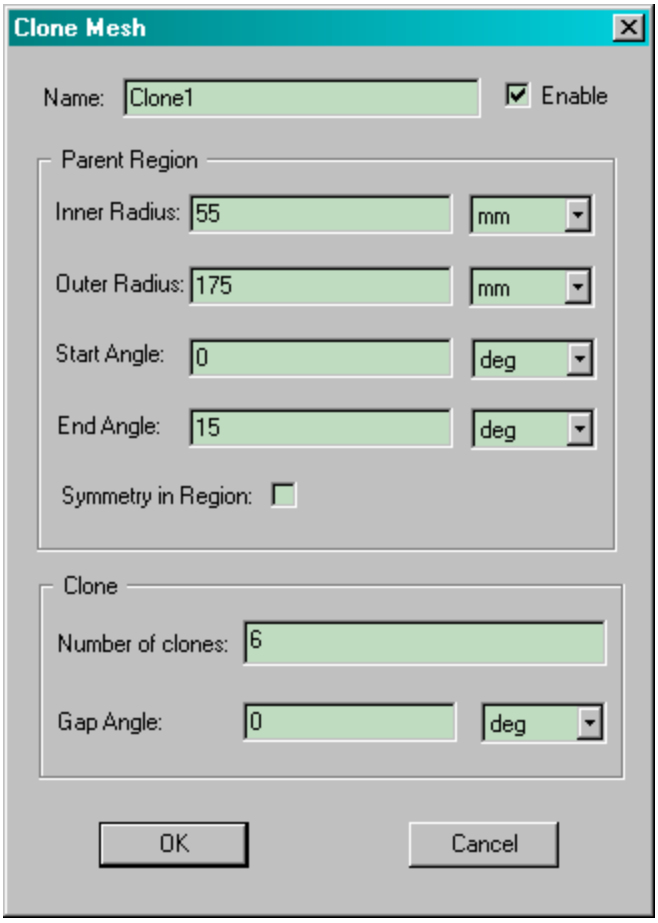
Note	For non-Transient solution types, this operation is applied only on the initial mesh. If you do adaptive refinement, the meshes will no longer match; the operation is not reapplied during adaptive refinement.



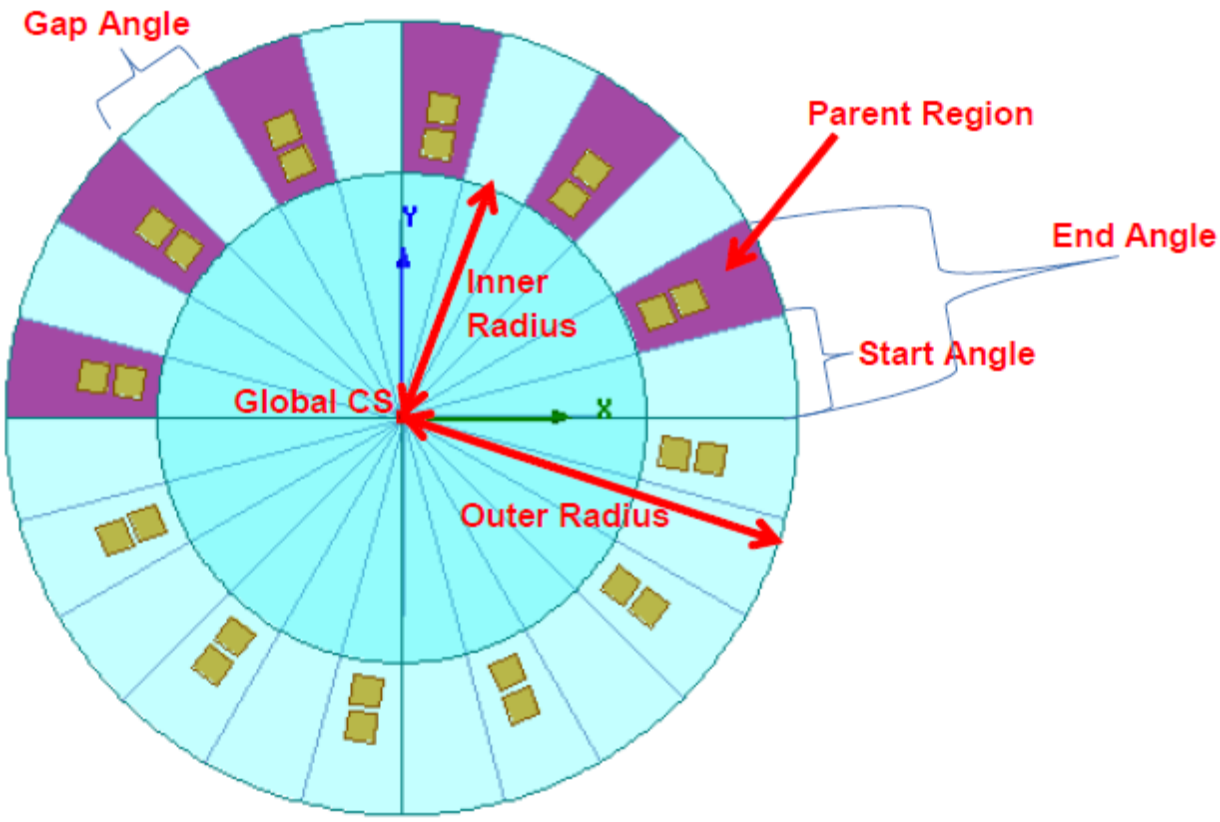
Clone mesh operations are performed after all other mesh operations are done.

Note	To use clone mesh, you must also setup Length-Based Mesh Refinement Inside Objects.

1. To begin a clone mesh operation, select **Maxwell 2D>Mesh>Assign Mesh Operation>Clone Mesh...** to open the **Clone Mesh** dialog box.



2. First set up a **Parent Region**. (Refer to the following figure.)



To set up the parent region, define the following parameters:

- **Inner Radius**
- **Outer Radius**
- **Start Angle** (default=0)
- **End Angle**
- **Symmetry in Region** - treat the region (parent and clone) as symmetric inside the region

3. Specify how to clone the parent region by defining the following parameters:
   - **Gap Angle** (default=0) - angular spacing between clones
   - **Number of clones** - number of periodic regions (including the parent)
4. Like other mesh operations, the user can enter a **Name**, which can be enabled and disabled. Multiple clone mesh operations (with different names) can be created.
5. When finished, click **OK**.
6. To edit the clone mesh setup data, use the dialog or the Properties window.

Modifying the Model Resolution

(Setting Model Resolution applies to Maxwell3D Designs only)

The model resolution parameter is used by the meshmaker to distinguish large features from small features in the model. This setting controls how large a feature must be to be resolved by the meshmaker. For example, if you set the model resolution length to 20 mm, any model features smaller than 20 mm are not represented in the mesh. Neither the model nor the model files are changed. The resolution only controls how the mesh for the model is represented.

While removing small details, if the meshmaker finds that the representation of the model is not accurate enough, it returns an error condition. The meshmaker then starts with the most accurate representation and prunes away the details smaller than the model resolution length. It returns an error if the specified model resolution length forces the final representation to deviate too greatly from the model.

You can set Model Resolution on one or more objects to remove unnecessary details from the mesh representation. This can be used to reduce the mesh complexity of the selected objects.

A cautionary note is needed concerning the use of model resolution. It can sometimes make model faces fail to be represented in the mesh, which can effectively remove some of your boundary conditions. This can only happen if faces are closer together than the model resolution distance you specify.

To modify the model resolution:

1. Select the object or objects on which to specify a Model Resolution operation.
2. Click **Maxwell 3D>Mesh>Assign Mesh Operation>Model Resolution**.

   The **Model Resolution Mesh Operation** dialog box appears.

   Alternatively, you can display the same dialog if you:

   a. Right-click on **Mesh** in the Project Tree to display the shortcut menu.
   b. Click on **Assign Mesh Operation>Model Resolution** on the shortcut menu.

   The **Model Resolution Mesh Operation** dialog contains text fields for the mesh operation Name and radio buttons with choices for the following

   - **Auto Simplify Using Effective Thickness**

     The mesher calculates the resolution length based on each object's effective thickness. One mesh operation can be assigned to many objects, and each will be simplified based on its own dimensions. Use the **Auto Simplify** selection:

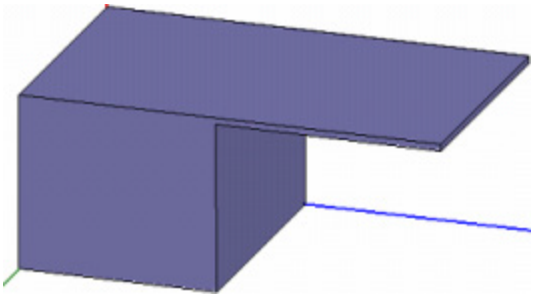
     - To remove many details while retaining an object's overall shape and size
     - For objects of generally uniform thickness
     - To assign one mesh operation to many objects

   - **Use Model Resolution length**

     This enables fields for you to specify the resolution value and units. Use this selection for:

     - Tighter control of mesh accuracy.
     - Objects of non-uniform thickness. For example, the thin section of the object shown

below might be lost with **Auto Simplify**.



3. After defining the operation, click **OK**.

   This adds the named Model Resolution operation under the **Mesh** icon in the Project Tree.

Note	Setting Model Resolution will invalidate any existing solutions. When two objects in contact have different model resolution lengths, the smaller length will apply for the common regions.

Technical Notes: *Model Resolution*

Reverting to the Initial Mesh

The initial mesh is the mesh that is generated the first time a design variation is solved. It includes surface approximation settings but does not include defined mesh operations.

If you have modified the design setup, and do not want to use the existing current mesh, revert to the initial mesh before solving.

To revert to the initial mesh before solving:

- Click **Maxwell>Analysis Setup>Revert to Initial Mesh**.

Reverting to the initial mesh is useful when you want to evaluate how a different solution frequency affects the mesh generated during an adaptive analysis. You lose all solution data for a solve setup and all of its sweeps when you revert to the initial mesh for that setup. You can do this for all solve setups at once by selecting the command through Analysis in the menu system or project tree, or for a specific solve setup via its right mouse click menu in the project tree.

Related Topics

Plotting the Mesh

Technical Notes: The Mesh Generation Process

Generating the Mesh Without Solving

The mesh is automatically created when you run a solution analysis.

If you want to refine the mesh on a face or volume but do not want to generate a solution at the time, you can apply the mesh operations you have assigned without running the full analysis. Applying mesh operations without solving enables you to experiment with mesh refinement in specific problem regions without losing design solutions. You cannot undo the applied mesh operations, but you can discard them by closing the project without saving it.

To refine the mesh without solving, do one of the following after defining mesh operations:

- Click **Maxwell>Analysis Setup>Generate Mesh**.
- In the project tree, under **Analysis**, right-click the desired solution setup, and select **Generate Mesh**.

The same solve machine rules that apply to solving any other setup also apply here. The mesh operation will be sent to the default solve machine, or the Maxwell **Server Setup** dialog may appear to allow you to interactively specify a solve machine if "Prompt for analysis machine when launching analysis" is selected under **Tools>Options>General Options>Analysis Options** tab.

- If a current mesh has been generated, Maxwell refines it using the defined mesh operations.
- If a current mesh has not been generated, Maxwell applies the mesh operations to the initial mesh.
- If an initial mesh has not been generated, Maxwell generates it and applies the mesh operations to the initial mesh.
- If the defined mesh operations have been applied to the selected face or object, the current mesh is not altered.

Hint	Define a new mesh operation rather than modify an existing mesh operation. Maxwell does not re-apply a modified mesh operation.

Note	Mesh operations at the target design of a mu (permeability) link are ignored.

Specifying Initial Mesh Settings

You can specify the initial mesh settings, including the surface approximation and the meshing approach for both Maxwell 3D and Maxwell 2D designs. For most Maxwell 3D designs, you can let the solver automatically choose which of two meshing approaches to take. Maxwell predicts which one gives the best results, balancing mesh reliability, speed, quality, size and design

characteristics. In most cases, Maxwell uses **TAU** mesh, rather than the **Classic** mesh. In general, it looks for specific features (for example, stacks of large planar parallel facets with small gaps) and situations where the initial TAU mesh is four times larger than the Classic. For Maxwell 2D designs **TAU** mesh is the default.

In a few cases, you may decide to override the automatic or default choice and designate the mesher to use. To do so:

1. Select **Maxwell>Mesh>Initial Mesh Settings...** or in the Project tree, right-click on **Mesh**, and select **Initial Mesh Settings** from the shortcut menu. Alternatively, on the **Simulation** tab of the ribbon, select **Mesh Settings**.

   The **Initial Mesh Settings** dialog box appears with the **General** tab selected.

2. In the **Mesh Method** pane:

   For Maxwell 3D, you can select:

   - **Auto** (the default) – the solver automatically selects the mesher. In most cases, this will be **TAU**
   - **TAU** – only specific curve faces will be remeshe (for example, equation-based axisymmetric faces). If a curve face has connection to other non-remeshed curve faces, this curve face will not be remeshed. If the curve faces cannot be remeshed, faceting triangles will be used as the surface mesh. Mesh quality depends on how the faceting triangles are made. If the surface mesh is generated by TAU, this shows in the profile as Mesh TAU (Surface). If you check **Use alternative mesh methods as fall back** on the **Advanced** tab, this can fall back to Mesh TAU(Wrapper). This, in turn, can fall back to Mesh (stitch), which is classic.
   - **Classic** – this is based on the version 11 mesher. This setting must be used if you wish to use the Phi Mesher, for which you must also check **Allow Phi for layered geometry (Classic only)** on the **Advanced** tab.

   For Maxwell 2D, you can select:

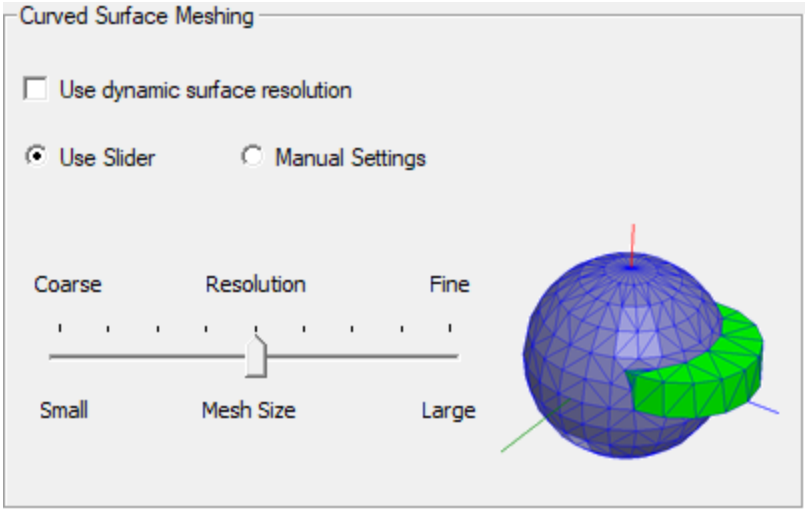
   - **TAU** (the default).
   - **Classic** – this is based on the version 11 mesher.

3. For Maxwell 3D only, you can also uncheck or check **Apply curvilinear meshing to all curved surfaces**. For models with curved surfaces, checking this increases accuracy, though it costs more memory.

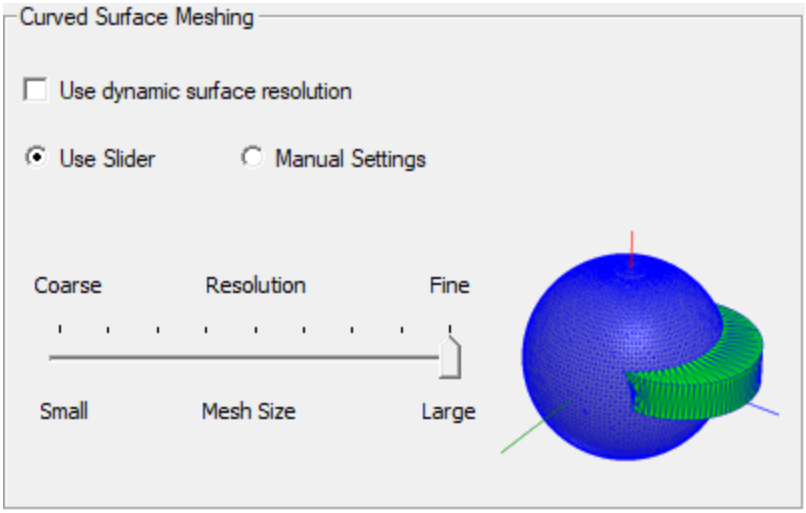
4. Under **Curved Surface Meshing**, you can chose to **Use dynamic surface resolution**, select **Use Slider** or specify **Manual Settings**.

   The slider includes a visual representation of the resolution you choose as ranging from **Coarse** Resolution with a **Small Mesh Size** through a nine position scale to a **Fine** Resolution with a **Large** mesh size.

   For example moving the slider to the left changes the figure as follows:

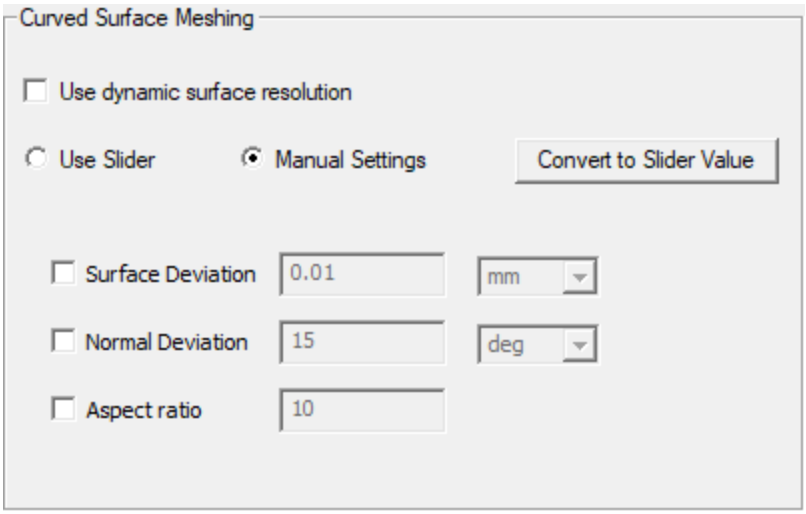


Moving the slider to the right changes the figure as follows:



5. Selecting **Use dynamic surface resolution** in the **Curved Surface Meshing** panel specifies the best-practice mesh operations over the geometric models. This mesh operation will support 3D volume mesh and surface mesh in all products. The default mesh operations or user defined mesh operations may or may not be replaced by the optimized mesh operations with model analysis. In general, large curve faces, curve faces with small gaps, or skewed cables get more smooth curvature representation while small curve faces, such as fillets, small curve objects, and so forth, get relatively coarse triangulations so that overall mesh size will be reduced.
   If you select dynamic surface resolution, you can optionally use the slider bar to adjust surface representation levels as: coarse (1-3), normal (4-6), and fine (7-9). You can also adjust the surface representation level for a specific group of faces by specifying slider bar, as described in Modifying Surface Approximation Settings.

6. If you choose **Manual Settings**, the dialog changes to show text fields.



Use the check boxes to enable the desired fields.

- For **Surface Deviation**, enter the distance between the true surfaces of the selected faces and the meshed faces in the text box.
- For **Normal Deviation**, enter the angular distance between the normal of the true surface and the corresponding mesh surface in the text box. Maxwell 3D's default normal deviation setting for the selected faces is 15 degrees. Maxwell 2D's default normal deviation setting is 3 degrees.
- For **Aspect ratio**, enter a value in the text box. This value determines the shape of the triangles. The higher the value, the thinner the triangles. Values close to 1 will result in well-formed, wide triangles. Maxwell's default aspect ratio settings for the selected faces are 10 for curved surfaces and 200 for planar surfaces.

The **Convert to Slider** button converts the manually entered values to an equivalent slider setting, and returns the panel to the slider view.

7. To make your choices the default, use the **Save as default** check box.
8. The **Advanced** tab lets you specify a **Set Length** for **Model Resolution**.

This setting is for experienced users who have a good understanding of how particular values will affect their models. In general, the **Auto** setting provides good results.

9. For Maxwell 3D models only, selecting the **Use Flex meshing for TAU volume mesh** feature enables a version of the TAU mesher that will rarely fail to generate a mesh. In most cases, the TAU Flex mesh is as accurate as traditional TAU or Classic meshes. However, for some complex models with bad translation or poorly defined surfaces that would fail to produce a strict mesh on all objects, relaxed tolerances will be applied. In these cases the user should review the mesh to evaluate whether it is acceptable for simulation. See *TAU Flex Meshing* for more details.

Note	TAU Flex meshing does not support RMxprt models.

10. **Use legacy faceter for TAU volume mesh** (both 2D and 3D models): By default, TAU uses the latest faceter to generate geometric model for meshing. Occasionally, the mesher may fail, and TAU will automatically fall back to use the legacy faceter to make a second attempt. In such cases, directly using the legacy faceter can get the mesh in the first attempt so total meshing time will be saved. The legacy faceter is not actively maintained by Spatial and will be retired soon. This option should be used only as a last resort.
11. For Maxwell 3D models only, selecting **Use alternative mesh methods as fall back** enables the **TAU** and **Classic** mesh methods (chosen on the **General** tab) to fall back to alternative mesh methods if the solver fails to generate the initial mesh.

    You can also select **Allow Phi for layered geometry (Classic only)**, which enables the **Classic** mesh method (chosen on the **General** tab) to use the Phi mesher for layered geometry.

    For example, the the sequence of mesher methods might go like this: When the mesh method is **TAU**: TAU(>Phi)>Classic. When mesh method is **Classic**: Classic(>Phi)>TAU. Note: the options do not affect the Auto mesh setups.
12. Click **OK** to apply your choices.

The settings will be applied to the initial mesh generated.

Defining Mesh Operations

TAU 2D Mesh Generation

TAU Flex Meshing

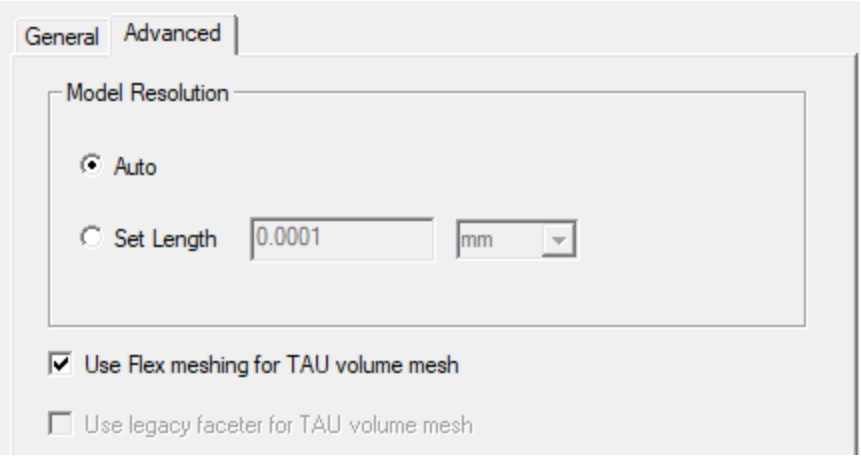
TAU Flex Meshing

TAU Flex is designed for guaranteed mesh success, and may also reduce meshing time. It provides a mesh even for complex and “dirty” geometry model without any preliminary geometric healing or repair.

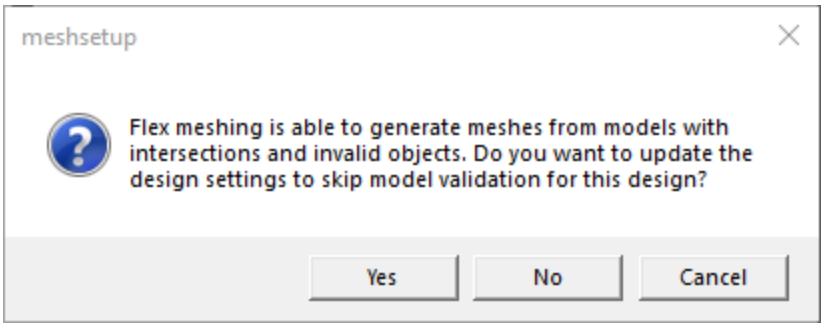
TAU Flex is a multi-domain, priority mesher which provides more efficient and reliable meshing. The priority mesh generation is driven by solver requirements for materials (metal/non-metal), boundary conditions (ports, radiation etc.), conduction paths, and so forth. The constraint tolerant meshing method gives the TAU Flex mesher flexibility to excuse mesh difficulties in lower-priority regions so that the resulting mesh can still provide acceptable simulation results.

Steps for Using TAU Flex

1. Navigate to the **Initial Mesh Settings** window.
2. Click the **Advanced** tab and select **Use Flex meshing for TAU volume mesh**.

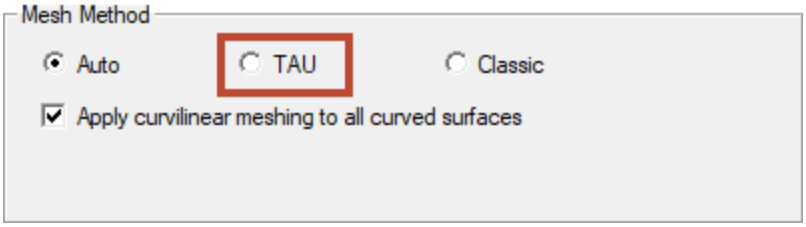


Selecting this option opens a dialogue. Click **Yes** to continue.



To get the full benefits of TAU Flex, especially for complex or “dirty” models, follow these recommended steps:

1. On the **General** tab of the **Initial Mesh Settings** dialog box, select **TAU**.



2. Click [*solver*]>**Design Settings** to open the **Design Settings** dialog.

   Check **Enable material override** in the **Set Material Override** tab to activate TAU's priority meshing method based on metal/non-metal materials.

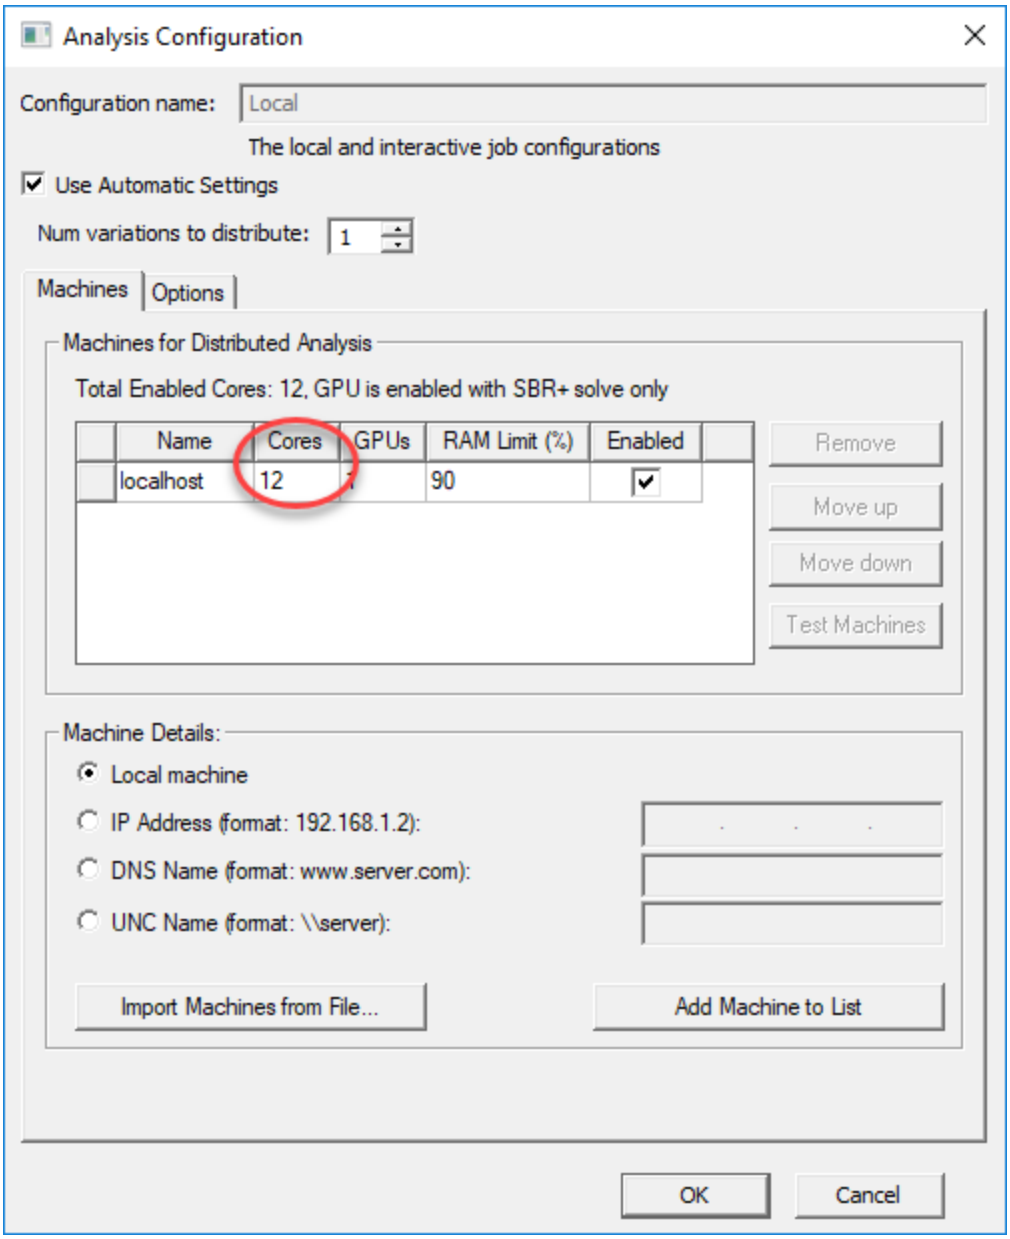
4. Select the **Validations** tab of the **Design Settings** dialog and select **Perform minimal validations**.

   This reduces pre-processing time for complex models, and allow simulation of "dirty" geometry for which TAU Flex can provide a mesh.

5. Because TAU Flex is a parallel mesher for many processes, you should specify multiple cores in **HPC and Analysis Options** to speed up the meshing process.Access the Analysis Configuration window one of two ways:

- Select the Simulation tab on the ribbon and click **Analysis Config**.
- Use **Tools** > **Options** > **HPC and Analysis Options** or select the **Simulation** tab on the ribbon and click **HPC Options**. Then double-click a configuration.

The **Analysis Configuration** window appears.



Specify the number of cores to use.

7. In most cases, TAU Flex can provide mesh as accurate as TAU or Classic, though not always. Therefore, we recommend that you **Generate Mesh** without solving; and that you review the mesh before proceeding with the simulation.

TAU Flex Warning Messages

In cases where TAU Flex has difficulty making a strict mesh on some objects, mesh warnings are given for those objects. You should review the mesh on those objects before proceeding to the simulation. You can exercise discretion in deciding whether a given mesh issue needs to be addressed (for example, critical antenna geometry) or can be ignored (for example, a small “leak” in a dielectric substrate far from the source).

There are three types of warnings, in decreasing order of severity: “Mesh Leak”, “Major Mesh Repair”, or “Minor Mesh Repair”.

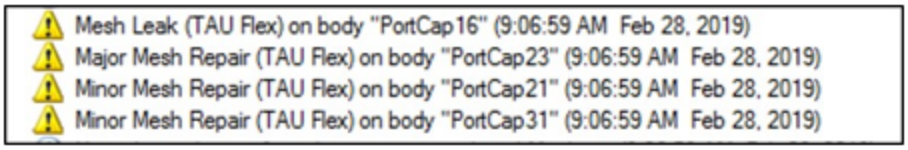
- **"Mesh Leak"** – *The most severe warning*. A body does not have any mesh element, or it has mesh elements with a significant mismatch of surface area between the mesh and geometry – larger than 10% of planar area, or 20% of curved area.
- **"Major Mesh Repair"** – A body has major surface area mismatch between the mesh and geometry – larger than 5% of planar area, or 10% of curved area.
- **"Minor Mesh Repair"** – *The least severe warning*. A body has minor surface area mismatch between the mesh and geometry – less than 5% for planar area, or 10% for curved area.

Reviewing TAU Flex Mesh Warnings

TAU offers three ways for you to view mesh warnings:

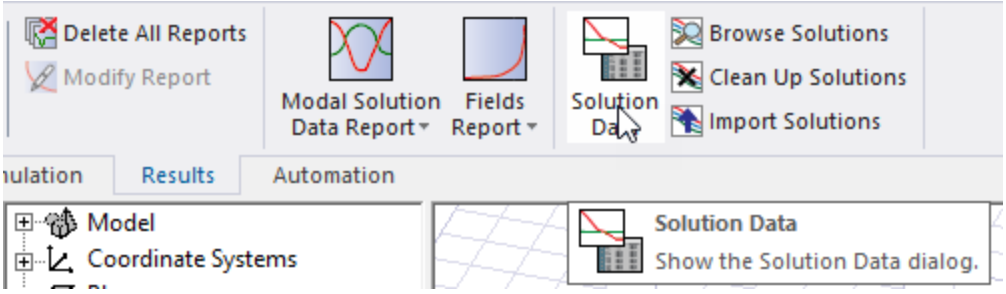
1. **Message Manager**:

   Immediately after the mesh generation is done, if a tolerant mesh is given, warnings will be displayed in the Message Manager of the Desktop. If the window is hidden, click **Show Messages**.

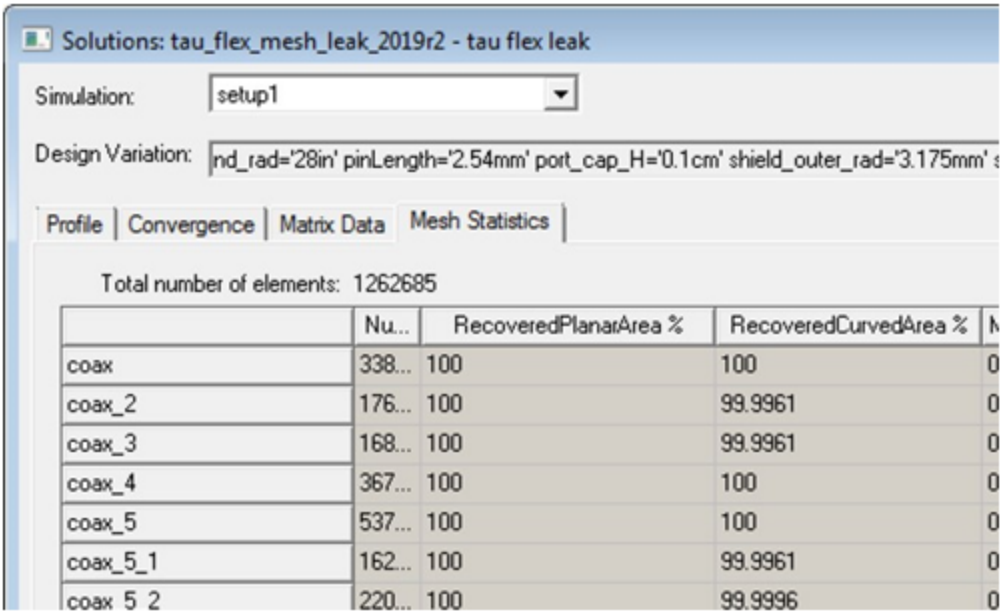


2. **Mesh Statistics**

   Use the **Solutions Data** icon in the **Simulation** tab of the ribbon to open a **Solutions** dialog box.

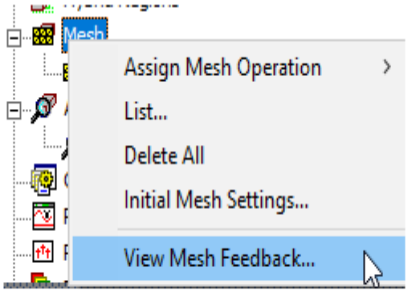


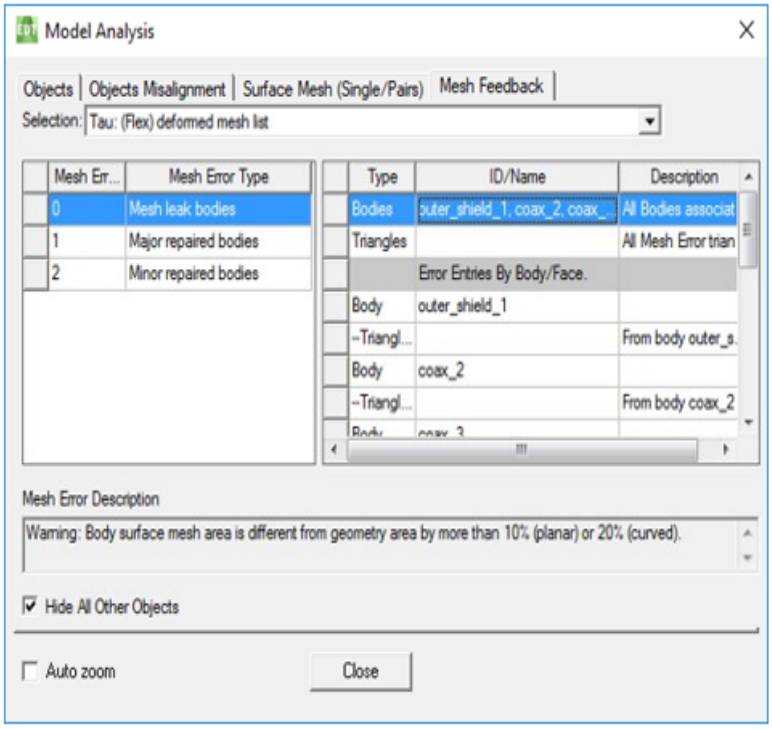
In the **Mesh Statistics** tab of the **Solutions** dialog box, if a tolerant mesh is generated, the surface area difference between the mesh and geometric model at body level is listed as “RecoveredPlanarArea” and “RecoveredCurveArea”. 100% means that the body has a strict mesh. You can click the surface area tab to sort the body list and see the tolerant mesh bodies first.



3. **Model Analysis dialog**, **Mesh Feedback** tab

   To view the details of the tolerant mesh, click **Modeler>Model Analysis>Show Analysis Dialog>View Mesh Feedback** to launch the **Model Analysis** dialog box.





Click on the top list to display objects that have tolerant mesh.

Click on the “Triangles” to display the mesh on the tolerant objects.

Individual objects will be listed under “Error Entities By Body/Face”. You can select one or multiple bodies to view the mesh at a more detailed level.

Addressing TAU Flex Mesh Issues

In cases where TAU Flex has difficulty making a strict mesh on some objects you can address the problem by using one of the following techniques:

1. Redraw the geometry in question in the native modeler
2. Heal the geometry either with the integrated healers in Maxwell or perhaps in SpaceClaim
3. If the objects has curved or true surfaces consider applying a localized surface mesh operation which creates a finer than default mesh.
4. Remove difficult objects that are not critical to the simulation.

Generating the Mesh without Solving

Mesh Feedback Tab

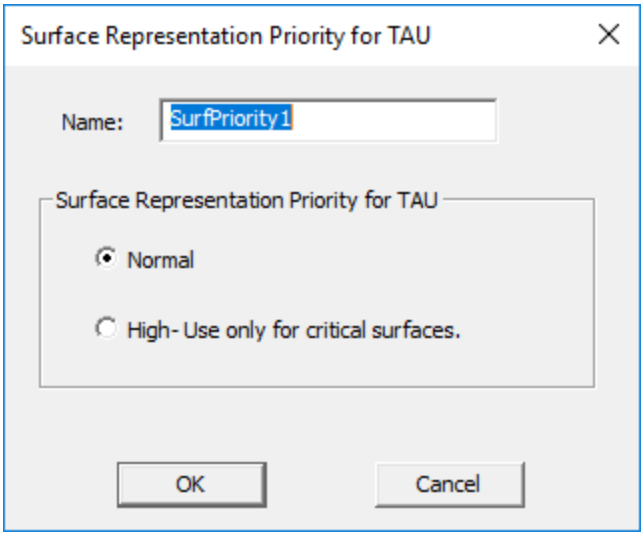
Specifying Surface Priority for TAU Mesher

You can choose to specify the surface representation priority for the TAU mesher. For most designs, you can let the solver automatically choose which of two meshing approaches to take. The solver predicts which one gives the best results, balancing mesh reliability, speed, quality, size and design characteristics. In most cases, the solver uses TAU mesh, rather than the classic mesh. In general, it looks for specific features (for example, stacks of large planar parallel facets with small gaps) and situations where the initial TAU mesh is 4 times larger than the Classic. Experienced users may choose to designate a high surface representation priority for the critical surfaces with the TAU mesh is used.

> **Important:**
>
> Use this mesh operation with caution. Use this option only if the model has tiny elements or critical boundary conditions since the solver performs several additional strict mesh verification steps on the selected objects.

1. Select the surface of interest.
2. If desired, specify a Name for the Mesh operation.
3. Right-click the **Mesh** icon in the Project tree to view the shortcut menu and select **Assign Mesh Operation** > **Surface Priority for Tau**.

   The **Surface Representation Priority for Tau** dialog box appears.



4. Select **High** for the critical surface.
5. Click **OK**.

   The Mesh operation appears in the Project Manager.

TAU 2D Mesh Generation

The Maxwell TAU (Triangular Adaptive Uniform) 2D mesher provides a fully-automated initial mesh generation method that creates a uniform, high quality, solver-driven mesh. It is designed for solvers without adaptive passes, or demanding high quality mesh. Several meshing methods are used by the TAU 2D mesher, such as skin depth layer mesh, clone mesh, rotational sweep mesh, and remeshing.

To benefit from these meshing technologies for Maxwell 2D designs, ensure that **TAU** is selected as the **Mesh Method** on the **Initial Mesh Settings** dialog **General** tab by right-clicking the Mesh icon in the Project Manager and selecting **Mesh>Initial Mesh Setting**, or by selecting **Maxwell>Mesh>Initial Mesh Settings...**. Note that **TAU** mesh is the default setting for new 2D designs.

When TAU 2D mesh is selected, its meshing methods are applied to specific local regions. The local regional meshes are then assembled as the final step for the simulation.

The following sections describe TAU 2D mesh generation methods for rotational models, for non-rotational models; and the Skin Depth Layer Mesh Generation method, which can be applied to any model.

TAU 2D Mesh Generation for Rotational Models

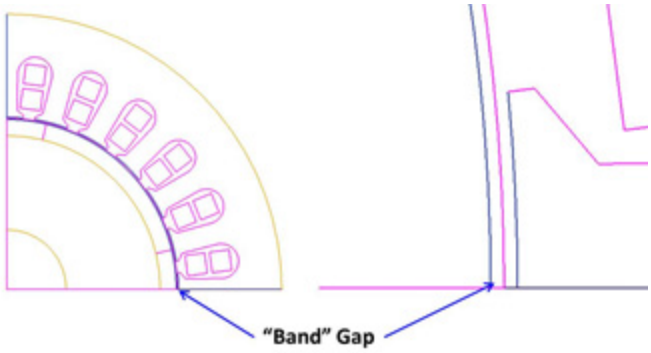
If the mesher determines that a model is a rotational model, rotational mesh generation is used, in which the clone mesh and rotational sweep mesh methods described below are used.

To determine if the model is a rotational model, the curves around the origin are calculated. The smallest rotational gap is defined as the “Band” gap. The model shown below is an example of a rotational transient model.



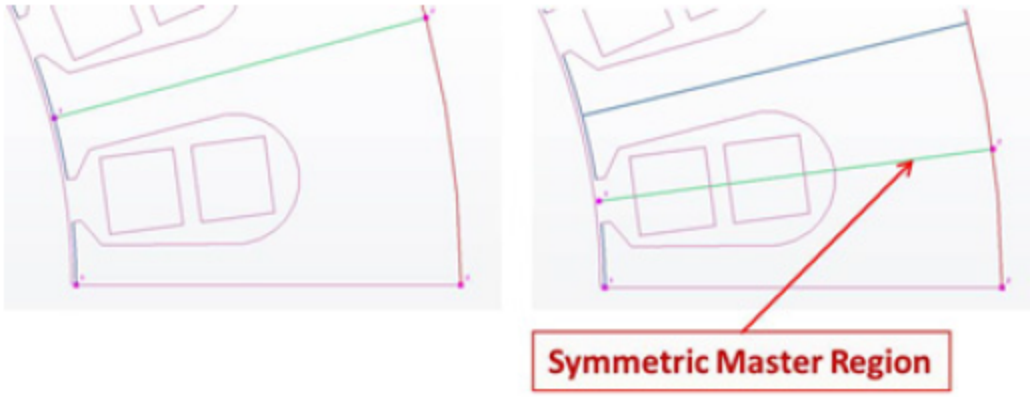
Two major regions: a static region and a moving region are classified by the Band gap.

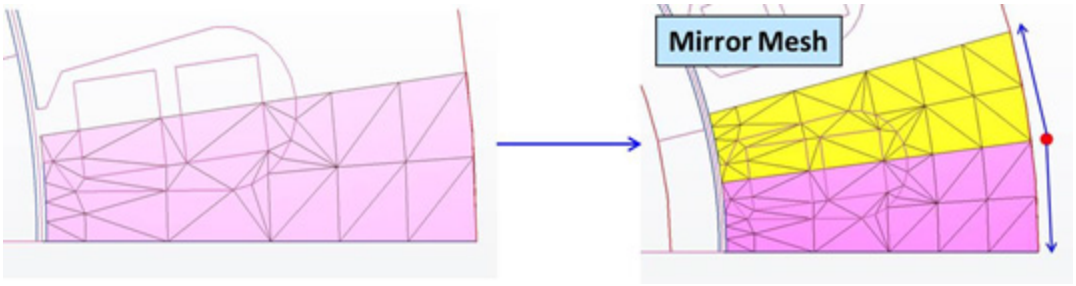
TAU 2D Clone Mesh Generation

Note	To use clone mesh, you must also setup Length-Based Mesh Refinement Inside Objects.

The static geometric model in the local rotational region is analyzed to determine whether it has multiple duplicate sub-regions. If a model has duplicate sub-regions, the TAU clone meshing is automatically activated to generate the mesh so that each sub-region has the topologically identical mesh. The following example shows a static clone region with six identical sub-regions - a master and clone regions.

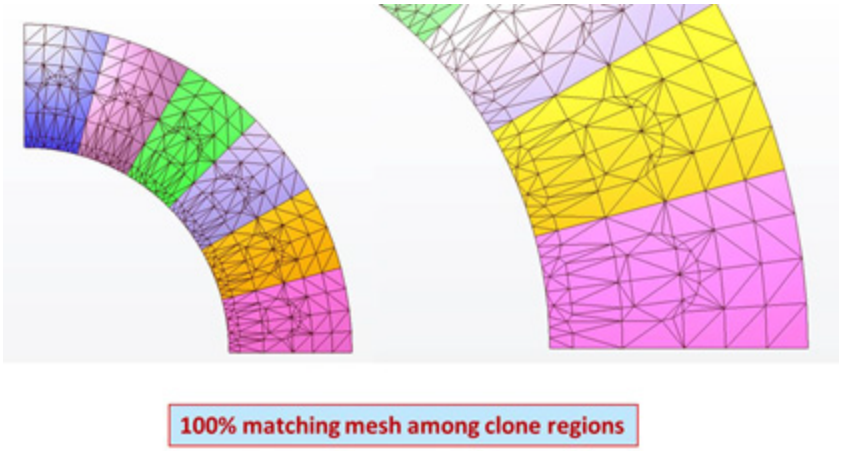
In the Clone region, the Master region is calculated and analyzed. If the Master region has the symmetric feature, the symmetric mesh is generated.



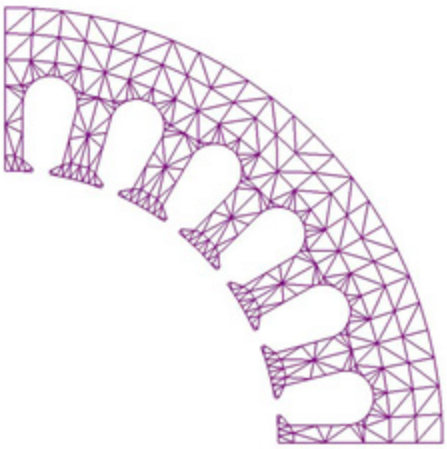


As shown above, a uniform mesh will be generated in one half of the Master region first, then the mesh is mirrored about the symmetric central line to generate the symmetric mesh in the Master region.

Because all the child regions have identical geometric features, the mesher uses copy-paste to replicate the Master mesh at each of the child regions, rotating it to the appropriate angles.



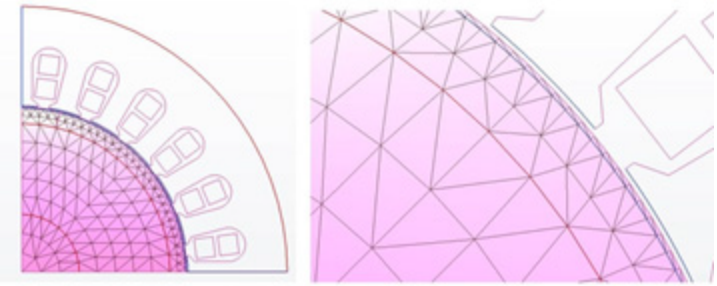
This ensures the identical mesh in the different regions, especially for the teeth.



TAU 2D Rotational Sweep Mesh Generation

If the local region does *not* have identical geometric sub-regions and thus the clone mesh is *not* generated, then geometric analysis is performed to verify whether the region is rotational.

Around the rotational center, if a region has two or more rotational curves, this region can be defined as a “rotational” region. In this case, “Rotational sweep” mesh generation is used proceeding in the radial direction with layers while using uniform sweep elements in the rotational direction. This meshing method controls the aspect ratio in the radial direction, while maintaining the uniform sweep in the rotational direction.



Rotational Sweeping Mesh

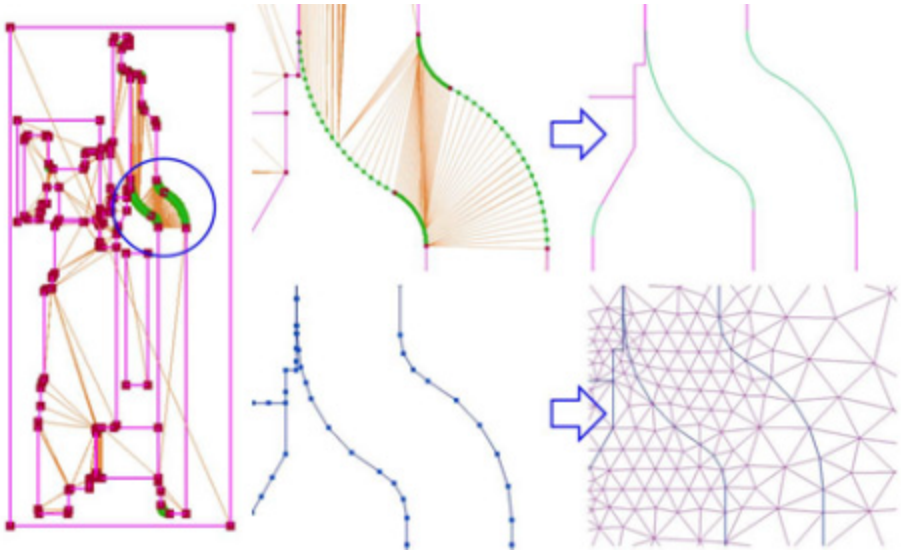
TAU 2D Regular Mesh Generation (Non-Rotational Models)

TAU 2D Skin Depth Layer Mesh Generation

TAU 2D Mesh Assembly

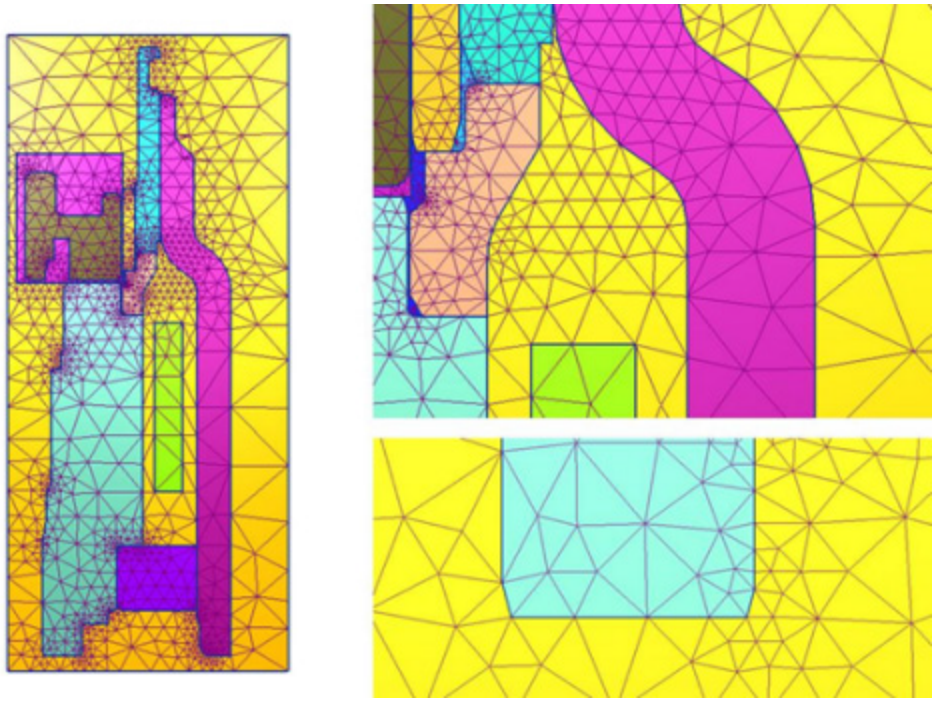
TAU 2D Regular Mesh Generation (Non-Rotational Models)

If the model is not identified as a rotational model, the TAU 2D regular mesher is used to generate the mesh. TAU 2D mesher does not use Parasolid union as the Classic mesher does. Instead it reads the objects individually as-is. Remesh technology is used to get the best representation of the curves with minimum mesh points.



The TAU 2D regular mesher uses a top down meshing algorithm that starts the mesh from a uniform base mesh, then adapts the mesh in the necessary regions, and does the boundary recovery later. Mesh quality is controlled and maintained during the entire meshing process. To

maintain a uniform mesh, 1:2 splitting method is used for the transitions from small elements to large elements.



In most cases, users do not need to add any additional seed refinement mesh operations. The mesh can be directly used to do the transient simulation. For solvers with adaptive passes, a few passes can be saved for the convergence although the initial mesh is larger since it is high quality and uniform.

TAU 2D Skin Depth Layer Mesh Generation

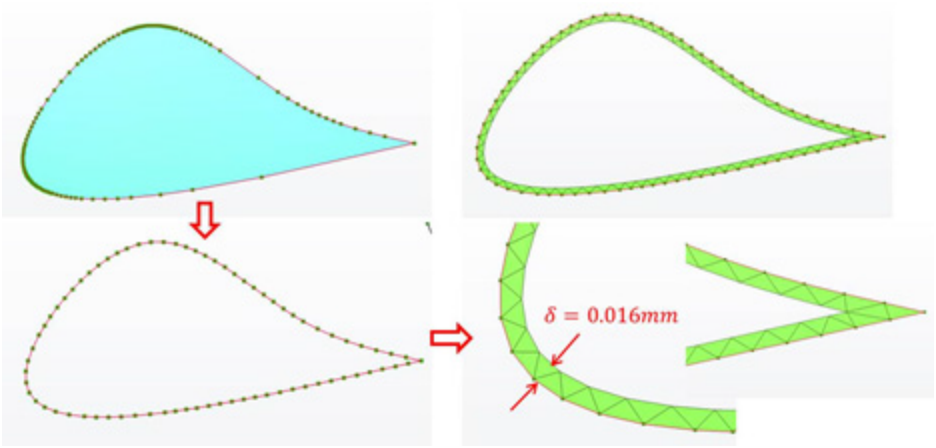
TAU 2D Mesh Assembly

TAU 2D Skin Depth Layer Mesh Generation

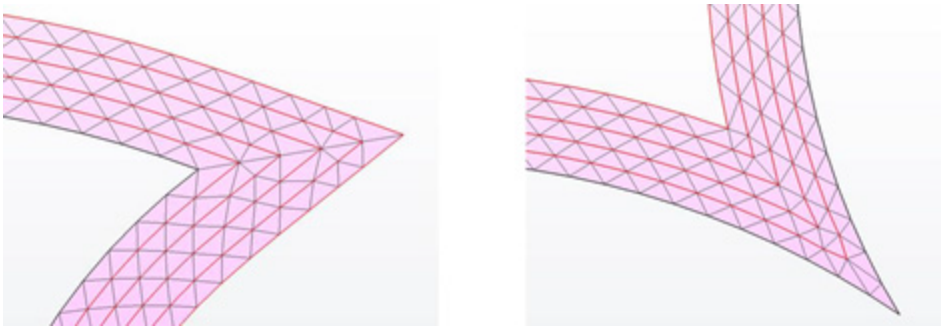
For this mesh generation method, the number of layers and the thickness can be specified by selecting one or more body edges. They will be exactly respected in the TAU mesh unless the layer thickness is too large, or layers from other directions overlap, intersect, or leave a narrow gap.

The layer mesh starts from the specified edges, and advances toward the direction of the body region layer-by-layer. If two bodies contact each other, the edges from these two bodies at the contact region may coincide, *appearing* as one edge even though there actually are two or more edges. Therefore, please be careful when picking the edges in multiple body contact regions. In

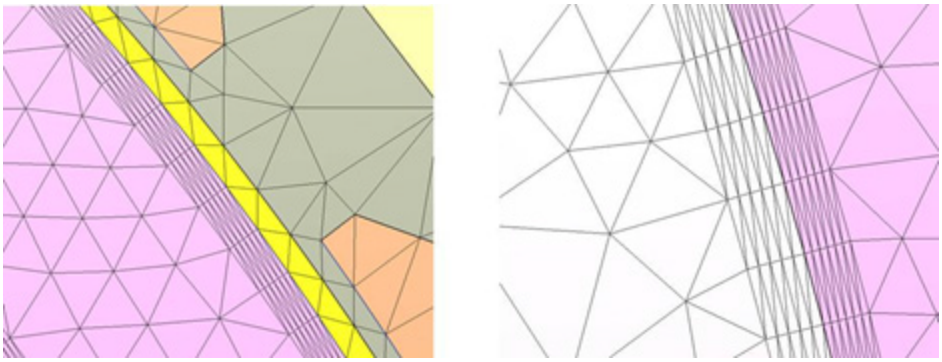
such cases, it is recommended that you hide all other bodies and only display the desired body, then make the edge selections. Remesh technology is then used to generate the mesh on the edges based on the thickness of the first layer to maintain the mesh quality.



The aspect ratio in the layer mesh is defined by the element length in the tangential and normal directions. The ratio will be in the range of 1 to 40 based on the smallest thickness in the layers. Different layer mesh methods are using depending on the ratios. If the ratio is smaller than 4.0, the middle points of the edges are used to advance layers forward as shown below.



If the ratio is more than 4.0, edge points are used to advance layers.



Messages are displayed if the thickness is too small or too large.

Layer Mesh Generation for 3D Rotational Models

Layer Mesh generation for 3D rotational models can only be applied to non-skewed bodies in Maxwell rotational models in which the CylindricalGap mesh operation is used.

- Only body level selection is allowed.
- Rotational Layer mesh can only be generated on non-skewed objects for current release.
- User can select multiple bodies, and assign a layer mesh operation to all of them.
- Rotational layer mesh is only generated for bodies near the band.
- For selected bodies, no layer mesh will be generated in the axial direction, or for matching boundaries.

There are three types of layer meshes for 3D rotational models.

- Edge Cut Layer Mesh
- Rotational Layer Mesh
- Edge Cut + Rotational Layer Mesh

These mesh operations will work only if the clone mesh works.

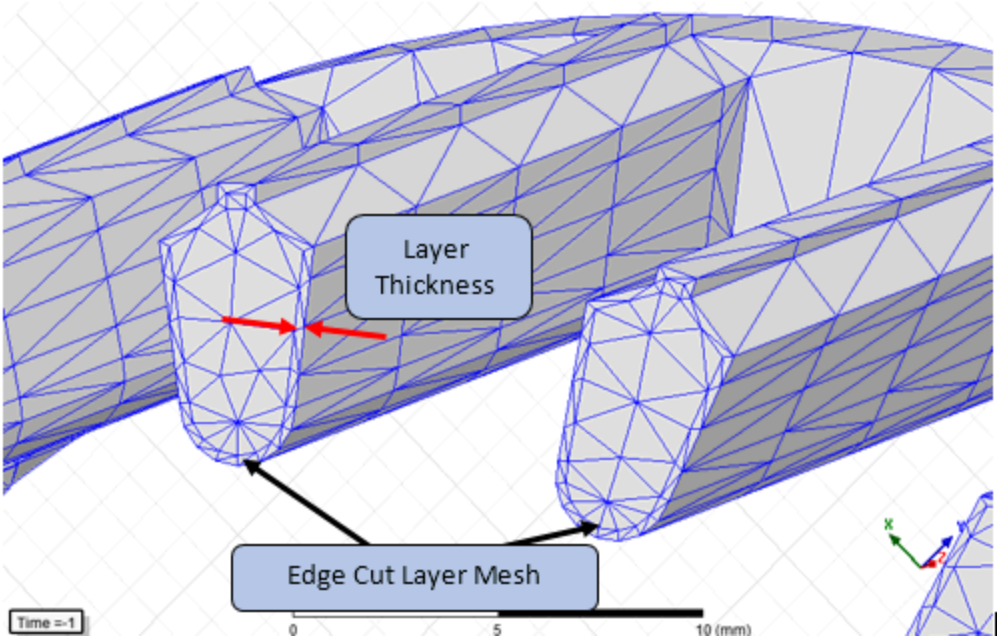
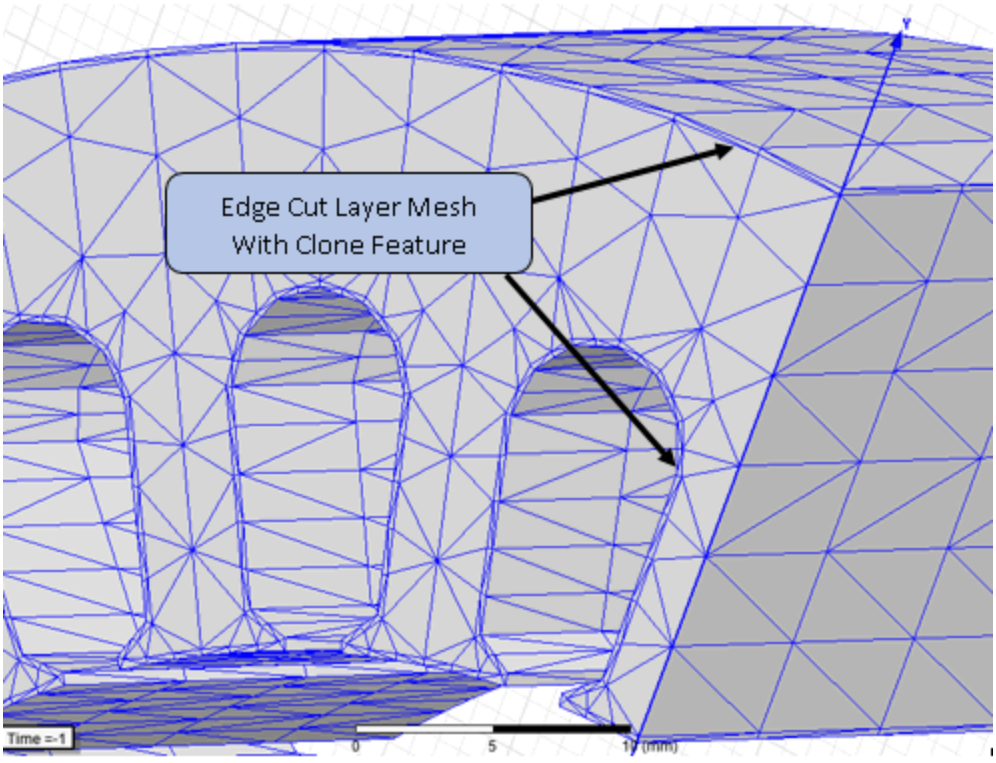
"Changing Properties and Reassigning Mesh Operations" on page 15-69

Edge Cut Layer Mesh Generation

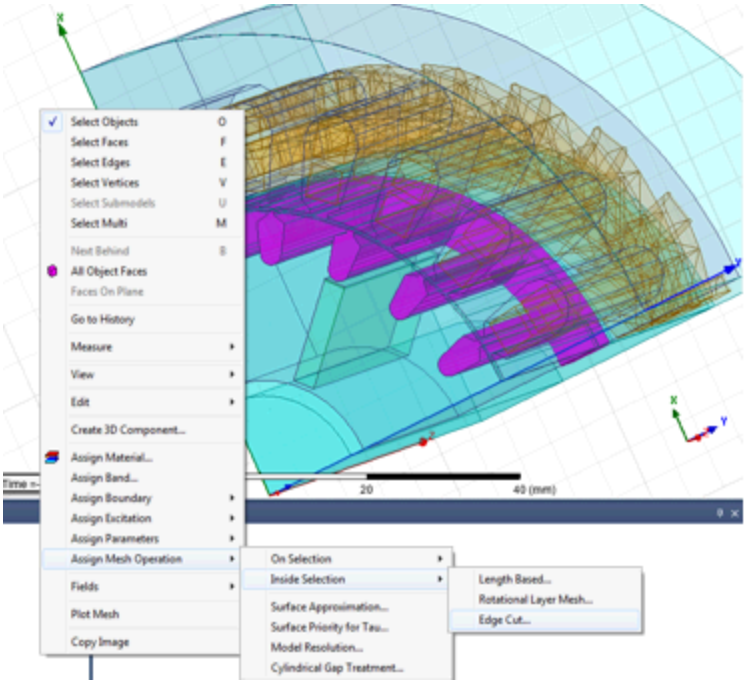
Edge Cut Layer Mesh creates one layer of mesh on the bodies with the layer thickness defined by user input. Layer mesh will not be created at the top or bottom of the axial direction and matching boundary faces. If the object has clone feature, the layer mesh will be coupled with the clone mesh.



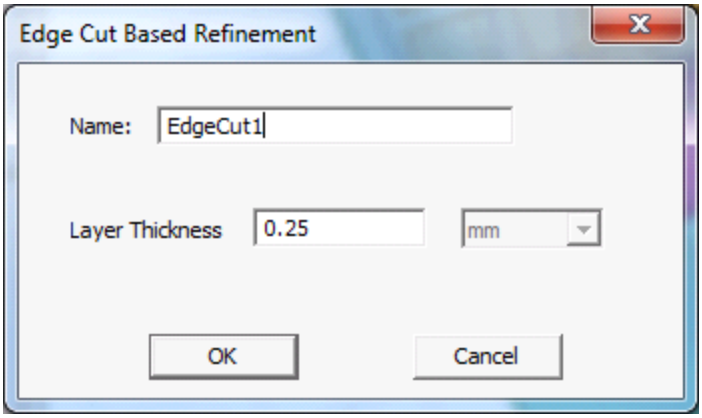


To apply Edge Cut Layer Mesh:

1. Select the desired bodies near the band.
2. Right click to open the context menu, and select **Assign Mesh Operation>Inside Selection>Edge Cut Based**.



3. In the **Edge Cut Based Refinement** dialog box, you can rename the mesh operation, and specify the layer thickness. The recommended layer thickness is the band gap distance.



4. Click **OK**.

Related Topics

"Layer Mesh Generation for 3D Rotational Models " on page 15-63

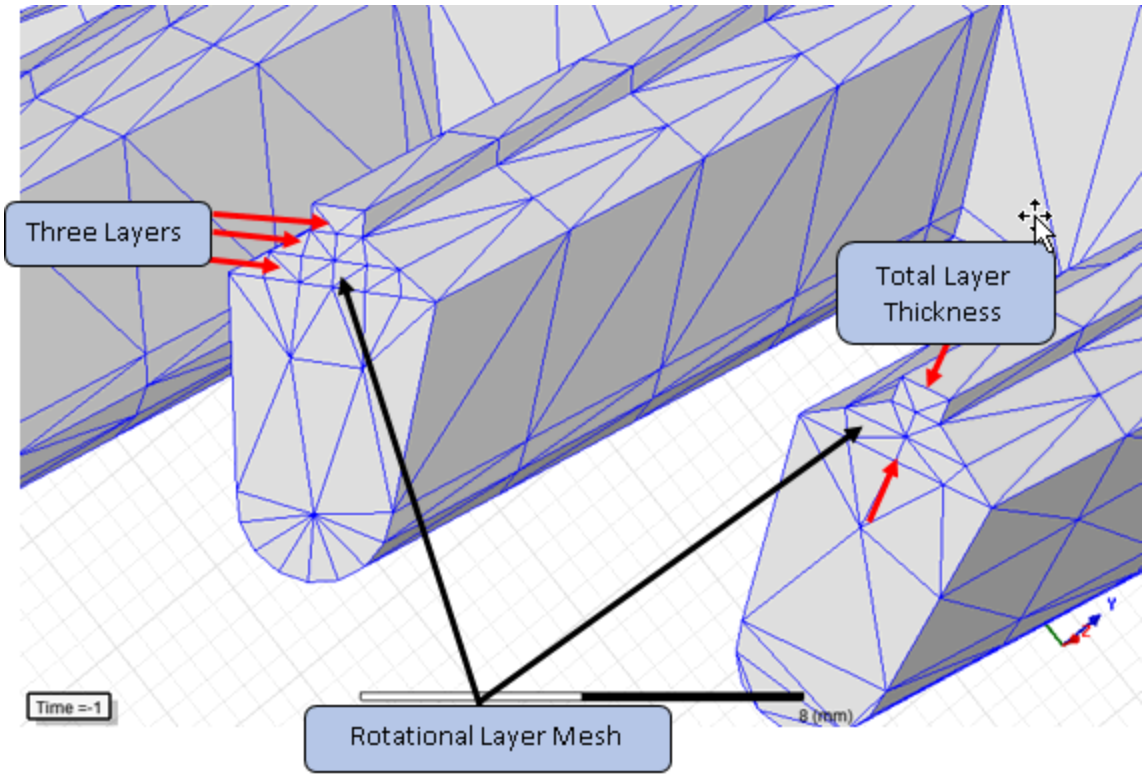
"Edge Cut + Rotational Layer Mesh Generation" on page 15-68
"Changing Properties and Reassigning Mesh Operations" on page 15-69

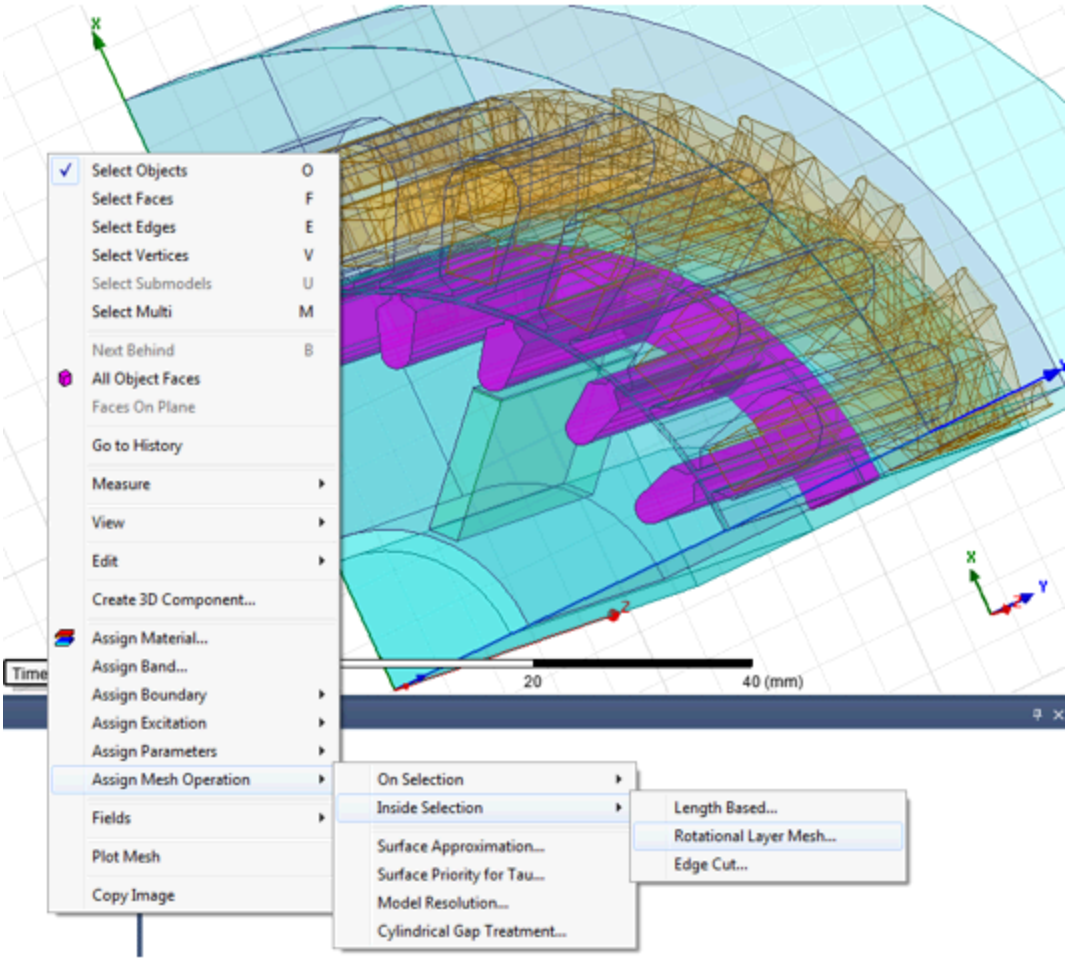
Rotational Layer Mesh Generation

Rotational Layer Mesh creates up to three layers in the radial direction starting from the faces most adjacent to the “Band”. You can define the **Number of Layers** (up to three) and **Total Layer Thickness**.

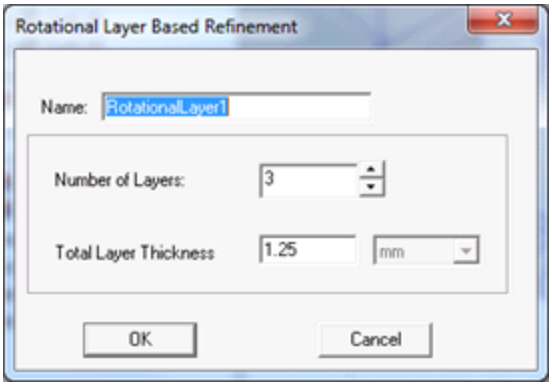


To apply Rotational Layer Mesh:

1. Select the desired bodies near the band.
2. Right click to open the context menu, and select **Assign Mesh Operation>Inside Selection>Rotational Layer Mesh**.



3. In the **Rotational Layer Based Refinement** dialog box, you can rename the mesh operation, specify the number of layers (maximum of 3), and the total thickness of all the layers combined.



4. Click **OK**.

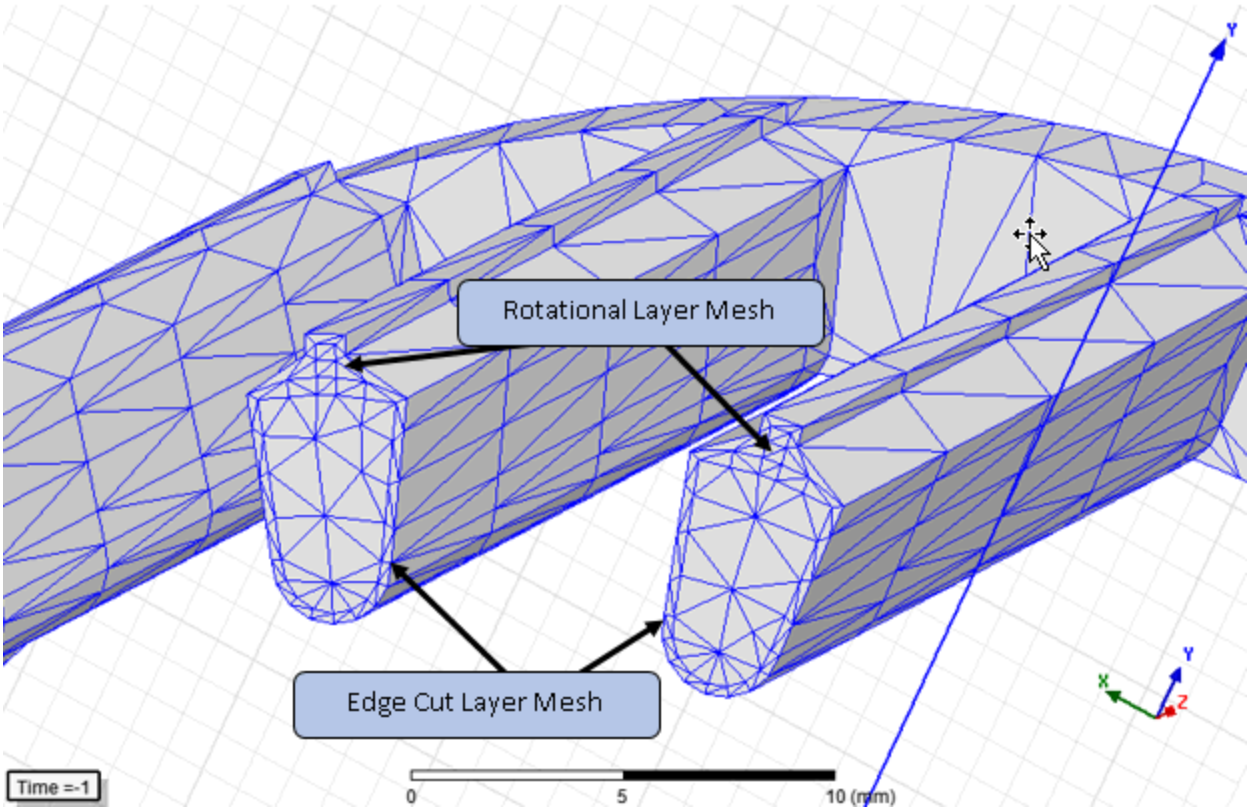
"Edge Cut + Rotational Layer Mesh Generation" below
"Changing Properties and Reassigning Mesh Operations" on the facing page

Edge Cut + Rotational Layer Mesh Generation

These settings are a combination of Edge Cut Layer Mesh and Rotational Layer Mesh settings, and as such has the properties of both. One layer of edge cut mesh will be generated first, then extra multiple layers will be added by the rotational layer mesh settings.



To apply Edge Cut + Rotational Layer Mesh:

1. Select the desired bodies near the band.
2. Right-click to open the context menu, and select **Assign Mesh Operation>Inside Selection>Edge Cut**.
3. In the **Edge Cut Based Refinement** dialog box, you can rename the mesh operation, and specify the layer thickness. The recommended layer thickness is the band gap distance.
4. Reselect the same bodies.

5. Right-click to open the context menu, and select **Assign Mesh Operation>Inside Selection>Rotational Layer Mesh**.
6. In the **Rotational Layer Based Refinement** dialog box, you can rename the mesh operation, specify the number of layers (maximum of 3), and the total thickness of all the layers combined.
7. Click **OK**.

Deleting All Previously-Assigned Mesh Refinements

To delete previously-assigned mesh refinement data:

- Click **Maxwell>Mesh>Delete All**.

Note	This will not alter any existing meshes that have already made use of one or more mesh refinement operations. However, deleted mesh operations will not be used again after reverting to the initial mesh.

Viewing List of Mesh Operations

To list all mesh operations for the project, do the following from the project tree:

1. Right-click **Mesh**.
   A shortcut menu appears.
2. Select **List** from the shortcut menu.
   The **Design List** dialog box appears, with the **Mesh Operations** tab displayed.
3. Click **Done** to close this dialog box.

Reassigning a Mesh Operation

To reassign a previously-assigned mesh setup, do the following in the project tree:

1. Select the object or objects to which you want to reassign the mesh operation.
2. Under **Mesh**, right-click the mesh refinement you had previously completed.
   A shortcut menu appears.
3. Select **Reassign** from the shortcut menu.
   The mesh operation is reassigned to the currently selected objects.

To view the objects to which a mesh operation is assigned:

1. In the Project tree, select the mesh operation.
2. Right-click the mesh refinement you had previously completed.
   A shortcut menu appears.
3. Select **Select Assignment** from the shortcut menu.
   The objects to which the operation is assigned are selected.

Related Topics

Defining Mesh Operations

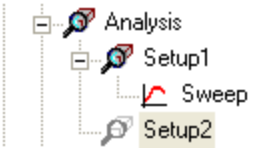
Viewing Mesh Properties

To view mesh properties, do the following in the project tree:

1. Under **Mesh**, right-click the mesh refinement you had previously completed.
   A shortcut menu appears.
2. Select **Properties** from the shortcut menu.
   The dialog box for the type of mesh operation associated with the selected mesh refinement appears.

16 - Specifying Solution Settings

Specify how Maxwell computes a solution by adding a *solution setup* to the design. You can define more than one solution setup per design.



Each solution setup includes:

- General data about the solution's generation.
- Adaptive mesh refinement parameters if you want the mesh to be refined iteratively in areas of highest error.

To add a solution setup to a design:

1. Select a design in the project tree.
2. Click **Maxwell3D**>**Analysis Setup>Add Solution Setup** or **Maxwell2D**>**Analysis Setup>Add Solution Setup**.
   - Alternatively, right click **Analysis** in the project tree, and then click **Add Solution Setup** on the shortcut menu.

   The **Solve Setup** dialog box appears containing several tabs.

   For Non-Transient Solutions

   The following tabs are present for non-transient solutions:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Convergence	Includes settings for convergence.
Expression Cache	Contains an optional list of expressions that you can specify for convergence criteria.
Solver	Includes settings for nonlinear residual and matrix solver type.
Frequency Sweep	Includes setting for varying the frequency of an Eddy Current or AC Conduction solution. **NOTE:** This tab is present only for Eddy Current and AC Conduction solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

   For Transient Solutions

   The following tabs are present for transient solutions:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Save Fields	Enables you to create a time point list for saving field solutions.
Advanced	Supports user control program, import mesh options, and starting/continuing from a previously solved setup.
Solver	Includes settings for nonlinear residual solver type, for enabling the solver to fast reach steady-state, and for selecting the Time Decomposition Method.
Expression Cache	Contains an optional list of expressions that you can specify for evaluating solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

For Electric Transient Solutions

The following tabs are present for electric transient solutions:

General	Includes general solution settings. Also contains a button for setting **HPC and Analysis Options**, which allows you to select or create an analysis configuration.
Solver	Includes settings for initial condition, temporal tolerance, computing power loss data, and importing a mesh.
Expression Cache	Contains an optional list of expressions that you can specify for evaluating solutions.
Defaults	Enables you to save the current settings as the defaults for future solution setups or to revert the current settings to Maxwell's standard settings.

3. Specify the desired settings on the tabs.
4. If you want to disable an individual analysis, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.
5. If you want to use the default values, click **Use Default**.
6. Click **OK**.

Analysis Parameters

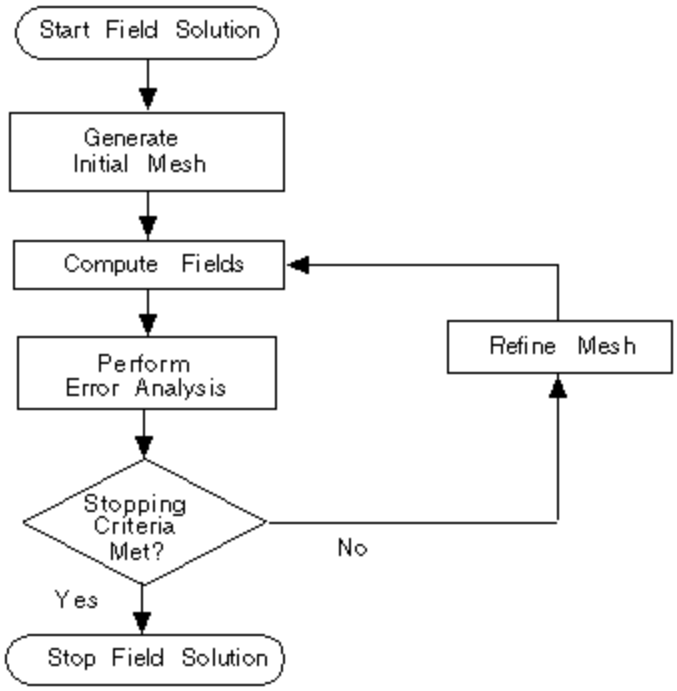
During adaptive analysis the system iteratively refines the starting mesh in order to reduce the size of individual elements in areas of high error — thus improving the accuracy of the solution.



When an adaptive analysis is performed:

- Maxwell generates a field solution using the specified mesh.
- It then analyzes the accuracy of the solution by calculating an energy value based on the error in the solution. The exact mechanism for evaluating the error varies by solution type. For example, in magnetostatic it can use Curl H to find the current density and then subtract all input currents and other sources. For a perfect solution the result would be zero, for a real, finite mesh the result is some amount of residual current density. An energy value calculated from this residual current density is called the error energy. The “Energy Error %” is the error energy as a percentage of the total energy (calculated with the original sources).
- If more than 1 pass has been completed, the software also calculates the change in total energy from the previous pass. The percentage difference is the “Delta Energy (%)”. Adaptive refinement continues until both the “Energy Error %” and the “Delta Energy (%)” are below the target Percent Error specified by the user (or until it reaches the Maximum Number of Passes requested).
- When the error targets are not satisfied the mesh is refined. This is generally done by subdividing the elements with the highest error energy into smaller elements.
- The user can optionally request to “Use Output Variable Convergence”. This is an additional stopping criterion. The Energy Error % and the Delta Energy must still be below the target Percent Error, but the software will also compute the specified Output Variable for each adaptive pass and will calculate the percentage change in that value for each pass after the first (this is the “Output Var. Delta (%)”). The solution will continue until the energy error criteria are met and the Output Var. Delta is below the target “Max. Delta Per Pass” specified by the user for output variable convergence (or until Maximum Number of Passes).

Related Topics

Setting Analysis Parameters for Non-Transient Solutions

Setting Analysis Parameters for Transient Solutions

Setting Analysis Parameters for Non-Transient Solutions

When you set up an analysis, define the parameters on the following tabs of the **Solve Setup** dialog box (which appears when you click **Maxwell**>**Analysis Setup>Add Solution Setup**):

- General (Name, Adaptive Setup, Parameters)
- Convergence
- Expression Cache
- Solver
- Frequency Sweep (Eddy Current and AC Conduction solutions only)
- Defaults

Defining Settings on the General Tab for Non-Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for non-transient solutions:

- Setup Name
- Adaptive Setup
- Parameters

Setup Name for Non-Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Adaptive Setup for Non-Transient Solutions

To specify adaptive settings, click the **General** tab in the **Solve Setup** dialog box and use the options in the **Adaptive Setup** section. Adaptive settings include the following:

- **Maximum Number of Passes.** The **Maximum Number of Passes** is the maximum number of mesh refinement cycles you would like Maxwell to perform. This value is a stopping criterion for the adaptive solution; if the maximum number of passes has been completed, the adaptive analysis stops. If the maximum number of passes has not been completed, the adaptive analysis continues unless the convergence criteria are reached.

Note	The size of the finite element mesh — and the amount of memory required to generate a solution — increases with each adaptive refinement of the mesh. Setting the maximum number of passes too high can result in Maxwell requesting more memory than is available or taking excessive time to compute solutions.

- **Percent Error**. The **Percent Error** allows you to control the desired solution accuracy. Smaller values produce more accurate (but slower) solutions; larger values produce less accurate (but faster) solutions. At each step in the adaptive process, the energy and error energy are computed, and you can view the most recent solutions as soon as they are completed. After the mesh is refined, the matrix is calculated on the refined mesh. The relative change between the previous matrix and the current matrix is then computed and reported as the matrix delta; the target matrix delta is the **Percent Error**. A small delta indicates that further mesh refinement will probably not change the solution.

Parameter Settings

On the **General** tab of the **Solve Setup** dialog box, if you want to solve for fields only and no other parameters, then click the **Solve Fields Only** check box.

When this check box is cleared, the following options are available:

- **Solve Matrix**. Select **After last pass** or **Only after converging**.

Defining Settings on the Convergence Tab for Non-Transient Solutions

To set the convergence data, click the **Convergence** tab in the **Solve Setup** dialog box. Convergence settings can be standard or optional. Standard convergence settings include the following:

- **Refinement Per Pass** – The percent you set for **Refinement Per Pass** determines how many tetrahedra are added at each iteration of the adaptive refinement process. The tetrahedra with the highest error are refined.
- **Minimum Number of Passes** – The minimum number of adaptive passes even if the convergence criteria are reaches.
- **Minimum Converged Passes –** The minimum number of adaptive passes to continue after the convergence criteria are reached.

Optionally, convergence criteria can also be based on the value of an output variable. This condition is in addition to the normal stopping criteria. To base the convergence criteria on an output variable value, refer to Defining Expressions for Non-Transient Solutions.

For 2D Eddy Current solutions only, improved accuracy may be obtained by including loss in the convergence criteria. To include the loss calculation in convergence, select the **Use Loss Convergence** check box.

Note	Maxwell 2D versions prior to version 12 did not use loss in the convergence calculation.

Related Topics

Defining Expressions for Non-Transient Solutions

Defining Expressions for Non-Transient Solutions

You can specify additional convergence criteria through the use of expressions and output variables. The **Maximum Delta** or the **Maximum Percent Delta** defined for expression convergence represents the difference in values of the expressions between consecutive adaptive passes. If the difference in the value of the expression between consecutive passes is less than the **Maximum Delta** or the **Maximum Percent Delta** value this part of the convergence criteria is satisfied.

To set expressions as convergence criteria:

1. Right-click on the Analysis icon in the Project tree to open the **Solution Setup** dialog box.
2. Click the **Expression Cache** tab and click the **Add...** button to open the **Add to Expression Cache** dialog box.
3. Specify the Context for the expression, including **Report Type**, **Solution**, **Parameter**.
4. Under the **Trace** tab, select from the **Category**, **Quantity**, and **Function** lists to create expressions.

   Selecting a listed category lists the Quantities and Functions available for each category. If you have defined one or more output variables, you can see them by selecting the **Output**

Variables category. The **Output Variables** button opens a dialog box that lets you define output variables. See Specifying Output Variables.

When you have created an expression, it appears in the **Expression** field of the **Trace** tab. If desired, you can use the **Range Function** button to select range functions to apply to the expression.

Under the **Calculation Range** tab, you can view the values of available sweep variables. Clicking the ellipsis **[...]** button in the **Edit** column opens a list of values from which you can select.

5. When finished defining the expression that you want to add to the cache, click the **Add Calculation** button.

   This adds the selected expression and the associated context to a table in the **Expression Cache** tab. You can define additional expressions with contexts and add them in the same way.

6. When finished adding expressions, click **Done** to close the **Add to Expression Cache** dialog box.

   The **Expression Cache** tab lists the expressions you have added in a table.

   - The **Title** field is editable, by default showing the name as built from the expression (with underscores removed).
   - The **Expression** field shows the full expression. If necessary, you can resize the **Solution Setup** dialog box. You can also resize each columns in the table.
   - The **Context** column shows None for Modal solutions, or the appropriate geometry for Fields calculations.
   - The **Intrinsics** column shows a clickable button that opens an **Edit Calculation Range** dialog box. If the **Intrinsics** column button shows **None** you cannot edit the value. If the button shows variables, click the ellipsis **[...]** in the **Edit** column to display a list of the variable values from which you can select. Click **OK** to close the **Edit Calculation Range** dialog box and apply your selections to the **Expression Cache**.

7. To designate one or more expressions for convergence, click the field for the **Convergence** column for each expression.

   This opens an **Adaptive Convergence** dialog box. Check **Use this expression for convergence** to enable the radio buttons. You can then specify the **Maximum Delta** (an absolute change in value between passes) or the **Maximum Percent Delta** (a percentage change in value between passes) criteria. The **Maximum Delta** provides a way around a potential issue if your expression is essentially zero and the numeric noise from pass to pass causes the maximum percentage delta to remain high. In that case adaptive refinement continues until you get to the maximum number of passes.

8. Optionally, buttons allow you to **Edit** and **Remove** selected expressions, and to **Remove All** expressions in the table.

9. For Eddy Current only check boxes allow you to save the expression cache either with **Evaluate Cache vs. Pass**, **Evaluate Cache vs. Freq**, or both.

10. When finished defining expressions, click **OK** to close the **Solution Setup** dialog box.

Defining Settings on the Solver Tab for Non-Transient Solutions

The settings on the **Solver** tab of the **Solve Setup** dialog box depend on the solution type selected for that project.

- Magnetostatic Solver Settings
- Eddy Current Solver Settings
- Electrostatic Solver Settings
- AC Conduction Solver Settings
- DC Conduction Solver Settings

Magnetostatic Solver Settings

For magnetostatic solutions, you can define the following settings on the **Solver** tab of the **Solve Setup** dialog box:

- Enter a value in the **Nonlinear Residual** text box.
- For both 2D and 3D magnetostatic designs, you can select the **Smooth BH Curve** check box. This allows the solver to "smoothen" the list of points to make a refined BH curve for better solving. If this option is not selected, the solver just uses the discrete points.
- For 3D magnetostatic designs only, you can Enable Iterative Solver.
- For both 2D and 3D magnetostatic designs, you can select the **Number of Nonlinear Iterations** check box. This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.
- **Advanced Option** settings allow you to perform more sophisticated simulations of the magnetostatic field.
    - **Use pre-computed permeability data** (for general soft magnetic materials) uses a previously solved mu (apparent permeability) distribution from a linked source design. Selecting this option enables the **Setup Link** button, and automatically opens the **Setup Link** dialog in which you set up the link. Optionally, you can override the solved mu with a user-specified program, which you can specify on the **Advance** tab of the **Setup Link** dialog box. Select the **Including magnets** check box if magnets are included in the distribution. Refer to "Permeability Options for Magnetostatic Solutions " on the facing page for details on using these settings.
    - The **Import mesh** check box can be selected in the target design if the mesh for the same geometry in the linked source design is to be used in the analysis. Selecting

this option enables the **Setup Link** button, and automatically opens the **Setup Link** dialog in which you set up the link. Refer to "Import Mesh for Non-Transient Solutions " on page 16-20 for details on using this setting.

- If an advanced option has previously been set up, you can click the **Setup Link** button to open the **Setup Link** dialog and edit the link settings.

Note	The data link used to link source and target designs uses data caching technology. Therefore, if the design changes, to make sure the new data (from the source design) is used in the target design, right-click the **Analysis** field of the target design in the project tree, and select **Clear Linked Data**. This flushes existing data.

Related Topics

"Enabling the Iterative Solver" on page 16-24
"Import Mesh for Non-Transient Solutions " on page 16-20
"Permeability Options for Magnetostatic Solutions " below
"Setup Link for Non-Transient Solutions" on page 16-22

Permeability Options for Magnetostatic Solutions

To set permeability options in the **Solve Setup** dialog box:

1. Click **Maxwell**>**Analysis Setup>Add Solution Setup** to open the **Solve Setup** dialog box.
2. Click the **Solver** tab.
3. In the **Advanced Option** section, select **Use pre-computed permeability data**, which uses a previously solved mu (apparent permeability) distribution from a linked source design. Selecting this option enables the **Setup Link** button, and the **Setup Link** dialog opens, allowing you to specify the source project, design, and solution containing the desired information. The mesh between the two linked designs is the same. You can use the apparent permeability that has been frozen from a previously solved source design.

   By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled. 
	To enable settings, you can select **Edit Link**.

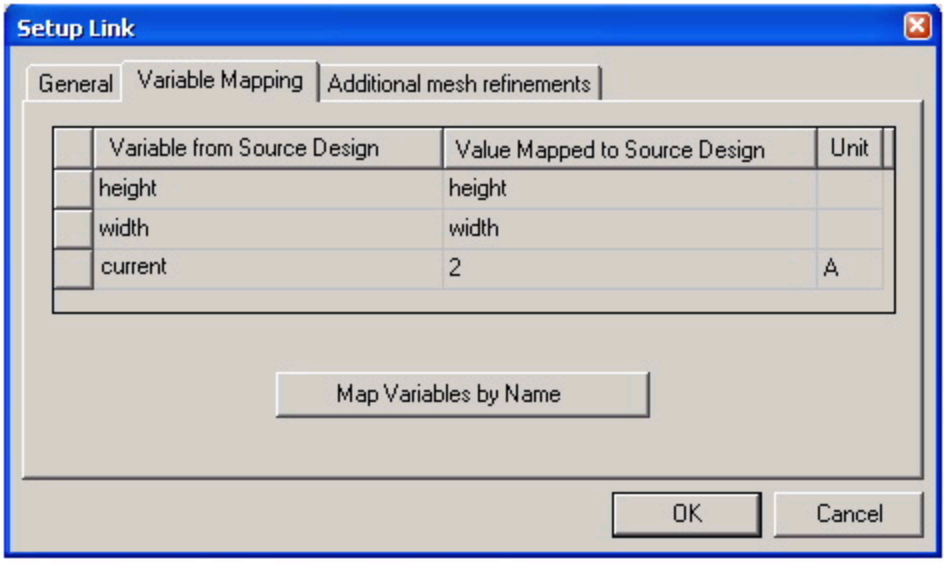
4. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

   Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.
5. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup – the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most designs, it is LastAdaptive.
6. Use the check box to specify whether to **Simulate source design as needed**.
7. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
8. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. In this example the variables “height” and “weight” are mapped to the Source, whereas the “current” variable does not have a same named counterpart, and retains its value in the source design.



9. Optionally, you can override the solved mu with a user-specified control program, which you can specify on the **Advance** tab of the **Setup Link** dialog box. Additionally, because the non-linear characteristics of many magnetic materials are too complex to be defined through the definition of a BH-Curve, an advanced feature allows the permeability characteristic of the target design to be obtained by mathematical manipulation of the permeability from the source design via a user-defined control program. To use this feature:

    a. Check **Enable user program**.
    b. Specify the **Absolute path of program** to the user control program.
    c. Specify any **Additional arguments** needed by the user control program.

Note	For detailed information on using this feature, refer to *Using the Advanced Permeability Option*.

10. Click **OK** to accept the setup and close the Setup Link dialog and return to the Solve Setup dialog.
11. After setting up the link, you can select the **Including magnets** check box if magnets are included in the distribution.
12. When you are finished specifying solution settings, click **OK** to close the **Solve Setup** dialog box and finalize the solution setup.

Note	The usual way to create the linked designs is by copying and pasting an existing design from the project of your choice once the design is complete. Occasionally an existing design (possibly from a different project) can be used as a source. The data link automatically attempts to solve the linked (source) design if necessary (if no solution exists), then automatically copies the mesh and necessary data (calculated distribution of permeability), and finally performs the requested calculation in the target design. This data link allows you to calculate

	the magnetic field to be performed in a design with, for example, modified sources while keeping the permeability in a "frozen" state calculated in a different design (the same geometry and mesh but with different sources).

Using the Advanced Permeability Option

The non-linear characteristics of many magnetic materials are too complex to be defined through the definition of a BH-Curve. This feature enhances the existing permeability-link by enabling the permeability characteristic of the target design to be obtained by mathematical manipulation of the permeability from the source design. The nonlinear “apparent” permeability from the source design is frozen (linearized) and used by the target design. Because the permeability in the target design is linear, the apparent and the incremental permeabilities will be identical and the apparent and incremental inductances will also match.

This manipulation is done via a user-supplied control program. A user-specified executable is launched at the beginning of target design simulation and the linked permeability data (i.e., the “frozen” mu) from the source design is overridden by the values calculated by the user control program. The target design solver is then launched and uses the overridden value in its calculation.

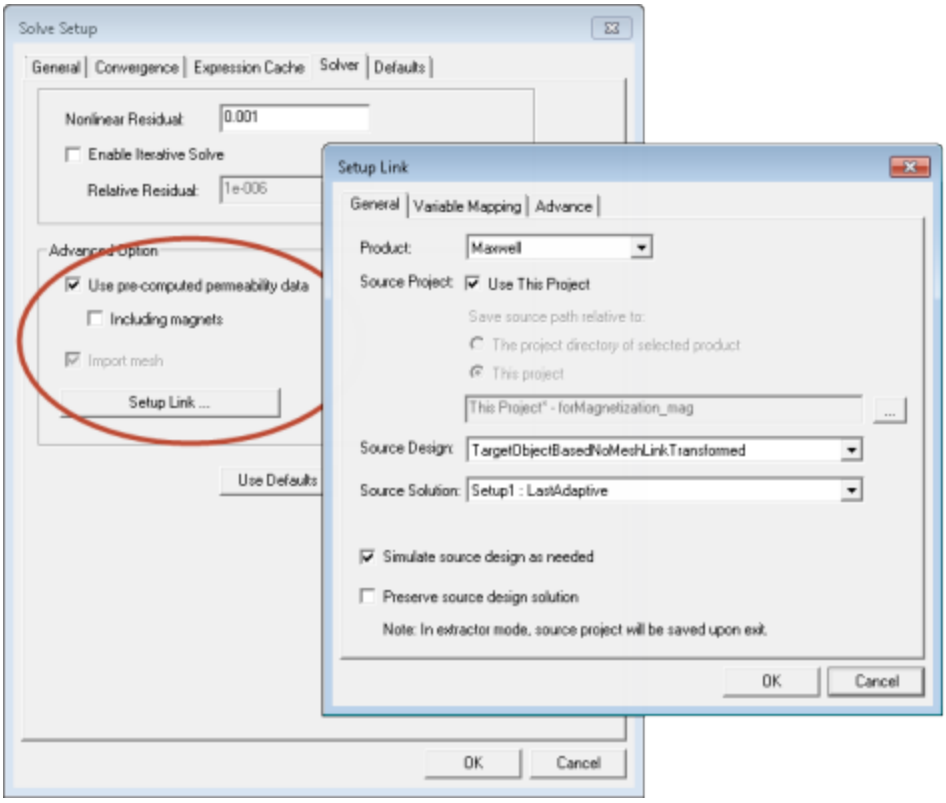
The user control executable program is launched with two file names as arguments:

1. **Per mesh element permeability value.** This is the solved mu (i.e., the apparent permeability not the incremental permeability) from the source design. Note that the format of this file is different between 2D and 3D designs.
2. **Per mesh element information.** Information includes the centroid location (x, y, z), Bx, By, Bz at the centroid and Hx, Hy, Hz at the centroid. The format of this file is the same between 2D and 3D designs.

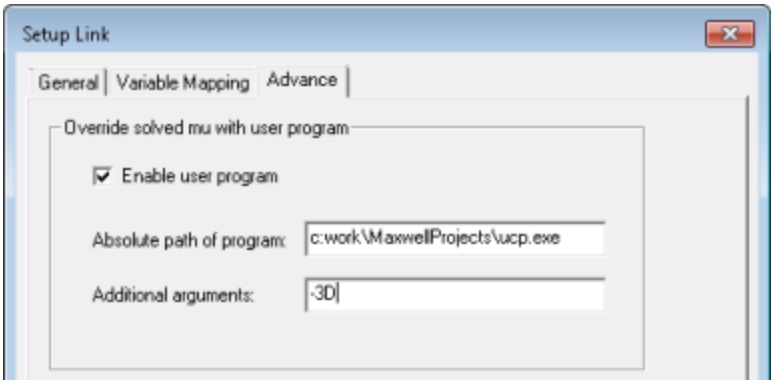
Note	Refer to Advanced Permeability Option File Formats for information on these file formats.

Considerations for using this feature

1. to set up the advanced user control program option for permeability, select **Setup Link** on the Solver tab to open the Setup Link dialog.



2. Specify the **Source Design** on the **General** tab.
3. On the **Advance** tab, select the check box **Enable user program** and provide the absolute path to the executable, and provide any **Additional arguments** needed by the user program.



4. Simulate the target design.

   Simulation of the source design will be automatically started if it is not already simulated. The user-supplied executable is launched. Additional information is logged in **Setup>Profile** regarding the launch of user executable.
5. Simulation of the target design continues after user executable exits.

Note the following:

- Field post processing of target design will use the user-overridden mu.
- Editing boundary/excitation setup in the target design invalidates the current solution in target design.
- Linked data remains valid when boundary/excitation is changed. On next simulation of the target design, the prior user-overridden permeability will be used.
- Edit of the link setup (this includes the path to the user control program, or “removing” the user control program will invalidate the current solution and also the cached linked data. On the next simulation of the target design, the “frozen” permeability will be extracted again from the source design. If the link setup has opted to enable the user control program, the currently designated user program will be launched. If the link setup has opted *not* to override the linked data, the extracted mu from the source design will be used as-is.
- **Clear Linked Data** in the target design invalidates the current solution and cached linked data in the target design.
- On the next simulation of the target design, the frozen permeability will be extracted again from the source design. The user executable will be launched to allow the permeability to be overridden.
- Editing the source design has no effect on the existing solution in the target design. Users need to **Clear Linked Data** in target design if a new simulation in the target design is desired.
- After the simulation of the target design, the user-overridden “mu” becomes part of the solution of the target design and this target design can then be used as the source of another design. This is explained in more detail with the following workflow.

Advanced Permeability Option File Formats

The following are the file formats for this feature:

3D Per mesh element permeability value.

This is the solved mu (i.e., the apparent permeability not the incremental permeability) from the 3D source design.

```
SolidID  6   14
h  230  79578.5
h  231  79578.5
h  232  79578.5
h  233  79578.5
h  234  79578.5
h  235  79578.5
h  236  79578.5
h  237  79578.5
h  238  79578.5
h  239  79578.5
h  240  79578.5
h  241  79578.5
h  242  79578.5
h  243  79578.5
E_DATA
```

The average permeability calculated by Maxwell solver. The average is calculated from the value at each of the nodes of the mesh element.

In the above example, SolidID, h, and E_DATA are keywords. “6” is the object ID. “14” is the number of elements in the object with ID “6”. “230”, “231”, etc. are element IDs.

Note that there could be multiple "blocks" of the above data if there are multiple non-linear objects in the design, as illustrated below.

```
SolidID  6   17
h  351  79578.5
h  352  79578.5
.
.
.
h  366  79578.5
h  367  79578.5
SolidID  93   12
h  1954  79578.5
h  1955  79578.5

.
.
.
h  1963  79578.5
h  1964  79578.5
h  1965  79578.5
E_DATA
```

2D Per mesh element permeability value.

This is the solved mu from the 2D source design.

```
The format is:
<number of total elements>
```

```
<objectID> <elementID> <X/R center position of element> <Y/Z center
position of element> <mu>
```

For example, the following solved mu indicates that there is ONE object that has TWO mesh elements. The first element has a mu value of 2.7482 and the second element has a mu of 2.76553.

```
2
76 1   0.000866667  6.66667e-005 2.7482
76 15  0.000733333 -6.66667e-005 2.76553
end
```

The following solved mu indicates a total of 16 mesh elements that belong to two objects.

```
16
64 24   0.000733333 -0.000533333 1.90406
64 27   0.000866667 -0.000266667 1.88459
64 28   0.000733333 -0.000266667 1.89191
64 41   0.000666667 -0.000333333 1.88789
64 42   0.000666667 -0.000466667 1.8909
64 53   0.000933333 -0.000333333 1.87607
64 69   0.000833333 -0.0005 1.91924
64 70   0.000966667 -0.0005 1.93687
64 71   0.0009 -0.000433333 1.89957
64 74   0.000933333 -0.000566667 2.0507
64 75   0.000866667 -0.000566667 1.95098
76 20   0.000666667 0 1.94237
76 21   0.000933333 0 1.92467
76 22   0.0008 0.000133333 2.06578
76 25   0.000866667 -0.000133333 1.89876
76 26   0.000733333 -0.000133333 1.90766
end
```

Per mesh element centroid location (x, y, z), Bx, Bx, By, Hx, Hy, Hz at the centroid. (All values in SI units.)

```
SolidID 6 14
h 230 x y z Bx By Bz Hx Hy Hz
.
.
.
E_DATA

Eddy Current Solver Settings

For an eddy current solution:

1. For 2D and 3D designs, enter a frequency value in the **Adaptive Frequency** text box, and select the desired units. Use of variables and expressions are also supported.
2. For 2D and 3D designs, enter a value in the **Nonlinear Residual** text box.
3. For 2D and 3D designs, you can select the **Smooth BH Curve** check box. This allows the solver to "smoothen" the list of points to make a refined BH curve for better solving. If this option is not selected, the solver just uses the discrete points.
4. For 3D designs, you can optionally Enable an Iterative Solver.
5. For 2D and 3D designs, you can select the **Number of Nonlinear Iterations** check box. This provides an option for you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 0. By default the values for **Minimum** and **Maximum** are 1 and 100, respectively. Maximum number should be greater than the Minimum number.
6. For 3D designs, you can optionally choose to **Use higher order shape functions**. Enabling the higher order option gains better accuracy for eddy current regions.

   > **Note:** Higher order shape functions are not supported for a project with windings. For this case the solver falls back to lower order shape functions.

7. For 3D designs, you can optionally choose to **Use pre-computed permeability data**. Refer to Using the Permeability Link Option for Eddy Current Solutions for details on this option.
8. If desired, you can Import Mesh.

Using the Permeability Link Option for 3D Eddy Current Solutions

For projects with materials whose permeability is nonlinear, setting the permeability link in a 3D Eddy Current design enables it to use the permeability data calculated in a source 3D magnetostatic design, whose matrix/permeability computation setting is **Apparent** (refer to Matrix/Permeability Tab Computation Settings for Magnetostatic Solutions). In this scenario, the nonlinear analysis is only performed in the 3D magnetostatic source design. In the 3D Eddy Current target design, the nonlinear material is treated as linear material using the “frozen” permeability data from the source design. The target design will be solved based on the mesh and permeability data imported from the source design. Small signal analysis is a typical application for this feature.

The permeability link option can also serve as the link if incremental permeability is desired in Eddy Current solutions by setting the matrix/permeability computation as **Incremental** in the source design settings (refer to Matrix/Permeability Computation Tab Settings for Magnetostatic Solutions).

Prerequisites

- Source design - Maxwell 3D Magnetostatic
- Target design - Maxwell 3D Eddy Current
- The geometry of the source and target designs must be identical.

To set up and use the pre-computed permeability link for projects with nonlinear material:

1. Create a 3D Magnetostatic source design using nonlinear material.
2. Solve the 3D Magnetostatic design.
3. Create a 3D Eddy Current target design, whose geometry and materials are identical to the source magnetostatic design.
4. On the Eddy Current **Solve Setup** dialog box, **Solver** tab, select **Use pre-computed permeability data**, to use the permeability data that has been frozen from a previously solved 3D magnetostatic source design. Selecting this option enables the **Setup Link** button, and the **Setup Link** dialog opens, allowing you to specify the 3D magnetostatic source project, design, and solution containing the desired information. The mesh between the two linked designs is the same.

   By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.  To enable settings, you can select **Edit Link**.

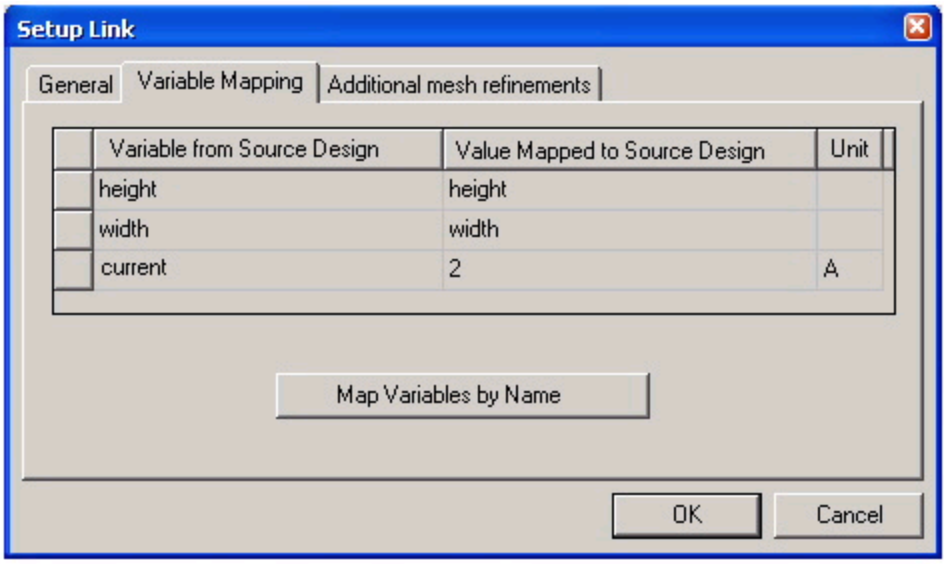
5. On the **Setup Link** dialog **General** tab, select the source 3D magnetostatic design and solution. The geometry of the source and target designs must be identical.
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path relative to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

Use the radio buttons to specify whether to save the source path relative to **The project directory of selected product** or **This project**.

6. Use the check box to specify whether to **Simulate source design as needed**.
7. Use the check box to specify whether to **Preserve source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
8. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to "map" these variables to constant values, expressions, or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and the source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. In this example the variables "height" and "weight" are mapped to the Source, whereas the "current" variable does not have a same named counterpart, and retains its value in the source design.



9. Click **OK** to accept the setup and close the Setup Link dialog and return to the Solve Setup dialog.
10. When you are finished specifying solution settings, click **OK** to close the **Solve Setup** dialog box and finalize the solution setup.
11. Solve the target 3D Eddy Current design.

Note	If the geometry of the source and target designs is not identical, an error message displays.

Eddy Current Solver Settings

Matrix/Permeability Tab Computation Settings for 3D Magnetostatic Solutions

Electrostatic Solver Settings

For an electrostatic solution you can:

- For 3D designs, you can Enable an Iterative Solver.
- Import Mesh.

AC Conduction Solver Settings

1. 1. For 2D and 3D designs, enter a frequency value in the **AdaptiveFrequency** text box, and select the desired units. Use of variables and expressions are also supported.
2. For 3D designs, enter a value in the **Nonlinear Residual** text box. This value specifies how close each solution must come to satisfying the equations that are used to compute the electric field.
3. For 3D designs, selecting the **Number of Nonlinear** Iterations check box allows you to set both a **Minimum** iteration number to avoid non-converged solution, and a **Maximum** iteration number to avoid taking too much computation time. These values must be integers greater than 1. The default values for **Minimum** and **Maximum** are 2 and 50, respectively. The **Maximum** number should be greater than the **Minimum** number.
4. If desired, you can Import Mesh.

DC Conduction Solver Settings

For a DC Conduction solution:

1. If desired, you can Import Mesh.
2. For 3D designs: optionally Enable an Iterative Solver.

Import Mesh for Non-Transient Solutions

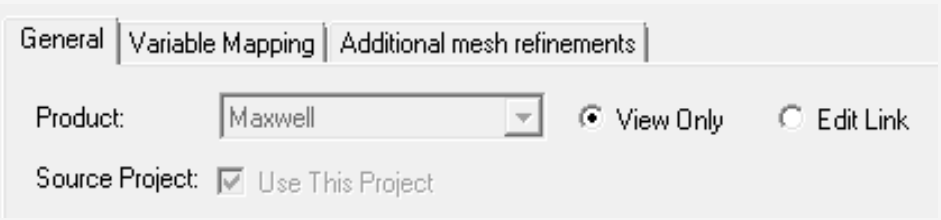
The **Import mesh** check box can be selected in the “target” design if the mesh for the same geometry is to be used in the analysis. This setup is designed to be generally applicable to all solutions.

If the **Import mesh** feature is selected, the **Setup Link** button becomes active, the **Setup Link** dialog box automatically appears, and the mesh will be imported from the source design to the target design.

Note	The usual way to create geometrically equivalent designs is by copying all geometry objects from one design and then using **Import From Clipboard** in the other design.

1. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.



To enable settings, you can select **Edit Link**.

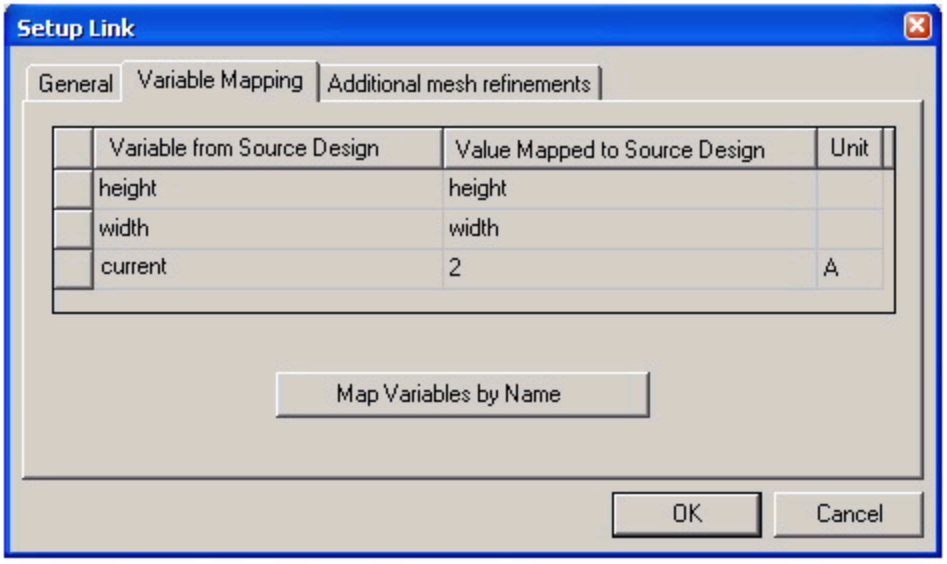
2. To select a source project do one of the following:
   - To use the current project as the source, check **Use This Project**. This disables the **Save source path to:** radio buttons and the ellipsis **[...]** button and its associated text field.
   - To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

     Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.
3. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.” In a Transient solution type, it is “Transient.”
4. Use the check box to specify whether to **Simulate source design as needed**.
5. Use the check box to specify whether to **Preserve the source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.
6. The **Variable Mapping** tab lets you view any variables contained in the selected Project.

   When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.

   For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. In this example the variables “height” and “weight” are mapped to the Source, whereas the “current” variable does not have a same named counterpart, and retains its value in the source design.



7. You can select the **Additional mesh refinements** tab to either **Apply mesh operation in target design on the imported mesh** (default), or **Ignore mesh operations in target design**.
8. Click **OK** to accept the setup and close the **Setup Link** dialog box.

Setup Link for Non-Transient Solutions

If you selected the **Use pre-computed permeability data** option (refer to *Permeability Options for Magnetostatic Solutions* or to *Using the Permeability Link Option for Eddy Current Solutions*), or **Import mesh**, do the following to specify the source project, design, and solution containing the information you want to use. You can also view and map variables and, for Import Mesh, specify additional mesh refinements.

General Tab

1. By default, the **Setup Link** dialog opens on the **General** tab with only the **This project** radio button selected.

Note	If a link had previously been set up, the **Setup Link** dialog opens in **View Only** mode with all settings disabled.  To enable settings, you can select **Edit Link**.

2. To select a source project do one of the following:

- To use the current project as the source, check **Use This Project**. This disables the **Save source path to:** radio buttons and the ellipsis **[...]** button and its associated text field.
- To specify a source project file other than the current project click the ellipsis **[...]** button to open a file browser window. When you have selected the project, click the **Open** button to accept the project file for the setup. You can use the check box to **Open as read only**.

Use the radio buttons to specify whether to save the source path relative to **The project directory of the selected project** or **This project**.

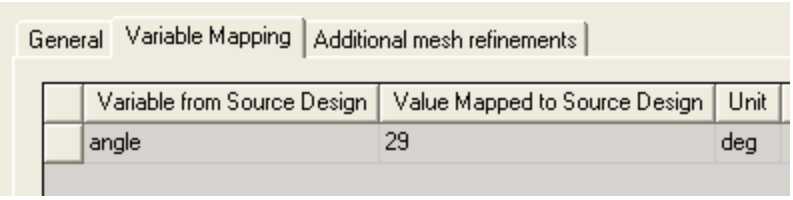
3. When you select a source project file, the **Source Design** and the **Source Solution** fields are filled in with default values, and their drop down menus contain any available designs and solutions. You can use the drop down menus to choose from the available designs and solutions.

   The “Default” solution is the product-dependent solution of the first Setup. That is the setup listed first in the source design's project tree (alphanumerical order). A product-specific solution of this setup becomes the default solution. In most products, it is “LastAdaptive.” In a Transient solution type, it is “Transient.”
4. Use the check box to specify whether to **Simulate source design as needed**.
5. Use the check box to specify whether to **Preserve the source design solution**. Note that in the extractor mode, the source project will be saved upon exit. Extractor mode means that the software is opened during the link solely for the purpose of solving.

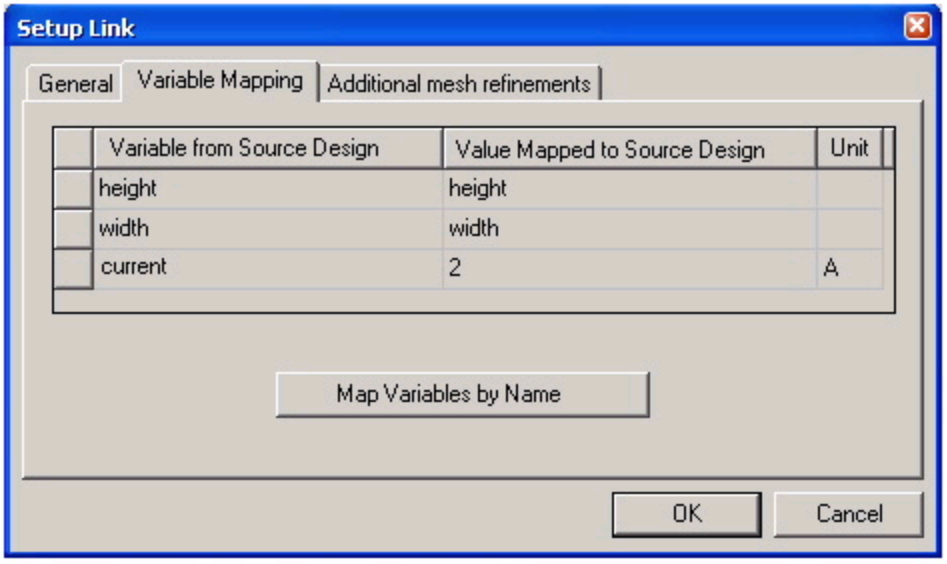
Variable Mapping Tab

The **Variable Mapping** tab lets you view any variables contained in the selected Project.

When there are variables in the source design, you can choose to “map” these variables to constant values, expressions or variables in the target designs. Variable mapping becomes more important when the datalink type requires source and target design to be geometrically identical and source design is geometrically parameterized.



For linked designs with variables of the same name, you can click **Map Variables by Name** to automatically map same named variables. In this example the variables “height” and “weight” are mapped to the Source, whereas the “current” variable does not have a same named counterpart, and retains its value in the source design.



Additional mesh refinements Tab

Note	This tab is present only for **Import mesh** link operations.

If you are setting up an Import mesh link you can use the radio buttons on the **Additional mesh refinements** tab to either **Apply mesh operation in target design on the imported mesh** (default), or **Ignore mesh operations in target design**.

Advance Tab

Note	This tab is present only when using "Permeability Options for Magnetostatic Solutions " on page 16-9 .

If you are setting up a link for the magnetostatic solver **Use pre-computed permeability data** option, you can select the **Advance** tab to override the solved mu value from the source file with a user-specified control program. Refer to "Permeability Options for Magnetostatic Solutions " on page 16-9 for details on using this feature:

Enabling the Iterative Solver

The iterative solver provides an alternative to the direct solver. When you select the **Enable Iterative Solver** option, Maxwell invokes the iterative solver. Maxwell automatically switches to

the direct solver if the iterative solver fails in convergence.

For more detail, see the technical notes for *Iterative Matrix Solver*.

To enable the iterative solver:

1. On the **Solution Setup** dialog box **Solver** tab, check the **Enable Iterative Solve** check box.

   This enables the **Relative Residual** input field.
2. Enter a value for the **Relative Residual**. The residual measures the convergence of the iterative solver. The default value is **1e-6** for the magnetostatic and electrostatic solvers and **1e-4** for the eddy current solver.

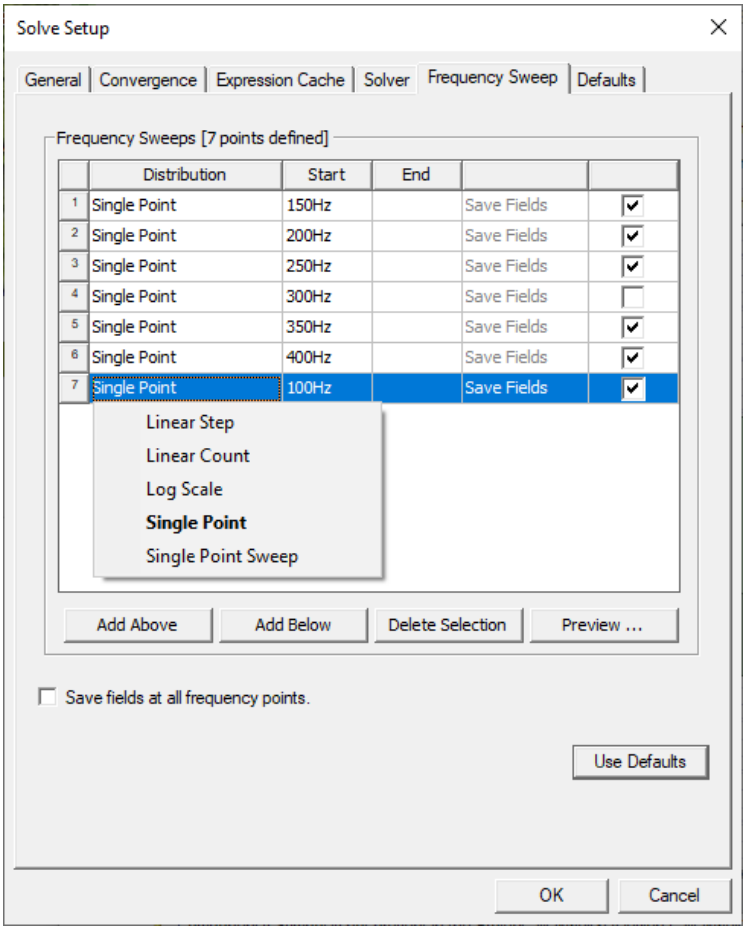
Technical Notes: *Iterative Matrix Solver Technical Details*

Defining Settings on the Frequency Sweep Tab for Eddy Current and AC Conduction Solutions

On the **Frequency Sweep** tab of the **Solve Setup** dialog box:



1. Use the **Add Above**, **Add Below**, and **Delete Selection** buttons to add or remove sweeps. Each row represents a separate sweep. Selecting a sweep's **Distribution** activates a drop-down menu allowing you to select the type of sweep. Information in the columns varies with the type of sweep.
    - **Linear Step** – A linear range of frequency points for which you specify a constant step size. Maxwell will solve the frequency point at each step in the specified frequency range, including the start and stop frequencies. For example, specifying 10Hz for the **Start** frequency, 20Hz for the **End** frequency, and 2.5Hz for the step size instructs Maxwell to compute a solution for frequencies of 10, 12.5, 15, 17.5, and 20 Hz.
    - **Linear Count** – A linear range of frequency points for which you specify the number (count) of points within the frequency range defined by the **Start** and **End** frequencies. Maxwell will divide the frequency range, which includes the start and end frequencies, by the count you specify and solves each frequency point in the count.
    - **Log Scale** – A range of points for which you specify the **Start**, **End**, and number of samples. Maxwell assigns the sampled points using intervals based on a logarithmic

scale.

- **Single Point** – Individual frequency points for which you specify the **Start** value only. A check mark in the **Save Fields** column indicates that the fields for the point will be saved.
- **Single Point Sweep** – Converts the current selection to single points. This is convenient if you want to save (or not save) fields at specific frequency points.

2. Click the **Preview** button to display the currently defined sweep(s).
3. Optionally, you can check **Save fields at all frequency points** to save fields for the entire set of sweep ranges – except for **Single Point** entries that are unselected.

Defining Settings on the Defaults Tab for Non-Transient Solutions

Default analysis parameters are used to initialize the data for new setups.

To set up the default analysis parameters, define the following parameters under the **Defaults** tab of the **Solve Setup** dialog box:

1. Click **Save Defaults** if you want to save the defaults based on the data for the current setup.
2. Click **Revert to Standard Defaults** to clear the existing values.
3. Click **OK**.

Setting Analysis Parameters for Transient Solutions

When you set up an analysis, define the parameters on the following tabs of the **Solve Setup** dialog box (which appears when you click **Maxwell**>**Analysis Setup>Add Solution Setup**):

- General
- Save Fields
- Advanced
- Solver
- Expression Cache
- Defaults

Defining Settings on the General Tab for Transient Solutions

The following settings can be defined on the **General** tab of the **Solve Setup** dialog box for transient solutions:

- Setup Name
- Transient Setup (2D) or Transient Setup (3D)
- HPC and Analysis Options

Setup Name for Transient Solutions

By default, **Setup1** appears as the name of the first analysis you set up.

To change the name of the setup, type the new name in the **Name** text box on the **General** tab of the **Solve Setup** dialog box.

To disable the setup, uncheck the **Enabled** check box. Refer to *Disabling and Enabling an Analysis Setup* for additional information.

Transient Setup (2D)

To set up a 2D transient analysis, define the following parameters on the **General** tab of the **Solve Setup** dialog:

Adaptive Time Step

1. Determine whether you want the software to adaptively alter the time step during the simulation to optimize the solution for speed and accuracy. If so, check the **Adaptive Time Step** check box. If not, continue with step _ .
2. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
3. Enter the **Initial Time Step**. This will be the time step used to start the simulation and begin the adaptive process.
4. Enter the **Maximum Time Step** and **Minimum Time Step** to set the allowable range the adaptive process use to alter the time step
5. Enter a value for the **Error Tolerance**. Generally this value should be smaller than the minimum time step specified by at least an order of magnitude.

Non-Adaptive Time Step

1. Enter the **Stop Time**, which is the value at which the solution will stop, and select the units.
2. Enter the **Time Step** for the analysis, which defines the time increments, and select the units. The time step can also be defined as the function of time, speed, and position.
